Conclusion: Altogether, liver-specific Tsg101KD causes a time dependent activation of inflammation and apoptosis, accumulating into hepatocyte death, organ failure and ultimately a lethal phenotype. Our finding suggests a regulatory role of Tsg101 in TNFR signaling and degradation, where Tsg101 protects against liver inflammation.

B cell reactivation in autoimmune hepatitis after immunosuppression withdrawal

Elena Perpinan[1], George Koutsoudakis[2], Laura Patricia Llovet[3], Thais Leonel[3], Mar Riveiro Barciela[4], Montserrat García-Retortillo[5], Mercé Roget[6], Alberto Sanchez-Fueyo[7], Maria Carlota Londoño[3].
[1]King's College Hospital, London, United Kingdom; [2]Hospital Clínic Barcelona; [3]Hospital Clínic Barcelona, Liver Unit, Barcelona, Spain; [4]Hospital Vall d'Hebron, Liver Unit, Barcelona, Spain; [5]Hospital del Mar, Barcelona, Spain; [6]Consorci Sanitari de Terrassa, Terrassa, Spain; [7]King's College Hospital, London, United Kingdom
Email: mlondono@clinic.cat

Background and aims: Long-term immunosuppression therapies increase the risk of treatment-related side effects and subsequent reduce quality of life in autoimmune hepatitis (AIH) patients. The optimal strategy for immunosuppression withdrawal (ISW) is still controversial as relapse rates vary between 25 and 100% despite previous sustained complete biochemical response. Moreover, the pathogenesis of AIH is uncertain and no studies have explored the effect of ISW on the immune response. Therefore, we aim to understand the B and T cell repertoire in AIH patients undergoing ISW.

Method: Thirty-seven patients with type 1 AIH, complete biochemical response on first-line treatment for at least 3 years and histological activity index <3 were prospectively included. Detailed characterization of peripheral B and T cell responses was performed through high-dimensional spectral flow cytometry and unsupervised clustering before and after ISW (median time of 9 months).

Results: Fifty-one percent of patients were female (n = 19) with a median age of 60 years (22–80), and a median time on remission of 4 years (3–11). Most of the patients were on monotherapy with azathioprine at the time of ISW (n = 27, 74%). After a median follow-up of 31 months (12–34), 21 (57%) patients remained in remission and 16 (43%) patients required reinstitution of therapy (6 of them were still on low-dose immunosuppression when presented the flare). Before ISW, patients who reached remission displayed elevated frequencies of immature transitional 2 marginal zone precursor cells and early plasmablasts relative to patients who presented a flare ($p = 0.02$ and $p = 0.03$, respectively). However, both B cell populations together with the transitional T1, T2 and T3 subsets increased in all patients regardless of the outcome of ISW, and positively correlated with serum transaminases and IgG levels after discontinuation of treatment ($p < 0.01$). Of note, the expansion of B cell precursors was accompanied by a decrease in the frequency of switched resting memory cells ($p < 0.01$). In contrast, no differences were observed in the T cell compartment before or after ISW.

Conclusion: In AIH patients, ISW results in a state of immune activation orchestrated by B cells with no detectable changes in the T cell compartment, regardless of the clinical outcome. This suggests that clinical remission does not entail the restoration of immune tolerance to liver antigens and provides an explanation for late relapses observed after ISW.

FRI469

Serum sterols indicate modified cholesterol homeostasis in cirrhotic patients with PBC and correlate with response to treatment with ursodeoxycholic acid

Wiktor Smyk[1], Beata Kruk[2], Tadeja Rezen[3], Miha Moskon[4], Ewa Wunsch[5], Dieter Lütjohann[6], Frank Lammert[7], Piotr Milkiewicz[5,8], Marcin Krawczyk[2,9]. *[1]Medical University of Gdansk, Department of Gastroenterology and Hepatology, Gdańsk, Poland; [2]Medical University of Warsaw, Laboratory of Metabolic Liver Diseases, Department of General, Transplant and Liver Surgery, Centre for Preclinical Research, Warsaw, Poland; [3]University of Ljubljana, Centre for Functional Genomics and Bio-Chips, Institute for Biochemistry and Molecular Genetics, Faculty of Medicine, Ljubljana, Slovenia; [4]University of Ljubljana, Faculty of Computer and Information Science, Ljubljana, Slovenia; [5]Pomeranian Medical University in Szczecin, Translational Medicine Group, Szczecin, Poland; [6]University Hospital Bonn, Institute of Clinical Chemistry and Clinical Pharmacology, Bonn, Germany; [7]Hannover Medical School (MHH), Health Sciences, Hannover, Germany; [8]Medical University of Warsaw, Liver and Internal Medicine Unit, Department of General, Transplant and Liver Surgery, Warsaw, Poland; [9]Saarland University, Department of Medicine II, Saarland University Medical Center, Homburg, Germany*
Email: marcin.krawczyk@uks.eu

Background and aims: Primary biliary cholangitis (PBC) is a chronic autoimmune cholestatic liver disease of unknown aetiology. Ursodeoxycholic acid (UDCA) is the first-line therapy in PBC however, some patients present insufficient biochemical response to UDCA, indicating worse disease course and survival. Cholesterol is involved in diverse biological activities and derives from de novo synthesis or intestinal absorption. Here, we aim to investigate and correlate serum sterol profiles and PBC phenotypes.

Method: Overall, we included 129 patients with PBC (age 32–93 years, 119 women). A total of 44 individuals presented with cirrhosis at diagnosis, and 13 were transplanted due to PBC before inclusion. Biochemical response to UDCA was assessed according to Barcelona criteria. Follow-up data (range: 1–13 years) were available in 62 (48%) patients. Serum sterol levels were measured by gas chromatography/mass spectrometry (GC/MS) at inclusion. Machine learning (ML) algorithms were used to determine a model that can predict UDCA response.

Results: Cirrhotic patients with PBC demonstrated significantly higher sitosterol ($p = 0.0001$), campesterol ($p = 0.0042$) and cholestanol ($p < 0.0001$) serum concentrations as compared to non-cirrhotic individuals. Patients with cirrhosis showed increased phytosterols:cholesterol but decreased lathosterol:cholesterol ratios (all $p < 0.0001$). Desmosterol:cholesterol ratio did not differ between patients with or without cirrhosis. Individuals after transplantation displayed increased serum concentrations of 7α-hydroxycholesterol

compared with non-transplanted patients, which might indicate increased radical oxidation. The ML Support Vector Classifier model including 24-hydroxycholesterol, 27-hydroxycholesterol, campesterol, cholesterol, desmosterol, lanosterol and stigmasterol, revealed high accuracy, precision and sensitivity (all >80%) in predicting non-response to UDCA treatment. In contrast, none of the used sterol models was not able to accurately forecast the deterioration of LFTs during follow-up.

Conclusion: PBC patients with cirrhosis are characterized by decreased cholesterol synthesis and increased sterol absorption as compared to individuals without cirrhosis. Serum levels of algorithmically selected sterols correlate with biochemical non-response to therapy with UDCA in PBC.

Preserved MAIT cell proinflammatory function in children with autoimmune liver disease

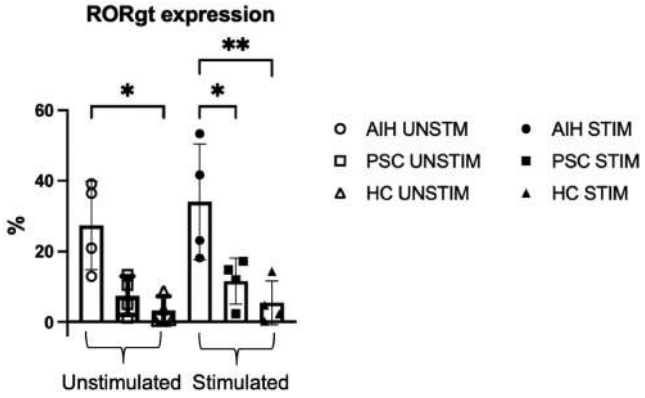
Suzan Warner[1], Deirdre Kelly[2], David Wraith[1], Ye Htun Oo[3].
[1]*University of Birmingham, Institute of Immunology and Immunotherapy, Birmingham, United Kingdom;* [2]*Birmingham Children's Hospital, The Liver Unit, Birmingham, United Kingdom;* [3]*University of Birmingham, Centre for Liver and Gastrointestinal Research, Birmingham, United Kingdom*
Email: S.Warner@bham.ac.uk

Background and aims: Mucosal-associated invariant T (MAIT) cells are significant players in autoimmune liver disease (AILD), a spectrum of conditions which often starts in childhood. Biological characterisation of MAIT cells and their functional activity in children with AILD has seldom been investigated. We aim to 1) characterise the deep immunophenotype of paediatric MAIT cells in AILD compared to healthy controls and 2) assess their cytokine capabilities.

Method: We performed mass cytometry (CyTOF; Cytometry by time of flight) analysis of peripheral blood mononuclear cells (PBMC) from paediatric patients with AILD (AIH Type 1, N = 4, median age 14 yrs (range 9–14), and PSC, N = 4, median age 14 yrs (range 12–14)) and from healthy children (HC) (N = 4, median age 8.5years (range 5–14). These PBMC samples were treated with a cell stimulation cocktail containing phorbol 12-myristate 13-acetate (PMA) and ionomycin and incubated for 4hours prior to downstream investigation by mass cytometry with a custom MAIT cell CyTOF panel designed by the investigators. Results were compared to controls (unstimulated matched PBMCs from the same patients). Cytobank and GraphPad Prism 9 were used for data analysis..

Results: Compared to the cohort of healthy children, peripheral blood MAIT cells from children with AILD had increased expression of retinoic acid related orphan receptor gamma t (RORγt), a transcription factor of T helper 17 (Th17) cells, and the proinflammatory cytokine interleukin 17A (IL-17A). This was observed at baseline ($p = 0.002$) and post stimulation (($p = 0.001$).

Higher expression of RORγt was observed in AIH Type 1 patients compared to healthy children ($p = 0.005$) Figure 1. There was also a significant difference between AIH Type 1 and PSC IL-17A activity post stimulation ($p = 0.034$). Post-stimulation IL-17A expression was highest in the PSC cohort compared to their unstimulated counterparts ($p = 0.003$). In addition, TNFα, IFNγ and GMCSF cytokine production were preserved in the children with AILD (AIH Type 1 and PSC), with levels comparable to those in the healthy cohort. This finding was most pronounced in TNFα production ($p = 0.0042$) which differs from peripheral blood MAIT cells in adults with AILD where there is decreased cytokine production.



Conclusion: Peripheral blood MAIT cell cytokine profile in children with AIH Type 1 and PSC are similar to MAIT cells from healthy children. Furthermore, MAIT cells from children with AIH Type 1 and PSC have greater RORγt expression and IL-17A activity at rest and post stimulation, suggesting that MAIT cells with a Th17-like phenotype may play a role in disease pathogenesis.

Cirrhosis and its complications: Portal Hypertension

FRI485

TIPS insertion leads to partial reversal of systemic inflammation in patients with decompensated liver cirrhosis

Lena Stockhoff[1], Anja Tiede[1], Zhaoli Liu[2], Hannah Schneider[3], Valerie Ohlendorf[3], Jan Hinrichs[4], Jennifer Witt[3], Denise Menti[3], Heiner Wedemeyer[3], Bernhard Meyer[4], Markus Cornberg[2,3], Cheng-Jian Xu[2], Christine Falk[5], Benjamin Maasoumy[1,2]. [1]*Hannover Medical School, Gastroenterology, Hepatology and Endocrinology, Hannover, Germany;* [2]*Centre for Individualised Infection Medicine (CIIM), Hannover, Germany;* [3]*Hannover Medical School, Gastroenterology, Hepatology and Endocrinology, Hannover, Germany;* [4]*Hannover Medical School, Diagnostic and Interventional Radiology, Hannover, Germany;* [5]*Hannover Medical School, Institute of Transplant Immunology, Hannover, Germany*
Email: maasoumy.benjamin@mh-hannover.de

Background and aims: Patients with decompensated liver cirrhosis are characterized by a state of systemic inflammation (SI), which is closely linked to several complications e.g. sarcopenia. Portal hypertension is widely considered to play a central role in this process. Transjugular intrahepatic portosystemic shunt (TIPS) is an effective treatment option for portal hypertension. The aim of this study was to investigate the impact of TIPS insertion on SI in patients with liver cirrhosis.

Method: In this cross-sectional study a number of 177 consecutive cirrhotic patients receiving a TIPS at Hannover Medical School were included. C-reactive protein (CRP) and white blood cells (WBC) were compared between baseline and 6/12, 24 and 36 months after TIPS insertion. In a subset of 59 patients we were able to perform more detailed analysis on the inflammation status measuring 48 different cytokines. The respective plasma samples were prospectively collected from the cubital vein at baseline as well as 1, 3 and 6 months after TIPS insertion. Blood samples from 5 healthy individuals served as control. Changes of cytokine levels were correlated with the physical status as indicated by body mass index (BMI), hand grip strength (HGS) and mid-arm muscle circumference (MAMC).

Results: Median age of the patients was 56 years and median MELD was 12. Most frequent TIPS indication was refractory ascites (RA)

(76%). Median CRP and WBC were 9.2 mg/L and 5 × 103/μL, respectively. CRP levels but not WBC significantly decreased after TIPS (p < 0.001). Of note, decrease in CRP levels was significantly associated with a better survival (p = 0.012). As expected, cytokine levels were significantly higher in the cirrhotic patients as compared to healthy controls affecting 30 of 48 measured cytokines (FDR < 0.05). Pattern of SI did not differ between patients with RA and variceal bleeding except from IL-6, which was significantly higher in patients with RA (p < 0.001). One month after TIPS most cytokines were still measured at levels comparable to baseline and some, e.g. IL-2, were even increased. However, during further follow-up we documented a continuous decrease in the majority of cytokines. For 25 cytokines, including IL-6 and IL-2, levels were significantly lower at month 6 compared to the time of TIPS insertion (FDR < 0.05; figure). Moreover, 7 of the 30 cytokines (including IL-2), which were elevated prior to TIPS, did not show any statistical difference anymore compared to healthy controls. When correlating cytokine changes with the clinical status, IL-6 appeared to be of particular interest: Decrease in IL-6 was associated with a significant improvement in MAMC and numerical increase in HGS and BMI.

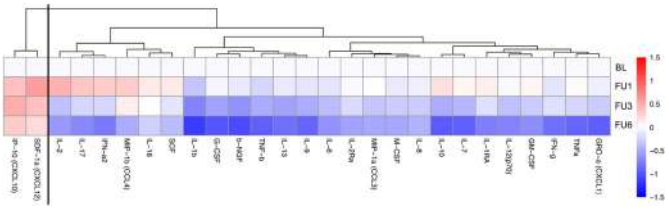


Figure: Decrease in SI after TIPS.

Conclusion: Decreasing portal hypertension via TIPS insertion leads to a significant improvement of SI over time, which is associated with a favorable clinical outcome.

FRI486

RWE evaluating patients with cirrhosis and features of portal hypertension reveals significant comorbidities

Philip Ambery[1], Peter Greasley[2], Daniel Pettersen[2], Nerissa Lee[3], Steven Kiddle[4], Phillip Hunt[5], Victoria Parker[6]. *[1]Astrazeneca, Late CVRM clinical research, Gothenburg, Sweden; [2]Astrazeneca, Early CVRM, Gothenburg, Sweden; [3]University of Bristol, United Kingdom; [4]Astrazeneca, Health Data Science, Cambridge, United Kingdom; [5]Astrazeneca, Epidemiology, Washington, United States; [6]Astrazeneca, Early CVRM, United Kingdom*
Email: phil.ambery@astrazeneca.com

Background and aims: Development of portal hypertension is associated with high risk of variceal haemorrhage, ascites, encephalopathy and death. In over 100, 000 individuals identified with portal hypertension we identify significant comorbidities that should be addressed to improve outcomes in this vulnerable population.
Method: Individuals with features of portal hypertension were identified using the TriNetX federated health records. Three groups of patients were identified, Group 1 with confirmed variceal haemorrhage (19, 454 in total, of which 12, 968 were incident), Group 2 with varices but no haemorrhage (43, 583 in total, of which 30, 083 were incident), and Group 3 with portal hypertension but no diagnosed varices (48, 496 in total, of which 31, 611 were incident). Significant comorbidities were identified across all 3 groups.
Results: Higher rates of ischaemic heart disease (IHD), heart failure and chronic kidney disease (CKD) were found in Group 3 versus the other two groups:

	CKD (%)	Heart failure (%)	Ischaemic heart disease (%)
Incident group 1	9.0	8.5	14.5
Incident group 2	11.3	10.2	16.2
Incident group 3	16.3	16.1	19.8

Conclusion: In the absence of variceal haemorrhage portal hypertension is under recognised. Comorbidities affecting patients in group 3 reported at higher levels than in groups 1 and 2 include CKD, IHD and heart failure. In patients with portal hypertension it's important to address comorbidities in addition to the underlying liver disease.

FRI487

Durability of immune response to SARS-CoV-2 vaccination in patients with liver cirrhosis (LC) as compared to healthcare workers (HW)

Alessandra Mangia[1], Valeria Piazzolla[1], Maria Squillante[1], Giovanna Cocomazzi[1], Vito Ciciriello[1], Vincenzo Giambra[2], Nicola Serra[3]. *[1]Liver Unit, IRCCS "Casa Sollievo della Sofferenza", San Giovanni Rotondo, Italy; [2]ISBREMIT, IRCCS "Casa Sollievo della Sofferenza", San Giovanni Rotondo, Italy; [3]University "Federico II", Public Health, Napoli*
Email: a.mangia@tin.it

Background and aims: Patients with advanced liver disease have well recognized deficiencies in innate and humoral immunity. Phase 3 trials on both BNT162b2 and mRNA-1273 included an extremely limited number of pts with liver diseases. Real life data on vaccine response in cirrhotics are lacking. To characterize the longitudinal anti-SARS-CoV-2 response in LC as compared to an age and gender matched HW population.
Method: In pts with established diagnosis of LC ± portal hypertension, levels of binding antibodies at baseline before the first BNT162b2 dose, 7 and 31 days after the first dose and 90 and 180 days after the second dose were evaluated and compared to HW levels at similar time-points. Semiquantitative serological testing for IgG antibodies anti S1 domain was performed by anti-SARS-CoV-2 QuantiVac ELISA (EUROIMMUN); cut-off for positivity = 32.5 BAU/ml. Swab test was performed in suspected cases by RT-PCR kit (ROCHE Diagnostics). Micro neutralization test using wild type virus is ongoing. LC pts were matched 3:1 with HW. Both pts and HW had received BNT162b2 vaccine.
Results: Among 207 LC pts identified so far, 178 have results currently available at the different time-points. After a careful analysis of the swab tests results, 28 pts COVID experienced were identified. Of 150 SARS-CoV-2 naive, 86 (58%) were male, mean age 65.4 ± 4. Pts with HCV etiology were 67%, pts with portal hypertension 29%. Geometric Mean of anti-SARS-CoV-2 antibody levels overall and by gender among LC pts and HW in the Table. Higher levels of anti-SARS-CoV-2 were observed in HW as compared LC at d7 (p = 0.007) and d31 (p = 0.063), as well as at d90 (p = 0.0049) and d180 (p = 0.039). At d180, the number of pts with results lower than the assay's threshold was higher among LC than in HW (5 vs 0, P = 0.0028). Irrespective of age, female pts were more likely to have higher anti-SARS-CoV-2 levels as compared to male at late time points.

	HW (n = 50)				LC (n = 150)			
Timepoints	d7	d31	d90*	d180*	d7	d31	d90*	d180*
Total	9.78 (5.94-16.10)	680.66 (532.45-870.13)	305.97 (240.7-388.94)	153.59 (127.15 - 185.53)	4.04 (2.82-5.79)	442.1 (320.72-609.49)	192.31 (128.43 - 287.96)	83.1 (38.32-180.19)
Male (54%)	11.92@ (6.24-28.8)	638.78 (477.35-854.81)	246.81 (181.1-336.33)	164.46 (124.09 - 217.96)	4.33 (2.68-6.99)	470.62 (306.63-722.32)	216.30 (127.23 - 367.71)	125.94 (32.24-463.2)
Females (46%)	7.89 (3.51-17.71)	732.23 (473.05-1133.42)	389.01° (268.48-563.66)	143.01 (109.15 - 187.37)	3.68 (2.10-6.43)	409.89 (246.83-682.03	173.62 (92.07-327.29)	63.61 (21.74-186.13)

*after the second dose; ° P = 0.028; @P = 0.024

Conclusion: Pts with LC showed an initial response to SARS-CoV-2 vaccination weaker than that of HW. An earlier antibody decline was also observed. The number of pts with absent anti-SARS-CoV-2 after 180 days was higher than in HW. This ongoing study highlights the need of a possibly more intensive vaccination schedule in LC as compared to HW.

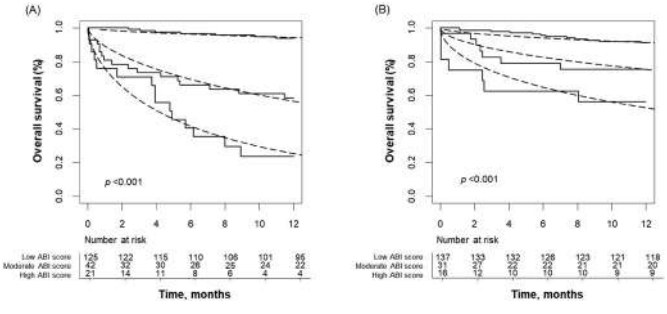
FRI488

A simple model for predicting survival in cirrhotic patients undergoing portosystemic shunt embolization

Won-Mook Choi[1], Seungbong Han[2], Young Seok Kim[3], Dong Hyun Sinn[4], Dong Il Kwon[5], Young-Suk Lim[1]. [1]*Asan Medical Center, University of Ulsan College of Medicine, Department of Gastroenterology, Seoul, Korea, Rep. of South;* [2]*Korea University College of Medicine, Department of Biostatistics, Seoul, Korea, Rep. of South;* [3]*Soonchunhyang University Bucheon Hospital, Division of Gastroenterology and Hepatology, Bucheon, Korea, Rep. of South;* [4]*Samsung Medical Center, Department of Medicine, Seoul, Korea, Rep. of South;* [5]*Asan Medical Center, University of Ulsan College of Medicine, Department of Radiology, Seoul, Korea, Rep. of South*
Email: limys@amc.seoul.kr

Background and aims: Portosystemic shunt embolization (PSSE) is an effective treatment for hepatic encephalopathy and gastric varix in patients with portosystemic shunt. However, some of the patients rapidly progress to hepatorenal syndrome and hepatic failure after PSSE. The aim of this study was to develop a prognostic model for predicting survival in patients treated with PSSE.
Method: We included 188 patients with portosystemic shunt who received PSSE for gastric varix or recurrent hepatic encephalopathy to develop a prediction model for 1-year mortality using a Cox proportional-hazard model incorporating significant prognostic factors, which was validated in a separate cohort of 184 patients.
Results: Using multivariable analysis, baseline serum levels of total bilirubin, albumin, and international normalized ratio (INR) were the independent prognostic factors that were significantly associated with the 1-year survival of the patients. An Albumin-Bilirubin-INR (ABI) score was developed assigning 1 point for ≥1.5 mg/dL of total bilirubin, <3.0 g/dL of albumin, and ≥1.5 for INR, respectively. Time-dependent area under the curve of the ABI score for predicting 6-month and 1-year survival were 0.851 (95% confidence interval [CI], 0.778–0.923) and 0.857 (95% CI, 0.793–0.921) in the development cohort and 0.777 (95% CI, 0.664–0.829) and 0.727 (95% CI, 0.624–0.829) in the validation cohort, which was comparable to the MELD score and the Child-Pugh score, indicating excellent discrimination performance. The ABI score showed a batter calibration performance than other scores, especially in patients at high-risk.

Fig. Overall survival in the development cohort (A) and validation cohort (B), according to three risk groups: high (ABI score 3), moderate (ABI score 2), and low (ABI score 0 or 1). Solid lines indicate Kaplan-Meier estimates of overall survival. Dashed lines indicate estimated overall survival according to the Cox proportional hazard model. ABI, Albumin-Bilirubin-INR.



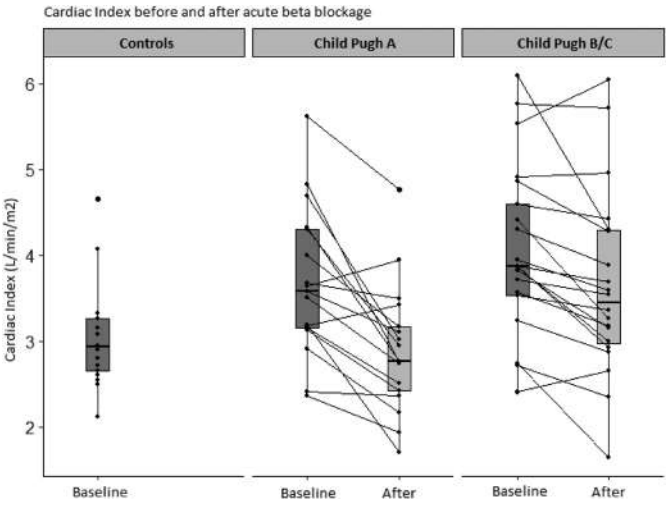
Conclusion: The novel ABI score, which is easier to calculate than MELD or Child-Pugh scores, may help identify a proper indication for PSSE in cirrhotic patients with portosystemic shunt.

FRI489

Blunted cardiovascular effects of beta-blockers in patients with cirrhosis: relation to severity?

Puria Nabilou[1], Karen Danielsen[1], Nina Kimer[2], Jens Hove[3,4], Flemming Bendtsen[1,4], Søren Møller[4,5]. [1]*Hvidovre Hospital, Gastro Unit, Medical Division, Hvidovre, Denmark;* [2]*University of Copenhagen, Bridge Translational Excellence Program, Novo Nordisk Center for Basic Metabolic Research;* [3]*Hvidovre Hospital, Department of Cardiology, Hvidovre, Denmark;* [4]*Hvidovre Hospital, Department of Clinical Medicine, Hvidovre, Denmark;* [5]*Hvidovre Hospital, Department og Clinical Physiology and Nuclear Medicine, Center for Functional and Diagnostic Imaging and Research, Hvidovre, Denmark*
Email: purianabilou@hotmail.com

Background and aims: Patients with cirrhosis and portal hypertension are at high risk of developing complications such as variceal hemorrhage, ascites, and cardiac dysfunction known as cirrhotic cardiomyopathy. Since non-selective betablockers may aggravate hemodynamic complications we investigated the effect of real-time propranolol infusion on cardiac function in patients with varying degrees of cirrhosis.
Method: Thirty-eight patients with Child-Pugh A (n = 17), B (n = 17) and C (n = 4) had liver vein catherization and cardiac magnetic resonance imaging performed. We assessed the effect of real-time propranolol infusion on the hepatic venous pressure gradient, cardiac index, stroke volume, ejection fraction, heart rate, and contractility. 19 patients were classified responders to beta-blocker therapy.
Results: When pooling Child-Pugh B & C patients, the decrease in cardiac index by beta-blockade was blunted, compared to Child-Pugh A patients (−8.5% vs. −20.5%, p = 0.043).
The effect of NSBB on portal pressure was inversely correlated to the changes on left atrium since the left atrial volume changed by 4 ml ± 18 in the responders compared to 15 ml ± 11 in the non-responders (p = 0.03). Finally, baseline ejection fraction correlated inversely with the decrease in portal pressure r = −0.39, p = 0.02.



Conclusion: We found a blunted effect of beta-blockade on cardiac index in patients with advanced cirrhosis compared to patients with early cirrhosis indicating impaired compensatory cardiac reserve and underlying cirrhotic cardiomyopathy with disease progression. The differential effects of beta-blockade on the left atrium may predict the beta-blocker response on portal pressure but further studies are warranted on this matter.

FRI490

Gender affects the association between serum creatinine levels and clinical response to terlipressin in patients with hepatorenal syndrome type of acute kidney injury

R. Todd Frederick[1], Chris Pappas[2], Khurram Jamil[3]. [1]*California Pacific Medical Center, Department of Transplant, San Francisco, United States;* [2]*Orphan Therapeutics, LLC, Longboat Key;* [3]*Mallinckrodt Pharmaceuticals, Hampton, United States*
Email: fredertz@sutterhealth.org

Background and aims: Hepatorenal syndrome (HRS)-acute kidney injury (AKI) is a rare and serious complication of cirrhosis, with serum creatinine (SCr) used diagnostically. Women generally have less muscle mass and consequently lower SCr levels than men with similar renal function. Terlipressin more effectively reverses HRS when started at lower SCr levels. The largest randomized, prospective database of placebo-controlled studies in patients (pts) with HRS-AKI was examined to assess a gender-based impact on treatment response.

Method: Pooled data from 3 phase III US studies (OT-0401, REVERSE, CONFIRM) were used; pts with HRS-AKI were treated with terlipressin plus albumin (terli) or placebo plus albumin (pbo). Associations between baseline (BL) SCr (SCr upon treatment initiation) and clinical response (complete response [CR]: HRS reversal, SCr [1.5 or less] or partial response [PR]: at least 30% improvement in SCr) stratified by treatment and gender were assessed. Overall response rate (ORR) comprised pts with a CR or PR; p values were calculated using a Fisher's exact test.

Results: Males in the terli group with BL SCr <3 had significant improvements in CR and ORR, relative to pbo, while females did not (Figure). Among pts with a BL SCr of 3–5, both males and females had a significant improvement in ORR (terli vs pbo); however, only males had significant improvements in CR. Across genders, pts with a BL SCr >5 demonstrated limited response to treatment.

	BL SCr <3			BL SCr 3–5			BL SCr >5		
Parameter, n (%)	Terli	Pbo	p value	Terli	Pbo	p value	Terli	Pbo	p value
Male	74	47		112	96		27	22	
HRS Reversal	36 (48.6)	13 (27.7)	0.024	35 (31.3)	11 (11.5)	<0.001	2 (7.4)	1 (4.5)	1.000
ORR	42 (56.8)	15 (31.9)	0.009	54 (48.2)	24 (25.0)	<0.001	5 (18.5)	3 (13.6)	0.715
Female	52	37		71	46		16	8	
HRS Reversal	26 (50.0)	12 (32.4)	0.129	16 (22.5)	5 (10.9)	0.141	2 (12.5)	0	
ORR	27 (51.9)	13 (35.1)	0.135	24 (33.8)	6 (13.0)	0.016	3 (18.8)	0	0.526

Conclusion: Pts in the terli group had a greater clinical response vs pbo for BL SCr of <5. Males were more likely to have a CR and ORR than females, especially those with BL SCr 3–5. Despite matched SCr, females had a lower response than males, likely reflecting more advanced renal dysfunction upon treatment initiation. New guidance recommending initiation of vasoconstrictor treatment based on SCr change from BL rather than absolute cut-offs may improve outcomes for female pts. Additional biomarkers to evaluate renal dysfunction should also be evaluated.

FRI491

A novel cirrhotic ascites severity score predicts one-year mortality better than the classification into refractory or diuretic-responsive ascites

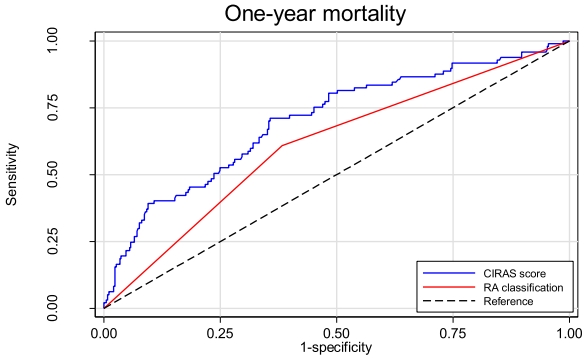
Rasmus Hvidbjerg Gantzel[1,2], Niels Kristian Aagaard[1], Hendrik Vilstrup[1,2], Hugh Watson[1,3], Peter Jepsen[1,2], Henning Grønbæk[1,2]. [1]*Aarhus University Hospital, Department of Hepatology and Gastroenterology, Århus N, Denmark;* [2]*Aarhus University, Department of Clinical Medicine, Århus N, Denmark;* [3]*Virology, Evotec ID, Lyon, France*
Email: ragant@rm.dk

Background and aims: Ascites formation is a common manifestation of cirrhosis decompensation and heralds a poor prognosis. Refractory ascites (RA) denotes a worsened state of this condition, where pharmacotherapies are ineffective or induce significant side-effects. The current definition of RA remains largely unaltered through the past 25 years, and rests on a panel of diagnostic criteria including the introduction of intensive diuretic therapy and a modest salt-restrictive diet, and evaluations of renal sodium excretion, weight loss, ascites recurrence rate, and diuretic-induced complications. Further, the traditional binary RA classification may be too simplistic as a predictive measure. We aim to develop a prediction model that relies on easily obtainable ascites-related variables and predicts one-year mortality more accurately than the traditional RA classification.

Method: We included 478 patients from the placebo-groups of trials for the treatment of cirrhotic ascites. The outcome was mortality hazard during one year of follow-up. Fractional polynomials were included to investigate the functional form of continuous variables. We used Cox regression with stepwise backward variable selection of ascites-related predictors of mortality. Candidate variables were: age, sex, serum sodium, ascites discomfort score, and a categorical variable based on ascites accumulation and diuretic treatment (ascites accumulation with no, moderate, and intensive diuretic treatment, and no ascites accumulation with any diuretic treatment). We compared the final model's discriminative ability (Harrell's C index) with that of the traditional RA classification.

Results: The final prediction model included age, serum sodium, and the categorical accumulation/diuretics variable. The CIRrhotic Ascites Severity (CIRAS) score was computed as 0.041* (age-56)-0.078* (serum sodium-137) and then add 0.718 if ascites accumulation and no diuretics, or add 0.407 if ascites accumulation and intensive diuretic treatment, or subtract 0.270 if no ascites accumulation and any diuretic treatment.

The CIRAS score had a C index for one-year mortality of 0.70 (95% CI: 0.64–0.75) which was statistically significantly better than the traditional RA classification with a C index of 0.60 (95% CI: 0.55–0.65) (p < 0.001, Figure).



Conclusion: The novel CIRAS score combining age, serum sodium, diuretic treatment, and ascites accumulation has better discriminative ability than the traditional RA classification during a one-year follow-up. These findings warrant validation in external cohorts.

FRI492

A network meta-analysis of numbers needed to treat to prevent an episode of overt hepatic encephalopathy in patients with cirrhosis treated for at least 6 months with lactulose alone, or lactulose plus rifaximin-alpha

Juha Halonen[1], Roland Henrar[1], Eric Ngonga Kemadjou[2]. [1]*Norgine Ltd, Harefield, United Kingdom;* [2]*JB Medical Ltd, Little Cornard, Sudbury, United Kingdom*
Email: jhalonen@norgine.com

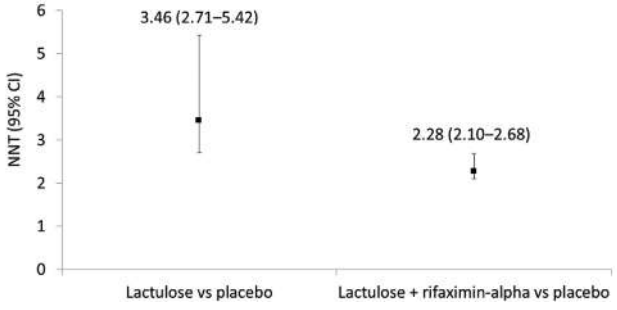
Background and aims: Overt hepatic encephalopathy (OHE) occurs in 30–40% of patients with cirrhosis during their clinical course.

Frequent hospitalisations and high mortality make prevention of OHE essential. Current treatment options for OHE include nonabsorbable disaccharides (e.g. lactulose) and antibiotics (e.g. rifaximin-alpha 550 mg). We conducted a network meta-analysis (NMA) of data from a previously published literature review (Hudson M, Schuchmann M. Eur J Gastroenterol Hepatol 2019;31:434–50) to determine the comparative long-term efficacy, in terms of number needed to treat (NNT) to prevent an additional OHE episode, of lactulose versus placebo and lactulose + rifaximin-alpha versus placebo.

Method: Literature searches were previously conducted in PubMed of titles and abstracts only, with language restricted to English and the data range unrestricted up to the cut-off date (05 March 2018), using the following search terms: 'hepatic encephalopathy + rifaximin' and 'hepatic encephalopathy + lactulose'. Randomized controlled trials (RCTs) with long-term (>/= 6 months) effectiveness endpoints for lactulose and/or rifaximin-alpha were selected for NNT analysis if statistically significant between-group differences were reported in the rate of OHE recurrence. In this analysis, we conducted an indirect treatment comparison analysis using the odds ratio (OR) for OHE recurrence for NNT mapping. The NMA was conducted using the Mantel-Haenszel approach, with placebo used as the reference treatment and only the fixed effect analysis considered.

Results: A total of 570 articles, including 201 with primary clinical data, were identified. Long-term treatment was reported in 8 articles for lactulose alone and in 19 articles for rifaximin-alpha, alone or in combination with lactulose. NNTs were calculated from 4 studies. When the ORs for the relative efficacy of each treatment versus each of the remaining treatments were calculated, the ORs (95% confidence intervals) for lactulose versus placebo and lactulose + rifaximin-alpha versus placebo were 0.276 (0.164–0.466) and 0.081 (0.042–0.158), respectively. The resulting NNTs were lower for lactulose + rifaximin-alpha versus placebo (2.28) than for lactulose versus placebo (3.46; Figure).

NNT (95% CI) for prevention of one additional OHE episode following long-term (>/=6 months) treatment with lactulose versus placebo and lactulose + rifaximin-alpha versus placebo. CI, confidence interval; NNT, number needed to treat; OHE, overt hepatic encephalopathy



Conclusion: This NMA based on NNTs demonstrated that, in comparison with placebo, lactulose + rifaximin-alpha may be more effective than lactulose alone in preventing OHE recurrence.

FRI493

Transjugular intrahepatic portosystemic shunt versus balloon-occluded transvenous obliteration for the management of ectopic varices

Ranya Selim[1], Jenna Yousif[2], Daniel Hillman[3], Scott Schwartz[3], Kylie Springer[4], Dilip Moonka[1]. *[1]Henry Ford Hospital, Gastroenterology and Hepatology, United States; [2]Wayne State University School of Medicine, United States; [3]Henry Ford Hospital, Radiology, United States; [4]Henry Ford Hospital, Biostatistics, United States*
Email: ranyaselim@gmail.com

Background and aims: Bleeding ectopic or non-gastroesophageal varices occur uncommonly in the setting of portal hypertension. Both transjugular intrahepatic portosystemic shunt (TIPS) and balloon-occluded antegrade or retrograde transvenous obliteration (BA-RTO) are potential treatment options. Our study is the first to assess and compare TIPS vs. BA-RTO for the management of ectopic varices.

Method: This is a retrospective cohort study at a tertiary liver center. All interventional radiology procedures performed for bleeding varices between 2006 and 2020 were identified. Only patients undergoing TIPS and BA-RTO for bleeding ectopic varices were included. Demographics, pre-procedural data and outcome data was collected and compared between BA-RTO and TIPS groups.

Results: Eleven patients undergoing BA-RTO were compared to seven patients undergoing TIPS. In 6 of the BA-RTO patients, TIPS was deemed unfeasible. Mean age at procedure was 55.6 ± 10.0. 55.6% were men and 83.3% were white. There were 8 rectal varices, 7 peristomal, one duodenal, one cecal and one superior mesenteric. The mean MELD-Na prior to procedures was 20.8 ± 10.4 in the BA-RTO group vs. 19.0 ± 6.4 in the TIPS groups (p = 0.69). In the BA-RTO vs. TIPS groups, respectively, the mean MELD-Na at 30 days after procedure was 18.8 ± 9.9 vs 21.7 ± 5.5 (p = 0.67) and at 90 days after procedure was 18.0 ± 4.2 vs 24.0 ± 7.5 (p = 0.39). Rebleeding rates during admission were 9.1% for BA-RTO vs. 14.3% for TIPS (p = 1.00). The mean length of stay for BA-RTO vs. TIPS was 10.6 ± 8.9 vs. 7.9 ± 8.1 days (p = 0.41), mean paracenteses 90 days prior and after procedure were 1.9 ± 3.6 vs. 0.0 ± 0.0 (p = 0.12) and 2.0 ± 3.9 vs. 0.0 ± 0.0 (p = 0.082), in the BA-RTO vs TIPS groups, respectively. The rates of hepatic encephalopathy in the BA-RTO vs TIPS groups at 90 days before and after the procedure were 45.4% vs. 57.1% (p = 1.00) and 28.6% vs 33.3% (p = 1.00), respectively. The mortality rates were 27.3% vs 28.6% (p = 1.00) in the BA-RTO vs TIPS groups.

Conclusion: Our results demonstrate that both TIPS and BA-RTO are effective treatment modalities for bleeding ectopic varices, with comparable post-procedure outcomes. Patients undergoing BA-RTO had a higher MELD at procedure but lower MELD at 30 and 90 day post-procedure and less HE though no differences were significant. BA-RTO is an excellent option for bleeding ectopic varices, primarily rectal and peristomal, and especially in patients not candidates for TIPS.

FRI494

Identification of potential new serum biomarkers for clinically significant portal hypertension by proteomic profiling of circulating extracellular vesicles

Frane Pastrovic[1], Grgur Salai[2,3], Stela Hrkač[2], Ruđer Novak[2], Lovorka Grgurević[2,4], Marko Žarak[1], Kristian Podrug[5], Tajana Filipec Kanizaj[6], Tomislav Bokun[1,7], Ivica Grgurević[1,7,8]. *[1]University Hospital Dubrava, Zagreb, Croatia; [2]Center for Translational and Clinical Research, Department of Proteomics, School of Medicine, University of Zagreb; [3]Teaching Institute of Emergency Medicine of the City of Zagreb; [4]Department of Anatomy, "Drago Perovic", School of Medicine, University of Zagreb; [5]University Hospital Centre Split, University of Split School of Medicine, Croatia; [6]KB Merkur; [7]University of Zagreb Faculty of Pharmacy and Biochemistry; [8]School of Medicine, University of Zagreb, Zagreb*
Email: ivicag72@gmail.com

Background and aims: Portal hypertension (PH) is a driving force for the progression of chronic liver disease. Complications from PH develop when hepatic venous pressure gradient (HVPG) exceeds 10 mmHg, defining the presence of clinically significant portal hypertension (CSPH). However, measuring HVPG is invasive method, with limited availability. Thus, reliable non-invasive tools would be welcome alternative. Circulating extracellular vesicles (ECV) originating from the cells are valuable source of information pertaining the ongoing pathophysiological process including the molecules which might serve as the biomarkers. In this study we aimed to identify potential new serum biomarkers for CSPH in patients with compensated advanced chronic liver disease (cACLD) by proteomic profiling of serum ECV.

Method: Severity of PH was assessed by HVPG measurement that served as the reference standard. Serum samples were pooled based on HVPG measurement in two groups: with and without CSPH. ECV were isolated from the serum pools using ultracentrifugation and vesicle membranes were lysed by sonication. ECV protein cargo was analyzed by Liquid Chromatography-Mass spectrometry (LC-MS). Samples were analyzed in triplicates and proteins identified with at least one peptide were considered relevant for analysis. Functional enrichment analysis of the isolated proteins was conducted using FunRich 3.1.3 analysis tool.
Results: A total of 48 patients were included (30 in the CSPH group and 18 in the non-CSPH group, 75% males; median age: 59, 9 ± 9, 8 years; majority with alcoholic (48%) and non-alcoholic fatty liver disease (23%)). LC-MS analysis of ECV content resulted in identification of 733 proteins (38 distinctive for CSPH, and 75 for non-CSPH group), that were furtherly classified based on their cellular origin and function. Proteins involved in platelet degranulation, integrin-mediated signaling pathway, receptor mediated endocytosis and regulation of cholesterol efflux were more represented, whereas those involved in opsonization, phagocytosis, complement activation, immune and inflammatory response were less represented in the CSPH group. Among the individual proteins that showed the most significant difference between the studied groups phospholipid transfer protein and beta-2-glycoprotein 1 were more represented, whereas complement C1q, C1r and C1s subcomponents and annexin A2 were less represented in the CSPH group.
Conclusion: Results of this study provide additional insights into pathophysiological processes taking place along the development of PH in patients with cACLD. Distinctive protein profiles are identified between the patients with respect to the presence of CSPH. Several individual proteins are identified that should be furtherly studied as the potential non-invasive biomarkers of CSPH.

FRI495

Factors influencing survival in cirrhotic patients with hepatic hydrothorax

Sarah Romero[1], Andy Lim[2], Gurpreet Singh[3], Chamani Kodikara[1], Rachel Shingaki-Wells[1], Lynna Chen[3], Samuel Hui[1], Marcus Robertson[1,2]. *[1]Monash Health-Clayton Hospital Main Entrance, Gastroenterology, Clayton, Australia; [2]Monash University Clayton Campus; [2]Department of Medicine, School of Clinical Sciences, Clayton, Australia; [3]Austin Hospital, Gastroenterology & Liver Transplantation, Heidelberg, Australia*
Email: s.romero.md@gmail.com

Background and aims: Hepatic hydrothorax (HH) remains a challenging complication of cirrhosis with limited treatment options. We sought to identify factors associated with mortality in hospitalised patients with confirmed HH treated with current standards-of-care.
Method: We performed a retrospective multi-center cohort study of cirrhotic patients with HH admitted to 3 tertiary hospitals (2010–2018). HH was defined as pleural effusion in the absence of cardiopulmonary disease. The primary outcomes were overall and transplant-free survival at 12-months after the index admission. Cox proportional hazards analysis was used to determine factors associated with the primary outcomes.
Results: 84 patients were included. Mean age 58.3 ± 11.5 years and 54.8% were male. The median Model for End-stage Liver Disease (MELD) score was 29 (IQR 25–33). Management of patients aligned with AASLD guidelines. Diuretics alone achieved resolution of HH in only 12% patients. At least 1 thoracocentesis was performed in 73.8% patients, of which 15% were complicated by pneumothorax. Within 12-months of the index admission, 33% patients received liver transplantation (LT) and 11.9% had transjugular intrahepatic porto-systemic shunt (TIPS) insertion, none of whom subsequently required LT. At least 1 hospital readmission was required in 63 (75%) patients, most commonly due to recurrent hydrothorax (38%) and decompensated cirrhosis (41%). Overall and transplant-free survival at 12-months were 68% and 41% respectively. The majority of deaths occurred early after the index admission, with a 45-day overall survival of 80%. The most common cause of deaths was complications of end-stage liver disease and multiorgan failure (75%). No deaths were recorded in patients receiving LT. In the multivariable analysis, increasing age (per 5-year increase, HR 1.3 (CI 1.1–1.7), p = 0.04), increasing MELD score (per 5 points, HR 1.5 (CI 1.1–1.7), p = 0.02), current smoking (HR 8.7 (CI 3.4–21.9), p < 0.01) and acute kidney injury (AKI) (HR 2.9 (CI 1.2–7.0), p = 0.01) were associated with a significantly increased risk of death. After bootstrapping and correcting for MELD score and age, a current smoker had 8.7 times the hazard of death of a non- or ex-smoker and AKI was associated with a 2.9-fold increase in the hazard of death (Figure).

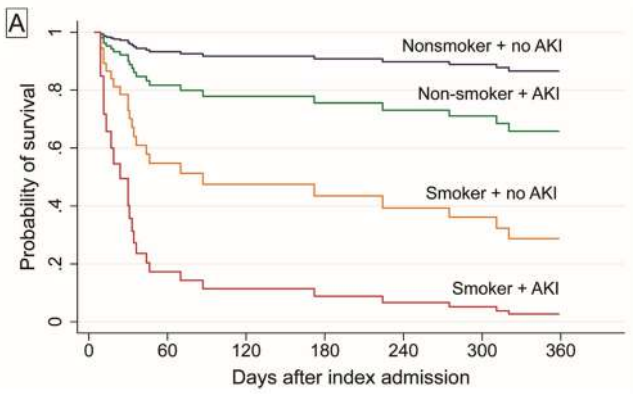


Figure: Multivariable Cox regression of overall patient survival showing survival estimates by smoking and AKI status (age and MELD scores held at mean values).

Conclusion: Cirrhotic patients with HH continue to have a poor 12-month survival despite current treatments and a high-risk of treatment-related complications. LT assessment should be considered in all cases. Current smoking and episodes of AKI are potential modifiable factors affecting survival.

FRI496

Hepatic venous pressure gradient (HVPG) measured at events is lower in non-alcoholic fatty liver disease (NAFLD) associated cirrhosis as compared to alcoholic cirrhosis

Lubomir Skladany[1], Daniela Jancekova[1], Michal Žilinčan[2], Stanislav Okapec[2], Janka Vnencakova[1], Svetlana Adamcova Selcanova[1], Michal Kukla[3], Tomáš Koller[4]. *[1]F.D.Roosevelt Teaching Hospital, HEGITO (Div Hepatology, Gastroenterology and Liver Transplant) of the Dept Internal Medicine 2, Banská Bystrica, Slovakia; [2]F.D.Roosevelt Teaching Hospital, Radiology, Banská Bystrica, Slovakia; [3]Faculty of Medicine, Jagiellonian University Medical College, Gastroenterology, Krakow, Poland; [4]University Hospital of Bratislava, Faculty of Medicine Comenius University, Div Gastroenterology Hepatology of Dept Internal Medicine 5, Bratislava, Slovakia*
Email: lubomir.skladany@gmail.com

Background and aims: In our region, alcohol-associated liver disease (ALD) and NAFLD are the most prevalent and the fastest-growing cirrhosis etiologies, respectively. We have recently demonstrated, that a natural history of cirrhosis differs in NAFLD as compared to ALD. HVPG is a strong surrogate of cirrhosis severity but its value in NAFLD is yet to be clarified.
We aimed to compare HVPG in NAFLD with ALD according to the indication (compensated and decompensated disease) with a particular focus on variceal bleeding (VB) and refractory ascites (RA).
Method: In our hospital system, we have retrospectively identified patients who underwent HVPG measurement and scrutinized them

against our RH7 cirrhosis registry (NCT04767945). Then we retrieved patients' etiologies-ALD, NAFLD and other (viral [VIR], autoimmune [AI])-as well as indications for HVPG measurement-VB, RA (or hydrothorax), liver resection, differential diagnosis with transjugular liver biopsy, or implantation of TIPSS. We excluded patients with other etiologies, malignancies, and those with less than 6months of follow-up.
Results: We enrolled 220 patients. Cirrhosis was due to NAFLD and ALD in 52 and 128 pts (VIR and AI in 26 and 14), respectively. Patients with NAFLD vs. ALD had similar age (60.4 vs. 56.9), a higher proportion of females 67.3 vs. 31.2), lower MELD scores (13.0 vs. 16.0), and a lower white blood cell count (4.9 vs. 6.15). Overall, the median HVPG in NAFLD and ALD (VIR and AI) was 14.0 and 18.0 (12.5 and 10.0) mmHg (P-value for trend <0.001), respectively. In 30 and 19 (17 and 8) compensated pts, HVPG was 11.5 and 10.0 (12.0 and 6.5) mmHg (p = 0.4). Among decompensated pts with VB, in 16 and 51 (7 and 5) the HVPG was 15.5 and 19.0 (13.0 and 18.0) mmHg, respectively (p = 0.02). In 6 and 31 (2 and 1) of pts with RA, the median HVPG was 16.5 and 19.0 (16.0 and 16.0) (p = 0.75). Transplant-free survival at 3 and 6 months did not differ between NAFLD and ALD (84.6 vs. 85.2, and 82.7 vs. 75.8%).
Conclusion: Overall, and in decompensated cirrhosis, the NAFLD etiology was associated with lower values of HVPG compared with ALD, likely reflecting a lower HVPG threshold for VB in NAFLD.

FRI497
Low subcutaneous adipose tissue is associated with mortality independently from portal hypertension in patients with cirrhosis

Xun Zhao[1], Balqis Alabdulkarim[1], Dana Kablawi[1], Marc Deschenes[1], Philip Wong[1], Tianyan Chen[1], Benjamin Rehany[1], Mohamed Abu-Nada[1], David Valenti[1], Ali Bessissow[1], Giada Sebastiani[1], Amine Benmassaoud[1]. [1]*McGill University Health Centre Glen Site (MUHC), Montréal, Canada*
Email: amine.benmassaoud@mcgill.ca

Background and aims: Sarcopenia and adipopenia are associated with worse outcomes in patients with cirrhosis. To this date, it is unclear if muscle and adipose tissue mass predict mortality independently of portal hypertension. The aim of our study was to investigate whether body composition could predict mortality while adjusting for the severity of portal hypertension by using the gold standard, the Hepatic Venous Pressure Gradient (HVPG).
Method: This was a single center retrospective cohort study of adult patients with cirrhosis who underwent HVPG measurement between November 2012 and June 2020 and had available cross-sectional imaging at the 3rd lumbar vertebrae (L3). Participants were excluded if HVPG was not reliable or if imaging was performed more than 12 months before or 1month after HVPG. Body composition was determined using CoreSlicer, a dedicated radiology software. Total psoas muscle index (PMI), total skeletal muscle index (SMI), subcutaneous and visceral adipose tissue indeces (SATI, VATI) were calculated at L3 by measuring their respective areas and dividing by the height squared ((in cm^2/m^2). Factors associated with death were assessed using univariate and multivariate logistic regression.
Results: We included a total of 81 patients (mean age 60.2years, 62% males, 31% with non-alcoholic fatty liver disease, 20% with alcohol-related liver disease and 17.3% with viral hepatitis, 52% with HVPG above 10 mmHg, 54% with decompensated cirrhosis at baseline, and median MELD 13). During follow-up, 27 (33.3%) patients died. Patients who died were older (64.6 yrs vs 58 yrs, p = 0.018), had higher HVPG (13.7 mmHg vs 9.2 mmHg, p = 0.004), lower muscle mass (PMI: 4.5 vs 5.6, p = 0.002; SMI: 41.3 vs 48.5, p = 0.002), lower SATI (45.6 vs 74.2, p = 0.002), and tended to have a higher MELD (15.3 vs 12.9, p = 0.067). Sex, BMI and VATI were not associated with mortality. On separate models for each compartment, after adjusting for age and HVPG, SATI (aOR = 0.98, 95%CI 0.96–0.99) was the only body compartment associated with mortality whereas PMI, SMI and VATI did not. Similarly, when adjusting for age and MELD, SATI (aOR = 0.98, 95%CI 0.97–0.99) and SMI (aOR = 0.94, 95%CI 0.88–0.99) were associated with mortality, but not PMI or VATI.
Conclusion: We have shown that SATI is associated with mortality independently of HVPG. Future larger studies should review the strength of this association separately for males and females and propose cut-offs.

FRI498
Association of low mechano-energitic efficiency and prognosis in liver cirrhosis

Sannia Sjöstedt[1], Signe Wiese[2], Flemming Bendtsen[3,4], Søren Møller[1,4]. [1]*Hvidovre Hospital, Department of Clinical Physiology and Nuclear Medicine, Hvidovre, Denmark;* [2]*Gastro Unit, Medical Division, Hvidovre;* [3]*Hvidovre Hospital, Gastro Unit, Medical Division, Hvidovre;* [4]*Copenhagen University, Department of Clinical Medicine, Faculty of Health Sciences, Copenhagen, Denmark*
Email: sannia@dadlnet.dk

Background and aims: In cirrhosis, cardiac systolic dysfunction as part of cirrhotic cardiomyopathy (CCM) affects development of complications and course of the disease and prognosis. Myocardial mechano-energetic efficiency (MEE) is an estimate of left ventricular performance and reduced MEE is associated with poor prognosis in heart failure patients. In this study we aimed to investigate the relation of MEE to patient characteristics and its impact on survival in patients with cirrhosis.
Method: We included 283 patients with cirrhosis of different severity according to the Child-Pugh classifications (A/B/C: 106/87/90). All patients had a liver vein catheterization and a hemodynamic investigation performed including determination of cardiac output (CO), stroke volume, and heart rate (HR). These data were used to assess MEE, which was defined as (stroke volume/HR)*1.666.
Results: Eighty-nine percent of the patients had portal hypertension (Hepatic venous pressure gradient >5 mmHg) and 80% indications of a hyperdynamic circulatory state with increased CO and HR. There was no difference in MEE in Child-Pugh class C patients (2.03) vs Child-Pugh class A (1.98) and B (2.05) patients. In Child-Pugh class C patients, low MEE was associated with a poorer prognosis (median survival 886 days vs 2693 days).

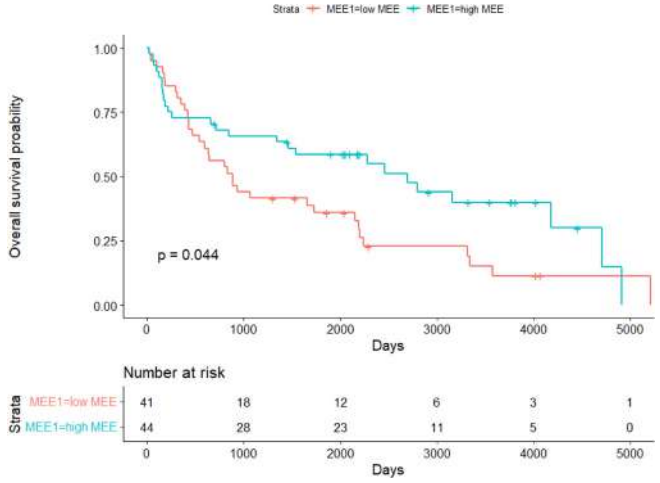

Figure: Kaplan-Meier plot showing differences in survival in liver cirrhosis patients classified as Child C stratified by MEE (low MEE below the median value and high MEE above the median value). A significantly poorer survival is seen in patients with low MEE.

Conclusion: In our study, MEE does not seem to be associated with severity of the liver disease, but in patients with advanced disease low MEE is associated with a poorer prognosis. The prognostic impact of MEE should be further investigated in future prospective studies.

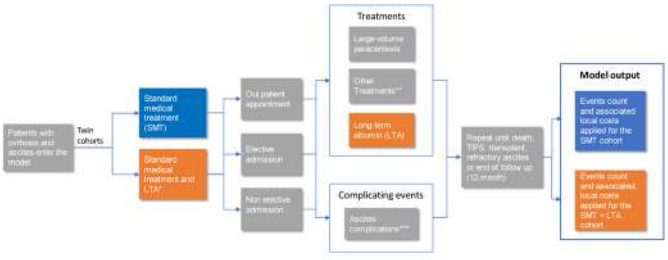
Long term albumin administration is associated with reduced healthcare resource use in patients with uncomplicated cirrhotic ascites: results from a simulation model

Kris Bennett[1,2], Elisabet Viayna[3], Murat Gunal[4], Duncan Stacey[5], Anne Davis[6], David Southern[7], Matthew Cramp[1]. [1]*University Hospitals Plymouth NHS Trust, South West Liver Unit, Plymouth, United Kingdom;* [2]*University Hospitals Plymouth NHS Trust, South West Liver Unit, Plymouth, United Kingdom;* [3]*Grifols S.A., Sant Cugat del Vallès, Spain;* [4]*Simarter, Instanbul, Turkey;* [5]*Grifols UK, Cambridge, United Kingdom;* [6]*Employed by Grifols SSNA, NC, United States;* [7]*SSB Research Ltd., United Kingdom*
Email: kbennett6@nhs.net

Background and aims: Decompensated cirrhosis is associated with high rates of complications and costs. The ANSWER trial showed that long-term human albumin infusions (LTA; 40 g twice/week for 2 weeks, 40 g/week thereafter) added to standard medical treatment (SMT) led to significant reduction of complications and mortality in patients with uncomplicated ascites. We developed a discrete event simulation (DES) model to estimate economic and clinical impacts of LTA in patients with cirrhosis and uncomplicated ascites in the UK. Real-world rates of hospital visits, treatments, and complications in the UK are used as model inputs. The potential benefit of LTA is modelled on data from the ANSWER trial.
Method: We developed a DES model using Simul8 Professional 2021 software to simulate individual patients' disease course by tracking health events (treatments, complications, hospitalizations, death) over time. We compared outputs for 2 patient cohorts: 1) SMT only, 2) SMT + LTA per ANSWER protocol. Model inputs for the SMT cohort were health event probabilities retrieved from Hospital Episode Statistics for 10 UK hospitals between Apr-2016 and Mar-2020. This real-world data gathered from 873 cirrhotic patients with uncomplicated ascites comprised 12-month rates for hospital visits, cirrhosis complications, treatments, and death. These were transformed into costs using NHS tariffs. Reduction in health event probabilities for the SMT + LTA cohort was based on ANSWER trial data.
Results: A hypothetical cohort of 100 patients with cirrhosis and uncomplicated ascites was simulated over 12 months, first with all patients treated with SMT, and then with 30% of patients treated with SMT + LTA; 30% was felt to represent an achievable patient volume for administering LTA in cirrhotic cohorts. In our model, the use of LTA decreased hospital admissions by 12.6% and reduced incidence of cirrhosis-related complications. The development of refractory ascites decreased from 37% to 30% in the LTA group. In the model, SMT + LTA in 30 out of 100 patients with uncomplicated cirrhotic ascites may save up to £264, 589/year in total healthcare costs.



*LTA as per ANSWER protocol: twice weekly for 2 weeks followed by weekly infusions
**Ascites other treatments: Transjugular intrahepatic portosystemic shunt; Liver transplant; Diuretics + other drug management
***Ascites complications: Bacterial peritonitis; Hepatic encephalopathy; Renal Dysfunction; Hepatorenal syndrome type I; Gastro-oesophageal varices with bleeding

Figure: Graphical representation of the discrete event simulation model.

Conclusion: Our DES model suggests that, if outcomes reported in the ANSWER trial translate to similar real-world benefits in UK patients, the use of LTA in cirrhotic uncomplicated ascites could lead to cost-savings, even when administered to a proportion of those eligible.

FRI500

Improved survival rates in hepatic encephalopathy after a decade of clinical practice with the addition of rifaximin-alpha to lactulose: a real-world data meta-analysis

Juha Halonen[1], Roland Henrar[1]. [1]*Norgine Ltd, Harefield, United Kingdom*
Email: jhalonen@norgine.com

Background and aims: Hepatic encephalopathy (HE) is a frequent complication of liver cirrhosis with a high risk of both short-term and long-term mortality [1]. Real-world longitudinal data on mortality rates in HE are scarce. This meta-analysis of two available studies compared the survival rates attained over approximately one decade.
Method: In HE, real-world mortality rates over 5 years were initially reported in patients with alcohol-related liver cirrhosis [1] and more recently in patients with HE who received combination treatment with rifaximin-alpha plus lactulose [2, 3]. Our meta-analysis calculated survival rates at 1, 12 and 60 months in the first study, and at 12, 36 and 60 months in the more recent study. Survival rates at 12 and 60 months were compared between studies using two-sided t-tests, assuming equal variance.
Results: The first study (conducted in 1993–2006) included 169 patients with HE and survival rates at 1, 12 and 60 months were 55%, 36% and 15%, respectively. The more recent study (conducted in 2014–2019) included 136 patients with HE and survival rates after 12, 36 and 60 months were 72%, 49% and 35%, respectively. Survival rates were significantly higher in the more recent study in comparison with the previous study at both 12 months (72% vs 36%; $p = 0.029$) and 60 months (35% vs 15%; $p < 0.001$). In the more recent study, all patients received lactulose plus rifaximin-alpha 550 mg; in the previous study, treatments were not reported but were likely to consist of lactulose alone. Notably, the number needed to treat to prevent an HE death, when comparing the more recent study versus the previous study, was 2.8 at 12 months and 4.9 at 60 months.
Conclusion: Direct comparison of the two studies is limited by different countries and by expected clinical improvements over a decade. Nevertheless, these real-world results suggest that treating patients with a combination of rifaximin-alpha 550 mg twice daily plus lactulose, rather than lactulose alone, may improve both 1-year- and 5-year survival rates in HE in current clinical practice.

Background and aims: The management of hepatic encephalopathy (HE) during treatment for advanced hepatocellular carcinoma is crucial because it may cause interruption of molecular targeted therapy. However, the incidence of HE and the risk of its development has not been sufficiently clarified. In this study, we investigated the incidence and risk factors of HE in cirrhotic patients with advanced hepatocellular carcinoma after the first-line chemotherapy.
Method: This retrospective study enrolled 316 cirrhotic patients with advanced hepatocellular carcinoma diagnosed by contrast-enhanced

computed tomography (Child-Pugh A 242 cases/B 74 cases) who received molecular targeted agents as first-line chemotherapy between July 2009 and February 2019 and measured ammonia levels before (pre-treatment) and 1 week after treatment (post-treatment). We examined the incidence and predictors of HE within 2 weeks after treatment.

Results: Incidence of HE: Pre-treatment serum ammonia levels elevated significantly compared to post-treatment (56.9 ± 30.6 vs. 79.9 ± 48.3 μmol/L, P < 0.001), and hepatic encephalopathy was observed in 14 patients (4.4%) within 2 weeks after chemotherapy.

Risk factors for the development of HE: Multivariate analysis showed that higher pre-treatment ammonia levels (Odds ratio 1.022 [1.008–1.036], P = 0.002) and the greater maximum diameter of portosystemic shunts (Odds ratio 1.094 [1.014–1.179], P = 0.020) were significant predictive factors for the development of HE.

Predictive model for the development of HE using a decision-tree-based approach: The final selected tree-discriminated cases were classified according to the following 3 subpopulations; low-risk group (ammonia levels <73 μmol/L; development of HE, 0.9%), intermediate-risk group (ammonia levels ≥73 μmol/L and portosystemic shunt diameter <6.2 mm; development of HE, 4.2%), and high-risk group (ammonia levels ≥73 μmol/L and portosystemic shunt diameter ≥6.2 mm; development of HE, 20%).

Conclusion: The development of HE after molecular targeted therapy could be clearly risk-segmented according to the ammonia level and the diameter of portosystemic shunts. Therefore, treatment for HE should be considered in cases with higher ammonia levels and large portosystemic shunt before molecular targeted therapy.

ABC: a novel algorithm to stratify decompensation risk in patients with cACLD (CHESS2102): an international, multicenter cohort study

Chuan Liu[1], Jia Li[2], Yu Jun Wong[3], Qing Xie[4], Masashi Hirooka[5], Hirayuki Enomoto[6], Tae Hyung Kim[7], Amr Hanafy[8], Zhujun Cao[4], Lili Zhao[2], Yanna Liu[1], Yifei Huang[1], Xiaoguo Li[1], Ning Kang[1], Yohei Koizumi[5], Yoichi Hiasa[5], Takashi Nishimura[6], Hiroko Iijima[6], Young Kul Jung[7], Hyung Joon Yim[7], Xin Li[9], Qing-Lei Zeng[10], Xiaolong Qi[1]. *[1]The First Hospital of Lanzhou University, CHESS Center, Institute of Portal Hypertension, China; [2]Department of Gastroenterology and Hepatology, Tianjin Second People's Hospital, Tianjin, China; [3]Department of Gastroenterology & Hepatology, Changi General Hospital, Singapore; [4]Department of infectious disease, Ruijin hospital, Shanghai Jiao Tong university school of medicine, Shanghai, China; [5]Department of Gastroenterology and Metabology, Ehime University Graduate School of Medicine; [6]Department of Internal Medicine, Division of Gastroenterology and Hepatology, Hyogo College of Medicine, Nishinomiya, Japan; [7]Division of Gastroenterology and Hepatology, Korea UniversityAnsan Hospital, Ansan-si, Gyeonggi-do, Republic of Korea; [8]Division of Gastroenterology, Hepatology and Endoscopy, Internal Medicine, Zagazig University Faculty of Medicine, Egypt; [9]Department of radiology, Tianjin second people's hospital, Tianjin, China; [10]Department of Infectious Diseases and Hepatology, The First Affiliated Hospital of Zhengzhou University, Zhengzhou, 450052, China*
Email: qixiaolong@vip.163.com

Background and aims: Liver-related death is preceded by clinical decompensation; therefore, the risk stratification of decompensation in compensated advanced chronic liver disease (cACLD) is extraordinary significant. This study intended to investigate a novel algorithm to stratify the decompensation risk in patients with cACLD.

Method: The international, multicenter study included two cohorts from January 2009 to August 2020. In training cohort, the unfavorable Baveno VI criteria patients were used to develop the novel CHESS criteria to stratify decompensation risk. The Algorithm based on Baveno VI criteria plus CHESS criteria (ABC model) was validated in validation cohort.

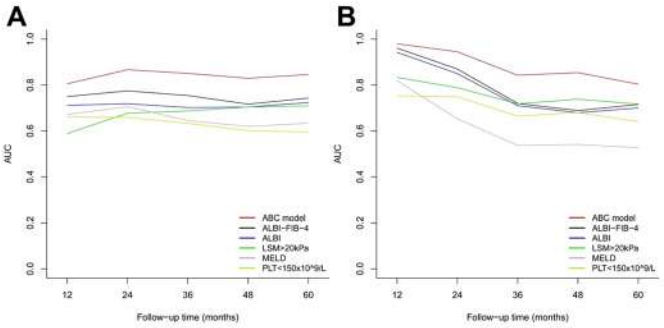

Figure 1. Comparisons of different models for predicting hepatic decompensation in training (A) and validation (B) cohorts.

ABC, Algorithm based on Baveno VI criteria plus CHESS criteria; ALBI-FIB-4, albumin-bilirubin (ALBI) and fibrosis-4 (FIB-4); LSM, liver stiffness measurement; MELD, model of end-stage liver disease; PLT, platelet count.

Results: A total of 1118 cACLD patients were enrolled in training cohort and validation cohort. In training cohort, multivariate analysis revealed that liver stiffness measurement (LSM), platelet count (PLT), albumin, alanine aminotransferase (ALT) and varices were the independent risk factors for hepatic decompensation. The novel CHESS criteria was produced, and <−4.4, −4.4 to −3.1 and >−3.1 indicated the low risk, medium risk, and high risk of decompensation, with a 3 year-time-dependent area under the curve (tAUC) of 0.851 (0.800–0.901) (Figure 1 A). In validation cohort, the 3 year-tAUC of ABC model was 0.843 (0.742–0.943) (Figure 1 B).

Conclusion: The ABC model can stratify the risk of decompensation in cACLD. HVPG evaluation can be waived in both low risk and high risk cACLD patients as they can be managed by Baveno VI criteria and non-selective β-blockers intervention, respectively, and the remaining medium risk patients need further HVPG evaluation.

FRI503

Quantitative parameters of esophageal varices based on computed tomography may be used for predicting severe varices in patients with liver cirrhosis

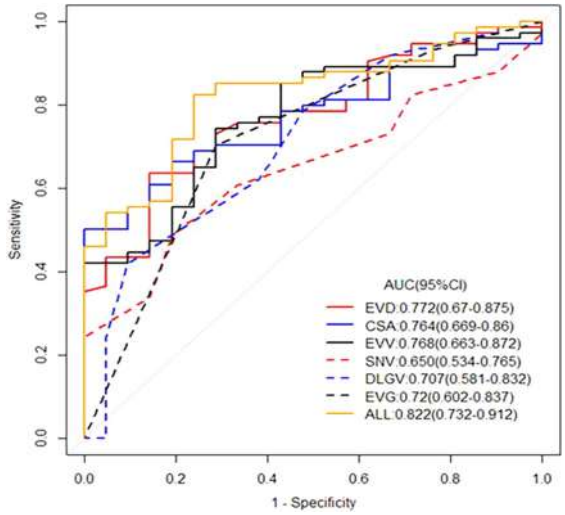
Shang Wan[1], Bin Song[1]. *[1]West China Hospital, West China School of Medicine, Sichuan University, Radiology, Cheng Du, China*
Email: songlab_radiology@163.com

Background and aims: Esophageal varices (EV) are the most common complication in patients with portal hypertension resulted from liver cirrhosis, and the subsequent variceal bleeding is the leading cause of death in those patients. The invasive procedure of endoscopy is now regarded as the reference standard for evaluation of EV, however, the utility of it is limited due to the invasive nature and the high-cost effectiveness. Thus, in this study, we aimed to assess whether the quantitative computed tomography (CT)-derived parameters can noninvasively predict the severity of EV and the risk of esophageal variceal bleeding (EVB).

Method: In this retrospective study, a total of 145 endoscopically confirmed EV patients were included and were divided into a conspicuous (mild-to-moderate EV, n = 39) and a non-conspicuous EV group (severe EV, n = 106), a bleeding (n = 89) and a non-bleeding group (n = 56). EV grade (EVG), EV diameter (EVD), cross-sectional surface area (CSA), EV volume (EVV), spleen volume (SV), splenic vein (SNV), portal vein (PV), diameter of left gastric vein (DLGV), and the opening type of LGV were measured independently using 3D-slicer. Univariate and multivariate logistic analysis were used to determine the independent factors and the receiver operating characteristic (ROC) curves were performed to evaluate the diagnostic performance.

Results: The difference of EVG, EVD, CSA, EVV, DLGV, SNV between the conspicuous and non-conspicuous EV group were statistically significant (p < 0.05), area under the curves (AUCs) of them for predicting severe EV were 0.72, 0.772, 0.704, 0.768, 0.707, 0.65, with corresponding sensitivities of 70.3%, 63.5%, 50%, 74.3%, 52.7%, 48.6%, specificities

of 71.4%, 85.7%, 100%, 71.4%, 81%, 81% respectively. EVG, CSA (odds ratio (OR):3.258, 95% confidence interval (CI):1.597–6.647; OR:1.029, 95% CI:1.008–1.050) were found to be independent predictive factors. However, there was no significant difference of the included parameters between the bleeding and non-bleeding group ($p > 0.05$).



Conclusion: CT can be used as a noninvasive method to effectively predict the severity of esophageal varices, which may reduce the invasive screening of endoscopy and be used as a supplementary procedure in patients with portal hypertension.

FRI504

A cost-effectiveness evaluation of the GORE® VIATORR® TIPS Endoprosthesis versus large volume paracentesis in the management of portal hypertension complications in the Spanish healthcare system

Mitesh Nakum[1], Thomas Wiersma[2], Francesca Di Stasi[3]. *[1]W. L. Gore & Associates (UK) Ltd., Health Economics, United Kingdom; [2]W.L. Gore & Associates B.V., Tilburg, Netherlands; [3]W.L. Gore & Associati Srl, Verona, Italy*

Email: mnakum@wlgore.com

Background and aims: The GORE® VIATORR® TIPS Endoprosthesis is widely used in patients for the treatment of portal hypertension and its complications such as refractory ascites in Spain, however little is known about the cost-effectiveness of the GORE® VIATORR® Device in the Spanish healthcare system. The aim of this analysis was to establish the cost-effectiveness of the GORE® VIATORR® Device versus large volume paracentesis (LVP) in refractory ascites with the Spanish healthcare system.

Method: A published markov model[1] was updated to simulate economic outcomes at two years from the Spanish healthcare perspective. Clinical parameters were derived from an updated published literature review[2]. Costing information was gathered from national tariffs, existing literature and expert opinion. Uncertainty was tested using deterministic and probabilistic sensitivity analyses.

Results: The GORE® VIATORR® Device was estimated to be cost-saving by 21, 493 Euros versus LVP over the time frame of the analysis. The GORE® VIATORR® Device also resulted in +0.60 QALYs versus LVP and so was cost-effective. Savings with the GORE® VIATORR® Device was from reduced LVP resource utilisation costs and reduced inpatient stay. The GORE® VIATORR® Device also remained over 98% cost-effective in a probabilistic sensitivity analysis versus LVP (see figure below).

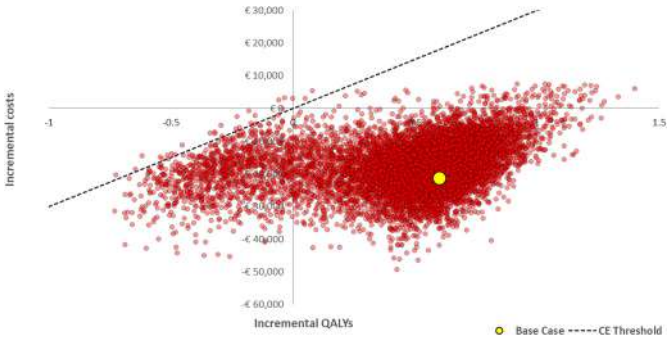


Figure: Probabilistic Sensitivity analysis of incremental Costs versus Incremental QALYS of GORE® VIATORR® TIPS Endoprosthesis versus LVP; CE threshold 30, 000 Euros.

Conclusion: From the Spanish healthcare perspective, this economic analysis suggests that the GORE® VIATORR® Device was cost saving and cost-effective at two years compared to LVP. Cost-savings were primarily driven by reduced LVP sessions and decreased inpatient hospital stay. Based on this economic evaluation the consideration of the GORE® VIATORR® Device in refractory ascites is cost-saving to the hospital provider and may improve patient health-related quality of life. Further long term studies are required in providing health economic evidence in this space.

Factor VIII/protein C ratio does not reflect coagulation but is linked to pathophysiological mechanisms driving disease progression in patients with advanced chronic liver disease

Lorenz Balcar[1,2], Bernhard Scheiner[1,2], Rafael Paternostro[1,2], Benedikt Simbrunner[1,2], Lukas Hartl[1,2], Mathias Jachs[1,2], David JM Bauer[1,2], Albert Stättermayer[1,2], Georg Semmler[1,2], Matthias Pinter[2], Peter Quehenberger[3], Michael Trauner[2], Thomas Reiberger[1,2], Ton Lisman[4], Mattias Mandorfer[1,2]. *[1]Medical University of Vienna, Vienna Hepatic Hemodynamic Lab, Division of Gastroenterology and Hepatology, Department of Internal Medicine III, Vienna, Austria; [2]Medical University of Vienna, Division of Gastroenterology and Hepatology, Department of Internal Medicine III, Vienna, Austria; [3]Medical University of Vienna, Department of Laboratory Medicine, Vienna, Austria; [4]University Medical Center Groningen, Surgical Research Laboratory and Section of Hepatobiliary Surgery and Liver Transplantation, Department of Surgery, Groningen, Netherlands*

Email: j.a.lisman@umcg.nl

Background and aims: We and others have demonstrated that the ratio of procoagulant factor VIII to anticoagulant protein C (FVIII/PC) is a versatile predictor of hepatic decompensation/liver-related death in patients with advanced chronic liver disease (ACLD). Of note, the association between FVIII/PC and thrombomodulin-modified thrombin generation assay (TM-TGA) results is confounded by liver disease severity.

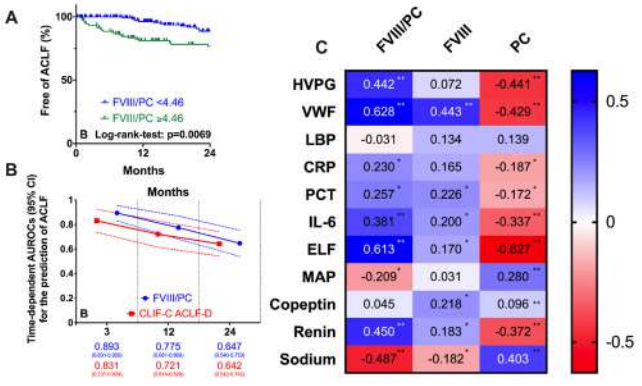
To substantiate the notion that FVIII/PC is unrelated to coagulation potential and provide an alternative explanation for its prognostic value, we investigated its association with (i) bleeding and thrombotic events, and (ii) key pathophysiological mechanisms promoting liver disease progression.

Method: In cohort (i) including ACLD patients undergoing HVPG measurement at the Vienna Hepatic Hemodynamic Lab with information on FVIII/PC ($n = 576$), we evaluated the development of major bleeding as well as arterial/venous thrombotic events (*Schulman S, et al, J Thromb Haemost 2010*) during follow-up. Moreover, incidence of ACLF was assessed. In cohort (ii), associations between FVIII/PC and pathophysiology-oriented biomarkers were assessed in 142 patients from the prospective VIenna CIrrhosis Study (VICIS).

Results: (i) During a follow-up of 31.8 (IQR:12.0–60.3) months, major bleedings were observed in 44 (7.6%) patients and bleedings were attributed to portal hypertension in 35 (6.3%) of the first bleeding events. Non-malignant thrombotic events were diagnosed in 50 (8.7%) patients. FVIII/PC was associated with neither the incidence of major bleedings (hazard ratio [HR]: 1.03[95%CI:0.98–1.09];p = 0.272), nor the occurrence of thrombotic events (HR: 1.03[95%CI:0.98–1.09]; p = 0.269). However, it predicted ACLF (adjusted HR: 1.10[95%CI:1.02–1.19];p = 0.015) in decompensated patients, independently of CLIF-C ACLF-D.

(ii) As demonstrated in the attached Figure, FVIII/PC showed moderate to strong correlations with HVPG (Spearman's ρ = 0.442; p < 0.001), von Willebrand factor (ρ = 0.628;p < 0.001), serum sodium (ρ = – 0.487;p < 0.001), and renin (ρ = 0.450;p < 0.001), as well as associations with systemic inflammation: C-reactive protein (ρ = 0.230;p = 0.006), interleukin-6 (ρ = 0.381;p < 0.001), and procalcitonin (ρ = 0.257;p = 0.002). Finally, it also strongly correlated with the enhanced liver fibrosis (ELF) test, as an indicator of fibrogenesis/matrix remodelling (ρ = 0.613;p < 0.001).

Figure. **A** Probability of remaining free of ACLF according to the Youden-optimized cut-off for ACLF-development in dACLD patients. **B** Time-dependent AUROC analyses for the prediction of ACLF development in dACLD patients. **C** Correlations of FVIII/PC, FVIII, and PC with portal hypertension severity (HVPG), markers of bacterial translocation (LBP) and systemic inflammation (CRP, PCT, and IL-6) as well as liver fibrogenesis/matrix remodelling (ELF test), and markers of hyperdynamic circulation/systemic hemodynamic impairment (MAP, copeptin, renin, and serum sodium). *Indicates p-values <0.05, whereas **denotes p-values p<0.001.



Conclusion: Baseline FVIII/PC was associated with neither thrombotic events nor major bleedings during follow-up, i.e., the clinical correlates of coagulation. Hence, results from previous studies on FVIII/PC require reinterpretation. However, FVIII/PC was associated with key pathophysiological mechanisms involved in disease progression, including those promoting further decompensation and ACLF, which may explain its prognostic utility.

FRI506

Prognostic impact of variants in TM6SF2 and MBOAT7 in patients who have progressed to advanced chronic liver disease

Lorenz Balcar[1,2], Bernhard Scheiner[1,2], Markus Urheu[1], Patrick Weinberger[1], Rafael Paternostro[1,2], Benedikt Simbrunner[1,2], Georg Semmler[1,2], Nicole Auer[1], Claudia Willheim[1], Matthias Pinter[1], Michael Trauner[1], Thomas Reiberger[1,2], Mattias Mandorfer[1,2], Albert Stättermayer[1,2]. *[1]Medical University of Vienna, Division of Gastroenterology and Hepatology, Department of Internal Medicine III, Vienna, Austria; [2]Medical University of Vienna, Vienna Hepatic Hemodynamic Lab, Division of Gastroenterology and Hepatology, Department of Internal Medicine III, Vienna, Austria*
Email: mattias.mandorfer@meduniwien.ac.at

Background and aims: Genome-wide association studies revealed genetic variants that modulate the susceptibility for (advanced) chronic liver disease (A)CLD. We have previously shown that a *PNPLA3* variant promotes hepatic decompensation/death in ACLD, while *HSD17B13* did not impact prognosis at this stage. Importantly, the impact of the *transmembrane 6 superfamily 2* (*TM6SF2*) *rs58542926* and *membrane-bound O-acyltransferase domain-containing 7* (*MBOAT7*) *rs641738* single nucleotide variants (SNV) in patients who have already progressed to ACLD are unknown.

Method: The impact of *TM6SF2*/*MBOAT7* variants on liver-related events was evaluated in 938 ACLD (as defined by HVPG ≥6mmHg; viral hepatitis and alcohol-related or non-alcoholic fatty liver disease) patients undergoing HVPG-measurement at the Vienna Hepatic Hemodynamic Lab.

Results: Mean age was 55 ± 11 years, mean HVPG was 15 ± 7 mmHg and mean MELD was 11 ± 5 points. The main etiologies were viral hepatitis (n = 495, 53%) alcohol-related liver disease (n = 342, 37%) and non-alcoholic fatty liver disease (n = 101, 11%).

While 754 (80%) patients harboured the *TM6SF2* wild-type (*C/C*), 174 (19%) and 10 (1%) patients had one or two *T*-alleles, respectively. Patients with at least one *TM6SF2 T*-allele had more pronounced portal hypertension (HVPG: 16 ± 7 vs. 15 ± 7 mmHg; p = 0.031), higher gamma-glutamyl transferase levels (123 vs. 97 $U \times L^{-1}$; p = 0.002), and more commonly hepatocellular carcinoma (HCC, 17% vs. 12%; p = 0.049). Patients with at least one *MBOAT7 T*-allele also tended to have a higher HCC prevalence at baseline (14% vs. 10%; p = 0.051), while other baseline characteristics were comparable.

In univariable Cox regression analyses, carriers of the *TM6SF2 T*-allele showed a trend towards an increased risk for decompensation/liver-related death during follow-up (hazard ratio [HR]: 1.26 [95% confidence interval (95%CI): 0.98–1.62]; p = 0.072); in the viral hepatitis subgroup, the association attained statistical significance (HR: 1.53 [95%CI: 1.03–2.29]; p = 0.036). After adjusting for age, HVPG, MELD, and albumin levels, neither the *TM6SF2* nor the *MBOAT7* genotype had an effect on decompensation/liver-related death during follow-up.

These results were unaffected by restricting our analysis to patients at increased risk of hepatic decompensation/liver-related death, i.e., those with clinically significant portal hypertension.

Conclusion: While SNVs in *TM6SF2* and *MBOAT7* modulate the risk of progression to ACLD, both genotypes had no independent impact on liver-related outcomes in ACLD patients but were potential risk factors for HCC development. Thus, these variants have limited value for risk stratification in patients with ACLD as HCC screening is warranted anyway.

FRI507

Hepatocellular carcinoma and number of elastic bands per session are strong predictors of bleeding after prophylactic endoscopic variceal bleeding

Renato Medas[1], Rodrigo Liberal[1], Tiago Ribeiro[1], João Afonso[1], Rosa Coelho[1], Hélder Cardoso[1], Guilherme Macedo[1]. *[1]Centro Hospitalar Universitário São João, Gastrenterology and Hepatology, Porto, Portugal*
Email: renatogmedas@gmail.com

Background and aims: Endoscopic variceal band ligation (EVL) is considered a standard care for high-risk varices treatment in cirrhosis. Despite being globally safe, procedure-related bleeding is a potential complication, with an estimated incidence up to 15% in some series, requiring hospitalization and blood transfusion. However, risk factors associated with this serious complication are not well established. The aim of our study was to evaluate factors associated with increased risk for upper gastrointestinal bleeding (UGIB) within 30 days after prophylactic EVL.

Method: We performed a single center retrospective study in a tertiary hospital during a 6-year period (between 09/2015 and 09/2021). All patients with clinically significant portal hypertension due to liver cirrhosis, submitted to prophylactic EVL, were considered eligible for the study. After EVL, all patients received oral proton pump inhibitor and sucralfate, according to an internal protocol. Statistical analysis was performed with SPSS®v.25.0.

Results: A total of 871 prophylactic EVL procedures, performed in 281 patients were analysed. Most procedures were primary prophylaxis (70.3%). 79.9% of patients were male (79.9%) and median age was 60 years (IQR 54–68). Alcohol was the main etiology for cirrhosis (57.9%), followed by hepatitis C virus (14.9%). UGIB 30-days after EVL occurred in 21 cases (2.4% of all EVLs) within a median time of 9 days (IQR 8–17) after index procedure. In 15 patients (68.2%) ligation ulcers were identified as the potential source of bleeding. On univariate analysis the number of elastic bands per session, platelets, albumin, total bilirubin, sodium, hepatocellular carcinoma (HCC) and portal venous thrombosis were associated with increased risk of UGIB 30-days after EVL. After multivariate logistic regression, only the number of elastic bands applied per session [above 7] (*odds ratio* [*OR*] 4.76, 95% confidence interval [CI] 1.97–13.02, $p = 0.001$), presence of HCC (*OR* 3.79, 95% CI 1.16–9.02, $p = 0.006$) and sodium (*OR* 0.86, 95% CI 0.78–0.95, $p = 0.002$) reached statistical significance. Age, sex, cirrhosis etiology, high-risk varices, concomitant gastric varices, ligation system, creatinine, international normalized ratio, antiplatelet and anticoagulant therapy were not associated with increased risk of bleeding after EVL.

Conclusion: Our study describes a relative low incidence of post-EVL UGIB in accordance with previous reports, reinforcing EVL as a safe procedure for prophylaxis of variceal bleeding. The number of elastic bands applied per session, serum sodium and presence of HCC, rather than platelets or coagulopathy, are predictors of bleeding after prophylactic EVL in patients with liver cirrhosis. These data suggest that prophylactic administration of blood or coagulation products are not necessary. In addition, a minimal EVL strategy should be considered in selected patients.

FRI508

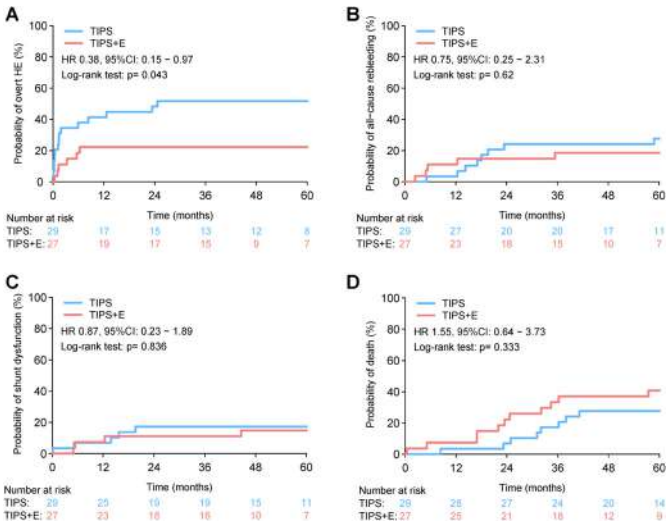
Simultaneous large spontaneous portosystemic shunt embolization for the prevention of overt hepatic encephalopathy after TIPS: a randomized controlled trial

Yong Lv[1], Hui Chen[1], Bohan Luo[1,2], Wei Bai[1,2], Kai Li[1], Zhengyu Wang[1,2], Dongdong Xia[1,2], Wengang Guo[1,2], Xiaomei Li[1,2], Jie Yuan[1,2], Zhanxin Yin[1,2], Daiming Fan[1], Guohong Han[1,2]. *[1]National Clinical Research Center for Digestive Diseases and Xijing Hospital of Digestive Diseases, Fourth Military Medical University, Department of Liver Diseases and Digestive Interventional Radiology, Xi'an; [2]Xi'an International Medical Center Hospital of Digestive Diseases, Department of Liver Diseases and Digestive Interventional Radiology, Xi'an, China*
Email: 13991969930@126.com

Background and aims: Large spontaneous portosystemic shunt (SPSS) is associated with increased risk of hepatic encephalopathy (HE) in patients undergoing transjugular intrahepatic portosystemic shun (TIPS). This study aimed to evaluate whether prophylactic embolization of large SPSS at the time TIPS creation could reduce the incidence of post-TIPS HE in patients with cirrhosis and variceal bleeding.

Method: From June 2014 to August 2017, 56 patients with cirrhosis and large SPSS planning to undergo elective TIPS for the prevention of variceal bleeding were randomly assigned (1:1) to receive TIPS alone (TIPS group, n = 29) or TIPS plus simultaneous SPSS embolization (TIPS+E group, n = 27). The primary endpoint was overt HE.

Results: TIPS placement and SPSS embolization was successful in all patients. During a median follow-up of 59.0 months in the TIPS group and 45.3 months in the TIPS+E group, the primary endpoint was met in 15 patients (51.7%) in the TIPS group and 6 patients (22.2%) in the TIPS+E group (p = 0.045). The 2-year cumulative incidence of overt HE was significantly lower in the TIPS+E group (21.2% vs 48.3%; HR: 0.38, 95%CI, 0.15–0.97; p = 0.043) compared with TIPS group. The incidence of recurrent bleeding (18.5% vs 27.6%, p = 0.627), shunt dysfunction (14.8% vs 17.2%, p = 0.995), death (40.7% vs 31.0%, p = 0.632) and other adverse events was not significantly different between the 2 groups.



Conclusion: In patients with cirrhosis treated with TIPS, simultaneous large SPSS embolization reduced the risk for overt HE without increasing other complications. Simultaneous large SPSS embolization should therefore be considered for prophylaxis of post-TIPS HE.

FRI509

Use of second-harmonic generation microscopy for automated detection of septa and nodules in needle liver biopsies of NASH cirrhosis

Mazen Noureddin[1], Dean Tai[2], Elaine Chng[2], Yayun Ren[2], Pol Boudes[3], Harold Shlevin[3], Stephen Harrison[4], Guadalupe Garcia-Tsao[5], Naga Chalasani[6], Zachary Goodman[7]. *[1]Division of Digestive and Liver Diseases, Comprehensive Transplant Center, Cedars-Sinai Medical Center, United States; [2]HistoIndex Pte. Ltd., Singapore; [3]Galectin Therapeutics, United States; [4]Pinnacle Clinical Research, San Antonio, TX, USA; [5]Section of Digestive Diseases, Yale University and CT-VA Healthcare System, Connecticut, USA; [6]Division of Gastroenterology and Hepatology, Department of Medicine, Indiana University School of Medicine, USA; [7]Inova Fairfax Hospital, Falls Church, Virginia, USA*
Email: mazen.noureddin@cshs.org

Background and aims: Cirrhosis, previously considered irreversible, is now recognized as capable of regression or progression. Most staging systems oversimplify all degrees of cirrhosis into one category. Portal hypertension, defined by hepatic venous pressure gradient (HVPG), correlates with key histological features of cirrhotic liver biopsies, including septa and nodules, which might make a biopsy an acceptable surrogate for clinical outcome. Using second harmonic generation/two-photon excitation fluorescence (SHG/TPEF), this exploratory analysis aims to develop an artificial intelligence (AI) tool based on septa and nodule microscopy for use in natural history monitoring and evaluate treatment response in cirrhotic NASH trials.

Method: 25 liver biopsies from 15 NASH patients with compensated cirrhosis were included from a phase 2a trial. Digitized images stained with Sirius red and immunostain for smooth muscle actin were used by an expert pathologist to identify all septa and cirrhotic nodules. 2 image algorithms were developed to automatically detect septa and nodules based on pathologist's annotations, named qSepta and qNodules, respectively. Agreement between the algorithm detection results and annotations were determined, and the images were rotated to establish repeatability.

Results: Concordance between the pathologist annotations and algorithm identification was determined after excluding technical artifacts. 284 septa were annotated by the pathologist ("true septa") and 294 septa were detected from the SHG/TPEF images using qSepta algorithm. Comparing the qSepta results versus true septa, 91% of the true septa were detected by the algorithm and 85% of the algorithm

detection results were true septa. 587 nodules were annotated from 25 H&E images by the pathologist. 525 nodules were detected from the SHG/TPEF images using qNodules. Comparing the qNodules results and true nodules, 82% of the true nodules were detected by the algorithm and 95% of the algorithm detection results were true nodules. The repeatability of qSepta and qNodules were 95% and 99% respectively.

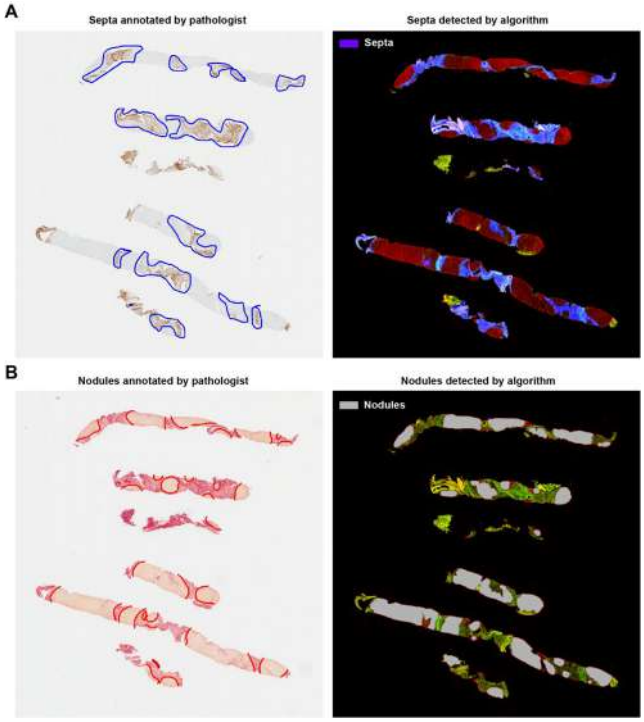


Figure: Examples of septa and nodules detection.

Conclusion: qSepta and qNodules algorithms can accurately detect septa and nodules in NASH cirrhotic patients. This can be used to develop more sophisticated algorithms to correlate with HVPG and study the natural history of NASH cirrhosis and treatment response.

FRI510

Hepcidin is higher in patients with more severe liver disease independent of portal hypertension

Robin Greinert[1], Alexander Zipprich[2], Laura Popp[3], Cristina Ripoll[2].
[1]*Martin-Luther-University Halle-Wittenberg, Department for Internal Medicine I, Halle (Saale), Germany;* [2]*University of Jena, Department for Internal Medicine IV, Jena, Germany;* [3]*Kreiskrankenhaus Delitzsch GmbH, Innere Medizin, Delitzsch, Germany*
Email: cristina.ripoll@med.uni-jena.de

Background and aims: Hepatocytes are the main source of hepcidin. Hepcidin expression is driven by iron load, although also inflammation, hypoxia and erythropoietic drive. The aim of this study is to evaluate hepcidin in cirrhosis and its association to the main pathophysiological drivers of cirrhosis: portal hypertension, liver insufficiency and systemic inflammation.
Method: Prospective study including consecutive patients between 2014 and 2016 who underwent a hepatic hemodynamic study. Measurement of ferritin, transferrin saturation and hepcidin (in hepatic vein and in peripheral blood) were performed besides standard measurements of liver function. Portal hypertension was estimated by means of HVPG, liver insufficiency was quantified by means of MELD score. SPSS v21 was used. Results are presented as proportions or median with IQR. Categorical variables were evaluated by means of the Chi-square test. Continuous variables were evaluated by the U-Mann Whitney or Spearman correlation as appropriate.
Results: Fifty-one patients (31 male, median age 62 (56–67) years, Child Pugh A 12 (23%), B 28 (55%) C 11 (22%) were included. Median hepcidin (nmol/L) in the peripheral vein was 2.2 (0.5–7.6) and in the hepatic vein 2.1 (0.5–9.2) with a positive correlation between both (rho Spearman 0.85, $p < 0.001$). 31 and 36% of the patients had levels of hepcidin ≤0.5 nmol/l (lower limit of detection) in peripheral and hepatic vein respectively. Those with hepcidin >0.5 nmol/l had vs those below: greater MELD [16 (11–19) vs 10 (19–12) and Ferritin (229 (154–473) vs 37 (26–80)]. No differences were observed according to CRP & leukocytes. Hepcidin was higher in patients with more severe liver disease [MELD: $r = 0.436$, $p = 0.003$; Child B&C vs A: 2.7 (0.5–11.8) nmol/l vs 0.5 (0.5–3.3) nmol/l $p = 0.05$]. No relevant association to HVPG.
Conclusion: No significant differences in peripheral and hepatic vein can be observed, suggesting that the liver remains a main source of hepcidin production even in end-stage liver disease. Increased levels of hepcidin are associated to more severe liver disease and ferritin and have no relevant association to portal hypertension.

FRI511

Effect of thrombocytopenia and platelet transfusion on outcomes of acute variceal bleeding: a real world experience

Sagnik Biswas[1], Manas Vaishnav[1], Piyush Pathak[1], Aditya Vikram Pachisia[1], Rithvik Golla[1], Amit Goel[2], Dr. Shalimar[1].
[1]*All India Institute of Medical Sciences, New Delhi, Gastroenterology and Human Nutrition, New Delhi, India;* [2]*Sanjay Gandhi Post Graduate Institute of Medical Sciences, Gastroenterology, Lucknow, India*
Email: drshalimar@yahoo.com

Background and aims: Thrombocytopenia is a feature of portal hypertension. In patients with thrombocytopenia and acute variceal bleeding (AVB), platelet transfusion is recommended by few guidelines and is common in routine clinical practice. However, the effect of thrombocytopenia and platelet transfusion on acute variceal bleeding (AVB) outcomes is unclear. We aimed to assess the outcomes in AVB patients with thrombocytopenia and the effect of platelet transfusion on rebleeding and mortality.
Method: Prospectively maintained database of the patients who presented with AVB were reviewed to study their outcome. Patients were grouped as platelet count <20, 000/mm^3, 20, 000–50, 000/mm^3 and >50, 000/mm^3. The outcomes were assessed as the risk of rebleeding at days 5 and 42, and risk of death at day 42 from the onset of AVB. Outcomes were compared among patients with and without platelet transfusion during AVB management. Statistical comparisons were done using Kaplan-Meier curves with log-rank tests for rebleeding and logistic regression for 42-day mortality.
Results: A total of 913 patients- males 762 (83.5%); mean age 44.4 ± 12.8 years, MELD 16.6 ± 7.9; Child Class A 374 (41.0%), B 361 (39.5%) and C 178 (19.5%); platelet count <20, 000/mm^3, 20, 000–50, 000/mm^3 and >50, 000/mm^3 in 23 (2.5%), 137 (15.0%) and 753 (82.5%) patients, respectively. Forty-eight (5.2%) patients experienced a rebleed at 5 days with 3 (13%), 7 (5.1%) and 38 (21.3%) patients in each group respectively. Among patients with platelet count <20, 000/mm^3, 20, 000–50, 000/mm^3 and >50, 000/mm^3, 5 (21.7%), 25 (18.2%) and 108 (14.3%) patients respectively had 42-days rebleeding ($p = 0.296$, log-rank test; figure 1a); similarly, 42-day mortality was 3 (13.0%), 33 (24.1%) and 130 (17.3%), respectively ($p = 0.137$, log-rank test; figure 1b). Ninety-one patients received platelet transfusions-Child A/B/C 8.8%/9.4%13.5%, respectively; MELD score 16.6 ± 8.0 vs 16.4 ± 7.6, $p = 0.252$). Among three platelet groups, 10/23 (43.5%), 51/137 (37.2%) and 30/753 (4.0%) ($p < 0.001$) respectively received transfusion. Logistic regression analysis identified MELD score (Odds ratio 1.12[1.109–1.15], $p < 0.001$) but not the platelet counts or platelet transfusion as predictors of 42-day mortality. Rebleeding rates in patients with platelet count <20, 000/mm^3 were similar in those who underwent endotherapy as compared with those who did not.

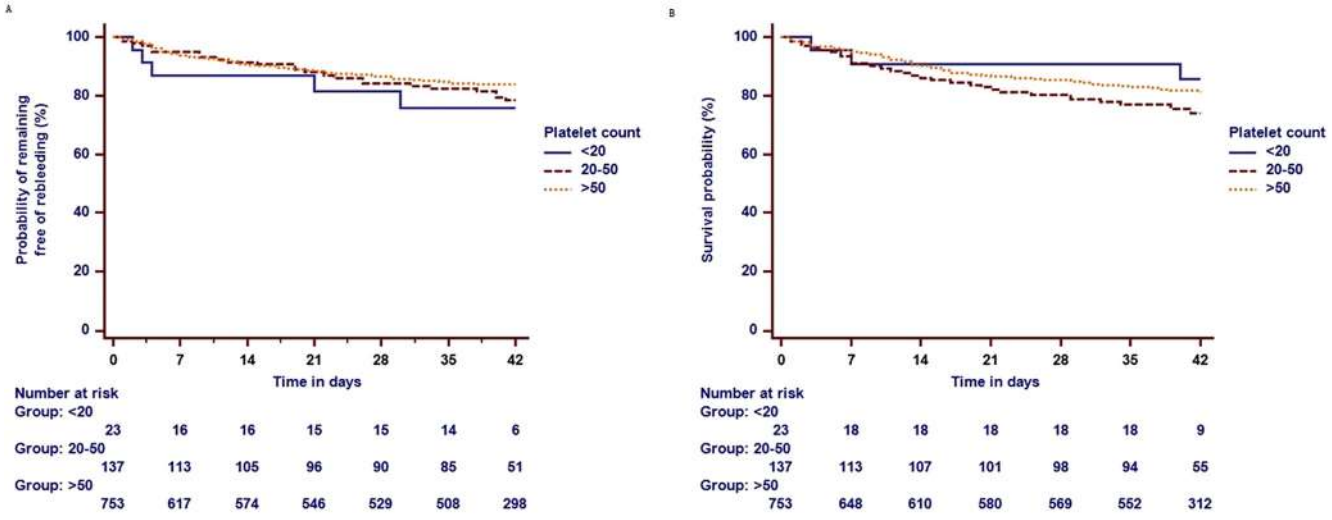

Figure: (abstract FRI511)

Conclusion: Platelet counts and platelet transfusion is not associated with the risk of rebleeding and mortality during follow-up in patients with AVB. Endotherapy is safe in patients with severe thrombocytopenia and not associated with higher rebleed rates.

FRI512

Personalized preemptive TIPS treatment for patients with Child-Pugh B cirrhosis and acute variceal bleeding by applying individualized of prediction of treatment effect

Yong Lv[1], Wei Bai[1,2], Kai Li[1], Dongdong Xia[1,2], Zhengyu Wang[1,2], Bohan Luo[1,2], Xiaomei Li[1,2], Jie Yuan[1,2], Zhanxin Yin[1,2], Daiming Fan[1], Guohong Han[1,2]. *[1]National Clinical Research Center for Digestive Diseases and Xijing Hospital of Digestive Diseases, Fourth Military Medical University, Department of Liver Diseases and Digestive Interventional Radiology, Xi'an, China; [2]Xi'an International Medical Center Hospital of Digestive Diseases, Department of Liver Diseases and Digestive Interventional Radiology, Xi'an, China*
Email: 13991969930@126.com

Background and aims: To evaluate whether individualized treatment effect prediction approach can assist in personalized treatment of acute variceal bleeding (AVB) with pre-emptive transjugular intrahepatic portosystemic shunt (p-TIPS) among patients with Child-Pugh B cirrhosis.

Method: Data of 1021 consecutive patients with Child-Pugh B cirrhosis and AVB from 13 university hospitals in China who were treated with p-TIPS (p-TIPS group, n = 297) or standard of care (medical group, n = 724) were used to predict treatment effects for individual patients in terms of absolute risk reduction (ARR) of death. Predictions were based on a refitted Chronic Liver Failure Consortium Acute Decompensation score (CLIF-C ADs) and on a newly developed prediction model. The net benefit of different p-TIPS treatment-strategies was compared: (i) treat none, (ii) treat all, (iii) risk-stratification strategy (i.e. selective treatment of patients at high-risk of death), and (iv) prediction-based treatment strategy (i.e. selective treatment of patients whose predicted treatment effect exceeds a decision threshold).

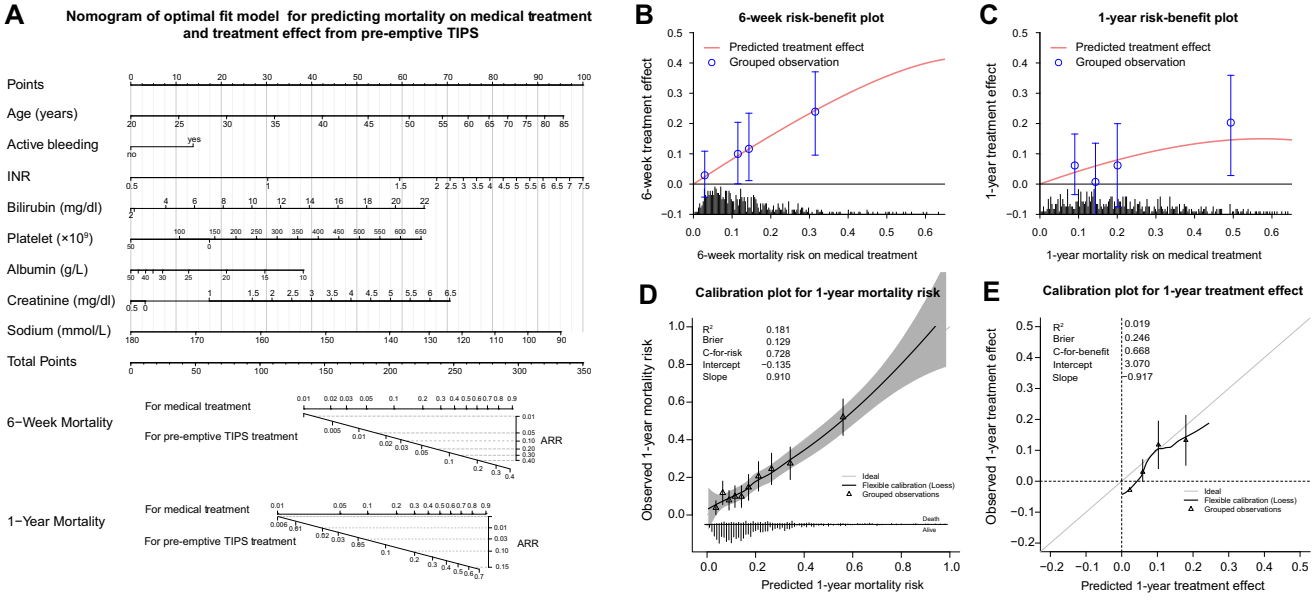

Figure: (abstract FRI512)

Results: After propensity score matching, the probability of death was significantly lower in p-TIPS group (15.9% vs 25.6% at 1 year, HR 0.52, 95%CI: 0.35–0.78; p = 0.002) compared with medical group. A Cox proportional hazards model comprising 9 easy-to-measure clinical predictors (age, active bleeding, albumin, bilirubin, creatinine, INR, sodium, platelet, and treatment status) was built for predicting treatment effects of p-TIPS, which had higher values of concordance-statistic-for-benefit and better calibration compared with the refitted CLIF-C ADs model. Net benefit analyses showed that prediction based treatment strategy were associated with more net benefit than other treatment strategies.
Conclusion: The treatment effects of p-TIPS can be predicted for individual patients based on routinely available patient characteristics. Individualized prediction treatment strategy is associated with optimal net benefit.

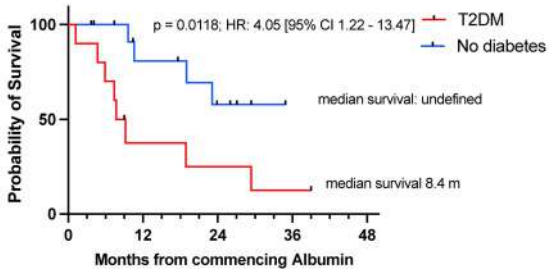
FRI513

Real-world survival outcomes in patients with decompensated cirrhosis receiving long term human albumin infusions

Nicholas Hannah[1,2], Douglas Tjandra[1], Ashwin Patwardhan[1], Kelsey Rutland[1], Siddharth Sood[1,2]. [1]*The Royal Melbourne Hospital, Department of Gastroenterology, Parkville, Australia;* [2]*University of Melbourne, Medicine, Dentistry and Health Sciences, Parkville, Australia*
Email: nick.m.hannah@gmail.com

Background and aims: The ANSWER study demonstrated the benefit of long term outpatient human albumin (HA) infusions in patients on diuretics for cirrhosis related ascites. HA is commonly used at our institution for cirrhotic patients with refractory ascites requiring repeated paracentesis, including those with ongoing alcohol consumption and renal impairment. We evaluated patient survival outcomes on HA infusions in an unwell but real-world cirrhotic cohort.
Method: We present a single-centre cohort study of patients receiving outpatient HA infusions at The Royal Melbourne Hospital between April 2017-June 2021. Inclusion: age >18 years and cirrhosis with ascites requiring paracentesis. Demographics, clinical data, including outcomes such as time on HA, trans-jugular portosystemic shunt (TIPS), liver transplant and death were recorded. Child-Pugh and Model for End-Stage Liver Disease-Sodium (MELD-Na) score were calculated. Patients received regular outpatient HA infusions up to 40 g/week. Primary outcomes were assessed 12 months after first HA infusion.
Results: 24 patients received at least 1 month of HA infusions (range 1.2–28.2, median 9.3 months). Median age 59.5 years, and 7 were female (29.2%). Aetiology included alcohol (50%), non-alcoholic steatohepatitis (NASH) (16.7%) and viral/alcohol (12.5%). Median MELD-Na 18.5, with Child-Pugh Scores A (4.2%), B (50%) and C (45.8%). Comorbidities included chronic kidney disease 37.5% and Type 2 diabetes mellitus (T2DM) 41.7%. Median follow-up was 16 months and median TIPS/transplant-free survival (TTFS) 10.5 months. Median serum sodium (134 mmol/L to 136.5 mmol/L, p = 0.014) and albumin (28.5 g/L to 39 g/L, p = 0.003) increased significantly over 12 months, whilst Child-Pugh score improved from 9 to 7.5 (p = 0.0172). On multivariate analysis, T2DM (not NASH) had a significant TTFS disadvantage (HR 6.16; 95% CI 1.23–30.84, p = 0.027), while time on HA infusions showed a TTFS advantage (HR 0.84, 95% CI 0.72–0.99, p = 0.031). Median TTFS improved in patients with a change in MELD-Na <1 at 1 month: 29.4 months versus 7.7 months (p = 0.011).

Kaplan-meier analysis of TTFS for those receiving albumin with T2DM



Conclusion: Outpatient HA infusions are associated with increased sodium and albumin levels and improvement in Child-Pugh score in a real-world cohort representing a more unwell population than the original ANSWER trial. T2DM was significantly associated with poorer outcomes, whilst an improvement in MELD-Na score at 1 month may predict those likely to benefit from HA. These results may help targeting of regular HA in decompensated cirrhotic patients.

FRI514

Impact of non-selective beta-blockers on survival and liver-related complications after TIPS-Insertion

Anja Tiede[1], Lena Stockhoff[1], Hannah Schneider[1], Bernhard Meyer[2], Heiner Wedemeyer[1], Jan Hinrichs[2], Markus Cornberg[1,3], Benjamin Maasoumy[1,3]. [1]*Hannover Medical School, Gastroenterology, Hepatology and Endocrinology, Hannover, Germany;* [2]*Hannover Medical School, Diagnostic and Interventional Radiology, Hannover, Germany;* [3]*Centre for Individualised Infection Medicine (CIIM), Hannover, Germany*
Email: maasoumy.benjamin@mh-hannover.de

Background and aims: Non-selective beta-blockers (NSBB) are commonly used to treat portal hypertension in patients with liver cirrhosis. An even more effective reduction and often normalization of portal pressure can be achieved by insertion of a transjugular intrahepatic portosystemic shunt (TIPS). So far, it remains unclear whether NSBB should be stopped immediately after TIPS. Recent data suggest that NSBB exert some additional e.g. anti-inflammatory effects that are independent from pressure reduction and may contribute to a favourable clinical outcome. The aim of this study was to evaluate if NSBB treatment is linked to survival and/or liver-related events after TIPS-insertion.
Method: A number of 235 consecutive cirrhotic patients receiving a TIPS between 2009 and 2019 were included. Patients were followed up for acute kidney injury (AKI), acute-on-chronic liver failure (ACLF), hepatic encephalopathy (HE), infections and mortality for one year after TIPS insertion. Intake of NSBB was assessed prior to TIPS insertion and at the time of hospital discharge. Incidence of periinterventional complications until hospital discharge was analyzed with binary logistic regression adjusting for the recently introduced FIPS-Score. Link between NSBB intake at hospital discharge and further survival and the development of liver-related complications was tested using a multivariable Cox Regression adjusting for TIPS indication (refractory ascites) and FIPS-Score.
Results: Median age of the patients was 59 years, median FIPS –0.15 and median MELD 12.0. TIPS insertion effectively treated portal hypertension in 234 patients (99.6%) as indicated by pressure reduction of >50% or a PSG value <12 mmHg after TIPS. At baseline 136 patients received NSBB therapy (57.9%). Patients in the NSBB group were younger (57 vs 61 years, p = 0.030) and had lower FIPS (–0.34 vs –0.02, p = 0.002) and MELD (11.5 vs 12.6, p = 0.014). Variceal bleeding as TIPS indication was more common in the NSBB group (38.2% vs 8.1%, p < 0.001). Periinterventional development of AKI, infections and HE as well as in-hospital mortality did not differ between the two groups. In contrast, NSBB therapy prior to TIPS-insertion was associated with a significantly lower incidence of ACLF

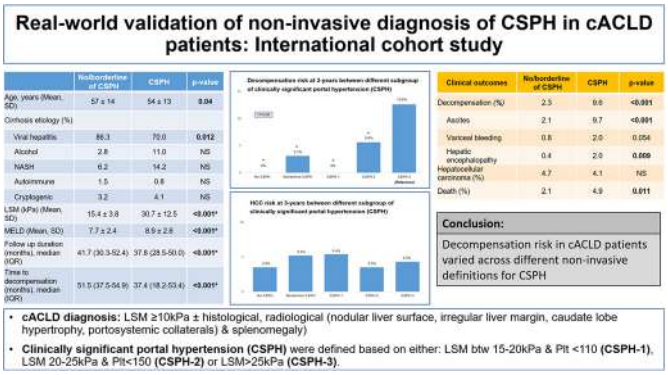
during hospitalization (p = 0.012); however, this did not remain significant after adjusting for FIPS.
Overall, 91 patients (40.3%) were still on NSBB treatment at the time of hospital discharge. NSBB therapy at discharge was neither linked to survival nor to development of AKI, ACLF or incidence of infections during further follow-up in the univariable and multivariable analysis.
Conclusion: Intake of NSBB prior to TIPS is not linked to the risk of periinterventional complications. Use of NSBB after TIPS has no impact on the risk for AKI, ACLF, infections and mortality. Thus, NSBB may be stopped in patients achieving sufficient pressure reduction after TIPS.

FRI515

Real world validation of BAVENO-7 non-invasive diagnosis for clinically significant portal hypertension in compensated advanced chronic liver disease: international cohort study

Yu Jun Wong[1,2], Junhui , Garrett Kang[3], Elisabetta Degasperi[4], Giulia Tosetti[4], Sanchit Sharma[5], Chuan Liu[6], Jia Li[7,8], Xiaolong Qi[6], Anoop Saraya[5], Massimo Primignani[4]. *[1]Duke-NUS Medical School, Singapore, Singapore; [2]Department of Gastroenterology & Hepatology, Changi General Hospital, Singapore; [3]Changi General Hospital, Singapore, Singapore; [4]Policlinico of Milan, Milano, Italy; [5]All India Institute Of Medical Sciences, New Delhi, New Delhi, India; [6]The First Hospital of Lanzhou University, Lanzhou, China; [7], Tianjin, China; [8]The Second Hospital of Tianjin, Tianjin, China*
Email: eugene.wong.y.j@singhealth.com.sg

Background and aims: The presence of clinically significant portal hypertension (CSPH) confer a 10-fold higher risk of decompensation in compensated advanced chronic liver disease (cACLD) patients. Recent BAVENO-7 consensus proposed that non-invasive criteria may be used to identify cACLD patients with CSPH using liver stiffness measurement (LSM) and platelet count. Whether non-invasive diagnosis of CSPH could predict clinically meaningful outcomes such as decompensation, hepatocellular carcinoma (HCC) and death, remained unclear. We aim to validate the real-world performance of Baveno-7 CSPH criteria to predict liver decompensation in cACLD patients.
Method: We analysed cACLD patients from 4 countries (Singapore, China, India and Italy). cACLD was diagnosed based on LSM > 10 kPa, with or without histological, radiological or clinical features of liver cirrhosis. CSPH was defined as either LSM between 15 and 20 kPa and platelet < 110 (*CSPH-1*), LSM 20–25 kPa and platelet <150 (*CSPH-2*), or LSM > 25 kPa (*CSPH-3*). Absence of CSPH was defined as LSM < 15 kPa and platelet >150. Patients who did not fulfilled either of the above criteria were categorized as borderline CSPH. Exclusion criteria were: prior or current liver decompensation, use of non-selective beta-blocker, untreated viral hepatitis and active alcohol drinking. Primary outcome was liver decompensation; secondary outcome were HCC and death.
Results: The cohort had 1, 166 cACLD patients, with a mean age of 55.4 years, 67% male; 69.5% Asian (Chinese 28.6%, Indian 26.6%, Malay 9.7%, Arabic 2.5%, others 2.1%) and Caucasian 30.5%. Primary etiology of cirrhosis was viral hepatitis (77.4%) followed by alcohol (8.8%), NASH (9%), autoimmune (1.1%) and others (3.7%).
Total of 54.5% fulfilled diagnosis of CSPH (CSPH-1: 11.6%, CSPH-2: 22.3%, CSPH-3: 66.1%), 12.3% without CSPH and 33.2% were borderline for CSPH. Presence of CSPH predict higher risk of decompensation (HR 4.6, 95%CI: 2.5–8.6) and mortality (HR 2.4, 95%CI: 1.2–4.8) at 3 years.
Decompensation occurred in 7.3% (ascites 6.3%, variceal bleeding 1.5%, encephalopathy 1.3%) over median follow-up of 40 months. The 3-year decompensation risk were 0%, 3.1%, 0%, 5.6%, 12.6% in cACLD patients without CSPH, borderline CSPH, CSPH-1, CSPH-2 and CSPH-3, respectively. The 3-year decompensation risk of CSPH-3 was significantly higher than cACLD patients with CSPH-2, CSPH-1 and borderline CSPH (p < 0.05 for all). The 3-year decompensation risk of CSPH-1 was similar to those without CSPH, and was significantly lower than CSPH-2 (0% vs 5.6%, p < 0.05). 3-year HCC risk were similar between CSPH subgroups.



Conclusion: Decompensation risk in cACLD patients varied across different non-invasive definitions of CSPH. LSM > 25 kPa is a reliable, non-invasive diagnosis for CSPH, which correlates with significantly higher risk of decompensation in cACLD patients.

FRI516

Derivation of machine learning histologic scores correlating with portal pressures and the development of varices in NASH patients with cirrhosis

Mazen Noureddin[1], Dean Tai[2], Elaine Chng[2], Yayun Ren[2], Pol Boudes[3], Harold Shlevin[3], Stephen Harrison[4], Guadalupe Garcia-Tsao[5], Zachary Goodman[6], Naga Chalasani[7]. *[1]Division of Digestive and Liver Diseases, Comprehensive Transplant Center, Cedars-Sinai Medical Center; [2]HistoIndex Pte. Ltd., Singapore; [3]Galectin Therapeutics, United States; [4]Pinnacle Clinical Research, San Antonio, TX, USA; [5]Section of Digestive Diseases, Yale University and CT-VA Healthcare System, Connecticut, USA; [6]Inova Fairfax Hospital, Falls Church, Virginia, USA; [7]Division of Gastroenterology and Hepatology, Department of Medicine, Indiana University School of Medicine, USA*
Email: mazen.noureddin@cshs.org

Background and aims: In clinical trials of non-alcoholic steatohepatitis (NASH) cirrhosis, primary efficacy endpoints have been hepatic venous pressure gradient (HVPG), liver histology and clinical outcomes. Conventional histological assessment of cirrhosis do not include important features such as septa thickness, nodules features, and fibrosis area. We have assessed these with a machine learning (ML) model.
Method: NASH patients with compensated cirrhosis and HVPG ≥6 mm Hg (n = 143) were included from the Belapectin phase 2b trial (NCT02462967). Liver biopsies, HVPG measurements, and upper endoscopy were performed at baseline (BL) and at end of treatment (EOT). A second harmonic generation/two-photon excitation fluorescence (SHG/TPEF) imaging-based tool provided an automated quantitative assessment of histologic features: 252 related to septa, 21 related to nodules, and 184 related to fibrosis (SNOF). We also created ML scores and tested their association with HVPG and clinically significant portal hypertension (CSPH: HVPG ≥10 mm Hg) and its changes as well as with the presence of varices (SNOF-V).
Results: Samples were divided into training (BL) and validation (EOT). We found that septa [r = 0.55 (training) and 0.56 (validation)], nodule [r = 0.52 (training), and 0.53 (validation)], and fibrosis [r = 0.57 (training) and 0.62 (validation)] parameters correlated individually with HVPG (Ps < 0.05). Combining these parameters in the SNOF score showed better correlations of r of 0.57 (training) and 0.70 (validation) with HVPG (Ps < 0.05). The SNOF score (≥11.78) distinguished CSPH at BL and in the validation cohort (BL + EOT) [AUC = 0.85 and 0.74, respectively]. The SNOF-V score (≥0.57) distinguished the presence of varices at BL and in the same validation cohort [AUC =

0.86 and 0.73, respectively]. The SNOF-C score differentiated those who had >20% change in HVPG against those who did not, with an AUROC of 0.89.

Table: Metrics of SNOF and SNOF-V scores at predicting HVPG and presence of varices

	BL					BL + EOT				
	AUC	Sensitivity	Specificity	PPV	NPV	AUC	Sensitivity	Specificity	PPV	NPV
SNOF score ≥ 11.78 to predict HVPG ≥ 10 (CSPH)	0.85	73%	86%	91%	62%	0.74	65%	76%	83%	54%
SNOF-V score ≥ 0.57 to predict varices	0.86	77%	86%	85%	78%	0.73	64%	78%	74%	70%

Conclusion: The ML algorithm accurately predicted HVPG, CSPH and its changes, development of varices in patients with NASH cirrhosis. Use of ML histology model in NASH cirrhosis trials may improve the assessment of key outcome changes.

FRI517

Ruling out varices needing treatment with a non-invasive score in patients with compensated HBV cirrhosis

Giacomo Emanuele Maria Rizzo[1], Pietro Graceffa[1], Fabrizio Bronte[1], Giuseppe Falco[1], Gabriele Rancatore[1], Ciro Celsa[1], Giada Reina[1], Fabio Simone[1], Sergio Peralta[1], Antonio Craxi[1], Vito Di Marco[1], Vincenza Calvaruso[1]. [1]*University of Palermo, Gastroenterology and Hepatology Unit, PROMISE, Palermo, Italy*
Email: vincenza.calvaruso@unipa.it

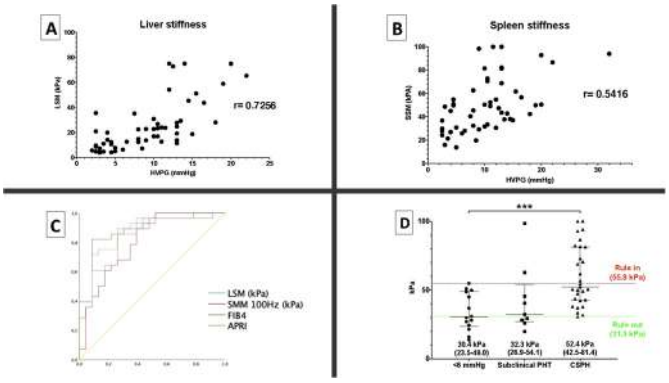
Background and aims: Non-invasive criteria to rule-out oesophageal varices needing treatment (VNT) in patients with compensated HBV cirrhosis on long-term treatment with nucleoside analogs (NUCs) are lacking. We have assessed the performance of an algorithm combining platelets and albumin (PLT-ALB) in a cohort of such patients under endoscopic (EGD) surveillance.
Method: All consecutive patients with compensated HBV cirrhosis who achieved HBV DNA suppression on NUCs since at least 1 year were classified at the moment of EGD as:-PLT-ALB IN (low risk for VNT) if platelets were >120 × 10^9/L plus serum albumin >3.6 g/dL-. -PLT-ALB OUT (high risk for VNT) if platelets were <120 × 10^9/L and/or serum albumin <3.6 g/dL. Primary outcome was the finding of VNT at EGD. Performance of PLT-ALB scoring to predict the outcome was assessed measuring the the receiver operating characteristic (AUROC) curve.. 87 patients in Child-Pugh A class (mean age 52 years, 75.9% males) were assessed, 46treated with Entecavir and 41 with Tenofovir. Seven patients (8%) had VNT, all being PLT-ALB OUT.
Results: Among the 41 PLT-ALB IN patients (47.1%) no VNT were found (NPV 100%). The PLT-ALB algorithm showed an AUROC of 0.76, potentially saving 47% of EGDs, with a false negative rate (FNR) of 0% and a false positive rate (FPR) of 48.1%.
Conclusion: APLT-ALB algorithmic approach based on widely available noninvasive parameters can avoid up to 50% EGDs aimed to screen for high-risk varices patients with compensated HBV cirrhosis under NUC suppression. Further validation in larger cohorts are needed before translating this approach into practice.

FRI518

Evaluation of clinically significant portal hypertension with a novel spleen-dedicated probe using transient elastography

Aitor Odriozola Herrán[1], Jose Ignacio Fortea[1], Angela Puente[1], Antonio Cuadrado[1], Emilio Fabrega[1], Maria Teresa Arias Loste[1], Paula Iruzubieta[1], Coral Rivas[1], Juan Carlos Rodriguez Duque[1], Ines García[1], Marina Cobreros[1], María Del Barrio[1], Álex García Tellado[2], Javier Crespo[1]. [1]*University Hospital Marqués de Valdecilla, Gastroenterology and Hepatology Service, Santander, Spain;* [2]*University Hospital Marqués de Valdecilla, Internal Medicine, Santander, Spain*
Email: aodrihe94@gmail.com

Background and aims: Most studies evaluating the association between spleen stiffness (SS) by transient elastography and the presence of portal hypertension (PH) have used the 50 Hz probe (range: 1.5–75 kPa). Whether the previously reported cut-off values can be extrapolated to those obtained by the spleen-dedicated 100 Hz probe (SSM@100 Hz, range: 6–100 kPa; FibroScan® Expert 630) is uncertain since there is only one study that has assessed its correlation with the hepatic venous pressure gradient (HVPG). In the current study, we aimed to examine its diagnostic accuracy for PH in comparison to other non-invasive tests.
Method: Retrospective single center study. Patients with available liver stiffness (LSM)-SSM and HVPG within 12 months were included. Patients with unstable liver disease (i.e., new decompensated events or any intervention that may impact PH between SSM and HVPG), non-cirrhotic PH, hepatocellular carcinoma (CHC) outside Milan criteria, liver transplants and transjugular intrahepatic portosystemic shunts were excluded. AUROC analysis was conducted to identify dual cut-offs (rule in and out) associated with the presence/absence of clinically significant PH (CSPH).
Results: A total of 56 patients were included with a median interval between HVPG and LSM/SSM of 3.3 months (interquartile range (IQR) 0.4–7.2). LSM and SSM were not feasible in 1 (2%) and 4 (7%) patients. Median age was 60 years (54–70), 71% were males and non-alcoholic fatty liver disease was the most prevalent underlying etiology (50%). Most patients were Child-Pugh A (82%, none C) with a median MELD score of 8 (8–10). A history of decompensation and CHC had occurred in 14 (25%) and 2 (4%) patients. CSPH was present in 29 patients (51.8%), 69% of whom had HVPG ≥12 mmHg. Median (IQR) LSM and SSM were 19.2 (10.5–30.8) and 46, 5 (31, 0–62, 5) kPa, and both showed positive correlation with HVPG (Figure 1A/1B). For CSPH, the AUROC of SSM was 0.81 (95% CI 0.68–0.93) and was lower than LSM [0.89 (0.79–0.98), APRI [0.84 (0.74–0.95)], and FIB-4 [0.87 0.77–0.98)] (Figure 1C). The SSM cutoffs to rule in and out CSPH were 55, 8 (positive predictive value 83, 8%) and 31, 3 kPa (negative predictive value 93.8%) (Figure 1D).



Conclusion: SSM@100 Hz constitutes a good non-invasive test for portal hypertension and can be used to rule in and out clinically significant portal hypertension. However, in our cohort its diagnostic performance was lower than other non-invasive tests, showing LSM the highest accuracy.

FRI519

Are psychometric tests helpful for the prediction of hepatic encephalopathy after TIPS insertion?

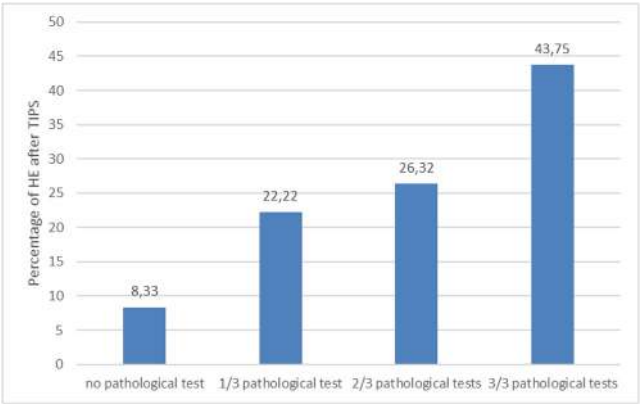
Alena Friederike Ehrenbauer[1,2], Hannah Schneider[2], Lena Stockhoff[2], Anja Tiede[2], Meike Dirks[1], Jennifer Witt[2], Katja Deterding[2], Henning Pflugrad[1], Maria Magdalena Gabriel[1], Denise Menti[2], Bernhard Meyer[3], Heiner Wedemeyer[2], Jan Hinrichs[3], Karin Weissenborn[1], Benjamin Maasoumy[2,4]. [1]*Hannover Medical*

School, Department of Neurology, Hannover, Germany; [2]Hannover Medical School, Department of Gastroenterology, Hepatology and Endocrinology, Hannover, Germany; [3]Hannover Medical School, Department of Diagnostic and Interventional Radiology, Hannover, Germany; [4]Center for Individualised Infection Medicine (CIIM), Hannover, Germany
Email: maasoumy.benjamin@mh-hannover.de

Background and aims: Hepatic encephalopathy (HE) is a frequent and severe complication in patients after transjugular intrahepatic portosystemic shunt (TIPS) insertion. Of note, risk factors for post-TIPS HE remain poorly defined. Presence of minimal HE (mHE) is a well-known risk factor for development of overt HE in cirrhotic patients without TIPS. Different psychometric tests, which differ in their diagnostic performance, have been suggested to diagnose mHE. However, their role for the prediction of post-TIPS HE still needs to be determined. We aimed to evaluate the value of three different psychometric tests for the prediction of HE after TIPS.

Method: We prospectively recruited 85 consecutive cirrhotic patients before TIPS insertion and monitored them for 180 days after TIPS insertion for development of HE. 65 patients underwent all psychometric tests: the Portosystemic Encephalopathy Syndrome Test (PSE, Version 2.0; 2020) (cut off <–4), the Animal Naming Test (ANT) (cut-off of <23 animals/minute) and the Critical Flicker Frequency (CFF) (cut-off <39 Hz). Association to HE development was tested using multivariable cox-regression analysis adjusting for all additional parameters with p-value<0.05 in univariable analysis.

Results: Median age was 59 and MELD 12. Indication for TIPS was refractory ascites in 75% of patients. Evaluation for mHE at baseline yielded pathological results in 67%, 24% and 66% of patients according to PSE (gold standard), CFF and ANT, respectively. The highest concordance was observed between PSE and ANT and lowest between PSE and CFF. After TIPS insertion, 24 patients (28%) developed at least one HE episode in the first 180 days. Among all parameters, a larger stent diameter (p = 0.049), higher serum-creatinine (p = 0.022) and pathological CFF (p = 0.001) were significantly associated with HE development in univariable analysis. Of note, pathological CFF values at baseline remained significant in the multivariable model (p = 0.001). In contrast, pathological PSE and pathological ANT values were not significantly associated with HE after TIPS neither in univariable (PSE p = 0.357 and ANT p = 0.098) nor in multivariable analysis (PSE p = 0.495 and ANT p = 0.050). However, also CFF had a limited value in predicting HE: sensitivity was 61%, specificity 80%, positive predictive value 45% and negative predictive value 85%. Predictive value slightly improved by combining all psychometric tests (figure). Among the 12 patients with normal results in all tests HE incidence was 8% (n = 1) compared to 44% (n = 7) among those 16 patients with concordant pathological values.



Conclusion: Development of HE after TIPS is a multifactorially influenced event. Psychometric tests, which were designed for diagnosis of mHE, have limited value for predicting HE after TIPS insertion. The relatively good predictive value of CFF could implicate altered pathomechanism of HE after TIPS.

Email: cvillanueva@santpau.cat

Background and aims: Non-selective β-blockers (NSBB) and endoscopic variceal ligation (EVL) are indicated to prevent first variceal bleeding in cirrhosis. However, compensated and decompensated cirrhosis differ in pathophysiology, prognosis and response to NSBB. Moreover, recent data show that NSBB may prevent ascites in compensated patients. We aimed to assess the efficacy of NSBB vs

EVL in patients with high-risk varices treated to prevent first bleeding, stratifying risk according compensation/decompensation of cirrhosis.

Method: A systematic review was performed to identify RCTs comparing NSBBs vs EVL, either in monotherapy or combined, for 1ry prevention of bleeding in cirrhosis. We performed a competing-risk time-to-event meta-analysis using individual patient data (IPD) obtained from principal investigators of RCTs, using an Inverse Probability of the Treatment Weights (IPTW) approach. Analyses were stratified according to present or previous decompensation (bleeding, ascites or encephalopathy). Outcomes included death, prevention of bleeding and prevention of ascites. OLT and death were competing-events.

Results: Among 25 RCTs eligible, 11 providing IPD were included. Overall, 1400 patients were included (656 compensated), 625 treated with NSBB, 546 with EVL and 229 with NSBB+EVL. There were no differences in baseline characteristics between groups. Over 19 months of follow-up, bleeding occurred in 16% compensated vs 16% decompensated (SHR = 1.09, 95% CI = 0.83–1.44, P = 0.537), and death in 15% vs 28% respectively (SHR = 2.58, 95% CI = 1.02–3.28, P < 0.0001). Overall, risk of death was similar with EVL vs NSBB (SHR = 1.04, 95% CI = 0.71–1.52, P = 0.848) and with EVL+NSBB vs either alone, with heterogeneity (I^2 = 77%). In compensated patients, mortality risk was lower with NSBB vs EVL (SHR = 0.57, 95% CI = 0.36–0.90; P = 0.016) and was similar with NSBB+EVL vs NSBB (p = 0.104), without heterogeneity (I^2 = 0.0%). In decompensated patients, mortality risk was similar with EVL vs NSBB (SHR = 0.81, 95% CI = 0.52–1.26, P = 0.350) and with NSBB+EVL vs NSBB (p = 0.469) and vs EVL (p = 0.357), without heterogeneity (I^2 = 34%). The risk of first bleeding was similar with EVL vs NSBB in compensated (p = 0.85) and decompensated patients (p = 0.64). The risk of ascites was higher with EVL vs NSBB (SHR = 2.66, 95% CI = 1.36–5.19, P = 0.004) in compensated patients and was similar in decompensated (p = 0.316).

Conclusion: In patients with compensated cirrhosis and high-risk varices treated to prevent bleeding, NSBB achieved better survival than EVL, without additional benefit by adding EVL to NSBB. The risk of bleeding was similar with both therapies but risk of developing ascites was lower with NSBB. In decompensated patients, survival was similar using NSBB or EVL or combining both. The NSBB may be preferable in compensated patients for prevention of bleeding, while either NSBB or EVL can be used in decompensated.

FRI521

Baseline plasma renin activity (PRA) predicts risk of AKI in patients with cirrhosis: a prospective observational study

Srinivasa Reddy Golamari[1]. [1]*ILBS/Vasant Kunj Sector A, Hepatology, New Delhi, India*
Email: srinivasareddygolamari@gmail.com

Background and aims: Plasma renin activity (PRA), is a measure of the activity of the plasma enzyme renin; which plays a major role in the body's regulation of blood pressure, thirst, and urine output. The degree of impairment in renal function, mainly decrease in renal perfusion and glomerular filtration rate (GFR) correlates with the activity of the endogenous vasoconstrictor system and both correlate with the severity of portal hypertension. Overactive RAAS system leads to renal vasoconstriction, renal injury and failure. We aimed to study the effect of PRA on organ injury/failure in cirrhosis.

Method: A total of 63 patients with cirrhosis, presenting for the first time with grade II/III ascites and no prior ascitic tap, were enrolled in a cross sectional study. At admission and during the hospital stay, presence and development of acute kidney injury (AKI) was studied and correlation with baseline serum PRA was determined.

Results: Altogether, 63 patients with ascites [62% males, with mean age 46.56 ± 12.59 years, CTP, 8.4 ± 1.1, MELD 18.4 ± 4.1, and MAP 74 ± 8.2 mmHg] were included. Forty two percent of patients had AKI at baseline. Ninety percent of the patients were on diuretics with a median dose of frusemide 15 mg (10–20) and spironolactone of 37.5 mg (25–50) per day. Mean PRA levels at presentation were 16.07 ± 1.4 (Normal-0.6–4.3 ng/ml/hr.). Baseline serum PRA levels were significantly associated with the presence or development of AKI during the hospital stay {p –0.001%, OR-1.22 95% CI: 1.096–1.36]. A PRA value of 16.7 ng/ml/hr increased the risk of AKI with AUC = O.95%, with a sensitivity of 0.83, and specificity of 0.87. Every 1 ng/ml/hr increase in the PRA level was associated with 0.03 mg/dl increase in serum creatinine from baseline.

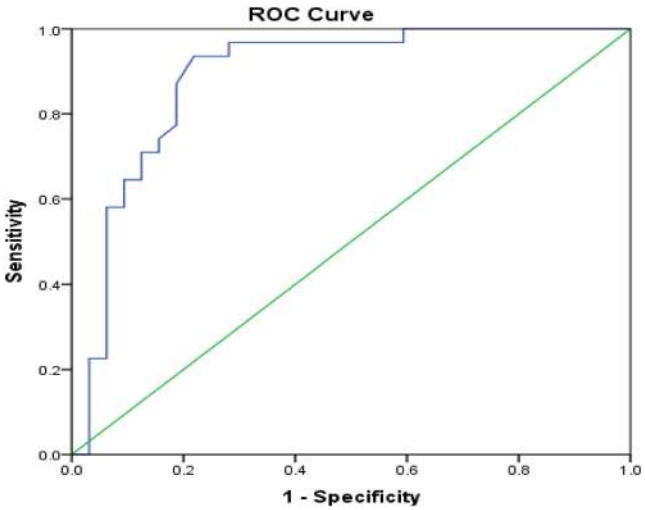

Figure 1: Correlation of serum PRA with AKI-A Kaplan-Meier analysis. [AUC = O.95%, Sensitivity = 0.83, Specificity = 0.87, 95% CI-79.8–97.5].

Conclusion: The serum PRA levels closely correlate with the acute kidney injury. Patients with high serum PRAs have a much higher risk of developingAKI. Therefore, baseline serum PRA can serve as a simple and reliable laboratory marker to assist in the prognosis of renal injury in decompensated cirrhosis patients.

Performance of spleen stiffness measured by point-shear wave elastography in esophageal varices screening

Mauro Giuffrè[1,2,3], Alessia Visintin[1,2,3], Cristiana Abazia[1,2,3], Flora Masutti[1,2,3], Saveria Lory Croce'[1,2,4]. [1]*Università Degli Studi Di Trieste, Dipartimento Universitario Clinico Di Scienze Mediche Chirurgiche e Della Salute;* [2]*Fondazione Italiana Fegato Onlus, Basovizza, Italy;* [3]*ASUGI Clinica Patologie del Fegato, Trieste, Italy;* [4]*ASUGI Clinica Patologie del Fegato, ospedale cattinara, Trieste, Italy*
Email: gff.mauro@gmail.com

Background and aims: According to Baveno VI guidelines, esophagogastroduodenoscopy (EGD) to stage esophageal varices (EVs) can be avoided in patients with chronic advanced liver disease who have a liver stiffness (LS) <20 kPa and a platelet count >150 × 10^3/μL. Current evidence suggests that spleen stiffness (SS) <46 kPa, measured by transient elastography, can safely predict absence of high-risk varices (HRV). Our aim is to externally validate those data by performing SS measurement with point-shear wave elastography.

Method: We enrolled 500 consecutive patients with compensated liver cirrhosis, of which n = 208 (40.4%) had esophageal varices (150 EVs, 58 HRV).

Results: Median SS values were 36 (28.5;45.3) kPa. Patients with EVs had higher median SS values if compared to patients without EVs (45.5 vs. 30 kPa, p < 0.001). A similar trend was detected in LS values (23 vs. 15 kPa, p < 0.001).

SS showed an AUROC of 0.88 (95% C.I. 0.85–0.9, p < 0.001) to discriminate between patients with and without EVs of any kind. Also, SS <30 kPa showed the highest sensitivity to rule-out EVs of any kind (sensitivity 100%, specificity 64%, accuracy 77%); SS >38.5 can rule-in the presence of EVS of any kind with a sensitivity of 87%,

specificity of 89%, accuracy 85%; SS >46 kPa can rule-in the presence of HRV with a sensitivity of 90%, specificity of 89%, accuracy 86%. Furthermore, SS showed a positive linear correlation with splenic bipolar diameter (R = 0.60, p < 0.001), splenic area (R = 0.70, p < 0.001), and a negative linear correlation with the platelet count (R = –0.79, p < 0.001).
Conclusion: The results of this study show how SS measurements can play an important role in the daily clinical management of cirrhotic patients. The SS (alone or combined with other indicators) may play an important role as a non-invasive screening test to predict the risk of EVs in patients with liver cirrhosis.

FRI523
Portal pressure decreasing effect of beta blockers in cirrhosis with clinically significant portal hypertension, according to the components of metabolic syndrome
Anna Brujats[1], Berta Cuyas[1], Edilmar Alvarado-Tapias[1,2], Claudia Pujol[1], Antoni Mombiela[1], Cristina Roig[1], Maria Poca[1,2], Xavier Torras[1], Àngels Escorsell[1,2], Càndid Villanueva[1,2]. *[1]Hospital de la Santa Creu i Sant Pau, Gastroenterology and Hepatology Department, Biomedical Research Institute Sant Pau (IIB Sant Pau). Universitat Autònoma de Barcelona; [2]Centro de Investigación Biomédica en Red de Enfermedades Hepáticas y Digestivas (CIBERehd). Instituto de Salud Carlos III*
Email: annabrujats@gmail.com

Background and aims: Patients with cirrhosis due to metabolic associated fatty liver disease (MAFLD) have higher risk of complications related to portal hypertension at any HVPG threshold than patients with HCV cirrhosis. MAFLD is associated with metabolic comorbidities such as obesity, diabetes mellitus (DM), arterial hypertension (AHT) and dyslipidemia (DLP), which may affect vascular response to beta blockers (NSBB). However, whether the unfavorable outcomes in patients with MAFLD can be related to an impact of metabolic comorbidities on the hemodynamic response to NSBB has not been clarified. We aimed to investigate whether the effect of NSBBs on portal pressure may be worse with metabolic comorbidities.
Method: Patients with cirrhosis and high-risk varices, were consecutively included. Hemodynamic measurements were performed at baseline and were repeated 15 to 20 minutes after intravenous administration of propranolol (0.15 mg/Kg). The HVPG response was investigated by grouping patients according to obesity, DM, AHT and DLP. The effect of propranolol was adjusted for baseline differences between groups using propensity score (PS).
Results: 585 patients were included (71% male, mean age 62 ± 11 years), 41% were Child Pugh class A and 59% class B/C, with MELD score of 12 ± 4. The etiology of cirrhosis was alcohol in 48%, HCV in 36% and MAFLD in 90 (15%). 178 (30%) patients had DM, 116 (20%) obesity, 220 (38%) AHT and 100 (17%) DLP. 191 (33%) had ≥1 metabolic comorbidity. After propranolol, mean decrease in HVPG was lower in patients with DM than in those without DM (9 ± 10% vs 13.4 ± 10%, p < 0.01), lower in obesity vs normo-weight (10.7 ± 9% vs 13.5 ± 10%, p = 0.04), lower in AHT vs without (10.7 ± 10% vs 13.1 ± 10%, p = 0.02) and lower in DLP vs without (9.7 ± 8% vs 12.7 ± 10%, p = 0.03). Adjusting by PS only HVPG changes in DM were significant (p = 0.03). Among metabolic comorbidities, only DM was independently associated with HVPG decrease by multivariate logistic regression (OR = 0.64, 95% CI = 0.41–0.99; p = 0.049). Patients with DM had lower rates of HVPG decrease ≥10% from baseline (46% vs 59%, p = 0.01) and of HVPG decrease ≥20% (8% vs 25%, p < 0.01). Patients with MAFLD also had lower decrease in HVPG after propranolol than those with cirrhosis not MAFLD related (9 ± 6% vs 14 ± 10%, p < 0.01). By multivariate logistic regression, only MAFLD and not metabolic comorbidities, was independently associated with HVPG decrease (p < 0.01). Among patients with MAFLD, HVPG decrease was <10% in all cases, either with or without each metabolic comorbidity.
Conclusion: Patients with MAFLD cirrhosis had worse hemodynamic response to NSBB than those with cirrhosis not MAFLD related. Among metabolic comorbidities, only the presence of DM has an independent negative influence on acute hemodynamic response to NSBB. However, the influence of MAFLD on hemodynamic response to NSBB was independent of DM or other metabolic comorbidities.

FRI524
Transjugular, intra-hepatic portosystemic shunt (TIPS) in elderly patients: preliminary analysis of a multi center retrospective cohort
Davide Roccarina[1], Laura Turco[2], Claudia Campani[1], Dario Saltini[2], Silvia Aspite[1], Vincenza Calvaruso[3], Umberto Arena[1], Marco Senzolo[4], Fabrizio Fanelli[5], Cristian Caporali[2], Stefano Gitto[1], Michele Citone[5], Chiara Di Bonaventura[1], Filippo Schepis[2], Francesco Vizzutti[1], Oliviero Riggio[6], Patrizia Burra[4], Erica Villa[2], Calogero Camma[3], Fabio Marra[1], Marcello Bianchini[2]. *[1]University of Florence, Firenze, Italy; [2]University of Modena and Reggio Emilia, Modena, Italy; [3]Università degli Studi di Palermo, Palermo, Italy; [4]University of Padua, Padova, Italy; [5]Careggi University Hospital, Firenze, Italy; [6]Sapienza University of Rome, Roma, Italy*
Email: fabio.marra@unifi.it

Background and aims: TIPS is largely used in patients with cirrhosis affected by portal hypertensive (PH) complications such as bleeding gastro-esophageal varices (GEV) or refractory ascites (RA). However, data regarding its effectiveness and safety in elderly patients are limited. The objective of this study was to evaluate if TIPS might represent an effective and safe option in this group of patients.
Method: We retrospectively analyzed patients with cirrhosis who underwent TIPS implantation for RA and/or bleeding GEV at three Italian referral centers (Florence, Modena, Padua) between 2004 and 2021. A cut-off value of 70 years was considered to define elderly patients. Control of PH consequences, such as ascites and/or bleeding GEV, incidence of complications such as hepatic encephalopathy and deterioration of hepatocellular function, and death were evaluated in the two groups.
Results: A total of 347 consecutive patients, mean age 63.4 ± 8.2 y, 74% males, 35.7% alcohol, 27% HCV and 20% NASH, with a median follow-up of 609 days (IQR 1035) were included and divided into two groups: 252 (72%) were 69 years old or younger (<70 y, mean age 59.4 ± 5.5 y) and 95 (28%) were 70 years or older (≥70 y, mean age 74 ± 3.2 y). There were no statistically significant differences between the two groups before TIPS when comparing gender, BMI, TIPS indication, MELD or porta-caval gradient. In the <70 y group there was a higher number of patients with more advanced liver disease (Child-Pugh B and C 68.9% vs 59.3% and 7.5% vs 3.3%, respectively, p = 0.027), while in the ≥70 y group there were significantly more patients with at least one comorbidity (>0.001). During follow-up, no significant differences between the two groups were observed in the overall incidence of all-grade encephalopathy or rebleeding episodes. Moreover, control of ascites or deterioration of hepatocellular function, evaluated at 1, 3, 6, and 12 months, were similar in the two groups. Regarding ascites control, similar results were obtained when the groups were stratified for Child-Pugh classification. Survival was significantly longer in the <70 y group (p < 0.001). Age and MELD score before TIPS were predictors of mortality.

Conclusion: In elderly patients, TIPS implantation is an effective option for the treatment of complications of PH. In this population, the incidence of post-derivative encephalopathy and deterioration of liver function is similar to the one observed in younger patients.

FRI525

Endoscopic glue injection v/s endoscopic human thrombin injection for bleeding gastric varics -a randomized controlled trial

Ashok Jhajharia[1]. [1]*SMS Medical College, Gastroenterology, Jaipur, India*
Email: drashokjhajharia@gmail.com

Background and aims: Acute gastric variceal bleeding (AGVB) is a potentially fatal consequence of portal hypertension, accounting for 10–30% of all variceal bleeding. Although endoscopic cyanoacrylate glue injection is a common treatment for acute hemostasis, it has been linked to significant side effects. In the treatment of AGVB, there is limited evidence of the efficacy and relative safety of endoscopic human thrombin injection over glue injection.
Method: A total of 52 AGVB patients were randomized to receive either thrombin injection (25 patients) or glue injection (27 patients). The primary outcome was the incidence of any glue or thrombin injection-related post-therapy complications. Initial hemostasis, rebleeding, and mortality were all secondary end goals.
Results: Both groups had comparable baseline data. Hemostasis of active bleeding at endoscopy was 100.0% (10/10) in the thrombin group and 87.5% (7/8) in the glue group (p = 0.44). Treatment failure after 5 days occurred in two patients (6.1%) in the glue group compared to none in the thrombin group (p = 0.165). Between 6 and 42 days after index bleeding, rebleeding occurred in 4 patients in the thrombin group compared to 12 patients in the glue group (p < 0.03). In the thrombin group, none of the patients had post treatment ulcers on gastric varices compared to 14.81% (4/27) that occurred in the glue group (p < 0.045). Overall, complications occurred in 4 (20%) and 11 (40.7%) patients in the thrombin and glue groups, respectively (p = 0.105). Two patients in glue group died.
Conclusion: In order to achieve successful AGVB hemostasis, endoscopic thrombin injection was identical to glue injection. However, glue injection may be linked to a higher rate of rebleeding and post-therapy gastric varices ulcerations.

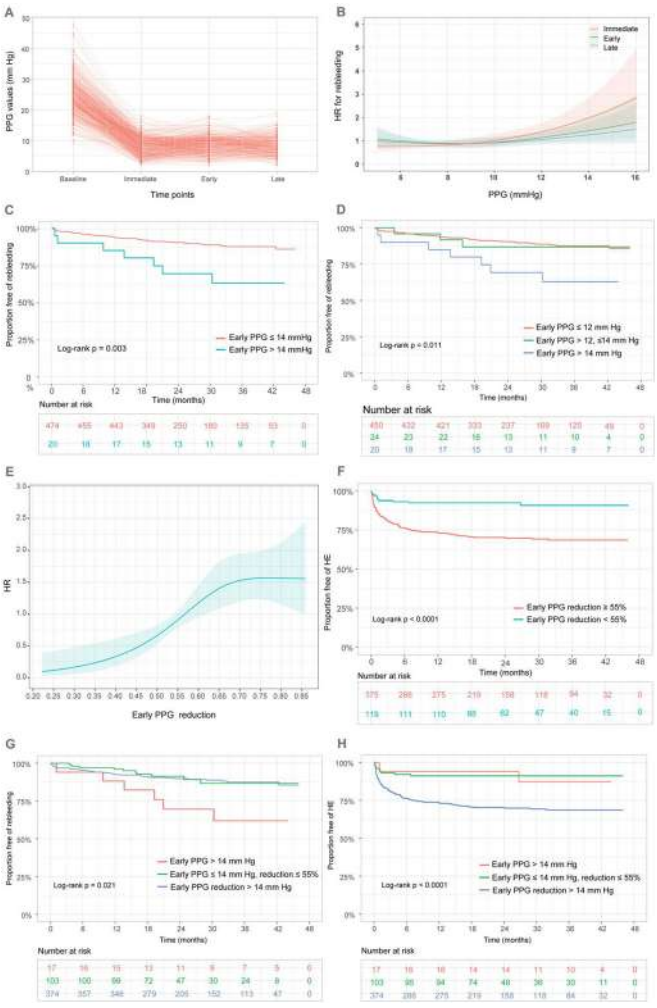
FRI526

Updating target PPG value to reduce clinical events in patients receiving covered-TIPS for the prevention of variceal rebleeding

Qiuhe Wang[1], Bohan Luo[1], Wei Bai[1], Kai Li[1], Wengang Guo[1], Zhengyu Wang[1], Jie Yuan[1], Xiaomei Li[1], Yong Lv[1], Dongdong Xia[1], Zhanxin Yin[1], Jielai Xia[2], Guohong Han[1]. [1]*Department of Liver Diseases and Interventional Radiology, Digestive Diseases Hospital, Xi'an International Medical Center Hospital, Northwestern University, Xi'an, China;* [2]*Department of Medical Statistics, Fourth Military Medical University*
Email: 13991969930@126.com

Background and aims: A portosystemic pressure gradient (PPG) value of ≤12 mm Hg or ≥20% decrease has long been established as the target for TIPS in preventing variceal rebleeding. However, this value was defined in the era of bare stents, when dysfunction rate was high with constantly increased PPG. Moreover, not reaching this target does not necessarily indicate rebleeding. We aimed to confirm the optimal time point to measure PPG as an outcome predictor and update its target value in the scenario of covered TIPS for the prevention of variceal rebleeding.
Method: Consecutive patients receiving TIPS for acute variceal bleeding or secondary prophylaxis of rebleeding during January 1st, 2017 to October 31st, 2019 were included. TIPS procedures with local anesthesia and 8 mm covered stents was performed. PPG was meausred preoperatively, immediately after stenting (immediate PPG), within 24–72 h post-operatively (early PPG), and at 1 month (late PPG).

Results: TIPS indications were secondary prophylaxis of rebleeding in 463 (93.7%) patients and pre-emptive TIPS in 31 (6.3%) patients. Median follow-up was 24.4 (17.2–36.7) months. Baseline, immediate, early, and late PPG values were 24.4 ± 5.8, 8.2 ± 3.0 mm Hg, 8.9 ± 3.1 mm Hg, and 8.7 ± 3.2 mmHg, respectively (Fig. 1A). Absolute early and late PPG were independent predictors of rebleeding in multivariate analyses, with similar HRs (1.11 [1.02–1.21], p = 0.015, vs. 1.09 [1.01–1.20], p = 0.029) and restrictive cubic spline curves (Fig. 1B). Given the easy access of early PPG before discharge, it was designated as the preferred timepoint. The cut-off value with the best discrimination for early PPG in predicting rebleeding was 14 mm Hg (Fig. 1C). Patients were then stratified into three subgroups: early PPG ≤12 mmHg, >12 mm Hg but ≤14 mmHg, and >14 mmHg. Patients with early PPG ≤14 mm Hg, whether lower than 12 mm Hg or not, had similar rates of variceal rebleeding, yet both strata exhibited lower rebleeding rates compared to that with early PPG >14 mm Hg (log-rank p = 0.011, Fig. 1D). As for HE, multivariate analyses indicated that early PPG reduction ([baseline PPG-early PPG]/baseline PPG) was an independent predictor (HR 1.05 [1.03–1.07], p < 0.001, Fig. 1E), with optimal cut-off being 55% (Fig. 1F). Given these results, the optimal window of PPG should be an absolute early PPG value ≤14 mm Hg (to control rebleeding), with early PPG reduction ≤55% (to avoid excessive HE). Indeed, this subgroup of patients present the most satisfying results regarding both rebleeding and HE, as compared with other subgroups (Fig 1G, and 1H).



Conclusion: The optimal timepoint to measure PPG as an outcome predictor should be early after the procedure (within 24–72 h). Raising the bar of absolute early PPG value from ≤12 mm Hg to

≤14 mm Hg does not affect rebleeding rates, while a relative reduction of 55% might reduce HE in the era of covered TIPS.

FRI527

Impact of alcohol abstinence in patients with alcohol-related cirrhosis and portal hypertension

Benedikt Hofer[1,2,3], Benedikt Simbrunner[1,2,3], Lukas Hartl[1,2], Mathias Jachs[1,2], Lorenz Balcar[1,2], Rafael Paternostro[1,2], Philipp Schwabl[1,2,3], Georg Semmler[1,2], Bernhard Scheiner[1,2], Albert Stättermayer[1], Michael Trauner[1], Mattias Mandorfer[1,2], Thomas Reiberger[1,2,3]. *[1]Medical University of Vienna, Division of Gastroenterology and Hepatology, Department of Internal Medicine Iii, Vienna, Austria; [2]Medical University of Vienna, Vienna Hepatic Hemodynamic Laboratory, Division of Gastroenterology and Hepatology, Department of Internal Medicine Iii, Vienna, Austria; [3]Medical University of Vienna, Christian Doppler Lab for Portal Hypertension and Liver Fibrosis, Vienna, Austria*
Email: thomas.reiberger@meduniwien.ac.at

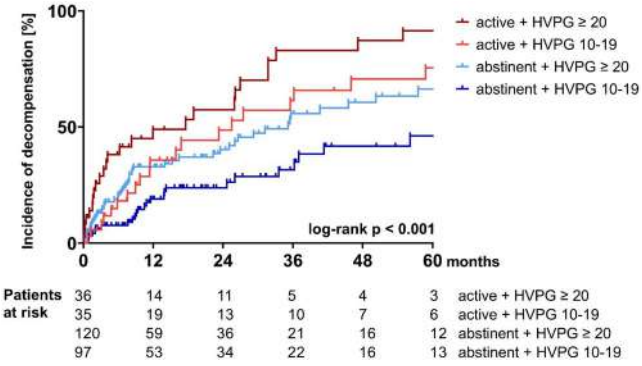
Background and aims: Alcohol-related liver disease (ALD) is a leading cause of liver-related mortality worldwide. Alcohol abstinence is a major determinant of its natural history. However, the impact of abstinence on the disease course in patients who have already progressed to cirrhosis and clinically significant portal hypertension (CSPH) is less well-established. The aim of this study was to examine the impact of alcohol abstinence on decompensation and mortality in ALD patients with CSPH.

Method: Alcohol abstinence, CSPH-related decompensation and mortality were assessed in a cohort comprised of retrospectively and prospectively (Vienna Cirrhosis Study, NCT03267615) recruited ALD patients diagnosed with CSPH (hepatic venous pressure gradient (HVPG) ≥10 mmHg). Patients were classified into four groups according to alcohol abstinence during follow-up and the presence of low (HVPG 10–19 mmHg) or high (HVPG ≥20 mmHg) risk portal hypertension at baseline: abstinent-low (n = 97), abstinent-high (n = 120), active-low (n = 35) and active-high (n = 36).

Results: We included 288 ALD patients (mean age: 56.7 ± 9.9 years; 74.7% male; 88.2% decompensated), who were followed for a median of 21.8 (IQR: 9.1–41.8) months. During the study period, 217 patients (75.3%) remained abstinent, while 71 patients (24.7%) showed continuous alcohol consumption. The mean baseline HVPG of the overall cohort was 20.2 ± 5.0 mmHg (abstinent: 20.2 ± 5.1 vs. active: 20.1 ± 4.8 mmHg; p = 0.858).

First/further hepatic decompensation was less frequent in abstinent patients compared to patients with continued alcohol consumption (26.5% vs. 42.4% at one year; 32.8% vs. 53.0% at two years; log-rank p < 0.001). Importantly, abstinent patients survived significantly longer, with a median transplant-free survival time of 68.2 (95%CI: 37.3–99.1) vs. 41.9 (95%CI: 27.7–56.0) months in patients with ongoing alcohol intake (log-rank p = 0.006).

Following the sub-stratification according to HVPG, the cumulative incidence of hepatic decompensation varied significantly between the subgroups, with 19.0%/23.9% in abstinent-low, 32.8%/40.2% in abstinent-high, 35.7%/48.6% in active-low and 48.9%/57.4% in active-high at one and two years respectively (log-rank p < 0.001). HVPG ≥20 mmHg and continued alcohol intake negatively impacted survival, as demonstrated by a median transplant-free survival time of 94.7 (95%CI: 40.1–149.3) months in abstinent-low, 63.3 (95%CI: 34.1–92.4) months in abstinent-high, 61.3 (95%CI: 32.8–89.8) months in active-low and 36.5 (95%CI: 27.5–45.4) months in active-high (log-rank p = 0.034) ALD patients.



Conclusion: Alcohol abstinence and severity of CSPH are key determinants in the clinical course of ALD patients with cirrhosis and CSPH. ALD patients with low-risk CSPH but a continued alcohol consumption still have a poor prognosis that is similar to abstinent patients with high-risk CSPH.

FRI528

Hepatic recompensation according to Baveno VII criteria significantly reduces liver-related mortality in patients with decompensated alcohol-related cirrhosis

Benedikt Hofer[1,2,3], Benedikt Simbrunner[1,2,3], Lukas Hartl[1,2], Mathias Jachs[1,2], Lorenz Balcar[1,2], Rafael Paternostro[1,2], Philipp Schwabl[1,2,3], Georg Semmler[1,2], Bernhard Scheiner[1,2], Albert Stättermayer[1], Michael Trauner[1], Mattias Mandorfer[1,2], Thomas Reiberger[1,2,3]. *[1]Medical University of Vienna, Division of Gastroenterology and Hepatology, Department of Internal Medicine III, Vienna, Austria; [2]Medical University of Vienna, Vienna Hepatic Hemodynamic Laboratory, Division of Gastroenterology and Hepatology, Department of Internal Medicine III, Vienna, Austria; [3]Medical University of Vienna, Christian Doppler Lab for Portal Hypertension and Liver Fibrosis, Vienna, Austria*
Email: thomas.reiberger@meduniwien.ac.at

Background and aims: Abstinence from alcohol constitutes the removal of the primary aetiologic factor in alcohol-related cirrhosis and has been linked to an improved outcome. However, the extent and prognostic value of clinical improvements after achieving alcohol abstinence in decompensated alcohol-related cirrhosis have not been sufficiently characterised. Thus, the aim of this study was to examine the impact of hepatic recompensation according to the novel Baveno VII criteria on liver-related mortality and the development of hepatocellular carcinoma (HCC) in patients with decompensated alcohol-related cirrhosis.

Method: Recompensation during follow-up was assessed in patients with decompensated alcohol-related cirrhosis and persistent alcohol abstinence who underwent a baseline hepatic venous pressure gradient (HVPG) assessment. Recompensation was defined according to Baveno VII criteria as resolution of ascites and hepatic encephalopathy (absence of clinical signs and cessation of medical therapy), absence of variceal bleeding and improvement in liver function. Achieving recompensation was regarded as a time-dependent covariate and analysed using Cox proportional-hazards models.

Results: 204 patients with alcohol-related cirrhosis (age: 56.9 ± 9.8 years, 75.0% male) and a median HVPG of 20 (18–24) mmHg were followed-up over a median of 24.4 months. Overall, 37 patients (18.1%) achieved hepatic recompensation. Baseline parameters linked to a higher probability of recompensation in a competing risk analysis included a lower HVPG, a lower Child-Pugh score, higher albumin, higher mean arterial pressure and a lower BMI. Achieving hepatic recompensation nearly abolished the risk of liver-related mortality (HR: 0.071 [95% CI: 0.010–0.527], p = 0.010), even after adjusting for baseline HVPG, MELD, albumin, C-reactive protein and age (adjusted HR: 0.091 [95% CI: 0.012–0.677]; p = 0.019; Table 1). With regard to

HCC development, we observed a trend towards a reduced risk in recompensated patients, yet this finding did not reach statistical significance (HR: 0.398 [95% CI: 0.084–1.878], p = 0.245).

	Univariate analysis			Multivariate analysis		
	HR	95% CI	p value	aHR	95% CI	p value
Recompensation	0.071	0.010–0.527	0.010	**0.091**	0.012–0.677	**0.019**
MELD (per point)	1.072	1.019–1.129	0.007	**1.078**	1.011–1.149	**0.022**
Albumin (per g/L)	0.957	0.917–0.999	0.046	**1.016**	0.961–1.076	0.572
HVPG (per mmHg)	1.101	1.040–1.166	0.001	**1.062**	1.000–1.129	0.051
CRP (per mg/dL)	1.257	1.079–1.464	0.003	**1.068**	0.895–1.275	0.465
Age (per year)	1.042	1.012–1.074	0.006	**1.039**	1.006–1.074	**0.020**

Conclusion: Hepatic recompensation according to Baveno VII criteria occurred in a considerable proportion of patients with decompensated alcohol-related cirrhosis and was associated with a significantly reduced risk of liver-related mortality. Of note, recompensated patients remain at risk of HCC.

FRI529

Covered TIPS reduces the risk of further decompensation: results from an individual patient data meta-analysis of 3924 patients with cirrhosis

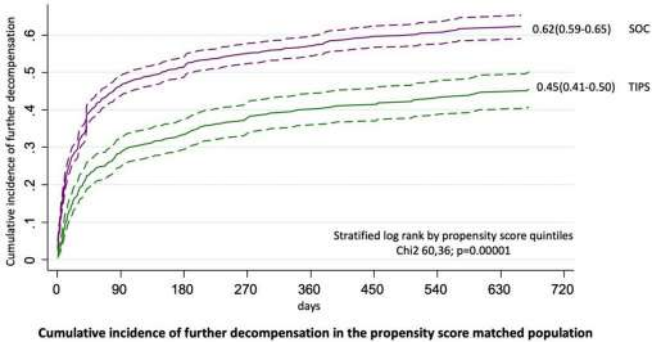
Email: bureau.c@chu-toulouse.fr

Background and aims: Baveno VII conference introduced the concept of further decompensation as a prognostic stage of cirrhosis that is associated with an even higher mortality than first decompensation. The effectiveness of transjugular intrahepatic portosystemic shunt (TIPS) has already been demonstrated for the prevention of rebleeding and recurrent ascites. Nevertheless, the effect of TIPS to decrease the overall incidence of further decompensation events remains unclear-mainly because of the risk of encephalopathy and liver failure. The aim of this study was to assess the incidence of further decompensation after TIPS, defined as new or worsening ascites, new or worsening hepatic encephalopathy or new portal hypertension (PH)-related bleeding or rebleeding, in comparison to standard of care (SOC).

Method: We conducted a review of the medline literature searching for controlled studies (randomized control trials (RCT) and cohorts) assessing TIPS in comparison to SOC in the indication of recurrent ascites, refractory bleeding, and secondary prevention of bleeding since the use of polytetrafluoroethylene-covered stents and until 2020. We collected individual patient data (IPD) to perform an IPD meta-analysis also using a propensity score (PS) matching by multivariate logistic regression. The comparisons were performed by stratified log-rank test by PS quintiles. The primary outcome was the incidence of further decompensation. The secondary outcome was overall survival.

Results: 12 databases among the 14 selected studies (5 RCT, 9 cohorts) were available. The whole population included 3924 patients (SOC: n = 3077; TIPS: n = 847). After PS matching, 2415 patients (SOC: n = 1802; TIPS: n = 613) were analyzed: 70% men, mean age 54 ± 12, alcohol-related cirrhosis 42%, mean Child-Pugh 9 ± 2, mean MELD score 14 ± 6 without significant differences between groups. The cumulative incidence function of further decompensation at 2 years in the PS-matched population was 0.45 (0.41–0.50) in the TIPS group vs. 0.62 (0.59–0.65) in the SOC group (stratified log-rank p = 0.00001), with mortality and liver transplantation as competing risk (figure). The benefit of TIPS was confirmed by IPD meta-analysis adjusted for age, treatment, history of ascites, of encephalopathy, of hepatocellular carcinoma, serum albumin and MELD (hazard ratio 0.47 (0.39–0.57)) without significant heterogeneity (I^2 = 8.4%; p = 0.365) and was consistent across study subgroups according to TIPS indication. The overall survival was significantly better in TIPS group: 74% (69%–78%) vs 63% (59%-66%) in SOC group (stratified log rank p < 0.0001).



Cumulative incidence of further decompensation in the propensity score matched population

Conclusion: This IPD meta-analysis demonstrates that TIPS decreases the risk of further decompensation in comparison to SOC, in patients with cirrhosis treated for recurrent ascites or in secondary prevention of PH-related bleeding and importantly, also improves survival.

FRI530

Sarcopenia increases the risk of cirrhosis disease progression and death in patients with cirrhosis

Puneeta Tandon[1], Sarah Wang[1], Moon Young Kim[2], Bart Van Hoek[3], Daphne Bot[4], Jeroen van Vugt[5], Berend Beumer[5], Jan Ijzermans[5], Sunil Taneja[6], Surender Singh[6], Maryam Ebadi[1], Aldo J Montano-Loza[1]. *[1]Division of Gastroenterology (Liver Unit), University of Alberta, Edmonton, Canada; [2]Department of Internal Medicine, Yonsei University Wonju College of Medicine, Wonju, Korea, Rep. of South; [3]Department of Gastroenterology and Hepatology, Leiden University Medical Center, Leiden, Netherlands; [4]Department of Dietetics, Leiden University Medical Center, Leiden, Netherlands; [5]Department of Surgery, Division of HPB & Transplant Surgery, Erasmus MC Transplant Institute, Erasmus MC, University Medical Centre Rotterdam, Rotterdam, Netherlands; [6]Department of Hepatology, Postgraduate Institute of Medical Education and Research, Chandigarh, India*
Email: ptandon@ualberta.ca

Background and aims: Sarcopenia in cirrhosis has been operationalized as low muscle mass. The skeletal muscle index (SMI) is a well-validated tool to identify sarcopenia in cirrhosis and has been associated with increased mortality in patients awaiting liver transplant (LT). To date, the impact of sarcopenia on cirrhosis progression is unknown. In this study, we aimed to explore the relationship between sarcopenia and the risk of: (i) a combined outcome of cirrhosis progression or mortality or (ii) mortality alone.
Method: The SMI was measured at baseline using abdominal CT imaging at the 3rd lumbar vertebra (L3). Sarcopenia was defined using established cut-offs in patients with cirrhosis awaiting LT as SMI <39 cm^2/m^2 in females and <50 cm^2/m^2 in males. Progression of cirrhosis was defined by an increase in clinical stage from baseline using the D'Amico classification. Factors associated with progression or death or death alone were evaluated using univariate and multivariate Cox regression models.
Results: 1624 adult patients with cirrhosis from five centers across Europe, North America and Asia were included. Mean age was 54 ± 9 years, 26% of patients were female, 31% had compensated disease at baseline, and the mean MELD-Na was 15 ± 7 years. Data on ethnicity was available in 1354 patients (48% Caucasian/European, 46% Asian, and the remainder other ethnicities). The top three etiologies of liver disease were alcohol (40%), hepatitis C (19%) and hepatitis B (13%). Both the SMI as a continuous variable and presence of sarcopenia were associated with the combined outcome of cirrhosis progression or mortality (HR 0.98, 95% CI 0.97–0.99, p < 0.001; and HR 1.37, 95% CI 1.17–1.61, p < 0.001; respectively); and mortality alone (HR 0.98, 95% CI 0.97–0.99, p < 0.001; and HR 1.39, 95% CI 1.16–1.67, p < 0.001; respectively). In multivariate analysis, sarcopenia was associated with increased risk of progression to the next cirrhosis stage or death (HR 1.25, 95% CI 1.06–1.47, p = 0.007) and increased risk of death alone (HR 1.25, 95% CI 1.04–1.50, p = 0.02), after adjusting for age, sex, and MELD score. The 1-year, 5-year and 10-year probabilities of death or progression-free survival were 71%, 37%, and 22% in patients with sarcopenia, compared to 83%, 43%, and 27% in patients without sarcopenia (p < 0.001, log-rank test; Figure 1a). Median survival for patients with sarcopenia was 52 months (95% CI 31–73), compared to 74 months (95% CI 50–97) in patients without sarcopenia (p < 0.001, log-rank test, Figure 1b).

Figure 1a

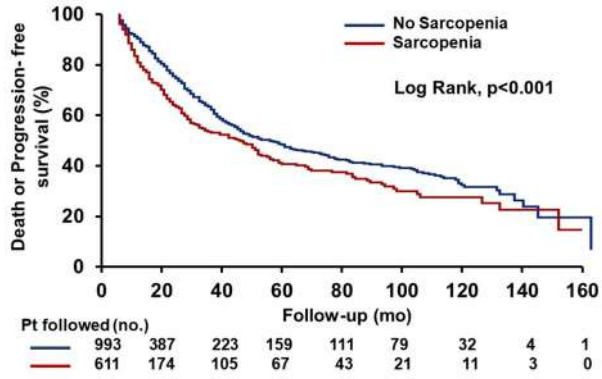


Figure 1b.

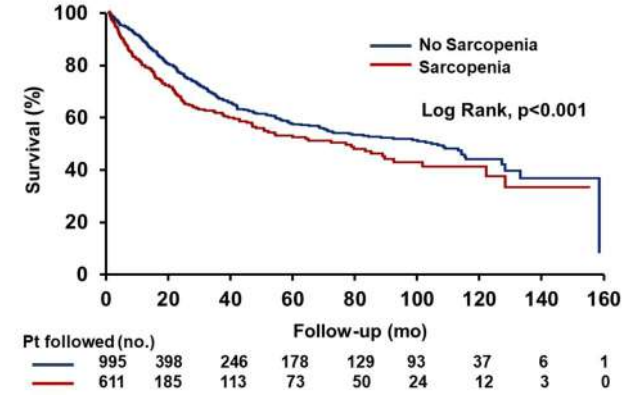

Figure: Survival probabilities for the a) combined outcome of cirrhosis progression or mortality and b) mortality alone in patients with and without sarcopenia.

Conclusion: Sarcopenia was an independent predictor of cirrhosis progression or death or death alone. Future studies are needed to evaluate the possibility of slowing cirrhosis disease progression by reversing or preventing sarcopenia.

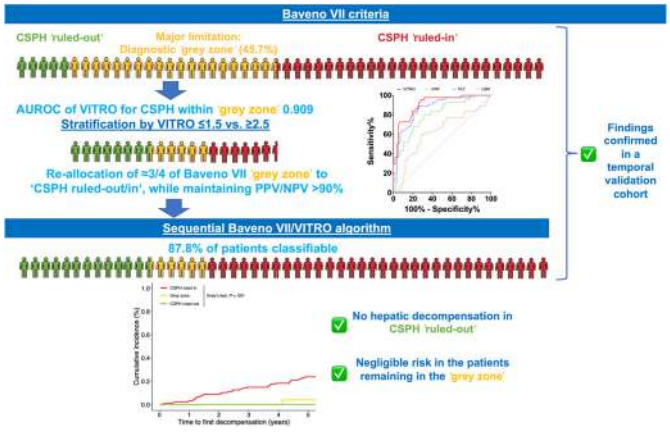
FRI531

Substantial reduction of the diagnostic grey zone of the Baveno-VII CSPH criteria by sequential consideration of VITRO

Lukas Hartl[1,2], Mathias Jachs[1,2], Benedikt Simbrunner[1,2,3], David JM Bauer[1,2], Rafael Paternostro[1,2], Bernhard Scheiner[1,2], Lorenz Balcar[1,2], Georg Semmler[1,2], Albert Stättermayer[1,2], Matthias Pinter[1,2], Peter Quehenberger[4], Michael Trauner[1], Thomas Reiberger[1,2,3], Mattias Mandorfer[1,2]. *[1]Medical University of Vienna, Division of Gastroenterology and Hepatology, Department of Medicine III, Vienna, Austria; [2]Medical University of Vienna, Vienna Hepatic Hemodynamic Lab, Division of Gastroenterology and Hepatology, Department of Medicine III, Vienna, Austria; [3]Medical University of Vienna, Christian Doppler Lab for Portal Hypertension and Liver Fibrosis, Vienna, Austria; [4]Medical University of Vienna, Department of Laboratory Medicine, Vienna, Austria*
Email: mattias.mandorfer@meduniwien.ac.at

Background and aims: Baveno-VII proposed liver stiffness measurement (LSM) and platelet count (PLT) criteria for non-invasive clinically significant portal hypertension (CSPH) diagnosis in compensated advanced chronic liver disease (cACLD; CSPH 'ruled-out': LSM ≤15 kPa plus PLT ≥150 G/L; CSPH 'ruled-in': LSM ≥25 kPa). However, a substantial share of patients remains in the diagnostic 'grey-zone'. We aimed to refine these criteria by sequential application of von Willebrand factor antigen (VWF)/thrombocytes (VITRO) score.

Method: Patients with evidence of cACLD (LSM ≥10 kPa) undergoing hepatic venous pressure gradient (HVPG) measurement at the Vienna General hospital between 2004 and 2021 were included. The performance of non-invasive tests (NIT) including VITRO, i.e., the ratio between VWF (%) and PLT (G/L), for the diagnosis of CSPH (HVPG ≥10 mmHg) were evaluated in a derivation (2004–2016; n = 221) and a validation (2017–2021; n = 81) cohort. A particular focus was put on patients who were unclassifiable by Baveno-VII criteria.
Results: Overall, viral hepatitis was the predominant etiology (50.7%), followed by alcoholic liver disease (15.2%) and non-alcoholic steatohepatitis (13.2%). CSPH prevalence was 62.3%.
According to Baveno-VII criteria, 45.7% of patients in the derivation cohort remained in the diagnostic 'grey-zone' for CSPH, in which VITRO showed an excellent performance for the detection of CSPH with an area under the receiver operator characteristic curve (AUROC) of 0.909 (95% confidence interval [95%CI]: 0.823–0.965). VITRO ≤1.5/≥2.5 'ruled-out' (negative predictive value [NPV]: 97.5%, specificity: 97.7%) and 'ruled-in' (positive predictive value [PPV]: 91.2%, sensitivity: 94.7%) CSPH in patients who were unclassifiable by Baveno-VII criteria. The application of a sequential Baveno-VII-VITRO algorithm re-allocated 73% of initial 'grey-zone' patients to the 'ruled-in'/'ruled-out' group, whilst maintaining a PPV/NPV >90%. Finally, 87.8% of patients were classifiable in regard to CSPH by the Baveno-VII-VITRO sequence. Importantly, all findings were confirmed in a temporal validation cohort.



Of note, not a single patient (0.0%) allocated to the 'CSPH ruled-out' group by the Baveno-VII-VITRO sequence developed decompensation within five years, while 5-year decompensation rates were substantial (23.9%) among 'CSPH ruled-in' patients and negligible (4%) in remaining 'grey-zone' patients.

Conclusion: The sequential application of VITRO ≥2.5 to patients who are unclassifiable by Baveno-VII-criteria improves the identification of cACLD patients with a high risk of CSPH and subsequent decompensation. In turn, VITRO ≤1.5 'ruled-out' CSPH in Baveno-VII 'grey zone' patients and indicated a favorable prognosis. Less than 15% of cACLD patients remained in the final 'grey zone' when applying the sequential Baveno VII-VITRO algorithm.

FRI532
Causes and predictors of 30-day readmission in patients with gastric varices requiring Balloon-occluded retrograde transvenous obliteration (BRTO)

Mohamed Ahmed[1], Vinay Jahagirdar[1], Wael Mohamed[1], Ifrah Fatima[1], Kevin Kennedy[2], Alisa Likhitsup[3]. [1]*University of Missouri-Kansas City Volker Campus, Internal medicine, Kansas City, United States;* [2]*Saint Luke's Hospital of Kansas City, Kansas City, United States;* [3]*University of Missouri-Kansas City*
Email: mohamedfayez1991@gmail.com

Background and aims: Variceal bleeding is one of the major complications of portal hypertension. Though gastric variceal bleeding is less common, it has a higher mortality than esophageal variceal bleeds. Endoscopic management of gastric varices (GV) is less effective, and Transjugular Intrahepatic Portosystemic Shunts (TIPS) and balloon-occluded retrograde transvenous obliteration (BRTO) are used. In BRTO, the portosystemic gastrorenal shunt is accessed via the left renal vein, from a trans-jugular or transfemoral approach. The shunt is occluded by a balloon and a sclerosing agent is injected into the variceal system. Studies have shown that BRTO can effectively control active gastric variceal bleeding and is a good alternative to TIPS. Diverting the blood towards the liver improves hepatic function and patient survival, but increased portal pressures may also worsen esophageal varices and ascites.
Method: Patients with GV who underwent BRTO were identified from the 2016–2018 Healthcare Cost and Utilization Project databases (HCUP) using the National readmission database (NRD) by using the International Classification of Diseases Code, 10th Revision Clinical Modification (ICD-10). 30-day readmission rate and diagnosis were identified. Multiple logistic regression model was used to identify the factors associated with readmission. SAS 9.4 was used for data analysis.
Results: Total of 608 patients who underwent BRTO were identified between 2016 and 2018. Mean age was 58.2 ± 12.6. 39.8% of patients were females. The 30- and 90-days readmission rate was 20.4% and 28.2% respectively). Significant increase length of stay (10.5 ± 10.1 vs 8.4 ± 6.5; p < 0.004) and total charges (238765 vs 185972; p = 0.001) was associated with the 30-day readmission patients. Most common diagnosis for 30-day readmissions were hepatic encephalopathy (13%), acute liver failure (8%), gastric varices (6%), Ascites (5%), systemic infection (4%), and acute blood loss anemia (4%). Multiple logistic regression analysis showed that 30-day readmission was associated with renal failure (OR 3.25, 95% CI 1.72–6.16, P = 0.003) but not associated with presence of bleeding esophageal varices (OR 1.27, 95%CI, 0.81–1.98), hepatic encephalopathy (OR 1.2, 95% CI 0.75–2.17), liver failure (OR 2.16, 95% CI 0.93–4.99) and DM with chronic complications (OR 1.39, 95% CI 0.91–2.14) at the index admission.
Conclusion: BRTO procedures are associated with high 30-day readmission rate. Patients with renal failure undergoing BRTO are at significantly higher risk of 30-day readmissions with OR of 3.25. Hepatic decompensation, Acute liver failure and systemic infections appears to be the most common causes of 30-days readmission in patient having BRTO.

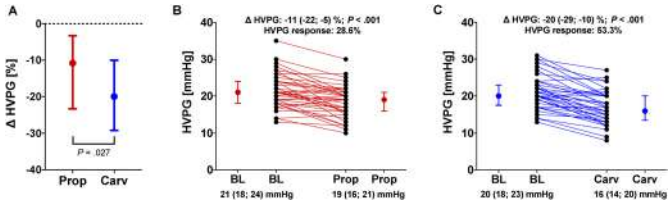
FRI533
Carvedilol is associated with superior hemodynamic response and rebleeding rates in comparison to propranolol in secondary prophylaxis of variceal bleeding

Mathias Jachs[1], Lukas Hartl[1], Benedikt Simbrunner[1], David JM Bauer[1], Rafael Paternostro[1], Lorenz Balcar[1], Benedikt Hofer[1], Nikolaus Pfisterer[1], Michael Schwarz[1], Bernhard Scheiner[1], Albert Stättermayer[1], Matthias Pinter[1], Michael Trauner[1], Mattias Mandorfer[1], Thomas Reiberger[1]. [1]*Medical University of Vienna, Division of Gastroenterology and Hepatology, Department of Internal Medicine III, Vienna, Austria*
Email: thomas.reiberger@meduniwien.ac.at

Background and aims: In primary prophylaxis of variceal bleeding, carvedilol offers more profound decreases in hepatic venous pressure gradient (HVPG) as compared to propranolol. However, limited data exists on its efficacy and safety after the first variceal bleed, i.e., in secondary prophylaxis.
Method: For this retrospective evaluation, patients who had previously bled and underwent paired HVPG measurements at our centre between 2004 and 2021 to guide non-selective betablocker (NSBB) therapy were included. All patients underwent band ligation in addition to NSBB therapy. The effects of NSBB treatment on HVPG and mean arterial pressure (MAP) was compared between

propranolol and carvedilol users. Long-term follow-up data on rebleeding, acute kidney injury (AKI) and ascites development/progression was recorded and analysed applying competing risk regression.

Results: Eighty-seven (carvedilol/propranolol: n = 45/n = 42) patients were included. Patients underwent their baseline HVPG measurement after a median of 2.2 months following their initial bleed and had a median (NSBB-naïve) baseline HVPG of 21 (IQR: 18; 24) mmHg. Ascites was present in 62% of patients, and 39%, 48% and 13% had Child-Turcotte-Pugh stage A, B and C cirrhosis, respectively. Carvedilol induced more marked reductions in HVPG as compared to propranolol (relative change: −20 [−29;−10] % vs. −11 [−22;−5] %, p = 0.027), resulting in a higher proportion of patients achieving chronic HVPG response, i.e., a reduction by ≥20% or to an absolute value ≤12 mmHg (53.3% vs. 28.6%, p = 0.034). Carvedilol was thus, associated with a lower cumulative incidence of rebleeding (2.4%/9.9%/10.4% vs. 9.9%/21.6%/34.9% at 1/3/5 years, Gray's test: p = 0.015) and liver-related death (5.0%/10.7%/10.7% vs. 7.4%/23.8%/33.9% at 1/3/5 years, p = 0.032) during long-term follow-up, as compared to propranolol. Notably, the incidence of AKI did not differ between the two groups (p = 0.139) despite more pronounced decreases in MAP induced by carvedilol (relative change: −12 [−17;−6] % vs. −6 [−17; 2] %, p = 0.044), and ascites development or worsening was less commonly observed in patients on carvedilol therapy (p = 0.034). Stratifying patients by HVPG response status yielded similar results.



Conclusion: Carvedilol was associated with higher rates of HVPG response and lower rebleeding rates in our retrospective study. Of note, the use of carvedilol was also linked to lower rates of non-bleeding further decompensation, i.e., ascites development/progression, whilst having similar impact on the incidence of AKI in our cohort, despite more marked reductions in MAP.

FRI534

Impact of early nasogastric tube feeding after endotherapy for acute variceal bleeding in patients with cirrhosis : a randomized controlled trial

Jatin Yegurla[1], Sanchit Sharma[1,2], Namrata Singh[1], Samagra Agarwal[1], Sumaira Qamar[1], Deepak Gunjan[1], Anoop Saraya[1]. [1]*All India Institute of Medical Sciences, Department of Gastroenterology and Human Nutrition Unit, New-Delhi, India;* [2]*John Radcliffe hospital, Translational Gastroenterology Unit, Oxford, United Kingdom*
Email: ansaraya@yahoo.com

Background and aims: Limited data exist on safety of early feeding in patients with cirrhosis after endotherapy for acute variceal bleeding (AVB). We studied the impact of early nasogastric (NG) tube feeding on relevant outcomes in these patients in a randomised controlled trial.

Method: Consecutive patients with cirrhosis undergoing endotherapy for AVB were randomized to receive either liquid diet through an NG tube (n = 40) [early-feeding (EF) group] or sips of water and lemon water orally (n = 40) [standard-of-care (SOC) group] for 48 hours after endotherapy. In early feeding group, 14 Fr NG tube (Ryle's tube) was placed immediately after endotherapy under endoscopic guidance and liquid diet was started one hour later which consisted of commercial polymeric formula feed for first 6 hours followed by home-made milk-based formula feed. Solid diet was resumed 48 hours later in both the groups. Primary end-point was 5-day rebleeding and secondary end-points included incidence of infections, hepatic encephalopathy during hospitalization and 6-week mortality.

Results: Eighty patients [Mean age: 41 ± 11.5 years; males (82.5%); Alcohol etiology (55%)] were included. Baseline characteristics were comparable in both the groups. The 5-day rebleeding rates in EF and SOC groups were 2.5% and 5%, respectively (p = 0.55). The incidence of infection [2.5% (EF) vs 2.5% (SOC), p = 1.00] and development of HE [5% (EF) vs 2.5% (SOC), p = 0.36] during hospitalisation were comparable. One patient in EF group developed mild epistaxis following NG tube insertion. Average calorie and protein intake by patients in EF group during the 48 hours was 1318 ± 240 Kcals and 43.4 ± 9.2 g of proteins per day. No patient in EF group developed feed intolerance. No significant difference was observed in mortality, rebleeding, infections or decompensations during the 6-week follow-up.

Table: Comparison of baseline characteristics and outcomes between early-feeding (EF) and standard-of-care (SOC) groups. All values are expressed as mean ± SD or frequency (percentage).

	EF group (N = 40)	SOC group (N = 40)	P value
Age (years)	39.4 ± 12.3	42.6 ± 10.5	0.23
	19 (47.5%)	25 (62.5%)	0.28

A multi-compartmental model of the HepQuant SHUNT test can quantify anatomic shunting and stratify risk for varices: combined results from the HALT-C and SHUNT-V studies

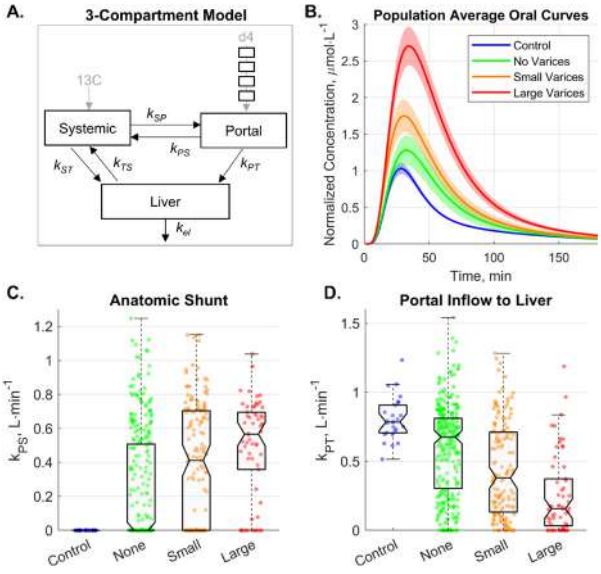
Michael McRae[1], Steve Helmke[2], Greg Everson[2]. [1]*Custom Diagnostic Solutions LLC;* [2]*HepQuant, Denver, United States*
Email: michaelpmcrae@gmail.com

Background and aims: In chronic liver disease (CLD), persistent inflammation and fibrosis impair hepatocyte function and increase portal pressure, resulting in portal venous collaterals and portal-systemic shunting. The HepQuant SHUNT test uses stable nonradioactive isotopes of carbon-13 cholate (13C-CA) intravenously and deuterium cholate (d4-CA) orally to simultaneously measure clearance from both portal and systemic circulations. The aim of this study was to determine whether compartmental analysis of the HepQuant SHUNT test could quantify anatomic shunting in patients with CLD and esophageal varices.

Method: A compartmental model was developed from the HepQuant SHUNT test results from 26 lean controls and 492 CLD patients with esophago-gastro-duodenoscopy findings (291 no varices, 143 small varices, and 58 large varices). Transfer between systemic, portal, and

liver compartments was modeled by a system of 18 first-order ordinary differential equations along with assumptions from measured or literature-derived values. The compartmental model and PK parameters were solved for each subject with three parameters estimated by nonlinear least-squares regression including the anatomic shunt flow (kPS). Compartmental analysis was completed using MATLAB Simbiology.

Results: The compartmental model (Fig 1A) fit the data with median adjusted R-squared across all patients of 0.99 for 13C-CA IV curves and 0.95 for d4-CA oral curves. Population-averaged oral curve simulations (Fig 1B) (mean and 95% confidence) from the compartment model show significant differences between controls, no varices, small varices, and large varices. The estimated median anatomic shunt flow, kPS, was 0, 0, 411, and 566 ml/min for controls, none, small, and large varices, respectively with significant difference between all groups (Wilcoxon rank-sum $p < 0.05$) (Fig 1C). In parallel, the model demonstrated reduced portal inflow to the liver (kPT) among varices groups, with median kPT values of 784, 676, 380, and 156 ml/min for controls, none, small, and large varices, respectively with significant difference between all groups ($p < 0.001$) (Fig 1D).



Conclusion: The compartmental model discriminated patients with small and large varices. The model also distinguished the individual contributions of hepatocyte function and anatomic shunting to the hepatic clearance of cholate. The individualized PK parameters estimated from this compartmental model, when combined with artificial intelligence or machine learning algorithms, have significant potential to enhance the diagnostic performance and clinical utility of the HepQuant test of global liver function.

FRI536

Expandable constrained 6 mm transjugular intrahepatic portosystemic shunt: an alternative approach for high-risk patients?

Hannah Schneider[1], Anja Tiede[1], Alena Friederike Ehrenbauer[1], Lena Stockhoff[1], Johanna Luise Charlotte Lorenz[1], Heiner Wedemeyer[1], Richard Taubert[1], Jan Hinrichs[2], Benjamin Maasoumy[1]. *[1]Hannover Medical School, Dept. of Gastroenterology, Hepatology and Endocrinology; [2]Hannover Medical School, Dept. of Interventional Radiology*
Email: schneider.hannah@mh-hannover.de

Background and aims: A transjugular intrahepatic portosystemic shunt (TIPS) can effectively overcome portal hypertension in patients with liver cirrhosis. However, in a considerable proportion of the respective patients relative or absolute contraindications such as cardiac impairment, recurrent hepatic encephalopathy (HE) or advanced hepatic impairment prevent TIPS insertion. In this study, we investigated whether a response-guided step-up approach using a constrained TIPS with a diameter of 6 mm may pose as an option for otherwise ineligible or high-risk patients.

Method: A number of 38 patients, considered to have a high risk for TIPS related complications due to the presence of relative contraindications, received a constrained 6 mm TIPS at Hannover Medical School between 10/2020 and 03/2022. During the TIPS procedure, a 6 mm stent graft was placed into the parenchymal tract to constrain expansion of the later inserted TIPS endoprosthesis. The 6 mm stent graft can be revised to >8 mm via balloon expansion in case of an insufficient clinical response, increasing shunt volume gradually. A control cohort of patients with conventional (8 mm) TIPS was generated using propensity score matching considering the FIPS (Freiburg index of post TIPS survival), history of HE and diastolic dysfunction. A caliper of 0.25 resulted in 28 patients per group. Patients were followed up for 6 months. Competing risk analysis was performed to evaluate clinical complications.

Results: Median age of patients with constrained TIPS was 61, the majority was male (60.7%), median FIPS was –0.12. Within the high-risk group indication for the constrained TIPS was cardiac impairment, poor liver function or history of HE in 15, 9, and 4 patients, respectively. The constrained TIPS procedure was successful in all patients without any major complication. However, TIPS dysfunction was significantly more frequent in the constrained TIPS cohort (n = 1 vs. 6; p = 0.03). In 2 patients constrained TIPS did not achieve adequate symptom control. Importantly, in all cases the constrained TIPS was successfully revised and/or dilated to 7/8 mm. While no constrained TIPS had to be reduced or occluded due to clinical complications, TIPS diameter had to be decreased in 2 of the control patients due to recurring HE and cardiac decompensation. Patients treated with the response-guided step-up approach less frequently developed overt HE during follow up (n = 15 vs. 5; p = 0.02). There was no significant difference concerning the development of cardiac decompensation (n = 6 vs. 9; p = 0.25) and survival (n = 4 vs. 6; p = 0.38) between the two groups.

Conclusion: The constrained 6 mm TIPS may offer a more careful step-up approach for selected high-risk TIPS patients. The technical procedure appeared to be safe and well feasible. Larger studies are needed to further explore promising results on TIPS related complications i.e. with regard to HE development.

FRI537

Early treatment with terlipressin in patients with hepatorenal syndrome yields improved clinical outcomes in 3 phase III North American studies

Michael Curry[1], Hugo E. Vargas[2], Alex Befeler[3], Nikolaos T. Pyrsopoulos[4], Vilas Patwardhan[1], Khurram Jamil[5]. *[1]Beth Israel Deaconess Medical Center; [2]Mayo Clinic; [3]Saint Louis University; [4]Rutgers-New Jersey Medical School University Hospital; [5]Mallinckrodt Pharmaceuticals*
Email: mcurry@bidmc.harvard.edu

Background and aims: Hepatorenal syndrome (HRS), a serious complication of advanced cirrhosis and a potentially reversible form of acute kidney injury, is associated with a rapid deterioration in kidney function. The vasopressin analogue, terlipressin, successfully reverses HRS. Patients (pts) with higher baseline serum creatinine (SCr) levels have a reduced response to terlipressin. The largest randomized, prospective database of placebo-controlled studies in pts with HRS was examined to assess terlipressin treatment response in pts with varying baseline SCr levels.

Method: Pooled data from 3 Phase III North American-centric, placebo-controlled clinical studies.
(OT-0401, REVERSE, and CONFIRM) were used. Post hoc analyses examined pooled data from terlipressin-treated pts with HRS (type 1; n = 352)—across 3 SCr subgroups (<3, ≥3 to <5, and ≥5 mg/dL)—to

delineate their correlation with HRS reversal (defined as at least 1 SCr level of ≤1.5 mg/dL on treatment), renal replacement therapy (RRT)-free survival, transplant-free survival (TFS), and overall survival (OS). Statistical analyses included the Wald test (logistic regression analysis), Chi-square/Fisher's exact test (HRS reversal), and the log rank test (survival estimates).

Results: SCr levels were significantly associated with HRS reversal in univariate and multivariate logistic regression analyses ($p < 0.001$) (Figure). Among pts with HRS, the incidence of HRS reversal inversely correlated with SCr subgroup: <3 mg/dL, 49.2%; ≥3 to <5 mg/dL, 28.0%; ≥5 mg/dL, 9.1% ($p < 0.001$). At Day 30 follow-up, RRT-free survival was significantly higher for pts with HRS in the lower SCr subgroups versus the highest subgroup (<5 mg/dL vs >5 mg/dL; $p = 0.01$). Terlipressin-treated pts with HRS who had a lower baseline SCr level had higher OS ($p < 0.001$) and TFS at Day 90 ($p = 0.04$).

Baseline parameters	Terlipressin n	Odds ratio	95% CI	p value
SCr	312	0.518	0.381-0.704	<.001
Model for end-stage liver disease score	312	0.939	0.902-0.977	.002
Prior midodrine and octreotide	312	1.849	1.106-3.091	.019

Figure: Multivariate logistic regression of baseline characteristics on HRS reversal (Terlipressin group, pooled intent-to-treat population)

Conclusion: Terlipressin-treated pts with HRS and a lower baseline SCr level experienced higher HRS reversal and survival outcomes. It is important to identify and treat pts with HRS early when they have lower SCr levels and a greater probability of clinical response to terlipressin.

FRI538

Non-invasive tools are suboptimal to predict the presence of varices needing treatment and risk of clinical decompensation in patients with autoimmune hepatitis related cirrhosis

Randeep Rana[1], Samagra Agarwal[1], Sanchit Sharma[1,2], Ujjwal Sonika[3], Syed Ahmed[1], Srikanth Gopi[1], Deepak Gunjan[1], Anoop Saraya[1]. *[1]All India Institute Of Medical Sciences New Delhi, Gastroenterology and Human Nutrition Unit, New Delhi, India; [2]Translational Gastroenterology Unit, John Radcliffe Hospital, Oxford, United Kingdom; [3]Govind Ballabh Pant Hospital, Gastroenterology, New Delhi, India*
Email: ansaraya@yahoo.com

Background and aims: Baveno VII consensus recommend the use of non-invasive tools (NITs) to predict the risk of clinical decompensation (CD) and detecting varices needing treatment (VNTs) in patients with compensated cirrhosis. The present study aimed to validate these recommendations in patients with autoimmune hepatitis (AIH) related cirrhosis.

Method: Diagnostic performance of Baveno-VI (LSM >20 kPa or platelet <1 50 000/mm^3), expanded Baveno-VI (LSM >25 kPa or platelet <1 10 000/mm^3) and platelet-albumin (albumin <3.6 g/dl or platelet <1 20 000/mm^3) criteria for detecting VNTs was assessed against the strategy of endoscopy for all to screen large varices using decision curve analysis (DCA). Patients were stratified using Baveno VII criteria for definite clinically significant portal hypertension (CSPH) (LSM>25 kPa), possible CSPH (LSM>15 kPa and platelet<1 50 000/mm^3) and no CSPH (LSM<15 kPa and platelets >1 50 000/mm^3). Cumulative incidence of clinical decompensations on follow-up were compared across different strata to assess its clinical relevance.

Results: One hundred ten (110) patients with AIH-related cirrhosis were included, with 37 patients having VNTs. At a threshold probability of 10% missed VNTs, platelet-albumin criteria was the most beneficial among NITs to detect VNTs with a potential to avoid 44 additional endoscopies before 1 additional VNT is missed. Rest of the NITs had similar benefit to performing endoscopy in all patients. At lower thresholds (<10% missed VNTs), performing endoscopy in all patients was the most beneficial strategy. Over a median follow-up of 30 months (IQR13–39 months), 30 of 96 patients with available follow-up developed clinical decompensation. The 1-year and 3-year rate of clinical decompensation in patients with definite CSPH, possible CSPH and no CSPH was (29.2%, 29.0%, 19.8%) and (35.6%, 39.5%, 29.0%), respectively (log rank test, $p = 0.75$).

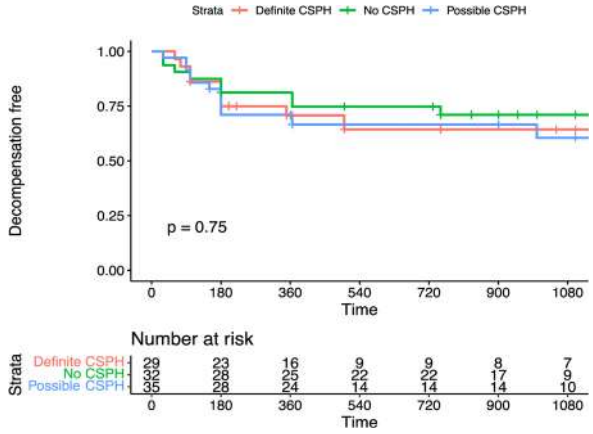


Figure: Figure shows 1-year and 3-year rate of clinical decompensation in patients with definite CSPH, no CSPH and possible CSPH in AIH related cirrhosis.

Conclusion: The strategy of endoscopy for all is superior to all NITs to detect VNTs at lower thresholds for treatment in patients with AIH. The Baveno VII criteria for predicting clinical decompensation is suboptimal to stratify patients of AIH.

FRI539

Improving of hepatic encephalopathy manifestations in cirrhotic patients with clinically significant portal hypertension treated with splenic artery embolization

Sergii Kozlov[1], Pavlo Ivanchov[2], Elina Manzhalii[3], Iryna Kostishyna[4], Oleksanr Kozlov[2], Illia Koshman[5]. *[1]Bogomolets National Medical University, Surgery, Kyyiv, Ukraine; [2]Bogomolets National Medical University, Surgery chair #3, Kyiv, Ukraine; [3]Bogomolets National Medical University, Gastroenterology, Kyiv, Ukraine; [4]Kyiv municipal hospital #12, Surgery, Kyyiv, Ukraine; [5]Kyiv municipal hospital #12, Surgery, Kyyiv*
Email: sergiinikol@gmail.com

Background and aims: In cirrhotic patients, hepatic encephalopathy (HE) is a severe complication in which hyperammonemia plays a leading role. At the same time, clinically significant portal hypertension with spontaneous venous portosystemic shunts is common clinical finding that aggravated the HE manifestation. Endovascular shunt occlusion considered to be a possible treatment option. We studied the efficacy of splenic artery embolization (SAE) in resolution HE symptoms as a perspective alternative RI treatment option for patients with high risk variceal bleeding.

Method: Selective endovascular embolization of the splenic artery was performed as secondary prophylaxis treatment in 120 patients with one or more episodes of variceal bleedings in history. Partial reduction of excessive splenic artery flow (no more than 70% of baseline levels) was achieved by insertion of several (from 2 to 5) flexible coils into the distal portion of the vessel. Serum levels of albumin and ammonia were evaluated before the procedure, 30 days and 12 months after the procedure. Hepatic encephalopathy grade was evaluated according to West Heaven criteria at the same time points. Standard supportive treatment included non-selective beta-blockers (40–60 mg daily) and UDCA (500–1000 mg daily) with dose adjustment according to BMI.

Results: The plasma ammonia levels improved after SAE from 107 ± 34 to 62 ± 25 μmol/l The mean serum albumin pre and post SAE were 29 ± 0.5, 27.8 ± 0.4 (1 month), and 32.5 ± 0.7 g/L (12 months) respectively. West Heaven score mean tended to decrease from 2.2 on the baseline to 1.9 (1 month) and 1.4 (12 months). Thus, basic liver

functions (protein synthesis and ammonia purification) demonstrated considerable improvement in the long-term observation period due to combined treatment. 65 (54.2%) of 120 patients had no bleeding episodes at the endpoint of 12 months, 39 (32.5%) were hospitalized with 1 (28) or more (11) minor bleedings. Fatal bleedings took place in 11 (9.2%) patients and not related to bleeding deaths-in 4 cases.

Conclusion: From our point of view, the improving of HE manifestations after SAE procedure could be explained by synergetic effects of reduction of the excessive splenic flow, restoring of liver synthetic function due to ameliorating splenic artery steal syndrome, and, as a result, liver tissue rearterialization. SAE showed a long-term reliable prophylactic effect in high-risk patients with CSPH and HE.

FRI540

Sequential algorithm of spleen stiffness measured by a dedicated 100 Hz examination and Baveno VII criteria for clinically significant portal hypertension in compensated cirrhosis

Ruiling He[1,2], Chuan Liu[1], Li Jie[3], Jianzhong Ma[4], Ying Guo[4], Xiaoqing Guo[4], Shirong Liu[5], Bo Gao[6], Ning Liu[5], Mingkai Chen[7], Hongwei Zhou[8], Tianyu Tang[9], Yu Shi[10], Shenghong Ju[9], Yan Huadong[11], Xiaolong Qi[1]. *[1]The First Hospital of Lanzhou University, CHESS Center, Institute of Portal Hypertension, China; [2]The First Clinical Medical College of Lanzhou University, China; [3]Nanjing Drum Tower Hospital, The Affiliated Hospital of Nanjing University Medical School, Department of Infectious Diseases, China; [4]The third people's Hospital of Taiyuan, Department of Hepatology, China; [5]Qufu People's Hospital, Department of Infectious Diseases, China; [6]Qufu People's Hospital, Medical Laboratory, China; [7]Renmin Hospital of Wuhan University, Department of Gastroenterology, China; [8]Zhujiang Hospital, Southern Medical University, Department of Laboratory Medicine, China; [9]Zhongda Hospital Affiliated to Southeast University, Department of Radiology, China; [10]Shengjing Hospital, China Medical University, Department of Radiology, China; [11]Shulan (Hangzhou) Hospital Affiliated to Zhejiang Shuren University Shulan International Medical College, Department of Infectious Diseases, China*
Email: qixiaolong@vip.163.com

Background and aims: The renewing Baveno VII consensus proposed that liver stiffness measurement (LSM) and spleen stiffness measurement (SSM) can be used to rule in and rule out clinically significant portal hypertension (CSPH) in patients with compensated cirrhosis; however, the thresholds of SSM should be further validated with spleen-dedicated 100 Hz examination. This study aims to assess the performance of sequential algorithm of SSM measured by a dedicated 100 Hz FibroScan® and Baveno VII criteria for CSPH in patients with well-characterized compensated cirrhosis.

Method: This is a prospective multi-center study (NCT05251272). Patients with well-characterized compensated cirrhosis undergoing a 100 Hz specific FibroScan® to evaluate SSM and LSM were consecutively enrolled between August 2021 and March 2022. CSPH was defined as the threshold of hepatic venous pressure gradient measurement above 10 mmHg.

Results: A total of 101 patients (71 male) with a mean age of 52 ± 9 years were recruited from 5 university centers, and 50 (49.5%) patients had CSPH. Applying the Baveno VII criteria for exclusion of CSPH (LSM ≤15 kPa and platelet count ≥150 × 10^9/L), 24/101 (23.8%) patients could rule out CSPH with 8.3% of patients being missed, and the negative predictive value (NPV) and sensitivity were 91.7% and 96.0%. The sequential algorithm for SSM and Baveno VII criteria [SSM <21 kPa OR (LSM ≤15 kPa and platelet count ≥150 × 10^9/L)] showed that 28/101 (27.7%) patients could rule out CSPH with 7.1% of patients being missed, and the NPV and sensitivity were 92.9% and 96.0%, respectively. Furthermore, the Baveno VII criteria for identification of CSPH (LSM ≥25 kPa) had 100% positive predictive value (PPV) and specificity, yet merely 5/101 (5.0%) patients would enable to identify correctly. Comparing with the former, the sequential algorithm of SSM >50 kPa OR LSM ≥25 kPa improved the proportion of ruling in CSPH (22.8% vs 5.0%, p < 0.001) with only 4.3% of patients misclassified, and the PPV and specificity were 95.7% and 98.0%, respectively.

Table: Performance of different methods for ruling out and ruling in clinically significant portal hypertension.

	CSPH Missed	Rule out CSPH	Non-CSPH Missed	Rule in CSPH
LSM ≤15 kPa and PLT ≥150 × 10^9/L	2/23 (8.3%)	24/101 (23.8%)	-	-
SSM <21 kPa OR (LSM ≤15 kPa and PLT ≥150 × 10^9/L)	2/28 (7.1%)	28/201 (70.5%)	-	-
LSM ≥25 kPa	-	-	0	5/101 (5.0%)
SSM >50 kPa OR LSM ≥25 kPa	-	-	1/23 (4.3%)	23/101 (22.8%)***

Data are presented as n (%) or n/N (%), where N is the total number of related cases. CSPH, clinically significant portal hypertension; LSM, liver stiffness measurement; SSM, spleen stiffness measurement; PLT, platelet count. ***p < 0.001, LSM ≥25 kPa compared to SSM >50 kPa OR LSM ≥25 kPa.

Conclusion: The sequential algorithm of SSM measured by a dedicated 100 Hz examination and Baveno VII criteria is useful to assess CSPH accurately, especially in ruling in CSPH compared to Baveno VII criteria only.

Liver tumours: Experimental and pathophysiology

FRI542

NKG2A hampers tumor surveillance of liver-infiltrating natural killer (NK) cells via TLR4 signaling pathway after liver transplantation

Xinxiang Yang[1,1], Kwan Man[1]. *[1]The University of Hong Kong, Surgery, Hong Kong*
Email: kwanman@hku.hk

Background and aims: Liver transplantation (LT) provides the best option for selected hepatocellular carcinoma (HCC) patients. However, tumor recurrence occurs at a rate of 10–20% within 5 years. Graft injury during LT significantly affects the outcome of tumor recurrence by changing the regional immune microenvironment. However, the immunological mechanism of hepatic natural killer (NK) cells in graft injury was not completely understood.

Method: 349 HCC patients who underwent LT in Queen Mary Hospital, Hong Kong were recruited in this study. The correlation among the number of intra-graft NK cells, liver function, recurrence free survival (RFS) rate was analyzed. The cytotoxic function of NK cells was evaluated by co-culture with primary HCC cells. Hepatic ischemia-reperfusion injury plus major hepatectomy (IRI + Hx) was performed in C57bl/6 mice to mimic the pathological changes during human LT. Tumor cells (Hepa 1–6) were injected into the liver via portal vein after IRI + Hx in TLR4 knockout and wild-type mice.

Results: The frequency of intra-graft NKG2A+NK cells was significantly increased in patients with tumor recurrence after LT, along with increased expressions of its ligand HLA-E and inflammation signatures (IL-1β, IL-6, NLRP3, HMGB1, and TLR4). GWR (the ratio of graft volume to estimated standard liver volume) <60% was an independent risk factor for tumor recurrence after LT. The frequency of circulating NKG2A + NK cells was significantly increased in the in the patients with GWR <60% compared with GWR ≥60% at 3, 6, 9, and 12 months post-LT. The cytotoxic function of NKG2A + NK cells was significantly decreased compared to NKG2A-NK cells when co-cultured with primary HCC cells, characterized by decreased expressions of Granzyme B and CD107a. In IRI+Hx mouse model,

NKG2A+ hepatic (NK1.1+) NK cells were increased at 6, 24, and 48 hours. Interestingly, the expression of NKG2A was increased in liver-infiltrated (CD49a- CD49b+) NK cells but not liver-resident (CD49a+ CD49b-) NK cells. In TLR4 knockout mice subjected to IRI+Hx and tumor cell injection, the tumor growth was significantly hindered and the expression of NKG2A on liver-infiltrated NK cells was significantly decreased compared to wild-type mice at week 4.
Conclusion: Hepatic IRI increased expression of NKG2A on liver-infiltrated NK cells via TLR4 signaling pathway, which provided a favorable immune microenvironment for late-phase tumor recurrence. Understanding the broad spectrum of NK cell functional diversity would help to explore NK cell-based immunotherapy against tumor recurrence.

FRI543

Cancer-associated fibroblasts nurture LGR5 marked liver tumour-initiating cells and promote their metastasis

Jiaye Liu[1], Qiuwei Pan[1]. [1]*Erasmus University Medical Center Rotterdam, Department of Gastroenterology and Hepatology, Rotterdam, Netherlands*
Email: q.pan@erasmusmc.nl

Background and aims: Tumor-initiating cells (TICs) are thought to be the main drivers of cancer development, progression and treatment resistance. We have recently identified the LGR5+ compartment as an important TIC population in liver cancer, representing a viable therapeutic target. Given that cancer-associated fibroblasts (CAFs) constitute a key component of the tumor microenvironment, this study aims to investigate the impact of CAFs on LGR5 marked TICs in liver cancer.
Method: Liver tumor organoids and CAFs were cultured from Diethylnitrosamine-induced liver tumors of LGR5-diphtheria toxin receptor (DTR)-GFP knock-in mice and Rosa 26-mT mice, respectively. 3D co-culture models of $LGR5^+$ TICs with CAFs, based on cell-cell contact or trans-well system, were established in vitro. Immunodeficient mouse-based xenograft model was used to investigate the effect on tumor formation and metastasis, as well as diphtheria toxin treatment for specific depletion of $LGR5^+$ cells.
Results: In primary tumors formed in the liver of LGR5-GFP reporter mice, we found high frequency of CAFs marked by alpha-smooth muscle actin surrounding LGR5 expressing cancer cells. In xenograft model, co-engraftment of liver tumor organoids with CAFs resulted in substantially higher number of $LGR5^+$ cells in formed tumors when compared with engrafting tumor organoids alone. Furthermore, ex vivo culture of isolated $LGR5^+$ cells from tumors of co-engrafted mice formed significantly larger size of organoids (68.1 ± 36.1 VS. 35.2 ± 18.3 um, $n = 40$, $p < 0.001$), although there is no statistical significance in the number of formed organoids. In vitro, co-culture of $LGR5^+$ tumor cells with CAFs, in both cell-cell contact and paracrine signaling based trans-well system, resulted in significantly larger size and number of formed organoids, when compared with culturing $LGR5^+$ cells alone. This promoting effect was eliminated by diphtheria toxin treatment which specifically deplete LGR5 cells due to transgenic expression of DTR. Consistently, subcutaneous co-engraftment of $LGR5^+$ tumor cells with CAFs formed significantly larger tumors compared with engrafting $LGR5^+$ cells alone (0.6 ± 0.2 VS. 0.3 ± 0.2 g, $n = 8$, $p < 0.05$). Most importantly, co-engraftment dramatically increased the probability of abdominal metastasis (7/8) compared with engraftment of $LGR5^+$ tumor cells alone (1/8). Diphtheria toxin treatment mediated depletion of $LGR5^+$ cells effectively inhibited tumor growth and metastasis in this xenograft model.
Conclusion: We here revealed robust nurturing effects of CAFs in promoting growth and metastasis of LGR5 marked TICs in experimental liver cancer. Understanding their intimate interactions shall help to decipher the mechanistic insight of liver cancer progression and to develop effective treatment for reducing tumor burden and preventing metastasis.

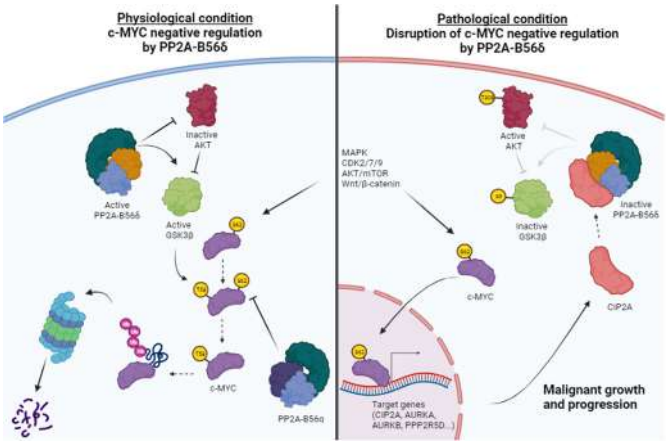
Molecular insights into the tumour suppressor role of Protein Phosphatase 2A B56 delta complex in human liver, and its clinically relevant inhibition by cancerous inhibitor of PP2A

Judit Domenech Omella[1], Bob Meeusen[2], Emanuela Cortesi[3], Karen Zwaenepoel[4], Rita Derua[1], Chris Verslype[5], Patrick Pauwels[4], Jukka Westermarck[6], Tania Roskams[7], Jos van Pelt[5], Veerle Janssens[1]. [1]*KU Leuven, Cellular and Molecular Medicine, Leuven, Belgium;* [2]*University of Copenhagen, Novo Nordisk Foundation Center for Protein Research, Copenhagen, Denmark;* [3]*KU Leuven, Imaging and pathology, Leuven, Belgium;* [4]*Universitair Ziekenhuis Antwerpen, Pathology, Antwerpen, Belgium;* [5]*KU Leuven, Oncology, Leuven, Belgium;* [6]*University of Turku, Turku Bioscience, Turku, Finland;* [7]*KU Leuven, Imaging and pathology, Leuven, Belgium*
Email: judit.domenechomella@kuleuven.be

Background and aims: The clinical prognosis of hepatocellular carcinoma (HCC) remains disappointing due to an incomplete understanding of the molecular mechanisms underlying HCC progression. Recently, we reported increased spontaneous HCC development in *Ppp2r5d* KO mice, devoid of Protein Phosphatase 2A (PP2A) regulatory B56delta subunit expression. All cases presented c-MYC Ser62 hyperphosphorylation, known to increase c-MYC stability and oncogenicity. Hence, our data underscored a tumor suppressive role of PP2A-B56delta in mouse liver. Here, we aimed to investigate the role of PP2A-B56delta as a tumor suppressor in *human* liver, and define PP2A-B56delta status in human HCC.
Method: B56delta was stably depleted in three human HCC cell lines using shRNA, and effects on colony formation (anchorage-independent growth) and tumor growth (xenograft assays) were assessed. mRNA expression of 28 'PP2A' genes was evaluated in four published HCC datasets and Spearman correlation analysis was performed. Expression of B56delta, c-MYC and Cancerous Inhibitor of PP2A (CIP2A) was analyzed by immunohistochemistry (IHC) in 19 human HCC samples. CIP2A interactors were identified by immunoprecipitation and mass spectrometry. Diethylenenitrosamine was injected in two-week-old wildtype and CIP2A KO mice to study HCC latency in a chemical-induced HCC mouse model.
Results: B56delta depletion resulted in increased colony formation *in vitro* and tumor growth *in vivo*, and correlated with increased c-MYC protein expression, hyperphosphorylation of AKT and GSK3beta, and upregulation of c-MYC target gene expression. B56delta and CIP2A gene expression correlated positively with patient HCC tumors, and their high mRNA expression was associated with a worse prognosis and decreased overall survival. IHC analysis of human HCC tissue did not show significantly altered B56delta protein expression, but identified increased co-expression of c-MYC and CIP2A. In addition, we identified B56delta as a CIP2A interactor. Underscoring an oncogenic role for CIP2A, its depletion resulted in decreased tumor growth *in vivo* and increased HCC latency.



Conclusion: Our work provides insights into how PP2A-B56delta suppresses human hepatocarcinogenesis and progression, and how its tumor suppressor activity is impaired in human HCC. Specifically, we show that PP2A-B56delta prevents c-MYC protein stabilization via regulation of AKT and GSK3beta, and PP2A-B56delta inactivation is mediated by CIP2A overexpression.

FRI545

Identification of new dominant neoantigens in hepatocellular carcinoma based on a single plasmid system with co-expressing patient's HLA and antigen

Pu Chen[1], Dongbo Chen[1], Shaoping She[1], Yao Yang[1], Liying Ren[2], Bigeng Zhao[2], Ruifeng Yang[1], Weijia Liao[2], Hongsong Chen[1]. [1]*Peking University Hepatology Institute, Beijing Key Laboratory of Hepatitis C and Immunotherapy for Liver Disease, Peking University People's Hospital, China;* [2]*Laboratory of Hepatobiliary and Pancreatic Surgery, Affiliated Hospital of Guilin Medical University, China*
Email: chenhongsong@bjmu.edu.cn

Background and aims: Hepatocellular carcinoma (HCC) is the sixth most common malignancy worldwide. Compared with plentiful neoantigens in melanoma, the paucity and inefficient identification of effective neoantigens in HCC remain enormous challenges in effectively treating this malignancy.
Therefore, we tried to identify new dominant neoantigens in HCC based on an innovative plasmid system.
Method: We established a single plasmid system with co-expressing patient's human leukocyte antigen (HLA) and antigen. To verify whether the system works normally, we connected a reported KRAS G12D neoantigen sequence in HCC and its corresponding wild antigen sequence to the antigen linker regions of the vectors respectively, which carry the corresponding HLA sequence. Subsequently, they were inserted into viral vectors and transduced to the target cells. Moreover, T cell receptor (TCR) T cells that could recognize the neoantigen were constructed and co-cultured with the target cells. Then, the cytotoxicity was detected by enzyme-linked immunospot assay (ELISPOT) and enzyme-linked immunosorbent assay (ELASA). Finally, the proliferation of TCR-T cells was detected by flow cytometry assay.
Besides, next-generation sequencing (NGS) was performed for the samples such as HCC tissue, portal vein tumor thrombosis (PVTT) and tumor infiltrating lymphocyte (TIL) to analyse gene variations, candidate neoantigens and tumor immune microenvironment (TIME). Then, tetramer staining assay was used to detect the specific T cells induced by the predicted candidate neoantigens. Finally, the positive candidate neoantigens were further validated by the single plasmid system.
Results: An innovative plasmid system was established, which includes 39 high-frequency HLA vectors for Asian. Then, we successfully constructed TCR-T cells which could recognize KRAS G12D neoantigen in HCC and used the single plasmid system to verify the immunogenicity of the neoantigen. Interestingly, we found TCR-T cells co-cultured with the target cells which express KRAS G12D could be specifically activated and proliferate. Hence, the single plasmid system works normally, which provides an efficient molecular tool for immunogenicity validation of antigen.
We found some new gene variations in 14 HCC patients and predicted candidate neoantigens. Moreover, we produced some tetramers for the detection of the specific T cells and identified several positive candidate neoantigen-specific T cells. Finally, we successfully identified several new dominant neoantigens produced by ALG1 A55S mutation (ENST00000586840) and other gene variations in HCC, based on our single plasmid system.
Conclusion: Based on our single plasmid system with co-expressed patient's HLA and antigen, we successfully identified several new dominant neoantigens in HCC. These neoantigens could be as potential immunotherapeutic targets for HCC.

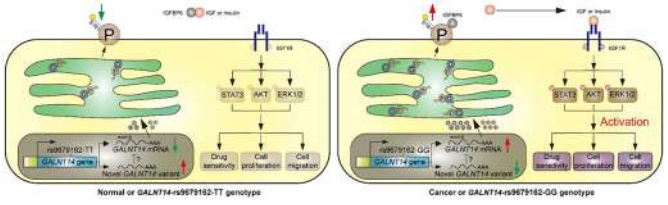
Polypeptide N-acetylgalactosaminyltransferase 14 mediated O-glycosylation on prohibitin-2 serine 161 modulates cell growth, migration and drug susceptibility in hepatocellular carcinoma

Chau-Ting Yeh[1], Yu-De Chu[2]. [1]*Chang Gung Memorial Hospital, Liver Research Center, Taoyuan, Taiwan;* [2]*Chang Gung Memorial Hospital, Liver Research Center, Taoyuan*
Email: chautingy@gmail.com

Background and aims: Worldwide, hepatocellular carcinoma (HCC) remained a leading cause of cancer-related death. A single nucleotide polymorphism (SNP), rs9679162, located on *Polypeptide N-Acetylgalactosaminyltransferase 14* (*GALNT14*) gene, differentially predicted the therapeutic outcomes for various gastrointestinal cancers including HCC, while the molecular mechanisms remained largely unknown.
Method: For clinical outcome analysis, 300 HCC patients having received surgical resection were retrospectively enrolled. Their paired liver tissue samples were subjected for SNP genotyping, RNA isolation, western blot, and immunohistochemical analysis. The key GALNT14 substrate was identified by the differential lectin capture method. Functional assessments of the candidate substrate protein were performed following site-directed mutagenesis.
Results: The GALNT14 level was significantly upregulated in the cancerous parts of HCCs. Higher cancerous/noncancerous ratios of GALNT14 were associated with rs9679162-GG genotype and unfavourable postoperative prognosis. A novel exon-6-skipped *GALNT14* mRNA variant was identified preferentially in the rs9679162-TT genotype, and was associated with lower GALNT14 expression and favourable clinical outcomes. Cell-based experiments showed that elevated GALNT14 levels promoted HCC growth, migration, and anticancer-drugs susceptibility. Differential lectin capture analysis identified prohibitin-2 (PHB2) as a major GALNT14-mediated O-glycosylation substrate. Site-directed mutagenesis experiments revealed serine-161 (Ser161) as the O-glycosylation site. Complementation assays demonstrated that PHB2-Ser161 O-glycosylation was required for GALNT14-mediated modulation of cell growth, migration, and anticancer drugs susceptibility. PHB2 O-glycosylation was positively correlated with GALNT14 expression in HCC. Finally, PHB2-Ser161 O-glycosylation was crucial for its interaction with Insulin-like Growth Factor-Binding Protein-6 (IGFBP6) and Insulin-like Growth Factor-1 Receptor (IGF1R) mediated signalling activation.



Conclusion: *GALNT14* SNP genotypes were associated with GALNT14 levels and differential expression of a novel *GALNT14* mRNA variant, linking to postoperative prognosis in HCC. The elevated GALNT14 level promoted HCC growth via O-glycosylation on PHB2-Ser161, leading to activation of the IGF1R-mediated cascade.

Gut bacteria modulate anti-tumour immunity in patients with hepatocellular carcinoma

Dhruti Devshi[1,2], Sandra Phillips[1,2], Helen Edwards[1,2], Nicola Harris[1,2], Melissa Preziosi[3], Abid Suddle[3], Antonio Riva[1,2], Shilpa Chokshi[1,2]. *[1]The Roger Williams Institute of Hepatology (Foundation for Liver Research), United Kingdom; [2]Faculty of Life Sciences and Medicine (King's College London), United Kingdom; [3]King's College Hospital, London, United Kingdom*
Email: s.chokshi@researchinliver.org.uk

Background and aims: The gut microbiota and their metabolites play a key role in the response to checkpoint receptor (CR) inhibitors. Interestingly, antibiotics can also limit cancer progression by modulating the gut microbiota and their metabolites. The role of bacteria and their metabolites in modulating anti-tumour immunity in hepatocellular carcinoma (HCC) is not understood and is the focus of this study.
Method: Peripheral blood mononuclear cells (PBMCs) from HCC patients were stimulated in vitro with a peptide pool spanning seven HCC tumour-associated antigens with/without priming with formaldehyde-fixed Escherichia coli DH5a (EC, 50 bacteria-per-cell) or EC supernatants (20% v/v, representing bacterial metabolites). After 3 days, the expression of inhibitory immune checkpoints and functional markers (including PD-1, PD-L1, Granzyme-B, Perforin, IL-10 and IFNg) were assessed on CD4, CD8 and MAIT T cells by flow cytometry. Thirty-four secreted cytokines (including IL-6, IL-23, IL-2, IL-1a, IL-10, IL-18 and IFNg) were measured in PBMC culture supernatants by Luminex. For the analysis, peptide-only PBMC cultures were compared with EC-cell-primed or EC-supernatant-primed peptide-stimulated PBMC cultures.
Results: Immunosuppressive PD-1, PD-L1 and IL-10 expression was significantly higher in bacteria-primed HCC-specific CD4+ T-cells ($p = 0.024$, 0.0061 and 0.037 respectively) compared to HCC peptide-stimulated only PBMCs. A significant increase in pro- and anti-inflammatory cytokines (including IL-6, IL-23, IL-2, IL-1a, IL-18, IL-10 and IFN gamma) was observed in bacteria-primed HCC peptide-stimulated PBMC cultures compared to HCC peptide-only stimulated PBMCs ($p = 0.037$, 0.037, 0.0098, 0.0061, 0.0061, 0.0061, respectively). No significant differences were seen in MAIT cells, or granzyme-B/perforin expression between HCC peptide-stimulated only and bacteria-primed HCC peptide-stimulated PBMC cultures.
Conclusion: These results reveal that bacterial priming induces inhibitory checkpoint receptor expression on anti-tumour T-cells and promotes an immunosuppressive inflammatory landscape in HCC. Further studies investigating bacterial modulation of anti-tumour immunity in HCC are warranted.

Lack of the E3-ubiquitin ligase TRIM21 promotes higher emergence of hepatocellular carcinoma nodules in diabetic mice with non-alcoholic steatohepatitis

Ghania Kara-Ali[1], Imerzoukene Ghiles[1], Melanie Simoeseugenio[1], Luis Cano[2], Annaig Hamon[1], Huma Hameed[1], Claire Piquet-Pellorce[1], Sarah Dion[1], Celine Raguenes-Nicol[1], Stefano Caruso[3], Jessica Zucman-Rossi[3], Michel Samson[1], Jacques Le-Seyec[1], Marie-Therese Biotrel[1]. *[1]Univ Rennes, Inserm, EHESP, Irset (Institut de recherche en santé, environnement et travail)-UMR_S 1085, F-35000 Rennes, France; [2]INSERM, INRAE, CHU Pontchaillou, UMR 1241 NUMECAN, Univ. Rennes, Rennes, France; [3]Centre de Recherche des Cordeliers, INSERM, Sorbonne Université, Université de Paris, Université Paris 13, Functional Genomics of Solid Tumors Laboratory, Paris, France*
Email: ghania.kara-ali@univ-rennes1.fr

Background and aims: The deregulation of the E3 ubiquitin ligase tripartite motif protein 21 (TRIM21), a central protein involved in different physiological processes such as cell cycle, cell death or immune response, can have serious pathophysiological consequences. Thus, a low TRIM21 expression has been linked to poor survival rate in different cancers such as diffuse large B-cell lymphoma, breast cancer and hepatocellular carcinoma (HCC) without knowing the involved mechanisms.
Method: Male mice of *Trim21*-WT or *Trim21*-KO genotypes, in a hypoinsulinemic state resulting from prior injection of streptozotocin at the neonatal stage, were fed with a high-fat high-cholesterol diet (HFHCD) for 4, 8 or 12 weeks. Mice included in this protocol progressively developed a non-alcoholic steatohepatitis (NASH) which systematically resulted in HCC development.
Results: Induced liver damage was more severe in *Trim21*-KO mice after 12 weeks on HFHCD, as attested by serum transaminase levels. In addition, higher number of HCC nodules arose at 12 weeks. At an earlier stage (4 weeks of HFHCD), a more pronounced pro-inflammatory hepatic microenvironment was already detected in *Trim21*-KO mice. However, 8 weeks later, the number of hepatic macrophages and lymphocytes significantly decreased in *Trim21*-KO mice. At the same timing, the spleen of *Trim21*-KO mice contained more $CD4^+$ T cells than in *Trim21*-WT mice. Further analysis showed a higher proportion of $CD4^+PD1^+$ and $CD8^+PD1^+$ T cells in Trim21-KO mice spleen.
Conclusion: The E3 ubiquitin ligase TRIM21 limits the emergence of HCC nodules in mouse developing NASH. The establishment of an effective anti-tumor immune response may require TRIM21, potentially by restricting the expression of PD-1 in lymphocytes and of PDL-1 in cancerous cells.

FRI549

Role of autophagy-mediated neuropilin-1 degradation on lenvatinib efficacy in human hepatocarcinoma

Paula Fernández-Palanca[1,2], Tania Payo-Serafín[1,2], Flavia Fondevila[1,2], Carolina Méndez-Blanco[1,2], Javier González-Gállego[1,2], José Luís Mauriz[1,2]. *[1]Institute of biomedicine (IBIOMED), University of León, León, Spain; [2]Centro de investigación biomédica en red de enfermedades hepáticas y digestivas (CIBERehd), Instituto de salud Carlos III, Madrid, Spain*
Email: pferp@unileon.es

Background and aims: Hepatocarcinoma (HCC) is one of the main causes of cancer-related death. Despite the effectiveness of therapeutic options such as tyrosine kinase inhibitors, loss of efficacy that leads to resistance acquisition is a frequent problem that needs to be addressed. Neuropilin-1 (NRP1) is a transmembrane glycoprotein whose role in cancer has become of special interest. We aimed to identify the *in vitro* role of NRP1 in the underlying mechanisms of lenvatinib efficacy in human HCC.
Method: The human HCC cell lines Huh-7 and Hep3B were employed. Lenvatinib was used for treatments and 100 nM bafilomycin A1 as specific autophagy inhibitor. Protein expression was analyzed by Western blot and immunocytochemistry, cell viability by Ki67 immunofluorescence, MTT and colony formation assay, and gene silencing was performed via transfection of a pool of NRP1 siRNA. Finally, cell migration ability was analyzed by wound-healing assay. Statistical analysis was done with GraphPad Prism 6, considering significance when $p < 0.05$.
Results: Antitumor efficacy of lenvatinib was observed by a reduction of cell viability and Ki67 proliferation index, showing also a decrease in NRP1 protein expression in both HCC cell lines. To identify the mechanism responsible of lenvatinib-derived NRP1 downregulation, a time-course with bafilomycin A1 alone and combined with lenvatinib was done. Autophagy inhibition prevented the reduction of NRP1 expression when combining with lenvatinib, thus blocking lenvatinib effect. Specific NRP1 gene silencing reduced cell viability,

showing even greater results when combining with lenvatinib. Interestingly, NRP1 silencing also blocked the loss of lenvatinib sensitivity in combination with bafilomycin A1, increasing lenvatinib antitumor effects even after inhibiting autophagy-derived NRP1 degradation induced by lenvatinib. Therefore, bafilomycin A1 was only able to revert antitumor effects of lenvatinib when NRP1 was not silenced. Likewise, lenvatinib decreased cell migration, and autophagy blockade re-established migration ability of both cell lines reducing lenvatinib efficacy on migration. However, NRP1 silencing was also able to restore migration inhibition of lenvatinib even when combining with bafilomycin A1.
Conclusion: Autophagy-dependent NRP1 degradation seems to play a key role in lenvatinib efficacy in HCC, highlighting the potential interest of NRP1 silencing as a novel strategy to prevent therapeutic failure in advanced HCC.

FRI550
Different acylcarnitines tissue profiles as metabolomics signatures of human hepatocellular carcinoma in non-alcoholic fatty liver disease according to fibrosis level
Benjamin Buchard[1], Natali Abeywickrama Samarakoon[2], Estelle Pujos-Guillot[3], Stéphanie Durand[3], Mélanie Petera[3], Delphine Centeno[3], Juliette Joubert[4], Aicha Demidem[2], Armand Abergel[1]. *[1]Chu Estaing, Service de médecine digestive et hépatobiliaire, Clermont-Ferrand, France; [2]Université Clermont-Auvergne, Unité de Nutrition Humaine, UMR 1019, Clermont-Ferrand, France; [3]INRA PFEM, PFEM, Saint-Gènes-Champanelle, France; [4]Chu Estaing, Service d'anatomopathologie, Clermont-Ferrand, France*
Email: benjamin.buchard@gmail.com

Background and aims: The incidence and prevalence of non-alcoholic fatty liver disease (NAFLD) are rising worldwide with the increase of obesity and diabetes. NAFLD is becoming a growing cause of hepatocellular carcinoma (HCC). NAFLD-HCC may rise in the absence of severe liver fibrosis in 20 to 50% of patients. However, current evidence does not support routine screening for HCC in this population. The aim of this study was therefore to identify metabolic pathways and putative biomarkers of NAFLD-HCC according to fibrosis level (F0F1 vs. F3F4).
Method: A non-targeted metabolomics strategy was applied to two groups of NAFLDHCC according to fibrosis level. We investigated 55 pairs of human HCC and adjacent non-tumoral tissues (NTT) which included 30 HCC developed in severe fibrosis or cirrhosis (HCC-F3F4) and 25 HCC developed in no or mild fibrosis (HCC-F0F1). Most of samples were provided by the French Tumor Biobank. Aqueous tissue extracts were analyzed using liquid chromatography coupled to mass spectrometry analysis. HCC was compared to its own NTT in these two groups.
Results: The comparison between HCC and NTT in each group revealed acylcarnitines (AC) as the main discriminant metabolites (figure). AC are known to allow the transportation of fatty acids (FA) across the mitochondrial membrane preceding mitochondrial beta oxidation for energy production. In HCC-F3F4 we found an accumulation of both medium chain acylcarnitines (MCAC, Carbon 12) and long chain acylcarnitines (LCAC, Carbon 14 -16- 18) while short chain acylcarnitines (SCAC-derived from Isoleucine and leucine) were decreased in comparison with NTT-F3F4. In contrast HCC-F0F1 was characterized by a significant increase of LCAC (Carbon 16 -18- 20) in comparison with NTT-F0F1. Notably, unlike HCC-F3F4, MCAC and SCAC were not detected in HCC-F0F1 group when compared to its own NTT.

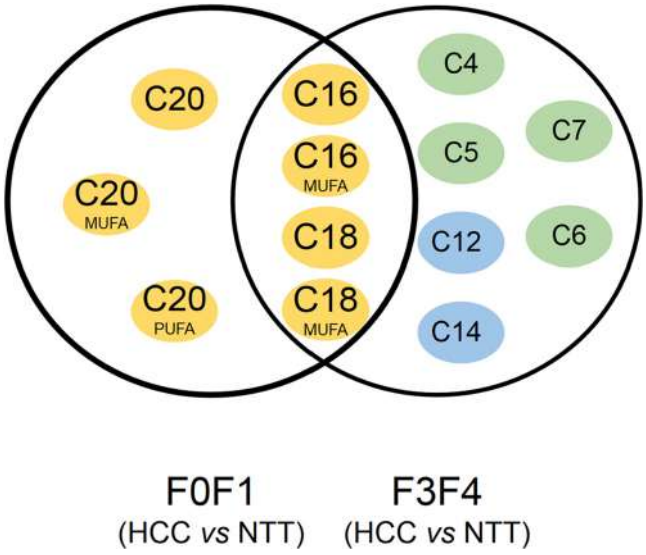

Figure: The Venn diagram displays the acylcarnitine profile that is unique to HCC-F0F1 or HCC-F3F4 and those common to both. MUFA, mono-unsaturated fatty acids; PUFA, poly-unsaturated fatty acids; C, carbon.
In addition, our preliminaries RT-PCR analysis suggest a dysregulation of the main genes coding for enzymes involved in *de novo* lipogenesis and FA oxidation in NAFLD-HCC in comparison with NTT.

Conclusion: Our results are the first one to highlight differences in AC metabolism in NAFLD-HCC and confirm the existence of two distinct metabolomics phenotypes according to underlying non tumoral fibrosis (Buchard et al, Metabolites 2021).

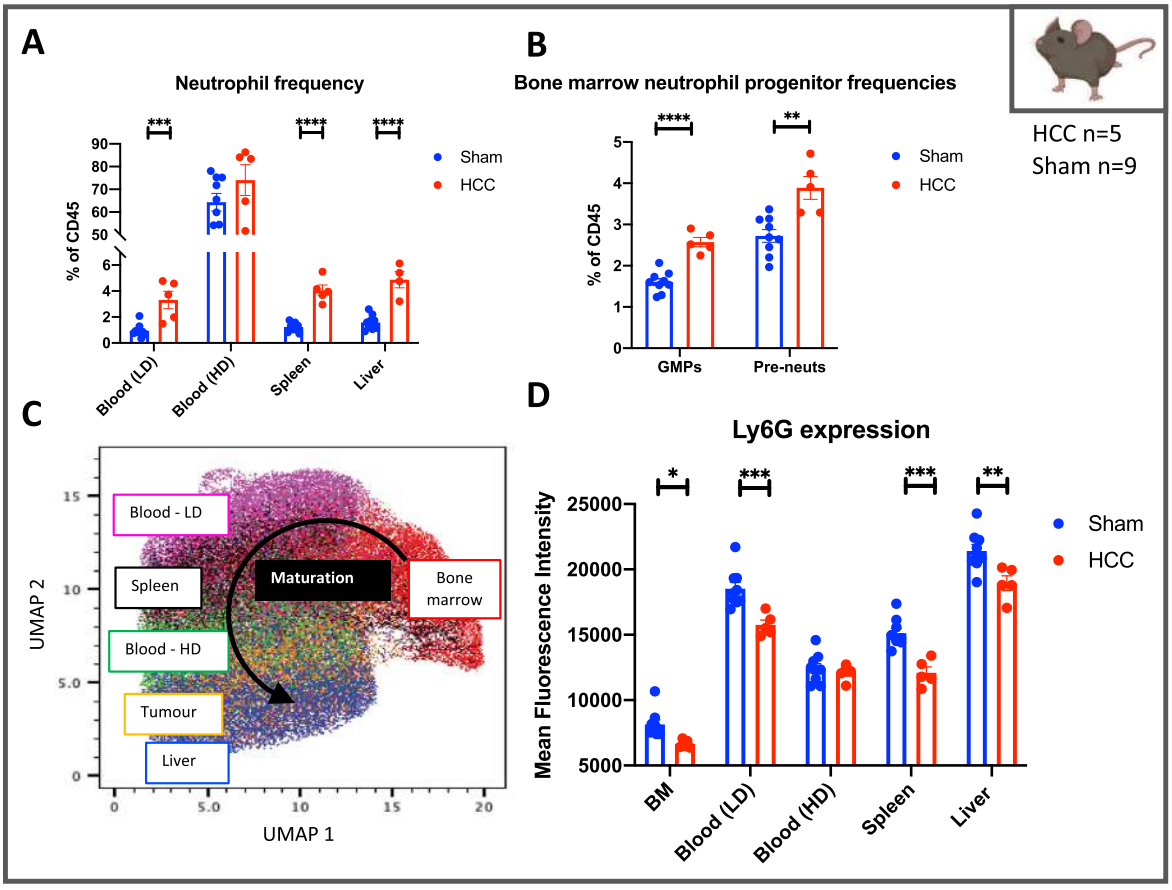
Hepatocellular carcinoma alters granulopoiesis to produce neutrophils with an immature phenotype
Daniel Geh[1], Erik Ramon-Gil[1], Maja Laszczewska[1], Saimir Luli[1], Amy Collins[1], Fiona Oakley[1], Jack Leslie[1], Helen L. Reeves[2,3], Derek A Mann[1]. *[1]Newcastle Fibrosis Research Group, Biosciences Institute, Faculty of Medical Sciences, Newcastle University, Newcastle upon Tyne, United Kingdom; [2]Translational and Clinical Research Institute, Faculty of Medical Sciences, Newcastle University, Newcastle upon Tyne, United Kingdom; [3]Hepatopancreatobiliary Multidisciplinary Team, Newcastle upon Tyne Hospitals NHS Foundation Trust, Freeman Hospital, Newcastle upon Tyne, United Kingdom*
Email: daniel.geh@newcastle.ac.uk

Background and aims: Despite immunotherapy being the first line treatment for advanced hepatocellular carcinoma (HCC), the majority of HCCs are resistant, especially in the context of non-alcoholic fatty liver disease (NAFLD). Neutrophils have emerged as important drivers of HCC, exerting pro-tumour functions such as creating an immunosuppressive tumour microenvironment. Despite this little is known about how HCC influences neutrophils. Here we aim to characterize the effect HCC has on neutrophil phenotype.
Method: *In vivo model.* High fat diet induced steatohepatitis plus orthotopic tumour implantations were conducted in C57BL/6J mice. Sham surgeries were conducted for controls. Neutrophils were isolated from the bone marrow, blood, spleen, liver and tumours. *Patient study.* HCC, chronic liver disease and healthy control patient blood samples were collected and neutrophils isolated by density gradient centrifugation. Neutrophils were analyzed by flow cytometry.
Results: In the murine HCC model neutrophil frequency increased across all compartments with disease progression (A). HCC induced altered granulopoiesis with a preferential increase in early neutrophil progenitor populations such as granulocyte-monocyte progenitor cells (GMPs) and pre-neuts (B). Overall neutrophil phenotype mainly corresponded to the tissue of residence and maturation (C), however



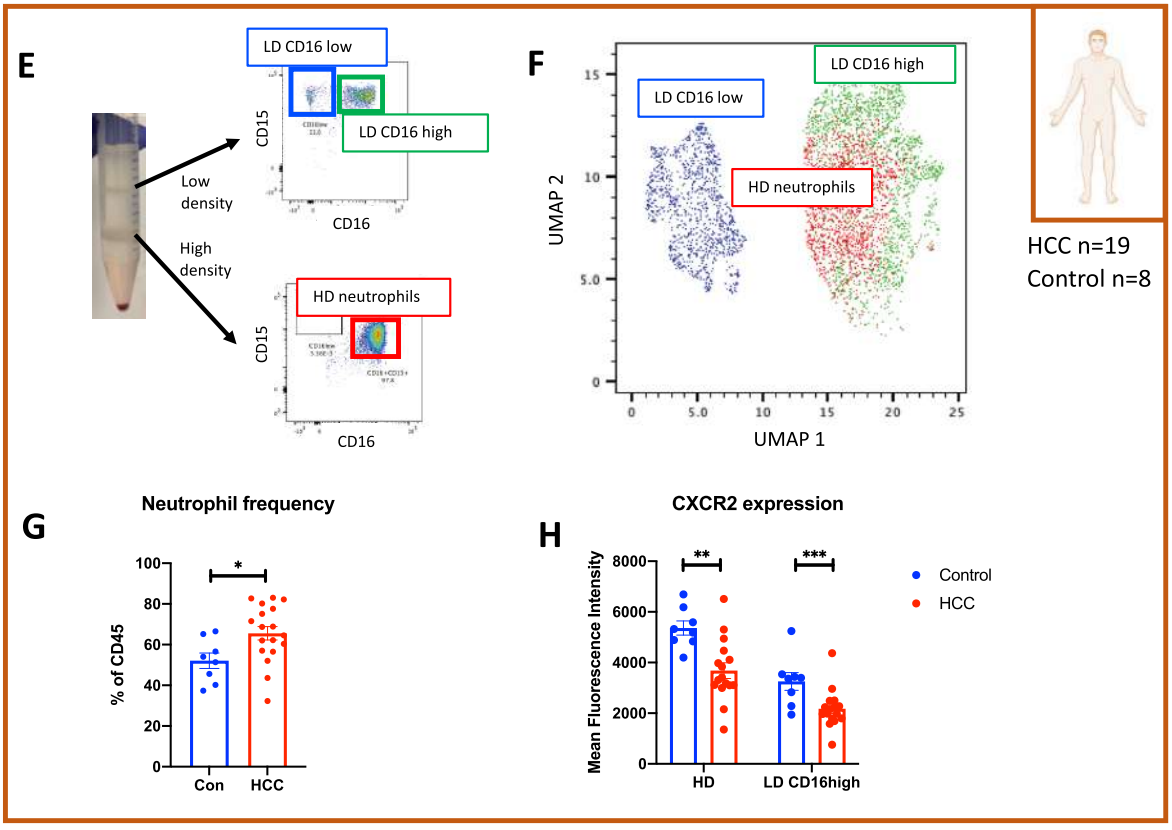


Figure: (abstract: FRI551)

across all compartments HCC gave rise to a more immature neutrophil phenotype as demonstrated by a reduction in Ly6G expression (D). There were also HCC associated changes in neutrophil immune checkpoint and chemokine receptor expression. In patient blood samples 3 neutrophil populations were identified; low density (LD) CD16 low, LD CD16 high and high density (HD) neutrophils (E). These populations could be distinguished based on activation marker and chemokine receptor expression (F). Similar to the murine model there was an increase in neutrophil frequency in HCC patients compared to controls (G) with HCC neutrophils displaying a more immature phenotype as demonstrated by a reduction in CXCR2 expression (H).

Conclusion: HCC induces large shifts in neutrophil dynamics starting during granulopoiesis causing an increase in neutrophil frequency and giving rise to a more immature neutrophil phenotype. We hypothesize that these immature neutrophils have tumour promoting functions, utilized by the HCCs to promote tumour progression. Manipulation of neutrophil maturation may represent an important immune-therapeutic strategy.

FRI552

Hippo inactivation drives BMI1-associated proliferative hepatocarcinogenesis in chronic hepatitis B virus infection

Xufeng Luo[1,2], Rui Zhang[3], Yaojie Liang[2], Stefan Schefczyk[2], Shi Liu[4], Hideo Baba[5], Christian Lange[6], Heiner Wedemeyer[7], Mengji Lu[8], Ruth Broering[2]. *[1]Affiliated Cancer Hospital of Zhengzhou University, Institute for Lymphoma Research, Zhengzhou, China; [2]University Duisburg-Essen, Dept. of Gastroenterology, Hepatoloy and Transplant Medicine, Essen, Germany; [3]Sun Yat-sen University-Sun Yat-sen Memorial Hospital, Department of Hepato-Pancreato-Biliary Surgery, Guangzhou, China; [4]College of Life Sciences-Wuhan University, State Key Laboratory of Virology, Wuhan, China; [5]University Duisburg-Essen, Institute for Pathology, Essen, Germany; [6]Ludwig-Maximilian University of Munich, Department of Internal Medicine, Munich, Germany; [7]Hannover Medical School, Department of Gastroenterology, Hepatology and Endocrinology, Hannover, Germany; [8]University Duisburg-Essen, Institute for Virology, Essen, Germany*
Email: ruth.broering@uni-due.de

Background and aims: Chronic hepatitis B virus (HBV) infection is one of the foremost sources of hepatocellular carcinoma (HCC). Efficient restraint of HBV viremia and necroinflammation via nucleos(t)ide analogue treatment could reduce the HCC incidence. However, hepatocarcinogenesis still occurs in the absence of active hepatitis, correlating with high hepatitis B surface antigen (HBsAg) serum levels. Nevertheless, the molecular mechanisms leading to neoplastic transformation remain elusive.

Method: Hemizygous HBsAg-transgenic mice (tg[Alb1HBV]44Bri) were investigated as a model of hepatocarcinogenesis. Verteporfin treatment were applied *in vivo and in vitro*. Functional analysis included chromatin immunoprecipitation, luciferase-based reporter assays and gain or loss of function assays. HCC tissues with and without HBV infection were analyzed.

Results: Gene set enrichment analysis suggested that signatures in HBsAg-transgenic mice correlated with YAP-downstream, cell cycle, DNA damage and spindle events (GSE84429). Flow cytometry revealed that polyploidy and aneuploidy frequently occurred in hepatocytes of these mice. Quantitative PCR, western blot and immunohistochemical staining revealed the downregulation of MST1/2, loss of YAP phosphorylation and the induction of BMI1 expression. In vitro, chromatin immunoprecipitation and the analysis of mutated binding sites in luciferase-based reporter assays indicated that the YAP/TEAD4 transcription factor complex binds and activates the Bmi1 promoter. Furthermore, overexpression or inhibition of YAP or BMI1 directly altered proliferation-associated events, including $p16^{INK4a}$, $p19^{ARF}$, p53 and Cyclin D1. Verteporfin treatment of HBsAg-transgenic mice, *in vivo*, and related hepatocytes *in vitro*, attenuated this BMI1-mediated proliferation. Analysis of liver biopsies from patients chronically infected with HBV revealed positive correlations between HBsAg, YAP and BMI1, which were further associated with proliferation events.

Conclusion: HBsAg-mediated inactivation of Hippo pathway, resulting in increased BMI1 expression, thereby promoting proliferative hepatocarcinogenesis through alterations in the cell cycle and chromosomal stability.

FRI553

RNA-Seq based transcriptome analysis revealed inhibiting methionine aminopeptidase 2 prevented hepatocellular carcinoma with inhibited angiogenesis

Yongtao Wang[1], Mozhdeh Sojoodi[1], Shijia Zhu[2], Wei Tang[3], Guoliang Qiao[1], Shike Wang[4], Stephen Barrett[1], Michael Lanuti[5], Motaz Qadan[1], Yujin Hoshida[2], Kenneth K. Tanabe[1]. *[1]Massachusetts General Hospital and Harvard Medical School, Division of Gastrointestinal and Oncologic Surgery, Boston, United States; [2]University of Texas Southwestern Medical Center, Department of Internal Medicine, Dallas, United States; [3]National Cancer Institute, Center for Cancer Research, Bethesda, United States; [4]The University of Texas MD Anderson Cancer Center, Departments of Thoracic/Head and Neck Medical Oncology, Houston, United States; [5]Massachusetts General Hospital and Harvard Medical School, Division of Thoracic Surgery, Boston, United States*
Email: ktanabe@partners.org

Background and aims: In our previous experiments with molecular and histologic assessments, we demonstrated that in a diethylnitrosamine (DEN)-induced *rat* hepatocellular carcinoma (HCC) model, inhibition of methionine aminopeptidase 2 (MetAP2) decreased HCC development by inhibiting cirrhosis progression, which was involved with inhibiting angiogenesis and neo-vascularization. In this study we investigated the hypothesis with RNA-Seq analysis, MetAP2 inhibition can reverse the global transcriptomic landscape of DEN-induced HCC with inhibited angiogenesis.

Method: Male Wistar rats received weekly intraperitoneal injections of 50 mg/kg DEN for 18 weeks, and were randomly assigned to 4 groups starting from 9th week: 1) water (control); or 2) MetAP2 inhibitor ZGN1345 (3 mg/kg) by daily gavage; 3) 0.15% DMSO (control); or 4) ZGN-1136 (0.3 mg/kg) by daily subcutaneous injection. Global transcriptomic landscape between DEN-induced *rat* HCC and normal *rat* liver, DEN-induced *rat* HCC before and post-MetAP2 inhibitor treatments were investigated with RNA Sequencing and Gene Set Enrichment Analysis (GSEA) analysis.

Results: Compared with normal *rat* liver, regulatory signatures of protein maturation, and signatures of collagen containing extracellular matrix, DEN-induced up-regulated genes in liver cancer and cancer keratinization, angiogenesis and vascular invasion in liver cancer were positively enriched in DEN-induced *rat* HCC. After inhibiting MetAP2 with ZGN1345 treatment, these signatures reflecting enhanced protein maturation, HCC and angiogenesis were significantly reversed in DEN-induced *rat* HCC. More detailed, regulatory signatures of protein mature were negatively enriched, indicating MetAP2-catalyzed protein maturation and MetAP2 function were inhibited. Signatures of collagen containing extracellular matrix and up-regulated genes in carcinoma associated fibroblast were negatively enriched and suppressed after inhibiting MetAP2. Of notable importance, signatures of cancer keratinization were also negatively enriched and inhibited. Moreover, negative enrichment of signatures of angiogenesis were observed after inhibiting MetAP2, indicating inhibited HCC development was involved with suppressed angiogenesis. Inhibiting MetAP2 with ZGN1136 treatment closely matched and further supported these observations.

Signatures	Protein mature	Collagen	Liver cancer	Angiogenesis
DEN-induced *rat* HCC *vs* Normal *rat* liver	↑	↑	↑	↑
ZGN1345 *vs* Water control	↓	↓	↓	↓
ZGN1136 *vs* Vehicle control	↓	↓	↓	↓

Figure 1. Summary of RNA-Seq based transcriptome analysis. ↑ indicates positive enrichment. ↓ indicates negative enrichment.

Conclusion: On the global transcriptomic level, MetAP2 inhibition effectively prevented HCC development, which was involved with inhibited angiogenesis. These data further suggest that inhibition of MetAP2 may represent a new prevention target for HCC.

Email: lcolyn@alumni.unav.es

Background and aims: Cholangiocarcinoma (CCA) is a deadly disease usually diagnosed at advanced stages. Animal models enable the understanding of pathological processes and its translation into diagnostic and therapeutic advances. Thioacetamide (TAA)-induced CCA in rats captures key features of the human carcinogenic process, including chronic liver injury, inflammation and stromal reaction. Molecular analysis of bile is an excellent liquid biopsy approach and may also help understanding CCA pathogenesis. Here we performed proteomic analyses of bile from control and TAA-CCA rats. Our findings provide further support to the clinical relevance of this model and allowed us to identify new molecular interactions in CCA.

Method: Male Sprague-Dawley rats were treated with TAA in drinking water for 30 weeks. Serum, bile and liver tissues were collected. We performed LC-MS based proteomic analysis of bile. Most relevant hits were validated by qPCR and immunohistochemistry. In vitro mechanistic studies were performed in human CCA cell lines, including Huh28 cells transduced with KRAS-G12D. Cell signaling, cell growth, gene regulation and C13-glucose-serine fluxomics analyses were performed.

Results: All TAA-treated rats developed liver fibrosis and CCA. More than 200 proteins were differentially represented in bile from TAA-rats. Ingenuity Pathway Analysis highlighted pathways related to inflammation, cell signaling, oxidative stress and glucose metabolism. The most relevant hits were confirmed by qPCR in rat liver tissues and in human CCA (TCGA). Activation of interleukin-6 (IL6) and epidermal growth factor receptor (EGFR)-ERK1/2 pathways, critical in CCA biology, as well as key genes in cancer-related glucose-serine metabolic reprogramming, were confirmed in TAA-CCA tissues. TAA-CCAs also showed increased expression of G9a histone-methyltransferase and DNA methyltransferase 1 (DNMT1), epigenetic pro-CCA effectors. In CCA cell lines we showed that IL6 expression can be triggered by EGFR-pathway activation and the presence of KRAS-G12D. We also show that the serine-glycine pathway, critically involved in cancer, is enhanced in CCA cells and can be inhibited upon G9a/DNMT1 pharmacological targeting. Mechanistically, KRAS-G12D promoted G9a binding to chromatin in CCA cells, and this was prevented by the inhibition of G9a self-methylation. Finally, we demonstrated that tumorigenic properties conferred by KRAS-G12D to CCA cells such as anchorage-independent growth are highly sensitive to G9a/DNMT1 inhibition.

Conclusion: Our study confirms the rat TAA-CCA model as a key resource for basic and translational CCA research. This model led us to identify the EGFR-ERK1/2 pathway as a critical driver for IL6 production, and to establish the relevance of the glucose-serine pathway in CCA. The G9a/DNMT1 epigenetic complex is further validated as a target for CCA therapy.

FRI555

Expression of hepatitis B surface antigen in vivo and in vitro induces endoplasmic reticulum stress, impairs autophagy and promotes proliferation

Email: ruth.broering@uni-due.de

Background and aims: Hepatitis B surface antigen (HBsAg) has been identified to increase the risk and contribute to hepatocellular carcinoma (HCC). However, factors and mechanisms that drive HBsAg-induced hepatocarcinogenesis remain poorly defined, thus hindering the development of new therapeutic strategies. Therefore, we explore how HBsAg mechanistically facilitates the transformation from normal liver cells to HCC.

Method: Data mining of the microarray set GSE84429 (from GEO datasets) indicated the potential candidate signatures of HBsAg-driven intracellular events. Hemizygous tg (Alb1HBV)44Bri/J mice were investigated for this HBsAg-driven carcinogenic events by western blotting, immunohistochemical (IHC) staining. Finally, the findings were verified in HBsAg-overexpressing Hepa1-6 cells, in which functional analysis was performed to study the contribution of these events in hepatocarcinogenesis.

Results: Gene set enrichment analysis identified significant signatures in HBsAg-transgenic mice correlating with ER stress, unfolded protein response (UPR), autophagy, cell cycle and proliferation. Clustered heatmap visualized distinct gene expression pattern for endoplasmic reticulum (ER) stress and autophagy in HBsAg-transgenic mice, compared to wild type. These events were further investigated in 2-, 8- and 12-month-old HBsAg-transgenic mice. Elevated BiP expression in HBsAg-transgenic mice indicated induction of UPR. Furthermore, our study indicates that HBsAg impaired the autophagic flux. In HBsAg-transgenic mice autophagy was enhanced at the early stage (increased Beclin1) and blocked at the late stage (increased p62 and LC3B-II). These ER stress and autophagy events could be verified in Hepa1-6 cells overexpressing HBsAg for up to 72 hours. In addition, HBsAg expression changed lysosomal acidification, visualized by acridine orange staining, and promoted proliferation, indicated by Ki67 staining of paraffin-embedded sections and CCK-8 staining and colony formation assay *in vitro*. IHC staining of cleaved caspase3, an apoptosis marker, revealed a slight increase in HBsAg-transgenic mice, indirectly indicating hepatocyte proliferation due to HBsAg accumulation.
Conclusion: Our findings revealed that HBsAg directly induces ER stress, impairs autophagy and promotes proliferation thereby driving hepatocarcinogenesis. Moreover, this study expanded the understanding of HBsAg-mediated intracellular events in carcinogenesis.

Cross-talk between cholangiocarcinoma cells and extracellular microenvironment drives desmoplastic matrix deposition

Gilles van Tienderen[1], Oskar Rosmark[2], Ruby Lieshout[1], Jorke Willemse[1], Floor de Weijer[1], Linda Elowsson Rendin[2], Gunilla Westergren-Thorsson[2], Michael Doukas[3], Bas Groot Koerkamp[1], Martin van Royen[3], Luc J.W. van der Laan[1], Monique M.A. Verstegen[1]. *[1]ErasmusMC Transplant Institute, Department of Surgery, Rotterdam, Netherlands; [2]Lund University, Department of Experimental Medical Science, Lund, Sweden; [3]Erasmus MC, Department of Pathology, Rotterdam, Netherlands*
Email: g.vantienderen@erasmusmc.nl

Background and aims: Cholangiocarcinoma (CCA) is a highly aggressive tumor which arises from the biliary duct epithelium. Currently available models fail to recapitulate the full complexity of CCA, particularly the desmoplastic environment and the interplay between cancer cells and the extracellular matrix (ECM). We aimed to study the role of tumor cells in ECM deposition and desmoplasia by combining patient-derived CCA organoids (CCAOs) and native liver and tumor scaffolds, obtained by decellularization.
Method: Native human CCA matrix (CCA-M) and tumor-free liver matrix (TFL-M) were decellularized and subsequently recellularized with CCAOs. The decellularized scaffolds were biochemically and mechanically assessed. Tumor cell behavior of CCAOs in CCA-M, TFL-M, and basement membrane extract (BME), was assessed by bulk RNA-sequencing and Stable Isotope Labeling by Amino acids in Cell culture (SILAC)-based mass spectrometry.
Results: Decellularization of CCA tumor and liver tissue resulted in effective removal of cells while preserving ECM structure and retaining important characteristics of the tissue origin, including stiffness and the presence of desmoplasia. When culturing CCAOs in CCA-M, the expression profile of differentially expressed genes much more resembled the transcriptome of primary CCA tumor tissue *in vivo* compared to TFL-M (correlation coefficient (CC) CCA-M 0.83 ± 0.03 vs CC TFL-M 0.70 ± 0.03, $p = 0.004$) and BME (CC CCA-M 0.88 ± 0.04 vs CC BME 0.63 ± 0.06, $p < 0.0001$). Furthermore, CCA-M induced specific extracellular matrix protein production in CCAOs, such as fibronectin 1 (FN1), which is related to desmoplasia and patient survival. In TFL-M, lacking desmoplasia, CCAOs were able to initiate a desmoplastic reaction directly through increased production of multiple collagen types (e.g. COL1A1, COL1A2, COL6A1, COL6A3).
Conclusion: This improved model of cholangiocarcinoma recapitulates key aspects of CCA tumor biology, including transcriptome profiles and ECM protein production. The increased production of extracellular matrix proteins suggests that tumor cells can contribute to their own desmoplastic environment.

DNA methylation regulates lncRNAs compromising hepatic identity during hepatocarcinogenesis

Miriam Recalde[1], María Gárate-Rascón[1], José María Herranz[1,2], María Elizalde[1], María Azkona[1], Juan Pablo Unfried[3], Bruno Sangro[2,4,5], Maite G Fernandez-Barrena[1,2,5], Puri Fortes[2,3,5], Matías A Avila[1,2,5], Carmen Berasain[1,2,5], Maria Arechederra[1,5]. *[1]Center of Applied Medical Research (CIMA), Program of Hepatology, Pamplona, Spain; [2]National Institute for the Study of Liver and Gastrointestinal Diseases (CIBERehd, Carlos III Health Institute), Madrid, Spain; [3]Center of Applied Medical Research (CIMA), Department of Gene Therapy and Regulation of Gene Expression, Pamplona, Spain; [4]Navarra University Clinic, Hepatology Unit, Pamplona, Spain; [5]Navarra Institute for Health Research (IdiSNA), Pamplona, Spain*
Email: macalderon@unav.es

Background and aims: We have previously identified a list of lncRNAs deregulated in hepatocellular carcinoma (HCC). In the present work, we aim to study the mechanism of lncRNA down-regulation in HCC and the contribution of this deregulation to the progression of liver tumorigenesis.
Method: We used public RNAseq, methylome and clinical data of HCC and other types of tumor patients from TCGA. Human HCC, peritumoral, cirrhotic and healthy liver samples were obtained from Biobanco Universidad de Navarra (Spain). PLC/PRF/5, HepG2 and well-differentiated HepaRG HCC human cell lines were used to determine the expression of selected lncRNAs and hepatic specific markers by RT-qPCR in control condition and after demethylating treatment with 5-aza-2′-deoxycytidine and lncRNA knockdown with LNA-gapmers. DNA methylation was determined by targeted bisulfite sequencing.
Results: We verified that the in-silico top-ranked downregulated lncRNAs showed decrease expression in HCC compared to paired peritumoral tissues and cirrhotic and healthy livers. As expected, these HCC downregulated lncRNAs were preferentially expressed in liver compared to other organs, yet a set expressed to a lesser extent in other tissues, were also downregulated in the corresponding tumors. Although the promoter regions of these lncRNAs are poorly represented in the published methylome data, we found that the available promoter CpGs were hypermethylated in HCC compared to control tissue, as well as in HCC human cell lines compared to primary hepatocytes. We validated these findings in a cohort of HCC and paired peritumoral tissues. Moreover, demethylating treatment induced the expression of these lncRNAs, thus demonstrating that DNA hypermethylation is responsible for lncRNA downregulation. To determine the relevance of these set of lncRNAs in HCC, we studied the clinical implication of their downregulation. Importantly, TCGA

data showed that their loss of expression was significantly associated with worse survival and poor tumor differentiation, supported by the lower expression of hepatic specific genes such as *Albumin*, *CYP3A4*, *MAT1A* or *HNF4alpha*. Accordingly, in vitro downregulation of a set of these lncRNAs in well-differentiated HepaRG cells resulted in the loss of hepatic specific markers.
Conclusion: All together, our results demonstrate that hepatocarcinogenesis is associated to the downregulation through DNA methylation of a set of lncRNAs essentials to ensure hepatic differentiation.

FRI558
Inhibiting IRE1a-endonuclease activity potentiates the effect of doxorubicin in hepatocellular carcinoma
Maria Kopsida[1], Femke Heindryckx[1], Natasa Pavlovic[1], Hans Lennernas[2], Jaafar Khaled[1]. *[1]Uppsala Universitet, Medical Cell Biology, Uppsala, Sweden; [2]Uppsala Universitet, Pharmaceutical Biosciences, Uppsala, Sweden*
Email: maria.kopsida@mcb.uu.se

Background and aims: Hepatocellular carcinoma (HCC) is the most common form of liver cancer, characterized by a high resistance to chemotherapeutic agents, such as doxorubicin (DOX). One potential contributing factor to this drug resistance, is the activation of the endoplasmic reticulum (ER) stress pathways. This is a cellular stress mechanism that becomes activated when the cell's need for protein synthesis exceeds the ER's capacity to ensure accurate protein folding, and has been implicated in creating drug-resistance in several solid tumors. However, its role in HCC remains unclear and requires further investigation.
Method: Publicly available data from the Human Protein Atlas (HPA) was used to find correlated expression of drug resistance/ER-stress markers in HCC-patients. A chemically induced mouse model for HCC was used and mice were treated twice per week with the ER-stress inhibitor 4u8C and/or DOX for 3 weeks, after the occurrence of tumors. Liver samples were taken for histological and molecular biology analyses.
Results: Data-mining of the HPA revealed that ER-stress markers are highly intertwined with different drug-resistance mechanisms in HCC-patients. Mice with HCC experienced a statistically significant weight loss compared to healthy mice. This was further exacerbated after DOX-treatment, while co-treatment with 4μ8C restored weight levels to nearly those of healthy mice. All treatments significantly decreased the number of tumors, with the strongest reduction in the 4u8C + DOX combination treatment. Staining for Ki-67 showed a significant increase in the number of Ki-67 positive cells in mice with HCC, which was significantly reduced in all treatment groups, with the strongest reduction in the 4u8C+DOX combination treatment. In mice with HCC, 4u8C and the combination of 4u8C and DOX significantly increased apoptosis compared to untreated mice. Interestingly, no increase of apoptosis was seen in the DOX-treated group, which could suggest an alternative form of cell death. As DOX is known to induce ferroptosis, Transferrin Receptor-staining in liver tissue was quantified. This showed that DOX increased the area of Transferrin Receptor positive staining, suggesting a possible increase in ferroptosis. Interestingly, treatment with 4u8C reduced this effect, which is in line with previous findings that ferroptosis is-at least in part-dependent on ER-stress pathways.
Conclusion: By using an *in vivo* model known for its similarity to human HCC, we show that using an ER-stress inhibitor can potentiate the cytotoxic effect of DOX. The long-term impact of our study could open the possibility of ER-stress inhibitors as adjuvant treatments for HCC-patients.

Genetic ablation of miR-22 fosters hepatic carcinogenesis in mice
Monika Gjorgjieva[1], Cyril Sobolewski[1], Anne-Sophie Ay[1], Daniel Abegg[2], Marta Sousa[1], Flavien Berthou[1], Margot Fournier[1], Christine Maeder[1], Xavier Montet[3], Alexander Adibekian[2], Michelangelo Foti[1]. *[1]University of Geneva, PHYME, Geneva, Switzerland; [2]The Scripps Research Institute, Chemistry, Jupiter, United States; [3]University of Geneva, Radiology, Geneva, Switzerland*
Email: monika.gjorgjieva@unige.ch

Background and aims: We previously reported that microRNA-22 (miR-22) deficiency exacerbated diet-induced obesity, hepatomegaly, and liver steatosis in mice by promoting hepatic glycolysis and lipid uptake. In HCC, miR-22 expression/activity is strongly downregulated in both mouse models of HCC and human HCC, suggesting an important role for this microRNA also in pre-cancerous stages and tumourigenesis. Herein, we investigated the role of miR-22 deficiency in HCC development associated or not with diet-induced obesity.
Method: Mir22-knockout (miR22KO) mice were used to investigated hepatic carcinogenesis induced either by DEN, or PTEN-deficiency, in mice fed a normal or obesogenic diet. Proteomic analyses of liver tissues from miR22KO mice were performed and metabolic alterations and cancer processes under the influence of miR-22 were investigated in transformed hepatic cancer cells.
Results: In vivo, the genetic deletion of miR-22 triggers a significant increase in the onset of hepatic tumoural nodules and multiplicity induced by DEN. This miR-22-asssociated phenotype was further exacerbated in diet-induced obese mice. A similar tumour promoting effect of miR-22 deficiency was observed in a genetic model of HCC spontaneous development induced by the liver specific deletion of the tumour suppressor PTEN (liver-specific miR-22/PTEN double KO mice). Consistent with these phenotypes, proteomic analyses of hepatic tissues from miR-22 KO mice indicate that miR-22 exerts tumour suppressive function in vivo by restraining the expression/activity of several oncogenic factors. Surprisingly, overexpression of miR-22 in Huh7 hepatic cancer cells triggers, in contrast to our in vivo observations, a clear induction of a Warburg effect with an increased glycolysis and an inhibited mitochondrial respiration consistent with an oncogenic role for miR-22 in these cells.
Conclusion: Our study indicates that in vivo miR-22 behaves as a strong tumour suppressive miRNA restraining tumour initiation. Our data further indicate that miR-22 may have a dual role in hepatic carcinogenesis by promoting tumour initiation but inhibiting then tumour progression when cells are already transformed.

FRI560
Focal nodular hyperplasia: a response to portal vein thrombosis followed by a sequence of arterio-portal shunting, hyperperfusion, focal retrograde sinusoidal blood and Wnt flow, and Wnt-induced activation of the bud maturation sequence
IanR Wanless[1], Ashley Stueck[1]. *[1]Anatomic Pathology, Halifax, Canada*
Email: ian2460@gmail.com

Background and aims: Focal nodular hyperplasia (FNH) is a hyperplastic lesion with abnormally high arterial blood flow. Subsequent events in the pathogenesis have not been elucidated. In studies of cirrhosis, we showed that regeneration occurs in the sequence: 1) activation of hepatocyte progenitor cells (HPCs) identified by glutamine synthetase activation (GSA), 2) Hepatocyte (HC) buds with tubular plates, and 3) HC remodeling into single-cell plates. This budding sequence may be initiated by local Wnt secretion. Wnt activates the Wnt/beta-catenin pathway causing regeneration and GSA. GSA in a "map-like pattern" is a defining feature of FNH.
We hypothesize that increased delivery of secreted Wnt to HPCs initiates focal HC hyperplasia. We studied morphology of FNH for an explanation of how Wnt, produced in hepatic veins, could be distributed to the HPC niche in portal tracts.

Method: A consecutive series of 50 resected FNH lesions were serially sectioned and stained with GS, CD34, CK19, reticulin.
Results: Most lesions had a large arterio-portal shunt (APS). Proximal sinusoids were mostly lined by CD34-positive sinusoidal endothelial cells (SEC), indicating a high-flow/high-pressure state. HPC activation and tubular HC plate structure confirmed that hyperplasia resulted from budding. Within FNH, GSA was markedly increased near small hepatic veins and absent in high flow areas revealed by CD34-positive SEC. This map-like distribution of GSA suggests that an APS focally pressurizes hepatic veins resulting in focal retrograde sinusoidal flow, delivering increased Wnt concentration to local parenchyma and small bile ducts, inducing HC hyperplasia by activation of budding sequence.

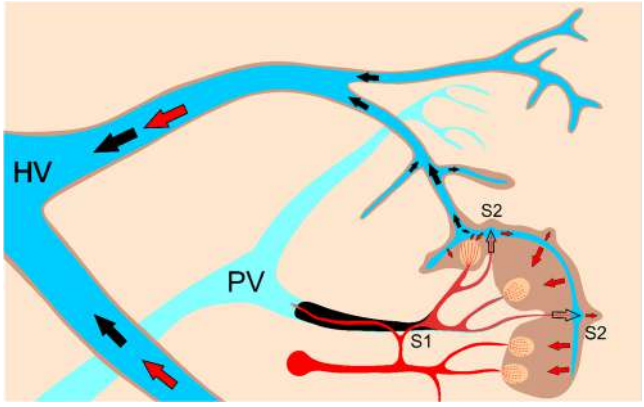

Figure: Early FNH lesion caused by focal portal vein thrombosis. Primary A-PV shunt (S1) and secondary A-HV shunts (S2) pressurize hepatic veins, reversing HV-sinusoid pressure gradients with retrograde Wnt flow, Wnt-driven HC GSA (brown areas), and Wnt-driven budding (yellow ovals). Dotted red lines are CD34+ sinusoids. Arrows red = Wnt flow, black = blood flow.

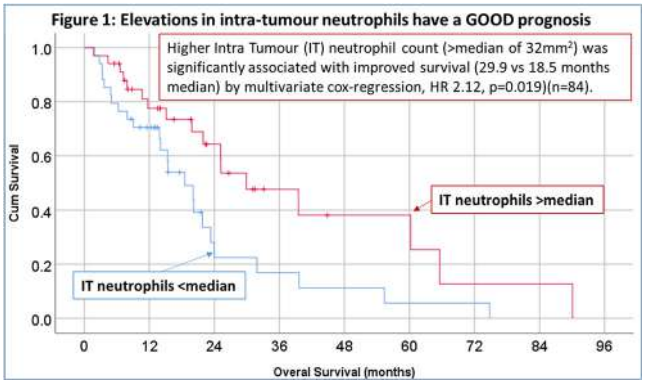
Conclusion: In FNH, hyperperfusion and focal retrograde sinusoidal flow, can explain the map-like distribution of Wnt effects, such as GSA and bud-derived hyperplasia. Most lesions likely begin with a local portal vein thrombosis with shunt forming during recanalization. Downstream arterialization and A-HV shunting provide the focal and variable HV-to-sinusoidal pressure gradients that determine direction of blood flow. Budd-Chiari lesions likely begin with HV thrombosis giving a distinct lesion (FNH-type 2).
FNH serves as a model for Wnt causing hyperplasia and GSA. Similar blood flow abnormalities occur in chronic liver disease, although in a less predictable and focused pattern. Thus, local Wnt concentration may be an important driver for regeneration in many liver diseases.

FRI561
Hepatocellular carcinoma and neutrophils-towards understanding positive and negative impacts on treatments and progression

João Maurício[1], Sandra Murphy[2], Misti McCain[1], Daniel Geh[1], Marcello Kadharusman[1], Jack Leslie[2], Robyn Watson[1], Steven Masson[3], Stuart Mcpherson[3], Alastair Burt[2], Ruchi Shukla[2], Derek A Mann[2], Caroline Wilson[2], Helen Louise Reeves[1,3]. *[1]Newcastle University Translational and Clinical Research; [2]Newcastle University Biosciences Institute; [3]Newcastle upon Tyne Hospitals NHS Foundation Trust, United Kingdom*
Email: h.l.reeves@ncl.ac.uk

Background and aims: As deaths from hepatocellular carcinoma (HCC) rise, understanding the tumour-immune axis is key. Elevated circulating neutrophils associate with poor survival in many cancers, including HCC. Understanding the pathophysiological mechanisms and consequences of changes in neutrophil numbers and behaviour may aid novel therapeutic strategies. We explored the human phenotype, function and proteome of circulating neutrophils, associated with tissues distribution and serum cytokines.
Method: 275 subjects (72 healthy; 42 chronic liver disease controls; 161 with HCC-all with Childs Pugh 'A' liver function-of whom 84 had tumor biopsy tissue available). Neutrophil immunohistochemistry (IHC), digital image analysis, serum cyto/chemokine 65-Plex panel (Eve Technologies), FACS, cytospin nuclear maturity, reactive oxygen species (ROS) generation, proteome (Orbitrap Fusion Lumos Tribrid mass spectrometer; MaxQuant and Perseus software) and patient data were analysed.
Results: The IHC density of intra-tumor (IT) CD66B+ neutrophils was higher in earlier TNM stage cancers ($p = 0.007$), associated with significantly better responses to therapies and independently with better survival (Figure 1). In contrast, peri-tumor (PT) neutrophils rose as cancers progressed, significantly associated with circulating neutrophil number (0.436; $p = 0.002$), size and vascular invasion. Four serum cytokines (IL-8, CXCL10, CXCL13, CCL21) were significantly elevated with HCC, regardless of cirrhotic state. Elevations in IL-8 were early and striking (up to 5X, $p < 0.001$), correlating with tumor number (0.531; $p = 0.001$), size (0.493; $p = 0.020$) and vascular invasion (0.595; $p = 0.004$). IT neutrophils correlated with IL-18 (0.587; $p = 0.035$) and PT neutrophils with CXCL10 (0.645; $p = 0.032$) and MCP-1 (−0.645; $p = 0.032$).



In the presence of cirrhosis, reductions in nuclear mature (70%>55%) and immature (25%>10%) circulating neutrophils, with increases in hypersegmented (5%<35%) were evident, with a proteome revealing reduced degranulation (MPO, AZU1, CTSG, GM2A, RNASE3). In cancers there was a sharp recovery in immature neutrophils, with a proteome supporting haem metabolism and oxidative phosphorylation (highly significant changes in multiple cytochrome oxidase and haemoglobin subunits and carbonic anhydrase). Functionally, ROS

production was elevated by the NADPH oxidase activator PMA, but less responsiveness to fMLF/receptor signaling.

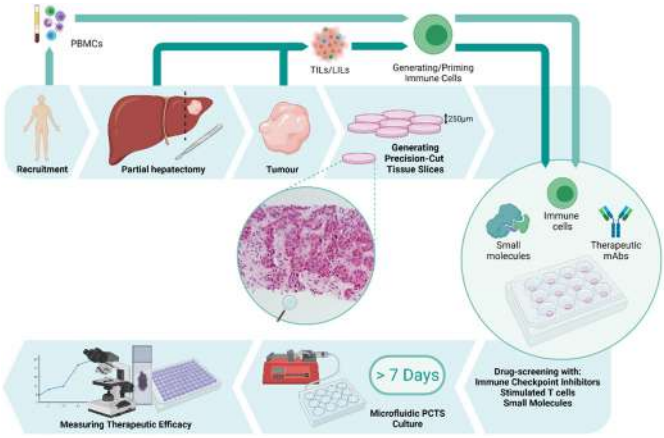
Conclusion: The development and progression of cancer is associated with changes in chemokines, restoration/elevation in circulating immature neutrophils, metabolic reprogramming and elevated ROS capacity. Elevations in IT neutrophils associated with better responses and outcomes, while accumulation of PT neutrophils associated with circulating neutrophils, and tumor progression.

FRI562

Dynamic organotypic culture of primary liver cancer as a personalised immunocompetent drug screening platform for immuno-oncology

Ravi Jagatia[1,2,3], Ewald Doornebal[1,2,3], Lorenzo Caciolli[1,2,4], Nicola Harris[1,2], Una Rastovic[1,2], Sara Campinoti[1,2], Melissa Preziosi[5], Marjorie Yumol[5], Rosa Miquel[5], Yoh Zen[5], Andreas Prachalias[5], Krishna Menon[5], Sara Mantero[4], Sandra Phillips[1,2], Nigel Heaton[5], Luca Urbani[1,2], Elena Palma[1,2,6], Shilpa Chokshi[1,2,6]. *[1]King's College London, Faculty of Life Sciences and Medicine, London, United Kingdom; [2]The Roger Williams Institute of Hepatology, London, United Kingdom; [3]Contributed Equally; [4]Politecnico di Milano, Department of Chemistry, Materials and Chemical Engineering "Giulio Natta," Milano, Italy; [5]Institute of Liver Studies, King's College London, London, United Kingdom; [6]Corresponding Author*
Email: s.chokshi@researchinliver.org.uk

Background and aims: Current primary liver cancer (PLC) models fail to truly encompass the human tumour immune microenvironment, exacerbating a recognised discord between the preclinical and clinical successes of emerging (immuno)therapeutics. The organotypic culture of 3D human Precision Cut Tumour Slice (PCTS) is a cancer explant model which retains tumour specific histoarchitecture, aetiological background, disease phenotype, resident immune landscape, and checkpoint (CP) expression for >5 days ex-vivo. Our study aims to (1) validate PCTS to assess patient specific therapeutic responses and (2) advance culture conditions using a proprietary Multi-well Plate (MuPL) perfusion bioreactor to extend PCTS lifetime and allow perfusion of immune cells through PCTS.
Method: PCTS generated from PLC (HCC & CCA) were treated with approved single agent or combinatory checkpoint inhibitor (CPI), monoclonal antibody (mAb) or kinase inhibitor (KI) therapy for up to 7 days. Therapeutic response was determined by evaluating histology (H&E and Sirius red), apoptosis/cell death (TUNEL, lactate-dehydrogenase release, cytokeratin 18), and proliferative capacity (PC; Ki67). Gene expression was assessed using QuantiGene RNA Assay. Resident immune cells were assessed by immunofluorescence and FACS. In addition, PCTS/immune cells co-cultured in the MuPL bioreactor were longitudinally assessed for viability, histology, and tissue integrity.
Results: Doxorubicin was used as a positive cell death control in all treated patients, decreasing PCTS viability and PC by day5. Overall immunotherapy response was patient specific. Compared to monotherapy, nivolumab + regorafenib therapy decreased the tumour to stroma ratio and PC in all patients by day7. Also, significantly increased apoptosis was detected in one patient, who comparatively showed higher CP expression including PD-1, PD-L1 and CTLA-4. Other combinatorial immunotherapies, including atezolizumab + bevacizumab and nivolumab + ipilimumab, reduced PC without affecting histology or viability. Additionally, PCTS and immune cells cultured in the MuPL bioreactor maintained viability, structural integrity and histoarchitecture for >7 days.



Conclusion: PCTS can be used as a powerful tool to study personalised responses to (immuno)therapeutics. In addition, PCTS can be successfully cultured in a perfusion system, recapitulating tumour-immune cell interactions, allowing assessment of response to cell and vaccine therapy ex-vivo.

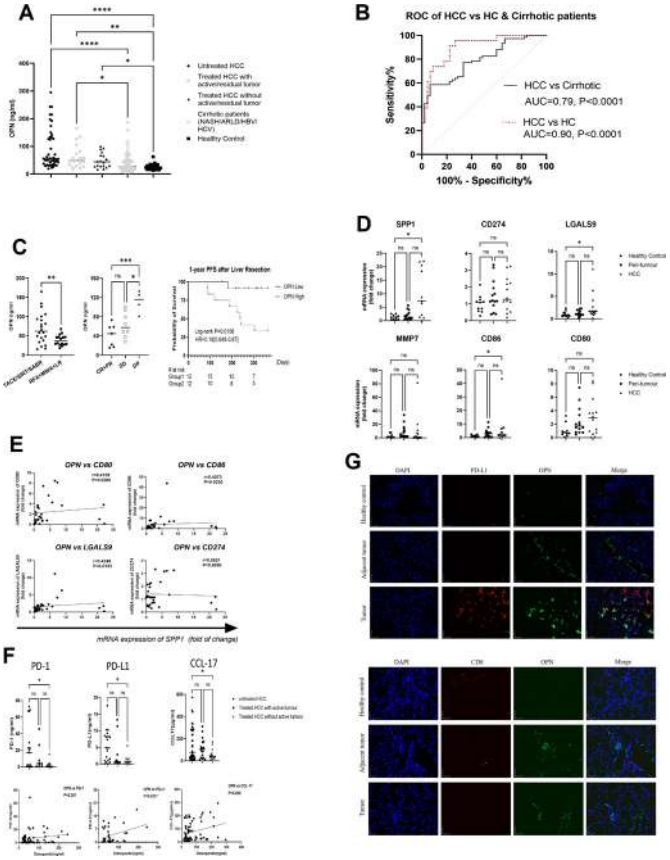
FRI563

High plasma level of osteopontin, a potential biomarker in hepatocellular carcinoma, is associated with weakened anti-tumour immunity

Tengfei Si[1], Zhenlin Huang[2], Shirin Elizabeth Khorsandi[1,3,4], Wayel Jassem[1,3], Xiaohong Huang[1], Abid Suddle[1], Mark J W McPhail[5], Francesca Trovato[1,5], Salma Mujib[1], Salvatore Napoli[1], Ellen Jerome[1,3], Yun Ma[1], Nigel Heaton[1,3]. *[1]King's College Hospital, Institute of Liver Studies, London, United Kingdom; [2]Shanghai University of Traditional Chinese Medicine, The MOE Key Laboratory for Standardization of Chinese Medicine, China; [3]King's College Hospital, Transplant Service, London, United Kingdom; [4]the Roger Williams Institute of Hepatology, London, United Kingdom; [5]King's College Hospital, Liver Intensive Therapy Unite, London, United Kingdom*
Email: yunma1@nhs.net

Background and aims: It has been shown that osteopontin (OPN) is closely associated with tumour invasion and metastasis in hepatocellular carcinoma (HCC). The mechanisms for the role of OPN in HCC has been defined in both animal models and carcinoma cell lines, but direct evidence derived from human studies are lacking. We aim to explore OPN's association with clinical outcome and anti-tumour immunity through a comprehensive analysis in a large cohort of HCC patients.
Method: A total of 92 HCC patients, 81 non-HCC patients with underlying liver cirrhosis (NASH/ARLD/HBV/HCV) and 25 healthy controls (HC) were recruited from our centre. Plasma levels of OPN, Th1/Th17 cytokines, soluble PD-1, PD-L1, CTLA-4, CCL17 and CXCL-9 were measured by ELISA. mRNA expression of OPN and ligands for immune checkpoint were assessed by quantitative real-time PCR across HCC and paired adjacent liver tissue (n = 16). Immunofluorescence staining was performed to co-stain OPN with CD8 and PD-L1 in HCC, paired adjacent tumour and healthy liver tissues.
Results: The plasma OPN level in untreated HCC (n = 48) was significantly higher than other groups (Fig1 A). ELISA results showed good diagnostic performance when compared with both healthy controls (AUC = 0.90, $p < 0.0001$) and cirrhotic group (AUC = 0.90, $p < 0.0001$) (Fig1 B). For patients receiving ablation (radiofrequency ablation, RFA; microwave ablation, MWA) or liver resection (LR) (n = 16), the OPN levels were much lower than those treated with radiotherapy (selective internal radiation therapy, SIRT; stereotactic ablative radiotherapy, SABR) or chemotherapy (transarterial chemoembolization, TACE) (n = 22). In some patients, low OPN level represented better treatment response to TACE and longer

progression free survival (PFS) (>1 year) after liver resection (Fig1 C). PCR results showed high expression of OPN in HCC tumour tissue (Fig1 D) and there was a positive correlation between OPN with the ligands of CTLA-4 (CD80/CD86) and TIM-3 (LGALS9) (Fig1 E). Plasma PD-L1 and CCL-17 levels in untreated HCC (n = 48) were both higher when compared to other HCC treated groups (n = 25; n = 19) and positively correlated with OPN. Furthermore, immunofluorescent staining showed that the expression of both OPN and PD-L1 were upregulated in tumour, with high signal of OPN around tumour vasculature. While CD8 was downregulated in tumour and paired adjacent tumour tissue.



Conclusion: OPN has been shown as a potential marker for both diagnosis and prognosis in HCC. The positive correlations between OPN, PD-L1 and chemokine of T-regulatory cells CCL-17 in plasma, suggest that high OPN levels is associated with a weakened anti-tumour immunity. This indication was further confirmed by PCR results and immunofluorescent staining.

Email: patricia.aspichueta@ehu.eus

Background and aims: One of the hallmarks of cancers is metabolic reprogramming, and its regulation is a possible therapeutic target. There is little information about rearrangements of lipid metabolism in cholangiocarcinoma (CCA), characterised by great heterogeneity and poor prognosis. Previous evidence suggests that *de novo* synthesis of fatty acids (FAs) is decreased in CCA, pointing to exogenous lipids as the main source of FAs. Here, we investigated the alterations in lipid metabolism in CCA and their role in tumour proliferation.

Method: *In vitro* proliferative and migration capacities and *in vivo* tumorigenic capacity of 5 human CCA cell lines were analyzed. Proteome, lipid content and metabolic fluxes were studied in CCA cells, using primary cultures of normal human cholangiocytes (NHC) as a control. Lipid content and metabolic fluxes were analyzed in liver samples of a mouse model of CCA based on the overexpression of *Akt1* and NOTCH1 intracellular cytoplasmic domain (*Nicd1*).

Results: The proteome of CCA cells showed a dysregulation of pathways involved in lipid and lipoprotein metabolism. The EGI1 CCA cell line showed the highest proliferative and migration capacity. We studied metabolic fluxes with radioisotopes and measured lipid content in high (EGI1) and low (HUCCT1) proliferative cell lines, and in liver tumor tissue from the mouse model of CCA. Both EGI1 and HUCCT1 incorporated more oleic and palmitic acid than NHCs, which resulted in an increased triglyceride storage. Similarly, the CCA mouse model showed a faster clearance and increased liver uptake of intravenous [^{3}H]-oleate. Highly proliferative EGI1 cells showed an increased uptake of very-low density lipoproteins (VLDL) and high density lipoproteins (HDL) than NHC and HUCCT1. This increased uptake of lipids was accompanied by a higher expression of CD36 and fatty acid binding protein FABP5. Unlike glucose or glutamine oxidation, fatty acid oxidation (FAO) rate was increased in EGI1 and downregulated in HUCCT1. Accordingly, FAO-related proteins showed a higher expression in the proteome of EGI1 and, therefore, pharmacological inhibition of FAO induced a more pronounced inhibition on proliferation in EGI1 than in HUCCT1. Expression of the first enzyme involved in FAO, the acyl-CoA dehydrogenase ACADM, whose protein levels are specifically increased in EGI1, was found to correlate with that of the proliferation marker PCNA in tumour tissue from CCA patients.

Conclusion: Highly proliferative human CCA cells are highly dependent on lipid and lipoprotein uptake to sustain an active catabolism of FAs. These results suggest that inhibition of FAO and/or lipid uptake may provide a novel therapeutic strategy for patients of this subclass of CCA.

Email: thomas.baumert@unistra.fr

Background and aims: Metabolic liver disease and hepatocellular carcinoma (HCC) are major global health burdens with unsatisfactory treatment options. HCC is the third most common cause of cancer-related death and the leading cause of death among cirrhotic patients. While new treatments for HCC have been recently approved, chemopreventive strategies for advanced fibrosis are lacking. By combining a cell-based system predicting liver disease progression and HCC risk and transcriptome analysis of fibrotic/cirrhotic patient liver tissues, we identified peroxiredoxin 2 (PRDX2) as a driver of disease progression and HCC risk. Here we aimed to uncover the role of PRDX2 in liver disease progression and HCC development.
Method: The role of PRDX2 in liver disease progression and HCC development was investigated by Prdx2 KO in a state-of-art CRIPSR/Cas9 mouse model for NASH-induced hepatocarcinogenesis and a cell-line-derived xenograft (CDX) mouse model. The mechanism of action was explored using RNA-Seq analyses of mouse liver tissues and validated by perturbation studies in human liver cell-based models.
Results: In patient liver tissues, PRDX2 expression is increased in tumor, suggesting a role of PRDX2 in hepatocarcinogenesis. In the CRIPSR/Cas9 NASH-induced HCC mouse model, KO of Prdx2 improved metabolic liver functions, robustly reduced liver steatosis through improvement of the AMPK/LXRα axis and significantly decreased HCC development. RNA-Seq analyses of mouse liver tissues confirmed that Prdx2 KO restored liver metabolic pathways (i.e cholesterol, fatty acid and bile acid metabolism), decreased inflammation (IL6/STAT3) and suppressed proliferative and pro-carcinogenic pathways (i.e EGFR/p38/MAPK, PI3 K/AKT/mTOR). Finally, PRDX2 loss-of-function studies in hepatoma cell-based models and a Huh7-CDX mouse model unraveled that PRDX2 mediates cancer cell proliferation, migration, invasion, and survival.
Conclusion: Our findings demonstrate an important functional role of PRDX2 in metabolic liver disease and hepatocarcinogenesis. Therefore, targeting PRDX2 may be a previously undiscovered therapeutic option for the treatment of metabolic liver diseases and to prevent NASH-induced HCC.

Loss of Actin-Binding LIM protein (ABLIM) plays a potential role in migratory cholangiocyte transformation

Lea Duwe[1], Patricia Munoz-Garrido[1], Juan Lafuente-Barquero[1], Colm O Rourke[1], Jens Marquardt[2], Jesper Andersen[1]. *[1]Biotech Research & Innovation Centre, Department of Health and Medical Sciences, University of Copenhagen, Copenhagen N, Denmark; [2]University Medical Center Schleswig-Holstein-Campus Lübeck, Department of Medicine I, Lübeck, Germany*
Email: jesper.andersen@bric.ku.dk

Background and aims: Actin cytoskeleton aberrations are a major aspect in migration and invasion during cancer development and progression. In bile ducts, rearrangements of the cytoskeleton undertake particularly important roles in polar cholangiocytes and their malignant transformation to invasive cholangiocarcinoma (CCA). Here, we have identified the Actin-Binding LIM protein (ABLIM) as a putative regulator of migratory cholangiocytes by modifying the actin cytoskeleton.
Method: We analyzed ABLIM expression in transcriptome data from 217 CCA patients and 143 surrounding livers (SL), followed by further investigation in TCGA-CHOL (36 CCA, 9 SL) and an additional dataset of microdissected iCCA and matched metastases (GSE40367). ABLIM expression and its localization was visualized in normal bile ducts and CCA tissues by ABLIM immunofluorescence and co-staining of beta-catenin (CTNNB1) for cell-cell adhesion junctions. The expression level was further validated in primary normal human cholangiocytes as well as patient-derived and established CCA cell lines by qRT-PCR, Western blot and immunofluorescence. For functional assays, we generated CRISPR/Cas9 knockouts in the immortalized normal cholangiocyte (H69) line and showed altered migratory phenotype by wound-closure assay.
Results: Transcriptomic analysis revealed a significant downregulation of ABLIM in CCA tissues compared to SL in our cohort ($p < 0.0001$, Mann-Whitney T-test) and TCGA-CHOL ($p = 0.0173$, Mann-Whitney T-test). In metastatic lesions, ABLIM expression levels tend to be lower compared to the primary CCA tumor site ($p = 0.067$, Paired T-test). Genetically mimicking the diminished expression of ABLIM by CRISPR/Cas9 knockout in H69 cholangiocytes revealed a more fibroblast-like morphology with increasing migratory phenotype ($p < 0.0001$, Mixed-effects analysis). In normal human bile ducts, ABLIM co-localizes with beta-catenin in adherens junctions, suggesting a significant role in cell-cell interactions and adhesion complex formation. We have confirmed the decreased expression ($p = 0.004$, Mann-Whitney T-test) and localization of ABLIM in our cell models for future experiments focusing on elucidating the mechanism of ABLIM in cell motility.
Conclusion: ABLIM is aberrantly expressed in CCA patients. Loss of ABLIM leads to an increased migratory phenotype of normal cholangiocytes in culture and may be important for tumor dissemination.

Modulation of the cholangiocarcinoma stem-like compartment by monounsaturated fatty acids

Giulia Lori[1], Chiara Raggi[1], Benedetta Piombanti[1], Mirella Pastore[1], Richell Booijink[2], Elisabetta Rovida[1], Jesper Andersen[3], Monika Lewinska[3], Paolo Montalto[4], Fabio Marra[1]. *[1]University of Florence, Firenze, Italy; [2]University of Twente, Enschede, Netherlands; [3]Copenhagen University, København, Denmark; [4]Azienda Usl Toscana centro - Firenze - Italy*
Email: fabio.marra@unifi.it

Background and aims: Identification of the molecular features of CCA may be helpful in designing new therapeutic approaches. Cancer cells are exposed to a metabolically challenging environment with scarce availability of nutrients, and alterations in lipid metabolism may affect the response of tumor cells to drugs. We hypothesize that fatty acids (FA) modulate the biology of CCA cells and the development of stemness features.

Method: CCA cells (HuCCT-1 OR CCLP1) were treated with monounsaturated FA (132mcM oleic or 100mcM palmitoleic acid). Responsiveness of CCA cells to cytotoxic drugs was tested with crystal violet staining. Epithelial-mesenchymal transition program, stem-like markers, ABC transporters and metabolic markers, were tested with real-time PCR. Self-renewal ability was tested with a colony formation assay. Cancer stem cell- (CSC)-enriched spheres were obtained growing cells in anchorage-independent conditions and selective medium. Five-year overall survival (OS) was analyzed in 104 patients with cholangiocarcinoma sub-grouped based on fatty acid synthase (FASN) expression. NSG mice were injected with spheres obtained from CCLP1 cells and treated for four weeks with the FASN inhibitor orlistat (240 mg/Kg).
Results: Exposure of CCA cell lines to FAs increased cell proliferation and activated growth and survival pathways, including AKT and ERK1/2. Exposure to FA before treatment with chemotherapeutic agents made CCA cells less sensitive to their toxic effects, and modulated the expression of ABC transporters involved in drug resistance. The colony forming ability of CCA cells was increased by FAs, and was associated with upregulation of genes controlling epithelial-mesenchymal transition and stemness. Expression levels of genes involved in lipid metabolism were upregulated in CSC-enriched spheres. In a series of CCA patients, the expression of FASN correlated with OS. FASN inhibition by orlistat decreased cell proliferation and CSC or EMT markers. In a xenograft model of CCA, tumor volume of mice treated with orlistat was significantly lower than in control mice.
Conclusion: Exposure of CCA cells to FA increases growth, invasiveness and resistance to antineoplastic drugs, and modulates stem-like features and self-renewal abilities. In the CCA stem-like subset, several key genes involved in FA synthesis and transport were upregulated, and FASN inhibition decreased cell proliferation and downregulated CSC markers. and FASN expression levels correlate with survival in patients with CCA. These data indicate that lipid metabolism could be a new potential target to affect CCA progression, especially in CSC subset.

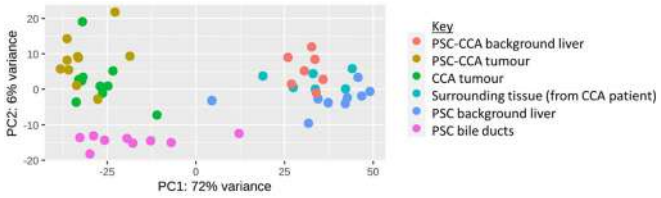
FRI568
Cyclophilin D knockout promotes cell death pathways in preventing HCC development in a streptozotocin-induced mouse model of diabetes-linked NASH
Winston Stauffer[1], Joseph Kuo[2], Daren Ure[3], Robert Foster[3], Philippe Gallay[1]. *[1]Scripps Research, Immunology and Microbiology, La Jolla, CA, United States; [2]Arena Pharmaceuticals, San Diego, United States; [3]Hepion Pharmaceuticals, Edison, NJ, United States*
Email: wstauffer@scripps.edu

Background and aims: Cyclophilins are a diverse family of peptidyl prolyl isomerases which promote protein folding and perform a variety of functions in the liver and other tissues. We have previously reported that the pan-cyclophilin inhibitor (CypI) compounds, CRV431, NV556 and Debio-025/Alisporivir, decreased the severity of non-alcoholic steatohepatitis (NASH) and hepatocellular carcinoma (HCC) in a streptozotocin (STZ)-induced HCC murine model. However, it is not known which cyclophilin family member (s) whose inhibition is causing this effect. Here, we report the effects of this HCC model in *Ppif*-/- mice lacking cyclophilin D (CypD), an important component of the mitochondrial permeability transition pore.
Method: 6-week-old male *Ppif*-/- and wild-type (WT) mice were injected with 200 mg/kg STZ to destroy pancreatic beta cells and induce a diabetic phenotype. Mice were nourished with chow with 21.1% fat, 41% sucrose, and 1.25% cholesterol by weight and high sugar solution (23.1 g/L fructose and 18.9 g/L glucose), which continued throughout. After 30 weeks on this diet, mice (n = 10 per group) were sacrificed. Body and liver weight were recorded. Livers were scored for HCC tumor burden. Histological sections of livers stained with H&E were scored for inflammation, steatosis, and ballooning. Liver sections were also stained with Sirius Red for examination of collagen fibrosis. RNA was extracted from frozen liver tissue for qRT-PCR analysis. PCR apoptosis arrays were purchased from Qiagen. Unpaired Student's t-tests were conducted with GraphPad Prism.
Results: Tumor burden scores were three times higher in WT mice compared to *Ppif*-/- mice, significant by Student's t-test ($p = 0.03$). Average tumor number was also significantly decreased with *Ppif*-/- mice, of which 8 out of 10 mice had no tumors, compared to just 3 of 10 in WT mice. A trend of reduced collagen deposition was also observed in livers of *Ppif*-/- mice relative to WT, but this was not significant. Inflammation, steatosis, and ballooning were similar between groups. Mechanistically, qPCR arrays for apoptosis genes revealed that the tumor suppressor *Fhit* was significantly elevated in *Ppif*-/- livers, while apoptosis inhibitor and oncogene *Birc5* was decreased.
Conclusion: Cyclophilin inhibition represents a promising avenue for the treatment of HCC development in mouse models. These data show for the first time that mice without CypD are significantly protected from HCC development, suggesting CypD inhibition is at least partly responsible for the previously established anti-tumor effects of CypI antagonist compounds. Molecular analyses suggest CypD inhibition may promote cell death pathways which act as tumor suppressors.

FRI569
Ribosomal protein encoding genes: potential drivers of primary sclerosing cholangitis associated cholangiocarcinoma
Megan Illingworth[1,2,3], Yoh Zen[3], Jeremy Nayagam[3], Deepak Joshi[3], Luca Urbani[1,2], Neil Youngson[1], Nigel Heaton[3], Shirin Elizabeth Khorsandi[1,2,3]. *[1]The roger williams institute of hepatology, foundation for liver research, London, United Kingdom; [2]King's college london, Faculty of life sciences and medicine, London, United Kingdom; [3]The institute of liver studies, kings college hospital, London, United Kingdom*
Email: megan.illingworth@kcl.ac.uk

Background and aims: Primary sclerosing cholangitis (PSC) patients have a 20% lifetime risk of cholangiocarcinoma (CCA), equating to a 250–1500 fold higher risk than that of the average population. Despite this, stratification of PSC patients at risk of CCA is currently not possible, with PSC patients who progress to CCA facing insufficient and unsuccessful treatment options and thus, a poor prognosis. The degree of similarity between CCA in PSC patients and non-PSC patients is unclear, and therefore the applicability of research into CCA targeted therapeutic for PSC associated CCA (PSC-CCA) patients remains unknown. This work aims to provide novel insight into gene expression in PSC-CCA to aid in the development of biomarkers for risk stratification and targeted therapeutics for this patient cohort. Additionally, this work aims to highlight novel differences in PSC-CCA and CCA not on a PSC background.
Method: Massive analysis of cDNA end (MACE) sequencing of formalin fixed and paraffin embedded tissue from CCA (n = 10), PSC-CCA (n = 10), PSC-CCA surrounding liver (n = 7), PSC bile ducts (n = 9), PSC surrounding liver (n = 9) and CCA adjacent liver (n = 6) was undertaken. Standard bioinformatic analysis was undertaken and differential gene expression determined.
Results: A total of 2567 genes were differentially expressed between PSC-CCA and CCA tumours. Ribosomal processes were significantly downregulated in PSC-CCA tumours when compared to both CCA tumours and PSC bile ducts and ion transport was significantly upregulated. Additionally, 849 of the 2567 genes were long non-coding RNAs, all of which were downregulated in CCA. Analysis of differential expression in the background liver identified 357 genes differentially expressed in PSC-CCA when compared to non-malignant PSC background livers. Apoptotic pathways were upregulated, and ribosomal processes downregulated in PSC-CCA background livers. Comparison of PSC-CCA tumours to PSC bile ducts identified 1717 differentially expressed genes. Ribosomal processes, the complement cascade and extracellular matrix organisation were all

downregulated in PSC-CCA tumours, while mitotic nuclear division and migration were upregulated in PSC-CCA tumours.



Conclusion: This transcriptomic dataset provides novel mechanistic insight into PSC-CCA and highlights a unique role for ribosomal proteins in PSC progression to CCA. The precise mechanism of this is currently unclear, warranting further investigation.

Email: margherita.correnti@gmail.com

Background and aims: Cholangiocarcinoma (CCA) is an extremely heterogeneous adenocarcinoma arising from malignant transformation of biliary tree. Spread of tumor cells in blood or lymphatic circulation as circulating tumor cells (CTCs) plays a major role in recurrence, metastasis and drug unresponsiveness. Assuming that CTCs are heterogeneous, we hypothesized the existence of CCA stem-like relapse-initiating cells. Consistent with cancer stem cells (CSC) hypothesis, stem-like CTCs might represent the potential source for cancer relapse and distant metastasis. The present study aimed to explore the evolution of stemness features during CCA progression.
Method: Enrichment of CCA stem-like subset by sphere culture (SPH) in established CCA cell line (HUCCT1) and primary CCA cell culture (MTCHC-01). Adherent monolayer (MON) cells as control. Set up of CCA orthotopic mouse model by intrahepatic injection of Luciferase-GFP transfected SPH and MON cells. Analysis of GFP+ disseminating tumor cells in target organs and bloodstream by FACS. Isolation of GFP+ tumor cells from primary and metastatic tumors by FACS sorting. Molecular characterization by qRT-PCR arrays focus on CSC, epithelial-to-mesenchymal transition (EMT), angiogenesis and drug resistance. Expression of CSC-like surface markers evaluated by FACS. Molecular data validation in human CCA samples.
Results: CCA SPH-primary tumor derived GFP+ cells showed CSC and EMT-related gene enrichment compared to MON-primary tumors. In accordance, SPH cells were responsible for enhanced tumor spread in secondary organs (lungs, spleen, peritoneum, mesenteric lymph nodes). CD45-/GFP+ tumor cells were detected in bloodstream of very few samples, suggesting that lymphatic circle is the preferential via to CCA dissemination. Notably, lung SPH-disseminated cells showed up-regulation of most of tested CSC, EMT, angiogenesis and drug resistance related genes compared to SPH-primary tumor cells. Despite some differences between cell lines and different mice, a panel of 35 genes commonly up-regulated was found in SPH-disseminated cells. Some of these genes were significantly up-regulated in 13 recurrent CCA tumor specimens compared to paired primary tumors.
Conclusion: These findings suggest that CCA SPH cells are enriched in stem-like disseminating tumor cells responsible for recurrence and metastasis formation. Moreover, our data indicate that a stemness-core is stably maintained during CCA-evolution starting from primary tumor initiation through disseminating process.

FRI571

miR34a-5p is a target of E2F2 transcription factor in MAFLD-related HCC

Maider Apodaka-Biguri[1], Francisco Gonzalez-Romero[1], Daniela Mestre Congregado[1], Igor Aurrekoetxea[1], Beatriz Gómez Santos[1], Igotz Delgado[1], Xabier Buque[1,2], Ane Nieva-Zuluaga[1], Mikel Ruiz de Gauna[1], Idoia Fernámdez-Puertas[1], Ainhoa Iglesias[3], Ana María Aransay[4,5], Juanjo Lozano[5,6], Cesar Augusto Martín[7,8], Irantzu Bernales[9], Ana Zubiaga[3], Patricia Aspichueta[1,2,5].

Email: patricia.aspichueta@ehu.eus

Background and aims: Metabolic associated fatty liver disease (MAFLD) is the most common cause of chronic liver disease in Western countries and a risk factor for hepatocellular carcinoma (HCC). E2F2 is a metabolic driver in MAFLD development and progression to HCC. A relationship between E2F2 and microRNAs (miRNAs) expression has been described in different pathologies, but not in liver disease. The aims here were: 1) to identify if liver E2F2 regulates miRNAs involved in MAFLD development and progression to HCC; 2) to investigate the metabolic relationship between E2F2 and the identified miRNAs in liver pathology.
Method: To induce MAFLD-related HCC, diethylnitrosamine (DEN) (25 mg/kg) was administrated to 14 day-old *E2f2*$^{-/-}$ and wild-type mice (WT), which were fed a high-fat diet (HFD) until sacrificed at 9 months. Chow diet-fed (CD) 3 month-old *E2f2*$^{-/-}$ and WT mice were also used. E2F2 was specifically upregulated in liver with adeno-associated viruses-serotype 8. miRNA sequencing and transcriptome analysis was performed in 9 month-old DEN-HFD WT and *E2f2*$^{-/-}$ mice livers. Selected differentially expressed liver miRNA candidates and genes were further validated by RT-qPCR analysis. Metabolic fluxes and lipid content were analyzed.
Results: The results obtained from miRNA sequencing and later validation by qPCR showed that in 9 month-old DEN-HFD *E2f2*$^{-/-}$ mice, resistant to MAFLD-related HCC, expression of miR-122-5p was upregulated while that of miR34a-5p, miR155-5p and miR146a-5p were downregulated. Among all, miR34a-5p was the only one decreased in CD-fed *E2f2*$^{-/-}$ while increased when E2F2 was specifically overexpressed in liver, as compared to the corresponding controls. The crosschecked analysis between the upregulated transcriptome genes underlying the resistance to develop MAFLD-related HCC in *E2f2*$^{-/-}$ mice and the miR34a-5p predicted interacting genes showed, among others, the enrichment in "Bile acid transport" and "lipid metabolism" biological pathways. Given the relevance of

cholestasis in liver disease, the expression and protein levels of HNF4, a critical regulator of bile metabolism, and of *Etnk2* and *Chpt1*, modulators of the synthesis of phosphatidylethanolamine (PE) and phosphatidylcholine (PC), required for bile secretion, were analyzed. The results showed higher levels of the regulators of bile metabolism in 9 month-old DEN-HFD *E2f2*$^{-/-}$ mice than in DEN-HFD WT mice together with increased PE and PC synthesis which led to higher PE, but not PC liver content, suggesting increased elimination into bile.
Conclusion: miR34a-5p is a target of E2F2 in MAFLD-related HCC. The results suggest that the E2F2-miR34a-5p axis induce inefficient bile secretion during MAFLD development and progression to HCC promoting development of the disease.

FRI572
TIA1 in fatty liver disease and hepatocellular carcinoma
Dobrochna Dolicka[1], Szabolcs Zahoran[2], Marta Sousa[1], Monika Gjorgjieva[1], Christine Sempoux[3], Margot Fournier[1], Christine Maeder[1], Martine Collart[2], Michelangelo Foti[1], Cyril Sobolewski[1,4]. *[1]University of Geneva, Faculty of Medicine, Department of Cell Physiology and Metabolism, Switzerland; [2]University of Geneva, Faculty of Medicine, Department of Microbiology and Molecular Medicine, Switzerland; [3]Lausanne University Hospital, University Insitute of Pathology, Switzerland; [4]Institute for Translational Research in Inflammation, Inserm, U1286, Faculty of Medicine, Pole Recherche, France*
Email: cyril.sobolewski@univ-lille.fr

Background and aims: Adenylate-Uridylate-rich elements binding proteins (AUBPs) contribute to the development of non-alcoholic fatty liver disease (NAFLD) and hepatocellular carcinoma (HCC) by regulating the expression of genes important for metabolic, inflammatory, and cancerous processes. This effect is mediated by their binding to target mRNAs, which elicits their recruitment into processing bodies (P-bodies) or stress granules (SGs), where mRNAs are degraded or kept translationally silent, respectively. Herein, we aimed at characterizing the role of TIA1, an AUBP with a poorly known function in the liver, in NAFLD and HCC.
Method: TIA1 expression was analyzed in datasets of mouse and human samples of NAFLD and HCC. The role of TIA1 *in vivo* was investigated in mice fed a methionine-choline-deficient (MCD) diet and in a liver-specific PTENKO mouse model of hepatic carcinogenesis, where TIA1 was silenced using AAV8 viruses. Finally, TIA1 functions were characterized *in vitro* in human hepatic cancer cells and a translatomic-based approach was used to identify the network of potential TIA1 targets.
Results: *In vitro* analyses indicate that TIA1 promotes cell proliferation and migration. *In vivo*, its silencing worsens NASH induced by the MCD diet and increases tumor number in LPTENKO mice. In agreement, the analysis of polysomal RNAs indicates that TIA1 regulates a whole network of tumor suppressors and oncogenes as well as genes related to lipid metabolism. Finally, TIA1 protein level is strongly downregulated in human HCC and represents an important marker of stress granules upon sorafenib treatment.
Conclusion: Our data emphasize TIA1's dual role in liver carcinogenesis and indicate that its downregulation and association with stress granules may represent potential diagnostic tools and/or therapeutic targets.

FRI573
Mitochondrial damage, revealed as key factor in cabozantinib efficacy against hepatocellular carcinoma, is potentiated by the BH3-mimetic navitoclax
Anna Tutusaus[1], Blanca Cucarull[1], Patricia Rider[1], Carlos Cuño[1], Pablo Garcia de Frutos[1], Loreto Boix[2,3], Montserrat Marí[1], Albert Morales[1,3]. *[1]IIBB-CSIC/IDIBAPS, Barcelona; [2]Unidad de Hepatología, Hospital Clinic, IDIBAPS, CIBEREHD, Barcelona, Barcelona, Spain; [3]Barcelona Clinic Liver Cancer (BCLC), Barcelona, Spain*
Email: amorales@clinic.cat

Background and aims: The mitochondrial damage induced by sorafenib and regorafenib plays an important antitumor role in hepatocellular carcinoma (HCC). Both Tyrosine Kinase Inhibitors (TKIs) induce mitochondrial dependent cell death that may be potentiated by specific BH3-mimetics, selective inhibitors of BCL-2 proteins. ABT-263, navitoclax, is a BCL-2 and BCL-xL inhibitor studied in clinical trials, such as with sorafenib in solid tumors (NCT02143401). Mitochondrial effects of cabozantinib have not been previously reported in HCC therapy.
Method: Hepatoma cell lines (HepG2, Hep3B, PLC5) were treated with cabozantinib and BH3-mimetics (ABT-263, navitoclax: BCL-2 and BCL-XL, ABT-199: BCL-2, A-1331852: BCL-xL). Western blots, qPCR and microarrays were performed. Mitochondrial functionality, caspase activation and induction of apoptosis were analyzed. Tumor growth was determined in a mouse syngeneic model after subcutaneous injection of Hepa1-6 cells treated with cabozantinib and/or ABT-263.
Results: Cabozantinib induced mitochondrial Reactive Oxygen Species (ROS) generation and cell death that was potentiated by BH3-mimetics in hepatoma cells. Cabozantinib induced loss of mitochondrial membrane potential, release of apoptogenic proteins and apoptotic cell death, particularly triggered after navitoclax addition. Sorafenib-resistant cells, which exhibited altered levels of BCL-2 proteins, were less sensitive to cabozantinib; effect that was suppressed by navitoclax co-administration. Moreover, the decreased tumor growth in an immunocompetent mice model induced by cabozantinib was potentiated in combination with navitoclax, promoting mitochondrial-dependent death as observed after tumor genetic and proteomic analysis.
Conclusion: Cabozantinib efficacy may be reduced following other TKIs treatments with mitochondrial impact, such as with sorafenib or regorafenib. In contrast, cabozantinib-induced cell death is potentiated in experimental HCC by mitochondrial directed drugs, such as navitoclax, providing a novel strategy for therapy.

Email: m.verstegen@erasmusmc.nl

Background and aims: Cholangiocarcinoma (CCA) is an aggressive hepatobiliary malignancy associated with high inter-patient heterogeneity. The de-ubiquitinase BRCA-1 associated protein-1 (BAP1) is a tumor suppressor gene found to be mutated in 16–32% of CCA tumors and is strongly associated with CCA progression. However, the biological role of BAP1 in CCA is not well understood. Here, we aimed to determine how mutations in BAP1 impact CCA tumor cell behavior in response to multiple programmed cell death stimuli.
Method: Organoids derived from CCA tumors (CCAOs, n = 3) and healthy donor liver (ICOs, n = 3). BAP1 mutations in CCAOs were mapped by genomic sequencing. BAP1 loss-of-function in ICOs ($ICO^{BAP1\text{-}KO}$) was introduced by CRISPR/Cas9 gene editing. Programmed cell death was induced in CCAOs and $ICO^{BAP1\text{-}KO}$ by exposure to TNF-α (T)/Smac mimic (S) (extrinsic apoptosis) or T/S/Z-VAD-FMK (Z) (necroptosis) or gemcitabine. Sensitivity to cell death induction was presented as a change in cell viability evaluated by an

ATP assay (CellTiterGlo). BAP1 protein and markers for apoptosis (cleaved caspase 3) and necroptosis (phosphorylated MLKL) were determined by immunostaining and immunoblotting.
Results: The three different CCAOs each harbor distinct BAP1 phenotypes: wild type ($CCAO^{WT}$), loss of heterozygosity ($CCAO^{LOH}$), and missense mutation combined with LOH ($CCAO^{Mut/LOH}$). Compared to PDO^{WT}, BAP1 protein expression could not be detected in $CCAO^{Mut/LOH}$ and was greatly declined in $CCAO^{LOH}$. The cell viability analysis and immunostaining showed that the resistance to either apoptotic or necroptotic induction was significantly increased in $CCAO^{Mut/LOH}$ ($p < 0.001$) compared to $CCAO^{WT}$. In contrast, $CCAO^{LOH}$ were more sensitive to cell death induction ($p < 0.001$). Similar increased sensitivity was also observed in $ICO^{BAP1\text{-}KO}$ compared to wild-type ICOs. Gemcitabine evoked extensive apoptosis in PDO^{WT} (IC50 0.06 μM), but the sensitivity of both PDO^{LOH} (IC50 0.34 μM) and $PDO^{Mut/LOH}$ (IC50 0.12 μM) was significantly lower. Likewise, $ICO^{BAP1\text{-}KO}$ displayed drastic resistance to gemcitabine compared to normal ICOs.
Conclusion: Mutations in the BAP1 gene causing loss of function, are associated with a lower sensitivity of CCAOs to extrinsic apoptosis, necroptosis, and gemcitabine cytotoxicity. Correction of the mutation in BAP1 using prime editing is currently effectuated to confirm the role of BAP1 in programmed cell death in CCA. Our findings reveal a promising strategy in CCA precision medicine by targeting BAP1 mutations.

Integrative clustering of multiple genomic data using organoid model with application to subtype analysis in intrahepatic cholangiocarcinoma

Hee Seung Lee[1], Dai Hoon Han[2], Kyung Joo Cho[3], Soo Been Park[3], Chanyang Kim[3], Galam Leem[1], Soon Sung Kwon[4], Chul Hoon Kim[4], Jung Hyun Jo[1], Hye Won Lee[1], Si Young Song[1], Jun Yong Park[1]. *[1]Yonsei University College of Medicine, Division of Gastroenterology, Department of Internal Medicine; [2]Yonsei University College of Medicine, Division of Hepatobiliary and Pancreatic Surgery, Department of Surgery; [3]Yonsei University College of Medicine; [4]Yonsei University College of Medicine, Department of Pharmacology*
Email: drpjy@yuhs.ac

Background and aims: Intrahepatic cholangiocarcinoma (ICC) has increased rapidly, and the 5-year survival rate is less than 20%. As the genomic analysis technology has been advanced, subgrouping is possible at the histological or molecular level in ICC. But, there was no well-representative model for subtypes of ICC to study developmental differences, carcinogenesis, and personalized drug response. We aimed to develop ICC organoid models that reflect phenotypical, molecular and genetic properties and performed integrative clustering of multiple genomic data using organoid models with subtype analysis.
Method: We enrolled a total of 16 patients who were pathologically diagnosed with cholangiocarcinoma. We made ICC organoid following the previous organoid culture protocol in nature protocol. In accordance with histological characteristics, S100P, N-cadherin, and CD56 expression, the ICC patients were subclassified into small duct type and large duct type. Immunofluorescence (IF), whole exome sequencing, and transcriptomic analysis were performed to characterize and investigate all cancer tissues and matched ICC organoids.
Results: We successfully established ICC organoids within a month. The morphology of ICC organoid was similar to matched primary cancer. Organoid derived xenograft also showed similar phenotype in H&E stain. IF stains showed the expression of cholangiocyte marker (CK19 and Sox9) but negative expression in liver cell marker (AFP and Albumin). The cancer immunotherapy marker, Programmed death-ligand 1 expression between the organoid and tumor tissue was similar. Large and small duct type organoids showed their typical histologic phenotype and stain. ICC organoids shared somatic mutations and showed high concordance of somatic mutation between primary tumor and organoids. Through the unsupervised PCA clustering showed the separation of each type of ICC. Using the differential gene expression between types, *KRAS* signaling pathway, *TGFβ* and *ERBB2* pathway were significantly enriched in large duct type compared to small duct type ($p < 0.05$). GSEA demonstrated that cholangiocarcinoma class2 signature by Andersen et al. was significantly enriched with LD type (enrichment score = 2.19, $p < 0.001$). Protein-protein interaction network analysis indicated that the significant hub proteins were ZNF217 (Odds ratio 4.96, $P = 0.0105$).
Conclusion: We succeeded in prospective modeling of histological subtype specification in patient-derived ICC organoids. Identification of type specific targetable pathway was possible through gene expression profile of ICC organoids.

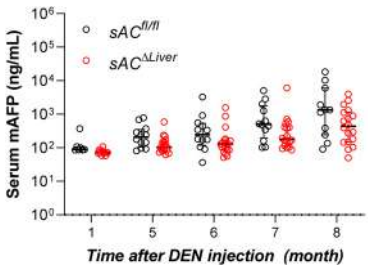
Role of soluble adenylyl cyclase in the formation and growth of liver tumours

Jung-Chin Chang[1,2], Suzanne Duijst[1], Simei Go[1], Dagmar Tolenaars[1], Rachel Thomas[2], Alain de Bruin[2], Arthur Verhoeven[1], Ronald Oude-Elferink[1]. *[1]Amsterdam University Medical Centers, Tytgat Institute for Liver and Intestinal Research, Amsterdam, Netherlands; [2]Utrecht University, Department of Biomolecular Health Sciences, Utrecht, Netherlands*
Email: j.chang1@uu.nl

Background and aims: Soluble adenylyl cyclase (*ADCY10*, sAC) mediates the cAMP signaling in the cytoplasm, mitochondria, and the nucleus. sAC is activated by metabolic signals (Ca^{2+}, ATP, and bicarbonate) and was recently shown to regulate AMP-activated kinase (AMPK) and transcriptional factor TAZ (WW domain-containing transcription regulator protein 1). The YAP (Yes-associated protein 1)/TAZ signaling pathway regulates the liver size, promotes liver regeneration, and is hyper-activated in liver cancers. Using human liver hepatoma cells HepG2, we recently showed that sAC-cAMP-Epac1 (exchange proteins activated by cyclic AMP 1) signaling regulates mitochondrial Complex I activity and is a metabolic switch between glycolysis and oxidative phosphorylation (PMID: 33412125). We observed that inhibition of sAC activity promotes a Warburg-like metabolic phenotype. Therefore, we hypothesized that reduced sAC activity could promote hepatic tumorigenesis.
Method: Liver carcinogenesis was evaluated in hepatocyte-specific sAC knockout mice ($Adcy10^{fl/fl}$ × *Alb-Cre*) and littermate controls ($Adcy10^{fl/fl}$) following a single dose of 25 mg/kg diethylnitrosamine (DEN) injection at 3–4 weeks of age. Tumor formation was monitored by plasma α-fetoprotein (Afp). Tumor burden was evaluated by liver-to-body weight index. Histologic grading was performed on hematoxylin-eosin stained, formalin-fixed tissues. HepG2 cells were used for the in vitro mechanistic study. Cell proliferation was evaluated by dsDNA quantification; pharmacological agents and intermediate metabolites of lipid and nucleotide synthesis were used to dissect the underlying mechanisms.
Results: Contrary to our expectation, hepatocyte-specific sAC deletion delayed the rise of plasma Afp and reduced the tumor burden in the liver. Preliminary results from histopathology analysis did not suggest a strong correlation between liver-specific sAC deletion and the histological grading of the liver tumors. The in vitro mechanistic study revealed that the suppression of sAC-cAMP-Epac1 signaling activates AMPK and inhibits proliferation of HepG2 cells, which could not be rescued by supplementing intermediates of lipid synthesis or nucleotide. Consistent with AMPK being an established regulator of YAP, we found that sAC inhibition suppressed YAP nuclear translocation.



Two-way ANOVA

Source of Variation	% of total variation	P value
Interaction	0.5276	0.90
Time after DEN injeciton	28.55	<0.001
Liver-specific sAC KO	6.943	<0.001

Conclusion: Hepatocyte-specific sAC deletion delays DEN-induced liver carcinogenesis in mice and reduced the overall tumor burden. Pharmacological inhibition of the sAC-cAMP-Epac1 signaling suppresses the growth of human liver cancer cells. The anti-tumor effect of sAC inhibition is likely mediated by the AMPK-dependent suppression of YAP signaling.

A targeted screen identifies Dmbt1 as an oncogene in cholangiocarcinoma

Pooya Shokoohi[1], Saumya Manmadhan[1], Christian Lechler[1], Birgit Kohnke-Ertel[1], Carolin Mogler[2], Thomas Engleitner[3,4], Rupert Öllinger[3,4], Roland Rad[1,3,4], Roland M Schmid[1], Ursula Ehmer[1]. *[1]Klinikum rechts der Isar der Technischen Universität München, Internal Medicine II, München, Germany; [2]Klinikum rechts der Isar der Technischen Universität München, Institute of Pathology and Unit of Comparative Experimental Pathology, München, Germany; [3]Technische Universität München, Institute of Molecular Oncology and Functional Genomics, School of Medicine, München, Germany; [4]Technische Universität München, Center for Translational Cancer Research (TranslaTUM), School of Medicine, München, Germany*
Email: ursula.ehmer@tum.de

Background and aims: Activation of RAS signaling is a common event in human cholangiocarcinoma (CCA). With direct targeting of Ras signaling in its infancy, identification of relevant pathways and genes in RAS-activated cholangiocarcinoma is a prerequisite to the development of novel therapies. To model RAS-activated cholangiocarcinoma, we generated the RPK mouse model that combines liver-specific expression of oncogenic *Kras* with genetic inactivation of the tumor suppressors *Rb* and p53. Upon Cre-mediated gene recombination, adult mice developed liver tumors resembling human intrahepatic CCA. To identify potential target genes in the context of activated RAS signaling we employed a targeted screening approach.
Method: Liver tumors from $Rb^{lox/lox}$; $p53^{lox/lox}$; $Kras^{LSL\text{-}G12D/+}$ (*RPK*) mice and liver tissue of age-matched control mice were microdissected and analyzed for RNA and protein expression. A curated subset of top upregulated genes in mRNA microarray analysis of RPK liver tumors were chosen for further investigation. Primary cells lines from RPK mice were transfected with lentiviral shRNA or sgRNA constructs to induce gene knock-down or CRISPR/Cas9-mediated gene mutation, respectively. Cells were analyzed for proliferation and clonogenic assay, followed by RNAseq, GSEA, and cell cycle analysis of cells mutated for the candidate gene *Dmbt*1.
Results: Microarray analysis showed several highly upregulated genes in RPK tumors in comparison to controls. shRNA constructs targeted against top upregulated genes showed a striking decrease in cell proliferation and clonogenic capacity with constructs targeting *Dmbt1*. RPK cells mutant for *Dmbt1* showed an enrichment of gene sets for E2F and G2/M checkpoint activation. Further analysis revealed that reduced proliferation upon inactivation of DMBT1 is associated with a G2/M cell cycle arrest.
Conclusion: Activation of RAS signaling is a common change in human CCA. In our screen, we identified *Dmbt1* as a potent oncogene in a model of *Ras*-mutant cholangiocarcinoma. While DMBT1 has been described as a tumor suppressor in other cancers by interacting with the immune system, we were able to identify a novel cell-autonomous oncogenic role of DMBT1 in CCA. Our results show that DMBT1 is essential for cell cycle progression and proliferation in RPK cancer cells. *DMBT1* expression is upregulated in a large subset of human CCA and its potential as a therapeutic target are currently under investigation.

FRI578

ACSL4-dependent ferroptosis promotes HCC progression

Julia Piche[1], Antje Mohs[1], Stephanie Erschfeld[1], Christian Trautwein[1], Tobias Otto[1]. *[1]Uniklinik RWTH Aachen, Aachen, Germany*
Email: jpiche@ukaachen.de

Background and aims: In industrialized countries the prevalence of non-alcoholic fatty liver disease, ranging from steatosis to non-alcoholic steatohepatitis (NASH), is increasing. Mechanisms triggering disease progression towards cirrhosis and hepatocellular carcinoma (HCC) are only incompletely understood. A newly discovered mode of cell death, ferroptosis, is triggered by accumulation of lipid peroxides and is iron-dependent. According to *in vitro* studies, acyl-CoA synthetase long-chain family member 4 (ACSL4) is an essential enzyme for ferroptosis. Interestingly, ACSL4 expression was shown to be upregulated in HCC tissue indicating that ferroptosis might play a role in HCC pathophysiology. Here, we aimed to investigate the relevance of ferroptosis for disease progression using hepatocyte-specific ACSL4 inhibition in experimental HCC models.
Method: We used a well-established fibrosis-driven HCC model. Tumor formation was induced by injecting the carcinogen diethylnitrosamine (DEN), followed by weekly injections of carbon tetrachloride (CCl_4). As a second model we applied the Streptozocin/HFD model. Wild-type (WT) and hepatocyte-specific ACSL4 knockout ($ACSL4^{\Delta hepa}$) mice were included to investigate the role of ferroptosis for cancer development.
Results: Our analysis in both models demonstrated that ACSL4-dependent ferroptosis is not involved in HCC initiation, but important for tumor progression. After DEN-CCl_4 treatment, serum transaminase levels were increased, but without significant differences upon ACSL4 deletion. Interestingly, the number of tumors, as well as overall tumor burden were significantly reduced in $ACSL4^{\Delta hepa}$ mice compared to WT mice. This was accompanied by significantly decreased liver-to-body-weight-ratio in $ACSL4^{\Delta hepa}$ mice. However, immune cell infiltration was not altered. Furthermore, ACSL4 deletion caused reduced proliferation in the liver and diminished tumor-promoting fibrosis.
Conclusion: Our results demonstrate that ACSL4-dependent ferroptosis promotes tumor progression by enhancing tumor-promoting fibrosis. Therefore, inhibition of ferroptosis or key molecules regulating cell death represents a possible therapeutic treatment for human HCC.

FRI579

Identification of risk factors for HBV-derived HCC using HLA-DPB1 genotype and HBV peptides for genome medicine

Masaya Sugiyama[1], Nao Nishida[1], Katsushi Tokunaga[1], Mizokami Masashi[1]. *[1]National Center for Global Health and Medicine, Japan*
Email: msugiyama@hosp.ncgm.go.jp

Background and aims: Hepatocellular carcinoma (HCC), caused by hepatitis B virus (HBV) infection, is a major problem worldwide. However, no biomarkers for early diagnosis have been discovered so far. In the present study, we focused on the genetic factors associated with HBV-derived HCC. To discover the genetic factors, we analysed the combined genomes of both humans and HBV.
Method: The genome-wide SNPs array and Luminex were applied to 2, 996 individuals (408 chronic hepatitis B (CHB) patients, 307 HCC patients with HBV and 2, 281 healthy volunteers (HVs)) from 10 hospitals. The obtained SNPs data were filled by imputation: the HBV genome was extracted from sera of CHB or HCC patients and prepared

for next generation sequencing (NGS). All sequence reads were converted into amino acid (AA) sequences to assess the effect of HBV mutations on replication and antigen expression in vitro.
Results: HLA-DPB1*02:01 allele was associated with protection against HCC development ($p < 4.53 \times 10^{-9}$, OR = 0.53). We then analysed the whole HBV genome of patients carrying the HLA-DPB1*02:01 allele. HLA-DPB1*02:01 homozygous patients were divided into HCC and non-HCC groups, matched for age, sex and HBV genotype. HCC with HLA-DPB1*02:01 The proportion of S166 in CHB and HCC was 51.5% and 0%, respectively ($p < 0.05$). In contrast, the proportion of L166 was 34.3% in CHB and 99.4% in HCC ($p < 0.05$). This variation was confirmed using a validation sample set ($p < 0.02$, OR = 18.2). Next, we prepared HLA-DPB1*05:01 homozygous patients and examined the AA variations of HBV protein. We then detected that the K130M and V131I mutations were associated with the HCC group ($p < 0.05$, OR = 8.8); the OR value of the 05:01 population was stronger than that of all patients with HCC (OR = 4.1). Interestingly, mutations in K130M and V131I (nt A1762T and T1764A) were strongly associated with the HLA-DPB1*05:01 homozygous population.
Conclusion: We have identified genetic factors, both host and viral, that are associated with clinical outcome. As only a small proportion of CHB patients develop HCC, these risk factors may be useful in optimising clinical diagnosis and follow-up time. The finding that certain combinations of HLA-DPB1 alleles and viral mutations are associated with a higher risk of developing HCC is novel, and this study is a proof-of-concept study to use genomic data from hepatitis B patients to predict prognosis.

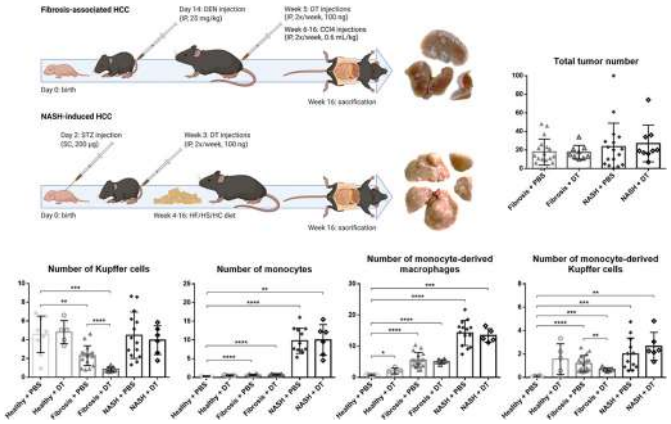
Early Kupffer cell depletion does not affect hepatocellular carcinoma progression in mice
Bart Van Derborght[1,2], Kevin De Muynck[1,2], Charlotte Scott[3,4], Alain Beschin[5,6], Martin Guilliams[3,7], Hans Van Vlierberghe[1,8], Lindsey Devisscher[2]. *[1]Ghent University, Internal Medicine and Pediatrics (Liver Research Center Ghent; Hepatology Research Unit), Ghent, Belgium; [2]Ghent University, Basic And Applied Medical Sciences (Liver Research Center Ghent; Gut-Liver Immunopharmacology Unit), Ghent, Belgium; [3]Ghent University, Biomedical Molecular Biology, Ghent, Belgium; [4]VIB-UGent Center for Inflammation Research, Laboratory of Myeloid Cell Biology in Tissue Damage and Inflammation, Ghent, Belgium; [5]Vrije Universiteit Brussel, Laboratory of Cellular and Molecular Immunology, Brussels, Belgium; [6]Vrije Universiteit Brussel, Myeloid Cell Immunology Laboratory, Brussels, Belgium; [7]VIB-UGent Center for Inflammation Research, Laboratory of Myeloid Cell Biology in Tissue Homeostasis and Regeneration, Ghent, Belgium; [8]Ghent University Hospital, Gastroenterology and Hepatology, Ghent, Belgium*
Email: lindsey.devisscher@ugent.be

Background and aims: Hepatocellular carcinoma (HCC) represents the majority of primary liver cancer cases. Its aggressive disease behavior and poor prognosis substantiate the critical need to urgently address the lack of effective HCC treatment options. HCC usually occurs in a background of chronic liver disease (CLD), characterized by chronic hepatic inflammation and fibrosis, in which Kupffer cells (KCs), resident liver macrophages, have been proposed to play a role. However, the role of KCs in HCC initiation and progression remains unknown.
Method: In order to investigate the role of KCs in HCC initiation, transgenic Clec4F-diphtheria toxin receptor mice were used. Diphteria toxin (DT)-mediated KC depletion was performed prior to the introduction of chronic liver damage in both a fibrosis-associated and a non-alcoholic steatohepatitis (NASH)-induced HCC mouse model.
Results: At the time of sacrifice, macroscopic hepatic tumors were present in approximately 100% of the cases in both HCC mouse models without differences between groups. Flow cytometric analysis of the liver tissue showed depletion of KCs and infiltration of monocytes and monocyte-derived macrophages (MoMfs), confirming previous literature, and the presence of monocyte-derived KCs (MoKCs) in both models. DT-mediated KC ablation at the initiation stage of HCC induction resulted in a decreased number of KCs and MoKCs at end-stage disease in fibrosis-associated HCC but not in the model of NASH-induced HCC. This altered hepatic macrophage pool composition was however not associated with significant changes in tumor burden, HCC markers or inflammatory, angiogenic and fibrotic components of the tumor microenvironment (TME). In NASH-induced HCC, depletion of the KCs resulted in decreased hepatic expression of alpha-smooth muscle actin and vascular endothelial growth factor, however, no differences were detected on histology for tumor burden, steatosis, inflammation and fibrosis, substantiating the limited effect of KC depletion in the initiation phase of HCC pathogenesis.



Conclusion: Despite the tolerogenic function of KCs in homeostasis and the reported role as early activators during inflammation, depletion of KCs during the initiation phase of HCC pathogenesis only has minor effects on the TME and does not affect disease severity or progression in HCC mouse models with different underlying backgrounds.

FRI581
RELB activation drives tumour aggressiveness and predicts prognosis in hepatocellular carcinoma

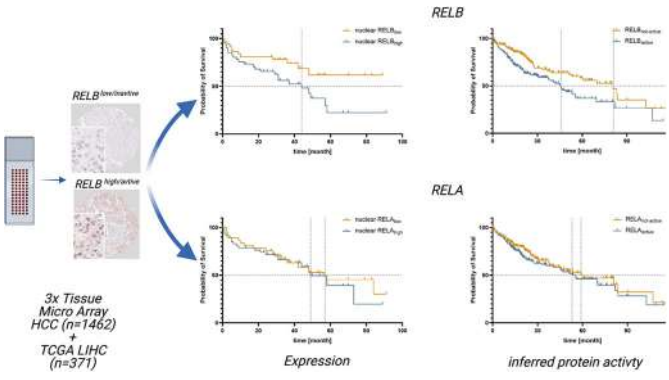
Email: bruno.koehler@nct-heidelberg.de

Background and aims: Hepatocellular carcinoma (HCC) is the fourth leading cause of cancer death worldwide with increasing incidence rates. Better molecular understanding to identify prognosticators and tailored therapy are urgently needed. The canonical nuclear factor kappa B (NF-kappaB) signaling branch has been shown to play a role in chronic liver disease and hepatocarcinogenesis. However, the role of the non-canonical part with its key transcription factor RELB remains unclear.
Method: Three tissue microarrays (TMA) were immunohistochemically (IHC) stained for NF-kappaB signaling components including RELB and scored for intensity. The TCGA-LIHC cohort served as a third validation set, to comparatively analyze mRNA expression and protein activity as inferred by the VIPER algorithm. Patients were grouped in $RELB^{high}$ and $RELB^{low}$ (expression) and $RELB^{active}$ and $RELB^{inactive}$ (inferred activity). Kaplan-Meier method and Cox proportional hazard models were used for overall survival (OS) analysis. Gene Set Enrichment Analysis (GSEA) was performed on differentially expressed (DE) genes between $RELB^{active}$ and $RELB^{inactive}$ cases.
Results: A total of 1462 (TMA) and 371 (TCGA-LIHC) cases were included. RELB was nuclear enriched in HCC compared to control tissue (IHC score 1.2 vs 6.3, $p \leq 0.0001$). The increase of RELB activity correlated with tumor grading (control vs. G1: p = n.s.; control vs. G2: p = 0.0193; control vs. G3/G4: p = 0.0004). Patients with a high nuclear RELB expression score had poorer overall survival (OS) compared to those with low RELB expression score (p = 0.0333; HR 2.129; 95% CI = 1.087 to 4.17). In the TCGA-LIHC cohort, $RELB^{active}$ cases showed worse OS compared to $RELB^{inactive}$ ones (46 vs 81 months; HR 1.69; 95%CI = 1.20 to 2.39; p = 0.003). Through GSEA of DE genes and clustering of functional terms, $RELB^{active}$ tumors showed a significant enrichment of pathways related to cell proliferation, differentiation and metabolic disregulation.



Conclusion: Non-canonical NF-kappaB signaling drives hepatocarcinogenesis by inducing proliferation and tumor aggressiveness. Activation of its key transcription factor RELB is a prognostic factor for HCC, identifying patients with poor overall survival.

FRI582

An aggressive subgroup of CTNNB1-mutated hepatocellular carcinomas with STEM-cell phenotype and immune tolerance

Lise Desquilles[1], Romain Désert[1], Valérie Monbet[2], Joyce Madison Giacofci[2], Luis Cano[1], Clémence Landreau[1], Natalia Nieto[3], Anne Corlu[1], Christelle Reynès[4], Orlando Musso[1].

Email: lise.desquilles@gmail.com

Background and aims: Hepatocellular carcinoma (HCC) is the 3rd cause of cancer-related death worldwide and its heterogeneity impacts patient management. Based on transcriptomic data from over 1300 human HCCs, we described two major dimensions explaining HCC heterogeneity. First, the inverse relationship between proliferation and differentiation. Second, the degree of preservation of periportal and perivenous metabolic zonation. This bidimensional approach revealed four subclasses: *PERIPORTAL, PERIVENOUS (PV), EXTRACELLULAR MATRIX* and *STEM CELL*, across a continuum of increasing aggressiveness. The aim of this work was to better understand the mechanisms governing phenotypic diversity within PV-type HCCs, which are characterized by beta-catenin (*CTNNB1*) gene mutations.
Method: To classify HCCs, we applied Curve Clustering to a transcriptomic training set (n = 264) and identified two subgroups of PV-type HCCs with differential aggressiveness: *BAD-PV* and *GOOD-PV*. By PLS-DA, we found a 44-gene signature sorting out *BAD-PV* from *GOOD-PV*, which was validated in three unrelated datasets (ICGC, n = 202; GSE14520[1], n = 242; Désert's meta-dataset[2], n = 1133). We integrated these sets with a 15-time point series of HepaRG phenotypic plasticity[3,4]; and 2 datasets of mouse liver development (GSE87795[5]; GSE90047[6]). To investigate the mechanisms driving aggressiveness in PV-type HCCs, we generated functional gene networks by Weighted Gene Correlation Analysis (WGCNA); assessed HCC mutations in the TCGA and ICGC datasets; gene methylation in TCGA and deconvoluted immune cell populations with the Immunophenoscore and Cibersort algorithms in TCGA and GSE14520 datasets. Finally, we compared *BAD-PV* and *GOOD-PV* cytoarchitectural features in the digital TCGA slide collection (n = 61).
Results: In *BAD-PV* HCCs, mRNA transcriptomes matched HepaRG-derived cancer stem/progenitor cells and early stages of mouse liver development; WGCNA identified 3 networks of co-expressed genes related to stemness; DNA methylation analysis revealed 468 key hypo-methylated genes involved in cell proliferation and development. Although *CTNNB1*-mutated HCCs show no inflammation and don't respond to immune checkpoint inhibitors, *BAD-PV* had increased Treg lymphocytes, CD4T memory cells and myeloid dendritic cells, high levels of inflammatory molecules, negative immune checkpoints (*PD1; PDL1; CTLA4*) and markers of plasmacytoid dendritic cells. Similarly, histological analysis showed that *BAD-PV* had higher Edmondson-Steiner's ($p = 1.3e^{-10}$) and inflammation ($p = 3.5e^{-5}$) scores, with higher density of plasma cells ($p = 1.7e^{-7}$).
Conclusion: We identified a subgroup of highly aggressive *CTNNB1*-mutated HCCs with stem cell phenotype and immune tolerance features.

FRI583

Single cell RNAsequencing derived signature of hepatocyte de-differentiation predicts development of hepatocellular carcinoma in patients with liver cirrhosis

Mikhail Gromak[1], Hendrik Luxenburger[1], Tobias Böttler[1], Robert Thimme[1], Maike Hofmann[1], Natascha Röhlen[1]. [1]*University Medical Center Freiburg, Department of Medicine II, Freiburg, Germany*
Email: natascha.roehlen@uniklinik-freiburg.de

Background and aims: Hepatocellular carcinoma (HCC) represents a major complication of liver cirrhosis, occurring at a rate of 1–5% per year. Hepatocytes are believed to represent the origin of malignant transformation in HCC. However, the molecular events determining HCC risk are poorly defined accounting for absence of chemopreventive strategies. Frequent overexpression of immature liver progenitor cell or bile duct markers in HCC suggests de-differentiation of hepatocytes to be involved in its pathogenesis.
Method: Applying single cell RNAsequencing (scRNAseq) derived marker genes of mature hepatocytes, cholangiocytes and progenitor cells we aimed to characterize hepatocyte de-differentiation in liver transcriptome data from different cohorts of patients with chronic liver disease (Geo database: GSE33814, GSE15654, GSE10140). To assess whether hepatocyte-dedifferentiation can be investigated non-invasively, serum levels of individual markers were determined by enzyme-linked immunosorbent assay (ELISA) in a cohort of patients with liver cirrhosis with (n = 31) or without (n = 74) HCC development.
Results: Stratification of healthy liver scRNAseq data derived cell cluster marker genes (GSE124395) was used to generate a transcriptomic signature of mature hepatocytes and bile duct-like cells. Gene set enrichment analysis (GSEA) of these scRNAseq derived signatures in liver tissue microarray data of patients with non-alcoholic steatohepatitis (NASH) and Controls suggested enrichment of bile duct-like cells in chronically diseased livers (GSE33814, n = 44, FDR < 0.001). Similar upregulation of progenitor markers on the single cell level in hepatocytes from cirrhotic livers (GSE136103, n = 5 donors) further support this enrichment to occur via de-differentiation of hepatocytes during chronic liver injury. Interestingly, transcriptomic signatures of hepatocyte de-differentiation strongly correlated with risk of HCC development. Indeed, cirrhotic livers of patients with no HCC development within a follow-up period of >10 years showed enrichment of mature hepatocyte marker genes (GSE15654, n = 216, FDR < 0.001), while immature bile duct marker genes were strongly enriched in cirrhotic livers of patients with HCC *de novo* development or recurrence (GSE10140, n = 82, FDR < 0.001). Among the top markers of hepatocyte de-differentiation, we could identify MCAM as a serum biomarker of HCC development (HCC vs. liver cirrhosis = 1064 vs. 413 ng/ml, p = 0.01).
Conclusion: Our results indicate hepatocyte de-differentiation to occur during chronic liver disease progression and to serve as a putative risk factor for HCC development. Detectable serum levels of multiple markers of our scRNAseq derived signature raise the outlook for non-invasive assessment of hepatocyte de-differentiation and its associated clinical HCC risk.

Detection of cholangiocarcinoma in mice with protease activity probes

Jesse Kirkpatrick[1,2], Pinzhu Huang[3], Yury Popov[3], Sangeeta Bhatia[1,2,4]. [1]*Massachusetts Institute of Technology, Harvard-MIT Division of Health Sciences and Technology, Cambridge, United States;* [2]*Koch Institute For Integrative Cancer Research, Cambridge, United States;* [3]*Beth Israel Deaconess Medical Center and Harvard Medical School, Division of Gastroenterology and Hepatology, Boston, United States;* [4]*Howard Hughes Medical Institute, Cambridge, United States*
Email: jessekirk11@gmail.com

Background and aims: Patients with primary sclerosing cholangitis (PSC) are at a 400-fold increased risk of cholangiocarcinoma (CCA), and are thus subjected to regular screening with magnetic resonance cholangiopancreatography (MRCP) (Lazaridis *et. al.* 2016). Unfortunately, MRCP findings are nonspecific for CCA in the setting of biliary fibrosis, and even invasive endoscopic retrograde cholangiopancreatography with brush cytology and fluorescence *in situ* hybridization often fails to yield a definitive diagnosis (Barr Fritcher *et. al.* 2015). We have previously developed a novel class of diagnostic agents, activatable zymography probes (AZPs), analogous to immunofluorescence probes for protease activity, that can be used to visualize tumour-associated protease dysregulation *in situ* and *in vivo* (Soleimany and Kirkpatrick *et. al.* 2021). Upon proteolytic cleavage, these probes electrostatically bind to positively charged tissue domains, thereby tagging and labelling proteolytically active cells (Fig. 1A). Because matrix metalloproteases (MMPs), including MMP7 (Leelawat *et. al.* 2010) and MMP1 (Metzger *et. al.* 2012) have been shown to be dysregulated in CCA, we aimed to develop MMP-sensitive AZPs to enable the differential diagnosis of CCA and benign biliary fibrosis.
Method: We induced CCA tumour formation in *Mdr2*-/- mice via hydrodynamic injection of sleeping beauty transposon-transposase plasmids encoding for *Akt* and *Yap1* (Fig. 1B), and harvested livers of tumour-bearing and untreated *Mdr2*-/- mice 5 weeks later. We then synthesized a panel of nine AZPs with peptide sequences designed to be cleaved by MMPs and applied them to fresh frozen liver tissue sections from CCA and *Mdr2*-/- mice.
Results: We found that four AZPs, most notably AZP6, specifically bound to CCA tumours, and that this binding was significantly abrogated by pre-treatment with broad-spectrum protease inhibitors ($p = 0.00015$ for AZP6) (Fig. 1C, D). Furthermore, these four AZPs bound significantly less efficiently to fibrotic portal tracts of *Mdr2*-/- mice ($p = 4.9 \times 10^{-8}$ for AZP6) (Fig. 1C, D). Finally, we incubated a panel of recombinant MMPs, including the CCA-associated MMP1, with a quenched fluorescent version of the AZP6 peptide substrate and found it be efficiently cleaved (Fig. 1E).

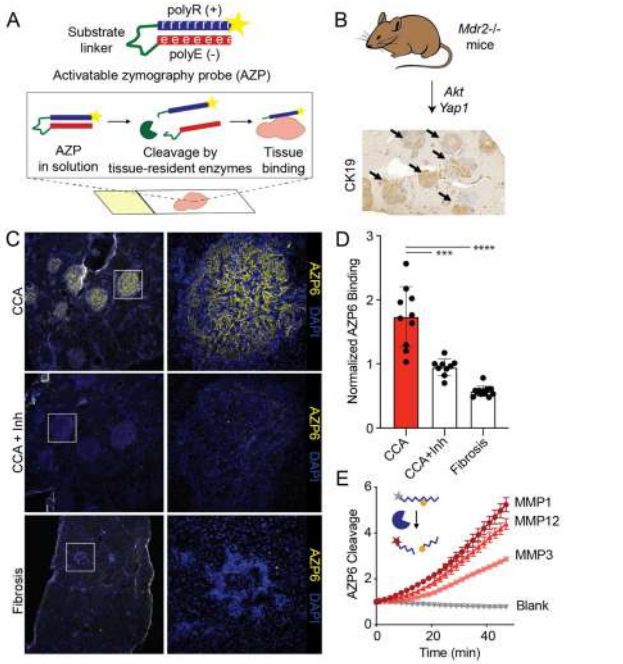

Figure 1: Activatable zymography probes specifically label CCA tumours. A) Principle of AZP staining method. B) Schematic of tumour induction protocol. Mice were sacrificed 5 weeks after hydrodynamic administration of *Akt* and *Yap1* plasmids. Immunohistochemical staining of tumour-bearing livers for CK19 is shown below. C) Fluorescence microscopy images of AZP6-treated liver tissue sections from tumour-bearing ("CCA") mice, without (top) or with (middle) broad-spectrum protease inhibitors ("Inh"), or *Mdr2*-/- ("Fibrosis") mice (bottom). D) Quantification of AZP6 staining. Each point represents one tumour ("CCA" and "CCA + Inh") or one portal tract ("Fibrosis"). ***, $p < 0.001$; ****, $p < 0.0001$ by two-tailed t-test. E) A quenched fluorescent version of the AZP6 peptide substrate was incubated with MMP1, 3, or 12 and fluorescence fold change was measured by fluorimetry.

Conclusion: MMP dysregulation in a mouse model of CCA is detected by AZPs, enabling differentiation of benign and malignant biliary disease *in situ*. Our next steps will be to adapt these probes for *in vivo* administration and assess their ability to noninvasively distinguish biliary malignancy from fibrosis in mouse models of CCA.

Critical investigation on the usability of hepatoma cell lines HepG2 und Huh7 as models for the metabolic representation of resectable hepatocellular carcinoma

Andrea Scheffschick[1,2], Gerda Schicht[1,2], Lena Seidemann[1,2], Sebastian Sperling[3], Julia Nerusch[1,2], Natalie Herzog[4], Jonas Babel[2], Jan Küpper[4], Daniel Seehofer[1,2,3], Georg Damm[1,2,3]. *[1]Saxonian Incubator of Clinical Translation (SIKT), Leipzig, Germany; [2]University Hospital, Department of Hepatobiliary Surgery and Visceral Transplantation, Leipzig, Germany; [3]Charité University Medicine Berlin, Department of General, Visceral and Transplantation Surgery, Berlin, Germany; [4]Brandenburg University of Technology Cottbus-Senftenberg, Faculty of Science, Senftenberg, Germany*
Email: georg.damm@medizin.uni-leipzig.de

Background and aims: Changes in energy metabolism are a known feature of hepatocellular carcinoma (HCC). Therefore, addressing the energy metabolism in hepatoma cells as a potential treatment is work in progress. Here, we compared the hepatoma cell lines HepG2 and Huh7 with appropriate controls based on primary cells to evaluate their usability in HCC research..
Method: We isolated control primary human hepatocytes (PHHs) from resected livers from non-HCC patients and primary human hepatoma cells (PHCs) and corresponding PHHs (HCC-PHHs) from HCC patients. As a model of proliferating PHHs we used Upcyte® hepatocytes (HepaFH3 clone) generated by lentiviral transduction of PHHs with proliferation-inducing genes. Cell types were characterized for specific HCC markers, enzymes and signaling proteins of the energy metabolism on RNA, protein and functional level.
Results: The characterization for established HCC markers revealed that advanced PHCs are closely related to hepatoma cell lines. In contrast, the identified metabolic key players showed lower expression in PHCs in comparison to hepatoma cell lines and PHHs. Hepatoma cell lines did not reflect anaerobic and fasting characteristics of PHCs. In line with that, clinical data of our donors indicated that their HCC were slowly growing tumors. In contrast, hepatoma cell lines showed similar metabolic characteristics to proliferating PHHs suggesting that the Warburg effect is a general feature of energy shortage in rapidly proliferating cells.
Conclusion: We show that HepG2 and Huh7 cells do not reflect the energy metabolism of PHCs. In particular anaerobic and fasting states of HCCs were not covered by cell lines under standard cell culture conditions.

Different immunological microenvironment in patients with different cirrhosis etiology and hepatocellular carcinoma

Andrea Dalbeni[1], Leonardo Natola[1], Filippo Cattazzo[1], Antonio Vella[2], Marta Garbin[1], Michele Bevilacqua[1], Anna Mantovani[1], Giovanna Zanoni[2], Alfredo Guglielmi[3], Michele Milella[4], David Sacerdoti[1]. *[1]AOUI Verona, Medicine, Verona, Italy; [2]University of Verona, Immunology department, Italy; [3]Univeristy of Verona, Surgery, Verona, Italy; [4]Università of verona, Oncology, Italy*
Email: andrea.dalbeni@aovr.veneto.it

Background and aims: Hepatocellular carcinoma (HCC) is the second leading cause of cancer-related death. Most cases (90%) of HCC arise in the setting of a chronic liver disease. The advanced stages of HCC are amendable only to systemic treatment. Systemic therapy has been revolutionized by immune-based therapies. However, a recent meta-analysis of three randomized phase III clinical trials that tested inhibitors of PD-L1 or PD1 in more than 1, 600 patients with advanced HCC, revealed that immune therapy did not improve survival in patients with non-viral HCC.
The aim of the study was to identify differences in immune cell population of patients with HCC, according to etiopathogenesis of cirrhosis, in order to identify different patterns that may be targeted for immunotherapy.
Method: We analyzed 50 leukocyte sub-populations, using flow cytometric technique, in a cohort of 111 consecutive HCC cirrhotic patients with different etiopathogenesis. Differences between groups were analyzed with the Mann-Whitney U test.
Results: We divided HCC patients with cirrhosis into five groups according to etiology of liver disease: alcoholic, viral (HCV/HBV), metabolic (NAFLD/NASH), overlap between etiological factors and other etiology. Leukocyte sub-populations were significantly different in two groups. Specifically in the group of alcoholic etiology there were increased levels of PMN ($p < 0.01$), monocytes ($p < 0.01$) and NKT cells CD57+RA- (4-8-) ($p = 0.011$), while in viral etiology group there were increased levels of T cells CD57-RA+ (4-8-) ($p = 0.007$) and T cell CD3+ (4-8-) ($p = 0.009$). No specific leukocyte subpopulation was significantly increased in the other groups, in particular in the metabolic one.
Conclusion: These data suggest that in liver disease with different etiopathogenesis there are different immunological microenvironments. Innate and innate-like cells are the principal regulators of immune response in alcoholic HCC, while adaptive immune system is predominant in viral etiology. This suggests that differences in cancer-mediated immune escape could explain the different response to immunotherapy and may be helpful in identification of responder patients to new HCC therapy.

FRI587

Cytokine levels and circulating DNA in plasma could be used as serological biomarkers of response to immunotherapy in hepatocellular carcinoma

Elena Vargas Accarino[1,2], Monica Higuera[1], Maria Bermúdez[1,2,3,4], Monica Pons[1,2,3,4], Maria Torrens[1], Gloria Torres[1], Marta Vila[5], Francisco Rodríguez-Frías[4,5], Xavier Merino[6], Beatriz Minguez[1,2,3,4]. *[1]Liver Diseases Research Group, Vall d'Hebron Research Institute, Barcelona, Spain; [2]Department of Medicine, Universitat Autònoma de Barcelona, Barcelona, Spain; [3]Liver Unit, Vall d'Hebron University Hospital, Barcelona, Spain; [4]CIBERehd, Instituto Carlos III, Barcelona, Spain; [5]Biochemistry and Microbiology Department, Clinical Laboratories Hospital Universitari Vall d'Hebron, Barcelona, Spain; [6]Radiology Department, Vall d'Hebron University Hospital, Barcelona, Spain*
Email: bminguez@vhebron.net

Background and aims: Immunotherapy and, in particular, immune checkpoint inhibitors (ICIs) have revolutionized the therapeutic landscape for advanced hepatocellular carcinoma (HCC). As monotherapy, they have shown antitumor activity in a subgroup of patients and the combination of anti-PDL1 antibody (atezolizumab) and VEGF-neutralizing antibody (bevacizumab) have become treatment of choice in first-line. One of the unsolved challenges is to identify and validate predictive biomarkers of response to these treatments in patients with HCC. The objective of this study was to identify potential serological markers of response to ICIs.
Method: Prospective cohort of 21 patients treated with ICIs (Nivolumab monotherapy (n = 15), Atezolizumab/Bevacizumab combination (n = 5) and Durvalumab/Tremelimumab combination (n = 1)). Plasma samples were collected at the beginning of ICI treatment and after three months of treatment. Twenty-four inflammatory cytokine levels were analyzed by ELISA as well as the levels of circulating cell free DNA (cfDNA) and its percentage of TERT mutation by ddPCR, at baseline and at 3 months of treatment.
Results: 86% of the study patients were male, with a mean age of 72 years and 76% were BCLC-C at starting ICIs treatment. 48% presented progression (PD), 9% complete response (CR), 14% partial response

(PR) and 29% stable disease (SD) as best radiological response. The underlying liver disease in most cases was hepatitis C virus (HCV) infection (62%). Lymphocyte Activation Gene type 3 (LAG-3) levels measured 3 months after starting ICIs treatment were significantly higher in PD [median (IQR)] 231.4 pg/ml (2668.3) than in CR, PR SD (median (IQR) 126.7pg/ml (245.5) (p = 0.031). Interleukin-21 (IL-21) levels after three months of treatment were significantly different between patients who presented the best radiological response at follow-up CR/PR (195.5 (155.9) pg/ml), SD (62.7 (29)) or PD (290.6 (689.6) pg/ml) (p = 0.05). The analysis of MCP-1 (monocyte chemoattractant protein 1) also showed significantly different levels depending on the response to treatment (CR/PR 88.9 pg/ml (62.4), SD 23 pg/ml (11.9) and PD 12.7 pg/ml (9.8)) (p = 0.002). The only baseline determination that showed significant differences was total cfDNA, which was significantly higher in patients who presented PD as the best radiological response (8 pg/ml (6.1)) compared to patients who had radiological response (CR/PR) or SD (3 pg/ml (2.9)) (p = 0.024). Changes in TERT mutation percentage after 3 months of treatment showed a trend to significance between patients experiencing PD and CR/PR/SD patients (p = 0.083).

Conclusion: Our findings suggest that LAG-3, IL-21 and MCP-1 levels determined after 3 months of ICI treatment and baseline cfDNA levels, could be serological biomarkers of response in patients with advanced HCC. Validation studies are currently ongoing.

RuvBL1 haploinsufficiency improves mTOR-driven NASH-HCC development in mice

Alice Guida[1,2], Irene Simeone[1,2], Simone Polvani[1], Elisabetta Ceni[1], Lucia Picariello[1], Gabriele Dragoni[1,2], Andrea Galli[1], Tommaso Mello[1].
[1]University of Florence, Clinical and Experimental Biomedical Sciences "Mario Serio", Florence, Italy; [2]University of Siena, Genetics, Oncology and Clinical Medicine "GenOMeC" PhD programme, Siena, Italy
Email: tommaso.mello@unifi.it

Background and aims: The AAA+ ATPase RuvBL1 participates in several cellular processes relevant to oncogenic transformation, including DNA repair, gene expression, telomerase complex assembly and mTOR pathway activity. RuvBL1 expression correlates with a worse prognosis in HCC patients, however its role in HCC is largely unexplored. We have previously demonstrated that RuvBL1 haploinsufficiency impairs insulin signalling affecting the PI3K/Akt/mTOR pathway in vivo. Considering the relevance of mTOR pathway hyperactivation in human HCC, we aimed to reduce mTOR-driven hepatocarcinogenesis by targeting RuvBL1 in $Pten^{hep-/-}$ mice, a genetic model of NASH progression to HCC.

Method: $Pten^{hep-/-}$ and $Ruvbl1^{hep\pm}$ mice were crossed to generate $Pten^{hep-/-}$ $Ruvbl1^{hep\pm}$ mice. The impact of RuvBL1 haploinsufficiency on NASH development was assessed by histology at 12 weeks of age. Metabolic and inflammatory markers were evaluated by qPCR and IHC. mTOR pathway cascade was analysed by western blot of liver lysates.

HCC development was assessed in mice aged to 15 months by multiplicity evaluation of macroscopic tumors and by histological classification by Edmondson-Steiner grading system.

Results: Oil red, Sirius red histological stain and F4/80 IHC revealed a significant reduction of steatosis, fibrosis, and inflammation in $Pten^{hep-/-}$ $Ruvbl1^{hep\pm}$ compared to $Pten^{hep-/-}$ at 12 weeks of age. Quantification of triglycerides extracts confirmed the reduced lipid content in Ruvbl1 haploinsufficient mice livers. Surprisingly, similar mRNA expression of mTOR-driven lipogenic targets was found in the two mice models. However, expression of *Ppara* and its target CPT1 was increased in $Pten^{hep-/-}$ $Ruvbl1^{hep\pm}$, indicating a lipid-lowering action mediated by PPARalpha in this mouse model. Western blot revealed an increase of p-AMPK and p-RAPTOR protein levels in $Pten^{hep-/-}$ $Ruvbl1^{hep\pm}$, suggesting a role of RuvBL1 at the interplay between mTOR and AMPK in hepatic lipid metabolism. $Pten^{hep-/-}$ $Ruvbl1^{hep\pm}$ mice aged to 15 months developed significantly less macroscopic tumours, which resulted better differentiated and of lower grade than $Pten^{hep-/-}$ ones. qPCR analysis showed a significant upregulation of key lipolytic genes, such as *Cpt1a, Acadl, Acadvl* and *Ppara* in $Pten^{hep-/-}$ $Ruvbl1^{hep\pm}$ at 15 months of age.

Conclusion: Targeting RuvBL1 mitigates the NASH metabolic and tumorigenic phenotype driven by mTOR hyperactivation in $Pten^{hep-/-}$ mice, likely promoting the switch from mTOR-driven lipogenesis to AMPK-induced fatty acid catabolism.

FRI589

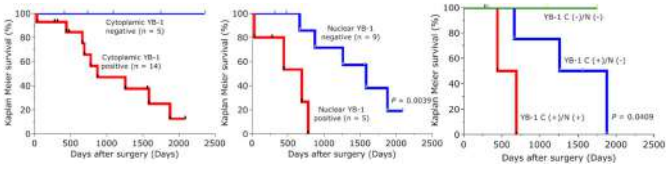
Cold shock protein YB-1 upregulates MDR1 transcription and thus contributes to chemoresistance against cisplatin treatment in cholangiocarcinoma

Tao Lin[1], Jonathan A. Lindquist[2], Peter Rene Mertens[2], Matthias Ebert[1], Steven Dooley[1], Jun Li[3], Stefan Munker[4], Honglei Weng[1]. *[1]UMM; [2]uni-magdeburg; [3]University Medical Center Hamburg-Eppendorf; [4]LMU*
Email: steven.dooley@medma.uni-heidelberg.de

Background and aims: Cholangiocarcinoma is a liver cancer with high mortality. Chemotherapy with cisplatin or gemcitabine is currently the main approach to treat cholangiocarcinoma patients with advanced stage. However, efficiency of these drugs is poor due to chemoresistance. To date, detailed mechanisms underlying chemoresistance in cholangiocarcinoma are largely unknown. In this study, we demonstrate a crucial role for the cold shock protein Y-box binding protein-1 (YB-1) in cholangiocarcinoma chemoresistance to cisplatin.

Method: Expression of YB-1 was examined by immunohistochemistry in 28 cholangiocarcinoma patients receiving surgery. Among them, 10 patients underwent chemotherapy following operation. Functional studies on the YB-1 effects were performed in cholangiocarcinoma cell lines to delineate the underlying mechanisms.

Results: YB-1 expression in cancer cells, in particular in nuclei, was closely associated with survival of patients. From 10 patients receiving chemotherapy, 2 patients without YB-1 expression, but only 3 out of 8 patients with YB-1 expression survived a 5-year follow-up. In vitro, immunofluorescence staining showed that cisplatin administration induced YB-1 nuclear translocation. ChIP assays demonstrated YB-1 binding to the multidrug resistance gene MDR1 promoter prior to induction of gene expression. Impressively, administration of cisplatin significantly increased MDR1 promoter binding activity of YB-1. Functionally, knockdown of YB-1 by RNAi inhibited cancer cell proliferation and increased cisplatin-dependent apoptosis.



Conclusion: YB-1 nuclear expression plays a crucial role in cholangiocarcinoma chemoresistance to cisplatin treatment through upregulating MDR1 expression. YB-1 expression in cancer cells might be a useful biomarker to predict chemotherapy efficacy in cholangiocarcinoma. Further, disrupting YB-1 function in cholangiocarcinoma is a promising treatment approach in clinical practice.

FRI590

Synergistic anti-tumor activity with a combination of anti-PD1 antibody and the cyclophilin inhibitor, rencofilstat, in the Hep53.4 fatty liver model of hepatocellular carcinoma

Daren Ure[1], Jack Leslie[2], Bhavesh Variya[1], Robert Foster[1], Jelena Mann[3], Derek A Mann[2,3]. [1]*Hepion Pharmaceuticals, Canada;* [2]*Newcastle University, United Kingdom;* [3]*Fibrofind Ltd, United Kingdom*
Email: dure@hepionpharma.com

Background and aims: Cyclophilins are a class of protein folding and regulatory enzymes that have been shown in preclinical studies to contribute to progression of several types of cancer, including hepatocellular carcinoma (HCC). Immunomodulation is one of the many therapeutic activities ascribed to cyclophilin inhibition and was the rationale for investigating the clinical phase cyclophilin inhibitor, rencofilstat (CRV431), in combination with anti-PD1 in a murine orthotopic model of HCC.
Method: Murine Hep53.4 HCC cells were implanted into either normal livers or fatty livers of C57BL/6 mice. Fatty livers were generated by feeding mice a western diet with sugar water for 3 months prior to surgical Hep53.4 implantation. Treatments included rencofilstat by once-daily oral gavage and anti-PD1 IgG twice weekly, alone or in combination, starting 2 weeks post-implantation. Anti-cancer effects were assessed by measuring tumor volumes at Week 4 post-implantation, immunohistochemical tumor analysis, and mouse survival in additional cohorts of mice.
Results: Rencofilstat and anti-PD1 IgG treatments, alone or in combination, similarly decreased tumor growth in non-fatty livers by 76–83% over 2 weeks of treatment compared to vehicle treatment. Immunohistochemical analysis showed that rencofilstat and anti-PD1 independently doubled CD4 and CD8 lymphocyte infiltration into tumors. Additionally, rencofilstat decreased the number of tumor neutrophils by 55%, whereas anti-PD1 had no effect on neutrophil infiltration. In the fatty liver model, neither rencofilstat nor anti-PD1 alone produced statistically significant reductions in tumor growth, but the combination decreased tumor growth by 84% compared to 2 weeks of vehicle treatment. Survival analyses in separate cohorts in the fatty liver-HCC model mirrored the tumor measurements in that monotherapies had no effect on survival whereas rencofilstat plus anti-PD1 extended median survival time by 26%.
Conclusion: The different outcomes in non-fatty versus fatty liver HCC models align with previous reports stating that HCC in fatty livers is more resistant to immune checkpoint inhibitor therapy. Combination treatment with rencofilstat and anti-PD1 synergistically decreased tumor growth and extended survival time, which supports clinical investigation in HCC.

FRI591

Rencofilstat, a pan-cyclophilin inhibitor, exerts diverse metabolic and transcriptional anti-tumor activities in a murine NASH-HCC model

Daren Ure[1], Joseph Kuo[2], Winston Stauffer[2], Lacey Haddon[1], Patrick Mayo[1], Robert Foster[1], Philippe Gallay[2]. [1]*Hepion Pharmaceuticals, Canada;* [2]*Scripps Research Institute, United States*
Email: dure@hepionpharma.com

Background and aims: Cyclophilins are protein folding and regulatory enzymes that have been shown in preclinical studies to contribute to progression of several types of cancer, including hepatocellular carcinoma (HCC). They are elevated in most types of cancer, and overexpression is prognostic of shorter survival. Current pharmacologic cyclophilin inhibitors exert anti-cancer activities but target multiple cyclophilin isoforms. The aim of the current study was to elucidate the predominant anti-cancer mechanisms of the pan-cyclophilin inhibitor, rencofilstat (CRV431), in an experimental murine HCC model.
Method: Rencofilstat was studied in a murine NASH-HCC model (streptozotocin + Western diet) characterized by a high mutational burden and spontaneous liver tumor development. Rencofilstat was administered by once-daily oral gavage from Weeks 20–30 following initiation of Western diet. Liver tumor and non-tumor tissue from vehicle-treated and rencofilstat-treated mice were analyzed by genomic, transcriptomic, and metabolomic methods.
Results: Once-daily, oral rencofilstat treatment decreased tumor burden at Week 30 by 50%. Whole exome sequencing of tumors and nontumor liver tissue revealed a diverse repertoire of somatic mutations that far exceeded the mutation burden of human HCC tumors. This was accompanied by extensive dysregulation of metabolic and transcriptional processes, i.e. changes in approximately 25% of all metabolites and gene expression. Rencofilstat treatment produced many alterations of the metabolic and transcriptional signatures in tumor and nontumor, NASH tissue consistent with anti-cancer effects. At a systems level, 47% of the differential metabolites and 59% of the differential gene expression in tumors were normalized by rencofilstat treatment to levels observed in nontumor tissue. Specific metabolism-related effects of rencofilstat in tumors included normalizations of the oncometabolite, fumarate, and the principal byproduct of methylation reactions, s-adenosylhomocysteine. At the transcriptional level, rencofilstat altered the expression of genes across a spectrum of cellular processes, including oncogenic signaling, cell cycle, cell death, unfolded protein responses, ubiquitination, and several metabolic processes. Noteworthy rencofilstat effects included attenuation of Wnt-β-catenin, Myc, C/EBPβ, Nupr1, Eif2ak3 (PERK), and Rac1.
Conclusion: The clinical phase drug candidate, rencofilstat, decreased tumor burden in an aggressive, hypermutated model of HCC, which was associated with a wide range of metabolic and transcriptional effects. These results suggest that pan-cyclophilin inhibition may be therapeutic across multiple tumor types in HCC or other cancers.

Establishing quantitative image analysis methods for tumor microenviroment evaluation

Caner Ercan[1,2], Mairene Coto-Llerena[1,2], Salvatore Piscuoglio[1,2], Luigi Maria Terracciano[1,3]. [1]*University Hospital Basel, University of Basel, Institute of Medical Genetics and Pathology, Basel, Switzerland;* [2]*Department of Biomedicine, University of Basel, Visceral surgery and Precision Medicine Research Laboratory, Basel, Switzerland;* [3]*Humanitas University, Department of Biomedical Sciences, Milan, Italy*
Email: caner.ercan@usb.ch

Background and aims: There is growing evidence that supports the role of the tumor microenvironment (TME) in the development and progression of hepatocellular carcinoma (HCC). However, the correlation between its composition and prognosis remain unclear. TME evaluation requires a combination of cell type and spatial information. These information can be obtained with the use of immunohistochemistry on patient derived slides. However, the IHC quantification remains a challenge. Computational methods such as artificial intelligence-based tool, may expedite the detection and classification thousands of different cells, expanding our understanding of the TME. Here, we aim to develop an AI based image analysis pipeline to define morphological and immunological characteristics of HCC-TME, as well as their relationship with clinicopathological features.
Method: We collected 98 HCC samples from liver resections available in the. TME composition of the tumors was evaluated and classified as inflamed, immune excluded and immune desert. Tumor slides were stained with a panel of TME markers (CD3, CD8, FOXP3, TIGIT, RORgt, ICOS, GranzymeB CD163, iNOS, PD-1, PD-L1) by IHC. The slides were digitalised and whole slide images were used for the quantification. The samples were split into training (80%) and test (20%) datasets and used to train convolutional neural network (CNN) models. For the quantification of immune cells, we trained two separate CNNs: cell detection and tumor-stroma segmentation. Cell nucleus instance segmentation was achieved using StarDist package

(Schmidt et al 2018). We trained a model with our slides and tested the pretrained model (2D_versatile_he) which is for H&E stained images. Immune cells were classified using random forest classifier in QuPath. Finally, we trained a CNN in UNET architecture with ResNet34 backbone for semantic segmentation of tumor tissue into parenchyma, stroma and debris classes, by fastai deep learning library.
Results: The accuracy of pretrained StarDist model was limited to 72% on IHC slide images. Thus, we trained a new cell nucleus instance segmentation StarDist model with our dataset and it reached 84% accuracy, 91.3% F1-Score, 92% true positive, 90.6% true negative rates on IHC slide images. Random forest classifier annotated immune cells at 98% accuracy. The tissue segmentation model classified tumor regions into parenchyma, stroma and debris at 95, 8% accuracy, 92.5% dice, 86.3% IuO.
Conclusion: In this study we developed a pipeline implementing open-source solutions to quantify IHC slides. The use of this semi-automatized computational pathology workflow can provide robust information in regard of the TME composition augmenting the discovering tumour specific TME features and pave way for the discovery of novel prognostic and therapeutic targets.

Development of hepatocellular carcinoma in the extended GAN diet-induced obese mouse model of NASH with advanced fibrosis

Andreas Nygaard Madsen[1], Denise Oró[1], Martin Rønn Madsen[1], Mogens Vyberg[2], Henrik B. Hansen[1], Michael Feigh[1]. [1]*Gubra, Hørsholm, Denmark;* [2]*Aalborg University, Center for RNA Medicine, Department of Clinical Medicine, Copenhagen, Denmark*
Email: mfe@gubra.dk

Background and aims: Non-alcoholic steatohepatitis (NASH) predispose to the development of severe fibrosis and hepatocellular carcinoma (HCC). Preclinical animal models resembling NASH-driven HCC development are important tools for exploring novel pharmacological interventions for HCC. The present longitudinal study aimed to characterize disease progression in the extended GAN (Gubra-Amylin NASH) diet-induced obese (DIO) mouse model of NASH.
Method: Male C57Bl/6J mice were fed the GAN diet (40% fat, 22% fructose, 10% sucrose, 2% cholesterol) for up to 88 weeks (n = 12–15/group). Disease progression in DIO-NASH mice was evaluated using the clinical NAFLD Activity Score (NAS) and fibrosis staging system, quantitative histology, macroscopic tumor evaluation and liver transcriptomics. Tumor histopathological classification was performed by an expert clinical pathologist.
Results: DIO-NASH animals demonstrated progressive NASH (NAS ≥5) and fibrosis (stage ≥F1) from 28 weeks of GAN diet feeding. Notably, advanced fibrosis (stage F3, bridging fibrosis) was observed ≥80% of animals from 48 weeks of GAN diet. Development of liver tumors was progressively observed with 100% tumor burden after 58 weeks of GAN diet-induction. Tumors demonstrated consistent architectural and cytologic features of HCC, notably loss of reticulin-stained fibers. Progressive HCC development was supported by increased quantitative histological markers of proliferation (Ki67), and hepatic biliary/progenitor cells (CK19). Disease progression was further highlighted by increased quantitative histological markers of steatosis (lipids, hepatocytes with lipid droplets), inflammation (number of inflammatory foci, galectin-3), fibrosis (PSR, collagen 1a1), activated stellate cells (alpha-SMA). Finally, liver whole-tissue transcriptome signatures demonstrated enhanced fibrogenesis (collagens, matrix metalloproteins) and tumorigenesis activity (cell cycle control, growth factors).
Conclusion: DIO-NASH mice show advanced fibrosis and high HCC tumor burden following extended GAN dieting. The GAN DIO-NASH-HCC mouse model is suitable for profiling novel drug therapies for advanced fibrosing NASH-driven HCC.

Non-canonical TGF-β signalling contributes to pro tumorigenic Smad3 linker phosphorylation in cholangiocarcinoma

Sophie Alex[1], Jan Albin[1], Diego F. Calvisi[2], Stefan Munker[3], Honglei Weng[1], Nuh N. Rahbari[4], Matthias Ebert[5], Anne Dropmann[1], Steven Dooley[1]. [1]*Medical Faculty Mannheim, University Heidelberg, Molecular Hepatology, Department of Medicine II, Mannheim, Germany;* [2]*University Regensburg, Department of Pathology, Regensburg, Germany;* [3]*Hospital of the University of Munich, Department of Medicine II, Munich, Germany;* [4]*Medical Faculty Mannheim, University Heidelberg, Department of Surgery, Mannheim, Germany;* [5]*Medical Faculty Mannheim, University Heidelberg, Department of Medicine II, Mannheim, Germany*
Email: S.Alex@stud.uni-heidelberg.de

Background and aims: TGF-β signal transduction commences with receptor-mediated C-tail phosphorylation of Smad3, complex formation with Smad4 and nuclear translocation for cytostatic target gene regulation in epithelial cells. Regulatory phosphorylation steps at serine/threonine residues in the Smad linker (L) domain generate phosphorylated forms with mitogenic functions by interfering with transcriptional activity and proteasomal degradation. TGF-β signaling is impaired in several human tumors. We now show that in intrahepatic cholangiocarcinoma (iCCA) pSmad3L levels are increased and we aimed at identifying if this may facilitate tumorigenesis.
Method: We examined 180 healthy and tumorigenic liver tissues from iCCA patients for their Smad3 phosphorylation status, discriminating C-tail (S423 and S425)- and linker residues (S204 and S213), using immunoblotting, immunofluorescence and immunohistochemistry with Smad phosphorylation site-specific antibodies and correlated these with clinical data. For functional studies, we treated cultured iCCA cells with inhibitors for Smad and non-Smad TGF-β signaling pathways in combination with TGF-β1 stimulation and the chemotherapeutics Cisplatin, Gemcitabine, Doxorubicin and 5-FU, and tested chemosensitivity and proliferative activity.
Results: C-tail Smad3 phosphorylation was evident similarly in healthy and tumorigenic liver tissue samples. Elevated pSmad3L levels were exclusively present in tumour tissue with 86% of CCA samples showing increased pSmad3L S213 and only 5% being positive for pSmad3L S204. CCA cell lines show decreased pSmad3C and increased pSmad3L (S213 and 204) levels as compared to non-tumorous cholangiocytes which show strong pSmad3C and weak pSmad3L staining. Treatment with inhibitors indicate a counter regulation of C-terminal versus linker phosphorylation. Intrinsic pSmad3L (S204 and S213) is decreased by treatment with a GSK-3β inhibitor. In this setting, TGF-β1 leads to a stronger phosphorylation of Smad3C. When instead inhibiting ALK5, TGF-β1 treatment enhances nuclear pSmad3L levels. High pSmad3L and low pSmad3C levels result in enhanced proliferation and robust chemoresistance. Interfering with linker phosphorylation of Smad3 by targeting GSK-3β reduces proliferative activity and sensitized the cells for chemotherapy. MMP-9, p21 and c-Myc mRNA expression levels correlate with the respective proliferative activity.
Conclusion: pSmad3L (S204 and S213) phosphorylation is predominant in CCA tissue and interferes with cytostatic pSmad3C (S423/425) signaling in cultured iCCA cells, thereby facilitating proliferative activity and chemoresistance of cancer cells. Canonical ALK5/C-terminal Smad3 phosphorylation and non-canonical Smad3 linker phosphorylation are counterregulated in vitro. A similar scenario in patient samples is currently not confirmed and requires further studies.

TGF-β-SOX9 axis-inducible SCUBE3 promotes proliferation, invasion and metastasis in hepatocellular carcinoma via epithelial-to-mesenchymal transition

Hong Ren[1,2,3,4], Qiang Luo[2], Pan Xu[1]. [1]*Institute for Viral Hepatitis, Chongqing, China;* [2]*Institute for Viral Hepatitis, Chongqing, China;* [3]*Institute for Viral Hepatitis, Yuzhong, Chongqing, China;* [4]
Email: renhong0531@cqmu.edu.cn

Background and aims: It was found that secretory SCUBE3 protein is highly expressed in lung cancer and osteosarcoma, is associated with proliferation, invasion and metastasis of lung cancer cells and breast cancer cells. Therefore, the aim is to explore the clinical significance of SCUBE3 in HCC and the specific molecular mechanism of SCUBE3 on the biological function.
Method: TCGA database and IHC were used to detect the SCUBE3 of cancer and paracancerous. CCK8, Clone formation and celigo experiment were used to detect the regulation of SCUBE3 on the proliferation of hepatoma cells. The apoptosis and cell cycle after knockdown of SCUBE3 were detected by flow cytometry. Cell migration and invasion were detected by cell scratch and Transwell. The invasion and EMT markers were detected by WB and qPCR. EMT markers in nude mouse tumours was detected by IHC. The cell movement was observed by the RTCA system. ROS reactive oxygen species assay was used to evaluate the effect of SCUBE3 on cell adhesion. The xenograft tumour and metastasis model of liver cancer were constructed. The interacting proteins were verified by confocal and IP assay. TGF β was added on the basis of knocking down SCUBE3. SCUBE3 recombinant protein induced EMT formation. The interaction between Sox9 and SCUBE3 was verified by Chip experiment.
Results: SCUBE3 in hepatocellular carcinoma was different from that in adjacent tissues ($p = 0.017$), and SCUBE3 was related to age and stage and grade of hepatocellular carcinoma.
SCUBE3 knockdown inhibit the HCC cell proliferation and colony formation, migration and invasion. The apoptosis increased and the transformation of the cell cycle from the G1 phase to S phase inhibited in KD group. The degree of ROS in different cells was different. The lung metastasis model of liver cancer evaluated the regulatory ability of SCUBE3 on the invasion and metastasis of liver cancer cells. The overexpression of metastatic tumors in the upper lung group was more than that in the control group.
Akt and TGFβ were the pathways related to the regulation of hepatoma cell proliferation, metastasis and EMT β/Smad2/3 pathway. SCUBE3 and TGFβ R II has interaction. Smad2/3 pathway was also inhibited in KD group. VEGF, N-cadherin also increased, E-cadherin decreased and Smad2/3 expression increased when TGF β was given in KD group. Sox9 and Runx1 were inhibited with SCUBE3 knockdown. The function of Sox9 was related to the prognosis of liver cancer. Chip experiment showed that there was SCUBE3 binding site in chromosome 1657–1665 region of Sox9 transcription factor.
Conclusion: TGF-β- Sox9-SCUBE3 axis regulates the Akt pathway and EMT to promote the proliferation, invasion and metastasis of HCC cells. SCUBE3 may become a new target for clinical diagnosis and treatment of HCC.
Keywords: SCUBE3, Signaling pathway, animal model, hepatoma cells, proliferation and metastasis.

Inhibition of Wee1 induces antitumoral effects in preclinical models of hepatocellular carcinoma independently of p53 mutational status

Julia Sophie Schneider[1], Liangtao Ye[1,2], Najib Ben Khaled[1], Heike Hermanns[3], Claude Haan[4], Andreas Geier[3], Enrico de Toni[1], Florian P Reiter[3]. Email: schneider-jul@t-online.de

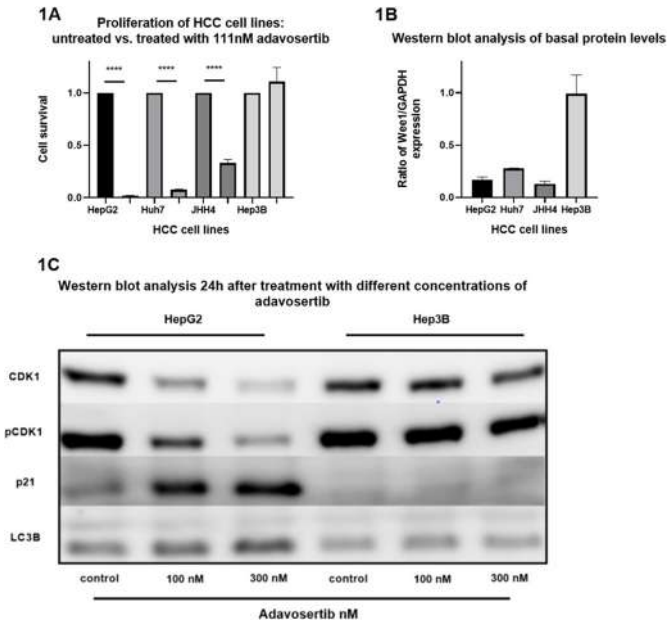
Background and aims: Hepatocellular carcinoma (HCC) is one of the leading causes of cancer-related death worldwide. In the majority of cases HCC is diagnosed in advanced stage when only palliative systemic treatment is feasible. The introduction of immune checkpoint inhibitors has greatly improved survival of HCC patients with advanced-stage HCC. However, the long-term survival characteristically observed in patients responsive to immunotherapy is observed in only a minor proportion of patients. Therefore, understanding tumor biology and establishing new effective and biomarker-guided targeted treatment options remains a priority. Wee1 is a central regulator of cell cycle and a target of several promising inhibitors currently being investigated in clinical trials, including adavosertib. Since Wee1 controls one checkpoint of DNA damage repair, it is postulated that tumors harboring p53 mutations are particularly susceptible to Wee1 inhibition and that mitotic catastrophe occurs in response to the simultaneous impairment of two crucial DNA repair checkpoints. Since p53 is frequently mutated in advanced HCCs, Wee1 inhibition could represent a potentially interesting therapeutic approach for treatment of HCC.
Method: Inhibition of Wee1 was investigated in p53 mutated (Huh7, JHH4, Hep3B) and p53 wildtype HCC cell lines (HepG2) by adavosertib and siRNA. Antitumoral efficacy was assessed by SYBR green assay, FACS analysis and colony formation assays. Western blot was used to assess the underlying mechanisms.
Results: Wee1 inhibition causes a pronounced loss of cell viability in several HCC cell lines (Figure 1A) independently of p53 status, as exemplified by the lack of sensitivity to Wee1 inhibition in Hep3B cells (harboring a loss-of-function p53 mutation). In contrast to resistant Hep3B, Wee1 inhibition mediated a remarkable increase of autophagy and of the G2/M phase cell fraction in sensitive HepG2 cells. Sensitivity to Wee1 inhibition was associated with lower basal Wee1 protein expression and was accompanied by the decrease of CDK1 and a correspondent increase of p21 expression (Figure 1B and 1C).



Conclusion: Wee1 inhibition induces antitumoral effects in HCC by induction of autophagy and impairment of cell cycle control. Further research should address the hypothesis that Wee1 mutational status and/or Wee1 protein expression may serve as biomarkers of response to Wee1 inhibition in systemic HCC treatment.

Extracellular concentration of nicotinamid adenine dinucleotide modulates CD203a on TH17 cells and is associated with recurrence of hepatocellular carcinoma

Felix Krenzien[1], Julia Babigan[1], Alexander Arnold[2], Philipp Brunnbauer[1], Can Kamali[1], Karl Hillebrandt[1], Katrin Splith[1], Moritz Schmelzle[1], Johann Pratschke[1], Christian Benzing[1]. *[1]Campus Charité Mitte and Campus Virchow-Klinikum, Charité-Universitätsmedizin, corporate member of Freie Universität Berlin, Humboldt-Universität zu Berlin, and Berlin Institute of Health, Department of Surgery, Berlin, Germany; [2]Charité-Universitätsmedizin, Corporate Member of Freie Universität Berlin, Humboldt-Universität zu Berlin, Institute of Pathology, Berlin, Germany*
Email: felix.krenzien@charite.de

Background and aims: T helper 17 cells (Th17 cells) are a subtype of T helper cells that are involved in a number of pathological processes, one of them being the carcinogenesis of malignant tumors through the secretion of cytokines. Herein, we investigated the influence of extracellular nicotinamide adenine dinucleotide ($eNAD^+$) on the ecto-nucleotide pyrophosphatase/phosphodiesterase 1 (CD203a, ENPP1 or PC-1) on Th17 cells with respect to the probability of HCC recurrence following liver resection.
Method: Heparinised blood plasma samples and liver specimen of 59 patients who underwent curative liver resection were compared with 10 control patients free of liver disease. The eNAD+ concentration of blood plasma was determined by a heat-based dichotomous pH extraction with a combined enzymatic cycling method, while fibrosis was histologically graded (Desmet score, F0–F4). Flow cytometry was used for cell analysis. Overall, an alpha value of $p < 0.05$ was applied.
Results: Plasma $eNAD^+$ concentrations were significantly reduced with increasing liver fibrosis grade ($p < 0.05$). The expression of CD203a on CD4+, CCR4+, and CCR6+ T cells was found to correlate significantly with eNAD+ concentrations ($p < 0.05$). Patients with a postoperatively high proportion of CD203a expressing Th17 cells (CD4+, CCR6+, CCR4+) showed a 6-fold increased risk of HCC recurrence and a median recurrence-free survival of 233 days ($p < 0.05$), when compared to low expression CD203a Th17 cells (CCR6+, CCR4+). Similarly, patients with a postoperatively high proportion of CD203a expressing Th17 cells (CD4+, CCR6+) showed a 5-fold increased risk for recurrence and a median recurrence-free survival time of 334 days ($p < 0.05$), when compared to low CD203a expressing Th17 cells (CCR6+).

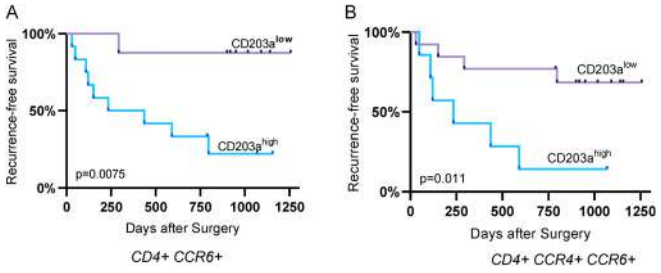

Figure: Frequency of recurrences after liver resection in patients with hepatocellular carcinoma. Patients with a postoperatively high proportion of CD203a expressing Th17 cells (CD4+, CCR6+, CCR4+) showed a 6-fold increased risk of HCC recurrence and a median recurrence-free survival of 233 days ($p < 0.05$), when compared to low expression CD203a Th17 cells (CCR6+, CCR4+).

Conclusion: Our data show that eNAD+ decreases in patients with liver fibrosis/cirrhosis and also correlates with the expression of the ectoenzyme CD203a on Th17 cells. Moreover, the probability of recurrence was significantly increased in patients with high expression of CD203a on Th17 cells, suggesting their potential as valuable prognostic markers and, furthermore, future therapeutic targets.

Characterizing and targeting CD44v6+ cells in liver carcinoma

Akshaya Srikanth[1], Klaus Dembowsky[2], Reinhold Schirmbeck[1], André Lechel[1]. *[1]Ulm University Hospital, Internal Medicine I, Ulm, Germany; [2]Amcure GmbH, Stutensee, Germany*
Email: akshaya-1.srikanth@uni-ulm.de

Background and aims: Liver carcinoma is one of the leading causes of cancer related deaths worldwide. The hyaluronic acid receptor variant CD44v6 is a marker for tumour stem cells, and has been shown to impact tumour formation and metastasis in several cancers including colorectal cancer and pancreatic cancer. The expression of CD44v6 dramatically increases in liver epithelial cells upon carcinogen exposure. With this study, we aim to target CD44v6 in primary human liver cancer cell lines by using an inhibitor, AMC303, and observe the effects of CD44v6 inhibition on proliferation, migration, invasion and EMT.
Method: CD44v6 expression was investigated in mouse and human liver and tumour tissue by immunohistochemistry. In addition, we used human HCC cell lines (Hep3B and PLC/PRF/5) and human CC cell lines (TFK1 and SZ1) to study the role of CD44v6 inhibition on cell proliferation, migration, invasion and EMT.
Results: Chronic liver damage resulted in the induction of CD44v6 positive epithelial cells in transgenic mouse models with chronic inflammation. The expression patterns of CD44v6+ cells were different in different mouse models of chronic liver damage. We observed clusters of hepatocyte-like cells with CD44v6 expression in a Hepatitis B mouse model and a CCl_4-treated liver fibrosis mouse model, which are characterized by the presence of diffuse inflammation. Interestingly, CD44v6 positive epithelial cells in Hepatitis C Virus- and IKK2/NF-κB activated- mouse models were located within ectopic lymphoid aggregates and resulted in increased formation of ICC. The number of CD44v6 positive cells was increased upon deletion of Trp53. CD44v6 expression was also upregulated in murine tumours compared to the liver, and coincided with Sox9 expression in the tumours, indicating that CD44v6+ cells were undifferentiated cells. CD44v6 expression was also upregulated in human HCC samples compared to normal adjacent tissue and cirrhotic livers.
Human liver carcinoma cell lines were analysed for CD44 expression and the CC cell lines were found to have a high expression of CD44 with 85–90% of cells positive for CD44 expression. Functional assays (wound healing assay and transwell migration assay) were performed using the CC cell lines. Treatment with the CD44v6 inhibitor AMC303 conferred a reduction in the migration potential of cells in CC cell lines, indicating that CD44v6 is crucial in regulating the migratory capacity of liver tumour cells.
Conclusion: Inhibition of CD44v6 in liver carcinoma cell lines led to a reduction in chemotaxis and migration. In conclusion, CD44v6 appears to be a promising targetable candidate in liver cancer.

Coordinating expression of tumorsuppressive microRNAs in hepatocellular carcinoma-a new role for p63 and p73 and their interaction with therapeutic agents

Lisa Kaser[1], Emily Ungermann[1], Claudia Kunst[1], Karsten Guelow[1], Martina Mueller-Schilling[1]. *[1]University Hospital Regensburg, Internal Medicine I, Regensburg, Germany*
Email: claudia.kunst@ukr.de

Background and aims: Hepatocellular carcinoma (HCC) is the most common type of liver cancer. Tumor suppressors such as the p53 family are supposed to prevent carcinogenesis. p53 is the best characterized family member and one of the most frequently mutated genes in tumors. Besides p53, p63 and p73 play an essential role in cellular stress response. Depending on their splice variant-with transactivation domain (TA) or dominant negative (DN), p53 proteins transcriptionally control specific target genes directly via promoter-binding or indirectly, e.g. via regulation of microRNAs (miRs). miRs are small, non-coding RNA molecules with a length of

~22 nucleotides. They play an important role in gene regulation and can exert tumor suppressive or oncogenic functions. p53 is known to regulate miRs in a range of cancer entities, but little is known about p63- and p73-dependent control of miRs in HCC. Aim of this study was to evaluate regulation of tumorsuppressive miRs by TAp63 and TA/DNp73 in HCC alone or in combination with HCC-relevant therapeutics.

Method: Hep3B cells were transduced with adenoviral vectors rAd-TAp63, -TAp73, -DNp73 or -GFP to induce expression of the respective p53 family member. (Non-)transduced cells were stimulated with different HCC therapeutics (Doxorubicin, Bleomycin, Regorafenib, Sorafenib, Tivantinib) for up to 72 hours. Expression profiles of tumorsuppressive miRs miR-34a, −145, −149, −192 and −194 were analyzed by RT-qPCR.

Results: Tivantinib induced an increase of all miRs analyzed in non-transduced Hep3B cells, with most effective induction of miR-34a and miR-145 (3.6×/7.4×), while other drugs had no effect. TAp63 transduction moderately increased miR-34a, −149, −192, and −194. TAp73 time-dependently induced miR-34a, −145 and −149, but had no effect on miR-192 and −194. Noteworthy, DNp73 did not induce any of the miRs, underlining the divergent functions of TA and DN isoforms. HCC therapeutics led to a moderate increase of all analyzed miRs in TAp63-transduced cells. In contrast, Tivantinib treatment highly increased (up to 15×) miR-34a, −145 and −149 in TAp73-transduced cells, whereas all other drugs resulted in induction rates of 4–8×. Importantly, in TAp73-transduced cells this reinforcing effect of Tivantinib also displayed a dose-dependency.

Conclusion: TAp63 and TAp73 regulate expression profiles of tumorsuppressive miRs and interact with HCC-relevant therapeutics to control miR expression profiles in HCC. In concordance with our previous data, DNp73 displayed divergent effects regarding miR regulation. Thus, specific combinations of p53 family members and HCC therapeutics-especially TAp73 and Tivantinib-have the capacity to reinforce tumorsuppressive miR expression. These findings provide novel knowledge to the complex network of p53 family-mediated tumor suppression and suggest novel therapeutic scope for the clinical management of HCC.

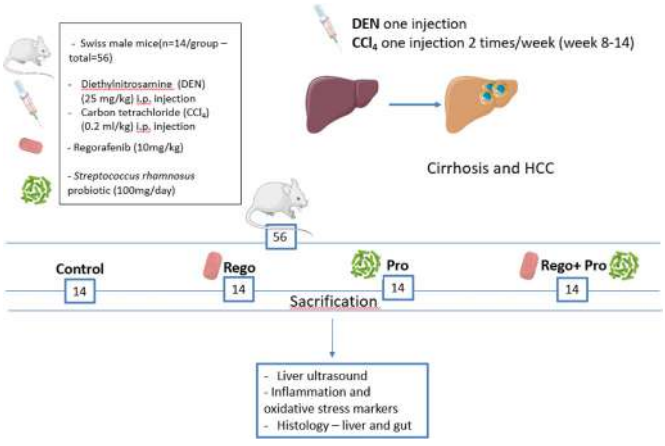
Trusting your gut-a new direction in multikinase inhibitors therapy in hepatocellular carcinoma

Iuliana Nenu[1], Diana Tudor[2], Horia Stefanescu[1], Bogdan Procopet[1], Zeno Sparchez[1], Gabriela Adriana Filip[2]. *[1]Regional Institute for Gastroenterology and Hepatology "Prof. Dr. O. Fodor", Hepatology, Cluj-Napoca, Romania; [2]Iuliu Hatieganu University of Medicine and Pharmacy, Physiology, Cluj-Napoca, Romania*
Email: iuliana.nenu@gmail.com

Background and aims: Hepatocellular carcinoma (HCC) has become a worldwide burden and its incidence is rising. The intestinal microbiota is responsible for inducing resistance to antitumoral drugs. The present study investigated the effects of the combined treatment of Regorafenib (Rego) and probiotic *Streptococcus rhamnosus* (Pro) on HCC bearing mice.

Method: We have induced cirrhosis and hepatocellular carcinoma on two-week Swiss male mice using diethylnitrosamine (DEN- 1 mg/kg) one intraperitoneal injection following carbon tetrachloride (CCl_4– 0.2 ml/kg) intraperitoneal administration two times per week for six weeks (between weeks 8 and 14). Abdominal ultrasound was performed to validate the presence of cirrhosis and liver tumors. Afterward, the mice were divided into four groups: in the first group (control group), the mice were treated with vehicle, the second group received Regorafenib (Rego) (10 mg/kg one time per day for one week), in the third group probiotic (100 mg/day for one week) was administered, and the last group received the combination of Rego and Pro. After the last treatment, liver and intestine fragments were taken for biochemical and histopathological analysis. Liver tumour and intestinal inflammation quantified by ELISA and western blot, oxidative stress and apoptosis markers, histopathological necrosis rate were assessed.

Results: IL-6 and IL-1 levels from both liver and intestine fragments decreased in the groups treated with probiotic compared to control but statistically insignificant ($p > 0.05$). Similarly, malondialdehyde levels dropped when Pro was added to Rego ($p < 0.05$). Tumor necrosis factor-alpha (TNF-α) and TLR-4 have a decreased levels in the combined regimen ($p < 0.05$) and in the Rego group ($p < 0.05$) when compared to the control group and correlate with the histological findings. Likewise, nuclear factor-κB (NF-κB) and IKKα expression decreased in the combined regimen. Intestinal inflammation assessed by determination of lipopolysaccharide (LPS) is reduced in the groups where probiotic was administered compared to the control and Rego group ($p < 0.05$). In addition, inducible nitric oxide synthase (iNOS) expression evaluated in intestine homogenate diminished in Rego and Rego associated with the probiotic groups ($p < 0.05$).



Conclusion: The association of *Streptococcus rhamnosus* probiotic with Regorafenib treatment improves the antitumoral activity of the multikinase inhibitor in animals with experimental HCC. Tumoral resistance and systemic adverse effects might be diminished when systemic and intestinal inflammation is lowered. Our results confirmed that the association of Regorafenib with probiotic proves a novel and promising approach. Manipulating and trusting your gut has never been so facile than in the present day for the oncology field.

The DNA damage response is involved in the metabolic dysregulation of MAFLD patients via inefficient fatty acid oxidation

Beatriz Gómez Santos[1], Idoia Fernámdez-Puertas[1], Ane Nieva-Zuluaga[1], Mikel Ruiz de Gauna[1], Maider Apodaka-Biguri[1], Francisco González-Romero[1], Diego Saenz de Urturi[1], Igotz Delgado[1], Igor Aurrekoetxea[1,2], Lorena Mosteiro González[2], Gaizka Errazti Olartekoetxea[2], Sonia Gaztambide[2], Luis A Castaño González[2], Luis Bujanda[3], Jesus Maria Banales[3], Ana Zubiaga[4], Xabier Buque[1], Patricia Aspichueta[1,2]. *[1]Faculty of Medicine and Nursing, University of the Basque Country UPV/EHU, Department of Physiology, Leioa, Spain; [2]Biocruces Bizkaia Health Research Institute, Barakaldo, Spain; [3]Biodonostia Health Research Institute-Donostia University Hospital, University of the Basque Country (UPV/EHU), Department of Liver and Gastrointestinal Diseases, San Sebastián, Spain; [4]Faculty of Science and Technology, University of Basque Country UPV/EHU, Department of Genetics, Physical Anthropology and Animal Physiology, Leioa, Spain*
Email: patricia.aspichueta@ehu.eus

Background and aims: A feature of the metabolic associated fatty liver disease (MAFLD) is the imbalance between processes that regulate lipid input and output. A chronic lipid-rich environment alters the oxidative capacity of the mitochondria generating species involved in the DNA damage response (DDR). The DDR is linked to MAFLD and to E2F transcription factors; however, the effect that the DDR plays in the altered lipid metabolism of MAFLD and the E2F involvement are still unknown. Aims: 1) Evaluate if DDR could be involved in the metabolic dysregulation of MAFLD identifying the involvement of E2F1 and E2F2; 2) Elucidate if the metabolic dysregulation induced by the lipid-rich environment is exacerbated by the DDR.
Method: An obese patient cohort with liver biopsies was used. The activity of mitochondrial complexes, pH2AX (marker of DNA damage) liver levels and liver and serum lipidome were analyzed. A cohort of C57/BL6 mice of different ages was also used. *E2f1* (*E2f1*$^{-/-}$) *and E2f2* (*E2f2*$^{-/-}$) knockout mice and their controls, injected with diethylnitrosamine (DEN), were fed a high-fat diet (HFD-DEN) for 10 weeks to induce progressive MAFLD. *In-vitro*, mouse primary hepatocytes were used.
Results: Liver pH2AX levels, increased in obese non-alcoholic steatohepatitis patients (NASH), correlated positively with metabolic features of worse prognosis. Mitochondrial activities were higher in NASH, mainly in those with increased DDR, in which liver triglycerides and diglycerides (DG) were higher; however, serum ketone bodies, an indirect marker of fatty acid oxidation (FAO), remained unchanged when compared with no-NASH patients, suggesting that the increased mitochondrial activity was not linked to increased FAO. In the mouse cohort, pH2AX levels also correlated with insulin resistance and liver DG content. Interestingly, *E2f1*$^{-/-}$ and *E2f2*$^{-/-}$ mice, protected from steatosis due to an efficient FAO activation, showed decreased pH2AX when treated with HFD-DEN. When hepatocytes were treated with the DDR inducers UV or H_2O_2, they were not able to catabolize the increased intracellular lipid levels when facing a lipid-rich environment. Finally, treatment with fatty acids alone was enough to activate DDR in hepatocytes.
Conclusion: DDR activation triggers metabolic changes related with mitochondrial dysfunction and facilitates lipid accumulation, both linked to disease progression. The results suggest that E2F1 and E2F2 might be intermediates promoting the DDR induced metabolic dysregulation.

SAT002

Hepatic miR-144 drives fumarase activity preventing NRF2 activation during obesity

Ruberti," Italy*
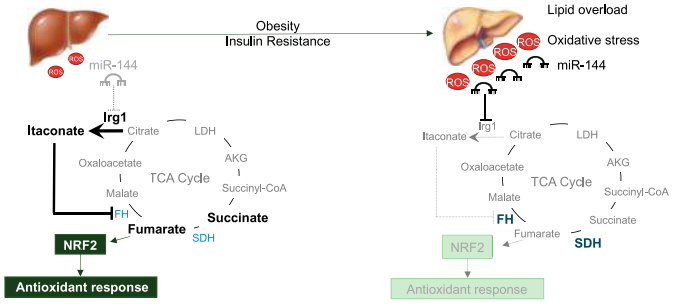
Email: myriam.aouadi@ki.se

Background and aims: Oxidative stress is central in the development of obesity-associated metabolic complications, including insulin resistance and non-alcoholic fatty liver disease. We recently discovered that microRNA miR-144 regulates the master mediator of the antioxidant response, NRF2. Upon miR-144 silencing, NRF2 target genes were significantly upregulated, suggesting that miR-144 controls NRF2 protein expression *and* activity. Here we explored a mechanism whereby upon obesity miR-144 inhibited NRF2 activity regulating a tricarboxylic acid (TCA) metabolite, fumarate.
Method: Transcriptomic analysis in liver macrophages (LMs) of obese mice identified the immuno-responsive gene 1 (*Irg1*) as a target of miR-144. IRG1 catalyzes the production of a TCA derivative, itaconate, which inhibits succinate dehydrogenase (SDH). TCA enzyme activities and kinetics were analyzed after miR-144 silencing in obese mice and human liver organoids using single cell activity assays *in situ* and molecular dynamic simulations.

 © 2022 All rights reserved.

ELSEVIER

Results: miR-144 upregulation in obesity was associated with reduced expression of *Irg1,* which was restored upon miR-144 silencing *in vitro* and *in vivo.* Furthermore, miR-144 overexpression reduces *Irg1* expression and the production of itaconate *in vitro*. In alignment with the reduction in *IRG1* and itaconate levels, SDH activity was upregulated during obesity. Surprisingly, also fumarate hydratase (FH) activity was upregulated in obese livers, leading to fumarate depletion. miR-144 silencing selectively reduced the activities of both SDH and FH resulting in the accumulation of their related substrates succinate and fumarate. Moreover, molecular dynamics analyses revealed the potential role of itaconate as a competitive inhibitor of not only SDH but also FH. Combined, these results demonstrate that miR-144 inhibits the *activity* of NRF2 through decreased fumarate production in obesity.



Conclusion: miR-144 triggers hyperactivation of FH in the TCA cycle and consumption of its substrate fumarate, eventually inhibiting NRF2 activity. Therefore, herein we unraveled miR-144 immunometabolic role in obesity in the regulation of endogenous antioxidant response.

SAT003

TNFR1 inhibition reduces lipogenesis and improves insulin resistance and fibrosis in NAFLD

Katharina John[1], Stephanie Liebig[1], Silke Marhenke[1], Heiner Wedemeyer[1], Heike Bantel[1]. [1]*Hannover Medical School, Department of Gastroenterology, Hepatology and Endocrinology, Hannover, Germany*
Email: bantel.heike@mh-hannover.de

Background and aims: Non-alcoholic fatty liver disease (NAFLD) shows an increasing prevalence and can result in the development of liver fibrosis/cirrhosis with associated complications. The molecular mechanisms of NAFLD progression remain largely unknown. TNFalpha has been implicated as an important mediator of NAFLD progression. TNF-mediated liver injury mainly occurs via TNFR1. We therefore investigated the role of TNFR1 signaling for liver steatosis, insulin resistance and fibrosis in NAFLD mice.
Method: HuTNFR1-k/i mice were fed with a high-fat, carbohydrate-rich diet for 32 and treated with anti-TNFR1 or control antibody for 8 weeks. Liver tissues were analysed for lipogenesis, MAP kinase pathway, insulin signaling as well as for NAFLD activity and fibrosis.
Results: Compared to control treatment, TNFR1 inhibition reduced the expression and activation of the transcription-factor SREBP1 and downstream target genes of lipogenesis, which was associated with reduced liver steatosis. NAFLD mice treated with TNFR1 antibody showed also reduced activation of the MAP kinase MKK7 and its target JNK which resulted in decreased insulin receptor substrate (IRS)-1 activation, thus restoring insulin sensitivity. Since SREBP1 transcriptionally repress IRS-2, which contributes to insulin resistance, we additionally analysed IRS-2 expression. We found enhanced IRS-2 mRNA expression in liver tissues from anti-TNFR1 compared to control antibody treated mice. Moreover, TNFR1 inhibition significantly decreased NAFLD activity, liver injury and fibrosis compared to control treatment of NAFLD mice.
Conclusion: The results implicate an important role of TNFR1 signaling for development of steatosis, insulin resistance and fibrotic liver injury in NAFLD. TNFR1 inhibition might therefore represent a promising therapy for fibrotic NASH.

SAT004

Obesity alters the partitioning of glycerol metabolism pathways in NAFLD

Jack Carruthers[1], Patricia Nunes[1], Paul Driscoll[2], Jim Ellis[2], James Macrae[2], Massimo Pinzani[3], Dimitrios Anastasiou[1]. [1]*Francis Crick Institute, Cancer Metabolism Laboratory, London, United Kingdom;* [2]*Francis Crick Institute, Metabolomics Science Technology Platform, London, United Kingdom;* [3]*University College London, Institute of Immunity and Transplantation, United Kingdom*
Email: jack.carruthers@crick.ac.uk

Background and aims: Circulating glycerol can originate from the diet and adipose tissue lipolysis, amongst other sources. Glycerol is metabolised by the liver and kidney, both of which express glycerol kinase, an enzyme that phosphorylates glycerol to produce glycerol 3-phosphate. Glycerol is a substrate for gluconeogenesis (GNG) and glycolysis, and can form the backbone of lipids such as triglycerides (TAG). It has been shown that glycerol supports augmented glucose production in type 2 diabetes and provides carbons for circulating TAGs in patients with non-alcoholic fatty liver disease (NAFLD). It is still unclear how glycerol metabolism is partitioned into downstream pathways as these pathological conditions develop. In this study we investigated how risk factors for NAFLD, such as age and obesity, affect the use of glycerol in hepatic glucose and lipid synthetic pathways whilst promoting NAFLD.
Method: C57BL/6J mice were fed either normal chow (NC) or a Western diet (WD) for 12, 25 or 50 weeks. Visceral adiposity and hepatic TAG content were evaluated by magnetic resonance imaging (MRI) and magnetic resonance spectroscopy (MRS). Hepatic insulin signalling was assessed by Western blotting. To measure the capacity of these animals to convert exogenous glycerol into glucose, glycerol tolerance tests were used. To understand whole-body and hepatic glycerol metabolism, mice were infused with ^{13}C-glycerol and ^{13}C-glucose tracers followed by metabolic analysis using gas chromatography-mass spectrometry (GC-MS) and nuclear magnetic resonance (NMR). Mass-isotopomer distribution analysis was applied to estimate the contribution of glycerol to GNG and TAG esterification.
Results: As expected, WD-fed mice had greater visceral adiposity and higher intrahepatic TAG content at all time points, consistent with the development of NAFLD. Whole-body glycerol turnover increased with age, particularly in WD-fed mice. After 50 weeks, WD-fed mice showed augmented glycaemia in response to a glycerol bolus compared to NC-fed animals. Also at 50 weeks, stable isotope tracing revealed that glycerol to glucose flux was higher in WD- than NC-fed mice. The flux of glycerol carbons into the TAG backbone was higher in WD- than NC-fed mice peaking after 25-weeks of diet. The proportionate contribution of glycerol to TAG was decreased in WD-fed animals. The transition of glycerol flux from TAG esterification to glucose production coincides with the development of changes in hepatic insulin sigalling as judged by decreased PI3 K signaling.
Conclusion: Chronic exposure to a WD alters the partitioning of glycerol from TAG to glucose. This transition coincides with the onset of alterations in hepatic insulin signalling. These observations present the possibility that glycerol metabolism could be targeted to alter the pathogenesis of obesity-related NAFLD and insulin resistance.

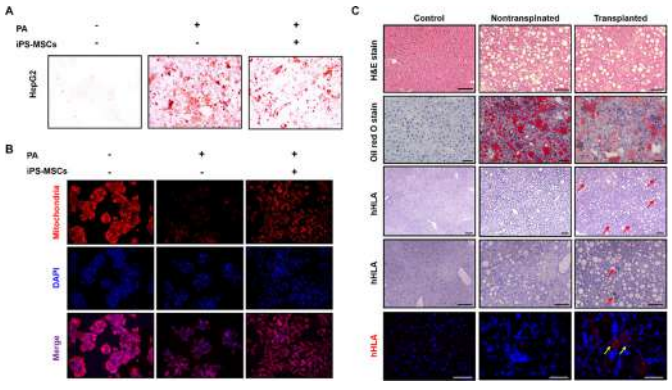
Human induced pluripotent stem cell-derived mesenchymal stem cells ameliorates mitochondrial oxidative dysfunction in non-alcoholic fatty liver disease

Min Kyung Park[1], Yun Bin Lee[1], Se-Mi Jung[1], Yoo-Wook Kwon[2], Jung-Hwan Yoon[1]. [1]*Seoul National University College of Medicine, Department of Internal Medicine and Liver Research Institute, Seoul, Korea, Rep. of South;* [2]*Seoul National University Hospital, Biomedical Research Institute, Seoul, Korea, Rep. of South*
Email: yblee@snu.ac.kr

Background and aims: Non-alcoholic fatty liver disease (NAFLD) is one of the most common chronic liver diseases worldwide, but its pathophysiology is not fully understood due to the complexity of the mechanisms involved in the disease. Moreover, pharmacological therapy for NAFLD is not yet available. We investigated therapeutic potential of induced pluripotent stem cell-derived mesenchymal stem cells (iPS-MSCs) on hepatic steatosis and mitochondrial oxidative function.

Method: HepG2 cells were treated with palmitic acid (PA) and then co-cultured with iPS-MSCs. Intracellular lipid accumulation was measured by oil red O staining. The mitochondrial oxidative function was assessed by quantifying mitochondrial mass and measuring reactive oxygen species (ROS) and activity of antioxidant enzymes. C57BL/6 mice were chronically fed with choline-deficient, L-amino acid-defined, high-fat diet (CDAHFD). At week 20, mice were injected with either phosphate-buffered saline (nontransplanted) or iPS-MSCs (transplanted; 1×10^6 cells). Four weeks later, liver histology and function were assessed.

Results: PA-induced intracellular lipid accumulation was attenuated when co-cultured with iPS-MSCs (Figure 1A). The functional mitochondrial mass was reduced by PA treatment and then was restored following co-culture with iPS-MSCs (Figure 1B). Increased cellular ROS production by PA treatment was attenuated after co-culture with iPS-MSCs. The activity of superoxide dismutases (SODs) and the ratio of reduced/oxidized glutathione were decreased by PA treatment and were restored by co-culture with iPS-MSCs. After infusion of iPS-MSCs, a successful engraftment of transplanted stem cell was confirmed, leading to amelioration of severe hepatic steatosis in CDAHFD-fed mice (Figure 1C). Decreased mitochondrial DNA content in CDAHFD-fed mice was reinstated to near-control level after transplantation of iPS-MSCs. Augmented hepatic ROS accumulation caused by CDAHFD was attenuated after transplantation of iPS-MSCs with dynamic changes in the activity of SODs and the ratio of glutathione.



Conclusion: Hepatic steatosis and mitochondrial oxidative dysfunction in NAFLD can be ameliorated by transplantation of iPS-MSCs. Our study findings suggest the therapeutic potential of iPS-MSCs in NAFLD and help understanding alterations in hepatic lipid metabolism, which may be restored by iPS-MSCs transplantation.

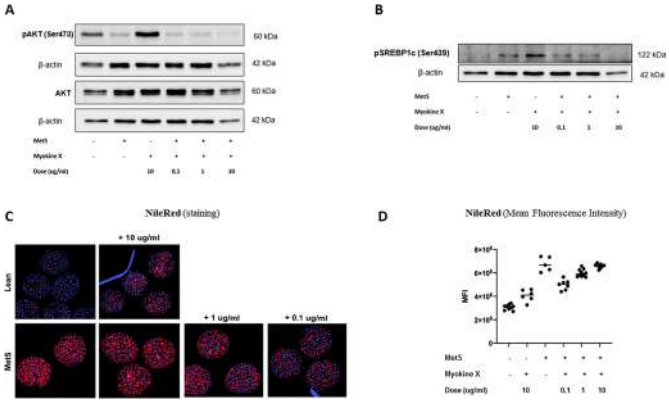
Skeletal muscle-derived myokine affects insulin sensitivity and lipogenesis in a human hepatocyte spheroid model

Jean-Baptiste Potier[1], Achilleas Fardellas[2], Aurore Dumond[1], Myriam Aouadi[2], Karim Bouzakri[1]. [1]*Centre européen d'étude du Diabète, Université de Strasbourg, Strasbourg, France;* [2]*Karolinska Institutet, Centre for Infectious Medicine, Department of Medicine, Huddinge, Sweden*
Email: j.potier@ceed-diabete.org

Background and aims: Inter-organ crosstalk has recently emerged as a crucial aspect of body homeostasis, especially in metabolic diseases such as type 2 diabetes (T2D) and NAFLD. Skeletal muscle is highly implied in this crosstalk, through the secretion of specifics cytokines called myokines. Among those, our laboratory has focused on the myokine X (MyoX). Due to our previous results on the prevention of diabetes and to the pathophysiological link between this disease and NAFLD, we chose to investigate the effect of the MyoX on the liver. Primary human hepatocytes (PHH) spheroids, the gold standard model for the *in-vitro* study of liver diseases, were used for our experiments.

Method: PHH spheroids were cultured in lean and metabolic syndrome (MetS) conditions treated, or not, with different concentrations of MyoX: 0.1, 1 and 10 μg/ml. Spheroids were then stimulated with insulin and protein lysates were collected. Effects of MyoX on the expression of proteins related to glucose (Akt, ERK1/2, GLUT2) and lipid (SREBP1c, FAS, CPT1A) metabolism, two pathways implied in NAFLD development, were assayed by western blot. Furthermore, Nile Red staining was performed for the measurement of triglyceride accumulation.

Results: Concerning glucose metabolism, noticeable effects were observed for the phosphorylation of Akt, which was stronger at a dose of 10 μg/ml in lean condition, suggesting that the MyoX might enhance the intensity of the insulin downstream. Likewise, in the same condition, the slight increase in triglyceride accumulation, observed with the Nile Red staining, could be explained by an insulin-dependent *de novo* lipogenesis mechanism confirmed by the increase of SREBP1c phosphorylation (an insulin-dependent transcription factor responsible for the storage of fatty acid as triglycerides). Concerning MetS conditions, beneficial effects were observed at the lower dose of MyoX, with a decrease in triglyceride amount related to the reduction of SREBP1c phosphorylation, associated with no detrimental effect on p-Akt.



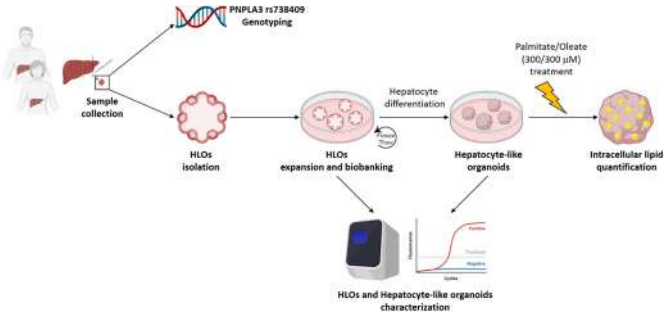
Conclusion: Taken together, our analysis suggest that high doses of MyoX might act as a sensitizer and exacerbates the effects of insulin in PHH in lean condition, enhancing the *de novo* lipogenesis. In MetS condition, potential beneficial effects were noticed for the lower dose of MyoX, suggesting that our protein might be of an interest for the prevention of NAFLD. Further studies should be performed to determine the optimal dose of the myokine.

SAT007

Patient-derived liver organoids to reveal PNPLA3 I148M role in Non-Alcoholic Fatty Liver Disease

Elia Casirati[1], Alessandro Cherubini[2], Melissa Tomasi[2], Ilaria Marini[2], Daniele Prati[2], Daniele Dondossola[3], Luca Valenti[1,2]. *[1]Università degli Studi di Milano, Department of Pathophysiology and Transplantation, Italy; [2]Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Transfusion Medicine and Hematology, Milano, Italy; [3]Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, General and Liver Transplant Sugery Unit, Milan, Italy*
Email: e.casirati@gmail.com

Background and aims: Non-alcoholic fatty liver disease (NAFLD) heritability is estimated to be within 25–75% and *PNPLA3* rs738409 C > G, encoding for the p.I148M protein variant, accounts for a large fraction of disease susceptibility. The p.I148M variant promotes intrahepatic lipid accumulation and progression to advanced fibrosis and hepatocellular carcinoma. A comprehensive human model to study the role and mechanisms of genetic variability in liver disease is still lacking. Aim of this study was therefore to generate patient-derived human liver organoids (HLOs) to clarify the impact and role of PNPLA3 variation in NAFLD onset and progression.
Method: We isolated HLOs from 14 surgical resection specimens. *PNPLA3* rs738409 was genotyped by 5′ nuclease Taqman assays. Single cells were embedded in Matrigel and a complete organoid medium to instruct signaling cues crucial for the growth of liver epithelial cells. To model fatty liver, HLOs were differentiated toward a hepatocyte-like phenotype (modified from Broutier L, Nat Protoc 2016) and exposed to free fatty acids (FFAs, 300/300 uM palmitic/oleic acid) for 5 days.
Results: We successfully isolated, grew for >150 days and biobanked organoids with different *PNPLA3* p.I148M genotypes (7, 1% were GG, 42, 8% were CG, 50, 1% were CC). HLOs showed a monolayer epithelial phenotype with a well-defined apical-basal polarity surrounding a central hollow lumen, and a cholangiocyte-like phenotype expressing KRT19 and SOX9. Differentiated HLOs showed high levels of hepatocyte markers mRNA (albumin, CYP2D6 and ApoA1, Fold Increase 85.8, p = 0, 0307; 1.27, p = ns and 324.8, p = 0, 0035 respectively; n = 5), while the epithelial staminal marker LGR5 was suppressed. The persistent expression of KRT19 suggests the presence of both hepatocellular and cholangiocyte populations, both involved in fibrogenesis. HLOs showed a high expression of PNPLA3 after isolation, which was maintained after hepatocyte differentiation (0.41 ± 0.1 fold compared to liver tissue). When exposed to FFAs, differentiated organoids showed an accumulation of lipid droplets, as examined by Oil Red O (ORO) staining (2.3 fold increase in organoid exposed vs. non-exposed).



Conclusion: We isolated, characterized and biobanked HLOs form 14 patients with different *PNPLA3* genotypes, obtaining a 3D in vitro model to investigate NAFLD within a personalized medicine framework with high translational potential.

SAT008

Transcriptomic analysis confirms that PNPLA3 I148M variant is associated with impaired mitochondrial function and antioxidant response in 3D cultured human hepatic stellate cells and liver tissue of patients with NAFLD

Elisabetta Caon[1], Maria Martins[1], Kessarin Thanapirom[1], Ana Levi[1], Walid Al-Akkad[1], Jeries Abu-Hanna[2], Pernille Juhl[3], Ida Villesen[3], Diana Leeming[3], Guido Alessandro Baselli[4], Jan-Willem Taanman[5], Michele Vacca[6], Luca Valenti[4], Stefano Romeo[7], Giuseppe Mazza[1], Massimo Pinzani[1], Krista Rombouts[1]. *[1]University College of London, Royal Free Campus, Division of Medicine, Institute for Liver and Digestive Health, London, United Kingdom; [2]University College of London, Royal Free Campus, Research Department of Surgical Biotechnology, Division of Surgery and Interventional Science, LONDON, United Kingdom; [3]Nordic Bioscience, Biomarkers and Research A/S, Herley, Denmark; [4]Universita' degli Studi di Milano, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Departmente of Pathophysiology and Transplantation, Milan, Italy; [5]University College of London, Queen Square Institute of Neurology, Department of Clinical and Movement Neurosciences, London, United Kingdom; [6]University of Bari "Aldo Moro", Clinica Medica "Frugoni", Interdisciplinary Department of Medicine, Bari, Italy; [7]University of Gothenburg, Institute of Medicine, Sahlgrenska Academy, Wllenberg Laboratory, Department of Molecular and Clinical Medicine, Gothenburg, Sweden*
Email: e.caon@ucl.ac.uk

Background and aims: We established that the I148M variant of the patatin-like phospholipase domain-containing 3 (PNPLA3) protein, a key risk locus for fibrogenic progression of chronic liver disease, is associated with mitochondrial dysfunction and defective antioxidant response. The antifibrotic Nuclear Receptor 4A1 (NR4A1) is a key element in mitochondrial metabolism and antioxidant response. By employing transcriptomic analysis we investigated the impact of *PNPLA3* I148M mutation on mitochondrial dysfunction, antioxidant response and NR4A1 expression in human hepatic stellate cells (hHSCs) and in an established cohort of patients with NAFLD. 3D culture models were employed to further validate the results.
Method: RNAseq was performed on primary hHSC genotyped for *PNPLA3* (I148M) variants CG/GG and cultured on plastic. Biopsies from livers of 125 obese individuals classified as normal liver/simple steatosis/severe NAFLD were genotyped for *PNPLA3* (I148M) variants CG/GG and RNAseq was performed. Cell behaviour of hHSCs CC/CG for *PNPLA3* variants was evaluated in 3D decellularized scaffolds from human healthy and cirrhotic liver with/without TGFB1 treatment. QRT-PCR, Western blot, NanoString, PRO-C1/PRO-C3 quantification and cytochrome-c-oxidase activity (COX) assay was performed.
Results: Transcriptomic analysis on liver biopsies genotyped *PNPLA3* CC/CG, where the *PNPLA3* variant had previously been identified as major driver of NAFLD disease severity and gene expression variability, were compared with transcriptomic data of 2D cultured primary hHSCs *PNPLA3* CC/CG genotyped. The comparison highlighted shared dysregulated pathways related to mitochondrial function, antioxidant response and ECM remodelling, the activated upstream regulator TGFB1 and the target gene NR4A1. Analogous pathways were dysregulated in the analysis of a 700 gene panel in hHSCs CC/CG for *PNPLA3* variants cultured in a 3D model of healthy and cirrhotic scaffolds. In particular, the "Oxidative stress" pathway was markedly upregulated by cirrhotic ECM compared to healthy ECM, and PRO-C1/PRO-C3 secretion was increased by TGFB1. The 3D model was used for further analysis: COX activity and expression, ROS scavenger CYGB gene expression and NRF2-repressor KEAP1 protein were significantly downregulated in CG-PNPLA3 hHSCs compared to CC-PNPLA3 hHSCs and in cirrhotic scaffolds. NR4A1 gene and protein expression were downregulated in CG-PNPLA3 hHSCs vs CC-PNPLA3 hHSCs in healthy scaffolds and by TGFB1 in cirrhotic scaffolds.
Conclusion: The PNPLA3 I148M variant in hHSCs is linked to disrupted mitochondrial function and antioxidant response. NR4A1, a TGFB1-regulated antifibrotic gene involved in mitochondrial

metabolism, is downregulated in CG-PNPLA3 hHSCs. Importantly, these defects were maximized in a 3D model recapitulating the ECM microenvironment of cirrhotic human liver.

HTD1801 (berberbine ursodeoxycholate), a unique single molecule with multiple beneficial effects in metabolic and liver diseases

Meng Yu[1], Ru Bai[1], Xinxiang Fu[1], Zhaobin Chen[1], Weijian Liu[1], Leigh MacConell[1]. [1]*HighTide Therapeutics USA, LLC, United States*
Email: lmacconell@hightidetx.com

Background and aims: A number of chronic liver diseases remain without adequate therapy and may require treatments with multiple mechanisms of action. Ursodeoxycholic acid (UDCA) has been shown to have beneficial effects in some liver diseases primarily through choleretic and anti-inflammatory effects. Berberine (BBR) has a long history of use in traditional medicine, emerging as a novel therapeutic with metabolic, antimicrobial, and anti-inflammatory effects. HTD1801 is a new molecular entity consisting of a salt of UDCA and BBR (1:1 stoichiometry), offering the benefits of its parent compounds and novel effects derived from its unique molecular structure. It has been shown to be beneficial in human studies of hyperlipidemia, NASH and PSC.
Method: The physico-chemical properties of HTD1801, BBR and UDCA were compared via x-ray diffraction, Fourier transform infrared spectroscopy, melting point analysis, LogD evaluation, and solubility analysis using fasted and fed state simulated intestinal fluid (FaSSIF and FeSSIF). Efficacy was evaluated in a preclinical NASH model (golden hamsters fed a high fat diet, 8/group) after 6 weeks of daily treatment of HTD1801, UDCA, or BBR-chloride (BBR-Cl).
Results: The crystal form of HTD1801 is a hemi-nonahydrate with a honeycomb-like 3-D structure distinct from BBR-Cl and UDCA. HTD1801 has a lower melting point (~120 °C) compared to BBR-Cl (204–206 °C) and UDCA (200–205 °C). LogD profiles were substantially enhanced for HTD1801 across the pH range for BBR and at pH 6.5 for UDCA vs BBR-Cl or UDCA alone. Dissolution in FaSSIF showed peak concentrations of BBR and UDCA from HTD1801 of ~0.6–0.7 mg/ml in contrast to <0.2 mg/ml for BBR-Cl and UDCA alone. Dissolution in FeSSIF showed peak concentrations of BBR and UDCA from HTD1801 of ~0.3–0.35 mg/ml in contrast to <0.15 mg/ml for BBR-Cl and UDCA alone. Studies in the NASH hamster model showed that HTD1801 at 200 mg/kg for 6 weeks significantly reduced ALT, AST, bilirubin, LDL-c and triglycerides (Table 1). Furthermore, significant histologic improvements were observed in Fibrosis and the NAS with HTD1801. In contrast, UDCA or BBR alone generally resulted in minimal changes in biochemical or histological parameters.

Table 1: Biochemical and Histologic Changes in Hamster Model of NASH After 6 Weeks of Treatment

Group	ALT (U/L)	AST (U/L)	Total Bilirubin (μmol/L)	LDL-c (mmol/L)	Triglycerides (mmol/L)	Fibrosis Score	NAFLD Activity Score (NAS)
Normal Control Group	86.1 ±15.4	66.0 ±2.9	0.8±0.1	1.4 ±0.2	1.4 ±0.2	0.1 ±0.1	0.5 ±0.3
Model Control Group	1334.7 ±133.0##	270.6 ±25.3##	3.2±0.9##	7.9 ±1.0##	3.6 ±0.6##	2.0 ±0.2##	7.1 ±0.4##
HTD1801 200 mg/kg	96.6 ±17.5**	66.4 ±4.6**	0.8±0.1**	1.3 ±0.2**	2.1 ±0.4**	1.1 ±0.2**	2.5 ±0.7**
UDCA 107.8 mg/kg	934.1 ±151.3	264.5 ±73.8	1.7 ±0.6*	3.8 ±0.5**	2.2 ±0.2**	1.8 ±0.2	5.3 ±0.8*
BBR-Cl 102.2 mg/kg	995.5 ±107.0	232.0 ±26.0	2.2±0.5	6.5 ±1.1	3.7 ±0.4	2.1±0.1	6.3±0.3

Data are Mean (SE).
#P<0.05, ##P<0.01 vs the normal control group.
*P<0.05, **P<0.01 vs the model control group.

Conclusion: These data show that HTD1801 has physico-chemical properties distinct from UDCA or BBR that provide improved dissolution and lipophilicity characteristics which may result in the beneficial effects seen in fibroinflammatory liver diseases.

SAT010

Metabolic, biochemical, histopathological and transcriptomic effects of long-acting FGF21 analogue in the GAN diet-induced obese and biopsy-confirmed mouse model of NASH

Malte H. Nielsen[1,2], Denise Oró[1], Henrik B. Hansen[1], Matthew Gillum[2], Michael Feigh[1]. [1]*Gubra, Hørsholm, Denmark;* [2]*University of Copenhagen, CBMR, Kbh N, Denmark*
Email: mni@gubra.dk

Background and aims: Fibroblast growth factor 21 (FGF21) plays a central role in energy, lipid and glucose metabolism and has been demonstrated to reduce hepatic steatosis, inflammation and fibrosis in rodent models of NASH. The long-acting FGF21 analogue efruxifermin has in a recent phase 2 clinical trial (BALANCED) demonstrated promising efficacy for both NASH resolution and improvement in fibrosis stage as compared to placebo controls (Harrison et al. Nature Medicine, 2021). The present study aimed to evaluate the metabolic, biochemical and histopathological effects of the long-acting FGF21 analogue PF-05231023 in the GAN (Gubra-Amylin NASH) diet-induced obese (DIO) mouse model of NASH with hepatic fibrosis.
Method: Male C57BL/6J mice were fed the GAN diet high in fat, fructose and cholesterol for 34 weeks prior to study start. Only animals with liver biopsy-confirmed NAFLD Activity Score (NAS) ≥5 and fibrosis (stage ≥F1) were included and stratified into treatment groups. DIO-NASH mice received (SC, BIW) vehicle (n = 14) or PF-05231023 (10 mg/kg, n = 14) for 12 weeks. Vehicle-dosed chow-fed C57BL/6J mice (n = 6) served as lean healthy controls. Pre-to-post liver biopsy histopathological scoring was performed for within-subject evaluation of NAS and Fibrosis Stage. Terminal quantitative liver histology, liver whole-transcriptome analysis, blood and liver biochemistry were assessed.
Results: The long-acting FGF21 analogue induced a body weight loss of approx. 8% from baseline and reduced hepatomegaly, plasma transaminases as well as plasma/liver lipids (total cholesterol, triglycerides)as compared to vehicle-treated animals. Notably, PF-05231023 treatment demonstrated ≥2 point significant improvement in NAS and 1-point significant improvement in Fibrosis Stage. Therapeutic effects of PF-05231023 were supported by reduced quantitative histological markers of steatosis (lipids, hepatocytes with lipid droplets) and inflammation (number of inflammatory foci, galectin-3). FGF21 did not improve histomorphometry markers of fibrosis (PSR, collagen 1a1), albeit a marker for activated stellate cells (α-SMA) was significantly reduced, suggesting attenuation of fibrogenesis activity. Finally, PF-05231023 improved NASH-associated transcriptome signatures, including lowered expression of hepatic genes associated with inflammation and fibrogenesis.
Conclusion: Long-acting FGF21 analogue PF-05231023 improved metabolic, biochemical and liver histological markers of steatosis, inflammation and fibrogenesis in biopsy-confirmed DIO-NASH mice. Consistent with clinical findings, PF-05231023 improved NAS and Fibrosis Stage. These findings further validate clinical translatability of the GAN DIO-NASH mouse model.

SAT011

NAFLD-induced encephalopathy is associated with low-grade brain tissue hypoxia and inflammation, as well as cerebrovascular, glial, metabolic and behavioural alterations

Anna Hadjihambi[1,2,3], Christos Konstantinou[2,3], Jan Klohs[4,5], Patrick Hosford[6], Adrien Le Guennec[7], I. Jane Cox[2,3], Rajiv Jalan[8], Salvatore Lecca[9], Chris Donnelly[1,10], Luc Pellerin[1,11]. *[1]UNIL, Department of Biomedical Sciences, Lausanne, Switzerland; [2]Foundation For Liver Research, The Roger Williams Institute of Hepatology, London, United Kingdom; [3]KCL, Faculty of Life Sciences and Medicine, United Kingdom; [4]University of Zurich and ETH Zurich, Institute for Biomedical Engineering, Switzerland; [5]University of Zurich and ETH Zurich, Neuroscience Centre Zurich, Switzerland; [6]University College London, Neuroscience, Physiology and Pharmacology, United Kingdom; [7]KCL, NMR Facility, United Kingdom; [8]UCL, Institute for Liver and Digestive Health, United Kingdom; [9]UNIL, The Department of Fundamental Neuroscience, Switzerland; [10]UNIL, Institute of Sports Science, Switzerland; [11]Université et CHU de Poitiers, Inserm U1082, France*
Email: ucbthad@ucl.ac.uk

Background and aims: Over the last decade, non-alcoholic fatty liver disease (NAFLD) has become increasingly known as a multisystem disease, with its clinical burden not only confined to liver-related morbidity and mortality. Indeed, the most common liver-related complication of NAFLD over a long period of follow-up is encephalopathy. To confirm this, using a mouse model of NAFLD, we investigated alterations in cerebral physiology, metabolism and behaviour.

Method: Behavioural tests were performed in mice (C57BL/6) following 16 weeks of control diet or high fat diet+high fructose/glucose in water (HFDHF/HG). Cerebral blood volume (CBV; indicator of vascular density), brain tissue oxygenation at baseline and in response to systemic hypercapnia (10% CO_2) were monitored under anaesthesia by optoacoustic tomography and optical fluorescence. Cerebral blood flow (CBF) was measured via arterial spin labelling MRI and blood pressure [BP] was monitored via a catheter under anaesthesia. Neuronal activity was assessed by *in vivo* electrophysiology. Cortical mitochondrial respiratory capacities (via oxygen consumption) and brain metabolite and lipid concentrations were measured by high-resolution respirometry and NMR spectroscopy respectively. Meso scale discovery and qPCR were used to evaluate plasma and cortical cytokines. Brain inflammation was further assessed by microglial (Iba-1) and astrocyte (GFAP) immunofluorescence. Liver steatosis was confirmed by histology.

Results: Mice with NAFLD exhibited: an anxiety and depression-related behaviour, but preserved learning and memory lower brain oxygenation attributed to the decreased CBV, brain inflammation, and cortical microglial and astrocytic alterations (increased number, % area covered and volume of cells), which led to elevated oxygen consumption increased lipid concentrations, but a decrease in some metabolites preserved cerebrovascular reactivity, neuronal activity and CBF compensated by the elevated BP.

Conclusion: This study provides evidence indicating a key role of NAFLD in inducing brain dysfunction likely due to the development of low-grade brain tissue hypoxia and inflammation, as well as cerebrovascular, glial, metabolic and behavioural alterations. Such chronic effects are expected to worsen with disease progression, leading to a NAFLD-induced encephalopathy, while increasing patients' risk for neurodegenerative conditions, such as Alzheimer's disease, that share the above pathophysiological mechanisms.

Targeted metabolomics reveals alterations in one-carbon metabolism in NAFLD patients

Mikkel Werge[1], Adrian McCann[2], Elisabeth Galsgaard[3], Dorte Holst[3], Anne Bugge[3], Lise Lotte Gluud[1]. *[1]Copenhagen University Hospital Hvidovre, Gastro Unit, Denmark; [2]Bevital AS, Norway; [3]Novo Nordisk A/S-site Måløv, Måløv, Denmark*
Email: mikkel.parsberg.werge@regionh.dk

Background and aims: One-Carbon Metabolism (OCM), represents the convergence of numerous metabolic pathways including homocysteine metabolism, glutathione biosynthesis, folate and methionine cycles, transsulphuration pathway, and the choline oxidation pathway. Several mechanisms such as hepatic lipid homeostasis and oxidative stress may link OCM to non-alcoholic fatty liver disease (NAFLD). We aimed to investigate biomarkers and related B-vitamin cofactors coupled to OCM in NAFLD.

Method: This prospective study included 100 patients with histologically verified NAFLD and 50 age and sex matched healthy controls. Targeted metabolomic analyses were performed on fasting plasma samples using tandem mass spectrometry paired with gas or liquid chromatography, or microbiological assay to measure B-vitamin cofactors and metabolites relevant to OCM and glutathione production.
RNA-sequencing was performed on 18 NAFLD liver biopsies with F0 to F4 fibrosis and 6 controls to measure expression levels of cystathionine β-synthase (CBS) and cystathionine γ-lyase (CSE).
Results: The included patients (50% with type 2 diabetes) had NAFLD with fibrosis score of F0 (n = 26), F1 (n = 25), F2 (n = 20), F3 (n = 12), and F4 (n = 17). Patients with NAFLD had higher BMI than controls (mean: 34.7 vs 26.6, p <0.0001). Cystathionine was increased in patients with advanced fibrosis (p = 0.006) and the GSG index (glutamate/(serine+glycine)), a proxy measure of glutathione synthesis, was increased in patients with NASH compared to those without NASH (p = 0.0003). Plasma concentrations of betaine and pyridoxal 5′-phosphate, the active from of vitamin B6, were lower in NAFLD patients compared to controls. Expression of CSE decreased with increasing fibrosis score (p = 0.0021).

	Controls (n = 50)	NAFLD (n = 100)	p	No NASH (n = 36)	NASH (n = 64)	p
Homocysteine	10.3 ± 3.6	10.8 ± 3.9	0.40	11.2 ± 3.5	10.6 ± 4.1	0.20
Cysteine	296 ± 42	310 ± 3	0.03	312 ± 48	309 ± 38	0.055
Methionine	27.1 ± 5.8	26.8 ± 3.9	0.71	27.4 ± 7.4	26.5 ± 5.1	0.89
Serine	118 ± 22	103 ± 21	$5.1*10^{-5}$	108 ± 20	100 ± 21	0.94
Glycine	273 ± 78	215 ± 53	$5.7*10^{-7}$	238 ± 54	208 ± 48	0.0009
Cystathionine	0.40 ± 0.36	0.56 ± 0.59	0.003	0.63 ± 0.59	0.52 ± 0.59	0.24
Glutamate	42.9 ± 17.5	87.1 ± 37.7	$5.1*10^{-15}$	74.1 ± 28.7	94.4 ± 40.3	0.011
GSG index	0.11 ± 0.05	0.29 ± 0.13	$7.0*10^{-17}$	0.23 ± 0.10	0.32 ± 0.14	0.0003
Choline	8.1 ± 1.4	8.3 ± 2.4	0.89	9.1 ± 2.4	7.8 ± 2.3	0.0073
Betaine	37.2 ± 9.5	31.8 ± 11.6	0.0003	34.7 ± 14.7	30.2 ± 9.2	0.22
Dimethylglycine	3.8 ± 1.1	4.8 ± 2.3	0.047	5.5 ± 2.7	4.4 ± 1.9	0.077
Pyridoxal 5′-phosphate	100.2 ± 91.5	50.8 ± 32.2	$4.6*10^{-8}$	52.2 ± 31.0	50.0 ± 33.1	0.68

Conclusion: The results suggest demand for metabolites central to OCM may be altered in NAFLD. This could be driven by increased need for glutathione and pyridoxal 5′-phosphate in response to oxidative stress and inflammation, as well as betaine for lipid metabolism in NAFLD patients. Expression of enzymes regulating OCM may be affected by advancing fibrosis.

SAT014

Metabolic NAFLD subtypes align with cardiovascular and genetic risk factors

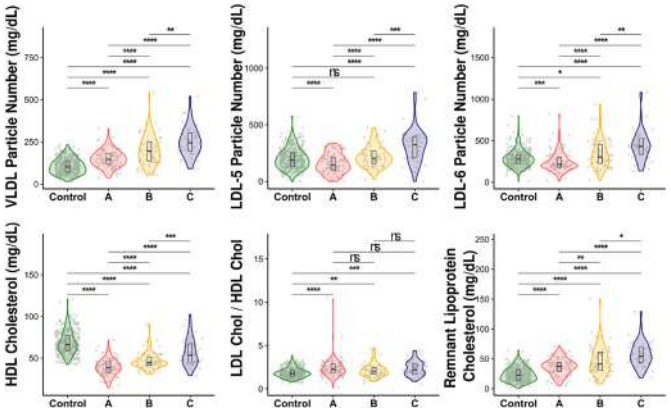
Background and aims: We previously identified subsets of non-alcoholic fatty liver disease (NAFLD) patients with different metabolic phenotypes. Here we align metabolomic signatures with cardiovascular (CV) and genetic risk factors, and lipid lowering medication.
Method: We analyzed serum from an international cohort of 1143 individuals with biopsy-proven NAFLD using mass spectrometry and NMR based metabolomics. We further analyzed the metabolomes of four mouse models with impaired VLDL-triglyceride (TG) secretion (Mat1a-KO, 0.1MCD, Mttp-LKO, Tm6sf2-LKO), and one (Ldlr-/-.Leiden/high fat fed) with normal VLDL-TG secretion.
Results: We identified three metabolic subtypes (A, B, and C; 47%, 27%, and 26% respectively). Subtype A phenocopied the metabolome of mice with impaired VLDL-TG secretion; subtype C phenocopied Ldlr-/-.Leiden mice; subtype B showed an intermediate signature. Percentage of patients with NASH and fibrosis were comparably distributed among subtypes, although subtypes B and C exhibited higher ALT, AST, and GGT levels than subtype A. Serum VLDL-TG levels and secretion were lower among subtype A compared to the subtypes B and C. Subtype A VLDL-TG was independent of steatosis, whereas subtypes B and C showed a curvilinear relationship. Serum TG, cholesterol (Chol), VLDL, small dense $LDL_{5,6}$ and remnant lipoprotein Chol, were lower among subtype A compared to subtypes B and C, while LDL-Chol-to-HDL-Chol ratio was similar. Subtype A associated with the *TM6SF2* NAFLD risk allele, lower percent of patients with intermediate/high CV disease risk (Framingham risk score ≥10% at 10 years), and higher percent of patients with lipid lowering medication.



Conclusion: Based on these results, we conclude that NAFLD subtype A stems from multiple nutritional and environmental factors that, acting on a susceptible genetic background, converge in reduced synthesis and export of VLDL-TG and the circulation levels of VLDL-TG exhibiting a reduced CV disease risk. This may account for the variation in hepatic *vs.* cardiovascular outcomes, offering novel, clinically relevant, risk stratification.

SAT015

Deletion of ATR in hepatocytes improves NAFLD features by increasing mitochondrial function

Maeva Saroul[1], Pierre Cordier[1], Christelle Kabore[1], Romain Donne[2], Ivan Nemazanyy[3], Fabienne Foufelle[4], Pasacale Bossard[5], Chantal Desdouets[1]. [1]*Team Proliferation Stress and Liver Physiopathology, Centre de Recherche des Cordeliers, INSERM, Sorbonne Université, Université de Paris, Paris, France;* [2]*Icahn School of Medicine at Mount Sinai, The Lujambio lab, Oncological sciences, New York, United States;* [3]*Platform for Metabolic Analyses, Structure Fédérative de Recherche Necker, INSERM US24/CNRS UMS 3633, Paris, France;* [4]*Team Metabolic Diseases, Diabetes and Co-morbidities, Sorbonne Université, Université de Paris, Paris, France;* [5]*Université de Paris, Institut Cochin, INSERM, CNRS, Paris, France*
Email: maeva.saroul@inserm.fr

Background and aims: Chronic diseases such as obesity and diabetes are now considered as a social and economic burden. The liver is a central organ affected by these conditions resulting in a high level of fat accumulation, defined as Non-Alcoholic Fatty Liver Disease (NAFLD). Alarmingly NAFL (steatosis) progresses pejoratively to Non-Alcoholic Steatohepatitis (NASH). NASH has the potential to progress to more severe stages as cirrhosis and hepatocellular carcinoma (HCC). The biological mechanisms underlying NALF/NASH are not entirely understood. In various chronic liver diseases, aberrant DNA Damage Response (DDR) is a hallmark of disease aggravation. In NAFLD, DNA damage are present in human fatty livers and increase with disease progression. We previously showed that fatty hepatocytes division is associated with the activation of the DDR mediated by the kinase ATR. Whether ATR, per se, participates to Non-Alcoholic Fatty Liver Disease remains largely unknown.
Method: We used a hepatic- specific *in vivo* CRISPR/Cas9 approach using AAV vector, to generate ATR^{DHep} mice. C57BL/6J ATR^{DHep} and control (CTR) mice were fed a Choline-Deficient High-Fat Diet (CD-HFD) for 16 and 24 weeks. RNAseq analyses combined with molecular and cellular approaches have been performed on ATR^{DHep} and CTR NAFLD livers. Metabolic parameters have been investigated using Liquid Chromatography associated to Mass-Spectrometry. We also collected data on primary hepatocytes cultures isolated from our NAFLD models.
Results: Unexpectedly, silencing of hepatocyte ATR in murine models of NASH reduced hepatocyte proliferation and cell death. We show, in particular, a decrease in Caspase 8 and cleaved Caspase 3 activities that parallels with a marked increase in *BCL2* expression. We also provide evidence that deletion of hepatic ATR improves fatty acid metabolism by regulating lipogenesis (e.g. *Fas*, *ACC SREBP1C*) and anti-oxidative response (e.g. *NQO1*, *GSTM3*, *HO1*). To go further, we isolated primary hepatocytes from our NAFD mice models to assess the mitochondrial function. ATR deletion led to activation of mitochondrial respiration in steatotic hepatocytes with a partial restoration of mitochondrial capacities, an improvement of basal/maximal respiration, ATP production and attenuation of proton leak. Flux analyses demonstrated also that ATR^{DHep} hepatocytes increase their glycolysis capacities. Finally, we observe in NAFLD primary hepatocytes that ATR deletion increases the anti-oxidative defense against paraquat-induced oxidative stress.
Conclusion: Inhibition of ATR improves NASH features in CD-HFD fed mice, particularly by acting on mitochondrial function. This suggest that ATR might be a potential marker of mitochondrial dysfunction in NAFLD.

Email: monmari@clinic.cat

Background and aims: Tyro3, AXL and MERTK are receptor tyrosine kinases activated by the ligand GAS6. AXL signalling is increased in non-alcoholic steatohepatitis (NASH) patients and promotes fibrosis through activation of hepatic stellate cells and inflammatory macrophages. Recent data shows that bemcentinib reduces experimental NASH by inhibiting AXL signaling and increasing hepatocyte survival through increased Gas6. In recent years the role of the innate and adaptive immune system in NASH has gained attention. We aim to determine which immune cells express AXL and how AXL inhibition affects the liver immune profile during NASH. This may provide clues for new NASH-directed therapies.
Method: Mice were fed chow or a high-fat methionine-restricted choline-deficient (HFCD) diet for 8 weeks to induce NASH, receiving daily doses of bemcentinib (3–100 mg/kg) or vehicle by oral gavage for the last two weeks. Hepatic inflammatory and fibrotic gene expression were measured by qPCR. Time-of-flight mass cytometry (CyTOF) was utilized to analyze the expression of more than 40 markers on single cells from dissociated livers. Cells were acquired on the Fluidigm Helios and cell populations were studied using machine learning.
Results: Bemcentinib was effective in reducing expression of fibrogenic genes in HFCD-fed mice at all tested dosages (3–100 mg/kg), and inflammatory gene expression at doses >30 mg/kg. CyTOF analysis revealed that Axl was co-expressed with MERTK in infiltrating macrophages and Kupffer cells, but exclusively expressed in conventional type 2 dendritic cells. Compared to chow animals, NASH strongly reduced the amount of Kupffer cells and increased infiltration of monocytes/macrophages and CD8+ T-cells. Bemcentinib partially rescued NASH-induced loss of Kupffer cells and reduced the proportion of both plasmacytoid dendritic cells and subsets of recruited macrophages. Bemcentinib induced a shift in the composition of the resident and recruited macrophages from $TGFb^{high}$ to $TGFb^{med}$ subgroup with an increased influx of $CX3CR1^{high}$ macrophages, associated with tissue remodelling and anti-inflammatory phenotype. Moreover, bemcentinib enhanced the expression of a subtype of CD8+ tissue resident memory T-cells characterized by the expression of CX3CR1 and $GranzymeB^{high}$ known to promote hepatic stellate cell apoptosis.
Conclusion: Bemcentinib reduces inflammation and fibrosis by inducing a dynamic change in liver macrophages and CD8+T cells subsets from pro-inflammatory towards tissue remodeling and anti-fibrotic phenotypes.

Human Liver Organoids with myeloid lineages model the multi-cellular crosstalk in Non-Alcoholic Steatohepatitis

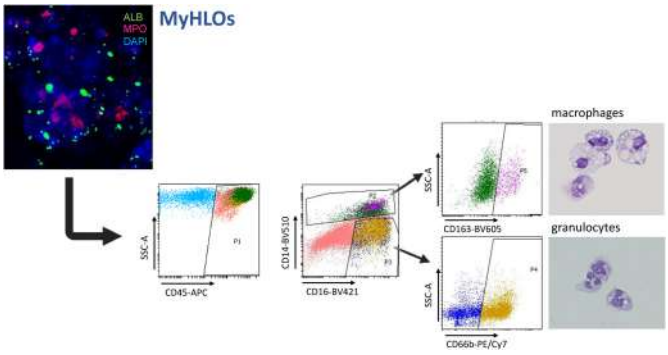
Milad Rezvani[1,2], Kyle Lewis[2], Kentaro Iwasawa[2], Yuqi Cai[2], Yuka Milton[2], Masaki Kimura[2], RanRan Zhang[2], Praneet Chaturvedi[3], Takanori Takebe[2,3,4,5,6]. *[1]Charité Campus Virchow Clinic, Department of Pediatrics, Division of Gastroenterology, Nephrology and Metabolic Medicine, Berlin, Germany; [2]Cincinnati Children's Hospital Medical Center, Department of Pediatrics, Division of Gastroenterology, Hepatology and Nutrition, Cincinnati, United States; [3]Cincinnati Children's Hospital Medical Center, Center for Stem Cell and Organoid Medicine (CuSTOM), Cincinnati, United States; [4]Cincinnati Children's Hospital Medical Center, Division of Developmental Biology, Cincinnati, United States; [5]Yokohama City University Graduate School of Medicine, Department of Regenerative Medicine, Yokohama, Japan; [6]Tokyo Medical and Dental University, Institute of Research, Bunkyo City, Japan*
Email: milad.rezvani@charite.de

Background and aims: Non-alcoholic Steatohepatitis (NASH) is characterized by hepatocyte injury due to lipotoxicity and inflammatory responses elicited by granulocytes and other myeloid immune cells. Developing therapies against NASH requires platforms modeling both processes. We previously described human liver organoids (HLOs) from induced pluripotent stem cells (iPSCs) recapitulating human hepatogenesis. In turn, studies demonstrated myelopoiesis in human fetal livers. We hypothesized that HLOs may recreate the complex fetal liver microenvironment to co-differentiate hepatocytes and myeloid lineages from iPSCs.

Method: We differentiated human iPSCs into gut spheroids *via* endoderm induction using activin A and Matrigel embedding. We analyzed HLOs via qRT-PCR, immunostaining, single-cell RNA sequencing (scRNAseq) and FACS. To generate HLOs with myeloid lineages (MyHLOs), we incorporated combinations of cytokines relevant to the differentiation of neutrophils, monocytes, macrophages, and Kupffer Cells.

Results: scRNAseq data from day 14 cultures revealed mesoderm, ectoderm and an immature hepatocyte population. We also identified a hemogenic endothelial population as putative source of myelopoiesis. We trialed basic myeloid differentiation, added IL-3, followed by GM-CSF and M-CSF, and found abundant macrophages by Giemsa stain. We diversified the myeloid cell subsets using defined cytokine and small molecular cocktails and completed the differentiation protocol with G-CSF. On day 30, we identified *via* Giemsa stain neutrophils, macrophages and their progenitors. We singularized MyHLOs and isolated CD45+CD14-CD16+CD66b+ Neutrophils that phagocytosed at similar levels but migrated faster than primary adult controls. To further assess neutrophil function, we injected MyHLOs into bone marrow-depleted mice modeling sinusoidal obstruction syndrome using Busulfan and Monocrotaline, respectively. Transplanted mice suffered from exacerbated liver injury with neutrophil-infiltrated necrotic foci. Next, we isolated from MyHLOs monocytes that predominantly expressed CD45+CD14+CD16+ with a CD163+ macrophage subset (12%).

Hepatocytes in MyHLOs were immature relative to HLOs by Albumin secretion and CYP3A4 activity. To develop an appropriate NASH model, we defined a hybrid media restoring mature secretory and metabolic function and allowing continued myelopoiesis. We added Palmitic Acid to MyHLOs and detected neutrophil-extracellular traps and reactive oxygen species. This stress response could be alleviated by adding neutrophil or macrophage activation inhibitors, demonstrating cellular crosstalk.



Conclusion: We developed MyHLOs as a novel human liver organoid platform consisting of hepatocytes and syngeneic neutrophils, monocytes and macrophages, which allows to interrogate inter-lineage crosstalk in a human NASH model.

SAT018

Senescence, hand in hand with hepatic iron overload during the progression of NAFLD

Miren Bravo[1], Jorge Simón[1], Naroa Goikoetxea[1], Sofia Lachiondo-Ortega[1], Leire Egia-Mendikute[2], Mate Maus[3], Serena Pelusi[4,5], Josep Amengual[6], Ester Gonzalez-Sanchez[6], Javier Vaquero[6], Ruben Nogueiras[7], Asís Palazón[2], Luca Valenti[4,5], Isabel Fabregat[6], Manuel Serrano[3,8], María Luz Martínez-Chantar[9]. *[1]CIC bioGUNE-Centro de Investigación Cooperativa en Biociencias, CIBERehd, Liver Disease Lab, Derio, Spain; [2]CIC bioGUNE-Centro de Investigación Cooperativa en Biociencias, Cancer Immunology and Immunotherapy Lab, Derio, Spain; [3]IRB Barcelona-Institute for Research in Biomedicine, Barcelona, Spain; [4]Mangiagalli Clinic IRCCS Cà Granda Foundation Ospedale Maggiore Policlinico, Department of Transfusion Medicine and Hematology-Translational Medicine, Milano, Italy; [5]University of Milan, Department of Pathophysiology and Transplantation, Milano, Italy; [6]IDIBELL Institut d'Investigació Biomèdica de Bellvitge, CIBERehd, TGF-β and Cancer Group, L'Hospitalet de Llobregat, Spain; [7]CIMUS, University of Santiago de Compostela-Instituto de Investigación Sanitaria, CIBERobn, Department of Physiology, Santiago de Compostela, Spain; [8]Catalan Institution for Research and Advanced Studies (ICREA); [9]CIC bioGUNE-Centro de Investigación Cooperativa en Biociencias, Liver Disease Lab, Derio, Spain*
Email: mlmartinez@cicbiogune.es

Background and aims: Increased hepatic iron stores are observed in non-alcoholic fatty liver disease (NAFLD) patients. Its disturbed homeostasis may potentiate the onset and progression of the disease, increasing oxidative stress and altering lipid metabolism. Moreover, iron dyshomeostasis has been related to senescence, which in turn is involved in the development of chronic metabolic and inflammatory disorders. In this work, we aimed to study the implication of hepatic iron burden and its interrelationship with senescence in the context of NAFLD.

Method: First, a transcriptomic analysis in obese individuals was corroborated in three different diet-induced NAFLD mice models (high fat diet; choline-deficient high fat diet, and 0.1% methionine and choline-deficient diet, 0.1%MCDD), and in primary hepatocytes treated with methionine and choline-deficient medium (MCDM). Second, male C57BL/6 mice fed with 0.1%MCDD were treated with deferiprone (1 mg/ml), an iron chelator, in drinking water.

Results: In 125 obese individuals (transcriptomic cohort), we found a direct correlation between histological NASH and both circulating and liver mRNA levels of ferritin (Ft). Moreover, tissue damage as well as Ft increase, positively correlated with the senescence marker p21 mRNA hepatic levels. All NAFLD models showed a tight correlation between hepatic Ft and p21 overexpression. In accordance, 0.1% MCDD fed mice, showed significantly increased iron levels both in

liver and serum. Oral treatment with deferiprone significantly improved liver histopathology (steatosis, inflammation, fibrosis and ROS) and normalized liver-to-body weight ratio. A decrease in hepatic CD45 infiltrating cells was also observed by FACS, where B-cell, granulocyte and macrophage counts were diminished; and serum transaminase (ALT and AST) and iron levels were decreased. Primary hepatocytes isolated from treated mice showed reduced mitochondrial ROS generation (MitoSOX) and increased ATP production. Accordingly, succinate dehydrogenase (SDH) activity and fatty acid oxidation (FAO) were increased. *In vitro,* deferiprone avoided lipid accumulation in MCDM treated primary hepatocytes, also increasing FAO and SDH activity, and prevented mitochondrial membrane potential decrease. Finally, iron chelation decreased the expression of p21 both *in vivo* and *in vitro*. In the latter approach, moreover, senescence-associated beta-galactosidase activity was suppressed.
Conclusion: Our results demonstrate that cellular senescence goes hand in hand with hepatic iron accumulation during the progression of NAFLD. We prove that mitochondrial function recovery by deferiprone plays an essential role in ameliorating lipid metabolism, but also modulating immune response. This points out iron chelation as a potential drug for the treatment of NAFLD, a chronic disease with an increasing prevalence worldwide.

SAT019

Increased liver content of omega-3-derived lipid mediators associates with enhanced mitochondrial oxidative phosphorylation, fatty acid oxidation and metabolic efficiency

Cristina López-Vicario[1,2,3], David Sebastián[4,5], Mireia Casulleras[1,3], Marta Duran-Güell[1,3], Roger Flores-Costa[1,3], Ferran Aguilar[3], Juanjo Lozano[2], Ingrid Wei Zhang[1,3], Esther Titos[1,2,6], Jing X Kang[7], Antonio Zorzano[4,5], Makoto Arita[8], Joan Clària[1,2,3,6]. Email: jclaria@clinic.cat

Background and aims: Mitochondrial injury is a common finding in metabolic dysfunction associated fatty liver disease (MAFLD). Since the membrane composition in polyunsaturated fatty acids (PUFA) is a major determinant of mitochondrial function, in the current study we investigated the liver mitochondrial phenotype of transgenic *fat-1* mice, which tissues are endogenously enriched with omega-3-PUFAs under resting conditions and following MAFLD induction. The effects of the omega-3-PUFA docosahexaenoic acid (DHA)-derived specialized pro-resolving mediators (SPM) on tumor necrosis factor (TNF)α-induced hepatocyte mitochondrial damage were also investigated.
Method: Liver mitochondria ultrastructure, oxidative phosphorylation, fatty acid β-oxidation (FAO) and bioenergetic metabolic fluxes were examined by transmission electron microscopy (TEM), high-resolution respirometry, radiolabeled [1-14C] oleate oxidation and $NADH/FADH_2$ production, respectively. Gene and protein expression were determined by real-time PCR and western blot. Mitochondrial injury was assessed in *fat-1* mice (n = 22) and wild-type (WT) counterparts (n = 33) induced to MAFLD by an obesogenic high-fat diet (HFD) or a fibrogenic choline-deficient L-amino acid-defined diet in combination with HFD (CDAHFD). Lipidomic analysis was performed using untargeted and targeted LC-MS/MS approaches.
Results: TEM images revealed that mitochondria of hepatocytes from *fat-1* mice had denser inner matrix with intact cristae and higher mitochondrial aspect ratio than WT mice. *Fat-1* mice also had increased TIM44 levels, enhanced oxygen consumption rate, FAO, insulin sensitivity and energy substrate utilization. Notably, *fat-1* mice were protected against HFD-induced MAFLD and CDAHFD-induced fibrosis. Untargeted lipidomics identified a specific phosphatidylethanolamine DHA-enriched lipid fingerprint in livers from *fat-1* mice. Targeted lipidomics uncovered higher hepatic content of the DHA-derived SPMs resolvin D1 and maresin 1, which in in vitro experiments protected hepatocytes from TNFα-induced mitochondrial dysfunction.
Conclusion: These findings indicate that a tissue environment enriched in DHA-derived SPM derivatives optimizes liver mitochondrial efficiency and protects this organ from MAFLD.

SAT020

Factors associated with increased gut permeability and severity of liver disease in diabetic patients with NAFLD

Roberta Forlano[1], Benjamin H. Mullish[1], Laura Martinez-Gili[1], Jesus Miguens Blanco[1], Tong Liu[1], Evangelos Triantafyllou[1], Charlotte Skinner[1], Mark Thursz[1], Julian Marchesi[1], Pinelopi Manousou[1]. [1]*Imperial College London, Department of Metabolism, Digestion and Reproduction, United Kingdom*
Email: r.forlano@imperial.ac.uk

Background and aims: The disruption of the gut-liver axis represents a crucial step towards the development and progression of non-alcoholic fatty liver disease (NAFLD). We investigated gut permeability and factors associated with it in patients with type-2 diabetes mellitus (T2DM) screened for NAFLD in primary care.
Method: Consecutive patients with T2DM were screened for liver disease by bloods, ultrasound and liver stiffness measurement (LSM). Elevated LSM was defined as LSM>8.1 kPa. Faecal metabolites were measured by liquid chromatography-mass spectrometry. Microbiota composition was analysed by 16 s rRNA gene sequencing, faecal cytokines by immunoassay. To assess gut-permeability, we set up an *in-vitro* model with monolayers of Madin-Darby canine kidney cells, whose permeability was estimated by trans-epithelial electric resistance (TEER) on epithelial volt/ohm meter. Faecal water (FW) was added to the model and TEER was measured across the monolayers at different time points. Experiments were replicated pre-treating FW with a cocktail of protease inhibitors. *E. faecalis* spent medium and phosphate-buffered saline (PBS) were used as positive and negative controls respectively.
Results: Three hundred patients were enrolled: 287 were included; 13 withdrew. Overall, 184 (73%) had NAFLD, 28 (10%) other causes of liver disease and 75 (26%) no liver disease.
Proteobacteria were higher in those with normal liver, while *Firmicutes* and *Bacteroidetes* were less abundant in those with NAFLD and elevated LSM (n = 17) compared to those with normal liver (n = 17). An *Anaeroplasma* ASV was less abundant in NAFLD vs normal liver, while *Monoglobus* ASV was less abundant in NAFLD and elevated LSM vs NAFLD and normal LSM. Moreover, those with NAFLD and elevated LSM showed significantly lower levels of faecal IFN-gamma ($p = 0.02$).
Stool samples were used in the model of gut permeability. Overall, FW from patients with NAFLD and elevated LSM caused the greatest change in the TEER vs those with normal liver. When inhibitors of bacterial proteases were added, the effect of FW on TEER was significantly weaker, suggesting a component of bacterial protease activity. In this sub-group of samples, faecal valerate was significantly lower in those with NAFLD and elevated LSM compared to normal liver (0.28 vs 0.47, $p = 0.007$). Clinically, TEER correlated inversely with BMI ($p = 0.029$) and waist circumference ($p = 0.019$) and positively with LSM ($p = 0.009$) and AST ($p = 0.036$). No association was found with HbA1 or HOMA-index.

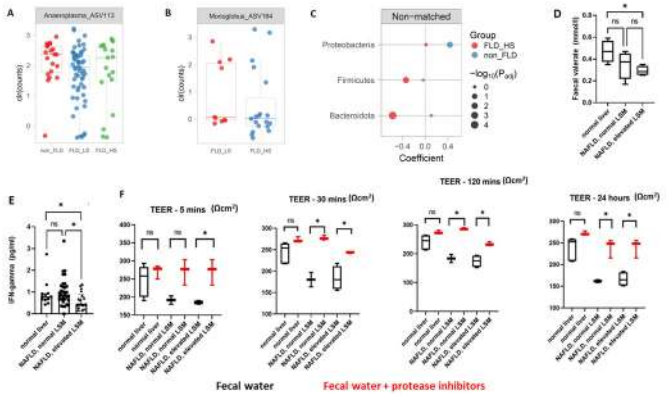

Figure 1. An *Anaeroplasma* ASV was less abundant in NAFLD vs normal liver (Figure A), while *Monoglobus* ASV was less abundant in NAFLD and elevated LSM vs NAFLD and normal LSM (Figure B). *Proteobacteria* were higher in those with normal liver, while *Firmicutes* and *Bacteroidetes* were less abundant in those with NAFLD and elevated LSM compared to those with normal liver (Figure C). Faecal valerate (Figure D) and IFN-gamma (Figure E) were significantly lower in those with NAFLD and significant liver disease. In the in-vitro model of gut permeability, the stool samples from those with liver disease caused the greatest drop in TEER (black) compared to normal and this effect was attenuated when inhibitors of bacterial proteases (red) were included in the sample (Figure F).

Conclusion: Diabetics with a diagnosis of NAFLD have lower abundance of pectin-dependent species as well as a pro-inflammatory milieu in the gut. Moreover, patients with NAFLD may have a leakier gut, which correlates with the severity of liver disease and visceral obesity. Measuring intestinal permeability may identify patients who could benefit the most from intestinal barrier interventions.

Email: nelyl@hotmail.it

Background and aims: Non-alcoholic fatty liver disease (NAFLD) encompasses a wide spectrum of liver damage, and genetic variation accounts for a large fraction of disease variability. Inflammation is involved in the progression of fatty liver to fibrosis and hepatocellular carcinoma (HCC). By performing whole exome sequencing in 72 severe NAFLD patients, defined as advanced fibrosis or HCC, vs 50 local healthy controls plus 33, 123 exome aggregation consortium (ExAC) non-Finnish-Europeans (NFE) individuals, we previously detected increased risk in carriers of interferon regulatory factor (*IRF3*) rs141490768, encoding for the p.A418T variant of the IRF3-CL isoform (OR 38.5, 95%CI 15.2–97; exome-wide adjusted p = 0.015). IRF3 is a transcription factor involved in the induction of inflammatory response. The aim was to validate these data and examine the role of IRF3 across the NAFLD spectrum.

Method: *IRF3* rs141490768 C > T was genotyped in an independent Validation cohort of 241 patients with severe NAFLD, vs. 32, 537 controls from the GnomAD-NFE database without ExAC. In the overall cohort, we tested the enrichment in *IRF3* rare variants (allelic frequency, AF <0.01) by ProxECAT (Proxy External Controls Association Test, accounting for differences in genotyping platforms) between 443 severe NAFLD cases compared to GnomAD-NFE (n = 64, 603).

IRF3/pIRF3 immunohistochemistry (IHC) was performed in 16 NAFLD patients stratified by disease severity.

IRF3 transcriptional activity was assessed in 125 obese individuals severe NAFLD (transcriptomic cohort) by using virtual inference of protein activity by enriched regulon analysis.

Results: We confirmed an enrichment of rs141490768 in the validation (OR 5.84, 95%CI 1.4–24.1; p = 0.044) and in the overall cohort (OR 13.6, 95%CI 6.3–29.5; $p = 1.5 \times 10^{-6}$).

Furthermore, we detected an enrichment in *IRF3* rare variants in patients with severe NAFLD vs. controls (ratio of functional mutations to proxies 7.0 in cases vs 0.3 in controls; $p = 1.2 \times 10^{-7}$).

IHC showed a progressive increase in nuclear pIRF3 staining in both hepatocytes and non-parenchymal cells with NAFLD severity (from normal liver to steatosis to NASH). Consistently, we observed increased expression of transcriptional targets (beta = 0.022 across disease severity; p = 0.013).

By using CRISPR/Cas9 genome editing in human HepG2 hepatoma cells, we generated IRF3-/-, IRF3-CL±, and rs141490768 knock-in clones to study the functional impact of *IRF3* variation on inflammation and fibrogenesis in 3D multilineage spheroids with hepatocytes and stellate cells.

Conclusion: We found an enrichment of *IRF3* rare variants in patients with severe NAFLD vs. controls. IRF3 activity was upregulated across the spectrum of NAFLD. Additional studies are required to uncover the mechanism underpinning predisposition to disease progression in carriers of *IRF3* variants.

SAT022

Sex-dependent hepatoprotective role of IL-22 in NAFLD-related fibrosis

Mohamed Noureldin Hassan Ali Abdelanbi[1], Manuel Flores Molina[1], Geneviève Soucy[2], Vincent Quoc-Huy Trinh[2], Nathalie Bédard[1], Sabrina Mazouz[1], Jessica Dion[1], Sarah Tran[1], Marc Bilodeau[3], Naglaa Shoukry[3]. [1]*Centre de Recherche du Centre hospitalier de l'Université de Montréal (CRCHUM), microbiologie, infectiologie et immunologie, Montreal, Canada;* [2]*Centre de Recherche du Centre hospitalier de l'Université de Montréal (CRCHUM), pathologie et biologie cellulaire, Montreal, Canada;* [3]*Centre de Recherche du Centre hospitalier de l'Université de Montréal (CRCHUM), Département de médecine, Montreal, Canada*
Email: mnabdelnabi86@gmail.com

Background and aims: Non-alcoholic fatty liver disease (NAFLD) is a major health problem with complex pathogenesis. The incidence and severity of NAFLD is higher in males than females but the mechanisms underlying this sex difference are not well understood. IL-22 is a pleiotropic cytokine that can be both protective and/or pathogenic during liver injury and inflammation. IL-22 was shown to be hepatoprotective in NAFLD-related liver injury. However, these studies relied primarily on exogenous administration of IL-22 and did not examine the sex-dependent effect of IL-22. Here, we sought to characterize the role of endogenous IL-22 signaling during NAFLD-induced liver injury in males and females.

Method: We used immunofluorescence (IF), flow cytometry, histopathological assessment and gene expression analysis to examine IL-22 production and characterize the intrahepatic immune landscape in human subjects with NAFLD (n = 20; 11 males and 9 females) and

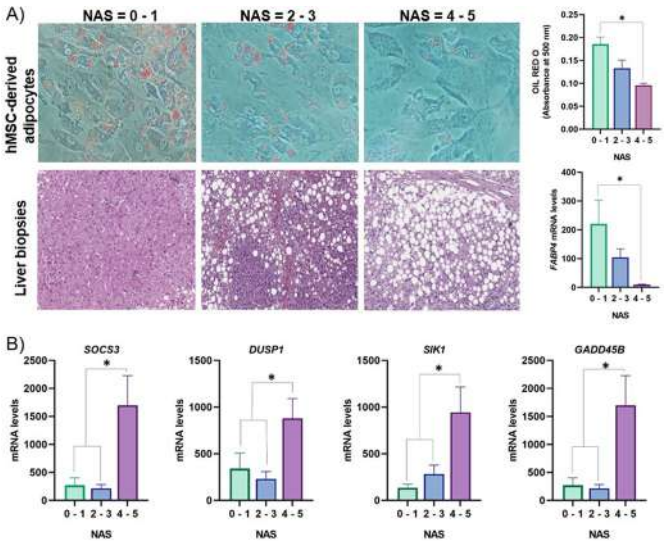
in an *in vivo* western high fat diet-induced NAFLD model in IL-22RA knock out (IL-22RA KO) mice and their wild type (WT) littermates.
Results: Examination of publicly available datasets from two cohorts with NAFLD demonstrated increased hepatic IL-22 gene expression in females as compared to males (p = 0.0327 and p = 0.0279, respectively). Furthermore, our IF analysis of liver sections from NAFLD subjects (n = 20) demonstrated increased infiltration of IL-22 producing cells in females (p = 0.0002). We validated the same observation in WT female mice with NAFLD (p = 0.0002). The lack of endogenous IL-22 signalling (IL-22RA KO) led to exacerbated liver damage, inflammation, apoptosis and liver fibrosis in female but not male mice with NAFLD.
Conclusion: Our data suggest a sex-dependent hepatoprotective antiapoptotic effect of IL-22 during NAFLD-related liver injury in females.

SAT023

Identification of novel targets in adipose tissue involved in non-alcoholic fatty liver disease progression

Marta Lopez-Yus[1], Silvia Lorente-Cebrian[2], Carlos Hörndler[3], Almudena Sobrino-Prados[3], Carmen Casamayor[3], Alejandro Sanz Paris[3], Vanesa Bernal Monterde[3], Jose M Arbones Mainar[1]. *[1]Instituto Aragonés de Ciencias de la Salud, Zaragoza, Spain; [2]University of Zaragoza, Zaragoza, Spain; [3]Hospital Universitario Miguel Servet, Zaragoza, Spain*
Email: jmarbones.iacs@aragon.es

Background and aims: Obesity is a major risk factor for the development of non-alcoholic fatty liver disease (NAFLD) as dysfunction of subcutaneous adipose tissue (scWAT) may lead to fat accumulation in other organs. It is therefore essential to identify the molecular mechanisms underlying progression of the disease and the role played by the adipose tissue. Our main objectives were: 1) to identify new dysregulated genes in scWAT potentially involved in the development of NAFLD, 2) to establish an *in vitro* model of hMSC-derived adipocytes (hMSC) that could reflect the different stages of NAFLD, and 3) to validate the expression of selected genes in our *in vitro* model.
Method: Biopsies from the abdominal scWAT from 45 patients were obtained and their respective transcriptomes sequenced (RNAseq). Using a computational analysis, we obtained a set of genes upregulated in patients with elevated fatty liver index (FLI). The expression of those genes of interest were validated by qPCR in a different cohort of 50 patients. In this case, the expression in scWAT levels of the genes of interest were correlated with the NAFLD Activity Score (NAS) of liver biopsies. Lastly, hMSC were also isolated from scWAT of patients of this cohort and differentiated into adipocytes to establish an *in vitro* model that could reflect the different stages of NAFLD. Differentiation capacity of these hMSC was compared and expression of selected genes was measured by qPCR in hMSC-derived adipocytes.
Results: We observed reduced expression of the adipocyte differentiation marker FABP4 mRNA, as well as an impaired lipid acumulation, measured by oil red O stain, in hMSC-derived adipocytes of NAFLD patients (Figure 1A). Four genes, first identified in the RNAseq cohort and then confirmed by qPCR in the validation cohort, also showed a differential regulation pattern in hMSC-derived adipocytes, increasing their mRNA expression accordingly to the degree of hepatic steatosis: *SOCS3, DUSP1, SIK1*, and *GADD45B* (Figure 1B).



Conclusion: Our results constitute a proof-of-concept of the great importance of adipose-liver crosstalk and suggest that impaired adipogenic capacity of hMSC is a critical event in promoting the development of NAFLD. We propose four genes as key players in NAFLD progression.

SAT024

Isoleucine and valine correct hepatic lipid processing, reduce liver steatosis and suppress inflammation in obese mice with manifest NASH

Eveline Gart[1,2], Wim van Duyvenvoorde[1], Jaap Keijer[2], Kanita Salic[1], Martine C. Morrison[1], Robert Kleemann[1]. *[1]TNO-Locatie Leiden-Gaubiusgebouw, Leiden, Netherlands; [2]Wageningen University and Research, Wageningen, Netherlands*
Email: eveline.gart@tno.nl

Background and aims: Non-alcoholic steatohepatitis (NASH) is associated with disturbed liver lipid handling and excessive accumulation of hepatic fat. Branched-chain amino acids (BCAAs) may beneficially modulate hepatic lipids, however it remains unclear whether individual BCAAs can attenuate already established NASH.
Method: After 26 weeks of obesogenic diet (FFD) run-in, mice were treated with individual BCAA, valine or isoleucine (3% of FFD), for another 12 weeks and were then compared to FFD controls.
Results: Valine and isoleucine did not affect obesity and dyslipidemia compared to FFD, but significantly reduced hyperinsulinemia. Valine and isoleucine significantly reduced ALT, CK-18m30, and total liver steatosis. Microvesicular steatosis was strongly decreased, by 61% (valine) and 71% (isoleucine). Hepatic 4-hydroxynonenal (4-HNE), a marker for oxidative stress induced lipid peroxidation, immunoreactivity was significantly decreased with valine and isoleucine. Functional transcriptome analysis demonstrated an upregulation of BCAA metabolism genes (e.g. BCAT, PP1MK, BCKDHA), deactivation of lipid synthesis regulators (SREBF1, AGT, IGF1) and activation of regulators involved in lipid oxidation (AMPK, ACOX1, EHHADH) and mitochondrial biogenesis (PPARGC1α, CLUH). This correction of critical metabolic pathways by valine and isoleucine was accompanied by significantly decreased lobular inflammation, and suppression of FFD-stimulated inflammatory pathways controlled by IL-1b and TNFα.
Conclusion: The intervention with either valine or isoleucine corrected multiple lipid metabolism processes and reduced NASH-associated steatosis and inflammation which was substantiated by suppression of critical inflammatory pathways.

SAT025

Butyrate protects against diet-induced NASH and liver fibrosis and suppresses specific non-canonical TGFB signaling pathways in human hepatic stellate cells

Eveline Gart[1,2], Wim van Duyvenvoorde[1], Karin Toet[1], Martien P. M. Caspers[1], Lars Verschuren[1], Aswin L. Menke[1], Roeland Hanemaaijer[1], Jaap Keijer[2], Kanita Salic[1], Robert Kleemann[1], Martine C. Morrison[1]. [1]*TNO-Locatie Leiden-Gaubiusgebouw, Leiden, Netherlands;* [2]*Wageningen University and Research, Wageningen, Netherlands*
Email: eveline.gart@tno.nl

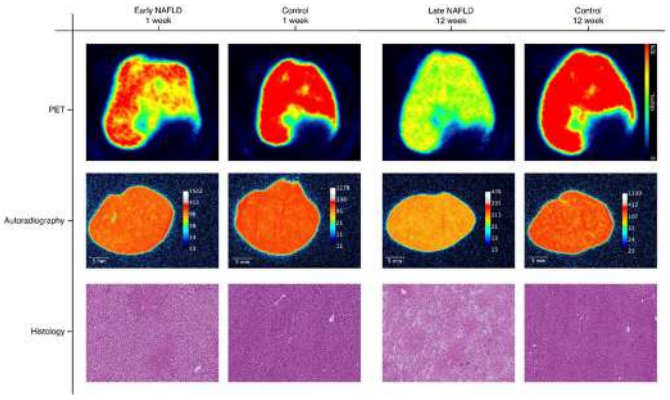
Background and aims: In obesity-associated non-alcoholic steatohepatitis (NASH), persistent hepatocellular damage and inflammation are key drivers of fibrosis, which is the main determinant of NASH-associated mortality. The short-chain fatty acid butyrate can exert metabolic improvements and anti-inflammatory activities in NASH. However, its effects on NASH-associated liver fibrosis remain unclear.
Method: Putative antifibrotic effects of butyrate were studied in Ldlr-/-.Leiden mice fed an obesogenic diet (HFD) containing 2.5% (w/w) butyrate for 38 weeks and compared to a HFD-control group. Antifibrotic mechanisms of butyrate were further investigated in TGF-β-stimulated primary human hepatic stellate cells (HSC).
Results: HFD-fed mice developed obesity, insulin resistance, increased plasma leptin levels, adipose tissue inflammation, gut permeability, dysbiosis and NASH-associated fibrosis. Butyrate corrected hyperinsulinemia, lowered plasma leptin levels and attenuated adipose tissue inflammation, without affecting gut permeability or microbiota composition. Butyrate lowered plasma ALT and CK-18M30 levels and attenuated hepatic steatosis and inflammation. Butyrate inhibited fibrosis development as demonstrated by decreased hepatic collagen content, αSMA and Sirius-red-positive area. In TGF-β-stimulated HSC, butyrate dose-dependently reduced collagen deposition and decreased procollagen1α1 and PAI1 protein expression. Transcriptomic analysis and subsequent pathway and upstream regulator analysis revealed deactivation of specific non-canonical TGF-β signaling pathways Rho-like GTPases and PI3 K/AKT and other important pro-fibrotic regulators (e.g. YAP/TAZ, MYC) by butyrate, providing a potential rationale for its antifibrotic effects.
Conclusion: Butyrate protects against obesity development, insulin resistance-associated NASH and liver fibrosis. These antifibrotic effects are at least in part attributable to a direct effect of butyrate on collagen production in hepatic stellate cells, involving inhibition of non-canonical TGF-β signaling pathways.

SAT026

Experimental non-alcoholic fatty liver disease causes regional liver functional deficits while total metabolic liver function is preserved

Peter Lykke Eriksen[1], Karen Louise Thomsen[1], Stephen Hamilton-Dutoit[2], Hendrik Vilstrup[1], Michael Soerensen[1,3,4]. [1]*Aarhus University Hospital, Department of Hepatology and Gastroenterology, Aarhus, Denmark;* [2]*Aarhus University Hospital, Institute of Pathology, Aarhus, Denmark;* [3]*Viborg Regional Hospital, Department of Internal Medicine, Viborg, Denmark;* [4]*Aarhus University Hospital, Department of Nuclear Medicine and PET, Aarhus, Denmark*
Email: ple@clin.au.dk

Background and aims: The increasing incidence of non-alcoholic fatty liver disease (NAFLD) has imposed a need for understanding how the disease affects metabolic liver function. The aim of this study was to investigate *in vivo* effects of the structural liver changes on hepatic metabolic function assessed by the regional and total capacity for galactose elimination in a rodent model of diet-induced NAFLD of different stages.
Method: Sprague Dawley rats were fed a standard chow (control) or a high-fat, high-cholesterol diet for 1 (n = 8) or 12 weeks (n = 8), resulting in development of early and late NAFLD, respectively. *In vivo* liver metabolic function was assessed directly in the liver tissue by 2-[^{18}F]fluoro-2-deoxy-D-galactose positron emission tomography. *Post mortem* liver tissue was used for autoradiography, histology and fat quantification.
Results: Early NAFLD livers had steatosis with 18 volume % fat. Late NAFLD livers had 32 volume % fat and showed features of non-alcoholic steatohepatitis (NASH) (inflammation, ballooning and fibrosis). Regional galactose metabolism was reduced in both early and late NAFLD with a median hepatic standardised uptake value (SUV) of 9.8 and 7.4 ($p = 0.02$), respectively, compared to ~12.5 in controls. Results were confirmed by the autoradiography measurements. In early NAFLD the decreased SUV was explainable by the degree of fat infiltration. In late NAFLD, SUV was decreased beyond that attributable to fat, likely related to the structural NASH features mentioned. Still, in both groups total capacity for galactose elimination remained intact. In late NAFLD, there was an increase in fat-free liver mass to 21 g vs. 15 g in early NAFLD and control rats ($p \leq 0.002$).



Conclusion: Metabolic function of the hepatic tissue was compromised by NAFLD. The deficit was related to replacement of liver tissue with fat and in the more advanced disease of late NAFLD probably also to other structural changes. Total liver function was preserved, in the late NAFLD rats by the marked growth of fat-free liver mass. The mechanism behind this functionally compensatory liver growth is not known.

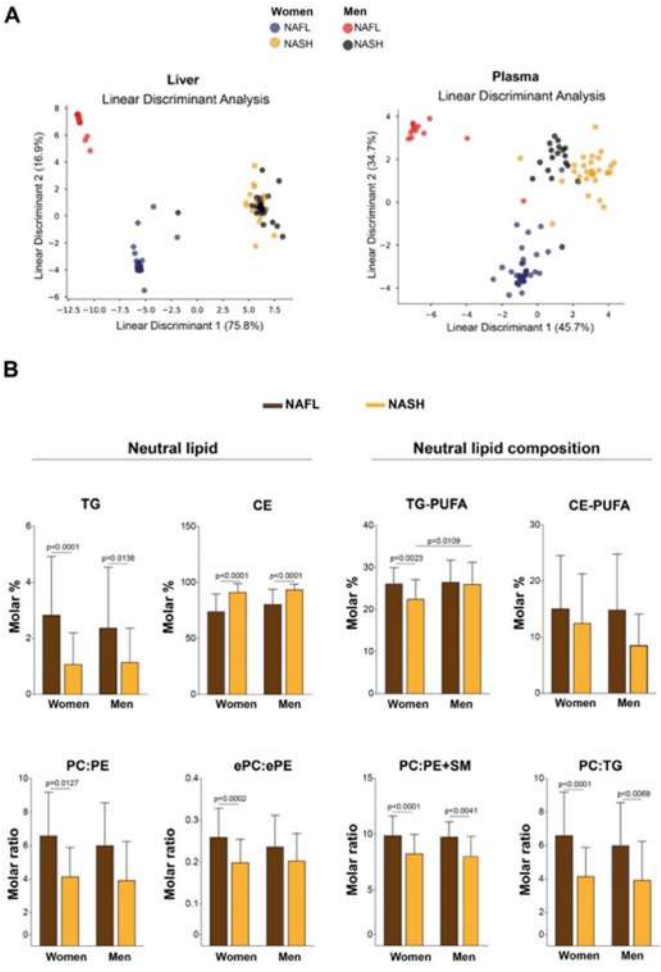
Email: elisabet.rodriguez@urv.cat

Background and aims: Metabolic Associated Fatty Liver Disease (MAFLD) is a spectrum of heterogenic fatty-liver disorders that affects a quarter of the population. Despite new findings, there is no effective drug treatment and lifestyle interventions to address this disease in a long term. Nevertheless, lipid droplet accumulation is the onset of the natural course of MAFLD being lipid composition a necessary field to approach. In this context, phospholipids are the main constituents of the plasma membrane and changes in its composition are linked with the progression of this disease. How these changes affect women and men is an unsolved question. Thus, the purpose of the study was to identify changes in the lipid signature and phospholipid metabolism during liver disease progression as well as to observe the influence of the liver in the plasma lipidome of morbidly obese women and men.

Method: Liquid Chromatography coupled with Mass Spectrometry was used to perform a semi-targeted lipidomic in plasma and liver tissue from morbidly obese patients with non-alcoholic steatohepatitis (NASH) (men = 18; women = 34) and non-alcoholic fatty liver (NAFL) (men = 13; women = 38) who underwent bariatric surgery.
Results: Different lipidome profiles between women and men were observed using linear discriminant analysis in plasma and liver tissue (A). Nevertheless, when the liver disease progress to NASH these sex differences disappear. In addition, we found changes in the lipids associated with hepatic lipid droplet. Concretely, we observed an impairment of triglycerides (TG) and an increase of cholesterol ester levels in both sexes (B). In opposite to liver findings, the plasma TG levels increased in women but not in men. Interestingly, women showed changes in the lipid droplet composition with a loss of polyunsaturated fatty acid (PUFA)-containing TG. In addition, we also observed a decrease in the phospholipid levels in both plasma and liver. Hepatic phosphatidylcholine/phosphatidylethanolamine (PC/PE) and ether-linked PC/PE molar ratio decreased, and fatty acid composition of phospholipids was less polyunsaturated in PC and sphingomyelin (SM) in women between NASH and NAFL. Instead, men did not show any significant difference.



Conclusion: Phospholipid metabolism and hepatic lipid droplet composition seem to be influenced by sex and plasma lipidome seem to mimic the hepatic alterations.

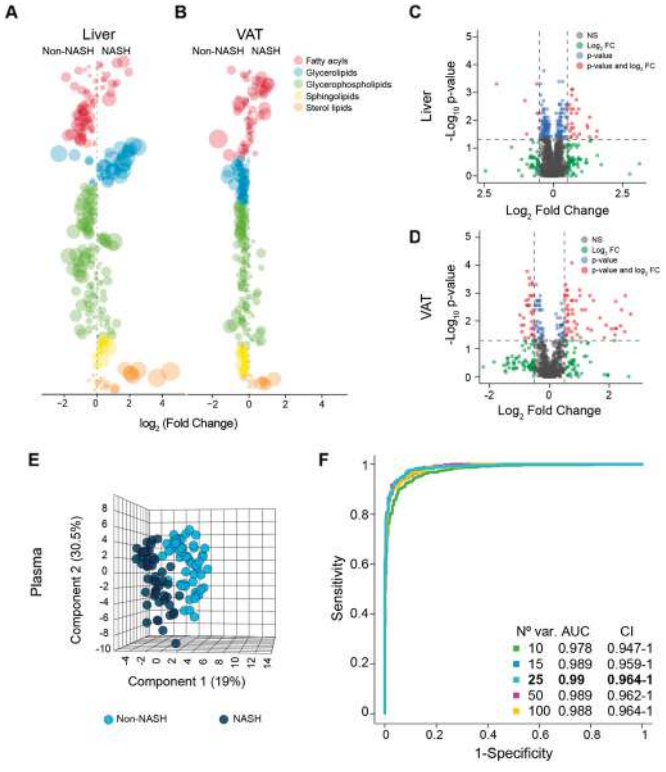
Lipidomics and proteomics reveal mitochondrial dysfunction in liver and visceral adipose tissue from patients with non-alcoholic steatohepatitis

Helena Castañé[1], Andrea Jiménez Franco[2], Elisabet Rodríguez-Tomàs[2], Gerard Baiges Gaya[1], Jordi Camps[3], Jorge Joven[2,3]. *[1]Institut d'Investigació Sanitària Pere Virgili, Unitat de Recerca Biomèdica, Reus, Spain; [2]Universitat Rovira i Virgili, Medicina i Cirurgia, Reus, Spain; [3]Hospital Universitari Sant Joan, Unitat de Recerca Biomèdica, Reus, Spain*
Email: helena.castanev@gmail.com

Background and aims: The association of chronic liver disease with obesity and diabetes is clinically important in the context of silent pandemics and there are no pharmacotherapeutic interventions. The initial step of the disease spectrum appears to be a simple accumulation of lipids, steatosis, but can progress to more severe forms initiated by non-alcoholic steatohepatitis (NASH). The pathogenic mechanisms leading to progression are not completely understood but growing evidence likely suggests metabolic dysfunction in multiple and related organs. Lipidomics and proteomics from liver and adipose tissue, with the help of machine learning algorithms, could explain clinical traits and shed light on interorgan crosstalk in patients with NASH. Also, alterations in circulating lipids in patients with NASH have not been previously explored in association with tissue-specific lipid signatures in obesity. We sought to distinguish obese patients with and without NASH identifying the lipidome in plasma, liver, and subcutaneous and visceral adipose tissue.
Method: Patients with extreme obesity (n = 118; n = 58 with NASH diagnostic, and n = 60 were non-NASH) that underwent metabolic surgery donated a liver and a visceral adipose tissue (VAT) biopsy, and blood sample, from which we extracted the lipidome and proteome.



Results: Liver and VAT shared a relatively common lipidome and proteome signature. Regarding lipidomics, mostly all lipid species were altered: glycerophospholipids were diminished in both tissues and tri and diglycerides were increased in liver and decreased in VAT. Volcano plots found more differences between NASH and non-NASH patients in their VAT than in their liver proteome, both tissues had proteins located in mitochondria and with essential roles in energy metabolism altered in NASH. Quantitative enrichment set analysis pointed to impaired mitochondrial beta-oxidation. On the other hand, plasma lipidome and proteome was different enough between NASH and non-NASH patients, thus machine learning algorithms were applied to build a predictive model which had high diagnostic ability.
Conclusion: Lipidomic and proteomic signature not only affects hepatic tissue, but also visceral adipose tissue. The alterations can also be observed in plasma, and the optimal combination of these variables could be a new biomarker of liver severity.

SAT029

Targeting liver glutaminase 1 modulates hepatic ammonia in experimental Non-Alcoholic Steatohepatitis

Maria Mercado-Gómez[1], Naroa Goikoetxea[1], Marina Serrano-Macia[1], Sofia Lachiondo-Ortega[1], Rubén Rodríguez Agudo[1], Petar Petrov[2], Miren Bravo[1], Claudia Gil-Pitarch[1], Irene González-Recio[1], Jorge Simón Espinosa[1], María Luz Martínez-Chantar[1], Teresa Cardoso Delgado[1]. *[1]CIC bioGUNE-Centro de Investigación Cooperativa en Biociencias, Derio, Spain; [2]La Fe University and Polytechnic Hospital, València, Spain*
Email: tcardoso@cicbiogune.es

Background and aims: Hepatic ammonia, a key nitrogen-containing compound, is augmented in NAFLD, specifically in more advanced stages of the disease such as NASH with potential implications in its treatment. Whereas both gut-derived ammonia and decreased hepatic ureagenesis have been shown to contribute to increased hepatic ammonia content under these conditions, the contribution of glutaminase 1 (GLS) expression for hepatic ammonia built-up in NASH has not been previously addressed.
Method: 3-month-old C57BL/6J male mouse were maintained for 6 weeks either on HFD, CD-HFD, CDAA or CDA-HFD. Serum, liver histological analysis (HandE, Oil red, F4/80 immunostaining, Sirius red, Nessler staining of ammonia) and hepatic transcriptional profiling with the nCounter® Metabolic Pathways Panel from nanoString® studies were carried out. Then, animals maintained for 6 weeks on CDA-HFD, a well-established mouse model of diet-induced NASH, presenting increased staining for hepatic ammonia without concomitant blood hyperammonaemia, considered thereby a latency period of abnormal ammonia metabolism, were randomly separated in two experimental groups: hepatic glutaminase 1 *(Gls)* silencing (n = 6) or non-targeting siRNA control silencing (n = 6) by tail vein injection of the respective siRNA and Invivofectamine™. After 48 h animals were sacrificed and the expression of key regulators of liver glutamine metabolism assessed, and ammonia content evaluated.
Results: Hepatic transcriptional profiling revealed decreased expression of pathways responsible for amino acid synthesis and arginine metabolism as well as pathways involved in fatty acid metabolism and mitochondrial respiration as the dietary model of NAFLD progressed. On the other hand, pathways associated with hypoxia, DNA damage repair, myc, glutamine metabolism, mTOR and glycolysis, among others, were overexpressed in NASH mouse models. Interestingly, as NAFLD progresses hepatic Nessler staining of ammonia is increased correlating with decreased expression of the enzymes involved in urea cycle, and increased expression of the isoform 1 of glutaminase. In addition, silencing of hepatic glutaminase 1 in CDA-HFD rodents for 48 h results in decreased glutaminase 1 mRNA levels as expected. On the contrary, the expression of urea cycle enzymes, suppressed under NASH conditions, remains unaltered. Likewise, zonula occludens staining in intestine, a marker for tight junction integrity in the intestinal barrier, is unaffected by hepatic glutaminase 1 silencing. Finally, we have shown that hepatic ammonia content is reduced after glutaminase 1 silencing, and this is associated with a mild reduction in the activation of hepatic stellate cells.
Conclusion: Our results show that targeting liver glutaminase 1 modulates hepatic ammonia in NASH which could be a therapeutic mechanism to halt fibrosis progression.

SAT030

Clinical relevance of an animal model of non-alcoholic steatohepatitis (NASH) and digital pathology with artificial intelligence (DP-AI) analyses of hepatic fibrosis

Yishuang Wei[1], Mengnan Zhang[1], Jiliang Zhang[1], Xiao Teng[2], Qiang Yang[3], Alvin Leong[2], Gideon Ho[2], Henry Lu[1], Deming Xu[1]. *[1]WuXi AppTec, Discovery Biology Unit, WuXi Biology, Shanghai, China; [2]HistoIndex Pte Ltd., Singapore, Singapore; [3]Hangzhou Choutu Technology Co., Ltd., Hangzhou, China*
Email: xu_deming@wuxiapptec.com

Background and aims: Clinical relevance of animal models for NASH is crucial for assessment of in vivo efficacy of compounds in development. The validity of efficacy assessment rests on histopathology of not only steatosis, ballooning and inflammation but also fibrosis. However, hepatic fibrosis varies from model to model. In the current study, we applied an automated quantitative DP-AI system to a mouse model of NASH to evaluate the hepatic fibrosis and the antifibrotic activity of obeticholic acid (OCA), in particular the fibrous septa that are typical in the late-stage of the NASH patients.
Method: In the mouse NASH model, after animals develop steatosis on feeding of high-fat diet (HFD), they are treated with carbon tetrachloride (CCL4) to induce hepatic fibrosis. Test compounds are administered during the CCL4 induction. The liver histopathology is analyzed by the standard means. For DP-AI analyses, second-harmonic generation (SHG)/two-photon excitation fluorescent (TPEF) microscopy is used for imaging of unstained liver sections. Collagen fibers are identified and quantified by an AI-based algorithm that recognizes the portal tract (PT) and the central vein (CV), and examines collagen bundles therebetween, with reference to septa diagnosed in the human NASH livers.
Results: Our previous studies indicated that the combination of HDF and CCL4 induces an extra level of fibrosis that is the target of antifibrotic activity of OCA. DP-AI analyses confirmed this observation. While CCL4 alone induced significant fibrosis, an extra level of fibrosis was induced by the combination, as determined by SHG% (of total area). With the treatment of OCA, the extra fibrosis was suppressed (Fig. 1-B). Although a basal level of fibrosis was observed in both the healthy control and the HDF induction by SHG% (Fig. 1-B), no or minimal septa were present in either (Fig. 1-C). The induction of septa was greatly increased when HDF and CCL4 were combined (septa% vs. SHG% in Fig. 1-B and -C). The OCA treatment reduced septa in the HDF+CCL4 model by ~50%, quantitatively much greater than that determined by SHG% (Fig. 1-B and 1-C). We then tested compounds that are in the NASH clinical trials, including agents targeting FXR, ASK1, PPAR-alpha/delta, pan-PPAR, CCR2/CCR5, THR-beta, ACC1/2, SSAO/VAP-1, and GLP1. Their efficacies were largely consistent with the respective clinical outcomes.

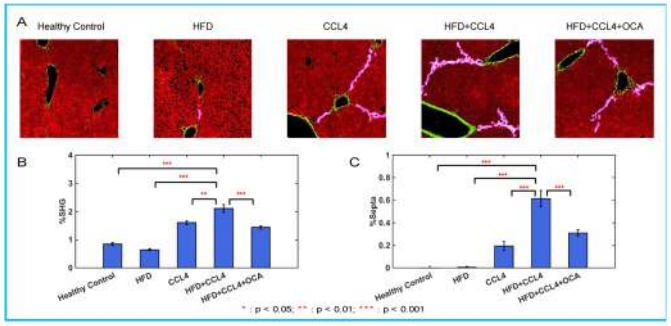


Figure1. The SHG/TPEF images and the quantification of hepatic fibrosis in the HFD+CCL4 mouse model. A. Images of selected regions of interest from labelled sources for illustration of SHG (in green), TPEF (in red) and septae (in pink). B and C. The total collagen areas (B) and septal collagen areas (C) in whole livers from labelled animal groups, with statistical significance indicated.

Conclusion: Our results demonstrate that the septa identified by the DP-AI system in the HFD+CCL4 model are NASH related, and they are the target of antifibrotic activities of NASH compounds with demonstrated clinical efficacies. Such septa could represent the bridging fibrosis as observed the NASH patients. The HFD+CCL4 model is therefore clinically relevant in terms of histopathological presentation and targets of NASH compounds.

SAT031

Small changes in the metabolism of bile acids by the gut microbiota are associated to NASH pathogenesis

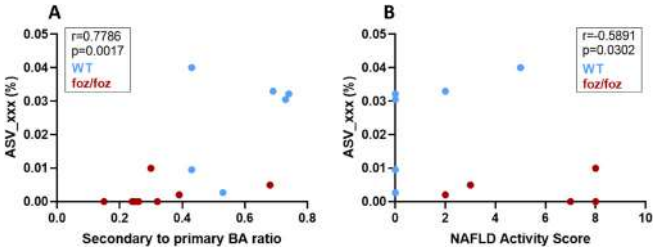
Justine Gillard[1,2], Morgane Thibaut[2], Martin Roumain[3], Giulio G. Muccioli[3], Anne Tailleux[4], Bart Staels[4], Laure Bindels[2], Isabelle Leclercq[1]. *[1]UCLouvain, Laboratory of Hepato-Gastroenterology, Institute of Experimental and Clinical Research, Belgium; [2]UCLouvain, Metabolism and Nutrition Research Group, Louvain Drug Research Institut, Belgium; [3]UCLouvain, Bioanalysis and Pharmacology of Bioactive Lipids, Louvain Drug Research Institut, Belgium; [4]University of Lille, Inserm, CHU Lille, Institut Pasteur de Lille, U1011-EGID, France*
Email: justine.gillard@uclouvain.be

Background and aims: Primary bile acids (BAs) synthesized by the hepatocytes are secreted, modified and reabsorbed in the gut. Specifically, gut bacteria deconjugate BAs through bile salt hydrolase (BSH) activity and transform primary to secondary BAs through 7alpha-dehydroxylation. We showed that BAs contribute to NASH pathogenesis and that the enterohepatic BA pool is altered and secondary BAs lowered in experimental NASH, suggesting impaired bacterial biotransformation. Here, our aim is to study the gut microbiota and its BA-metabolizing activities in a NASH experimental model.

Method: We co-housed and fed with HFD for 12 weeks *foz/foz* (NAS≥6) and WT (NAS ≤1) mice and harvested samples after 12 h fasting/4 h refeeding. We analyzed microbial composition of the caecal content using 16S rRNA gene sequencing, BAs by LC-MS/MS and measured BSH activity.

Results: Alpha-diversity (measured by the Shannon and the observed amplicon sequence variant (ASV) indexes); and beta-diversity (reported by the Morisita Horn index) within and among caecal samples were similar in *foz/foz* and WT mice. The proportion of the variance explained by the genotype was low (9.2%, p = 0.32). The relative abundances of bacterial phyla and families were not significantly different, except for the *Bacteroidaceae* family more abundant in the caecal content of *foz/foz* mice (3.13% vs 1.27% in WT, p = 0.007).

The BSH activity in caecal content was similar in both groups, matching the similar overall microbial composition. Nevertheless, the low secondary to primary BAs ratio and the low secondary BAs concentration suggested a lower 7alpha-dehydroxylase activity in *foz/foz* mice. One specific ASV was detected only in 38% of the *foz/foz* while present in 100% of the WT mice at low abundance. The relative abundance of this ASV correlated significantly with the secondary to primary BAs ratio (Fig A), with the concentration of the secondary deoxycholic acid (r = 0.8478, p = 0.0006) and with the NAFLD activity score (Fig B). We hypothesized that this ASV exhibits a 7alpha-dehydroxylase activity, which could explain that its lower prevalence leads to a reduced production of secondary BA, thereby contributing to NASH pathogenesis.



Conclusion: When co-housed and fed the HFD, the overall microbial composition is similar whether mice have NASH or not. Low concentration of secondary BAs in mice with NASH is associated to small changes in bacterial composition that likely impact the microbial 7alpha-dehydroxylase activity.

Email: markus.boesch@kuleuven.be

Background and aims: Non-alcoholic fatty liver disease (NAFLD) is the most common cause of chronic liver disease, thereby affecting 25% of the world population. Patients with non-alcoholic fatty liver (NAFL) can progress further to non-alcoholic steatohepatitis (NASH), characterized by steatosis and hepatic inflammation. It has been postulated that ongoing inflammation in the adipose tissue compartment, potentially driven by macrophages, accounts for this disease transition. Previous studies already showed a significant heterogeneity within the macrophage pool in obese adipose tissue. Here, we aim to unravel the human visceral adipose tissue macrophage population on a single cell level in a well-defined human NAFLD population.

Method: Visceral adipose tissue (VAT) biopsies were collected from obese patients undergoing bariatric surgery (UZ Leuven, Belgium). Liver biopsies were performed and assessed by expert liver pathologists based on the fatty liver inhibition of progression (FLIP) algorithm and steatosis, activity, and fibrosis (SAF) score to distinct patient groups. Adipose tissue macrophages were freshly dissociated and single cell RNA-seq was performed using 10X Genomics 3′v3 on samples of 2 obese controls without NAFLD, 3 NAFL and 4 NASH patients.

Results: The VAT contains multiple macrophage and monocyte subtypes with distinct transcriptional profiles. Among these, we observed an increased influx of pre-Inflammatory macrophages and pro-inflammatory monocytes in patients with NASH compared to their obese counterparts. Additionally, anti-inflammatory/angiogenic macrophages were almost completely absent in tissue from NASH patients as compared to obese controls. Velocity and pseudotime analysis also revealed that these macrophages are no longer replenished in NASH patients.
Conclusion: Our study characterized the landscape of human adipose tissue macrophages that points towards a NASH-related loss of anti-inflammatory/angiogenic macrophages. Further studies unraveling their tissue localization and function are ongoing.

Atorvastatin attenuates diet-induced non-alcoholic steatohepatitis in ApoE*3-Leiden mice by reducing hepatic inflammation

José A. Inia[1,2,3], Anita M. van den Hoek[1], Geurt Stokman[1], Martine C. Morrison[1], Elsbeth Pieterman[1], J. Wouter Jukema[2,3], Hans Princen[1]. [1]*The Netherlands organization for applied scientific research (TNO), Metabolic health research, Leiden, Netherlands;* [2]*Leiden university medical center (LUMC), Einthoven laboratory for experimental vascular medicine, Leiden, Netherlands;* [3]*Leiden university medical center (LUMC), Cardiology, Leiden, Netherlands*
Email: jose.inia@tno.nl

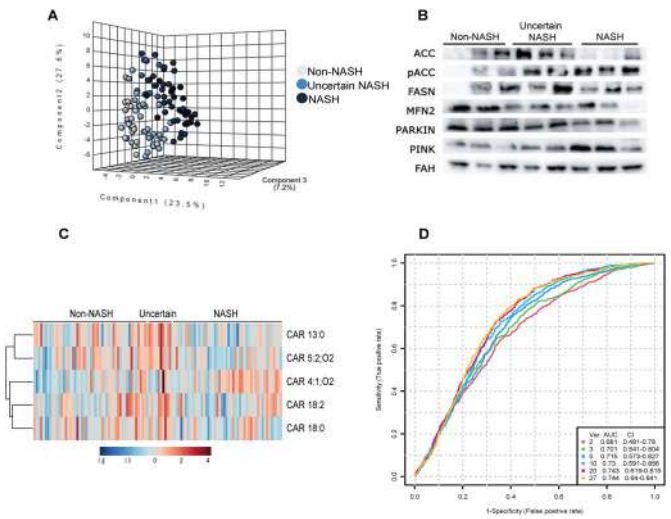
Background and aims: Non-alcoholic fatty liver disease (NAFLD) is considered the hepatic manifestation of the metabolic syndrome, and due to the worldwide obesity epidemic, the prevalence of both NAFLD and the more severe form non-alcoholic steatohepatitis (NASH) is rapidly rising. Patients with metabolic syndrome are often prescribed statins to prevent development of cardiovascular disease as a result of a disturbed lipoprotein metabolism. Although the effects of statins on cardiovascular disease are relatively well described, data on their effects on NASH are lacking. Here, we evaluated the effects of atorvastatin on NASH and liver fibrosis development and inflammatory parameters.
Method: ApoE*3-Leiden mice were fed a Westernized diet (WTD) with or without atorvastatin admixture for 32 weeks. Plasma parameters and inflammatory markers were evaluated and hearts and livers were histologically and biochemically examined at study end point.
Results: Atorvastatin significantly reduced the WTD-induced increase in plasma cholesterol levels (−43%, $p < 0.01$) and thereby significantly attenuated the development of atherosclerosis (lesion area −47%, $p < 0.01$ compared to WTD). Atorvastatin significantly reduced hepatic steatosis (−22%, $p < 0.01$) and resulted in a robust decrease of hepatic inflammation (−80%, $p < 0.01$) and fibrosis (−92%, $p < 0.001$) compared to mice that received the WTD only. Interestingly, atorvastatin almost fully blunted the accumulation and formation of hepatic cholesterol crystals (−78%, $p < 0.05$), structures that drive inflammation via inflammasome activation. Analyses on inflammatory markers substantiated this effect and revealed a significant reduction in infiltration of hepatic macrophages, neutrophils and monocytes as well as lower levels of pro-inflammatory cytokines.
Conclusion: Atorvastatin attenuates the development of NASH by reducing intrahepatic cholesterol crystals and cholesterol ester levels, hepatic steatosis, inflammation and fibrosis.

SAT034

Carnitine signature in liver corretales with non-alcoholic fatty liver disease progression

Andrea Jiménez Franco[1], Helena Castañé[2], Gerard Baiges Gaya[2], Elisabet Rodríguez-Tomàs[1], Jordi Camps Andreu[3], Jorge Joven Maried[3]. [1]*Universitat Rovira i Virgili, Medicine and surgery, Reus, Spain;* [2]*Institut d'investigació Pere Virgili, Medicine and surgery, Reus, Spain;* [3]*Hospital universitari Sant Joan de Reus, Medicine and surgery, Reus, Spain*
Email: andreajfranco99@gmail.com

Background and aims: NAFLD is a global silent pandemic that increases in parallel with obesity, that is unknown for most of the population. NAFLD begins with simple inflammation, steatosis, and can become a severer stage known as NASH (Non-alcoholic steatohepatitis), which can only be diagnosed by liver biopsy. In the livers of NASH patients there is mitochondrial dysfunction, which impairs metabolism of the cell, impacting in its global health. Mitochondria is closely related to lipid metabolism: carnitines support the transport of fatty acids into mitochondria for beta-oxidation, thus their concentration may be affected in the development of NAFLD and its progression to NASH.
We sought to distinguish patients with NASH from patients without NASH by measuring carnitine concentrations in both plasma and liver, and to evaluate whether there may be an association between these species and mitochondrial dysfunction.
Method: The study includes 110 morbidly obese participants from the Hospital Sant Joan de Reus who have undergone bariatric surgery. From the liver biopsy we characterized NASH by using NAFLD Activity Score (NAS). 51 patients were classified as Non-NASH, 49 patients as NASH and 10 patients as Uncertain NASH diagnostic.
We performed semi-targeted lipidomics to quantify carnitine species from liver and plasma samples, and we use Western blot to semi-quantify proteins of lipid metabolism and mitophagy in liver samples.
Results: Using multivariate analysis, we have been able to determine that in the liver there was a specific profile of the lipids. By comparing the concentrations in liver of NASH patients with Non-NASH patients revealed that most carnitine concentrations were found to be decreased in NASH. Western blot results determined that both beta-oxidation and autophagy of mitochondria is highly correlated with carnitines and NAFLD. Slight differences were observed between the plasma carnitine concentrations of the different patients. Carnitines could not be used as markers for this disease because were not specific enough.



Conclusion: Beta-oxidation and proteins associated to mitochondrial dynamics and mitophagy were found to be altered as the disease progressed. Mitophagy was activated, and fatty acid beta-oxidation was suppressed. On the other hand, as the liver severity increased, carnitine decreased with a specific signature.

SAT035

Type 2 diabetes and religious fasting: effects on metabolism and liver steatosis

Svenja Sydor[1], Ender Engin[1], Mustafa Özcürümez[1], Anja Figge[1], Josef Pospiech[1], Andreas Jähnert[1], Jan Best[1], Wing-Kin Syn[2], Ali Canbay[1], Lars Bechmann[1], Paul Manka[1]. *[1]University Hospital Knappschaftskrankenhaus Bochum, Department of Internal Medicine, Bochum, Germany; [2]Medical University of South Carolin, Division of Gastroenterology and Hepatology, Department of Medicine*
Email: svenja.sydor@rub.de

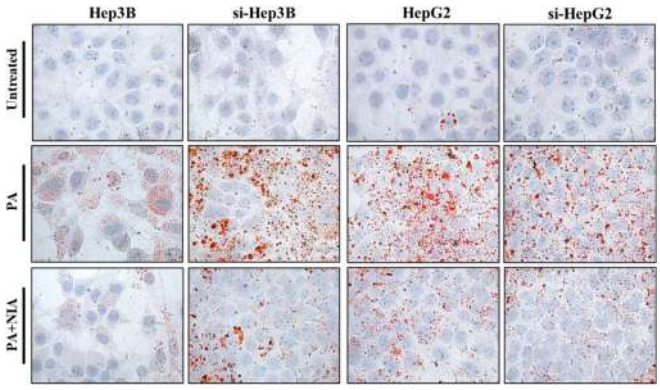
Background and aims: Religious fasting during the holy month of Ramadan requires abstaining from food and liquids during the day. After sunset, it is allowed to consume food and drinks in defined periods. Fasting results in a reduced and timed calorie intake and can be regarded as a form of intermittent fasting. Type 2 diabetes (TD2) is a significant risk factor for the development of non-alcoholic steatohepatitis (NASH), the progressive form of non-alcoholic fatty liver disease (NAFLD). Recently several studies suggested some benefits of interval fasting for patients with TD2 and NASH. Here, we aimed to characterize the impact of a one-month interval fasting period on liver health, glucose and lipid metabolism in a cohort of T2D patients.
Method: 20 muslim patients from a German metropolitan region were included. The status of the liver was assessed by Fibroscan®, including the measurement of the controlled attenuation parameter (CAP). Additionally to anthropometric measurements, patients' blood samples were collected at the beginning and end of the four-week fasting period to quantify key parameters of liver injury, lipid and glucose metabolism.
Results: Following the fasting period transient elastography measurements (8.0 ± 1.2 vs. 8.6 ± 1.6 before/after fasting) and CAp values (311.4 ± 9.6 vs. 302.6 ± 10.4 before/after fasting) showed modest changes. In contrast, LFTs, apoptosis marker (M30), and adiponectin significantly decreased after the fasting period. Serum levels of triglycerides were lower following the fasting period. Glucose levels did not change significantly, but serum levels of C-peptide and insulin increased following the fasting period. In addition, the patients experienced a significant weight loss at the end of the fasting month.
Conclusion: In this cohort of T2D patients, we demonstrated that a 4-week intermittent fasting period resulted in an improvement in different serum parameters associated with glucose, liver, and lipid metabolism.

SAT036

The I48M PNPLA3 variant mitigates Niacin beneficial effects: how the genetic screening in non-alcoholic fatty liver disease (NAFLD) patients gains value

Erika Paolini[1,2], Miriam Longo[1,3], Marica Meroni[1], Roberto Piciotti[1,3], Annalisa Cespiati[1,4], Rosa Lombardi[1,4], Anna Ludovica Fracanzani[1,4], Paola Dongiovanni[1]. *[1]General medicine and metabolic diseases, Fondazione IRCCS Cà Granda ospedale maggiore policlinico, Milan; [2]Università degli Studi di Milano, Milan, Italy, Department of Pharmacological and Biomolecular Sciences, Milan; [3]Department of Clinical Sciences and Community Health; [4]Università degli Studi di Milano, Fondazione IRCCS Cà Granda Ospedale Maggiore Policlinico, Milan, Italy, Department of Pathophysiology and Transplantation*
Email: paola.dongiovanni@policlinico.mi.it

Background and aims: The PNPLA3 p.I148M variant is the main genetic predictor of NAFLD and its impact on fat accumulation can be modulated by nutrients. Niacin (NIA) reduces triglycerides (TGs) synthesis and ROS production in NAFLD patients. However, the interplay between NIA and p.I148M polymorphism has not been explored yet. This study aims to:1) assess the dietary and circulating NIA levels in NAFLD patients stratified according to the presence of the p.I148M variant; 2) examine the efficacy of NIA in Hep3B and HepG2 cells, which are wild-type and homozygous for the p.I148M mutation, respectively.
Method: We enrolled 172 patients (Discovery cohort) with non-invasively assessed NAFLD. Dietary NIA was collected from food diary, while serum NIA was quantified by ELISA. Hepatic expression of genes related to NAD metabolism was evaluated by RNAseq in bariatric NAFLD patients (n = 125). HepG2 and Hep3B cells were transfected with a siRNA targeting *PNPLA3* and treated with palmitic acid (PA) 0.25 mM alone/plus NIA 0.5 mM for 24 hrs.
Results: At bivariate analysis NAFLD patients showed reduced dietary NIA ($p = 0.01$). The p.I148M variant was correlated with lower levels of alimentary and circulating NIA ($p = 0.01$, $p = 0.03$ *vs* non-carriers). At multivariate analysis, adjusted for sex, BMI, and alimentary NIA, the p.I148M mutation was associated with reduced serum NIA ($\beta = -18.01$; CI:-35.6–0.57; $p = 0.04$), suggesting that it may independently modulate NIA systemic availability. The expression of enzymes related to NAD biosynthesis was impaired in p.I148M carriers ($p = 0.006$).
NIA supplementation reduced TG synthesis alongside oxidative injury and ER stress in hepatoma cells ($p < 0.001$, $p < 0.05$ *vs* PA). The efficacy of NIA was hidden by the p.I148M variant in HepG2 cells, suggesting that the loss of lipase activity blunted the NIA protective role. Consistently, *PNPLA3* silencing masked the beneficial effect of NIA on TG overload in Hep3B cells, whereas it didn't affect fat accumulation in HepG2 ones ($p < 0.001$, $p < 0.05$ *vs* PA). The effectiveness of NIA on oxidative/ER stress was maintained in both cell lines silenced for *PNPLA3* ($p < 0.001$, $p < 0.05$ *vs* PA), thus suggesting that it might mitigate the protective role of NIA in lipid handling but not in hepatocellular damage.



Conclusion: NIA levels were reduced in NAFLD patients who carry the p.I148M variant. *PNPLA3* silencing compromised the efficacy of NIA in hepatoma cells, thus suggesting its supplementation in NAFLD patients should be preceded by genetic screening.

SAT037

The co-presence of PNPLA3, MBOAT7 and TM6SF2 loss-of-functions impairs mitochondrial morphology and number in severe NAFLD patients

Miriam Longo[1,2], Erika Paolini[1,3], Marica Meroni[1], Michela Ripolone[4], Laura Napoli[4], Roberto Piciotti[1,2], Marco Maggioni[5], Maurizio Moggio[4], Anna Ludovica Fracanzani[1,6], Paola Dongiovanni[1]. *[1]Fondazione IRCCS Cà Granda Ospedale Maggiore Policlinico, General Medicine and Metabolic Diseases; [2]University of Milan, Department of Clinical Sciences and Community Health; [3]University of Milan, Department of Pharmacological and Biomolecular Sciences; [4]Fondazione IRCCS Cà Granda Ospedale Maggiore Policlinico, Neuromuscular and Rare Diseases Unit; [5]Fondazione IRCCS Cà Granda Ospedale Maggiore Policlinico, Division of Pathology; [6]University of Milan, Department of Pathophysiology and Transplantation*
Email: paola.dongiovanni@policlinico.mi.it

Background and aims: Mitochondrial (mt-) dysfunction is a key event occurring in the progressive forms of non-alcoholic fatty liver

disease (NAFLD) up to hepatocellular carcinoma (HCC). We previously demonstrated that human HepG2 cells, homozygous for the I148M PNPLA3 variant and silenced for *MBOAT7* and *TM6SF2* genes (MBOAT7$^{-/-}$TM6SF2$^{-/-}$) by CRISPR/Cas9, enriched mt-mass and accumulated damaged mitochondria with loss of cristae paralleled by functional defects in the oxidative phosphorylation. In the attempt to translate *in vitro* results in human NAFLD, we aimed to: 1) assess whether mt-morphology, circulating *D-loop* copy number and expression, which reflect mt-mass, correlated with disease severity and number of the 3 at-risk variants (NRV = 3) in biopsied NAFLD subjects (n = 26, Discovery cohort); 2) evaluate circulating *D-loop* levels in a larger cohort of biopsied NAFLD patients (n = 773, Validation cohort), including n = 101 NAFLD-HCC. Hepatic *D-loop* levels were evaluated in intra- and extra-tumoral tissues of 3 NAFLD-HCC individuals.

Method: NAFLD patients were stratified according to NRV and to NAFLD activity score (NAS). Mt- morphology was assessed by transmission electron microscopy (TEM).

Results: In the Discovery cohort, NAFLD patients with NRV = 3 showed NAS = 5–7 along with the highest D-loop content compared to patients with 1–2 or no variants ($p < 0.01$), reflecting what observed in vitro. At TEM, patients carrying NRV = 3 showed an enrichment of mt-mass and an elevated pattern of mt-morphological alterations as swollen shapes with loss of internal matrix, rupture of double membranes or giant/elongated mitochondria. In the Validation cohort, the NRV = 3 associated with NAS and HCC risk ($p < 0.05$) at multivariate analysis adjusted for age, sex, BMI and diabetes. At ordinal regression analysis adjusted as above plus the presence of NRV = 3, the D-loop levels were independently associated with steatosis, necroinflammation, ballooning, fibrosis, and NAS ($p < 0.001$) and were significantly increased in NAFLD patients with NRV = 3 ($p = 0.03$). Finally, in 3 NALFD-HCC patients D-loop copies were higher in the intra-tumoral tissues compared to extra-tumoral ones, showing the highest number in one patient carrying all 3 at-risk variants.

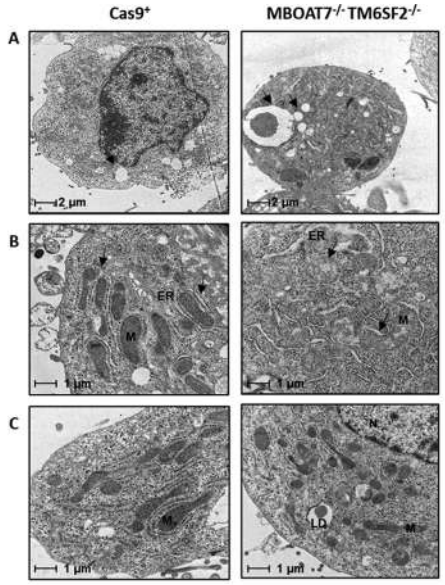


Figure: **A**) Representative TEM images of lipid droplets (LDs) accumulation in the MBOAT7$^{-/-}$ TM6SF2$^{-/-}$ *vs* HepG2 Cas9 positive cells exploited as wild-type control (Cas9^{+}). **B**-**C**) Representative TEM images of degenerative mitochondria (M) and mitochondrial biomass. TEM images were obtained by ultrathin 70 nm sections of hepatocytes (bar scale: 1-2 µm). Black arrows indicated LDs (**A**) or M (**B**) . Capital letters refer to nucleus (N) and endoplasmic reticulum (ER)

Conclusion: PNPLA3, MBOAT7 and TM6SF2 loss-of-functions impair mt-functionality and mass in vitro and NAFLD patients. The assessment of D-loop copies may be a useful biomarker for the evaluation of disease course in genetically predisposed subjects.

SAT038

The association of spleen volume with sex, age, type 2-diabetes, and non-alcoholic fatty liver disease-initial results from more than 35, 000 UK Biobank participants

Samuel Helgesson[1], Sambit Tarai[1], Taro Langner[2], Håkan Ahlström[1,2], Lars Johansson[2], Joel Kullberg[1,2], Elin Lundström[1,2]. [1]*Uppsala University, Department of Surgical Sciences, Radiology, Sweden;* [2]*Antaros Medical AB, BioVenture Hub, Mölndal, Sweden*
Email: samuel.helgesson@gmail.com

Background and aims: Non-alcoholic fatty liver disease (NAFLD) is defined as excessive hepatic fat infiltration not related to alcohol/drug abuse. When estimating liver fat with magnetic resonance imaging (MRI), a threshold of 5.56% is typically used for NAFLD (Szczepaniak *et al.* 2004). The contemporary pandemics of obesity and type 2-diabetes (T2D) drive a global increase in NAFLD, with a substantial risk of sequential progression to non-alcoholic steatohepatitis, fibrosis, and cirrhosis. As interconnected to the liver via the hepatic portal vein, the spleen can be enlarged due to increased portal venous pressure as a result of hepatic fibrosis. However, the current knowledge of the spleen volume (SV) distribution in a normal aging cohort, and its association with T2D and early stages of NAFLD, is limited and therefore the subject of investigation in this work.

Method: A deep-learning method for spleen segmentation and SV estimation was developed and validated (training data = 85 manual segmentations, Dice score = 93%, symmetric mean absolute percentage error = 7.88%) on neck-to-knee MRI images from the UK Biobank (UKBB). In total, 37, 019 subjects were included in the study after exclusion of 1, 800 subjects with potential failure segmentations, according to algorithmic quality ratings (Langner *et al.* 2020), and an additional 18 subjects diagnosed with alcoholic liver disease. Liver proton density fat fraction (PDFF) were available for 4, 613 subjects in the UKBB. Using deep regression on the abovementioned MRI images, liver PDFF was inferred for remaining subjects. The cohort was grouped into Controls (unlikely diabetic, n = 33, 970) and T2D subjects (n = 1, 558), using an algorithm developed on UKBB clinical data (Eastwood *et al.* 2016) and by discarding intermediate/possible diabetic subjects.

Results: Moving average curves of SV vs age, in controls and subjects with T2D, are presented in Fig 1A, with 95% confidence intervals (CI) of the weighted arithmetic average SV displayed. Similar curves of SV vs liver PDFF are presented in Fig 1B. The SV was larger in males than females and in T2D compared to controls, for both sexes, within the approximate age range 55–77 years. There was a similar pattern of age-related decrease in SV in male and female controls. Within certain age intervals, SV appeared to decrease faster with age in T2D subjects compared to in controls. Increasing SV with increasing liver PDFF was observed for both sexes already at low liver PDFF values. For liver PDFF >25%, the measurement uncertainty (CI) was relatively large, as influenced by the low sample size.

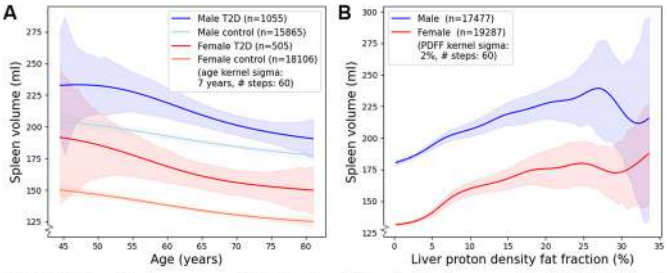

Figure 1. Moving weighted average curves of **(A)** spleen volume (SV) as a function of age, sex, and type 2-diabetes (T2D), and **(B)** SV as a function of liver proton density fat fraction (PDFF) and sex. Weighted arithmetic mean values and 95% confidence intervals are based on a gaussian age kernel sigma of 7 years (in A) and a gaussian PDFF kernel sigma of 2% (in B). Wider confidence intervals in the lowest and highest ages (in A) and highest PDFF values (in B) are influenced by the relatively low sample size in these ranges.

Conclusion: Clear patterns demonstrated men, younger subjects, and individuals with T2D and NAFLD to have larger spleens compared to

females, older subjects, and disease group controls, respectively. The enlarged spleen observed in disease could reflect an increased portal venous pressure occurring already early in NAFLD.

SAT039

Targeting adipose tissue macrophages ameliorates hepatic injury in a murine model of NAFLD

Celia Martínez Sánchez[1,2], Mar Coll[1], Delia Blaya[1], Octavi Bassegoda[1,3], Muhammad Fayyaz[4], Raquel A. Martinez Garcia de la Torre[1], Kelly Swanson[4], Pau Sancho-Bru[1], Andrew Smith[5], Pere Ginès[1,2,3], Isabel Graupera[1,3], Laia Aguilar[1]. *[1]Institut d'Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS), Liver Unit, Barcelona, Spain; [2]Centro de Investigación Biomédica en Red de Enfermedades Hepáticas y Digestivas (CIBEREHD), Spain; [3]Hospital Clínic de Barcelona, Spain; [4]University of Illinois at Urbana-Champaign, United States; [5]University of Illinois at Urbana-Champaign*
Email: celiamartinezsa@gmail.com

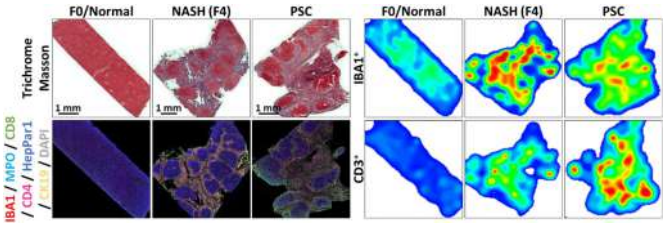
Background and aims: Adipose tissue dysfunction with infiltration of pro-inflammatory macrophages is a hallmark in obesity leading to an impairment of metabolic homeostasis. Non-alcoholic fatty liver disease (NAFLD) is intimately associated with obesity and it has been shown that pro-inflammatory adipose tissue macrophages (ATMs) induce hepatic inflammation although their role in fibrogenesis is still unknown. The aim of the present study is to assess the role of ATMs in hepatic fibrogenesis by modulating the pro-inflammatory phenotype of ATMs.
Method: Dextran (500 kDa) nanocarriers conjugated with dexamethasone (dexa) were used to modulate ATMs' phenotype in a NAFLD models based on high-fat (HFD) and high fat high cholesterol (HFHC) diets. After feeding animals for 5 months, dextran conjugates were administered i.p. twice per week for 5 additional weeks. In order to study dextran uptake, i.p. administration of dextran-FITC was evaluated by flow cytometry and immunofluorescence. Hepatic and AT macrophages' phenotype switch was assessed by flow cytometry and gene expression analysis. The anti-inflammatory effect of dexa-conjugates in liver and adipose tissue was evaluated by assessing key inflammatory markers expression by qPCR and immunostaining. Changes in hepatic fibrosis and NAS score were explored by histopathological analysis. In-vitro phenotypic modulation of human ATMs incubated with dextran conjugates were evaluated by qPCR. The effect of human ATMs on hepatic stellate cells (HSCs) activation was assessed by culturing HSCs with ATMs conditioned media.
Results: Animals fed with HFHC diet displayed increased liver and adipose tissue macrophage infiltration with an enhanced pro-inflammatory phenotype compared to animals receiving HFD. Compared to HFD, liver tissue from HFHC model showed higher NASH score and fibrosis degree. Dextran-dexa conjugates were predominantly engulfed by macrophages from the AT. Conjugated nanocarriers administration significantly switched the pro-inflammatory phenotype of ATMs without significant differences in liver macrophages. Dextran-dexa treatment caused a significant reduction of hepatic inflammation, NAS score, and hepatic fibrosis in the HFHC model. Human ATMs treated with dextran-dexa attenuated their pro-inflammatory phenotype and reduced HSCs activation.
Conclusion: Dextran-dexamethasone conjugates administrated i.p. are predominantly uptaken by adipose tissue macrophages inducing a switch of their pro-inflammatory phenotype which in turns attenuates liver inflammation and fibrosis. In vitro modulation of human ATMs by dextran nanocarriers reduce activated phenotype of HSCs. These results demonstrate that modulating the pro-inflammatory phenotype of ATMs might be a good strategy to reduce hepatic fibrosis and inflammation in NAFLD.

SAT040

Multiplex immunostaining and transcriptomic profiling identify novel immune cell markers for non-alcoholic steatohepatitis and primary sclerosing cholangitis

Adrien Guillot[1], Marc Winkler[1], Milessa Silva Afonso[2], Abhishek Aggarwal[3], Hilmar Berger[1], David Lopez[4], Marlene Kohlhepp[1], Hanyang Liu[1], Sangeetha Mahadevan[3], Lauri Diehl[3], Ruchi Gupta[2], Frank Tacke[1]. *[1]Charité Universitätsmedizin Berlin, Department of Hepatology and Gastroenterology, Berlin, Germany; [2]Gilead Sciences, Department of Fibrosis Biology, United States; [3]Gilead Sciences, Department of Nonclinical safety and Pathobiology, United States; [4]Gilead Sciences, Department of Research Data Sciences, United States*
Email: adrien.guillot@charite.de

Background and aims: The progression of non-alcoholic fatty liver disease (NAFLD) towards non-alcoholic steatohepatitis (NASH) and of primary sclerosing cholangitis (PSC) is accompanied by hepatic infiltration of immune cells. This study aims to combine multiple novel analytic methods for the evaluation of disease stage associated transcriptomic, proteomic and histological changes, and for identifying similarities and differences between NAFLD, NASH, and PSC patients.
Method: Human liver samples (total n = 85) from two independent patient cohorts and mouse samples from a diet induced obesity (DIO) model of NASH and Mdr2-deficient mice (total n = 35) were used. RNA-sequencing and immunostaining by using InSituPlex multiplex immunofluorescence technology were performed on human samples. A specific, adapted sequential immunostaining method for hepatic parenchymal and immune cells was used on all human and mouse samples. Imaging cytometry and clinical or phenotypic data were combined for multidimensional analysis. Key findings on immune cell composition and phenotypes were validated in human clinical samples and functionally tested in mouse models.
Results: NASH and PSC disease stage was associated with significant loss of parenchymal areas, increased fibrosis and defined infiltration of myeloid and lymphoid cell populations. NASH patients predominantly exhibited myeloid cell infiltration, whereas PSC patients had a pronounced lymphoid cell response (Figure). Both diseases displayed intense ionized calcium-binding adapter molecule 1 (IBA1+) macrophage accumulation in the perilobular areas. Using a machine learning-based algorithm, IBA1 in combination with hepatocyte and ductular cell immunostaining predicted advanced disease stage in NASH and PSC. These findings were validated in mouse models of NASH and PSC and macrophage phenotype was further characterized in rodent samples.



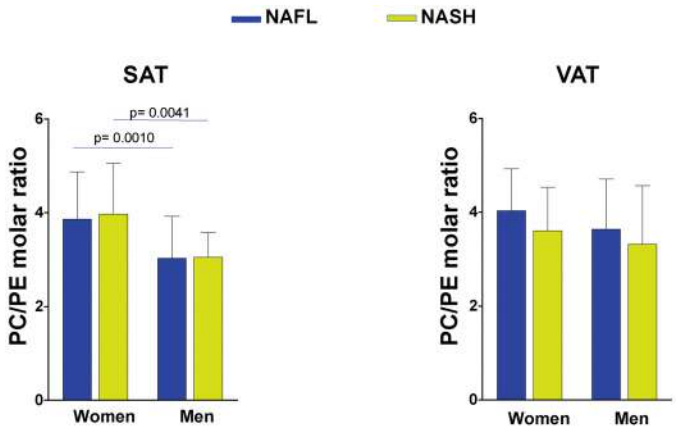
Conclusion: Monocyte/macrophage infiltration and accumulation represents the dominant histological feature associated with the progression of NAFLD, NASH and PSC. Our findings show that IBA1, a pan-macrophage marker, is predictive of disease progression in human and mouse livers.

SAT041

Phospholipid fingerprints reveal sex differences in the adipose tissue phospholipid composition from morbidly obese patients

Gerard Baiges[1,2], Elisabet Rodríguez-Tomàs[2], Helena Castañé[1,2], Andrea Jimenez Franco[2], Jordi Camps[3], Jorge Joven[1,2,3]. *[1]Fundación Instituto de Investigación Sanitaria Pere Virgili, Tarragona, Spain; [2]Rovira i Virgili University, Tarragona, Spain; [3]Hospital Universitari Sant Joan de Reus, Reus, Spain*
Email: gerardbaiges93@gmail.com

Background and aims: Obesity is a metabolic disease that requires adipose tissue mechanisms of hyperplasia and hypertrophy to ensure energy storage. Nevertheless, men show a higher risk to have insulin resistance, diabetes mellitus and liver disease at a lower weight than women. Phospholipid metabolism plays an important role in the development of adipocytes as well as in determining their size. Concretely an enrichment of phosphatidylcholine (PC) in the plasma membrane of adipocytes increases their fluidity and size too. Thus, the purpose of the study was to explore the phospholipid metabolism in both subcutaneous and visceral adipose tissue to observe if their regulation is influenced by sex and the liver disease severity.
Method: Semi-targeted lipidomic was carried out from abdominal-subcutaneous (SAT) and omental-visceral adipose tissue (VAT) morbidly obese patients candidates to undergoing bariatric surgery. The patients were classified based on pathology severity: non-alcoholic fatty liver (NAFL)- NAFLD activity score (NAS) between 0 and 2 (38 women and 13 men); non-alcoholic steatohepatitis (NASH)-NAS ³ 5 (34 women and 18 men).
Results: We observed the phospholipid levels were not influenced in both tissues by the liver disease progression. Nevertheless, we found that women showed a higher PC/PE molar ratio than men, independently of the disease severity. In addition, we found a less content of polyunsaturated fatty acids in the sn2-position of lysophosphatidylcholines (sn2LPC) between women and men, evidencing different responses in the lipid remodelling. This lipid remodelling in women was associated with an increase of fatty acids (C22) as well as the number of desaturation (n-6). Taken together, C22:6 fatty acid has been associated with anti-inflammatory lipid mediators, indicating women could be more resistant to adipose tissue inflammation than men.



Conclusion: These results demonstrate that women and men have a different phospholipid fingerprint, conferring different biological properties to adipocytes. Thus, the higher PC/PE molar ratio observed in women could explain the intrinsic capability to get more fat in SAT regions than men.

SAT042

Ubiquitination of GSDMD regulated by NEDD4 is involved in hepatocyte pyroptosis of non-alcoholic steatohepatitis

Rui Jin[1], Xiaoxiao Wang[2], Feng Liu[2], Huiying Rao[2]. *[1]Peking University People's Hospital, Peking University Hepatology Institute, Beijing, China; [2]Peking University People's Hospital, Peking University Hepatology Institute, Beijing, China*
Email: rao.huiying@163.com

Background and aims: Hepatic injury and death are significant histological features of non-alcoholic steatohepatitis (NASH). Previous studies have shown that gasdermin D (GSDMD)-mediated pyroptosis is involved in the progression of NASH, but its specific mechanism is still unclear. This study intends to clarify further the signaling pathway of GSDMD involved in pyroptosis of of liver cells in NASH and further explore the role of ubiquitin enzymes regulating GSDMD in the pathogenesis of NASH.
Method: Methionine-choline deficient (MCD) diet fed male wildtype C57BL/6 mice aged 6–8-week mice to induce NASH mouse model. CRISPR technique (AAVDJ-TBG-GSDMD-SaCas9 system) was used to target and knock down hepatocellular GSDMD in mice. Immunoprecipitation combined with multi-dimensional mass spectrometry was used to identify the ubiquitinase regulating GSDMD. Normal human cell line L02 were also used to investigate the effect of pyroptosis in hepatocytes on liver inflammation and injury.
Results: Compared with control mice, the expression level of GSDMD mRNA in the liver of NASH mice was downregulated, however, the GSDMD protein levels were upregulated, suggesting that GSDMD protein might undergo post-translational modifications. By detecting the expression and cellular localization of GSDMD in the liver by immunohistochemical staining, we found that the GSDMD positive cells in the liver of NASH mice were mainly hepatocytes, suggesting that GSDMD mediated pyroptosis mainly occurred in hepatocytes. We also tried to identify the exact pathway that induced pyroptosis in NASH and found that Caspase1 protein levels and cleavage were increased in NASH mice compared with control ones, whereas Caspase11 protein levels were not significantly changed, suggesting that pyroptosis in the liver is mainly induced by the activation of classical pathway. Further detection found that the ubiquitination level of GSDMD was increased in Caspase1 knockdown mice, suggesting that the decrease of the ubiquitination level of GSDMD during the progression of NASH depends on caspase1. By analyzing immunoprecipitation combined with multi-dimensional mass spectrometry, compared with control mice, the expression level of E3 ubiquitin ligase NEDD4 downregulated in NASH mouse model. We further verified that NEDD4 was an interacting protein of GSDMD.
Conclusion: NEDD4 might be involved in the ubiquitination of with GSDMD to promote hepatocyte pyroptosis which depended on caspase1 in NASH development.

SAT043

Unraveling the transcriptional dynamics of NASH pathogenesis affecting atherosclerosis development

Anita M. van den Hoek[1], Serdar Özsezen[2], Martien P. M. Caspers[2], Geurt Stokman[1], Arianne van Koppen[1], Roeland Hanemaaijer[1], Lars Verschuren[2]. *[1]The Netherlands Organization for Applied Scientific Research (TNO), Department of Metabolic Health Research, Leiden, Netherlands; [2]The Netherlands Organization for Applied Scientific Research (TNO), Department of Microbiology and Systems Biology, Zeist, Netherlands*
Email: a.vandenhoek@tno.nl

Background and aims: The prevalence of non-alcoholic steatohepatitis (NASH) is rapidly increasing and is associated with an increased incidence of cardiovascular disease (CVD). In fact, CVD remains the major overall cause of mortality in patients with NASH. Although NASH and CVD share common risk factors, the mechanisms by which NASH may directly contribute to the development to CVD remain poorly understood. The aim of this study was to gain insight

into the dynamics of key molecular processes of NASH that drive atherosclerosis development.
Method: A time-course study was performed in Ldlr-/-.Leiden mice, a well-established model for hyperlipidemia that develop NASH with advanced fibrosis and atherosclerosis when fed a high fat diet. NASH and atherosclerosis development in the aortic root were histologically analyzed. Comprehensive transcriptome analysis of liver and aorta was used to identify the temporal dynamics of key processes in both tissues. Dynamical GENIE3 (dynGENIE3) was used for gene regulatory network (GRN) inference using the differentially expressed genes (DEGs) from time series. In this way liver regulators were identified for each aorta target gene by extracting dynamics in the liver that precede dynamics in the aorta and were linked to atherosclerosis development.
Results: The Ldlr-/-.Leiden mice developed obesity, hyperlipidemia, insulin resistance in a time-dependent manner with hepatic steatosis and development of hepatic inflammation preceding the atherosclerosis development. Transcriptome analysis of liver and aorta revealed a time-dependent increase of pathways related to NASH and fibrosis followed by an increase in proatherogenic processes the aorta. DynGENIE3 identified specific liver regulators related to lipid metabolism (SC5D and TM7SF2), inflammation (IL1A) and fibrosis (PDGF) linked to a set of aorta target genes related to vascular inflammation (TNFA) and atherosclerosis signaling (VCAM1 and CCL2).
Conclusion: Time-resolved analyses of NASH and atherosclerosis in Ldlr-/-.Leiden reveal pathogenic liver processes precede atherosclerosis development in the aorta. Gene regulatory network analysis identified hepatic key regulators and gene modules driving the atherogenic pathways and regulators in the aorta.

SAT044
Repeated weight cycling in obese mice improves hepatic inflammation

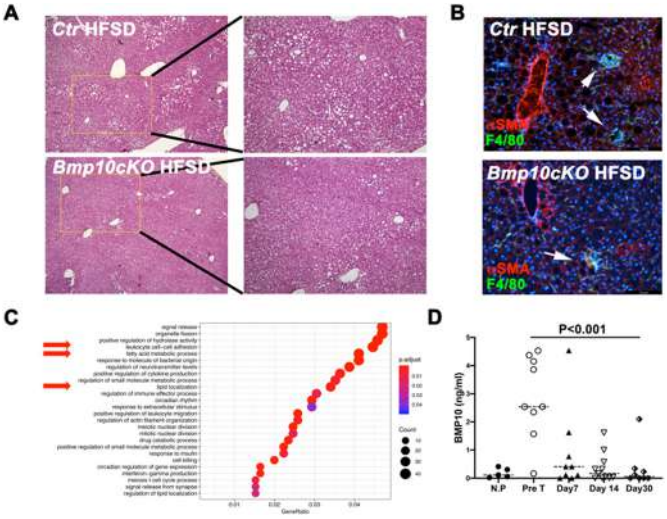
Jelle C.B.C. de Jong[1,2], Nanda Keijzer[1], Nicole Worms[1], Geurt Stokman[1], Nikki van Trigt[1], Aswin L. Menke[1], Anita M. van den Hoek[1]. [1]*The Netherlands Organization for Applied Scientific Research (TNO), Metabolic Health Research, Leiden, Netherlands;* [2]*Wageningen University, Human and Animal Physiology, Wageningen, Netherlands*
Email: a.vandenhoek@tno.nl

Background and aims: Lifestyle interventions aimed to reduce body weight remain the current treatment of choice for non-alcoholic steatohepatitis (NASH), but are difficult to maintain and often lead to cycles of weight loss and regain (weight cycling). Although pertaining literature on weight cycling remains controversial, numerous studies indicate that weight cycling leads to an increased risk of developing Type 2 Diabetes or cardiovascular disease. Relative few studies investigated the association between weight cycling and NASH and therefore this was the aim of our study.
Method: Ldlr-/-.Leiden mice received a high fat diet (HFD) for 20 weeks to induce obesity and NASH. Mice were then maintained for 16 weeks on the HFD (control group) or were subjected to 4 weight cycling episodes (using diet change). In addition, a group of mice on HFD were added with a similar body weight as the weight cycling group upon sacrifice (weight matched HFD reference group). The effects on body composition, plasma and liver biochemical variable and liver and fat histology were assessed.
Results: Weight cycling tended to slightly decrease body weight and total fat mass as compared to the HFD control group, but adipocyte size and fat inflammation were similar. Weight cycling did not result in a significant change in blood glucose or plasma insulin levels as compared to HFD control group, while plasma alanine transferase (ALT) levels were significantly reduced (with −40%, $p = 0.010$) and tended to be reduced as well as compared to weight matched HFD reference group (with −16%, $p = 0.051$). Hepatic macrovesicular steatosis was similar in the weight cycling and HFD control group (28% and 29%, respectively). Microvesicular steatosis tended to be increased upon weight cycling (from 17% in HFD control to 24% in weight cycling group, $p = 0.077$), but not as compared to the weight matched HFD reference group (20% microvesicular steatosis). Weight cycling resulted in a robust decrease in hepatic inflammation as compared to both HFD control group (with −67%, $p = 0.004$) and weight matched HFD reference group (with −60%, $p = 0.014$). Hepatic fibrosis was not affected by weight cycling.
Conclusion: The results of our weight cycling experiment argue against the postulate that weight cycling leads to unfavorable metabolic effects and in fact revealed a beneficial effect on hepatic inflammation.

SAT045
The functional roles of BMP10 in the pathogenesis of non-alcoholic fatty liver disease

Wenjun Zhang[1], Hanying Chen[2], Ying Liu[3], Zachary Rokop[1], Weinian Shou[3], Chandrashekhar Kubal[1]. [1]*Indiana University School of Medicine, Department of Surgery, Indianapolis, United States;* [2]*Indiana University School of Medicine, Genome Editing Center, Indianapolis, United States;* [3]*Indiana University School of Medicine, Department of Pediatrics, Indianapolis, United States*
Email: sakubal@iupui.edu

Background and aims: BMP10 belongs to the Transforming Growth Factor (TGF)-beta superfamily that comprises of more than 45 cytokines based on amino acid sequence homology. Unlike most of other BMP proteins that only function locally at the site of expression (autocrine/paracrine function), BMP10 can act on remote tissue as a circulating cytokine (endocrine function). Recently, BMP10 expression was detected in hepatic stellate cells in human liver. Here we investigated the roles of BMP10 in the regulation of homeostasis of liver metabolism and pathogenesis of non-alcoholic fatty liver disease (NAFLD).
Method: We generated *Bmp10*$^{lox/lox}$ mice and crossed with the *Rosa26-CreER*^{T2} mice to create BMP10 postnatal conditional knockout mice (named as *Bmp10cKO*), which *Bmp10* can be efficiently ablated via activated Cre recombinase activity in all adult tissues/cell types following estrogen agonist-tamoxifen induction in the postnatal mouse. *Bmp10cKO* mice (male, 8-week-old) and controls (*Bmp10*$^{lox/lox}$) were subjected to high fat high sucrose diet (HFSD) feeding for 20 weeks. A normal chow diet (ND) was used as feeding control. At the end of the diet exposure, we evaluated: (i) liver histology (ii) liver fibrosis by fast green/Sirius red staining; (iii) liver functional tests; (iii) immunoreactivity of selected inflammatory cell markers by IHC (F4/80) and *q*PCR of inflammatory genes. Total RNA samples for RNA-seq analysis were isolated from *Bmp10pCKO* (*BCK*) and their littermate control. Finally, we measured circulating BMP10 levels in sera of 9 patients with established cirrhosis undergoing liver transplantation (4 with non-alcoholic steatohepatitis (NASH)) before and after transplantation and compared to 5 healthy controls.
Results: After prolonged HFSD exposure, histological analyses demonstrated a significantly reduced degree of steatosis and fibrosis in the livers from *Bmp10pCKO* mice when compared with controls (Fig. 1A). There were a significantly fewer Kupffer cell (KC) clusters in *Bmp10pCKO* livers when compared to control livers (Fig. 1B). RT-PCR analysis demonstrated that the expression TNFα, IL1B and TGFβ were reduced in *Bmp10pCKO* livers. Transcriptomics analysis in combination with Gene Ontology (GO) analysis revealed that leukocyte cell-cell adhesion, fatty acid metabolism, and lipid localization process were among the most altered Biological Process (BP) (Fig. 1C). In cirrhotic patients undergoing liver transplantation, we found that circulating BMP10 levels are significantly elevated prior to transplantation as compared to the post-transplant levels and normal controls, reaching to an average value of 2.89 ± 1.46 ng/ml ($p < 0.001$) (Fig. 1D).



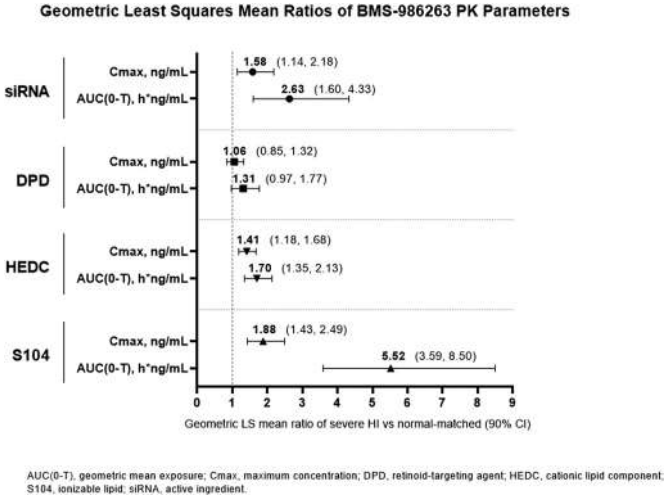
Conclusion: These data suggest that BMP10 plays a pivotal role in in the regulation of liver metabolism and pathogenesis of NAFLD/NASH.

SAT046

Pharmacokinetics, safety, and tolerability of BMS-986263, a lipid nanoparticle containing HSP47 siRNA, in participants with severe hepatic impairment

Giridhar Tirucherai[1], Eric Lawitz[2], Claudia De Oliveira[1], Hisham Qosa[1], Edgar Charles[1]. [1]*Bristol Myers Squibb;* [2]*The Texas Liver Institute, University of Texas Health San Antonio, San Antonio, United States*
Email: giridhar.tirucherai@bms.com

Background and aims: BMS-986263 is a retinoid-conjugated lipid nanoparticle delivering siRNA designed to degrade heat shock protein 47 (HSP47) mRNA and prevent synthesis of HSP47 protein, a collagen-specific chaperone involved in fibrosis development. Evaluation of BMS-986263 in patients with non-alcoholic steatohepatitis and compensated cirrhosis (NCT04267393) is ongoing. In part 1 of the hepatic impairment (HI) phase 1 study (NCT04225936), significant changes in pharmacokinetics (PK) and safety were not observed in participants (ppts) with mild or moderate HI compared with healthy ppts. Here, part 2 results (severe HI) are presented.
Method: Ppts with severe HI (Child-Pugh score 10–14) were matched by age and body mass index (BMI) to a cohort of ppts with normal hepatic function. All received a single intravenous 90 mg BMS-986263 infusion; serial blood samples were collected for PK analyses. The primary end point was PK of BMS-986263 components including siRNA (active ingredient), DPD (retinoid-conjugated targeting agent), and S104 (ionizable lipid). Secondary and exploratory end points were safety and PK of HEDC (cationic lipid component), respectively.
Results: The mean (SD) age and BMI for severe HI ppts (n = 8) were 55.5 (3.7) years and 34.3 (12.0) kg/m^2, respectively, compared with 56.1 (4.1) years and 30.6 (8.3) kg/m^2, respectively, for normal-matched ppts (n = 8). Relative to normal-matched ppts, siRNA geometric mean exposure (AUC $_{(0-T)}$) was 163% greater in ppts with severe HI, and C_{max} was higher by 58% (figure). DPD exposure was 31% higher in ppts with severe HI compared with normal-matched ppts and C_{max} was 6% higher. The severe HI cohort also had a 452% increase in S104 exposure (88% higher C_{max}), and a 44% increase in HEDC exposure (23% higher C_{max}) compared with normal-matched ppts. In total, 3/8 ppts had 4 adverse events (AEs) in the severe HI cohort (infusion-related reaction [IRR; n = 2], nausea [n = 1], and dysuria [n = 1]); no normal-matched ppts had AEs. Two ppts experienced treatment-related AEs that were IRRs of severe back pain/chest tightness that resolved in less than 30 minutes without requiring treatment or study discontinuation.



AUC(0-T), geometric mean exposure; Cmax, maximum concentration; DPD, retinoid-targeting agent; HEDC, cationic lipid component; S104, ionizable lipid; siRNA, active ingredient.

Conclusion: Single-dose BMS-986263 was generally safe and well-tolerated in ppts with severe HI. The PK of some BMS-986263 components were affected by severe HI; increased exposure of siRNA and S104 (163% and 452%, respectively) was observed in ppts with severe HI compared with normal-matched ppts.

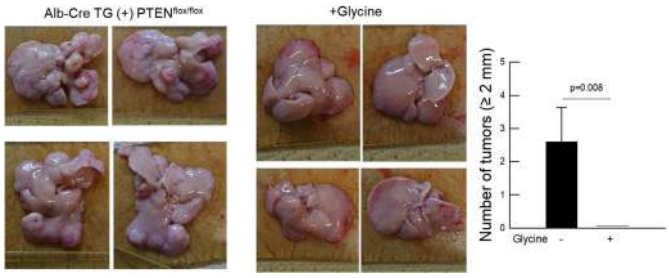
SAT047

Amino acid glycine suppresses steatohepatitis and tumorigenesis in hepatocyte-specific phosphatase and tensin homolog knockout mice

Kazuyoshi Kon[1], Kumiko Arai[1], Akira Uchiyama[1], Hiroo Fukada[1], Toshifumi Sato[1], Maki Morinaga[1], Kyoko Fukuhara[1], Reiko Yaginuma[1], Shunhei Yamashina[1], Kenichi Ikejima[1]. [1]*Juntendo University School of Medicine, Department of Gastroenterology, Tokyo, Japan*
Email: kazukon@juntendo.ac.jp

Background and aims: Establishing a preventive treatment for hepatocellular carcinoma (HCC) following non-alcoholic steatohepatitis (NASH) is an urgent issue. The Aim in the present study was to investigate the effect of the amino acid glycine on NASH-related HCC using hepatocyte-specific phosphatase and tensin homolog (PTEN)-deficient mice.
Method: Male Alb-Cre TG (+) PTEN$^{flox/flox}$ mice aged 11–17 weeks were fed a normal diet or a diet containing 5% glycine for 2 or 24 weeks. Wild-type or TG (-) mice fed a normal diet were used as control. The expression of 4-hydroxynonenal (4HNE) and CD8 was evaluated by immunohistochemical staining. Total glutathione level was measured using enzymatic method. The number of liver tumors with a diameter of 2 mm or more was counted. The expression of mRNA in liver tissue was measured by RT-PCR.
Results: PTEN$^{flox/flox}$ mice developed severe steatohepatitis with lobular inflammation and ballooning hepatocytes after 2 weeks, and serum ALT levels significantly increased to 163 ± 30 IU/L compared to 41 ± 4 IU/L in control, whereas the glycine-containing diet clearly improved steatohepatitis and significantly reduced serum ALT levels to 23 ± 10 IU/L. The expression of 4HNE was enhanced in the liver of PTEN$^{flox/flox}$ as compared with control, and was suppressed by glycine administration. Total glutathione in the liver tissue of PTEN$^{flox/flox}$ mice was significantly decreased from 2.2 ± 0.2 micro mol/g in the control to 1.4 ± 0.1 micro mol/g, and significantly increased to 1.8 ± 0.1 micro mol/g by glycine administration. After 24 weeks of experiment, the liver of Pten$^{flox/flox}$ developed a tumor of 2.6 ± 1.0, but glycine-containing diet completely suppressed tumor formation to 0 ± 0. The expression of IL12B mRNA was slightly increased in PTEN$^{flox/flox}$ mice compared to the control, and glycine administration further increased the expression to 4 times or more of the normal diet. In liver tissue, the expression of CD8-positive

lymphocytes of PTEN$^{flox/flox}$ mice was increased by glycine-containing diet.



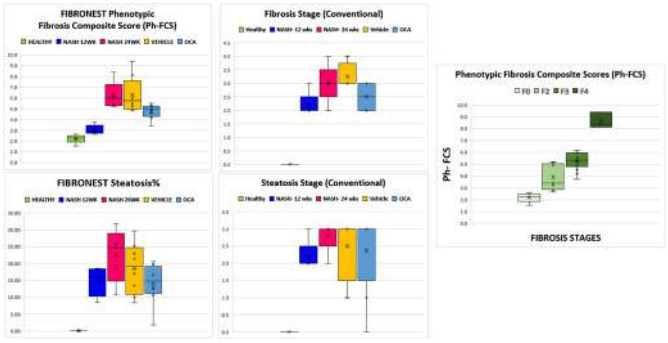
Conclusion: Glycine markedly improved steatohepatitis and inhibited hepatic tumorigenesis in hepatocyte-specific PTEN knockout mice. Our findings indicated that glycine acts as anti-oxidative stress to improve steatohepatitis in the early stages, and contributes to the activation of antitumor immunity and suppresses tumor formation in the carcinogenic stage. It was demonstrated that glycine has the potential to prevent NASH-related carcinogenesis.

SAT048

Advanced quantitative phenotypic fibrosis and steatosis scoring is more superior to histology-based conventional staging in NASH animal models

Li Chen[1,2], Dipankar Bhattacharya[3], Scott Friedman[3], Mathieu Petitjean[1]. *[1]PharmaNest, Princeton, United States; [2]PharmaNest Inc, Princeton, United States; [3]Icahn School of Medicine at Mount Sinai, New York, United States*
Email: li.chen@pharmanest.com

Background and aims: The defining pathologic elements of non-alcoholic steatohepatitis (NASH) are fat accumulation, inflammation, and fibrosis. While conventional histopathology remains the gold standard for diagnosis and staging, this method has limitations, as it uses a narrow range for scoring, qualitative evaluation, and it is also prone to inter-observer variability. The Phenotypic Fibrosis Composite Score (Ph-FCS) calculated by the FibroNest image analysis platform is a novel continuous phenotypic scoring and quantifier of fibrosis and steatosis. Here, we compared Ph-FCS to the conventional scoring in the FAT-NASH model, whose features closely align with human NASH (Tsuchida et al, J. Hepatology 2018; doi: 10.1016/j.jhep.2018.03.011).
Method: Mice (n = 5 per group) were fed a normal diet or the FAT-NASH regimen (high fat, high fructose, high cholesterol, very low dose CCl_4) for 12 or 24 weeks to induce NASH. In other groups, NASH mice (n = 8) were treated with vehicle or with the clinical-stage drug obeticholic acid (OCA, 30 mg/kg, by gavage) for 24 weeks. Liver histological sections were stained with picrosirus red for collagens and imaged at 40X in white light with an Aperio Digital Pathology system. FibroNest®, a cloud-based image analysis platform, was used to quantify the fibrosis phenotype including 32 traits for collagen content and structure, fiber morphometry, and architecture (measures the organization of the fibers). Principal quantitative fibrosis traits (up to 315 qFTs) are automatically detected and combined into a normalized Phenotypic Composite Fibrosis Score (Ph-FCS).
Results: For Healthy vs NASH at 12 wks and 24 wks, FibroNest Ph-FCS FIBROSIS scores (averages) 2.21, 3.08 (p = 0.01), and 6.21 (p = 0.001) respectively, while the conventional method scores 0, 2.2 (p = 0.0003), and 3 (p = 0.0006). For Vehicle vs OCA, FibroNest Ph-FCS FIBROSIS scores were 6.27 and 4.47 (p = 0.03) respectively, while the conventional method scores were 3.3 and 2.5 (p = 0.09). For Healthy vs NASH at 12 wks and 24 wks, FibroNest STEATOSIS scores (averages) were 0.08, 14.71 (p = 0.001), and 22.43 (p = 0.003) respectively, while the conventional scores were 0, 2.2 (p = 0.0003), and 2.8 (p = 0.0001). For Vehicle vs OCA, FibroNest STEATOSIS scores 18.53 and 14.0 (p = 0.2) respectively, while the conventional scores 2.5 and 2.4 (p = 0.8). Thus, both fibrosis and steatosis progress from 0 to 24 wks NASH, however OCA only provided anti-fibrotic but not anti-steatosis effects.



Conclusion: FibroNest shows a markedly wider dynamic range of difference between the groups in the FAT-NASH study. This allows greater detection and sensitivity for subtle changes. FibroNest® provides a more sensitive and reliable evaluation of fibrosis severity and progression in NASH and for the evaluation of therapeutic drug efficacy.

SAT049

Chemical suppression of adipose triglyceride lipase improves non-alcoholic steatohepatitis in a diabetic and hyperlipidemic mouse model

Emmanuel Dauda Dixon[1], Alexander D Nardo[1], Thierry Claudel[1], Claudia Fuchs[1], Veronika Mlitz[1], Tatjana Stojakovic[2], Hubert Scharnagl[3], Gernot Grabner[4], Robert Zimmermann[4], Michael Trauner[1]. *[1]Medical University of Vienna, Hans Popper Laboratory of Molecular Hepatology, Division of Gastroenterology and Hepatology, Department of Internal Medicine III, Wien, Austria; [2]University Hospital Graz, Clinical Institute of Medical and Chemical Laboratory Diagnostics, Graz, Austria; [3]Medical University of Graz, Clinical Institute of Medical and Chemical Laboratory Diagnostics, Graz, Austria; [4]University of Graz, Institute of Molecular Biosciences, Graz, Austria*
Email: michael.trauner@meduniwien.ac.at

Background and aims: Metabolic comorbidity such as diabetes, obesity and metabolic syndrome plays a key role in the pathogenesis and progression of non-alcoholic fatty liver disease (NAFLD). Increased adipocyte triglyceride lipase (ATGL/PNPLA2) activity, because of insulin resistance, may result in enhanced release of fatty acids from white adipose tissue to the liver, where it precipitates the development and progression of NAFLD. Therefore, ATGL is an attractive target to avert metabolic liver injury. We tested whether the pharmacological ATGL inhibitor Atglistatin hinders metabolic syndrome and improves liver injury in STAM mice as a model of non-alcoholic steatohepatitis (NASH).
Method: Two-days-old C57BL/6j male mice received a single subcutaneous streptozotocin (STZ) injection (100 mg/kg body weight). HFD intervention in the STZ-injected mice representing STAM (diabetic and hyperlipidemia condition) commenced at the age of four weeks and continued for further four weeks. NASH developed within 8 weeks. For the pharmacological inhibition of ATGL, STZ-injected mice were fed an HFD supplemented with 2 mmol/kg Atglistatin for four weeks.
Results: Atglistatin reduced body weight (–2.54 g), despite a comparable consumption of food between the STAM and Atglistatin groups. The bodyweight reduction was due to a decrease in fat (-40%) and liver mass (–23%). Atglistatin treatment significantly improved fasting blood sugar (-12%). Interestingly, the intestinal length was longer (+50%) in the Atglistatin mice in comparison to the STAM mice.

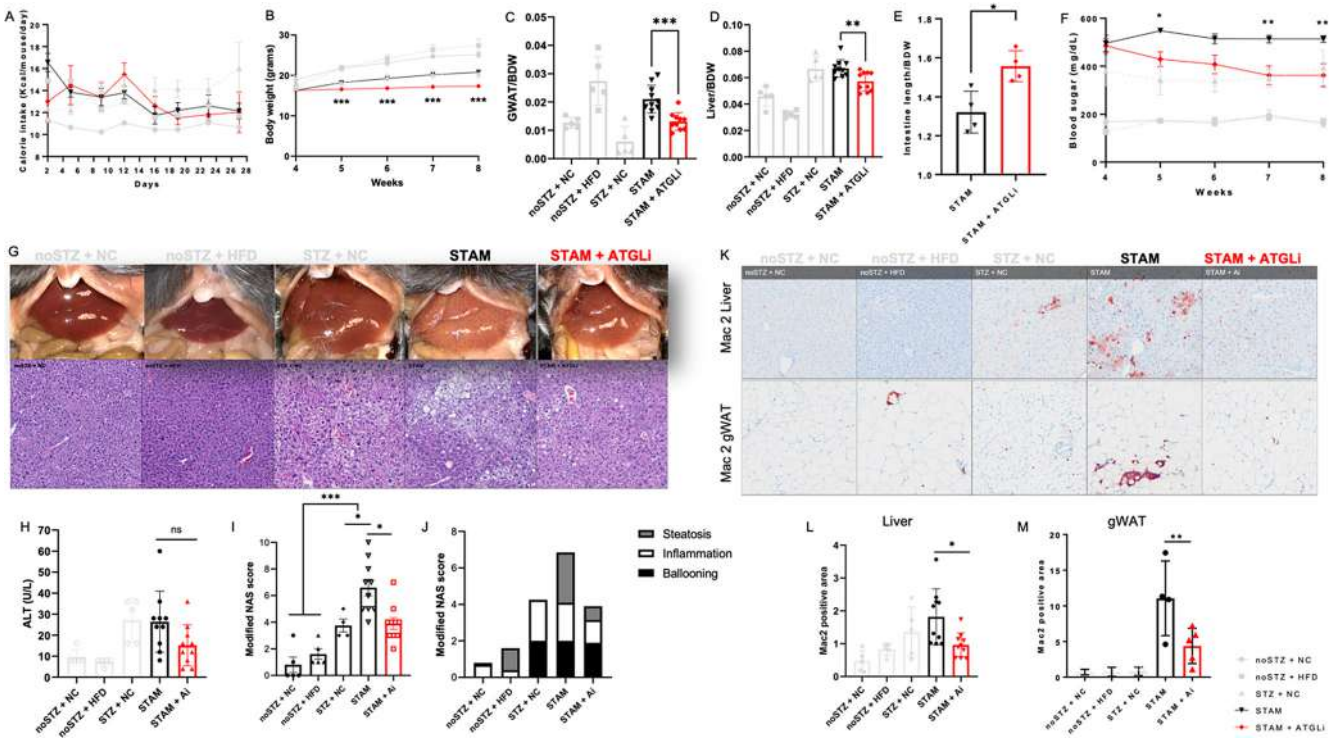


Figure: (abstract: SAT049)

In line with a trend for reduced ALT, there was a significant improvement in histological liver injury assessed by HandE staining and NAFLD score (−45%). The NAFLD score revealed improvement of steatosis (−60%) and inflammation (−35%) but not ballooning in the Atglistatin group. Immunochemistry showed that Atglistatin treatment significantly reduces Mac2 positive cells in the liver (−50%) and gonadal white adipose tissues (gWAT) (-60%) compared to the untreated STAM group, indicating a reduced infiltration of immune cells into the liver and gWAT.

Conclusion: Atglistatin improved metabolic features and liver injury in the STAM mice by reducing inflammation and fat accumulation in key metabolic tissues such as the liver, the adipose tissue, and the intestine.

Email: patricia.aspichueta@ehu.eus

Background and aims: High methionine and S-adenosylmethionine (SAMe) serum levels are related with obesity and both high and low liver SAMe levels promote non-alcoholic fatty liver disease with age. Dietary methionine restriction and deficiency in some enzymes of the methionine cycle confer resistance to obesity development. Here we investigated: *i*) if the pharmacological knockdown (KD) of methionine adenosyltransferase (*Mat1a*) gene, expressed exclusively in liver and which product synthesizes SAMe, provides beneficial outcomes in obesity and comorbidities. *ii*) The mechanism and molecular agents implicated in these outcomes.

Method: Liver *Mat1a* was silenced in high-fat diet (HFD)-fed and in genetically obese mice using antisense oligonucleotides (ASO). Liver specific fibroblast growth factor (*Fgf*) 21 knockout (KO) mice were used and KD of brown adipose tissue (BAT) *β-klotho* and *Ucp-1* was performed. Changes in body weight, glucose and fat management and energy expenditure were analyzed together with liver and BAT histologies and metabolic fluxes. Primary cultures of hepatocytes from HFD-fed *Mat1a* or control ASO-treated mice were also used

Results: In HFD-fed and in genetically obese mice, *Mat1a* silencing induced thermogenesis leading to a pronounced weight loss and reversion of insulin resistance and hypertriglyceridemia. *Mat1a* ASO

treatment induced the recovery from hepatosteatosis reducing liver *de novo* lipogenesis without changing fatty acid oxidation and triglyceride secretion. Serum transaminases and liver fibrotic and inflammatory markers remained unaltered in these mice, while serum FGF21 increased. *In vitro* experiments with hepatocytes from HFD-fed ASO-treated mice and *in vivo* experiments with liver specific *Fgf21*-KO mice showed that liver FGF21 was driving the recovery from obesity. Targeting *Mat1a* in HFD-fed BAT *β-Klotho*- and *Ucp1*-KD mice showed the involvement of thermogenesis in the phenotype. Hepatocyte FGF21 secretion was induced by the nuclear factor erythroid 2-related factor 2 (NRF2), a mediator of antioxidant response, as the binding to the *Fgf21* promoter in *Mat1a* ASO-treated HFD-fed mice hepatocytes and treatments with *Nrf2* siRNA, ML385 -a NRF2 inhibitor-, SAMe and the antioxidants glutathione and N-acetylcysteine showed.

Conclusion: Targeting *Mat1a* reverses obesity, dyslipidemia, insulin resistance and hepatosteatosis through the hepatocyte secretion of FGF21 in a mechanism driven by NRF2.

SAT051

NLRP3 inflammasome dependent cell death in myeloid cells drives liver inflammation and fibrosis in murine steatohepatitis

Benedikt Kaufmann[1,2], Agustina Reca[1], Aleksandra Leszczynska[1], Andre D. Kim[1], Laela M. Booshehri[1], Helmut Friess[2], Daniel Hartmann[2], Lori Broderick[1], Hal M. Hoffman[1], Ariel Feldstein[1].
[1]*Department of Pediatrics, University of California San Diego, La Jolla;* [2]*Department of Surgery, TUM School of Medicine, Klinikum rechts der Isar, Technical University of Munich*
Email: benedikt_kaufmann@hotmail.com

Background and aims: Non-alcoholic fatty liver disease (NAFLD) is the leading cause of chronic liver disease worldwide showing a rapidly rising prevalence among all age groups. Cellular death is crucial in the pathogenesis of NAFLD and driving liver inflammation as well as fibrosis. The NLRP3 inflammasome, a multiprotein complex promoting activation of caspase-1 as well as interleukin 1β (IL-1β) release, is recognized to promote programmed cell death in the form of pyroptosis. The cell-specific contribution of the activation of the NLRP3 inflammasome in myeloid cells in NAFLD remains unknown.

Method: A conditional Nlrp3 knock-out mouse was generated and bred to mice expressing Cre under the control of Lysozyme to investigate the role of NLRP3 inflammasome dependent cell death in myeloid cells, liver inflammation and fibrosis. Both acute (lipopolysaccharide (LPS)/adenosine-triphosphate (ATP)) and chronic (choline-deficient, L-amino acid-defined high-fat diet (CDAA-HFAT)) liver injury models were used to induce *in vivo* NLRP3 activation and fibrotic-non-alcoholic steatohepatitis (NASH). Cell death, liver inflammation and fibrosis were analysed.

Results: Myeloid-specific Nlrp3 knock-out resulted in a systemic and hepatic decrease of IL-1β release compared to control mice induced by LPS/ATP injection. NASH-associated cell death and hepatic inflammation was ameliorated in myeloid-specific Nlrp3 knock-out mice in the CDAA-HFAT model. In addition, fibrosis and hepatic stellate cell activation were decreased in myeloid-specific Nlrp3 knock-out mice.

Conclusion: This study provides new insights in the role of NLRP3 activation in myeloid cells in the pathogenesis of NAFLD and identifies myeloid specific NLRP3 inflammasome activation as crucial for the progression of NAFLD to fibrotic-NASH.

SAT052

The PNPLA3 I148M variant increases intrahepatic lipolysis and beta oxidation and decreases de novo lipogenesis and hepatic mitochondrial function in humans

Email: panu.luukkonen@fimnet.fi

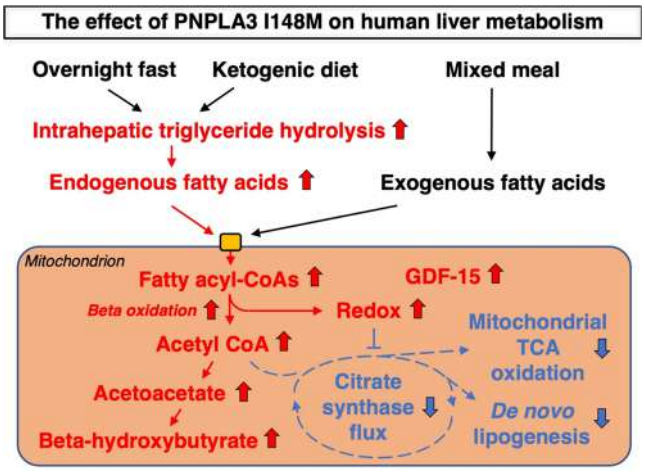
Background and aims: The PNPLA3 I148M variant explains >10% of the risk of cirrhosis but the underlying pathophysiology remains unknown. We studied the effect of this variant on hepatic metabolism *in vivo* under multiple physiological conditions by combining a recruit-by-genotype approach with state-of-the-art stable isotope techniques.

Method: We recruited a total of 93 healthy participants (mean age 53 ± 1 yrs, BMI 30 ± 1 kg/m^2, 19% men; 37 homozygous carriers [148MM] and 56 non-carriers [148II]). Hepatic *de novo* lipogenesis (DNL) was assessed in 48 participants after an overnight fast using D_2O (148MM, n = 19; 148II, n = 36). Hepatic fate of exogenous fatty acids (FA) was determined in 26 participants using a mixed meal enriched in ^{13}C-labeled FA (148MM, n = 12; 148II, n = 14). Rates of endogenous glucose production, ketogenesis and hepatic mitochondrial citrate synthase flux were assessed in 12 participants before and after a 6-day ketogenic diet by Positional Isotopomer NMR Tracer Analysis (PINTA) by infusing [3-^{13}C]-lactate, [$^{13}C_4$]-beta-hydroxybutyrate (BOHB) and [$^2H_7$]-glucose (148MM, n = 6; 148II, n = 6). Intrahepatic triglycerides (IHTG) were assessed by ^1H magnetic resonance spectroscopy and hepatic mitochondrial redox state was assessed by the ratio of plasma [BOHB] and [acetoacetate].

Results: After an overnight fast, the 148MM group had higher plasma BOHB concentrations (+104%, p <0.05) and lower DNL (-47%, p <0.01) than the 148II group, independent of plasma FA and insulin concentrations. After a mixed meal, exogenous ^{13}C-labeled FAs in the 148MM group were channeled more towards ketogenesis (+265%, p <0.001), which was associated with an increased hepatic mitochondrial redox state (+36%, p <0.05). During a ketogenic diet, the 148MM group manifested higher rates of intrahepatic lipolysis as reflected by a larger reduction in IHTG (77%, p <0.05) than the 148II group, which was associated with: *1*) increased plasma BOHB concentrations (+90%, p <0.05), *2*) increased mitochondrial redox state and *3*) decreased rates of hepatic mitochondrial citrate synthase flux (-31%, p <0.01). Plasma concentrations of GDF-15, a mitochondrial stress marker, were also increased by 40% (p <0.01) in the 148MM group compared to the 148II group.

Conclusion: Homozygous PNPLA3 I148M carriers have alterations in both intrahepatic anabolic/catabolic processes and mitochondrial function as reflected by increased rates of intrahepatic lipolysis, decreased rates of DNL and increased hepatic mitochondrial beta oxidation/ketogenesis. These changes in turn were associated with an increased mitochondrial redox state and reductions in hepatic mitochondrial citrate synthase flux. Taken together these results

provide new insights in the mechanisms by which the PNPLA3 I148M variant promotes liver disease (Figure).



SAT053

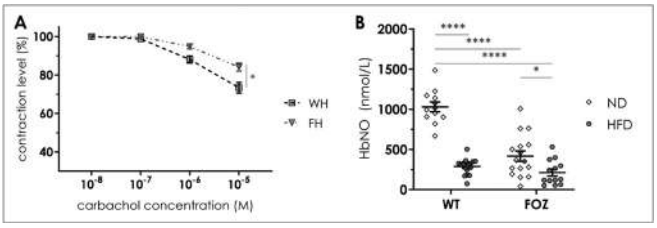
Two diseases, one model-assessing the suitability of FOZ mice to examine CVD in NAFLD

Sebastian Bott[1], Laurent Dumas[2], Dessy Chantal[2], Isabelle Leclercq[3], Evangelos-Panagiotis Daskalopoulos[4], Hrag Esfahani[4]. *[1]Institute of Experimental and Clinical Research (IREC), Laboratory for Hepato-gastroenterology (GAEN), Brussels, Belgium; [2]Institute of Experimental and Clinical Research (IREC), Pole of Pharmacology and Therapeutics (FATH), Université catholique de Louvain (UCL), Belgium; [3]Institute of Experimental and Clinical Research (IREC), Laboratory for Hepato-gastroenterology (GAEN), Belgium; [4]Pole of Cardiovascular Research (CARD), Institut de Recherche Expérimentale et Clinique (IREC), Université catholique de Louvain (UCLouvain), Brussels, Belgium*
Email: sebastian.bott@uclouvain.be

Background and aims: Non-alcoholic fatty liver disease (NAFLD) is an umbrella term which describes different states of liver disease, ranging from simple steatosis to non-alcoholic steatohepatitis (NASH), cirrhosis and finally hepatocellular carcinoma. NAFLD case numbers are constantly rising for three decades with around one quarter of the global population being affected today. Patients with NAFLD are at higher risk of developing cardiovascular disease (CVD)-whereby most fatalities in CVD relate to atherosclerosis. Actually, CVD-dependent mortality is more frequent in patients with NAFLD in comparison to liver-related mortality. This association is related to the common metabolic risk factors such as obesity, dyslipidemia, diabetes, and hypertension shared by both NAFLD and CVD. Even more, NAFLD itself is considered as an independent risk factor for CVD (the leading cause of death globally), the link for this latter association is however still unknown. Established pre-clinical animal models only focus on one of the two diseases, yet. Therefore, the aim of this study was to assess the opportunity of using a single mouse model to examine NASH and cardiovascular disease concurrently to facilitate analysis of potential mechanistic links between both diseases.

Method: Male fat aussie mice (FOZ) and their age-matched wildtype (WT) controls were fed regular chow and high fat diet (60% kcal fat) for 24 weeks. Animals were then sacrificed, liver samples were gathered for histological assessment of the hepatic conditions, blood was sampled for determination of nitrosylated hemoglobin (HbNO) levels via electron paramagnetic resonance spectroscopy (EPR), the aorta was searched for atherosclerotic plaques and rings of first order mesenteric arteries were isolated and utilized in a wire myograph to assess carbachol (10^-8M to 10^-5M)-triggered nitric oxide (NO)-dependent relaxation to search for endothelial dysfunction, an early hallmark of atherosclerosis.

Results: FOZ mice on high fat diet (FH) featured all hepatic characteristics of progressive NASH (steatosis, ballooning, inflammation, fibrosis; NAFLD activity score = 8). Although no plaques in the aorta were found, a significant reduction in their mesenteric arterial NO-dependent relaxation at a carbachol-concentration of 10^-5M compared with wildtype mice on high-fat diet (WH) was detected; [$p < 0.05$]; (A). In addition, EPR showed the lowest HbNO-level in FOZ mice fed a high-fat diet (B).



Conclusion: These results demonstrate suitability of the FOZ mouse model for studies to examine CVD in NAFLD since it develops all key characteristics of progressive liver disease and endothelial dysfunction, an essential hallmark in the development of atherosclerosis which represents the main cause of death in CVD.

SAT054

Oleic acid-induced acute lung injury in Ob/Ob mice fed with high-fat-diet exacerbate bile acid uptake and liver injury that was reversed by antagonizing their entry

Johnny Amer[1], Ahmed Salhab[1], Rifaat Safadi[1]. *[1]Hadassah Hebrew University Hospital, Liver Unit, Jerusalem, Israel*
Email: johnnyamer@hotmail.com

Background and aims: Acute respiratory distress syndrome (ARDS) is a serious complication of COVID-19 and present in a large percentage of COVID-19 deaths. Many studies suggest that people with obesity are at increased risk of severe COVID-19, however, mechanism on liver-lung axis remains unknown. We aimed to evaluate whether bile acid (BAs) trafficking interfere with acute lung injury (ALI) in animal model with obesity.

Method: Leptin deficient (*ob/ob*) mice fed with high-fat-diet (*Ob/Ob* ^{HFD}) were *i.p* injected with oleic acid (OA) to induce ALI. To modulate BAs uptake, mice were *i.p* treated with neutralizing antibody for sodium taurocholate co-transporting polypeptide (NTCP; BAs-transporter). Broncho-alveolar lavage fluid (BALF), lungs, livers and serum were obtained from mice and assessed for inflammatory (HandE staining, ALT and pro-inflammatory panel of cytokines), fibrosis (Sirius red staining, a-smooth muscle actin, collagen and fibronectin) and metabolic (BAs, cholesterol, triglyceride, glucose tolerance test (GTT) and fasting blood sugar (FBS)) profiles. In addition, alveolar-capillary membrane injury of surfactant D (SP-D) and the receptor for advanced glycation end-products (RAGE). BAs trafficking were assessed in primary lung cells and their impact on proliferation and apoptosis were evaluated.

Results: Compared to WT-littermates, OA-induced lung injury and was worsened in the in the *Ob/Ob* ^{HFD} in the histopathology outcome. In addition, BALF of the *Ob/Ob* ^{HFD} showed elevated levels of BAs (3-fold; $P = 0.002$) associated with increased GM-CSF, INF-g, IL-1, IL-6 and IL-8 ($p < 0.01$). Moreover, *Ob/Ob* ^{HFD} with OA showed elevated serum levels in liver enzymes, lipids, glucose and metabolic markers ($p < 0.01$). In addition, *Ob/Ob* ^{HFD} livers showed an exacerbated fibrosis profile. NTCP neutralizing antibody in *Ob/Ob* ^{HFD} while inhibited BAs uptake/trafficking in both primary alveolar type II (BALF showed 4-fold increase in BAs) and primary hepatocytes (serum showed 3-fold increase in BAs). SP-D, RAGE and serum metabolic

markers were suppressed to normal in line with enhance lung and liver histology and maintaining cell viability.
Conclusion: Modulation of BAs trafficking from the liver of obese mice to the lungs could be an important step in the pathogenesis of ALI. Antagonizing BAs uptake may suggest a therapeutic strategy in improving liver-lung axis.

SAT055
The ubiquitin-like modifier FAT10 is upregulated during NASH and impairs PPAR-alpha activity
Ludivine Clavreul[1], Alexia Cotte[1], Lucie Bernard[1], Joel Haas[1], Nathalie Hennuyer[1], An Verrijken[2,3], Luc Van Gaal[2,3], Sven Francque[2,4], Guillaume Lassailly[5], Bart Staels[1], Réjane Paumelle[1]. *[1]University of Lille, EGID, Inserm, CHU Lille, Institut Pasteur de Lille, U1011, Lille, France, UMR 1011, LILLE, France; [2]Faculty of Medicine and Health Sciences, University of Antwerp, Laboratory of Experimental Medicine and Paediatrics, Antwerp, Belgium; [3]Antwerp University Hospital, University of Antwerp, Department of Endocrinology, Diabetology and Metabolism, Antwerp, Belgium; [4]Antwerp University Hospital, Department of Gastroenterology and Hepatology, Antwerp, Belgium; [5]CHU of Lille, University of Lille, Department of digestive system diseases, U995, LIRIC, Lille, France*
Email: ludivine.clavreul.etu@univ-lille.fr

Background and aims: PPAR-alpha is a nuclear receptor involved in the regulation of lipid metabolism and inflammation in the liver. This transcriptional factor is known to prevent Non-alcoholic Steatohepatitis (NASH), a liver disease characterized by steatosis, inflammation, and ballooning. Indeed, PPAR-alpha is a promising target for the cure of this disease but its gene expression is decreased during NASH development. We show that FAT10, an ubiquitin-like protein known to be involved in proteasomal degradation, is overexpressed in NASH patient's livers and is inversely correlated to PPAR-alpha expression suggesting a role for FAT10 on PPAR-alpha modulation in hepatocytes during NASH progression.
Method: FAT10 and PPAR-alpha hepatic expressions during NASH development were characterized in mice fed two or five weeks with a choline-deficient (CDAA) diet inducing NASH by transcriptomic analysis and immunofluorescence and correlated to histological grade of NASH. The impact of FAT10 modulation on PPAR-alpha expression was then investigated *in vitro* in HepG2 cell line using either a stable overexpression and cytokine treatment inducing FAT10, or siRNA inhibiting FAT10. QPCR and western-blot were performed to assess FAT10 and PPAR-alpha expressions and functional effects on lipid metabolism were quantified by BODIPY staining and Seahorse. Finally, the interaction between FAT10 and PPAR-alpha was observed with co-immunoprecipitation and Proximity Ligation Assay (PLA).
Results: *In vivo*, FAT10 expression is increased in murine NASH livers and associated to a decreased PPAR-alpha expression. *In vitro*, FAT10 overexpression reduces the expression of PPAR-alpha target genes while FAT10 down-regulation increases them. Moreover, FAT10 overexpressing cells accumulate more lipid droplets and have an impaired fatty acid beta-oxidation. Finally, PPAR-alpha and FAT10 co-immunoprecipitate in human hepatocytes, and this interaction was confirmed by PLA *in vitro* and *in vivo*.
Conclusion: These observations show that FAT10 is overexpressed during NASH and correlates negatively with PPAR-alpha expression. Furthermore, FAT10 overexpression is associated with an impaired PPAR-alpha transcriptional activity leading to an inhibition of lipid metabolism in hepatocytes. The interaction observed between FAT10 and PPAR-alpha suggests that FAT10 could be a new modulator of PPAR-alpha activity in hepatocytes during NASH progression.

SAT056
TNF-alpha knockout mice are protected from diet-induced NAFLD in a model of non-obese NAFLD
Katharina Burger[1], Finn Jung[1], Anja Baumann[1], Annette Brandt[1], Raphaela Staltner[1], Victor Sánchez[1], Ina Bergheim[1]. *[1]University of Vienna, Department of Nutritional Sciences, Wien*
Email: ina.bergheim@univie.ac.at

Background and aims: By now, non-alcoholic fatty liver disease (NAFLD) is the most common liver disease worldwide being strongly associated with obesity and insulin resistance but also with dietary pattern. The pro-inflammatory cytokine tumor necrosis factor alpha (TNF-alpha) is thought to be a critical factor in many overweight associated diseases including NAFLD; however, the impact of dietary pattern herein has not yet been fully understood. In the present study we determined the effect of a fat-, sucrose- and cholesterol rich diet in the development of NAFLD in the absence of obesity in TNF-alpha knock out mice (KO) and wild-type animals.
Method: Male TNF-alpha KO and wild-type C57BL/6J mice (6–8 weeks old, n = 8) were pair-fed either a liquid control diet (C) or a liquid fat-, sucrose-, and cholesterol-rich diet (FSC) for 9 weeks. A glucose tolerance test (GTT) was performed in week 8. Markers of liver damage and inflammation as well as insulin signaling were determined in liver tissue. TLR 2 and TLR 4 ligands e.g. lipoteichoic acid and endotoxin were determined using a SEAP reporter activity cell assay in portal plasma.
Results: Despite similar body weight FSC-fed wild-type mice developed liver steatosis with beginning inflammation and insulin resistance when compared to C-fed wildtype mice, whereas FSC-fed TNF-alpha KO mice were significantly protected from inflammatory alterations in liver and impaired glucose tolerance. In line with these findings, mRNA expression of interleukin 1 beta (*IL-1ß)* and interleukin 6 (*IL-6)*, as well as levels of NO_x were also significantly higher in livers of FSC-fed wild-type mice while being almost at level of control in FSC-fed TNF-alpha KO mice. Expression of insulin receptor substrate 1 (*Irs1)* in liver tissue was also significantly higher in livers of FSC-fed mice compared to all other groups, whereas expression in liver of FSC-fed TNF-alpha KO mice was at the level of controls. Levels of TLR 2 and TLR 4 ligands in portal plasma of both FSC-fed groups were higher than in C-fed groups.
Conclusion: Taken together results of the present study suggest that a lack of TNF-alpha may attenuate the development of diet-induced insulin resistance and NAFLD in mice also in settings of non-obesity induced NAFLD. (This project was funded in part by the Austrian Science Fund)

Truman Memorial Veterans' Hospital (VA), Columbia, United States; [5]University of Missouri-Columbia, Department of Medical Pharmacology and Physiology, Columbia, United States*
Email: ibdahj@health.missouri.edu

Background and aims: Non-alcoholic fatty liver disease (NAFLD) is the most common chronic liver disease in the world, with limited therapeutic options. Mitochondrial dysfunction and decreased hepatic mitochondrial fatty acid oxidation (FAO) have been linked to its etiology. Thyroid hormone (TH) is an important regulator of lipid metabolism and may have the potential to treat NAFLD but its use is associated with adverse systemic effects. We hypothesized that

low dose thyroid hormone, which has the advantage of reduced potential for systemic effects, is effective in improving hepatic FAO and rescue of NAFLD. To test this hypothesis, we compared the effects of TH dose on hepatic FAO, mitochondrial quality, and NAFLD histological features in mice.

Method: Six-month-old wild-type male mice with a C57BL/6 background maintained on chow diet were used to compare the effects of TH dose on hepatic FAO. Phosphate buffered saline (PBS) was given intraperitoneally (ip) to control mice (n = 8) for 7 days; treatment groups (n = 8 per group) received low doses of triiodothyronine (T3) at 1 and 5 mcg/100 g weight and a higher dose of 25 mcg/100 g weight ip for 7 days. Complete FAO levels in fresh liver lysate were determined after sacrifice. Mitochondrial trifunctional protein (MTP), the main enzyme complex that catalyzes the last three steps of mitochondrial FAO, and key genes regulating mitochondrial biogenesis and mitophagy were also evaluated. In addition, two-month-old male mice were fed western diet (Research Diets Inc, D12451 Rodent Diet, 45 kcal percent fat, 1 percent cholesterol) for 16 weeks to induce NAFLD, then injected with either PBS (n = 6) or 1 and 25 mcg T3/100 g weight ip for 7 days (n = 6 per group). Effects on hepatic FAO, mitochondrial quality markers, and liver histology were assessed.

Results: As shown in Figure 1, T3 at various doses resulted in a 4-fold increase in total hepatic CO2 production in mice fed chow diet (p <0.001) and a 2-fold increase in mice fed a western diet (p <0.05). There was no statistical difference between effects of lower and higher doses of T3 on FAO. Hepatic MTP protein and RNA expression levels remained unchanged in mice injected with T3 compared to control mice suggesting that T3-induced FAO is not due to increased FAO enzyme expression. RNA expression studies suggest that T3 improves mitochondrial mitophagy and biogenesis. Both lower and higher doses of T3 were effective in rescue of NAFLD in western diet-fed mice with significant histological improvement of steatosis and inflammation, and reduction of ALT levels (p <0.05) compared to control mice.

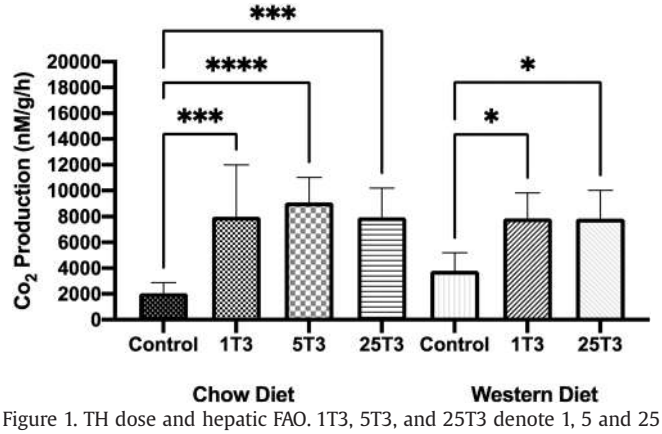

Figure 1. TH dose and hepatic FAO. 1T3, 5T3, and 25T3 denote 1, 5 and 25 mcg T3/100 g weight, respectively. Values expressed as Mean ± S.D. * p < 0.05; *** p < 0.001; **** p < 0.0001

Conclusion: TH at low dose improves hepatic FAO and rescues NAFLD in mice. This study suggests that low dose thyroid hormone is a potential treatment modality for NAFLD.

SAT058

Three-dimensional imaging of cleared human liver tissues reveals extensive fibrosis heterogeneity in non-alcoholic fatty liver disease

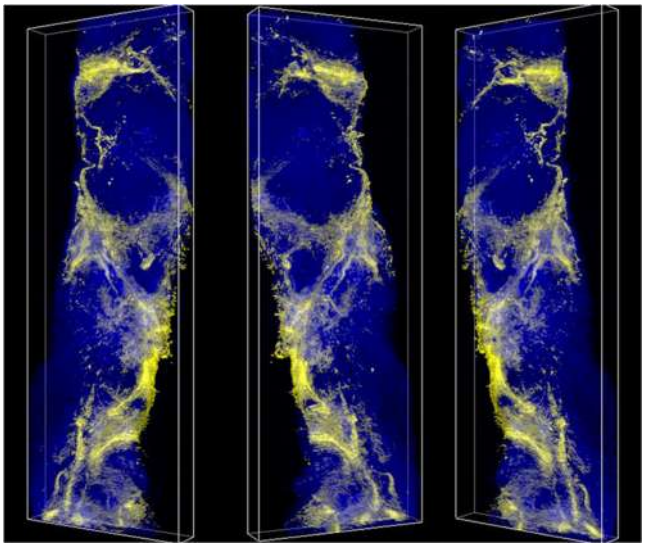
Background and aims: Liver fibrosis is a dynamic process of fibrogenesis and fibrolysis traditionally evaluated by liver biopsy. Accurate assessment of hepatic fibrosis is vital for optimal biomarker and drug development in the era of NASH clinical trials. The limitations of biopsy-based fibrosis staging include semi-quantitative assessment, sampling, and observer variability. In this study, we aimed to perform 3D imaging of optically transparent whole liver biopsy samples by light sheet fluorescence microscopy (LSFM) to quantify extra-cellular matrix proteins.

Method: Fifty seven NAFLD patients and eleven subjects without hepatic fibrosis were included into the study. Liver tissues were cleared by hydrogel embedding, polymerisation and clearing steps of CLARITY. Histological scoring was performed by an expert pathologist. 2D assessment of Sirius red staining was performed through collagen proportionate area (CPA) analysis. 3D imaging of collagen I and elastin was performed via in-house LSFM by acquiring multiple optical sections. Collagen proportionate volume (CPV) and Elastin proportionate volume (EPV) were calculated using over 100 optical sections per sample.

Results: We demonstrated a method which optically cleared various fibrotic stages of liver tissues and optimized non-destructive slide-free fibrosis pathology of whole liver biopsy samples. Cut-offs for CPV and EPV were established for fibrosis stages of NASH. CPV and EPV analysis showed a considerable optical section heterogeneity resulting in at least a fibrosis stage of variance within the sample. While coefficient variation of CPV sections demonstrating 61.5% of intermediate and 23.1% of high level variation, EPV sections showed 69.2% of intermediate and 15.4% of high level variation.



Conclusion: We report for the first time the 3D imaging of liver fibrosis pathology using an in-house developed light-sheet fluorescence microscopy system. Through the imaging of slide-free whole core liver biopsies, we showed that fibrosis variability occurs even in the different optical sections of the biopsy sample. Comprehensive mapping of hepatic extracellular matrix proteins and imaging of slide-free biopsy samples can improve the accuracy of histological assessment and stratification of NASH patients.

In vivo functional genetic screen with a pooled-shRNA library for therapeutic targets of non-alcoholic fatty liver disease

Yong-An Lee[1], Chee Chong Lek[1], Amanpreet Kaur[1], Rong Gao[1], Agnes Bee Leng Ong[1], Yee Siang Lim[2], Shirleen Soh[2], Winston Chan[3], Yock Young Dan[4], Huck Hui Ng[2], Torsten Wuestefeld[1,5,6]. *[1]Genome Institute of Singapore (GIS), Laboratory of in vivo genetics and gene therapy, Singapore, Singapore; [2]Genome Institute of Singapore (GIS), Laboratory of Precision Disease Therapeutics, Singapore, Singapore; [3]Guangzhou Regenerative Medicine and Health Guangdong Laboratory, China; [4]National University of Singapore, Department of Medicine, Singapore, Singapore; [5]National Cancer Centre Singapore, Singapore, Singapore; [6]Nanyang Technological University, School of Biological Sciences (SBS), Singapore, Singapore*
Email: wustefeldt@gis.a-star.edu.sg

Background and aims: With a rapidly increasing prevalence, non-alcoholic fatty liver disease (NAFLD) is recognized as the most common cause of chronic liver disease worldwide. The massive growth of NAFLD is causing a significant burden in health care with social and economic implications. However, unlike other highly prevalent diseases, it remains an underrepresented disease with limited therapeutic possibilities due to the absence of current approved pharmacological treatments. Therefore, there is an urgent need to develop innovative therapies. To address this, we are combining patient samples' transcriptomic profiling with the disease mouse models and in vivo functional genetic screens with the hope of developing therapeutics for this dreaded disease.
Method: We sequenced liver tissues from 130 patients covering different stages of NAFLD to determine dysregulated genes in the patients. Based on the transcriptomic data, a pooled transposon-based shRNA library targeting the dysregulated genes was generated for in vivo genetic screening. The library was directly and stably delivered into hepatocytes of two different mouse models by using hydrodynamic injection. Mice were fed with "Western Diet" supplemented with high fructose and Choline deficient L-amino acid defined high-fat diet (CDHFD) for two different models, respectively, to recapitulate human pathology of the NAFLD. As a control, normal chow-fed animals were served. Our approach's underlying idea is that shRNAs that confer benefits to the hepatocyte in the detrimental environment of the disease will be enriched over time. At the end of diet treatment, livers were harvested, and the abundance of each shRNA was determined by deep sequencing. Highly enriched shRNAs were validated for their potential therapeutic impact by various studies, including in vitro assays for proliferation and in vivo by repopulating FAH-/- mice so that every hepatocyte expresses the shRNA of interest. Repopulated mice were exposed to NAFLD-inducing diets, and histopathology parameters were evaluated.
Results: Our screens have identified novel shRNAs highly enriched in the disease models. One of the shRNAs has been validated for reducing liver fibrosis in the CDHFD model, the aggressive NAFLD model. From the various in vitro and in vivo assays, the candidate gene silencing showed promoted regeneration of hepatocytes without tumor developments.
Conclusion: We show that combining the study of NAFLD patient liver transcriptome with in vivo functional genetic screening in the disease mice models could discover new candidates as therapeutic targets of the disease. We identified and validated a new target for treating NAFLD through our approach. We are currently investigating the underlying molecular mechanisms. Our study may contribute to new insights into the therapeutic development of the disease.

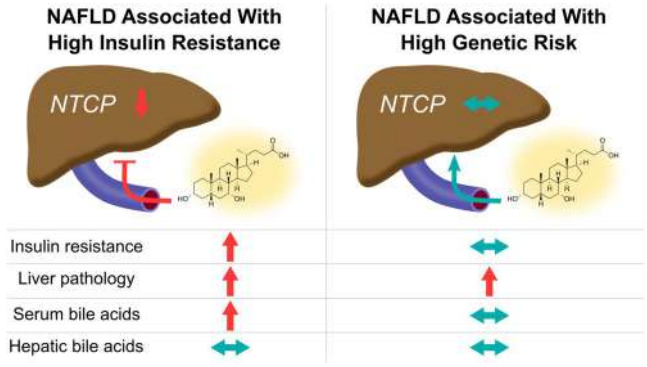
Email: hannele.yki-jarvinen@helsinki.fi

Background and aims: Non-alcoholic fatty liver disease (NAFLD) is associated with increased circulating bile acids (BAs). It is unknown whether this reflects altered intrahepatic BA metabolism due to NAFLD or the associated insulin resistance (IR). To dissociate steatosis from IR, we compared BA metabolism in NAFLD associated with either IR or high genetic risk.
Method: In 106 patients undergoing a liver biopsy, we analysed serum/liver BAs, the hepatic transcriptome (RNA-seq), and concentrations of plasma FGF-19 (marker of intestinal BA metabolism). Using HOMA-IR and a validated weighted Polygenic Risk Score (PRS) for NAFLD, we divided the patients into matched groups to compare the effects of NAFLD associated with IR ('High HOMA-IR' vs. 'Low HOMA-IR') or with high genetic risk ('High PRS' vs. 'Low PRS') on BA metabolism.
Results: An untargeted analysis identified distinct clusters of patients with simultaneously increased BAs, HOMA-IR, and liver fat content. Compared to 'Low HOMA-IR', patients with 'High HOMA-IR' had significantly higher total (+57%, $P = 0.011$) and especially conjugated (+82%, $P = 0.002$) serum BAs, but unchanged hepatic BAs. Expression of the primary hepatic BA uptake transporter NTCP was down-regulated, while plasma FGF-19 was unchanged. Despite having the same degree of steatosis and NASH compared to the 'High HOMA-IR' group, patients with 'High PRS' had similar serum/liver BAs

compared to those with 'Low PRS'. Stage F3-F4 liver fibrosis independently predicted higher serum BAs.



Conclusion: In NAFLD without advanced fibrosis, serum BAs are increased due to IR, which may impair hepatocellular BA uptake. Intrahepatic BAs are unchanged in NAFLD.

SAT061

Non-alcoholic fatty liver disease features a reduced reverse polyunsaturated fatty acid transport (free fatty acids/high-density lipoprotein) from the periphery to the liver

Gabriele Mocciaro[1], Michael Allison[2], Benjamin Jenkins[3], Vian Azzu[2], Isabel Huang-Doran[2], Richard Kay[3], Antonio Murgia[1], Davies Susan[2], Mattia Frontini[4], Antonio Vidal-Puig[3], Albert Koulman[3], Julian L. Griffin[1,5], Michele Vacca[1,3,6]. *[1]University of Cambridge, Department of Biochemistry, Cambridge, United Kingdom; [2]Addenbrooke's Hospital, Cambridge Biomedical Research Centre, Department of Medicine, United Kingdom; [3]Wellcome Trust-MRC Institute of Metabolic Science Metabolic Research Laboratories, United Kingdom; [4]National Institute for Health Research BioResource, Cambridge University Hospitals, United Kingdom; [5]University of Aberdeen, The Rowett Institute, United Kingdom; [6]Aldo Moro University of Bari, Department of Interdisciplinary Medicine, Clinica Medica "C. Frugoni", Italy*
Email: michele.vacca@uniba.it

Background and aims: Non-alcoholic fatty liver disease (NAFLD) is a cluster of liver diseases, ranging from simple steatosis to steatohepatitis (NASH), cirrhosis, and hepatocellular carcinoma. Steatosis arises when hepatic lipid input exceeds output therefore leading to net hepatic fat accumulation; hepatic steatosis does not correlate with disease outcomes that are instead associated with a relative increase in lipotoxic species (e.g. ceramides or diacylglycerols). Over the years, studies have widely reported characteristic changes in the fatty acid pools of tissue, whole serum and VLDL, pointing to NAFLD/NASH-associated increase in *de novo* lipogenesis, suppression of fatty acid oxidation, and depletion of polyunsaturated fatty acids (PUFA). Surprisingly, high-density lipoproteins (HDL) have been disregarded as a source of hepatic lipids despite being one of the possible routes (together with free fatty acids, FFA) delivering lipids from peripheral tissues to the liver.
By integrating whole serum and lipoprotein (HDL) lipidomics, this study points to HDL as a possible actor in the inter-organ cross-talk between peripheral tissues and the liver in NAFLD and advances our understanding of NAFLD pathophysiology.
Method: We studied 89 patients with a biopsy-proven NAFLD and 20 healthy volunteers (CTRL), matched for age and sex, whole serum (20 CTRL, 36 NAFL, 31 NASH F0-2, 22 NASH F3-4) and the HDL lipoprotein (9 CTRL, 11 NAFL, 11 NASH F0-2, 9 NASH F3-4) lipidomics by liquid chromatography-mass spectrometry. HDL were isolated via fast protein liquid chromatography. Lipid data were presented as absolute values after normalisation for respective internal standards and, for HDL lipids, also Apo-I concentration.
Results: In whole serum, NAFLD patients showed significantly higher absolute concentrations of saturated FFA coupled with a striking depletion of PUFA compared to controls (Fig. 1A); a similar trend was also observed in other lipid species. The lipoprotein lipidomic analysis showed that PUFA were substantially depleted in HDL, with phosphatidylcholine (PC; Fig. 1B) being the most affected lipid class. Additionally, we found that ceramides (Cer) in HDL were significantly increased in NAFLD compared to controls (Fig. 1C). FFA, HDL-PC, and HDL-Cer were also strongly correlated with insulin resistance and/or hepatic liver enzymes (Fig. 1D) suggesting that the concentration of these lipids in HDL might be associated with peripheral organ dysfunction and/or with the necro-inflammatory milieu in NASH.
Conclusion: Taken together, these data show that NAFLD is associated with a reduced absolute content of polyunsaturated FFA and phospholipids within HDL. We, therefore, speculate that an impaired PUFA transport from peripheral tissues to the liver (via FFA and HDL) might be a contributing factor in NAFLD pathophysiology (Fig. 1E).

SAT062

The role of XBP1 in regulating the progression of non-alcoholic steatohepatitis

Haoming Zhou[1], Qi Wang[1], Qingfa Bu[1], Xun Wang[1], Ling Lu[1]. *[1]The First Affiliated Hospital of Nanjing Medical University, Hepatobiliary Center*
Email: hmzhou@njmu.edu.cn

Background and aims: Non-alcoholic steatohepatitis (NASH) is associated with the dysregulation of lipid metabolism and hepatic inflammation. The mechanism underlying NASH is unclear. We aim to investigate the role of X-box binding protein-1 (XBP1) in the progression of NASH.
Method: Human liver tissues obtained from patients with NASH and control group were used to assess XBP1 expression. NASH models were developed in hepatocyte-specific Xbp1 knockout (Xbp1ΔHep), macrophage specific Xbp1 knockout (Xbp1ΔMϕ), macrophage-specific Nlrp3 knockout, and wild-type (Xbp1FL/FL or Nlrp3FL/FL) mice fed with high-fat diet for 26 weeks or methionine/choline deficient diet for 6 weeks.
Results: The expression of XBP1 was significantly upregulated in the liver samples from NASH patients. Hepatocyte-specific Xbp1 deficiency inhibited the development of steatohepatitis in the mice fed with the high-fat or methionine/choline deficient diets. Meanwhile, macrophage specific Xbp1 knockout mice developed less severe steatohepatitis and fibrosis than wild-type Xbp1FL/FL mice in response to the high-fat or methionine/choline deficient diets. Macrophage-specific Xbp1 knockout mice showed M2 anti-inflammatory polarization. Xbp1 deleted macrophages reduced steatohepatitis through decreased expression of NLRP3 and secretion of pro-inflammatory cytokines, which mediate M2 macrophage polarization in macrophage-specific Xbp1 knockout mice. Steatohepatitis was less severe in macrophage-specific Nlrp3 knockout mice than in wild-type Nlrp3FL/FL mice. Xbp1 deleted macrophages prevented the hepatic stellate cells activation through decreased expression of TGF-β1. Less fibrotic changes were observed in macrophage-specific Xbp1 knockout mice than in the wild-type Xbp1FL/FL mice. Inhibition of XBP1 suppressed the development of NASH.
Conclusion: XBP1 regulates the development of NASH. XBP1 inhibitors protect against steatohepatitis. XBP1 thus is a potential target for the treatment of NASH.

FXR binding and transcription in the liver is signficantly altered in obese patients with NAFLD

Martin Wagner[1], Emilian Jungwirth[1,2], Katrin Panzitt[1], David Moore[3], Tobias Madl[4], Gerhard Thallinger[2], Hanns-Ulrich Marschall[5].
[1]Division of Gastroenterology and Hepatology, Medical University Graz, Graz, Austria; [2]Institute of Biomedical Informatics, Graz University of Technology, Graz, Austria; [3]Nutritional Sciences and Toxicology, University of California, Berkeley, Berkeley, United States; [4]Division of Molecular Biology and Biochemistry, Medical University Graz, Graz, Austria; [5]Department of Molecular and Clinical Medicine/Wallenberg Laboratory, Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden
Email: martin.wagner@medunigraz.at

Background and aims: FXR binds to distinct hormone response elements on the chromatin to dictate gene regulation. In mice, these genomic FXR binding profiles are distinct in normal and obese mice, suggesting that FXR activation may produce different outcomes in a different metabolic background. We studied FXR binding profiles and transcriptional outputs in the livers from normal weight and morbidly obese patients with NAFLD, who were treated with either placebo or the FXR ligand obeticholic acid (OCA).

Method: We tested the hepatic FXR cistrome by FXR ChIP-seq and the transcriptome by RNA-seq in liver biopsies of normal and morbidly obese human subjects who had been enrolled in a clinical trial for the treatment with the FXR agonist OCA (NCT0162502). We matched the outcomes of these genomic studies with metabolic profiles of those patients.

Results: In ChIP-seq, a method to determine transcription factor binding on a genome-wide scale, FXR binding sites are inherently different between obese and non-obese patients. In obese patients, FXR bound 26605 sites and only 10270 in non-obese patients. Interestingly, while OCA could recruit additional binding sites in non-obese patients, OCA did not affect FXR binding in obese patients. To explore, which gene sets are selectively targeted by OCA-driven FXR activation in obese patients we integrated the FXR ChIP-seq data with their respective RNA-seq data. In contrast to FXR binding, which remained unaffected by OCA treatment, OCA significantly altered the transcriptome in RNA-seq (1456 genes were up- and 1674 genes downregulated by OCA) in obese patients. Integration of FXR cistromics with transcriptomics revealed activation of "classical" FXR targeted pathways such as bile acid or fatty acid metabolism, however, the top ranked differentially regulated pathways belonged to mitochondrial function. In line with the obese-specific "mitochondrial fingerprint," PGC-1α, a transcriptional master-regulator of mitochondrial biogenesis, appears to be a direct hepatic FXR target

gene preferentially in obese conditions. Proteomics studies revealed significant changes in proteins of redox metabolism with superoxide dismutase, a first line defence enzyme of oxidative stress, being a specific FXR target. NMR metabolomics studies further showed that in obese conditions glutathione levels significantly dropped in the liver tissue, but could be completely restored by OCA treatment.
Conclusion: The results from FXR cistromics overall suggest that the metabolic background dictates FXR binding and consequently FXR signaling in obese conditions differs from signaling in normal conditions. Activating FXR in obesity may have a major impact on mitochondrial biogenesis and metabolism, which appears to be a selective feature of FXR signaling in the obese condition. A major metabolic effect of OCA in the NAFLD condition may be to balance the redox states.

SAT064

Non-alcoholic fatty liver disease (NAFLD) progression to non-alcoholic steatohepatitis (NASH) and NASH-related hepatocellular carcinoma (HCC) evolves following a differential activation of endoplasmic reticulum stress responses

Alexander Finnemore[1], Jose Maria Herranz[1,2], Sergio Barace[1], Stefany Infante[1,3], Matías A Avila[1,2,4], Guillermo Garcia-Porrero[5], Sara Arcelus[1], Eva Santamaria[1,2], Josepmaria Argemi[1,2,4,5]. *[1]Centro de Investigación Medica Aplicada (CIMA), Hepatology Program, Pamplona, Spain; [2]Centro de investigacion biomedica en red (CIBER-EHD); [3]University of Piura. Lima campus, Miraflores, Peru; [4]Instituto de Investigacion de Navarra (IdisNA); [5]Clinica Universidad de Navarra, Liver Unit, Pamplona, Spain*
Email: jargemi@unav.es

Background and aims: Non-alcoholic fatty liver disease (NAFLD) is notoriously heterogeneous in both its pathophysiology and clinical progression phenotypes. Endoplasmic reticulum stress and the coping response through the Unfolded Protein Response (UPR) have shown to play a significant role in NAFLD-related lipotoxicity. Nevertheless, the dissection of the UPR activation in human and mouse NAFLD progression is poorly understood. The aim of this study was to gain a better understanding of the UPR activation in NAFLD progression.
Method: A total of six main regulators were identified as indicators of activation of different UPR-related pathways. The selected components belonged to the three arms of the UPR, named PERK/ATF4, IRE1A/XBP1 and ATF6. SIRT3 was considered the main regulator of the mitochondrial UPR. An exhaustive compilation of gene expression data was carried out from existing literature and Molecular Signature Database (MSigDB) curated collections and using unpublished RNA-sequencing data of the ATF6-null HCC cell line. Gene signatures were filtered and fine-tuned using controlled in vitro experiment using tunicamycin-treated HCC cell lines. *Mus musculus* gene symbols were replaced by their human orthologs. Gene set variation analysis (GSVA) and single sample Gene Set Enrichment Analysis (ssGSEA) were used to analyze the enrichment of the UPR signatures in human and mouse expression datasets. Statistical analysis was performed using t-student for comparing means of normally distributed continuous variables and Chi-Square was used for comparing categorical variables.
Results: Forty-seven preliminary signatures in both *Homo sapiens* and *Mus Musculus* were defined. After fine-tuning and filtering using controlled ER-stress cell model, a final set of sixteen *bona fide* UPR signatures were derived, which included 358 genes, distributed along 2 ATF4, 2 ATF6, 3 IRE1A, 7 XBP1, 1 PERK and 1 SIRT3 signatures. Using GSVA and ssGSEA these signatures were applied to two NAFLD progression (n = 304 patients, different stage of NAFLD progression F0-4) and two NASH-Hepatocellular Carcinoma (NASH-HCC) (n = 180 samples, including Normal, Cirrhosis, NASH and NASH-HCC and their peritumoural liver counterparts), human data sets. As NAFLD progresses to NASH and NASH-HCC, the expression of UPR branches is generally decreased. Patients can be split into distinctive groups regarding specific UPR profiles.
Conclusion: NAFLD progresses to NASH and NASH-HCC showing specific patterns of ER stress responses. The application of *bona fide* UPR signatures to human NAFLD gene expression data sets, allows for a UPR-based classification that could have potential prognostic and/or predictive value.

MPEP, an mGlu5 receptor allosteric modulator, reduces hepatic steatosis in obese high-fat-diet mice

Laura Giuseppina Di Pasqua[1], Marta Cagna[1], Clarissa Berardo[1], Anna Cleta Croce[2,3], Ferdinando Nicoletti[4,5], Mariapia Vairetti[1], Andrea Ferrigno[1]. *[1]University of Pavia, Department of Internal Medicine and Therapeutics, Pavia, Italy; [2]Institute of Molecular Genetics-Italian National Research Council (CNR), Pavia, Italy; [3]University of Pavia, Department of Biology and Biotechnology, Pavia, Italy; [4]Sapienza University of Rome, Department of Physiology and Pharmacology, Roma, Italy; [5]IRCCS, Neuromed, Pozzilli, Italy*
Email: lauragiuseppin.dipasqua01@universitadipavia.it

Background and aims: The metabotropic glutamate receptor 5 (mGluR5) regulates many central reward pathways as well as those affecting appetite (Bradbury et al., 2005). It is also involved in the alcoholic steatohepatitis regulation (Choi et al., 2019) and recent data proved that mGluR5 modulates body weight, adipose tissue and inflammation in an in vivo model of diet-induced obesity (Oliveira et al., 2021). In an in vitro model of acute hepatic fat accumulation, mGluR5 selective blockade by the negative allosteric modulator MPEP resulted in the reversion of the injury caused by oleic and palmitic acid exposure. On the contrary, the mGluR5 agonist DHPG worsened the fatty acid exposure-induced damage (Ferrigno et al., 2020). Aim of this work was to evaluate the role of MPEP in an in vivo model of hepatic steatosis.
Method: Male 606B6.V mice genetically modified for leptin gene (ob/ob mice), 7-week fed with high fat diet were concomitantly daily administered with MPEP or vehicle (20 mg/kg, IP). At the sacrifice, liver biopsies and hepatic nuclear fractions were collected. Total lipid content was evaluated by Nile Red dye, while lipid droplet areas were calculated by ImageJ software on histological samples fixed in formalin and stained with HandE. Lipid peroxidation and oxidative stress were evaluated by TBARS and ROS assays respectively. Protein analysis for mGluR5, PPAR-alpha, SREBP1, mTOR and NFKB were evaluated by Western blotting on tissue samples or nuclear fractions. The activation of NFkB and mTOR were assessed by calculating the ratio between the phospho-protein and the non-phosphorylated protein expression.
Results: No changes were detected in hepatic mGluR5 protein expression both in MPEP- or vehicle-treated group. MPEP-treated mice displayed a significant reduction in total lipid content compared with vehicle-treated group and lipid droplet areas decreased significantly after MPEP treatment. Levels of hepatic TBARS and ROS diminished significantly after MPEP administration and, in line with these findings, NFκB activation was significantly reduced in MPEP-treated mice with respect to vehicle-treated mice. Nuclear activated PPAR-alpha increased significantly in MPEP group, while nuclear activated SREBP1 was significantly down-regulated by mGluR5 blockade. mTOR activation did not show any significant difference between the two groups in the nuclear fraction.
Conclusion: These results demonstrate that MPEP administration reduces steatosis in obese mice fed by high fat diet. Oxidative stress parameters and inflammation are decreased by mGluR5 blockade, probably via PPAR-alpha that negatively regulates NFκB. Besides, intracellular lipid accumulation is prevented by SREBP1 down-regulation in an mTOR-independent way. Although further investigations are needed, this is the first time that MPEP beneficial effects are reported in an vivo model of hepatic steatosis.

SAT066

Pro-inflammatory liver-homing T cells in peripheral blood, liver and adipose tissue in patients with NASH and changes in post-bariatric surgery samples

James Hallimond Brindley[1], Falguni Tailor[1], Karthik Chandrasekharan[1], Kathryn Waller[1], Wenhao Li[1], Kalpana Devalia[2], Francesca Rosini[3], John Loy[2], William Alazawi[1].

Email: halbrindley@gmail.com

Background and aims: Non-alcoholic steatohepatitis (NASH), the inflammatory subtype of non-alcoholic fatty liver disease (NAFLD) associated with obesity and type2 diabetes mellitus (T2DM) can lead to advanced liver disease. There are limited data evaluating T cell subsets in multiple tissue compartments or following weight loss in NAFLD. We hypothesised that circulating and tissue T cells changed in advanced versus mild NASH.
Method: Prospective samples were collected under ethically-approved protocols; peripheral blood from 37 NAFLD patients and 7 controls, with primary comparisons between advanced (elastography >9.7kPa or ≥F3) and mild (elastography <8.2kPa or ≤F2) NAFLD. A subset undergoing bariatric surgery (n = 21) underwent additional simultaneous sampling of liver, visceral (VAT) and subcutaneous adipose tissue (SAT) for flow cytometry immuno-profiling, with further blood samples after weight loss.
Results: Peripheral blood MAIT cells were significantly reduced with greater activation in patients with advanced versus mild NAFLD or controls (0.8% vs 3.1%, 3.2% $p < 0.05$) although IFN gamma and TNF alpha expression was higher in all NAFLD MAIT cells (IL-17 in advanced) compared to control.
In bariatric patients, Th1 ($CD4^+CXCR3^+$) cells were more abundant in NASH vs no-NASH (33% vs 21% $p < 0.05$), particularly among patients with diabetes in whom pro-inflammatory Th1 and Th17 cells ($CD4^+CD161^+$) expressed higher levels of liver homing CXCR6.
After weight loss, the proportion of Th1, Th17 cells and activated ($CD69^+$) CD8+ T cells reduced.
The proportion of $CXCR6^+$ Th1 and Th17 cells reduced, as did IFN gamma expressing $CXCR6^+$Th17 cells.
In patients with T2DM NASH, intrahepatic Th17 cell numbers were higher and MAIT cells lower compared to other groups, with a similar reduction of MAIT cells in SAT. Conversely, SAT total T cell CXCR6 expression was higher in T2DM NASH than in other patient groups. In T2DM NASH, expression of tissue-retaining CD69 expression on Th1 cells was higher in the liver and lower in VAT.
Conclusion: A peripheral and adipose tissue pro-inflammatory, liver-homing T cell phenotype is evident in patients with T2DM and NASH with improvement in this after weight loss.

Email: florine.seidel@tno.nl

Background and aims: With the increased mortality that is associated with the obesity-related comorbidities non-alcoholic steatohepatitis (NASH) and atherosclerosis, there is a great need for therapeutic interventions to treat advanced stages of these diseases. Chronic inflammation has been shown to be an important driver in progression of both NASH and atherosclerosis. The complement system, one of the first lines of defence in innate immunity, is thought to play an important role in this chronic inflammatory response. However, the therapeutic value of complement system inhibition in already established disease has not been studied to date. In this study we investigated the potential health effects of therapeutic inhibition of the terminal complement system (via inhibition of complement component 5 (C5)) simultaneously on established NASH and atherosclerosis in a translational model of obesity-related disease.
Method: After 20 weeks of high-fat diet (HFD)-feeding, obese Ldlr-/-.Leiden mice were treated bi-weekly with an established anti-C5 antibody (BB5.1) or vehicle control, and a separate group of mice was kept on a chow diet as a healthy reference. To confirm adequate inhibition of C5, the complement system activity in plasma as well as the membrane-attack complex (MAC) deposition in the liver were quantified. After 12 weeks of treatment, NASH was analysed histopathologically and genome-wide hepatic gene expression was analysed by next-generation sequencing followed by pathway analysis. Atherosclerotic lesion area and severity were quantified histopathologically in the aortic roots.
Results: Anti-C5 treatment considerably reduced complement system activity in plasma and MAC deposition in liver. The histological examination of livers revealed that systemic anti-C5 treatment did not affect NASH progression, showing no effect on steatosis, inflammation or fibrosis. However, on the gene expression level, anti-C5 treatment did affect the pathways Oxidative phosphorylation and Mitochondrial dysfunction. Anti-C5 treatment was also revealed to be beneficial against atherosclerosis, limiting the total lesion size independently of an effect on plasma cholesterol. In addition, C5 inhibition reduced lesion severity, increasing the area of mild type I-III lesions and lowering the area of severe type IV and V lesions.
Conclusion: We show for the first time that targeting the complement system via C5 inhibition in advanced stages of NASH is not sufficient to reduce disease development, while therapeutic intervention against moderately-advanced atherosclerosis is beneficial to limit further progression of the lesions.

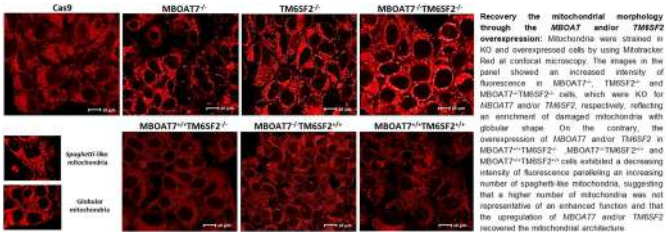
SAT068

The overexpression of TM6SF2 and/or MBOAT7 wild-type genes re-establishes the mitochondrial dynamics in an in vitro NAFLD model.

Erika Paolini[1,2], Miriam Longo[1,3], Marica Meroni[1], Giada Tria[1], Chiara Macchi[2], Roberto Piciotti[1,4], Adele Agresta[1], Massimiliano Ruscica[2], Anna Ludovica Fracanzani[1,4], Paola Dongiovanni[1]. [1]*General medicine and metabolic diseases, Fondazione IRCCS Cà Granda ospedale maggiore policlinico;* [2]*Università degli Studi di Milano, Milan, Italy, Department of Pharmacological and Biomolecular Sciences;* [3]*Università degli Studi di Milano, Milan, Italy, Department of clinical sciences and community health, Università degli studi di Milano;* [4]*Università degli Studi di Milano, Milan, Italy, Department of Pathophysiology and Transplantation*
Email: paola.dongiovanni@policlinico.mi.it

Background and aims: Mitochondria adaptability is hampered in the progression from NASH up to HCC. Recently, we demonstrated that HepG2 cells, homozygous for the PNPLA3 I148M variant, and silenced

for *MBOAT7* and/or *TM6SF2* genes by CRISPR/Cas9 spontaneously developed fat accumulation, exhibited an enrichment of damaged mitochondria, an unbalance in their turnover and finally a higher proliferation rate together with reduced apoptosis.
In the attempt to deepen the impact of *PNPLA3/MBOAT7/TM6SF2* loss-of-function on mitochondrial abnormalities, we aim to assess whether the overexpression of *MBOAT7* and/or *TM6SF2* wild-type forms restores the mitochondrial dynamics which was lost in knock-out (KO) models.
Method: *MBOAT7* and/or *TM6SF2* were overexpressed through lentiviral vectors. Mitochondrial morphology and number were assessed by confocal microscopy and D-loop TaqMan Copy Number Assay whereas the function was evaluated by qRT-PCR, Western Blot, Seahorse assay and immunohistochemistry.
Results: At Oil Red O staining, the overexpressed cells exhibited a reduction of lipids compared to KO models. The upregulation of *MBOAT7* and/or *TM6SF2* lowered D-loop levels and increased *spaghetti*-like globular shape ratio of mitochondria, enhancing the number of normo-shaped ones. The overexpressed models reduced the mRNA levels of *PGC1α*, master regulator of mitobiogenesis, which was activated in KO cells in response to fusion-fission unbalance, prompted the expression of *Mfn1* and *Mfn2* (mitochondrial outer membranes proteins involved in fusion) and decreased *FIS1* (fission protein) levels, thus re-establishing the mitochondrial turnover. The increased COX-I/SDHA ratio paralleled the oxygen consumption rate after the overexpression of *MBOAT7* and/or *TM6SF2*, recovering the OXPHOS activity which was impaired in KO cells. Consistently, ROS content, lipid peroxidization and ER/Golgi stress (*ATF4*, *ATF6*, *XBP1* and *GRP78*) decreased, confirming the recovery of mitochondrial derangement. Additionally, the upregulation of *MBOAT7* and/or *TM6SF2* reduced the expression of *DUSP1* (cell proliferation) according to MTS and wound healing assays and fostered the apoptotic pathways, thus attenuating the tumorigenic phenotype.



Recovery the mitochondrial morphology through the *MBOAT* and/or *TM6SF2* overexpression: Mitochondria were stained in KO and overexpressed cells by using Mitotracker Red at confocal macroscopy. The images in the panel showed an increased intensity of fluorescence in MBOAT7+/+, TM6SF2+/+ and MBOAT7+/+TM6SF2+/+ cells, which were KO for *MBOAT7* and/or *TM6SF2*, respectively, reflecting an enrichment of damaged mitochondria with globular shape. On the contrary, the overexpression of *MBOAT7* and/or *TM6SF2* in MBOAT7-/-TM6SF2-/-, MBOAT7-/-TM6SF2+/+ and MBOAT7+/+TM6SF2+/+ cells exhibited a decreasing intensity of fluorescence paralleling an increasing number of spaghetti-like mitochondria, suggesting that a higher number of mitochondria was not representative of an enhanced function and that the upregulation of *MBOAT7* and/or *TM6SF2* recovered the mitochondrial architecture.

Conclusion: Genetics may be involved in the mitochondrial maladaptation during NAFLD and the overexpression of *MBOAT7* and/or *TM6SF2* in KO HepG2 cells re-established the mitochondrial dynamics and reduced the proliferation rate.

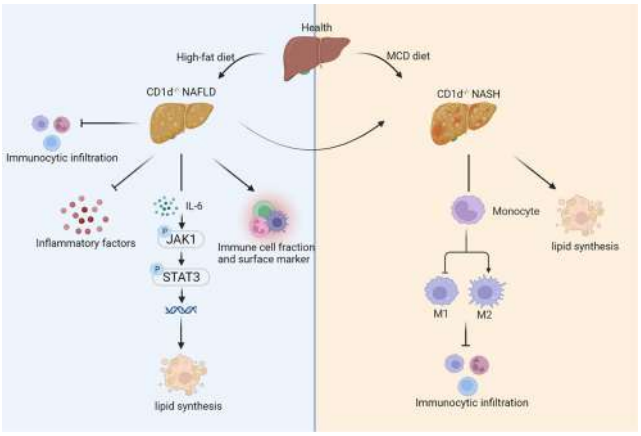
SAT069

CD1d knockdown promotes NAFL lipid synthesis by activating the IL6-JAK1-STAT3 signal pathway and reduces inflammatory factors in NASH by decreasing macrophage polarisation towards M1 and increasingn polarisation towards M2

Dandan Shan[1,2], Qiuxian Zheng[1], Zhi Chen[1]. [1]*Hangzhou, Diagnosis and Treatment of Infectious Diseases, Hangzhou, China;* [2]*The First Affiliated Hospital, Zhejiang University School of Medicine, Hangzhou, China*
Email: zjuchenzhi@zju.edu.cn

Background and aims: Non-alcoholic fatty liver disease (NAFLD) is a chronic progressive liver disease. NAFLD involves multiple complex biological effects that help activate innate and adaptive immunity and exacerbate NAFLD development. CD1d proteins mediate the delivery of self or microbial lipid and glycolipid antigens to activate immune cells, rapidly produce large amounts of cytokines, and trigger innate and adaptive immune responses. Here, we explored the role for CD1d in NAFLD.

Method: Flow cytometry and Cytometry by Time of Flight (CyTOF) was used to measure and analyze the expression level of markers on the surface of immune cells in liver tissues of NAFL mice, and the distribution map of immune cells was established. M1 and M2 macrophages in liver tissues was also detected.
Results: Compared with the WT HFD group, the CD1d$^{-/-}$ HFD group mice showed a significant increase in liver index, a significant increase in liver steatosis ($p < 0.05$), ALT level ($p < 0.01$), AST level ($p < 0.05$) and a significant increase in serum LDL level ($p < 0.01$). Transcriptome analysis showed that IL6-JAK1-STAT3 signaling pathway was significantly enriched in CD1d$^{-/-}$ HFD group compared with WT HFD group. The gene expression level in CD1d$^{-/-}$ HFD group was significantly increased compared with WT HFD group. In vitro studies showed that CD1d gene knockout aggravated FFA-induced NAFL lipid droplet formation and lipid deposition. AG490 inhibition of IL6-JAK1-STAT3 signaling pathway alleviates liver steatosis and down-regulates the gene expression level of lipid metabolism in THE CD1d knockout NAFL group. The expression level of liver immune cells in CD1d$^{-/-}$ HFD group was lower than that in WT HFD group. Compared with WT NCD group, the expression level of immune cells and inflammatory factors was increased in WT MCD group. The expression levels of liver immune cells and inflammatory factors in CD1d$^{-/-}$ MCD group were lower than those in WT MCD group. The expression level of M2-polarized surface markers in macrophages in CD1d$^{-/-}$ MCD group was higher than that in WT MCD group, while the expression level of M1-polarized surface markers in macrophages was lower. CD1d gene knockout aggravated FFA-induced lipid accumulation in mouse laparoscopic macrophages, inhibited M1 polarization of peritoneal macrophages, and promoted M2 polarization of peritoneal macrophages. CD1d gene knockout aggravated fatty acid induced lipid accumulation in mouse BMDM cells, inhibited M1-type polarization of BMDM cells, and promoted the M2-type polarization.



Conclusion: CD1d plays a protective role in the process of NAFL steatosis, and CD1d deficiency can increase hepatic lipid accumulation and hepatic steatosis by activating il6-JAK1-STAT3 signaling pathway.
In NASH stage, CD1d deficiency can promote M2-type polarization of macrophages by inhibiting M1-type polarization of macrophages, thus reducing the level of liver inflammation.

SAT070

The role of immune semaphorins in NAFLD-a pilot study

Ivana Knezevic Stromar[1], Maja Mijic[2], Lara Samadan[3], Slavko Gasparov[2], Adriana Vince[3,4], Neven Papic[3,4]. [1]*University hospital centre Zagreb, Zagreb, Croatia;* [2]*University hospital Merkur, Zagreb, Croatia;* [3]*School of medicine, University of Zagreb, Zagreb, Croatia;* [4]*University hospital for infectious diseases Zagreb, Zagreb, Croatia*
Email: npapic@bfm.hr

Background and aims: Non-alcoholic fatty liver disease (NAFLD) is associated with chronic low-grade inflammation, impaired immune response and microvascular endothelial dysfunction. Semaphorins, a large family of biological response modifiers, were recently recognized as one of the key regulators of immune response, possibly also associated with chronic liver diseases. However, their role in NAFLD has not been described. The aim of this study was to identify semaphorins associated with NAFLD and to investigate relationship with steatosis and fibrosis stages.
Method: This was a prospective, multicentric, case-control study. The degree of steatosis was estimated using the controlled attenuation parameter (CAP) and transient elastography (TE) was used to measure fibrosis stage. A routine clinical, demographic, anthropometric and laboratory data were collected and serum semaphorin concentrations (SEMA3A, −3C, −4A, −4D, −5A and −7A) were measured by ELISA. Immunohistochemical staining of liver tissue was performed. The correlation between serum semaphorin concentrations and steatosis and fibrosis grade was analyzed.
Results: Ninety-five patients with NAFLD (51.6% males; median age of 54, IQR 44-56 years) and 35 controls (40% males, 41, IQR 31–52 years) were included. Patients with NAFLD more frequently had diabetes mellitus (30.5% vs 8.6%), arterial hypertension (49.5% vs 8.6%), dyslipidemia (28.4% vs 11.4%) and obesity (BMI 31 kg/m2 vs 24 kg/m2). 39 patients with NAFLD had no fibrosis (F0), and in 27, 15, 6 and 8 patients F1 to F4 was detected, respectively. A significantly higher serum concentrations of SEMA3A, −3C and −4D, and lower of SEAMA5A and −7A were found in NAFLD group compared to the healthy controls. There was no difference in semaphorin concentrations according to steatosis grade, but there was significant difference according to fibrosis stage, SEMA3A being lower and SEAMA3C and −4D higher in advanced fibrosis. Immunohistochemistry confirmed the higher expression of SEMA3C and SEMA4D in advanced fibrosis.

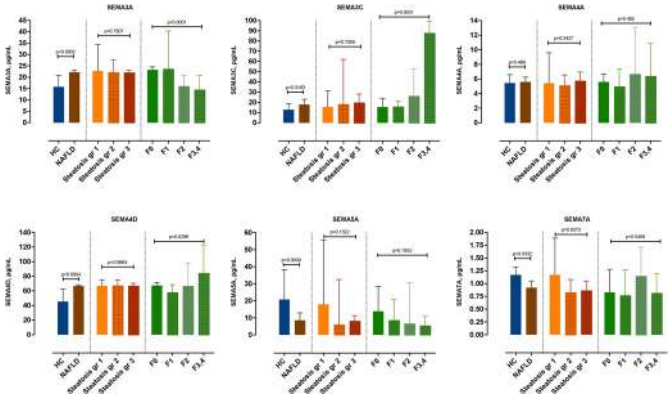


Figure: SEMA3A, −3C, −4A, −4D, −5A and −7A sera concentrations according to the steatosis and fibrosis stage in patients with NAFLD.

Conclusion: We provide the first evidence that immune semaphorins are a promising marker of liver fibrosis in patients with NAFLD. Due to their immunomodulatory role, they could be useful in predicting liver capacity to answer challenges of infection, but also potential diagnostic and therapeutic targets in NAFLD.

SAT071

Machine learning-enabled continuous scoring of histologic features facilitates prediction of clinical disease progression in patients with non-alcoholic steatohepatitis

Janani Iyer[1], Charles Biddle-Snead[1], Quang Le[1], Pratik Mistry[1], Isaac Finberg[1], Victoria Mountain[1], Rob Myers[2], Chuhan Chung[3], Andrew Billin[3], Tim Watkins[3], Ilan Wapinski[1], Michael Montalto[1], Andrew Beck[1], Murray Resnick[1], Katy Wack[1]. [1]*PathAI, Boston, United States;* [2]*The Liver Company, Palo Alto, United States;* [3]*Gilead Sciences, Inc., Foster City, United States*
Email: katy.wack@pathai.com

Background and aims: Histologic grading and staging of disease severity are typically performed using ordinal scoring systems, which often lack sufficient sensitivity to characterize changes in histology over short periods of time or in response to treatment during clinical trials. Here we demonstrate the prognostic utility of machine learning-facilitated continuous scoring of histologic features.
Method: Liver biopsies and central pathologist (CP) Ishak and Clinical Research Network (CRN) disease severity scores were collected from subjects enrolled in the Ph3, placebo-controlled STELLAR (ST) trials of selonsertib (NCT03053050, NCT03053063). All subjects had CRN fibrosis stage 3 or 4 at baseline (BL) and were assessed for progression to either cirrhosis or liver-related events (LREs). Treatment arms were combined due to lack of measured drug efficacy. PathAI AI-based measurement of NASH histology (AIM-NASH) models were deployed to generate ML-derived predictions for ordinal and continuous CRN grades/stages for steatosis, hepatocellular ballooning, lobular inflammation, and fibrosis (Figure 1A). Cox proportional-hazards, receiver operating characteristic, and Kaplan-Meier (KM) analyses were employed to assess associations between ML-derived disease severity metrics and patient outcomes.

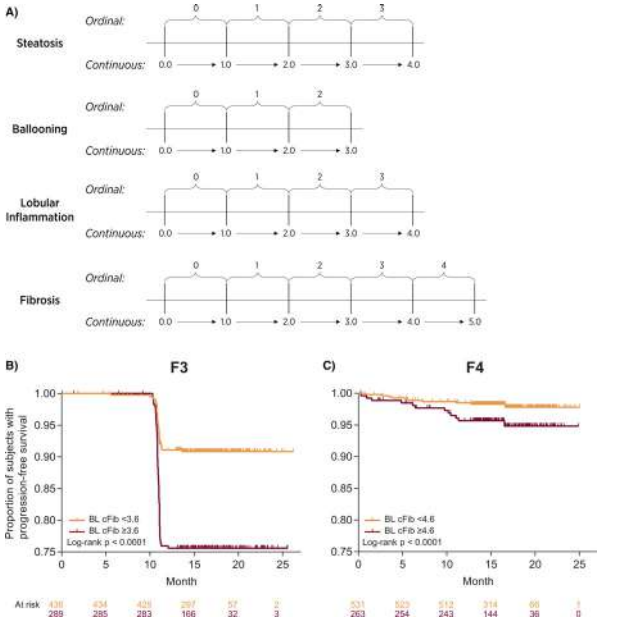

Figure: (A) Mapping of PathAI NASH CRN ordinal to continuous scores; (B) KM analysis showing progression to cirrhosis; (C) KM analysis showing progression to LRE.

Results: During a median follow-up of 16.5 or 15.8 months, 14.9% (N = 108/725) of F3 subjects progressed to cirrhosis, and 2.5% (N = 20/794) of F4 subjects had liver-related events (LREs) respectively. Progression to cirrhosis in subjects with F3 fibrosis at BL was associated with higher ML continuous and ordinal fibrosis stage and higher manual (Ishak) scoring at BL. Lower ML-derived ordinal but not manual steatosis grade was also associated with progression to cirrhosis. In subjects with F4 fibrosis at BL, lower BL continuous

steatosis grade and ordinal Ishak fibrosis stage were predictive of progression to a LRE. BL continuous fibrosis stage cutoffs of 3.6 and 4.6 stratified subjects into slow vs. rapid progressors to cirrhosis or LREs, respectively (Figures 1B and 1C). ML-derived continuous scoring showed higher discriminatory accuracy to predict progression to cirrhosis and to LREs than ML-derived ordinal scoring (AUROC [90% CI] = 0.66 [0.61, 0.71] vs. 0.59 [0.55, 0.63] and 0.61 [0.52, 0.7] vs. 0.54 [0.47, 0.59] in ST3 and ST4, respectively.

Conclusion: AIM-NASH analysis of biopsies from two completed Ph3 NASH clinical trials demonstrates the prognostic potential of continuous histologic scoring methods. These results support further investigation into the value of ML-based continuous histologic scoring methods for measuring clinically meaningful therapeutic effects in NASH clinical trials.

SAT072

Increasing plasma concentration of aldo-keto reductase family 1 member B10 and its significance in the progression of non-alcoholic fatty liver disease

Hye Eun Lee[1], Dae Ho Lee[1]. [1]*Gachon University College of Medicine, Gil Medical Center, Incheon, Republic of Korea, Department of Internal Medicine, Incheon, Korea, Rep. of South*
Email: esthel0513@gmail.com

Background and aims: Understanding of hepatic gene expression during non-alcoholic fatty liver disease (NAFLD) progression may help to find traceable therapeutic targets. Although efforts to examine the transcriptomic changes that occur as NAFLD progresses have largely used, studies have been limited independent validation. We investigated the feasibility of secretory protein for diagnosis of NAFLD and evaluated the diagnostic accuracy of biomarkers.

Method: We incorporated transcriptomic data on healthy subject and NAFLD patient biopsy-proven samples, representing the full histological range from normal liver tissue to steatohepatitis-cirrhosis-hepatocellular carcinoma in both publicly available data base (n = 853) and a separate replication cohort (n = 102). To validate the finding form the transcriptomic data analysis, we confirmed protein level in serum, blood, and liver tissue form patient. In addition, supporting the biological plausibility of these data, we assessed its expression in primary hepatocytes from mice under various metabolic stresses and other stresses, which caused AKR10B expression.

Results: We discovered tentative secretory proteins that reflect the progression of NAFLD with a consistent and stepwise increasing pattern for the diagnosis of NASH. We found 4 secretory proteins (AKR1B10, annexin A2P2, ZNF468, and CD24) and we showed through our own cohort study that plasma AKR1B10 could be a clinically applicable biomarker for NAFLD (AUROC 0.834) and for advanced fibrosis (AUROC 0.914) at a cutoff level (≥1078.2 pg/ml). We applied our protocol to monitor NAFLD in patients undergoing bariatric surgery, showing that plasma AKR1B10 levels decreased markedly after surgery. Translating these findings to the protein level, we optimized in vitro cell model using primary mouse hepatocytes treated with free fatty acid and high glucose.

Conclusion: In the present study, the circulating concentrations of proteins AKR1B10 were strongly associated with disease activity and fibrosis stage. Plasma AKR1B10 could be a useful non-invasive biomarker for the diagnosis of NAFLD as progression of disease. Further validation studies in the future as a biomarker and a probable therapeutic target for NAFLD will be warranted.

SAT073

Validation of the ADAPT score for the diagnosis of clinically significant fibrosis in patients with non-alcoholic fatty liver disease (NAFLD)

Email: arun.sanyal@vcuhealth.org

Background and aims: There is an unmet need for validation of diagnostic tools to identify patients with NAFLD who have stage 2 or greater fibrosis that meet regulatory standards for qualification. The ADAPT score is anchored on PROC3, a collagen fragment released during fibrogenesis and being developed for this purpose. PROC3 is measured either with ELISA or on the COBAS platform. The aims of this secondary analysis of the NIMBLE circulating work stream stage 1 dataset were to: (1) evaluate the utility of the ADAPT score (Pro-C3-based fibrosis algorithm that includes **A**ge, **D**iabetes, **P**ro-C3 and Pla**t**elet count)for the diagnosis of clinically significant fibrosis (≥stage 2), advanced fibrosis (≥stage 3) or cirrhosis (stage 4) in patients with NAFLD, and (2) determine if ADAPT performance varies based on whether PROC3 is measured by ELISA or COBAS.

Method: A retrospective analysis of a sample set from the NIDDK NASH CRN DB2 adult cohort curated to avoid spectrum bias by balanced representation of fibrosis stages (0–4) was performed. Histology was independently read by the NASH CRN pathology committee using validated protocols. All samples were obtained within 90 days of a liver biopsy demonstrating NAFLD; a FIB4 score was computed from the same sample as the PROC3. Both ELISA and COBAS based PROC3 results were obtained on each sample. The primary hypothesis was that the ADAPT score would diagnose the fibrosis strata noted above with an AUROC >0.7 with confidence limits that do not intersect 0.5 at the Youden index. The secondary hypothesis was that the AUROC at Youden index would be superior to FIB4 for the same fibrosis strata.

Results: A total of 1070 patients, each providing a single set of the readouts, were studied. The distribution of fibrosis stages was: (0 = 222, 1 = 114, 2 = 262, 3 = 277, 4 = 198). Those with stages 0–1 had more NAFL and had a lower NAFLD activity score compared to those ≥stage 2. Comparison of PROC3 results from ELISA and COBAS methodologies did not show appreciable differences in performance. Data using ELISA are presented below (* primary hypothesis validated, ** secondary hypothesis validated).

	Youden cutpoint	Sensitivity	Specificity	AUROC	FIB4 AUROC
≥stage 2	≥6.2	76.4	76.8	0.849*	0.799**
≥stage 3	≥6.9	74.9	78.7	0.832*	0.790**
Stage 4	≥7.1	85.9	68.1	0.824*	0.81

Conclusion: The ADAPT score was validated to diagnose clinically significant and advanced fibrosis in those with NAFLD and was superior to FIB4 for both purposes.

SAT074

Obeticholic acid reduces hepatic matrix metalloproteinase activity in a diet-induced ob/ob mouse model of NASH

Marta Cagna[1], Giuseppina Palladini[1,2], Laura Giuseppina Di Pasqua[1], Anna Cleta Croce[3], Luciano Adorini[4], Andrea Ferrigno[1], Mariapia Vairetti[1]. [1]*University of Pavia, Dept of Internal Medicine and Therapeutics, Pavia, Italy;* [2]*Fondazione IRCCS Policlinico San Matteo, Pavia, Pavia, Italy;* [3]*Institute of Molecular Genetics, Italian National Research Council (CNR), Pavia, Italy;* [4]*Intercept Pharmaceuticals, San Diego, California, USA*
Email: marta.cagna02@universitadipavia.it

Background and aims: Hepatic matrix metalloproteinases (MMPs) play a role in fibrogenesis of NASH contributing not only to the balance between formation and degradation of connective tissue components, but also to signal transduction for tissue repair. We have previously shown that the FXR agonist obeticholic acid (OCA) reduces hepatic MMP activity by restoring RECK, an MMP regulator tissue reversion-inducing cysteine rich protein with Kazal motifs, after ischemia/reperfusion injury (Ferrigno et al, 2020). Here, the effects of OCA on hepatic MMP activity and RECK content were evaluated in a diet-induced NASH model in ob/ob mice.
Method: $Lep^{ob/ob}$ (ob/ob) NASH mice fed high fat (HF) diet (AMLN-diet; D09100301, with trans-fat, cholesterol and fructose) or control diet were used. After 9 weeks on diet, mice were treated with OCA dosed via dietary admixture 0.05% (30 mg/kg/d) or HF diet for 12 weeks. Liver weight, serum transaminase, alkaline phosphatase, bilirubin, cholesterol, triglycerides, MMP-2 and MMP-9 activity as well as RECK levels were quantified at the end of the study.
Results: HF diet induced a significant increase in liver MMP-9 when compared with mice treated with control diet; OCA administration reduced MMP-9 to levels observed in control diet animals. Although not significant, the same trend occurred for MMP-2. A down-regulation of tissue RECK observed in HF group was recovered by OCA to values comparable to control diet group. A significant increase in liver weight was found in HF diet mice compared to control diet group. OCA treatment reduced liver weight to values comparable with those observed in the control diet group. Serum bilirubin and cholesterol increased in HF diet-treated mice and OCA administration markedly counteracted these increases. OCA did not affect serum transaminase, alkaline phosphatase and triglyceride levels compared to HF diet mice.
Conclusion: Thus, OCA confers protection in a model of NASH, as shown by reduced serum bilirubin and cholesterol levels. This is the first study showing the positive effect of OCA on hepatic MMP-9 via restoration of RECK levels in a NASH model. These are intriguing findings considering a) the crucial role of MMPs in extracellular matrix homeostasis due to stellate cell activation into a profibrogenic phenotype occurring during inflammation and b) the emerging role of RECK in regulating inflammatory and fibrogenic processes. Further studies are necessary to better understand the implications of OCA-induced decrease in hepatic MMPs, and its role in the therapy of NASH.

SAT075

Evaluation of semisynthetic high-fat diets in development of a 4-week mouse NASH model

Ozren Majstorović[1], Maja Antolić[1], Snježana Čužić[1], Lucija Mušak[1], Matea Cedilak[2], Hrvoje Brzica[1], Martina Bosnar[2], Ines Glojnarić[1]. [1]*Fidelta Ltd, In vivo pharmacology and toxicology, Zagreb, Croatia;* [2]*Fidelta Ltd, In vitro pharmacology, Zagreb, Croatia*
Email: ozren.majstorovic@fidelta.eu

Background and aims: Non-alcoholic fatty liver disease (NAFLD) represents the most common chronic liver condition worldwide. Non-alcoholic steatohepatitis (NASH) is characterized by hepatic steatosis, inflammation, hepatocellular damage, and further, fibrosis. At present, no pharmacological NASH therapy was approved by the FDA, creating a necessity for a reliable preclinical model reflecting disease characteristics seen in humans. Most widely used animal models of NASH are set on nutritional basis, however, their long duration counteracts the need for rapid efficacy testing. In this study, two semisynthetic high-fat diets that act as disease inducers alone, or in combination with 2-hydroxypropyl-β-cyclodextrin (CDX) or fructose, were evaluated with the aim to develop a shorter but reliable mouse NASH model for screening of potential drug candidates.
Method: C57BL/6 male mice were fed with choline-deficient, L-amino acid-defined, high-fat (60 kcal%) diet (CHAHFD) consisting of 0.1% methionine or high-fat (60 kcal%), cholesterol (1.25%), and cholic acid (0.5%) (HFCC) diet. In addition, both dietary regimens were supplemented with either 2% CDX, a cyclic oligosaccharide with high affinity to sterols, or 30% fructose in drinking water. After four weeks of feeding, sera were analysed for biomarkers of liver damage (ALT, AST), cholesterol (CHOL), and fasting glucose levels. Livers were weighed and analysed for triglyceride (TG) content and expression of inflammatory (*Tnf-alpha*, *IL-10*, and *Ccl2*) and fibrosis related genes (*Col1a1*, *Timp1*, *Pai1*, *Ctgf*, *Tgf-beta*, and *Acta2*). Histopathological evaluation was conducted using modified NAS score and immuno-histochemistry (IHC) for Collagen 1A1 (COL1A1) and macrophage population (F4/80).
Results: Addition of CDX to HFCC diet resulted in a significant increase in inflammation and fibrosis, as confirmed by NAS, F4/80, and COL1A1 positive area as well as higher expression of both gene panels. In contrast, addition of fructose resulted in a significant increase in steatosis score. CDX addition to CDAHFD resulted in increase of liver damage biomarkers, while inflammation score, COL1A1 surface, and consequently total NAS, where most affected by addition of fructose. When comparing two diets, significantly higher serum CHOL levels were observed in all HFCC groups, while significant increase in liver TG content was achieved in all CDAHFD combinations. Disease progression to perisinusoidal/periportal fibrosis was observed with significantly higher intensity of overall parameters when using CDAHFD, however, accompanied by a transient body weight loss.
Conclusion: This study provides the successful recapitulation of main clinical features of NASH in a 4-week dietary induced mouse model, while favoring use of CDAHFD and emphasizing a need for tailored approach in testing pharmacological candidates based on their targets and mode of action.

SAT076

Tyrosinase mutations, a novel predisposing genetic factor for enhanced non-alcoholic steatohepatitis susceptibility

Kaushalya Kulathunga[1], Arata Wakimoto[2], Michito Hamada[2], Satoru Takahashi[2]. [1]*Faculty of Medicine-University of Sabaragamuwa Sri Lanka, Department of Physiology, Ratnapura, Sri Lanka;* [2]*University of Tsukuba, department of anatomy and embryology, Tsukuba, Japan*
Email: kkulathunga@med.sab.ac.lk

Background and aims: Non-alcoholic fatty liver disease (NAFLD) is an alarmingly rising metabolic disorder. Non-alcoholic steatohepatitis (NASH) is the progressive liver damage with inflammation, leading to fibrosis and carcinogenesis. Interestingly, enhanced susceptible for NASH was observed in B6 albino mice (albino) with high cholesterol diet (HCD), compared to wild type B6 black mice (black), a phenotype not reported before. This study was led to understand the underline mechanism of elevated NASH susceptibility of albino mice.
Method: B6 albino mice carry G291 T point mutation in *tyrosinase (Try)* gene and this is the only genetic difference compared to B6 black mice. Albino and black mice were fed with HCD for 10 weeks. Normal diet fed mice used as controls. Body weights, blood indices and liver damage related serum parameters were monitored. Liver samples were histologically analyzed. Small intestinal lipid absorption and the expression of intestinal cholesterol transporters were investigated. Mice carrying only the G291 T mutation were developed using

CRISPR/Cas9 technology and employed to confirm that the observed phenotype is resulted from that specific mutation.
Results: Liver injury with elevated ALT, AST levels were observed in albino mice from post day 1 HCD feeding. 2 weeks of HCD induced NASH in albino mice, but no symptom was observed in black mice even after 10 weeks of diet. Histological analysis of albino mice livers revealed significant inflammatory cells and lipid infiltration, and severe fibrosis. Increased serum chylomicron and very low density lipoprotein levels were observed in albino mice partly because of the low serum lipoprotein lipase levels and partly as the expression changes in small intestinal cholesterol transporters. Similar to B6 albino, CRISPR generated mice exhibited the same liver damage phenotype, confirming the contribution of G291 T mutation.
Conclusion: To validate our data in human context, in-silico analysis was carried out investigate the allele frequencies of two main *Try* single nucleotide polymorphisms (SNPs). Interestingly, it was revealed that Hispanic populations with highest prevalence of NAFLD/NASH exhibit relatively high allele frequencies with two main *Try* SNPs, G140Aand G316C. This work uncovered a novel possible genetic factor for NASH development. Further studies are carried out to uncover the contribution of human *Try* SNPs in the development of NAFLD/NASH.

SAT077

SIRT5 rs12216101 T > G variant is associated with mitochondrial dysfunction and disease severity in patients with NAFLD

Federico Salomone[1], Rosaria Maria Pipitone[2], Francesco Malvestiti[3], Paola Dongiovanni[3], Miriam Longo[3], Angela Maria Amorini[4], Alfio Distefano[4], Giovanni Li Volti[4], Giuseppe Lazzarino[4], Ester Ciociola[5], Grazia Pennisi[2], Rossana Porcasi[2], Daniela Cabibi[2], Antonio Craxi[2], Anna Ludovica Fracanzani[3], Luca Valenti[3], Salvatore Petta[2], Stefania Grimaudo[2]. [1]*Azienda Sanitaria Provinciale di Catania;* [2]*University of Palermo;* [3]*University of Milan;* [4]*University of Catania;* [5]*University of Gothenburg*
Email: federicosalomone@rocketmail.com

Background and aims: Sirtuin 5, encoded by the SIRT5 gene, is a NAD +-dependent deacylase modulating mitochondrial metabolic processes through post-translational modifications. In this study, we aimed to examine the impact of SIRT5 rs12216101 T > G non-coding SNP on disease severity in patients with non-alcoholic fatty liver disease (NAFLD).
Method: The rs12216101 was genotyped in 2606 consecutive European patients with biopsy-proven NAFLD. Transcriptomic analysis was performed in a subset. Effects of SIRT5 pharmacological inhibition was evaluated in HepG2 cells exposed to excess free fatty acids (FFA) and mitochondrial energetics was investigated by HPLC.
Results: In the whole cohort, the frequency distribution of SIRT5 rs12216101 TT, TG and GG genotypes was 47.0%, 42.3% and 10.7%, respectively. At multivariate logistic regression analysis adjusted for gender, age>50 years, diabetes, and PNPLA3 rs738409 status, SIRT5 rs12216101 T > G variant was associated with presence of NASH (OR 1.20, 95% C.I. 1.03–1.40) and F2-F4 fibrosis (OR 1.18, 95% C.I. 1.00–1.37). Transcriptomic analysis showed that rs12216101 T > G variant was associated with altered SIRT5 mRNA splicing and upregulation of transcripts involved in mitochondrial metabolic pathways, including the oxidative phosphorylation system (OXPHOS), thus suggesting that the G risk allele may confer an overall gain of function of SIRT5. Consistently, western blot analysis demonstrated an up-regulation of OXPHOS complexes III, IV and V. Administration of a pharmacological SIRT5 inhibitor to HepG2 treated with FFA preserved mitochondrial function as evidenced by restored ATP/ADP, NAD+/NADH and NADP+/NADPHs ratios.
Conclusion: The SIRT5 rs12216101 T > G variant is associated with liver damage, heightened SIRT5 activity and impaired mitochondrial function in patients with NAFLD, thus highlighting SIRT5 as a novel candidate target for NAFLD therapy.

SAT078

Recapitulating insulin resistance in a 3D human liver model for efficacy testing of drug candidates

Radina Kostadinova[1], Lisa Hoelting[1], Simon Hutter[1], Arianna Menghini[1], Anna Zehnder[1], Wolgang Moritz[1], Francisco Verdeguer[1], Olivier Frey[1]. [1]*InSphero, Schlieren, Switzerland*
Email: radina.kostadinova@insphero.com

Background and aims: There is a close link between metabolic liver diseases, type 2 diabetes, and obesity resulting in a severe dysregulation of glucose and lipid metabolism. Understanding the mechanism of inter-cellular and tissue crosstalk and how it relates to metabolic homeostasis, offers a great potential to identify novel therapeutic opportunities. Conventional cell culture models lack complex multi-cellular interactions found in the human body and are unable for accurate disease modeling and predictive drug efficacy testing *in vitro*. Here, we modeled de novo lipogenesis (DNL) and steatosis conditions by the recapitulation of glucose metabolism in 3D human liver co-culture and for efficacy testing of anti-steatotic and anti-diabetic compounds.
Method: We have cultured 3D human liver tissues (hLiMTs) consisting of primary hepatocytes, Kupffer cells and liver endothelial cells in a 96-well format under pathophysiological insulin and glucose conditions in absence (DNL model) or presence of free fatty acids (FFA, OA:PA, steatosis model). After incubation of the tissues with disease stimuli, -the insulin and glucagon sensitivity of hLiMTs was assessed by measurement of the tissue triglyceride levels as well as quantifying glycogen content and gluconeogenesis (GNG) upon hormonal stimulation.
Results: Glucagon induced glycogen storage depletion in hLiMTs. Additional, assay conditions were optimized to quantify GNG by measuring glucose release from fasted hLiMTs. The amount of glucose produced through GNG increased in the presence of increasing concentrations of glucagon. In contrast, increasing concentrations of insulin resulted in reduced glucose release from hLiMTs, indicating an inhibition of GNG. Importantly, insulin resistance was observed in hLiMTs incubated in high glucose and high insulin with and without FFA. Triglyceride levels were increased by about 10-fold in the DNL model and 20-fold in the steatosis model as compared to the healthy control. Treatment with 0.5 µM Firsocostat, an ACC1 inhibitor, decreased significantly the triglyceride levels in the DNL model.
Conclusion: The presented 3D human liver model replicates the features of glucose and lipid handling in a highly scalable format and its application for efficacy testing of anti-steatotic and anti-diabetic compounds. It constitutes one of the three central elements for building a multi-tissue MPS besides pancreatic islets and adipose microtissues to study human glucose and lipid homeostasis.

SAT079

Novel endosomal trafficking adaptor for the regulation of NAFLD to NASH progression

Karsten Motzler[1], Karsten Nalbach[2], Revathi Sekar[1], Ana Alfaro[1], Martin Hrabe de Angelis[3], Matthias Blüher[4], Michael Roden[5], Stephan Herzig[1], Natalie Krahmer[6], Christian Behrends[2], Anja Zeigerer[1]. Email: karsten.motzler@helmholtz-muenchen.de

Background and aims: Membrane trafficking through the endosomal transport system has gained increased attention for metabolic regulation in recent years. Cells within organs sensitive to metabolic cues, such as the liver, need to reorganize e.g. transporters and hormone receptors upon alterations in nutrient availability. This

reorganization is achieved by the endosomal trafficking machinery and is especially important in highly polarized hepatocytes for the secretion or delivery of certain proteins to apical (biliary) membranes while other proteins must be transported to basolateral (sinusoidal) membranes. Part of the needed specificity is given by different adaptor proteins (APs), aiding cargo recognition and coat protein recruitment during vesicle formation. Here, we are reporting on a novel role of the epsilon subunit of the AP-4 complex (AP4E1) in metabolism and implications for NAFLD to NASH progression. Connecting the two fields of endocytosis and metabolism offers a more thorough understanding of NAFLD and NASH and might help to identify new drug targets.

Method: Using mice with hepatocyte-specific knockout (KO) of Ap4e1 and different models of diet-induced NASH together with proteomic and RNA sequencing approaches, we aim to dissect the crosstalk of hepatocytes with other cell-entities within the liver. By assessing the membranome and secretome of primary hepatocytes, we try to identify novel cargo proteins of Ap-4 and how this transport is affecting the transition of NAFLD to NASH.

Results: Here, we identify a thus far unknown role for an endocytic membrane trafficking adaptor protein, Ap4e1, in NASH development and progression. Interestingly, we find Ap4e1 to be upregulated both in livers of human NASH patients, and in livers of multiple mouse models of NASH. This is associated with a positive correlation of Ap4e1 protein levels with hepatic fibrosis in mice, suggesting a potential connection between Ap4e1 and NASH progression. Indeed, reduction of Ap4e1 exacerbates the development of fibrosis, indicating a regulatory role of Ap4e1 in NASH. Membranome and secretome assessment of primary hepatocytes depleted of Ap4e1 reveal interesting hits on novel cargo proteins of this adaptor that are connected to fibrosis development and are currently investigated further. In addition, ongoing scRNAseq analysis of KO NASH livers is conducted to provide insights into the crosstalk between hepatocytes and other cell types within fibrotic mouse livers to shed light onto the intrahepatic communication pathways that drive disease progression.

Conclusion: Taken together, our data reveal a novel role of Ap4e1 in the regulation of NAFLD to NASH transition. As Ap4e1 depletion exacerbates disease outcome, we aim to identify the responsible cargo proteins that could reveal a new mechanism to understand NASH development and potentially serve as targets for therapeutic applications.

SAT080

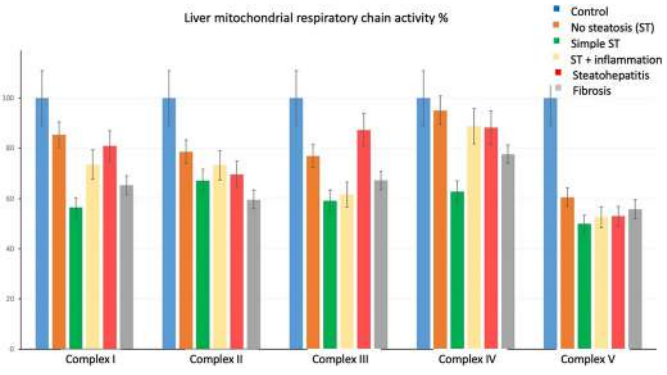
Enzymatic activity dysfunction of the mitochondrial respiratory chain, in the full spectrum of the metabolic associated fatty liver disease

Alberto García Picazo[1], Pilar Gómez Rodríguez[1], Pilar del Hoyo Gordillo[2], Carolina Ibarrola de Andrés[3], Javier Salamanca Santamaría[3], Elías Rodríguez Cuéllar[1], Cristina Martín-Arriscado[4], Jennifer Villa[5], Ana Martin Algibez[6], Inmaculada Fernández Vázquez[6], Miguel Ángel Martín Casanueva[4], Mercedes Pérez-Carreras[6]. *[1]12th October University Hospital, General Surgery, Madrid, Spain; [2]12th October University Hospital, Mitochondrial disease, Spain; [3]12th October University Hospital, Pathology, Spain; [4]12th October University Hospital, Imas 12 Research Institute, Spain; [5]12th October University Hospital, Microbiology, Spain; [6]12th October University Hospital, Gastroenterology, Spain*
Email: alberto.gpicazo@gmail.com

Background and aims: Patients with morbid obesity (MO) develop a huge range of histological injuries related to the metabolic associated fatty liver disease (MAFLD). Those lesions could be a trustful model to study their relation with the mitochondrial dysfunction, which appears in this disease. The main objective is to determine the existence of mitochondrial liver dysfunction in patients with MO and MAFLD.

Method: A prospective case-control study was designed, the case group was composed of MO patients having received bariatric surgery, whereas the control group was non-hepatopathy patients. In both groups surgical liver biopsy was performed between 2019 and 2021. Demographic, anthropometric, metabolic, blood test and histological (SAF classification) variables were measured. All patients were divided according to their histological injury grade and the dysfunction of the mitochondrial breath chain, and compared to the control group. Liver mitochondrial respiratory chain (MRC) activity was measured by spectrophotometry. The variables were analysed with Stata version 16 software, statistically significance was set at $p < 0.05$.

Results: Case group (n = 53): 66% women, 48 ± 11 years, BMI 45 ± 6; Control group (n = 10): 50% women, 54 ± 13 years, BMI 24 ± 2. MRC activity in case group vs control group: Complex I, 39.8 vs 53.9 ($p = 0.01$), II- 190.3 vs 275.2 ($p < 0.001$), III-87.6 vs 119 ($p = 0.04$), IV- 92.6 vs 115 ($p = 0.02$) and V- 82.8 vs 155.8 ($p < 0.001$). Figure 1: decreased percentage in the MRC activity related with the histological damage: No steatosis (10/53), simple steatosis (7/53), steatosis + inflammation (7/53), steatohepatitis (17/53), Fibrosis (12/53). A relation between HOMA-IR and high levels of insulin with the activity in the complexes I and II ($p < 0.05$) was identified.



Conclusion: The enzymatic activity of the 5 complexes of the liver MRC are decreased in patients with MO and MAFLD. This alteration affects the synthesis of ATP (complex V). Insulin resistance and insulinemic index are associated with defects in complexes I and II. Mitochondrial disfunction already appears in subjects with MO without liver injury and is different according to histological severity. There is less enzymatic activity in early and advanced stages of MAFLD, while it increases with MAFLD inflammatory activity. These enzymatic changes could be due to adaptive disorders of the mitochondria in MAFLD.

SAT081

Lipid-induced phenotypic differences in human non-alcoholic fatty liver disease models determined by matrix-assisted laser desorption/ionization mass spectrometry

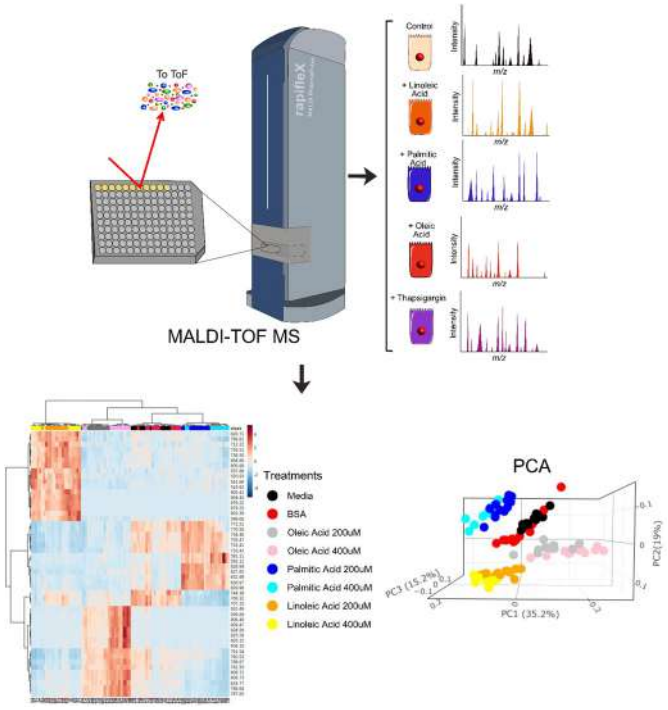
Ruth Walker[1], Michalina Zatorska[2], Jose Luis Marin-Rubio[1], Matthias Trost[1], Maria Emilia Dueñas[1], Olivier Govaere[2]. *[1]Biosciences Institute, Faculty of Medical Sciences, Newcastle upon Tyne, United Kingdom; [2]Translational and Clinical Research Institute, Faculty of Medical Sciences, Newcastle upon Tyne, United Kingdom*
Email: olivier.govaere@newcastle.ac.uk

Background and aims: Accumulation of lipids is a key part of the pathogenesis of non-alcoholic fatty liver disease (NAFLD) and has recently been associated with endoplasmic reticulum (ER) stress. *In vitro* lipid loading is often used as an experimental model for NAFLD, though a high-throughput screening platform to understand metabolic changes and lipotoxicity is still lacking. Matrix-assisted laser desorption/ionisation-time-of-flight mass spectrometry (MALDI-TOF MS) is a fast, reproducible, and label-free technology, used for assays in pharmaceutical research and development, drug discovery and

chemical biology. This offers the potential to perform comprehensive phenotypic characterisation of biomolecules, including metabolites, and screen for novel therapeutic strategies. The aim of this work was to establish a fast and robust high-throughput screening technique for determining metabolite and peptide/protein changes in a NAFLD cell model.

Method: Human hepatoma HepG2 cells were treated with saturated and unsaturated fatty acids including linoleic, oleic and palmitic acid at concentrations of 200 µM and 400 µM, or with the ER stress inducer thapsigargin (1 mM). Cells were mixed one-to-one with 2, 5-dihydroxyacetophenone matrix and analysed by MALDI-TOF MS to determine differences in the phenotypic profiles of metabolites and high molecular weight (HMW) biomolecules. Principal component, hierarchical clustering and multivariate analysis were carried out to identify differences.

Results: Overall, 1372 metabolite and 753 protein unique features were identified by MALDI-TOF MS. Distinctive metabolite profiles were established for each condition, allowing multiplexing and identification of biomarkers. A dose-dependent effect is evident for all lipids and whilst linoleic and oleic acid are often used interchangeably in the field, they induce significant differences in cellular metabolic profiles, having 243 and 76 unique metabolites respectively. Moreover, although thapsigargin and high concentrations of palmitic acid induces ER stress and cellular cytotoxicity respectively, they present substantial differences, indicating that mechanistic differences between these two conditions. Of the lipid treatments, only 400 µM palmitic acid has a significant effect on the profiles of HMW biomolecules, having 605 unique biomolecules, and 47 common proteins.



Conclusion: Taken together, we have developed a fast MALDI-TOF MS comparative screening technique for determining metabolite and HMW biomolecule changes in a human in vitro NAFLD models. Moreover, our data provides distinctive metabolic and stress fingerprints that are relevant during the progression of NAFLD. Biomarkers from these fingerprints may be used as a screening method for therapeutic interventions.

SAT082

Regulation of NEAT1 in NAFLD by RNA-binding proteins

Lisa Ahne[1], Ahmad Barghash[2], Shinichi Nakagawa[3], Alexandra K. Kiemer[4], Sonja Keßler[1]. [1]*Institute of Pharmacy, Experimental Pharmacology for Natural Sciences, Halle (Saale), Germany;* [2]*School of Electrical Engineering and Information Technology, Amman, Jordan;* [3]*Faculty of Pharmaceutical Sciences, RNA Biology Laboratory, Sapporo, Japan;* [4]*Institute of Pharmacy, Pharmaceutical Biology, Saarbrücken, Germany*
Email: lisa.ahne@pharmazie.uni-halle.de

Background and aims: The long non-coding RNA *NEAT1* with its two most abundant transcripts *NEAT1_v1* and *NEAT1_v2* has been shown to play a role in NAFLD. *NEAT1* is strongly regulated via stability and closely associated with paraspeckles and mitochondria. However, the underlying interactions remain unclear so far. RNA-binding proteins (RBPs) are major regulators of post-transcriptional regulation.
Aim of this study was to investigate the role of RBPs in the regulation of *NEAT1* in NAFLD.

Method: Experiments were performed either in wildtype, hepatocytic *TTP*$^{-/-}$, or *Neat1*$^{-/-}$ mice. Mice were fed either a high-fat diet (HFD), a methionine-choline deficient diet (MCD), a Lieber De Carli diet (LDC), or a control diet. Gene expression was analyzed by qPCR, gene arrays, or RNA-Seq. RIP of HuR/ELAVL1 was performed. In vitro experiments were conducted in HepG2, HUH7, or PLC/PRF/5 cells and two human data sets (GEO) were analyzed.

Results: *Neat1* was upregulated in livers of HFD-, Lieber de Carli, and MCD-fed mice. *Neat1*$^{-/-}$ mice gained less weight on an HFD. Hepatic gene expression data of these *Neat1*$^{-/-}$ mice revealed several enriched GO terms related to metabolism. Concordantly, in an *in vitro* steatosis model, treatment of HepG2 cells with oleic acid or palmitic acid induced *NEAT1* expression, particularly of the long *NEAT1* variant. Interestingly, gene expression of paraspeckle RBPs *Sfpq* and *Pspc1* were also significantly increased in the MCD-fed animals. The increase of *Neat1*, *Sfpq*, and *Pspc1* expression seems to particularly take place in hepatocytes, since expression levels were unchanged in Kupffer cell depleted livers.In inflammatory conditions, two oppositely regulated RBPs play a major role in the regulation of inflammatory factors: TTP/ZFP36 and HuR/ELAVL1. Human data sets revealed a contrary deregulation of both RBPs in human steatohepatitis and murine NAFLD models. The target AU-rich motifs of TTP and HuR could be found above average in the *NEAT1_v2* sequence. Both RBPs exhibit a large overlap of target RNAs containing AU-rich sequences that are stabilized by HuR but degraded by TTP. In *TTP*-/- livers, a significant induction of *Neat1* expression was observed. Overexpression of TTP in liver cells decreased *NEAT1_v1* and *NEAT1_v2* levels. For HuR, RIP experiments in total HUH7 cell lysates confirmed binding of HuR to human *NEAT1* in liver cells.

Conclusion: Our data suggest that *NEAT1* is regulated by the RBPs TTP and HuR in steatohepatitis.

SAT083

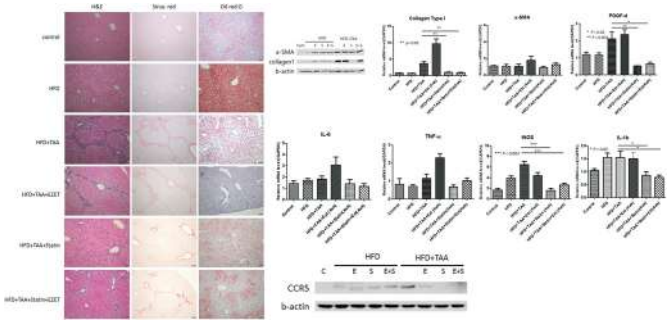
Anti-inflammatory effect of simvastatin-ezetimibe combination therapy via inhibition of macrophage in NASH related mouse model

Han Seul ki[1], Moon Young Kim[1]. [1]*Wonju Severance Christian Hospital, Department of Internal Medicine, Division of Gastroenterology and Hepatology, Wonju-si, Korea, Rep. of South*
Email: drkimmy@yonsei.ac.kr

Background and aims: There are few clinical options for management of Non-alcoholic steatohepatitis (NASH)-related cirrhosis. In both vivo and vitro studies, we aimed to investigate the effects of statin and ezetimibe combination therapy and putative anti-inflammation capacity in NASH-related liver fibrosis.

Method: A High-fat diet and Thioacetamide (300 mg/kg, intraperitoneal injection twice a week for 8 weeks) was given to establish mice models with non-alcoholic steatohepatitis (NASH) related

histological change. Statin (5 mg/kg) and ezetimibe (10 mg/kg) were administrated during last 4 weeks.
Results: Ezetimibe, statin monotherapy and combination therapy were improved hepatic steatosis.
We got liver tissue showing histologically NASH-related change from high fat diet for 12 weeks and administration of TAA for 8 weeks. The improvement of steatosis and inflammation was more pronounced in the statin group, ezetimibe group and combination group. In particularly, ezetimibe shows lower fat contents and statin shows improvement of inflammation.
Simvastatin mono treatment and combination with ezetimibe treatment suppress hepatic fibrosis
The improvement of fibrosis was more pronounced in the statin and ezetimibe group. These results were confirmed as decreased a-SMA and collagen protein level by Western analysing. In PCR transcription, there was lower transcription level of collagen type I and PDGF-d, suggesting there is lowering fibrosis in statin, ezetimibe treated group. There was elevation of collagen type I and a-SMA, PDGF-d in ezetimibe monotreatment group, but it was not correlated a histological finding.
Simvastatin and ezetimibe combination treatment suppresses hepatic inflammation.
The effects about IL-6, IL-1b, and TNF-a were evaluated by quantitative real-time PCR. And it is suggesting that simvastatin mono-treatment and simvastatin, ezetimibe combination therapy exhibits anti-inflammatory effects. IL-6, TNF-a, IL-1b and iNOS was decreased in statin and combination group. In this study, Ezetimibe mono-treatment group shows elevation of IL-6, TNF-a.
Simvastatin and ezetimibe combination therapy inhibits macrophage migration via downregulating CCR 5 and macrophage activation
In vitro, Statin and ezetimibe downregulate of expression of CCR5. Many macrophages were also observed in HFD-TAA histology and the number of macrophages was decreased in simvastatin, simvastatin + ezetimibe combination treatment group.



Conclusion: In the NASH-cirrhosis mouse model, ezetimibe showed the improvement of steatosis and statin showed anti inflammatory effect. And the combination therapy showed improvement of fibrosis through macrophage migration and suppression, resulting in TNF-a inhibition. Ezetimibe mono-treatment in NASH-cirrhosis need to be evaluated because of potential side effects.

SAT084

The different modulation of KLB expression impacts on liver damage in NAFLD patients and in an in vitro model: a novel druggable target?

Marica Meroni[1], Nadia Panera[2], Giada Tria[3], Roberto Piciotti[3,4], Miriam Longo[3,5], Erika Paolini[3,6], Antonella Mosca[7], Annalisa Crudele[2], Anna Ludovica Fracanzani[3,4], Anna Alisi[2], Paola Dongiovanni[1]. *[1]Fondazione IRCCS Cà Granda Ospedale Maggiore Policlinico, Milan, Italy; General Medicine and Metabolic Diseases, Milan, Italy; [2]Bambino Gesù Children's Hospital-IRCCS, Research Unit of Molecular Genetics of Complex Phenotypes, Rome; [3]Fondazione IRCCS Cà Granda Ospedale Maggiore Policlinico, Milan, Italy; General Medicine and Metabolic Diseases, Milan; [4]University of Milan, Department of Pathophysiology and Transplantation, Milan; [5]University of Milan, Department of Clinical Sciences and Community Health, Milan; [6]University of Milan, Department of Pharmacological and Biomolecular Sciences, Milan; [7]Bambino Gesù Children's Hospital-IRCCS, Hepatology Gastroenterology and Nutrition, Rome*
Email: paola.dongiovanni@policlinico.mi.it

Background and aims: We previously shown that the rs17618244 variant in β-Klotho (KLB) gene, encoding the hepatic co-receptor of fibroblast growth factor receptor 4 (FGFR4), increases the risk of developing severe NAFLD, NASH and fibrosis both in adults and children, due to lower KLB hepatic/plasma levels. Aim of this study was to investigate the impact of another variant in *KLB*, the rs12152703, on liver damage in NAFLD patients and to evaluate the effect of *KLB in vitro* genetic ablation on fat accumulation, oxidative/ER stress, inflammation and cell proliferation.
Method: We evaluated the effect of the rs12152703 variant in 1311 biopsied NAFLD patients of whom 261 were children. Hepatic and circulating KLB levels were measured in a subset of patients (n = 125 and n = 290, respectively). Next, we generated a full knock-out model of *KLB* gene in HepG2 cells ($KLB^{-/-}$) by CRISPR/Cas9.
Results: At multivariate analysis, the rs12152703 *KLB* variant was associated with reduced transaminase levels and with protection against NASH and advanced NAFLD activity score (NAS) ($p < 0.05$). Hepatic and circulating KLB concentrations were increased in NAFLD patients carrying the variant ($p < 0.05$).
Concerning the *in vitro* model, KLB mRNA and protein levels were strongly dampened in $KLB^{-/-}$ cells ($p < 0.01$), along with the expression of genes implicated in cholesterol metabolism, suggesting an overall altered KLB signaling ($p < 0.05$). $KLB^{-/-}$ cells displayed a reduced intra-cellular triglyceride (TG) content ($p < 0.05$), related to the suppression of genes involved in lipogenesis and TG synthesis ($p < 0.05$). *KLB* deletion strongly induced oxidative and ER stress, increasing ROS/RNS production, aldehyde derivate concentrations and ROS-induced DNA damage ($p < 0.05$). These events triggered the release of pro-inflammatory cytokines into the $KLB^{-/-}$ cultured media ($p < 0.05$), resembling severe NAFLD. Finally, $KLB^{-/-}$ cells also showed an elevated proliferative rate and invasiveness ($p < 0.05$).
Conclusion: In sum, the rs12152703 *KLB* variant protected against severe NASH, whereby enhancing KLB levels differently from the rs17618244 at-risk variation.
Our *in vitro* results outlined that *KLB* shutdown may be causally involved in the switching towards progressive forms of liver damage, by inducing ER/oxidative stress, inflammation, and enhanced proliferation, even in the absence of excessive fat accumulation. Thus, KLB may constitute a novel druggable target for the prevention of severe NAFLD.

SAT085

Utilization of gluconeogenic glucose-6-phosphate via pentose phosphate pathway is increased in mice fed a high fat/high sugar diet compared to a high sugar diet alone

Getachew Debas Belew[1,2], Ana Costa[1], Maria Joao Meneses[3], Ludgero Tavares[1], Paula Macedo[3], John Jones[1]. *[1]University of Coimbra, Center for Neuroscience and Cell Biology, Coimbra, Portugal; [2]Addis Ababa Science and Technology University, Biotechnology, Addis Ababa, Ethiopia; [3]CEDOC-Chronic Diseases Research Center, NOVA Medical School, Nova University of Lisbon, Lisbon, Portugal*
Email: gechap4@gmail.com

Background and aims: In hepatocytes, the pentose phosphate pathway (PPP) is an important generator of NADPH for *de novo* lipogenesis (DNL) and for the maintenance of reduced glutathione in antioxidant defense. The development of non-alcoholic fatty liver disease (NAFLD) secondary to high sugar and/or high fat intake is characterized by elevated DNL rates and increased oxidative stress. It is not known whether PPP fluxes are modified in these settings. We developed a double tracer method that provides information on both

DNL and PPP fluxes in feeding mice. We applied this to compare DNL and PPP fluxes in mice fed a normal chow diet supplemented with high-fructose corn syrup (HFCS-55) with a more obesogenic diet composed of high fat chow supplemented with HFCS-55.

Method: Twelve C57BL/6 mice were provided with standard chow (SC) with the drinking water supplemented with 30% (w/v) of HFCS-55 (55/45 mixture of fructose and glucose) for 18 weeks. Eleven mice were placed on high-fat chow (HFC) with the same HFCS-55 supplement over the same period. At the beginning of the final evening, all mice were administered with 99% deuterated water containing and the HFCS-55 fructose component was enriched to 20% with [U-$^{13}C_6$]fructose. On the following morning, mice were deeply anesthetized with ketamine/xylazine and sacrificed by cardiac puncture. Arterial blood was collected and centrifuged to isolate plasma, livers were freeze-clamped, and the samples were stored at −80°C until further processing. Liver triglyceride and glycogen were purified and analyzed for ^{2}H and ^{13}C-enrichments by NMR. DNL rates were quantified from lipid ^{2}H-enrichment and adjusted for liver triglyceride levels. Whole body adiposity was estimated from body water ^{2}H enrichment. The fraction of gluconeogenic glucose-6-phosphate (G6P) utilized by the PPP was quantified from glycogen ^{13}C-isotopomer analysis.

Results: Mice fed HFC + HFCS-55 has greater body weight (50 ± 1 vs 37 ± 1 g, $p < 0.0001$), higher whole-body adiposity (29 ± 1 vs 16 ± 2%, $p < 0.0001$), and higher liver triglyceride levels (15 ± 2 vs 8 ± 2 g/100 g liver, $p < 0.025$) compared to those fed SC + HFCS-55. DNL rates were not significantly different between the two groups although the high-fat chow mice had a tendency for higher rates (1.02 ± 0.1 vs 0.75 ± 0.1 g/100 g liver, p = 0.2109). However, the fraction of gluconeogenic G6P utilized by the PPP was significantly higher for the high-fat chow mice (17.0% *versus* 13.8%, $p = 0.034$).

Conclusion: A diet high in both fat and sugar is more obesogenic than a diet high in sugar alone. In the presence of high fat, DNL rates were sustained while PPP utilization of G6P derived from gluconeogenesis was significantly increased. This may be explained by additional demand for NADPH above and beyond that consumed by DNL, possibly in response to increased oxidative stress.

SAT086

A novel microwell platform to analyse single-cell secretion dynamics and cell communication in NAFLD progression

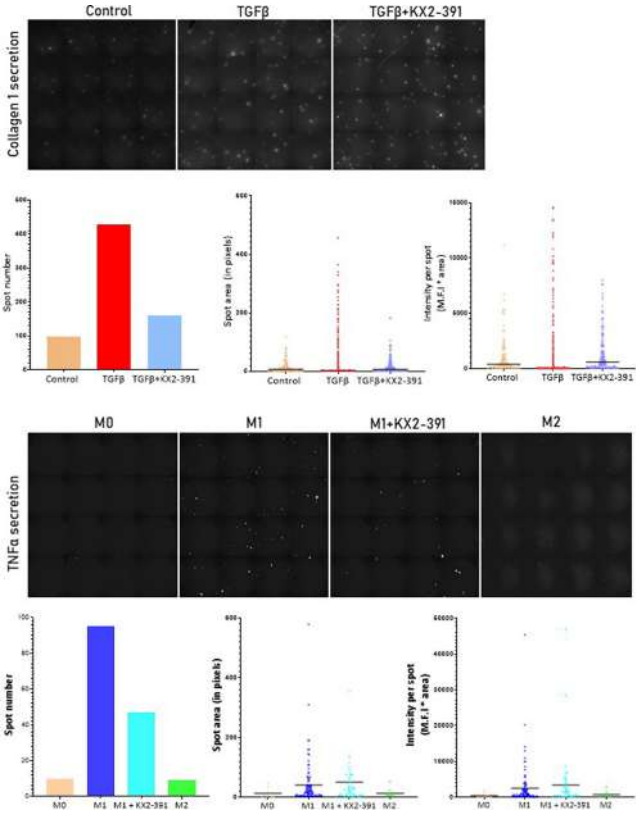
Richell Booijink[1,2], Ruchi Bansal[1,2], Leon Terstappen[1]. [1]*University of Twente, Medical Cell Biophysics, Science and Technology, Netherlands;* [2]*University of Twente, Translational Liver Research, Medical Cell BioPhysics*
Email: r.s.booijink@utwente.nl

Background and aims: Liver inflammation and fibrosis are the hallmarks of non-alcoholic steatohepatitis (NASH). Here, activated and differentiated hepatic stellate cells (HSCs) together with infiltrating and activated immune cells maintain a continuous cycle of cellular activation, inflammation and fibrogenesis. To do this, these non-parenchymal cell populations in the liver microenvironment secrete factors including cytokines and proteins to communicate with their surroundings. Many studies confirmed heterogeneity within these cells on a genomic level. However, how this heterogeneity translates to cellular secretion and communication, and its influence on NALFD progression remains unclear.

We propose a novel model that enables simultaneous analysis and correlation of single-cell secretion, phenotype, genome and transcriptome, using a self-sorting microwell platform.

Method: The self-sorting microwell chip is developed containing 6400 microwells with a diameter of 70 µm, volume of 1.4 nl and 5 µm single pore at the bottom of each well. While placing a cell suspension on the chip, single cells are distributed over the wells, and identified by fluorescent microscopy. The chip is brought into contact with a PVDF membrane, which collects secreted molecules from the single cells. Upon removing the membrane, the concentration of secreted molecules can be determined and correlated to the individual cell that produced them. Thereafter, cells of interest can be isolated from the chip and used for further molecular (DNA and RNA) analysis, by punching out the bottom of the microwell into a PCR tube.

Results: To validate the model, human HSCs (LX2) and PMA-differentiated human macrophages (THP1) are used to measure collagen-I and TNF-alpha secretion respectively. Upon TGF-β activation, we observed an increase in the number of HSC-secreted collagen-I spots with increased spot intensity and area, which varied greatly per individual cell, confirming the cellular heterogeneity in collagen-I secretion in non-activated and activated cells. Interestingly, treatment with Src kinase inhibitor, KX2-391, led to an average decrease-again with large variety-in the amount of collagen-I secretion.



Furthermore, upregulation of TNF-alpha secretion was observed in pro-inflammatory LPS-stimulated M1 macrophages, seen by an increased number of cells that produced detectable TNF-alpha spots. Again, we saw a heterogeneous distribution in TNF-alpha secretion, and treatment with KX2-391 led to a reduction in the amount of TNF-alpha secreted per cell.

Conclusion: We established a method to determine the phenotype and secretome, that can be integrated with genome and transcriptome, of single cells in the NASH microenvironment. Building upon this model by multiplexing cell populations and multiple secreted molecules allows us to map the NASH secretome, exploring novel avenues for NASH treatment.

Dysregulation of the urea cycle enzymes determines a more severe NAFLD phenotype in a DIAMOND preclinical model

Rocío Gallego-Durán[1,2], María del Rosario García-Lozano[1,2], Douglas Maya[1,2], Lucía López-Bermudo[3,4], Rocío Montero-Vallejo[1,2], Sheila Gato Zambrano[1,2], Antonio Cárdenas-García[3,4], Vanessa García Fernández[1,2], Blanca Escudero-López[3,4], Rocio Munoz Hernandez[1,2], Antonio Gil-Gomez[1,2], Angela Rojas Alvarez-Ossorio[1,2], Helena Pastor[1,2], Franz Martin-Bermudo[3,4], Manuel Romero Gomez[1,2,5], Javier Ampuero[1,2,5]. *[1]Instituto de Biomedicina de Sevilla/CSIC/ Universidad de Sevilla, SeLiver Group, Spain; [2]Hepatic and Digestive Diseases Networking Biomedical Research Centre (CIBERehd); [3]Andalusian Center of Molecular Biology and Regenerative Medicine (CABIMER)-CABIMER-, University Pablo Olavide-University of Seville-CSIC, Spain; [4]Biomedical Research Network on Diabetes and Related Metabolic Diseases (CIBERDEM); [5]Hospital Universitario Virgen del Rocío, Digestive Diseases Unit*
Email: jampuero-ibis@us.es

Background and aims: Non-alcoholic fatty liver disease (NAFLD) is one of the most prevalent liver diseases worldwide, showing a plethora of different pathogenic factors. In this scenario, previous studies have shown an association between the urea cycle dysregulation and different stages of hepatic injury in both patients and preclinical models of NAFLD. The main aim was to evaluate changes in urea cycle enzymes (UCEs) in a DIAMOND preclinical animal model of NAFLD under different dietary interventions.
Method: DIAMOND mice (n = 28) were randomized to three dietary regimens: high-fat diet supplemented with fructose/glucose in drinking water (HF-HFD), choline-deficient high-fat diet model supplemented with 0.1% methionine (CDA-HFD) or standard diet, which was used as a control. HF-HFD and control animals were sacrificed after 21 or 30 weeks of diet intake. CDA-HFD animals were sacrificed after 12 weeks to avoid weight loss along with other adverse outcomes linked to more prolonged exposure to this type of diet intervention. Liver damage characterization includes well-established markers for fibrosis (collagen deposition and COL3A1, COL1A1, and α-SMA expression levels) and inflammation (TNF-α and IL-6 expression), together with body weight and standard biochemical measurements recorded each week or month, respectively. UCEs and glutaminase (GLS) expression levels were evaluated by qRT-PCR.
Results: HF-HFD animals displayed signs of dyslipidemia (hypercholesterolemia), insulin resistance (higher glucose levels), and liver damage (raised AST and ALT levels) together with a 25% and 300% increase in body and liver weight, respectively. CDA-HFD animals displayed similar AST levels, higher ALT levels, and a 200% increase in liver weight but did not show any of the other metabolic disturbances observed in HF-HFD animals. Both diet interventions promoted a general upregulation of fibrotic markers (COL3A1, COL1A1, α-SMA, and collagen deposition) along with a significant upregulation of the pro-inflammatory marker TNF-α. Transcriptomic evaluation of UCEs revealed a significant mRNA downregulation in carbamoyl phosphate synthetase-1 (CPS1) and ornithine transcarbamylase (OTC1) in both CDA-HFD and HF-HFD animals *versus* controls, together with an increase in GLS1 expression in all groups of animals.

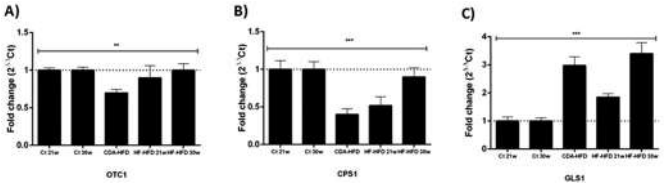

Figure: Hepatic expression of UCEs and GLS1 in DIAMOND mice stratified according to ALT tertiles. A) OTC1 B) CPS1 C) GLS1.

Conclusion: DIAMOND mice, a preclinical model that mimics NAFLD, showed urea cycle dysregulation under different dietary interventions. These enzymes could play a key role in the development and progression of NAFLD.

SAT088

Quantitative multimodal anisotropy imaging enables automated fibrosis assessment of HandE-stained tissue

Yibo Zhang[1], Jun Zhang[1], Michael Drage[1], Janani Iyer[1], Brian Gosink[1], Tan Nguyen[1], Waleed Tahir[1], Victoria Mountain[1], Murray Resnick[1], Michael Montalto[1], Aditya Khosla[1], Andrew Beck[1], Justin Lee[1]. *[1]PathAI, Boston, United States*
Email: justin.lee@pathai.com

Background and aims: Clinical Research Network (CRN) histologic scoring of non-alcoholic steatohepatitis (NASH) requires staining two tissue sections per FFPE block: one with HandE (for grading steatosis, inflammation, and ballooning) and one with Masson's Trichrome (MT; for staging fibrosis). This multi-stain procedure is cumbersome, costly, and inconsistent, introducing interpretability challenges due to variability in staining and intra-biopsy sample heterogeneity. In this study, we develop and evaluate a tool for automated fibrosis assessment based on quantitative multimodal anisotropy imaging (QMAI) of HandE-stained NASH tissue sections. We demonstrate that quantifying HandE-derived fibrosis proportionate area (FPA) using QMAI yields results that correlate strongly with MT-stain color-based fibrosis quantification.
Method: 24 liver core needle biopsies from NASH patients with paired HandE and MT sections (48 slides, CRN fibrosis stages 0–4) were used in this study. HandE sections were imaged using a custom-built multimodal microscope, and MT sections were imaged using a Leica Aperio AT2 scanner. Whole-slide images were reviewed by a board-certified expert NASH pathologist and regions of tissue artifact were excluded from analysis. A pixel-intensity threshold was applied to QMAI images of HandE sections to locate fibrotic regions and compute FPA. For MT sections, color-based segmentation was employed to obtain a binarized fibrosis heatmap from which FPA was quantified. For all sections, a background/foreground algorithm generated the denominator for fibrosis proportion measurements. Concordance between HandE and MT-derived FPA was evaluated via Lin's Concordance.
Results: Slide-level FPA quantification from paired HandE and MT sections showed strong correlation (Lin's CCC = 0.950). Visual examination of detected fibrosis on HandE and MT sections corroborates this result and explains discrepancies between QMAI vs. MT fibrosis quantification (Fig. 1).
Conclusion: Quantitative multimodal anisotropy imaging enables fibrosis quantification from HandE-stained NASH biopsy samples that is consistent with conventional fibrosis quantification from MT-stained tissue. By eliminating the need for MT-stained slides, automated fibrosis quantification and staging from HandE sections may simplify and reduce the cost of NASH studies as well as lessen the impact of MT stain-variability and intra-sample heterogeneity on subject screening and end point assessment. Additionally, detecting fibrosis from HandE sections may enable improved interrogation of spatial relationships between fibrosis and various NASH features commonly assessed on HandE (e.g., steatosis, ballooning, and/or inflammation).

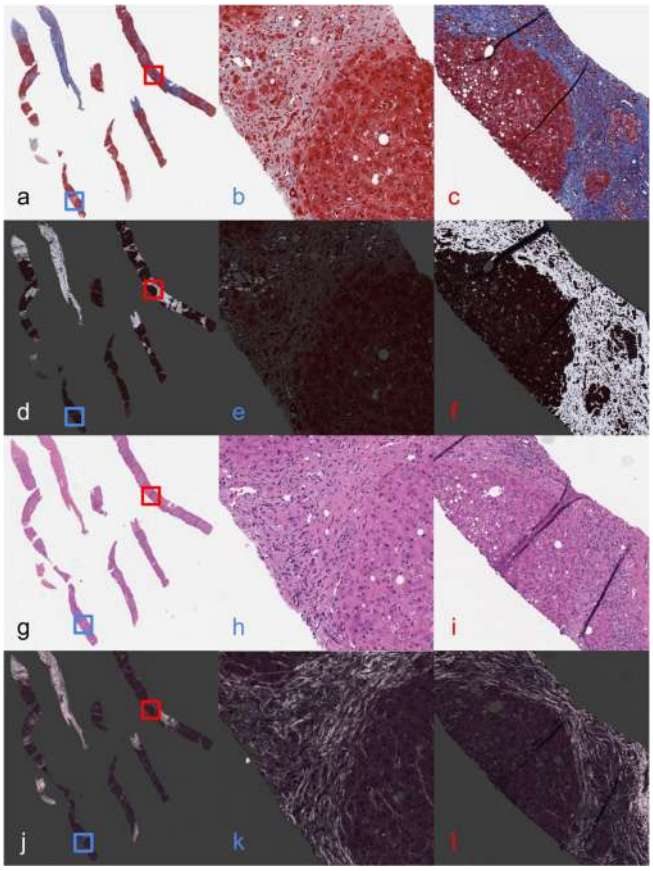

Figure 1: Example paired MT (a-c) and HandE (g-i) tissue areas and their corresponding fibrosis overlays (d-f and j-l, respectively).

Email: cedric.peleman@uantwerpen.be

Background and aims: Immunohistochemical stains (IHC) often reveal differences between different zones of the liver lobule in health and disease, including non-alcoholic fatty liver disease (NAFLD). However, evidence from IHC often depends on representative images. In NAFLD, lipid vacuoles from macrovesicular steatosis occupy part of the surface and hamper correct interpretation. We developed an image analysis method to quantify IHC staining area of hypoxia marker pimonidazole (Pimo) within different zones of the liver lobule of steatotic livers.

Method: Male C57BL/6J mice were fed the choline-deficient L-amino acid-defined high-fat diet (CDAHFD) or standard diet (SD) for three weeks and received an intraperitoneal injection of Pimo (100 mg/kg) one hour prior to sacrifice (n = 6). Serial sections of formalin-fixed paraffin-embedded liver tissue were stained with haematoxylin-eosin (HandE) and IHC for glutamine synthetase (GS) and Pimo adducts were visualised with 3, 3′-diaminobenzidine (DAB). Whole slide image (WSI) acquisition was performed with the Zeiss Axioscan 1. A script for FIJI open-source image analysis freeware was developed to measure DAB pixel intensities as a function of the relative location (with respect to the central vein and the boundary) within a liver lobule. The autothreshold algorithm 'Percentile' binarised the pixels into positive or negative for Pimo based on the global WSI DAB intensity. Data were processed in R Studio, using the additional package "dplyr" for grouped summary statistics.

Results: CDAHFD induced non-alcoholic steatohepatitis (NASH) with panlobular Pimo positivity, whereas hypoxia was present in the centrolobular area in normal livers in SD group. Liver lobules follow the Voronoi principle wherein each lobule originates from a central vein identified by HandE and centrolobular GS staining. These landmarks were manually annotated for each lobule after which the image analysis script calculated the intensity distribution as a function of the pixel position within the lobule. After exclusion of datapoints belonging to fat vacuoles, the percentage of Pimo positive area was calculated in different parenchymal zones. The Pimo positive area was significantly higher in the periportal zone in NASH livers ($p < 0.05$, Fig. 1). Moreover, the ratio of Pimo positive area in periportal (PP) vs. centrolobular (CV) regions was significantly higher in NASH compared to SD ($p < 0.001$), demonstrating the panlobular nature of Pimo staining in NASH.

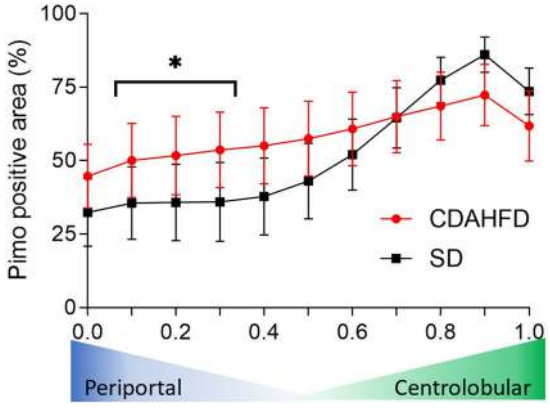

Figure 1. Data presented as mean ± standard deviation; Mann-Whitney test, *p < 0,05.

Conclusion: The method described herein accurately quantifies the difference in zonal distribution of hypoxia marker Pimo in WSI images of NASH and normal livers. This image analysis method should allow for objective zonal quantification of other epitopes assessed by IHC, including livers affected by NAFLD.

Email: rafael.kaeser@uniklinik-freiburg.de

Background and aims: Non-alcoholic fatty liver disease (NAFLD) associated with obesity and metabolic syndrome is emerging as a leading cause of chronic liver disease in western countries. Hepatic steatosis may lead to inflammation resulting in non-alcoholic steatohepatitis (NASH) and progressive liver disease. A role of hepatic T cells in driving inflammation is suspected, however, the immuno-pathogenesis of NASH remains incompletely understood. We therefore set out to characterize the immune landscape in NASH livers and non-inflamed livers in obese patients.
Method: Liver tissue was obtained from heavily obese patients undergoing bariatric surgery. Clinical data and blood samples were collected at baseline and longitudinally after surgery. 52 patients were included in the study and stratified into a group with no indication of inflammation (n = 28) and a NASH group with high levels of inflammation (n = 24) according to histologic scoring and clinical parameters. Liver and blood samples were characterized by flow cytometry [n = 28], validated by mass cytometry [n = 20] and subsequently further investigated by single cell RNA sequencing [n = 4] for a broad range of immune cell subsets.
Results: CD4T cells were significantly enriched within the inflamed hepatic tissue compared to uninflamed liver samples (Figure A). In contrast, CD8T cells and other immune cells showed no significant differences between the groups. Subsequent cluster analysis confirmed a distinct CD161-expressing CD4+ CD25hi T cell subset in the liver, which was enriched in the group of patients with high inflammation (Figure B). Further analysis of this subset by mass cytometry identified CD26, CD127, OX40 and CXCR3 as additional markers defining this inflammation-associated CD4T cell cluster. Interestingly, these differences were only detectable in the liver, but not the peripheral blood, suggesting specific changes of tissue-resident immune populations during NASH.

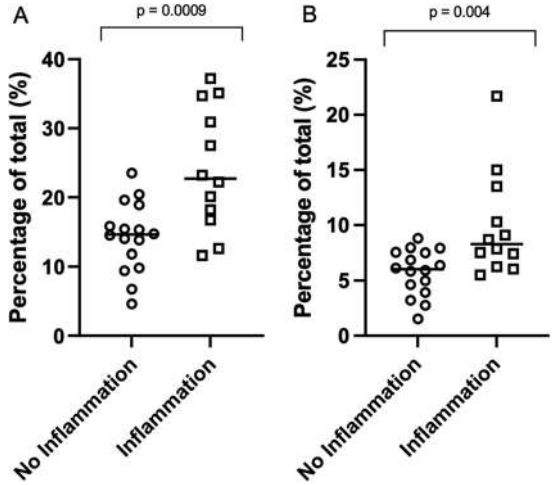

Figure: The proportions of CD4+ T cells (A) and CD4+ CD25+ CD161+ T cells (B) in the liver, n = 28, unpaired t-test.

Conclusion: A distinct hepatic CD161-expressing CD4+ CD25hi T cell population is significantly enriched in NASH patients from NAFLD patients undergoing bariatric surgery. Further studies are required to dissect their function and mechanistic role in driving inflammation in NASH patients.

SAT091

GL0034, A novel long-acting glucagon-like peptide 1 receptor agonist exhibits significant efficacy in aged db/db mouse model of non-alcoholic fatty liver disease (NAFLD)

Rajamannar Thennati[1], Vinod Burade[1], Adolfo Garcia-Ocana[2], Richard E Pratley[3], Guy Rutter[4], Tina Vilsbøll[5], Bernard Thorens[6].

Email: rajamannar.thennati@sunpharma.com

Background and aims: Obesity and type 2 diabetes are the major risk factors for non-alcoholic fatty liver disease (NAFLD) and advanced liver fibrosis. GL0034 is a novel long-acting human glucagon-like peptide 1 (GLP-1) receptor agonist, which selectively activates the GLP-1 receptor.
Method: db/db mice (age: 22–24 week) were divided into vehicle control; GL0034 (20 nmol/kg) or semaglutide (20 nmol/kg). Animals were treated with vehicle or test item every third day (q3d) up to day 27. On day 28, HbA1c, plasma triglycerides, serum alanine aminotransferase (ALT), aspartate aminotransferase (AST), liver transforming growth factor β (TGF-β) and malondialdehyde (MDA) were quantified. Liver steatosis was evaluated using Oil- Red O staining and HandE (haematoxylin and eosin) staining.
Results: Subcutaneous treatment with GL0034 led to a significant reduction in HbA1c, body weight, plasma triglycerides, ALT/AST and liver TGF-β (Table). Insulin levels increased (4.5-fold). Reduction in steatosis was confirmed using Oil- Red O/HandE staining and liver MDA (2-fold decrease) level.

	HbA1c (%) Mean±SD		body weight change (%) Mean ± SD	triglycerides (mg/dl) Mean ± SD		serum ALT (U/L) Mean ± SD	serum AST (U/L) Mean ± SD	liver TGF-β (ng/g) Mean ± SD

Development of an ex vivo model for non-alcoholic fatty liver disease using precision-cut liver slices

Mei Li[1], Vincent de Meijer[2], Peter Olinga[1], Anika Nagelkerke[3], Yana Geng[1]. [1]*University of Groningen, Department of Pharmaceutical Technology and Biopharmacy, Netherlands;* [2]*University Medical Center Groningen, Department of Hepato-, Pancreato-, Biliary Surgery and Liver Transplantation, Netherlands;* [3]*University of Groningen, Department of Pharmaceutical Analysis, Netherlands*
Email: yana.geng@rug.nl

Background and aims: Non-alcoholic fatty liver disease (NAFLD) is an emerging healthcare problem, ranging from non-alcoholic fatty liver (NAFL) to non-alcoholic steatohepatitis (NASH), often progresses to fibrosis, cirrhosis along with hepatocellular carcinoma. Progress in this field depends on the availability of reliable preclinical models. In this respect, precision-cut liver slices (PCLS) could provide the preserved multicellular environment allowing for the interplay of various liver cell types. This study aims to investigate NAFLD development in mouse and human PCLS.
Method: Mouse PCLS (mPCLS), from male C57BL/6J mice liver, and human PCLS (hPCLS), obtained from surgical waste material of donor livers, were used. Slices were cultured in GFIPO (William's E Medium supplemented with Glucose (36 mM), Fructose (5 mM), Insulin (1 nM), Palmitic acid (0.12 mM for mPCLS/0.24 mM for hPCLS) and Oleic acid (0.24 mM for mPCLS/0.48 mM for hPCLS)) to mimic the NAFLD-inducing conditions, and WEGG (William's E Medium supplemented with Glucose (25 mM)) as control for up to 96 h. PCLS were collected to assess viability and fat accumulation by measuring ATP levels and triglyceride (TG) content. Inflammation and fibrosis were evaluated by RT-qPCR. Additionally, the conditioned medium of hPCLS were collected for culturing LX2 cells (a human hepatic stellate cell line) at 1:3 (v/v) ratio mixed with LX2 medium. The activation of LX2 cells were evaluated by assessing the protein levels and the mRNA expressions of collagen type 1/*COL1a1* and alpha smooth muscle actin/*ACTA2*.
Results: Slices remained viable for up to 96 hours incubation in both WEGG and GFIPO medium, and TG content was increased 71% (mPCLS) and 92% (hPCLS) in GFIPO compared with WEGG group. In GFIPO, mRNA expression of the inflammatory biomarker interleukin 6 was significantly upregulated compared to WEGG (3-fold in mPCLS, 6-fold in hPCLS), as well as interleukin 1b (3-fold in mPCLS, 42-fold in hPCLS), but no significant differences were observed for tumor necrosis factor a expression. *COL1a1* and *ACTA2* showed an increasing trend in GFIPO in both mPCLS and hPCLS, but only *ACTA2* was significantly increased in hPCLS (2-fold). In LX2 cells, the conditioned medium obtained from hPCLS cultured in GFIPO promoted the activation of LX2 cells comparing to that of hPCLS cultured in WEGG, shown as significantly increased protein level of collagen type 1 (2-fold), albeit not at mRNA expression level.
Conclusion: GFIPO increased the TG content as well as gene expression of inflammatory and fibrosis biomarkers in both mPCLS and hPCLS, without impairing viability. GFIPO introduced a pro-fibrotic environment in hPCLS, and its conditioned medium promoted collagen production in LX2 cells.

SAT093

The neolignan honokiol can improve intestinal barrier dysfunction in fructose-induced liver damage in mice

Anja Baumann[1], Verena Freutsmiedl[1], Julia Jelleschitz[1], Raphaela Staltner[1], Annette Brandt[1], Verena Dirsch[2], Ina Bergheim[1]. [1]*University of Vienna, Department of Nutritional Sciences, Vienna, Austria;* [2]*University of Vienna, Department of Pharmacognosy, Vienna, Austria*
Email: ina.bergheim@univie.ac.at

Background and aims: Several studies indicate that a fructose-rich diet may be a risk factor in the development of non-alcoholic fatty liver disease (NAFLD). Studies have shown that this is associated with intestinal barrier dysfunction, and subsequently, with an increased translocation of bacterial toxins. Honokiol, a neolignan found in Magnolia officinalis and used in traditional Chinese medicine, has a variety of biological activities including protective effects on the development of intestinal barrier dysfunction. The aim was to determine if an oral supplementation of honokiol improves intestinal barrier dysfunction in fructose-induced NAFLD.
Method: Female C57BL/6J mice (n = 7/group) were fed a 30% fructose solution or plain water ± 10 mg honokiol per kg body weight per day for 4 weeks. Markers of liver damage and intestinal permeability and toll-like receptor (TLR) 2 as well as TLR4 ligands in portal plasma were measured. In addition, effects of honokiol on fructose-induced intestinal permeability were assessed ex vivo in an everted sac model.
Results: As expected, fructose-fed mice developed liver steatosis which was significantly attenuated in fructose + honokiol-fed mice (NAFLD activity score: fructose vs. fructose + honokiol, $p < 0.05$). These protective effects of honokiol were associated with a significant protection against the increased intestinal permeability found in small intestinal tissue in fructose-fed mice. In line with the latter, TLR2 and 4 ligands were only significantly or by trend higher in portal plasma of fructose-fed mice while being at the level of controls in fructose + honokiol-fed animals. In support of the in vivo findings, honokiol also significantly attenuated fructose-induced permeability in the ex vivo model.
Conclusion: The results of the present study suggest that an oral supplementation of honokiol can improve intestinal barrier dysfunction in settings of fructose-induced liver damage being also associated with a lessened development of NAFLD.

Email: becky@madrigalpharma.com

Background and aims: Biopsy-based end points are recommended for assessing treatment efficacy in non-alcoholic steatohepatitis (NASH) clinical trials. While manual scoring of NASH histology is subject to intra- and inter-rater variability, AI-powered pathology may enable accurate and reproducible histologic assessment. Here we demonstrate the utility of an AI-based tool (AIM-NASH), for scoring NASH histology in a retrospective analysis of clinical trial liver biopsies.
Method: PathAI AIM-NASH algorithms were deployed on whole slide images of liver biopsies from 104 subjects enrolled in a Phase 2 (Ph2), placebo-controlled, 36-week study of the efficacy of MGL-3196 treatment in patients with NASH and NASH CRN stage 1–3 fibrosis (NCT02912260). Models predicted ordinal and continuous Clinical Research Network (CRN) scores in addition to exploratory features such as portal inflammation. Concordance between clinical pharmacology and AIM-NASH scores and features was evaluated. Differences in end point response rates and in changes in continuous scores and exploratory features between treated and placebo subjects were computed.
Results: All biopsy-based end points that were met via manual histologic scoring were also met by AIM-NASH (Table 1). ML continuous scoring revealed a statistically significant reduction in steatosis and a greater sub-ordinal reduction in fibrosis in treated versus placebo subjects. The measured reduction in continuous

fibrosis score was greater than the reduction in collagen proportionate area (CPA) in treated subjects. Change in ML-derived area proportion of portal inflammation was significantly correlated with change in portal inflammation scores from both central readers (p = 0.009 and p = 0.011, respectively), while concordance between both central readers for portal inflammation scoring was kappa = 0.298.

Table 1: Response rates per end point via manual vs. AI-based scoring

End point	Scorer	Response rate (MGL)	Response rate (Pbo)	p value
2-point or greater improvement in NAS	AIM-NASH	0.41	0.19	0.0327
	Central reader	0.56	0.26	0.0044
	Reader 2	0.42	0.19	0.0321
NASH resolution without worsening of fibrosis	AIM-NASH	0.26	0.07	0.0301
	Central reader	0.25	0.06	0.0226
	Reader 2	0.21	0.03	0.0190

Conclusion: This ML approach detected similar proportions of primary end point responders as manual scoring. ML-derived continuous features demonstrated sensitivity to changes in NASH histology and enabled more granular exploration of sub-ordinal treatment effects. Such AI-based tools show promise as assistive devices for NASH pathologists in clinical trial settings.

SAT095

Insights to molecular mechanism of Essentiale: In vitro studies in hepatic cell lines HepaRG and steatotic HepaRG

Dominik Wupperfeld[1], Gert Fricker[1], Beatrice Bois De Fer[2], Branko Popovic[3]. [1]*Ruprecht-Karls University of Heidelberg, Heidelberg, Germany;* [2]*Sanofi, Gentilly, France;* [3]*Sanofi, Frankfurt, Germany*
Email: branko.popovic@sanofi.com

Background and aims: Non-alcoholic fatty liver disease is the most common liver disease worldwide and treatment options are limited. Essential Phospholipids (EPL, Essentiale®), comprising of multiple unsaturated fatty acids, have shown therapeutic effects but the molecular mechanism remains to be investigated. Here, we report the impact of EPL on hepatocyte function through in vitro studies.
Method: Effects of non-cytotoxic concentrations of EPL (0.1 and 0.25 mg/ml) and its constituents polyenylphosphatidylcholine (PPC) and phosphatidylinositol (PI) (both at 0.1 and 1 mg/ml) on the release of pro-inflammatory cytokines caused by treatment with lipopolysaccharide (LPS) and lipid metabolizing enzymes were investigated in human hepatocyte cell lines (HepaRG, steatotic HepaRG) using ELISA and Glucose-6-phopsphate dehydrogenase (G6PD) activity assay kits. To induce steatosis in HepaRG cells, differentiated cells were treated with stearic acid and oleic acid for two weeks.
Results: Lipopolysaccharide (1, 5 µg/ml) treatment for 24 h induced release of cytokines. In LPS-treated HepaRG cells EPL (0.25 mg/ml; p, 0.0063), PPC (1 mg/ml; p, <0.0001), PI (0.1 mg/ml; p, 0.0396, 1 mg/ml; p, 0.0023) significantly reduced the release of IL-6. Treatment with EPL (0.1 mg/ml; p, <0.0001) and PI (1 mg/ml; p, 0.0029) increased the release of IL-6 in LPS-treated steatotic HepaRG cells. IL-8 secretion increased significantly (p < 0.001) in LPS treated HepaRG and steatotic HepaRG cells in response to all lipid formulations. G6PD activity was unchanged by all treatments in HepaRG and steatotic HepaRG cells. In HepaRG cells human lecithin cholesterol acyltransferase (LCAT) expression was significantly downregulated upon treatment with EPL (0.1 mg/ml; p, <0.0001, 0.25 mg/ml; p, 0.0436), PPC (1 mg/ml; p, <0.0001), PI (1 mg/ml; p, <0.0001) and upregulated by PPC (0.1 mg/ml; p, 0.0009). However, in steatotic HepaRG cells, a significant increase of expression of LCAT was observed upon treatment with PI (1 mg/ml; p, 0.0088). Endogenic expression of human acyl Coenzyme A oxidase 1 (ACOX1) and fatty acid synthase (FAS) was lower in HepaRG cells compared to steatotic HepaRG cells. While in HepaRG cells ACOX1 expression decreased upon treatment with EPL (0.1 mg/ml; p, 0.0126, 0.25 mg/ml; p, 0.0031), PPC (0.1 mg/ml; p, 0.0145, 1 mg/ml; p, 0.0434), PI (1 mg/ml; p, 0.0404), none of the treatments affected ACOX1 expression in steatotic HepaRG cells. FAS expression remained unchanged in HepaRG cells upon treatment with lipid formulations. However, in steatotic HepaRG cells, FAS expression was significantly reduced ($p \leq 0.0001$) in response to treatment with all lipid formulations in all concentrations.
Conclusion: In vitro investigations in hepatocyte cell lines provided valuable insights into the impact of EPL on pro-inflammatory cytokine release, lipid-metabolizing enzymes which may improve liver function.

Exposure to the SARS-CoV-2 spike protein in an in vitro model of steatosis enhances hepatocyte oxidative stress: implications for COVID-19 and accelerated disease progression

Angus Jacobs[1], Katie Morgan[1], Steven Morley[1], Kay Samuel[2], Jonathan Fallowfield[3], Peter Hayes[1], John Plevris[1]. [1]*The University of Edinburgh, Hepatology department, Edinburgh, United Kingdom;* [2]*Scottish National Blood Transfusion Service, Tissues, Cells, and Advanced Therapeutics, Edinburgh, United Kingdom;* [3]*The University of Edinburgh, Centre for Inflammation Research, Edinburgh, United Kingdom*
Email: anguskerrjacobs@gmail.com

Background and aims: Metabolic dysfunction-associated fatty liver disease (MAFLD) has been identified as a predictor of liver injury in patients hospitalised with coronavirus disease 2019 (COVID-19). The key severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) receptor, angiotensin converting enzyme 2 (ACE2), is suggested to play a protective role in the pathogenesis of MAFLD. Our unpublished data shows that human hepatic ACE2 expression correlates positively with increasing MAFLD progression, from steatosis through steatohepatitis to cirrhosis. The extent to which COVID-19 may accelerate MAFLD progression remains unclear. Here we use an *in vitro* steatosis model to investigate susceptibility to liver injury following exposure to SARS-CoV-2 spike protein S1 subunit and thus a possible role of COVID-19 in accelerating MAFLD progression.
Method: Following 24 h exposure of fully differentiated (day 14) HepaRG cells were exposed to the SARS-CoV-2 spike protein S1 subunit (0.05 µg/ml, 0.1 µg/ml, and 0.5 µg/ml), changes in cell conformation of the cell layer were measured using electric cell-substrate impedance sensing (ECIS). Cytokine secretion was quantified following exposure to a steatogenic stimulus (oleate) ± S1 subunit using a flow cytometry-based cytokine bead array assay and the metabolic effects assessed by measurement of reactive oxygen species (ROS) and ATP by chemiluminescence assays.
Results: Our data show that 24-h exposure to the SARS-CoV-2 spike protein S1 subunit caused a concentration-dependent alteration in HepaRG cell tight-junction integrity and/or basolateral adhesion. However, the S1 subunit had no significant effect on HepaRG cell viability at any of the tested concentrations. Treatment of HepaRG cells with oleate ± S1 significantly increased secretion of proinflammatory cytokine IL-6 (mean ± SEM; oleate alone: 31.3 ± 0.9 pg/ml; oleate + S1: 33.5 ± 2.9 pg/ml) compared to untreated cells (18.7 ± 2.9 pg/ml, both $p < 0.05$) and cells treated with the S1 subunit alone (16.0 ± 3 pg/ml, both $p < 0.05$). In our *in vitro* steatosis model, the addition of the S1 subunit appeared to have an additive effect, significantly increasing ROS production (mean ± SEM; 63, 700 ± 3500 relative luminescence units (RLU)) compared to untreated cells (40, 500 ± 2100 RLU, $p < 0.05$), but there was no effect on ATP production.
Conclusion: Our data indicate that the SARS-CoV-2 spike protein S1 subunit affects tight junction integrity and promotes oxidative stress in oleate-treated HepaRG cells, and that fat-loading increased

proinflammatory cytokine secretion. This could in turn cause activation of profibrotic signalling pathways and accelerate disease progression in MAFLD.

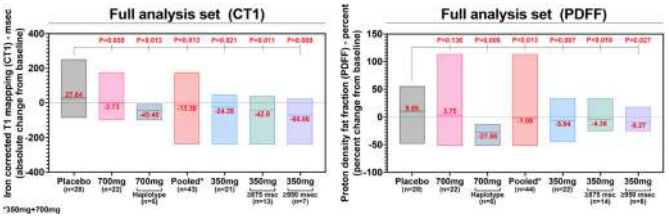
Efficacy and safety of leronlimab in patients with non-alcoholic steatohepatitis: topline results of NASH01 clinical trial

Mazen Noureddin[1], Eric Lawitz[2], Angela Ritter[3], Tarek Hassanein[4], Kelly Bowman[5], Scott Kelly[6], Eisa Mahyari[7], Jonah Sacha[8], Scott Hansen[8], Christopher Recknor[6]. *[1]Cedars Sinai, Liver Disease and Transplant Center, Los Angeles, United States; [2]The University of Texas Health Science Center San Antonio, Texas Liver Institute, San Antonio, United States; [3]Center for Advanced Research and Education, Gainesville, United States; [4]Southern California GI and Liver Centers, Coronado, United States; [5]Sensible Healthcare, Ocoee, United States; [6]CytoDyn Inc., Vancouver, United States; [7]Oregon Health and Science University, Genetics, Beaverton, United States; [8]Oregon Health and Science University, Vaccine and Gene Therapy Institute, Beaverton, United States*
Email: crecknor@cytodyn.com

Background and aims: CCR5 modulates key metabolic, inflammatory, and fibrogenic pathways in the pathogenesis of NASH. NASH01 was conducted to determine efficacy, dose and safety of leronlimab, a known CCR5 binding agent, in patients with NASH.
Method: In this multi-center phase 2a, dose ranging, two-part trial, part 1 was designed as a double-blind, randomized, placebo-controlled trial, patients with NASH phenotype who had MRI proton density fat fraction (PDFF) ³ 8% and corrected T1 (cT1) ³ 800 were randomly assigned 1:1 weekly SQ leronlimab 700 mg or placebo and part 2 as open label comparing leronlimab 350 mg to part 1 placebo group. Treatment duration was 14 weeks. The primary end point was change from baseline in PDFF and secondary end points were change from baseline in cT1 fibro-inflammatory activity and change in serum cK18 and K18 by M30-M65 ELISA at week 14.
Results: Analyses were conducted on the full analysis set (n = 72) of whom 44% were of Hispanic or Latino ethnicity and 58% with baseline moderate to severe fibro-inflammation (cT1 ³ 875 ms). Mean percent change from baseline PDFF was significantly reduced in the 350 mg group vs placebo (-5.94% vs +9.85%, p = 0.008) but not in the 700 mg group (+3.75% vs +9.85%, p = 0.135). Mean change cT1 was significantly reduced in the 350 mg group vs placebo (−24.38 ms vs +27.64 ms, p = 0.021) but not in the 700 mg group (−2.73 ms vs +27.64 ms, p = 0.059). Significant reductions were seen in the 350 mg subgroup with baseline cT1 ³ 875 ms in both PDFF and cT1 vs placebo (−4.37% vs +9.85%, p = 0.020 and −42.00 ms vs +27.64 ms, p = 0.011) respectively. In subjects with cT1 ³ 950 ms at baseline, PDFF and cT1 were significantly reduced with 350 mg vs placebo (-9.39% vs +9.85%, p = 0.027 and −68.85 ms vs +27.64, p = 0.009) respectively. Mean change in baseline to week 14 for M65 ELISA (cK18 and K18) decreased in the 350 mg group (340.55 to 332.4 U/L; −8.18) while increased in placebo (301.96 to 411.64 U/L; +109.78). In post hoc analyses, mean percent PDFF and mean cT1 were significantly reduced in the pooled 350 + 700 mg group compared to placebo (-1.09% vs +9.85%, p = 0.014 and −13.30 ms vs +27.64 ms, p = 0.013) and in the 700 mg group with genetic haplotypes known to over produce CCR5 compared to placebo (-27.9% vs +9.85%, p = 0.006 and − 45.4 ms vs +27.64 ms, p = 0.013). There was no grade 3 or higher drug related treatment emergent adverse event. Injection site reaction and mild diarrhea occurred more frequently with leronlimab than placebo but were not associated with discontinuation.



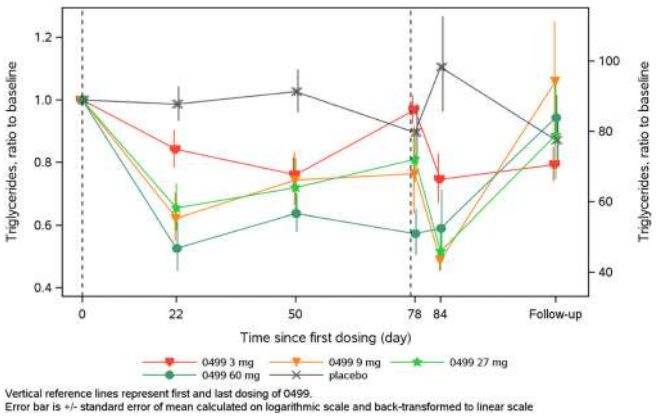
Conclusion: The primary end point (PDFF) and secondary end points (cT1) were met for the 350 mg group and moderate to severe fibro-inflammation by cT1 350 mg subgroup at baseline. The pooled 350 + 700 mg group also had significant reductions in PDFF, cT1 vs placebo. Treatment with leronlimab was well tolerated. These results are supportive of further trials with leronlimab for NASH.

SAT102

Reduced triglycerides and LDL cholesterol from once-weekly administration of the well-tolerated novel FGF21 analogue 0499

Kirsten Dahl[1,1], Jakob Schiøler Hansen[2], Jesper Clausen[1], Mads Sundby Palle[1], Cassandra Key[3], Birgitte Andersen[1]. *[1]Novo Nordisk A/S, Denmark; [2]Novo Nordisk Bio Innovation Hub, United States; [3]ICON Early Phase Services, United States*
Email: kdhl@novonordisk.com

Background and aims: Activation of the fibroblast growth factor 21 (FGF21) receptor complex has been associated with several attractive effects in preclinical models, including weight loss and decreased hepatic fat content. This has led to the pursuit of FGF21 for pharmacotherapy within obesity and non-alcoholic steatohepatitis (NASH), which has to date been limited by lack of suitable FGF21 analogues. Here we report an investigation of the safety and tolerability of repeated administration of a new FGF21 analogue 0499 in healthy participants.
Method: In a randomized, blinded, placebo-controlled, multiple ascending dose study, healthy males and females with body mass index ~ 30 kg/m^2 received weekly subcutaneous injections of placebo or 0499 for 12 weeks. FGF21 dose levels were 3, 9, 27, 60 and 120 mg. In each dose cohort, 9 participants were randomized to active treatment and 3 to placebo. Participants were followed for safety monitoring and pharmacokinetic sampling until 36 days after last dose. A total of 57 participants were randomized.
Results: There were no serious adverse events related to treatment. Weekly administration of doses from 3 to 60 mg/week were well tolerated. There were no notable findings from hematology, clinical chemistry or vital signs. Adverse events observed at doses from 3 to 60 mg/week were vomiting, increased appetite, nausea and diarrhea. Nausea and diarrhea were also observed with placebo. Statistically significant weight gain of 4.5%-points (%-pt) (placebo adjusted) was observed in the 3 mg group. In the higher dose groups, weight changes of ±2%-pt were observed (not statistically significant vs placebo). In the 120 mg cohort, all 6 participants who started treatment experienced tolerability issues within the first 3 weeks including moderate gastroesophageal reflux, vomiting, nausea and diarrhea. Further enrolment in the cohort and treatment with 120 mg were stopped. One participant experienced generalized urticaria at 9 mg/week. In total, 25 participants did not complete due to adverse events (n = 5) or other reasons. Withdrawals were distributed (3, 6, 3, 3, 6 and 4 participants in the 3, 9, 27, 80 and 120 mg, and placebo groups, respectively). The plasma half-life of 0499 was ~ 120 hours across dose levels. Low titers of anti-drug antibodies were detected with some neutralizing effect on endogenous FGF21. Sustained reductions in triglycerides (TG) and low-density lipoprotein (LDL) were observed. Placebo-adjusted reductions in the 3, 9, 27 and 60 mg dose cohorts were: for TG, 33%*, 52%*, 61%* and 48%*, respectively; for LDL, −7%, 1%, 13% and 20%*, respectively (*p <0.05).



Conclusion: The novel FGF21 analogue was well tolerated at doses up to 60 mg/week for 12 weeks. Treatment was associated with beneficial effects on lipid profile including lowering of TG and LDL levels. These results are encouraging for the further development of 0499 for treatment of NASH.

Multimodality assessment of hepatic fibrosis: ranked paired reading and artificial intelligence identifies fibrosis improvement with aramchol missed by conventional staging

Vlad Ratziu[1], Yusuf Yılmaz[2], Don Lazas[3], Scott Friedman[4], Carolin Lackner[5], Cynthia Behling[6], Oscar Cummings[7], Li Chen[8], Mathieu Petitjean[8], Yossi Gilgun-Sherki[9], Shaul Kadosh[10], Arun Sanyal[11]. *[1]Sorbonne Université, Institute for Cardiometabolism and Nutrition (ICAN) and 1Sorbonne Université, Institute for Cardiometabolism and Nutrition (ICAN) and Hôpital Pitié-, Salpêtrière, INSERM UMRS 1138 CRC, Paris, France; [2]Liver Research Unit, Institute of Gastroenterology, Marmara University, and Department of Gastroenterology, School of Medicine, Marmara University, Istanbul, Turkey; [3]ObjectiveHealth, Inc., United States; [4]Division of Liver Diseases, Icahn School of Medicine at Mount Sinai, United States; [5]Medical University of Graz, Graz, Austria; [6]Department of Pathology, Sharp Health System, United States; [7]Department of Pathology and Laboratory Medicine, Indiana University School of Medicine, Indianapolis, United States; [8]Pharmanest Ltd., United States; [9]Galmed pharmaceuticals, Israel; [10]Statexcellence Ltd., Israel; [11]Department of Gastroenterology, Virginia Commonwealth University, United States*
Email: vlad.ratziu@inserm.fr

Background and aims: Aramchol is a partial inhibitor of hepatic stearoyl-CoA desaturase with direct anti-fibrotic activity in pre-clinical models and histological improvement in a phase 2b trial. This open-label study explored the speed and extent of fibrosis reduction. We compared different methodologies of fibrosis scoring to optimize the design of a registrational placebo-controlled investigation.
Method: 46 Patients (pts) with NASH and fibrosis (28 F3, 11 F2, 7 F1) documented by biopsy were randomized 1:1:1 to receive Aramchol 300 mg BID and underwent a control biopsy at weeks 24, 48 or 72. Biopsies were read by 3 independent pathologists individually, followed by a consensus reading, which determined the final NASH CRN scoring. Three different assessments of the antifibrotic effect were studied on the same slides: 1) a ≥1 stage reduction by NASH CRN; 2) a ranked assessment (improvement/worsening/stable) of paired (pre and post baseline) biopsies, blinded to sequence; 3) an automated and continuous score of Fibrosis Composite Severity (FCS), using FibroNest™, a quantitative digital pathology image analysis and artificial intelligence (AI) Method: a 0.3 reduction in FCS (4 fold higher than the analytical variability) identified any reduction in fibrosis; a 25% relative decline in FCS, a strong reduction in fibrosis.
Results: Control biopsies were performed for 26, 15 and 5 pts at 24, 48, and 72 weeks, respectively. Mean (sd) baseline FCS was 5.05 (1.05). Table shows greater fibrosis improvement with longer duration of therapy for both conventional histology and digital pathology readings. Mean FCS reduction was −0.62 ($p = 0.017$) at Wk24 and −1.74 ($p < 0.0001$) at Wk≥48. AI evaluation was consistent with paired reading in 21/24 (87.5%) of the pts with fibrosis improvement. When analyzed by AI, 17/23 pts with unchanged NASH CRN stages had any fibrosis response, including 7 with a strong response. Similarly, 13/17 pts with stable ranking had a fibrosis response, including 5 with a strong reduction. No pts with worse CRN stages or worsening ranking had a strong AI fibrosis reduction.

Fibrosis reduction	Wk24, N = 26% (N)	Wk ≥ 48, N = 20% (N)
By NASH CRN ≥1 stage	27% (7)	40% (8)
By ranked assessment	42% (11)	65% (13)
By AI reading, any (delta FCS ≥0.3)	58% (15)	100% (20)
By AI reading, strong (-25% FCS)	27% (7)	65% (13)

Conclusion: Aramchol resulted in a high proportion of fibrosis improvement using three separate biopsy reading methodologies, with a larger treatment effect with longer duration of therapy. Both ranked assessments and AI evaluations identified more subjects with fibrosis improvement, indicating greater sensitivity to change vs categorical scoring. Digital pathology quantification by AI reveals a high level of fibrosis improvement that would have been missed by conventional histological measurements. AI technologies are promising for the detection of fibrosis changes in future clinical trials.

SAT104

The effect of glucagon on rates of hepatic mitochondrial oxidation and pyruvate carboxylase flux in man assessed by positional isotopomer tracer analysis (PINTA)

Kitt Falk Petersen[1], Gerald I. Shulman[1]. *[1]Yale University, Internal Medicine, New Haven, United States*
Email: kitt.petersen@yale.edu

Background and aims: Dual GLP-1/glucagon agonists are now in clinical trials for the treatment of T2D and NASH. In addition to promoting further reduction in food intake on top of GLP-1, the glucagon component of these dual agonists may also promote increased rates of hepatic mitochondrial fat oxidation.
Method: In order to investigate this possibility we assessed the glucagon-specific effects of a dual agonist on rates of hepatic mitochondrial oxidation (V_{CS}) and pyruvate carboxylase flux (V_{PC}) in humans by infusing glucagon to achieve a physiological increase in plasma glucagon concentrations in combination with a novel ^{13}C PINTA method to assess rates of hepatic V_{CS} and V_{PC} in 15 healthy volunteers using a paired study design. Following an overnight fast a 3-h IV infusion of [3-^{13}C]lactate (4.3 μmol/Kg-min) and [1, 2, 3, 4, 5, 6, 6-$^{2}H_7$]glucose (0.22 μmol/Kg-min) was begun and during the last 2 hours glucagon (GLG) was co-infused [6 ng/ (Kg-min)] or no GLG (CON).
Results: The GLG infusion resulted in a ~2.4 fold increase in plasma GLG conc. (from 75 ± 11 to 183 ± 20 pg/ml; *P < 0.0001*), which was associated with an ~20% increase in both plasma C-peptide (from 1.89 ± 0.17 to 2.30 ± 0.26 ng/ml; *P = 0.02*) and plasma insulin conc. (from 9.9 ± 2.0 to 12.0 ± 2.4 μU/ml; *P = 0.06*). Plasma glucose conc. increased from 4.90 ± 0.16 to 5.64 ± 0.19 mmol/L ($p = 0.0001$) which was associated with a tendency for increased rates of glucose production (CON:1042 ± 123 vs. GLG:1148 ± 122 μmol/min; *p = 0.086*) despite no change in rates of V_{PC} flux (CON: 403 ± 69 vs. GLG: 373 ± 55 μmol/min; *p = NS*). In contrast, this physiological increase in plasma GLG concentrations caused an 85% increase in rates of hepatic V_{CS} ($p < 0.05$).

Conclusion: Taken together these studies demonstrate that a physiological increase in plasma glucagon promotes increased rates of hepatic mitochondrial oxidation in humans, which may provide additional benefits to the anorexic effects of dual GLP-1/glucagon agonists to reduce hepatic steatosis.

SAT105

Identification of biomarkers of histological response in patients with non-cirrhotic NASH treated with Lanifibranor

Jerome Boursier[1], Hugo Herve[2], Clémence M Canivet[2], Marine Roux[2], Pierre Broqua[3], Michael Cooreman[3], Jean-Louis Junien[3], Jean Louis Abitbol[3], Philippe Huot-Marchand[3], Lucile Dzen[3], Sanjaykanumar Patel[4]. *[1]Angers University, HIFIH Laboratory UPRES EA3859, Angers; [2]Angers University, HIFIH Laboratory UPRES EA3859; [3]Inventiva; [4]Inventiva, France*
Email: jeboursier@chu-angers.fr

Background and aims: Lanifibranor, a pan-PPAR agonist, is a promising investigational compound for treating non-alcoholic steatohepatitis (NASH), as shown by histological efficacy in the phase 2b NATIVE trial (Francque SM et al 2021). We aimed to predict lanifibranor treatment response in NATIVE based on serum biomarkers.

Method: Patients receiving lanifibranor 800 or 1200 mg/d were pooled and those with end-of-treatment (EOT) liver biopsies were selected (n = 142). The histological end points 'NASH resolution and fibrosis improvement' (E1) and 'NASH resolution without worsening of fibrosis' (E2) according to NASH-CRN criteria were assessed. A panel of more than 70 biomarkers related to metabolism, inflammation, tissue injury and fibrosis were evaluated by assessing baseline, absolute and relative changes at EOT. Biomarker selection was done using classical univariate analysis, PCA and sPLS-DA, and combined in scores by logistic regression.

Results: 42 (30%) and 63 (44%) patients were respectively E1 and E2 responders; 4 parameters were independently associated with E1 response: baseline adiponectin and ferritin, and relative changes of MMP9 and transferrin. Combining these 4 parameters into an E1-score provided AUROC of 0.81 ± 0.08 for predicting E1 response, with Brier score of 0.17. 632+ bootstrap internal validation confirmed AUROC of 0.80 ± 0.10 and Brier score of 0.17. Negative (NPV) and positive (PPV) predictive value thresholds were 0.299 (rule-out with 80% NPV, corresponding sensitivity: 70%) and 0.592 (rule-in with 80% PPV, corresponding specificity: 95%). Using these thresholds, 72% of patients were biomarker E1 responders of whom 81% were confirmed histologically, leaving only 28% patients in the grey zone between the two thresholds. Baseline CK18 M65, absolute change of hyaluronate, and relative changes of fructosamine and ALT were independently associated with E2 response. The E2-score combining these biomarkers provided AUROC of 0.80 ± 0.08 and Brier score of 0.18 for E2 response (.632+ bootstrap: AUROC 0.78 ± 0.08, Brier score 0.21). PV thresholds were 0.453 (80% NPV, corresponding 79% sensitivity) and 0.646 (80% PPV, corresponding 89% specificity). Using these thresholds, 80% of patients were biomarker E2 responders (80% confirmed histologically), leaving only 20% patients in the grey zone.

Conclusion: Combined biomarker signatures have good positive and negative predictive value for histological response under lanifibranor treatment in NASH.

SAT106

TERN-101, a farnesoid X receptor agonist, demonstrated similar safety and efficacy in non-alcoholic steatohepatitis patients with coronavirus disease of 2019 (COVID-19) exposure compared to those with no COVID-19 exposure in phase 2a LIFT study

Eric Lawitz[1], Rohit Loomba[2], Douglas Denham[3], Diana Chung[4], Erin Quirk[4], Lois Lee[4], Tonya Marmon[4], Kris Kowdley[5]. *[1]Texas Liver Institute, San Antonio, United States; [2]University of California San Diego, La Jolla, United States; [3]Clinical Trials of Texas, Inc., San Antonio, United States; [4]Terns Pharmaceuticals, Foster City, United States; [5]Liver Institute Northwest, Seattle, United States*
Email: llee@ternspharma.com

Background and aims: TERN-101 is a non-steroidal farnesoid X receptor (FXR) agonist with enhanced liver distribution being developed for the treatment of non-alcoholic steatohepatitis (NASH). The phase 2a LIFT study (NCT04328077) was a double-blind, placebo-controlled study in adults with noncirrhotic NASH conducted during the COVID-19 pandemic. TERN-101 (5, 10, and 15 mg) administered for 12 weeks was overall safe and well-tolerated and significantly decreased alanine aminotransferase (ALT) and corrected T1 (cT1) relaxation time. We reviewed COVID-19 exposure in LIFT to explore any potential impact on TERN-101 safety and efficacy.

Method: COVID-19 antibody testing was performed at Screening, and Weeks 0, 6, and 12, and with ad hoc antibody and qualitative virus testing available in the event of COVID-19 symptoms. We evaluated overall safety and key efficacy parameters in patients with COVID-19 exposure, defined as patients with COVID-19 infection as an adverse event (AE) or detectable COVID-19 antibodies during the study.

Results: Of 100 enrolled and treated patients, 96% completed the LIFT study with no discontinuations due to AEs and no deaths; AEs occurred in 38.5% of the placebo and 56.8% of the TERN-101 groups. 97% of the patients had post-baseline COVID-19 antibody results. Of the 24 COVID-19 exposures identified, 4 had documented COVID-19 vaccination during the study (16.7%). COVID-19 infection was reported for 7 patients (7%): 6 who received TERN-101 and had mild to moderate AEs (Grade 1 or 2), and 1 placebo patient who developed a severe AE (Grade 3) that resolved. Among all 24 COVID-19 exposures, non-COVID-19 related treatment-emergent AEs were reported in 7 of 19 (36.8%) patients receiving TERN-101 vs 1 of 5 (20.0%) patients receiving placebo. ALT and cT1 changes at Week 12 among COVID-19 exposures were similar to patients without exposure of COVID-19.

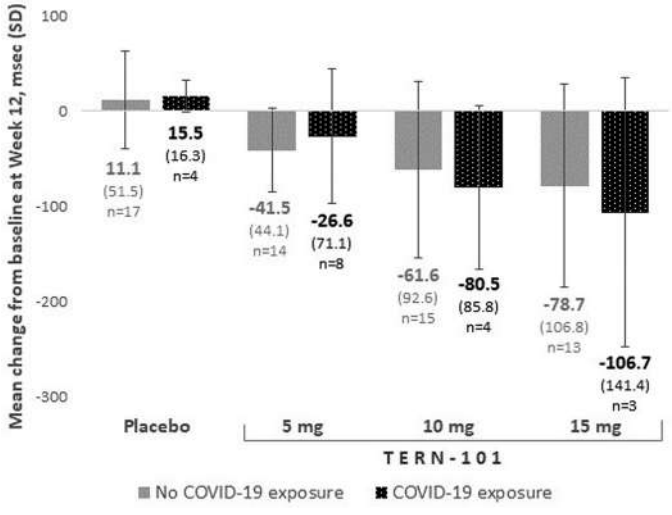

Figure: cT1 changes at Week 12

Conclusion: NASH patient recruitment and retention in the LIFT Study was feasible during the COVID-19 pandemic with successful

implementation of COVID-19 testing. The TERN-101 safety profile and cT1 responses were similar between the subset of patients with COVID-19 exposure and those without.

SAT107

Favorable lipid and pruritus profile of liver-distributed farnesoid X receptor agonist TERN-101 at clinically efficacious doses in non-alcoholic steatohepatitis phase 2a LIFT study

Kris Kowdley[1], Eric Lawitz[2], Rohit Loomba[3], Erin Quirk[4], Daria Crittenden[4], Diana Chung[4], Tonya Marmon[4]. Email: barry.crittenden@gmail.com

Background and aims: TERN-101 is a potent, non-steroidal farnesoid X receptor (FXR) agonist with enhanced liver distribution under investigation for treatment of non-alcoholic steatohepatitis (NASH). Dose-related pruritus and unfavorable lipid effects have raised concerns about FXR agonists as a treatment for NASH. In the phase 2a LIFT study, TERN-101 was overall safe and well-tolerated at all dose levels, with significant reductions in alanine aminotransferase (ALT) and corrected T1 (cT1) relaxation time at 10 and 15 mg. Here we report additional details on lipids and pruritus from LIFT.
Method: LIFT was a double-blind, placebo-controlled study (NCT04328077) evaluating 5, 10 and 15 mg TERN-101 for 12 weeks in 100 adults with non-cirrhotic NASH. Low-density lipoprotein (LDL) and high-density lipoprotein (HDL) cholesterol were assessed at baseline and every 4 weeks. Pruritus was captured as part of routine adverse event (AE) reporting.
Results: No difference in LDL percent change from baseline was observed for 5 and 10 mg TERN-101 vs placebo at any timepoint; 15 mg had significant differences at all timepoints (+15.9% at Week 12). HDL was not different from placebo at Week 12 for 5 and 10 mg TERN-101. Changes in LDL and HDL by thresholds were assessed post-hoc (Table). Pruritus AEs (including pruritic rash) were reported in 11 of 74 (14.8%) patients receiving TERN-101 and none receiving placebo. Onset of pruritus ranged from Day 2 to Day 73. Pruritus resolved with ongoing TERN-101 treatment for 8 of 11 patients. All events were mild or moderate (Grade 1–2), with incidence overall balanced across TERN-101 groups. Grade 2 pruritus occurred in two 10 mg patients (generalized pruritus) and one 15 mg patient (pruritus localized to bilateral forearms). No patient discontinued TERN-101 due to pruritus.

Table: Lipid changes by threshold at Week 12

		TERN-101		
n (%)	Placebo n = 23	5 mg n = 24	10 mg n = 25	15 mg n = 21
LDL increase ≥25 mg/dL	4 (17)	4 (17)	2 (8)	4 (19)
HDL decrease ≥10 mg/dL	1 (4)	1 (4)	2 (8)	5 (24)

Conclusion: LDL and HDL mean changes, and proportion of patients with lipid changes by specified thresholds, were similar for 5 and 10 mg TERN-101 and placebo at Week 12. Pruritus AEs were not dose-dependent and did not lead to treatment discontinuation. These data support an overall differentiated and favorable safety and tolerability profile for TERN-101 at potentially efficacious dose levels.

SAT108

Liver-distributed farnesoid X receptor agonist TERN-101 demonstrates potent target engagement with a favorable exposure-response profile in non-alcoholic steatohepatitis patients

Cara H. Nelson[1], Christopher Jones[1], Kevin Klucher[1], Feng Jin[2], Tonya Marmon[1], Diana Chung[1], Erin Quirk[1], Daria Crittenden[1]. [1]*Terns Pharmaceuticals, Foster City, United States;* [2]*Polaris Consulting, Foster City, CA, United States*
Email: cnelson@ternspharma.com

Background and aims: TERN-101 is a potent, non-steroidal farnesoid X receptor (FXR) agonist with enhanced liver distribution being developed for treatment of non-alcoholic steatohepatitis (NASH). In the dose-ranging phase 2a LIFT study (NCT04328077), TERN-101 demonstrated significant decreases in alanine aminotransferase (ALT) and corrected T1 (cT1) relaxation time in NASH patients, and was overall safe and well-tolerated with no discontinuations due to adverse events. We present the pharmacokinetic (PK) and pharmacodynamic (PD) results from the LIFT study.
Method: LIFT was a double-blind, placebo-controlled study in adults with noncirrhotic NASH. Patients (N = 100) were randomized and treated with placebo or TERN-101 (5, 10 or 15 mg) for 12 weeks. All patients had PK and PD samples collected at Week 0 (predose) and at trough timepoints (~24 hours post-dose) on Weeks 2, 4, 6, 8 and 12. Additionally, a subset of patients (N = 26) participated in an intensive PK/PD substudy at Weeks 0 and 12. PD markers of FXR agonism included 7-alpha-hydroxy-4-cholesten-3-one (C4) and fibroblast growth factor 19 (FGF19). A preliminary population PK model was used to estimate exposures in all patients.
Results: Sustained decreases in C4 were noted with levels significantly lower in the 10 and 15 mg groups vs placebo at most trough timepoints. In the PK/PD substudy, the maximal percent change in C4 and FGF19 occurred at 6 hours postdose. At Week 12, peak C4 decreases were dose-dependent and reached significance in the 10 and 15 mg groups (−56% and −96%, respectively); peak FGF19 change increased with dose and was significant in the 15 mg group (777%). FGF19 returned towards baseline levels at 24 hours postdose in all groups. TERN-101 exposures in the LIFT study were approximately dose proportional with some overlap in exposures between the 10 and 15 mg groups. An exposure-response analysis demonstrated a trend of greater decreases in change of cT1 with increasing exposures of TERN-101.
Conclusion: TERN-101 resulted in significant FXR target engagement in the liver relative to the intestine, as evidenced by sustained decreases in C4 at the 10 and 15 mg doses and transient increases in FGF19. Higher exposures of TERN-101 were associated with greater decreases in cT1, a marker of fibroinflammation improvement in NASH patients. These analyses support further development of TERN-101 for the treatment of NASH, either alone or in combination with other agents.

SAT109

EDP-297: a novel, highly potent, farnesoid X receptor agonist, results of a phase 1 study in healthy subjects

Alaa Ahmad[1], Christine Marotta[1], Ed Luo[1], Jart Oosterhaven[2], Sjoerd van Marle[2], Nathalie Adda[1]. [1]*Enanta Pharmaceuticals Inc, United States;* [2]*PRA, Netherlands*
Email: aahmad@enanta.com

Background and aims: EDP-297 is a potent FXR agonist under development for the treatment of non-alcoholic steatohepatitis (NASH). EDP-297 attenuates NASH-relevant pathways of steatosis, liver injury, inflammation, and apoptosis both in vitro and in vivo. Here, we present pharmacokinetic (PK), and pharmacodynamic (PD), food effect (FE), and safety results of a single ascending dose (SAD) and multiple ascending dose (MAD) phase 1 study in healthy subjects (HS).

Method: A randomized, double-blind, placebo-controlled (PBO) study was conducted to evaluate the safety, tolerability, PK/FE, and PD of single and multiple doses of EDP-297 in HS. Subjects received EDP-297 as a single dose (SAD, 5 cohorts, 20–600 µg) or once daily (QD) for 14 days (MAD, 5 cohorts, 5–90 µg), (6 active: 2 PBO/cohort), except in the SAD food effect cohort (8 active: 2 PBO). PD measurements included fibroblast growth factor 19 (FGF-19) and 7-α-hydroxy-4-cholesten-3-one (C4).
Results: A total of 82 subjects (n = 42 in SAD; n = 40 in MAD) received at least one dose of EDP-297 or PBO. EDP-297 was generally well tolerated. No severe adverse events or discontinuations due to adverse events (AEs) in SAD and MAD (up to 60 µg) were observed. Most AEs were mild and not related/unlikely related to study drug. In the SAD part, pruritus was observed in 300 µg (n = 2), 600 µg (n = 2), PBO (n = 1); during the MAD part, pruritus was reported in 30 µg (n = 1), 60 µg (n = 2), and 90 µg (n = 4), PBO (n = 2): the majority were mild or moderate, except for n = 4 severe cases at 90 µg MAD, with n = 1 that led to drug discontinuation. There were no clinically significant abnormal laboratory or abnormal ECG findings, except for n = 1 Grade 2 ALT elevation (MAD 90ug) that was not associated with other liver enzyme abnormalities. There were no clinically meaningful changes in the lipid profile, except for a trend towards decrease in HDL and increase in LDL at MAD 90ug; and mean lipids values were within normal range during the entire study. Plasma exposures increased with increasing single and multiple doses, with mean $t_{1/2}$ following multiple doses of ~9–12.5 hours. No food effect was observed. Strong FXR target engagement was demonstrated, with increase in FGF-19 and decrease in C4 up to 95% and 92%, respectively.
Conclusion: Overall, EDP-297, a potent and selective FXR agonist, was safe and well tolerated with PK suitable for once daily oral dosing, a strong target engagement and no food effect.

SAT110

Weight loss with semaglutide treatment or time-restricted feeding differentially improves non-alcoholic steatohepatitis in diet-induced obese insulin resistant mice

Francois Briand[1], Estelle Grasset[1], Natalia Breyner[1], Thierry Sulpice[1].
[1]*Physiogenex, Escalquens, France*
Email: f.briand@physiogenex.com

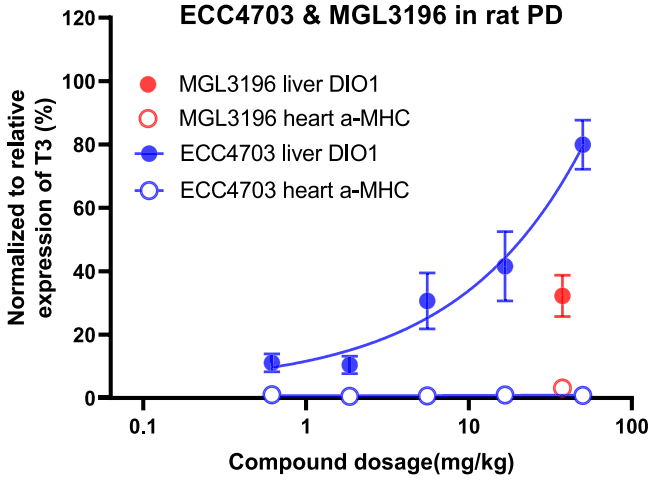
Background and aims: Due to its positive correlation with obesity/type 2 diabetes, the prevalence of non-alcoholic steatohepatitis (NASH) is increasing worldwide. Weight loss represents a promising therapeutic strategy for NASH and liver fibrosis. Here we compared the weight loss benefits of the glucagon-like peptide-1 (GLP-1) receptor agonist semaglutide (SEMA) or time-restricted feeding (TRF) on NASH/liver fibrosis in diet-induced obese insulin resistant mice.
Method: Male C57BL6/J mice were fed a 60% high fat/2% cholesterol diet with 10% fructose supplemented drinking water (HFCF diet) for 25 weeks to induce obesity and NASH/liver fibrosis. After the 25-week diet-induction period, mice were kept on HFCF diet and treated with vehicle (control) or SEMA 0.06 mg/kg s.c. QD or placed on TRF from the last 3 hours of the dark cycle till the end of the light cycle, without access to food, but free access to normal drinking water (i.e., without fructose) every day, for 6 weeks. After 6 weeks, blood and liver were collected for biochemistry and histology analysis.
Results: SEMA treatment for 6 weeks induced a 20% lower caloric intake, which led to a 21% lower body weight ($p < 0.001$ vs. control). TRF had a weaker effect on caloric intake (-9%) but also reduced body weight (−11%, $p < 0.05$ vs. control). Both SEMA and TRF reduced the HOMA-IR index of insulin resistance and significantly reduced plasma ALT and AST levels, but these effects were more pronounced with SEMA. TRF, and to a greater extent SEMA, significantly reduced liver weight (SEMA: −37%, TRF: −27%), hepatic fatty acids (SEMA: −61%, TRF: −41%), triglycerides (SEMA: −67%, TRF: −36%, $p < 0.05$) and total cholesterol (SEMA: −48%, TRF: −30%) levels. Accordingly, SEMA showed a stronger reduction in steatosis score than TRF, but both led to significantly lower NAFLD activity score. SEMA and TRF significantly reduced the hepatic gene expression of MCP-1 (inflammation), alpha-SMA, TGF-beta, Col1alpha1 and TIMP1 (fibrosis). However, SEMA did not alter liver fibrosis (as shown by Sirius Red staining), while TRF showed a clear anti-fibrotic effect in the liver, with significantly lower % Sirius Red labelling ($p < 0.05$ vs. control).
Conclusion: SEMA markedly reduced body weight and liver steatosis but did not improve hepatic fibrosis. Although its weight loss effect was less pronounced, TRF improved both NASH and liver fibrosis. These TRF benefits should be further investigated in the clinical setting.

SAT111

ECC4703, a full thyroid hormone receptor beta (THRb) agonist, demonstrated excellent selectivity and liver targeting properties and improvement of plasma lipid, NAFLD acitivty score and fibrosis in NASH animial model

Jianfeng Xu[1], Zhao Yongliang[1], Julie Zhu[1], Jianfeng Xu[1], Jingye Zhou[1].
[1]*Eccogene (Shanghai) Co., Ltd., Shanghai, China*
Email: jfxu@eccogene.com

Background and aims: Non-alcoholic steatohepatitis (NASH) is a metabolic liver disease featuring ectopic fat accumulation, hepatocellular damage, chronic inflammation, and progressive fibrosis. Resmetirom (MGL3196) as THRβ agonist has demonstrated THR β selectivity and liver targeting, which translate to plasma lipid lowering, potential of fibrosis improvement and thus NASH resolution in humans. However, MGL3196 is a partial agonist compared to the natural ligand T3 in ligand binding and liver target gene expression. A full agonist may provide superior efficacy for NASH and dyslipidaemia.
Method: Ligand binding to human THRα and THRβ was measured based on recruitment of a coactivating activator peptide to the receptors. Liver targeting was determined in PTU-induced rat hypothyroidism model with induction of THR target gene in liver and heart. Activities in rat and human primary hepatocyte were measured with a reporter gene driven by thyroid response elements. A diet-induced obesity with CCl4 in mice (DIO-CCl4) was applied to evaluate the effect of ECC4703 on plasma lipid and liver pathology.
Results: In a ligand bind assay, ECC4703 is a potent THRβ agonist with relative β vs α selectivity of 49. In PTU rat, ECC4703 elicited robust induction of liver gene DIO1 but no effects on heart gene α-MHC at up to 50 mpk, indicating superior liver targeting. It's noteworthy in both in ligand binding and liver gene expression, ECC4703 showed Emax equivocal to T3 which suggested full agonism. In rat and human hepatocytes, ECC4703 led to potent reporter gene expression, ensuring species translation. In DIO-CCl4 NASH model, ECC4703 treatment resulted in significant decrease in plasma lipid, improvement of liver NAS score and fibrosis, but no effects on heart weight.



Conclusion: In summary, ECC4703 is a novel full THRβ agonist with excellent in vitro and in vivo profile, and potentially best-in-class compound for NASH and dyslipidemia treatment.

SAT112

LIVRQNac increases fatty acid oxidization in a primary human hepatocyte model of non-alcoholic steatohepatitis

Matthew Russell[1], Christopher Newgard[2,3], Guofang Zhang[2], Arianna Nitzel[1], Michael Hamill[4], Karim Azer[1]. *[1]Axcella Therapeutics; [2]Duke Molecular Physiology Institute; [3]Department of Medicine, Duke University Medical Center; [4]Flagship Pioneering*
Email: mrussell@axcellatx.com

Background and aims: Endogenous metabolic modulators (EMM) are naturally occurring compounds with signaling and regulatory properties. When selectively combined, in unique stoichiometric ratios, EMMs can treat complex diseases with system-wide dysregulation of metabolic pathways. LIVRQNac, an EMM composition of 5 amino acids (AA) and n-acetylcysteine (Nac), decreased liver fat accumulation (*in vivo* and *in vitro*) by reducing triglyceride accumulation. AXA1125, the clinical formulation of these same EMMs, decreased liver fat content in subjects with non-alcoholic fatty liver disease by magnetic resonance imaging measurement of liver proton density fat fraction, MRI-PDFF. The present study investigated the *in vitro* dose-dependent effects of LIVRQNac on fatty acid oxidation (FAO), the putative mechanism of these effects, in a primary human hepatocyte (PHH) NASH model.
Method: PHHs were plated on collagen coated wells and incubated with 5% CO_2. On day 3, cells were incubated in custom media containing 500 µM carnitine, 10 µg/ml insulin, EGF, 1 µM dexamethasone, and custom AA concentrations (as in healthy human plasma) with and without LIVRQNac (10X and 30X) and with lipotoxic insult (saturated free fatty acids [2:1 oleate: palmitate] and tumor necrosis factor alpha (1 ng/ml). After 24 hours, cells were treated for 1 hour with medium containing LIVRQNac and lipotoxic insult with [U-^{13}C] palmitate replacing palmitate and then analyzed for ^{13}C-labeled palmitoylcarnitine, acetylcarnitine, acetyl-co-enzyme A, β-hydroxybutyrate, and other metabolites using liquid and gas chromatography-mass spectrometry.

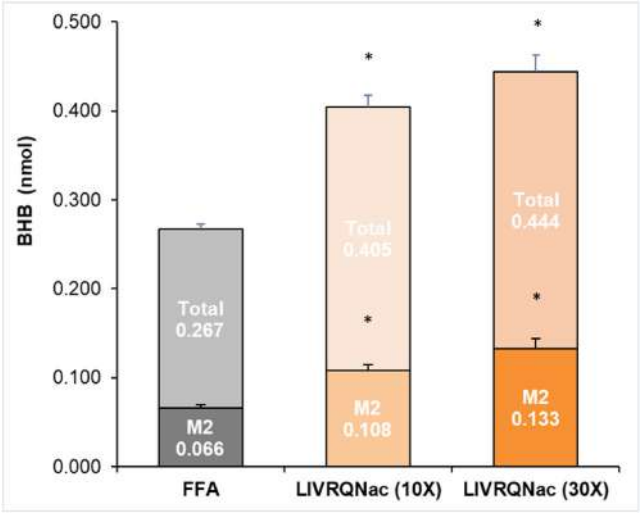


Figure: Increases (%) in labeling of the terminal FAO metabolite BHB, derived from [U-^{13}C] palmitate tracer, and total pool size are indicative of the dose-dependent increase in FAO with LIVRQNac. *p < 0.0001, analysis of variance; BHB, the ketone body, β-hydroxybutyrate; FAO, fatty acid oxidation; M2, mass isotopomers where number represents the number of heavy atoms in the molecule.

Results: ^{13}C labeling of fatty acid-derived metabolites (%) was significantly increased by LIVRQNac treatment vs control. Increases were observed in labeled palmitoylcarnitine (p < 0.001), acetylcarnitine (p < 0.05), and acetyl-CoA (p < 0.05) in LIVRQNac- 10X, and 30X treated cells vs control. M2 labelled β-hydroxybutyric acid (terminal FAO product) increased 102% in LIVRQNac-treated cells (0.108 nmol, 10X; 0.133 nmol, 30X) vs control (0.066 nmol; p < 0.0001; Fig).
Conclusion: Increases in labeled palmitoylcarnitine, acetylcarnitine and acetyl-coA reflected an increase in FAO in PHHs treated with LIVRQNac. Consistently, there was an increase in total and labelled β-hydroxybutyric acid in LIVRQNac-treated cells indicating an increase in ketogenesis. These data support a mechanism for AXA1125's clinical effect of decreasing liver fat, by increasing ketogenesis and increasing FAO.

SAT113

Assessment of therapeutic effect of liraglutide in newly established cell culture model of non-alcoholic and drug-induced fatty liver disease

Tea Omanovic Kolaric[1,2], Vjera Nincevic[2], Tomislav Kizivat[3], Milorad Zjalic[4], Lucija Kuna[2], Ines Bilic-Curcic[1,5], Martina Smolic[1,2]. *[1]Faculty of Medicine Osijek, Department of Pharmacology, Osijek, Croatia; [2]Faculty of Dental Medicine and Health Osijek, Department of Pharmacology and Biochemistry, Osijek, Croatia; [3]University Hospital Centre Osijek, Clinical Department of Nuclear Medicine and Radiation Protection, Osijek, Croatia; [4]Faculty of Medicine Osijek, Department of Medical Biology and Genetics, Osijek, Croatia; [5]University Hospital Centre Osijek, Clinical Department of Diabetes, Endocrinology and Metabolism Disorders, Osijek, Croatia*
Email: msmolic@mefos.hr

Background and aims: The impact of non-alcoholic fatty liver disease (NAFLD) on global health is becoming more significant with the growing incidence of obesity and drugs consumption. Therefore, more research is necessary in order to enlighten underlying pathophysiologic mechanisms for these conditions and possible therapeutic approaches. Aims of our study were to establish reliable in vitro models of non-alcoholic and drug-induced fatty liver disease (DIFLD) and also to investigate possible therapeutic solutions in these in vitro models.
Method: HuH7 cell culture models of NAFLD and DIFLD were established by incubation of Huh7 cells with 0, 5 mM oleic acid (OA), 5 µM to 20 µM of amiodarone, 1 µM to 10 µM of tamoxifen for various time periods (24 h, 48 h), respectively. Cells where cotreated with 1 nM to 100 nM of liraglutide in order to assess its potential beneficial effect in fatty liver models. Cell viability was measured by MTT ((3- (4, 5-dimethylthiazol-2-yl)-2, 5-diphenyltetrazolium bromide) assay. Changes in cell shape and the extent of hepatosteatosis were assessed by fluorescent microscopy as shown in Figure. Cell nuclei were stained with Hoechst, and fat droplets were stained with Oil-Red-O. Trigliceryde (TG) accumulation was measured by TGO-PAP method and the results were read on the microplate reader.

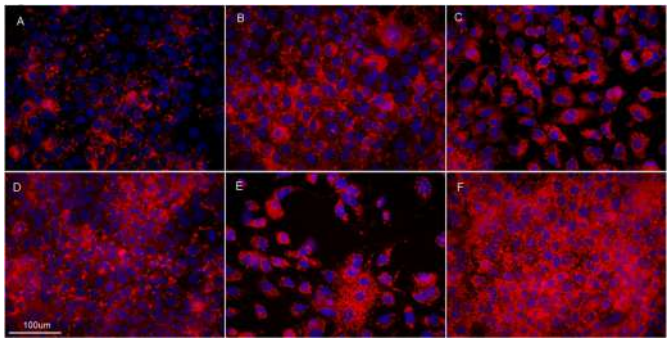

Figure: Effects of tamoxifen, amiodarone and OA on the fat accumulation in Huh7 cell culture after 24 h of treatment with: A- control, B- 10 µM tamoxifen, C- 20 µM tamoxifen, D- 20 µM amiodarone, E- 40 µM amiodarone, F- 0, 5 mM OA.

Results: Tamoxifen significantly reduced cell viability in a dose-dependent manner after just 24 h treatment, compared to amiodarone and OA. Liraglutide co-treatment improved cell viability and the effect was greater after a longer period of treatment, especially in tamoxifen-treated cells for almost 30% (p <0, 05). Microscopic observations demonstrated microsteatosis as the predominant form of liver cell injury in this time period, with the greatest accumulation of fat in OA model. Accordingly, TG accumulation was highest in OA model, while liraglutide diminished TG accumulation in all three models.
Conclusion: This newly established cellular Huh7 model of NAFLD and DIFLD could provide a new tool for further studies on these conditions. Nevertheless, further research is needed to better understand the onset of fatty liver changes, drug toxicity, and the possible role of liraglutide in their treatment.

SAT114

Efx treatment improved histopathology and non-invasive markers of liver injury and fibrogenesis to a similar extent in NASH patients with high-risk PNPLA3 genotypes, compared to those with lowest genetic risk: a post-hoc analysis of balanced study

Erik Tillman[1], Reshma Shringarpure[2], Guy Neff[3], Rashmee Patil[4], Peter Ruane[5], Bradley Freilich[6], Cynthia Behling[7], Erica Fong[8], Brittany de Temple[8], Kitty Yale[9], Stephen Harrison[10], Tim Rolph[8].

Email: tim@akerotx.com

Background and aims: The PNPLA3 **I148M** genetic variant confers increased risk of progressive NAFLD, cirrhosis, and HCC. Concurrent insulin resistance further increases the risk associated with I148M.[1] The aim of this analysis was to evaluate whether I148M presence influenced patients' baseline characteristics and/or response to the long-acting FGF21 analog efruxifermin (EFX) in the BALANCED Main Study.
Method: 80 NASH patients with F1-F3 fibrosis were randomized in a controlled design comparing EFX treatment for 16 weeks with placebo[2]. End-of-treatment liver biopsies were available for patients with ≥30% relative reduction in liver fat content (LFC) by MRI-PDFF after 12 weeks of EFX dosing. All EFX-treated patients with MRI-PDFF met this threshold. The PNPLA3 rs738409 SNP was genotyped in all consenting patients. Baseline characteristics and treatment responses were compared across PNPLA3 genotypes: I/I (lowest risk), I/M (intermediate risk), or M/M (highest risk) for all EFX-treated patients with available genotype, biomarker, and histology data.
Results: Of 42 EFX-treated patients genotyped for PNPLA3, 11 were I/I, 22 were I/M, and 9 were M/M.
At Baseline, carriers of the lowest risk (I/I) genotype were older, with more insulin resistance and hypertriglyceridemia, whereas those carrying the highest risk (M/M) genotype were younger, with less insulin resistance and lower triglyceride levels. Histologic response to EFX was observed across all 3 PNPLA3 genotypes, with larger improvements in histopathology seen in patients with M/M genotype. Although the extent of NASH resolution was similar across all genotypes at 40–56%, all 9 M/M carriers achieved ballooning resolution. The extent of fibrosis regression appeared greater in M/M than I/I patients: in EFX-treated patients with paired biopsies that consented to genotyping, 7/9 (78%) M/M carriers had a ≥1-stage improvement in fibrosis compared to 4/10 (40%) of I/I patients, while 4/5 (80%) M/M patients with F2/F3 fibrosis at baseline improved by 2 stages compared to 3/6 (50%) I/I patients. Improvements in metabolic and liver-related biomarkers were comparable across PNPLA3 genotypes.

SAT115

Oxygen-nutrient mismatch: a novel concept to explain how Obeticholic acid benefits NASH treatment

Gerond Lake-Bakaar[1], John Robertson[2], Charles Aardema[3].
[1]Presbyterian St. Luke's Medical Center, Transplant Center, Denver; [2]Blacksburg, Bioengineering, Blacksburg, United States; [3]Biomedinnaovations LLC, Denver, United States
Email: glakebak@verizon.net

Background and aims: The oxygen-nutrient mismatch concept, first proposed for alcoholic steatohepatitis, ASH, could also apply to non-alcoholic steatohepatitis, NASH. Both are consequences of the unique dual liver blood supply.
The hepatic artery, HA, accounts for 20 percent of liver blood flow. However, it provides over 50 percent of oxygen requirements and has myogenic elements for autoregulation. By contrast, the portal vein, PV, lacks autoregulatory capacity and carries deoxygenated blood, rich in nutrients. Thus, HA oxygen delivery could fail to match excess alcohol (ASH) or nutrient intake (NASH). Furthermore, chronic obstructive sleep apnoea (OSA) and intermittent hypoxia, common in NASH could induce chronic liver damage from tissue hypoxia.
Obeticholic acid (OCA), is a highly selective, potent agonist for the Farnesoid-X-receptor (FXR). It effectively treats NASH fibrosis. It can impact vasoactive responsiveness; however, the mechanism of action is unclear.

We studied the effects of OCA on HA, PV, and hepatic vein, HV, flow in porcine liver perfused ex vivo with a cardio-emulation pump, the CaVESWave® system to determine whether vascular effects could explain its efficacy in the treatment of NASH

Method: Six fresh porcine livers (two controls) were continuously perfused with phosphate buffered saline (PBS). OCA dosing was delivered in solution with methyl cellulose as carrier, directly into the portal vein catheter. Perfusion was initiated with the HA settings at 120/80 mmHg, PV around 15 mmHg and temperature at 15° C. Flow rates in HA, PV and HV were measured throughout. Carrier only was injected at 30 min intervals in the controls. For the treatment group, 0 mg OCA/kg liver weight, followed by 0.14, 0.28, 0.56 and 1.12 mg/kg, injected at 30 min intervals.

Results: The cardio-emulated waveforms showed little variability, either before or after drug treatment was started (figure 1). HA pressure varied between 117 and 122 mmHg (systolic) and 75–84 mmHg (diastolic); perfusate pH between 7.35 and 7.4; DO between 104 and 105 and temperature 15.8 and 17.5° C.

Control livers (n = 2) showed minor changes in flow after treatments with vehicle (figure 2). The maximum percentage increase in HA flow was 3.3 ± 3.5 and HV flow, 4.8 ± 2.8. By contrast, PV flow was reduced by up to −9.1 ± 5.9.

In OCA treated livers (n = 4), there was a clear dose-relationship between OCA and HA, HV and PV. Hepatic venous outflow and HA flow increased progressively to 11 ± 11.8 and 9.9 ± 8.9, respectively. Conversely, PV flow was reduced by up to −19 ± 16%.

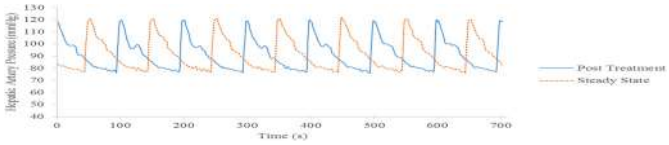

Figure 1:

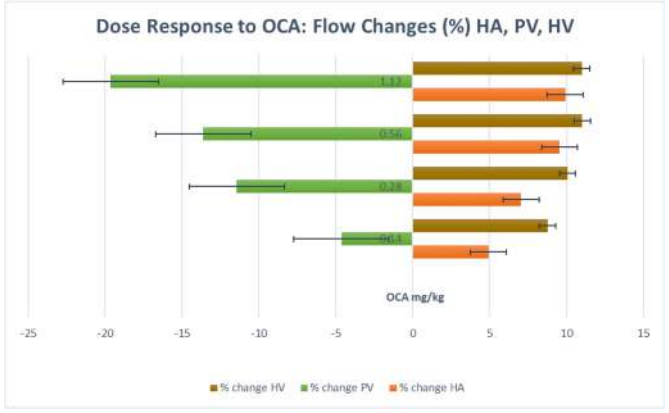

Figure 2:

Conclusion: OCA in dose responsive manner increased HA flow rates and inversely reduced PV flow, consistent with an active hepatic artery buffering response. Thus, increased delivery of oxygen rich HA blood, coupled with reduced nutrient rich PV blood, provides a rational concept for the beneficial effect of chronic OCA in NASH.

SAT116

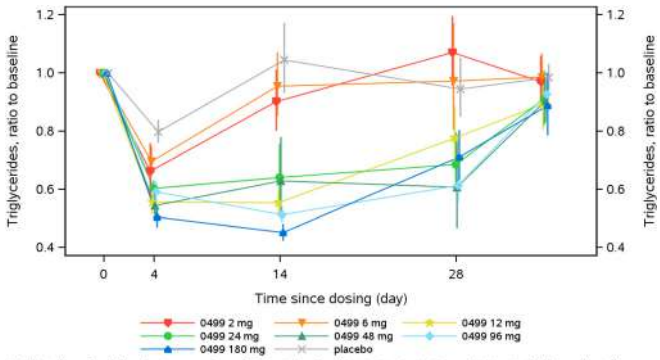
Sustained reduction of triglyceride and LDL cholesterol from single administration of the novel long-acting FGF21 analogue 0499

Kirsten Dahl[1], Martin Friedrichsen[1], Rasmus Ribel-Madsen[1], Jakob Schiøler Hansen[2], Jesper Clausen[1], Mads Axelsen[1], Mads Sundby Palle[1], Cassandra Key[3], Harumi Murakami[4], Birgitte Andersen[1]. *[1]Novo Nordisk A/S, Denmark; [2]Novo Nordisk Bio Innovation Hub, United States; [3]ICON Early Phase Service, San Antonio, TX, United States; [4]SOUSEIKAI Sumida Hospital, Tokyo, Japan*
Email: kdhl@novonordisk.com

Background and aims: Activation of the fibroblast growth factor 21 (FGF21) receptor complex has been associated with several attractive effects in preclinical models including weight loss and decreased hepatic fat content. This has led to the pursuit of FGF21 for pharmacotherapy within obesity and NASH, which has to date been limited by lack of suitable FGF21 analogues. Here we report the exploration of a new FGF21 analogue 0499 with the purpose of investigating the safety profile, pharmacokinetic (PK) and pharmacodynamic (PD) potential of the new molecule.

Method: In a randomized, blinded, placebo-controlled first human dose (FHD) study, healthy male participants with a BMI around 30 kg/m^2 received a single subcutaneous administration of either placebo or 0499 at dose level: 2, 6, 12, 24, 48, 96, or 180 mg. In a separate study in Japanese healthy male participants, 3 dose levels: 12, 30, and 96 mg were tested to confirm consistent safety profile and PK characteristics across ethnicity. In both studies, participants were followed for 36 days post-dose while blood samples were obtained for safety evaluation, PK and PD assessments. A total of 78 participants received a single dose of 0499.

Results: The safety profile, as well as PK and PD results were comparable for the two studies. The adverse events observed were mainly related to the gastrointestinal tract including nausea, diarrhea, frequent bowel movements and vomiting. Increased appetite was also observed. Treatment was not associated with changes in heart rate, body temperature, clinical laboratory safety parameters, or body weight. Plasma triglyceride and LDL cholesterol levels were decreased in a dose-dependent manner while HDL cholesterol was increased. The changes in the lipid parameters were sustained for up to 28 days after the single administration. The plasma half-life of 0499 was approximately 120 hours.



Administration of a single subcutaneous dose of 0499 at dose levels 2, 6, 12, 24, 48, 96, and 180 mg to healthy male study participants resulted in a dose-dependent reduction of plasma triglyceride, which was long-lasting corresponding to the plasma half-life of 0499 of approximately 120 hours.
Error bar is +/- standard error of mean calculated on logarithmic scale and back-transformed to linear scale

Conclusion: From the two studies of 0499 in healthy participants, it was concluded that the novel FGF21 analogue 0499 has an acceptable safety profile at all tested dose levels, and that the PK profile seems compatible with a once-weekly dose regimen. The remarkable improvement on the plasma lipid profile is encouraging for the further development of 0499 for treatment of NASH.

SAT117

Combination of an Acetyl-CoA carboxylase inhibitor and obeticholic acid reduced lipids and bile acids and altered lipid and amino acid metabolism in the liver of humanized mice

Wen-Wei Tsai[1], David Hollenback[1], Andrew Schwab[2], Megan Showalter[2], James Trevaskis[1]. [1]*Gilead Sciences;* [2]*Metabolon*
Email: wwtsai76@gmail.com

Background and aims: Inhibition of the acetyl-CoA carboxylase (ACC) isoforms ACC1 and ACC2 reduces lipogenesis, stimulates lipid oxidation, and improves histologic features and fibrosis-related biomarkers in non-alcoholic steatohepatitis (NASH). Obeticholic Acid (OCA), as an FXR agonist, reduces bile acid synthesis and regulates lipid metabolism in the liver. We evaluated the effect of an ACC inhibitor (ACCi) and OCA in combination on lipid and amino acid metabolism in the humanized liver of chimeric PXB mice (PhoenixBio, Japan).
Method: Adult male PXB mice (n = 10, randomized by blood human albumin concentrations) were administered with ACCi (an analog of firsocostat) and/or OCA (10 mg/kg, QD, PO for both compounds) for 18 days and livers were collected 2 h after the last dose. Untargeted metabolomic profiling of liver tissue was performed at Metabolon, Inc (Morrisville, NC, USA) using a combination of LC-MS methods (1).
Results: Humanized liver mice developed spontaneous steatosis due to the lack of FGF19 signalling in the liver as engulfed human hepatocytes did not respond to mouse FGF15. ACCi and OCA combination showed additive effects to reduce neutral lipids (triglycerides, diacylglycerols) and long chain fatty acids, and increase acyl-carnitines and 3-hydroxybutyrate. Although the combination reduced 7-hydroxycholesterol, OCA increased cholesterol and cholesteryl esters alone or in combination with ACCi. Primary and secondary bile acids were mainly decreased by OCA and further reduction was observed in combination. OCA and combination increased N-acetylated amino acids and combination also increased polyamines and nicotinamide adenine dinucleotide hydride.
Conclusion: Metabolomic analysis revealed that lipid metabolism and energetic profile were rapidly changed by ACCi or OCA treatment and combination of both agents reduced lipid synthesis and promoted fatty acid oxidation in the liver of humanized mice. These changes are similar to the clinical findings in NASH patients treated with ACCi and FXR agonist combination, and support the utility of humanized mouse model to elucidate molecular pathways mediated by NASH therapies.

SAT118

Identification of a fibrosis endotype in NAFLD patients more prone to interventions aimed at reducing fibrogenesis

Ida Villesen[1], Jadine Scragg[2,3,4,5], Diana Leeming[1], Olivier Govaere[3,6], Guy Taylor[2], Stuart Mcpherson[3,6,7], Kate Hallsworth[3,6,7], Morten Karsdal[1], Quentin Anstee[3,6,7]. [1]*Nordic Bioscience, Fibrosis, Herlev, Denmark;* [2]*Population Health Sciences Institute, Faculty of Medical Sciences, Newcastle University, Newcastle upon Tyne, United Kingdom;* [3]*Newcastle NIHR Biomedical Research Centre, Newcastle Upon Tyne Hospitals NHS Foundation Trust, Newcastle Upon Tyne, United Kingdom;* [4]*Nuffield Department of Primary Care Health Sciences, University of Oxford, Oxford, United Kingdom;* [5]*NIHR Oxford Biomedical Research Centre, Oxford, United Kingdom;* [6]*Translational and Clinical Research Institute, Faculty of Medical Sciences, Newcastle University, Newcastle upon Tyne, United Kingdom;* [7]*Liver Unit, Newcastle Upon Tyne Hospitals NHS Foundation Trust, Newcastle Upon Tyne, United Kingdom*
Email: ifv@nordicbio.com

Background and aims: Non-alcoholic fatty liver disease (NAFLD) is associated with inflammation and hepatocellular damage, leading to activation of fibroblasts and fibrosis development. Fibrosis is known to be the single most important factor for predicting liver-related clinical outcomes and is quantifiable by biomarkers of collagens including PRO-C3, PRO-C4 and PRO-C5, measuring formation of type III, IV and V collagen, respectively. However, patient heterogeneity is evident, and it remains largely unknown how to accurately identify patients in most need of treatment. Monitoring fibroblast activity through formation of collagen, may enable identification of fibrosis endotypes; a high or low activity stage of fibrosis formation. This segregation may identify patients more likely to experience anti-fibrotic effect due to therapy or weight loss.
Method: Clinically confirmed NAFLD patients, weight stable (±3%) since diagnoses, were recruited from hepatology clinics at a tertiary centre in the UK. Patients were prescribed an 8–12-week VLCD (~800 kcal/day) intervention. Serum markers were determined at baseline and every second week until end of diet, 4 weeks post-VLCD and at 5 months follow-up. The biomarkers PRO-C3, PRO-C4 and PRO-C5 were quantified by ELISA. For analysis, patients were stratified at baseline into high and low levels of formation of fibrosis, determined by the biomarkers.
Results: 26 patients (mean age 56 and BMI of 42) were included. With a mean weight loss of 9.7% all patients were found to improve liver measures including ALT and AST from baseline to post-VLCD. Yet, patients separated into high and low biomarker levels at baseline, based on the median, were found to differ in response to intervention. Thus, high levels of PRO-C3 (above 11.4 ng/ml) were found to associate with a decrease of 40% from baseline to end of diet while low levels remained unchanged, the same was seen for PRO-C4 (above 263.5 ng/ml) with ~55% decrease and PRO-C5 (above 857.4 ng/ml) with ~ 57% in high-level groups, indicating decreased formation of fibrosis following weight loss, while low biomarker levels remained unchanged throughout the course of the study.

Table 1: Patient baseline characteristics

	High PRO-C3	Low PRO-C3	High PRO-C4	Low PRO-C4	High PRO-C5	Low PRO-C5
BMI, mean (± SD)	42 (± 9)	39 (± 8)*	41 (± 8)	40 (± 8)*	41 (± 9)	41 (± 7)*
ALT, mean (± SD)	55 (± 41)	41 (± 17)**	56 (± 37)	38 (± 21)**	55 (± 39)	40 (± 19)**
AST, mean (± SD)	40 (± 21)	29 (± 12)	35 (± 20)	32 (± 16)*	33 (± 19)	35 (± 17)
ELF	10 (± 0.9)	10 (± 0.7)	10 (± 0.8)	10 (± 0.8)	10 (± 0.8)	10 (± 0.8)

p values indicate significant different from high group, calculated using t-test and indicated as $^{*}p < 0.05$, $^{**}p < 0.01$

Conclusion: NAFLD patients respond heterogeneously to intervention with regards to their fibrogenesis profile, in which some experience a decrease and other are unchanged, suggesting an endotype of patients more amendable to anti-fibrogenesis intervention.

SAT119

The pan-PPAR agonist lanifibranor improves markers of cardiometabolic health in patients with NASH independent of weight change

Michael Cooreman[1], Sven Francque[2], Martine Baudin[3], Philippe Huot-Marchand[3], Lucile Dzen[3], Jean-Louis Junien[3], Pierre Broqua[3], Manal Abdelmalek[4]. [1]*Inventiva, United States;* [2]*University Hospital Antwerp, Belgium;* [3]*Inventiva, France;* [4]*Duke University School of Medicine, United States*
Email: michaelpcooreman@msn.com

Background and aims: Lanifibranor therapy resulted in significant efficacy on the histological end point 'NASH resolution and improvement of fibrosis' as well as on markers of cardiometabolic health (CMH) in the phase 2b NATIVE study. Modest weight gain was reported as a PPARγ effect, which has been ascribed to the maturation of insulin-sensitive, metabolically healthy subcutaneous adipose

tissue. We evaluated markers of CMH by changes in weight in the lanifibranor and placebo arms.
Method: NATIVE enrolled 247 patients with SAF activity score 3–4, fibrosis stage F0-F3 in 3 arms: lanifibranor 800, 1200 mg/d and placebo for 24 weeks; 217 (lanifibranor: 144, placebo: 73) patients who completed the trial with weight data at baseline and end of treatment (EOT) were included in the analyses. Mean weight increase at EOT was 2.4 (2.6%) and 2.7 (3.1%) kg for 800 and 1200 mg lanifibranor, respectively; patients were divided in 3 groups according to % weight change: ≤2.5% (n = 73, 51%); 2.5–5% (n = 23, 16%); >5% (n = 48, 33%). Biomarkers of lipid and glucose metabolism, insulin resistance, inflammation, liver tests, diastolic blood pressure (DBP), hepatic steatosis (NASH-CRN grading) and Controlled Attenuation parameter (CAP) were evaluated at screening and EOT, and compared between the weight change groups.
Results: Improvement of CMH markers at EOT compared to baseline occurred to the same degree in the 3 weight change groups for the pooled lanifibranor arms: increase in HDL-cholesterol, and decrease in total triglycerides, APO-B, APO-B/APO-A1, APO-C3, fasting glucose and insulin levels, HbA1c, HOMA-IR and hs-CRP, along with decreases in hepatic steatosis, ALT, AST, GGT and DBP. Adiponectin, a PPARγ downstream mediator, increased in all 3 weight change groups, with a higher increase in the >2.5% weight increase groups, compared to the <2.5% weight increase group. With placebo, 12 (16%) patients with weight change >2.5% at EOT had no improvement of CMH markers, no change in adiponectin levels, and had increases in steatosis and worsening of liver tests, HOMA-IR and DBP.
Conclusion: Biomarkers of CMH improve with lanifibranor therapy, independent of weight change. These beneficial effects occur in parallel with a marked increase of adiponectin, which marks adipose tissue health and improves insulin sensitivity; the data provide further evidence that PPARγ-induced weight gain is metabolically distinct from lifestyle-related weight gain.

SAT120
Lanifibranor therapy reduces the FibroScan-aspartate aminotransferase (FAST) score associated with histological 'NASH resolution and improvement of fibrosis' and biomarker response
Michael Cooreman[1], Manal Abdelmalek[2], Martine Baudin[3], Philippe Huot-Marchand[3], Lucile Dzen[3], Céline Fournier[4], Jean-Louis Junien[3], Pierre Broqua[3], Sven Francque[5]. *[1]Inventiva, United States; [2]Duke University School of Medicine, United States; [3]Inventiva, France; [4]Echosens, France; [5]University Hospital Antwerp, Belgium*
Email: michaelpcooreman@msn.com

Background and aims: Lanifibranor, a pan-PPAR agonist, has shown efficacy on the histological end point 'NASH resolution and improvement of fibrosis' in the phase 2b NATIVE trial. We evaluated the effect of lanifibranor on the FAST score, a promising non-invasive test (NIT) for active NASH with significant fibrosis, and its correlation with histological and biomarker response in NATIVE-enrolled patients with F2-F3 fibrosis.
Method: Patients with non-cirrhotic NASH and SAF-activity score 3–4 enrolled in NATIVE (n = 247) received lanifibranor 800, 1200 mg/d or placebo for 24 weeks. A total of 112 patients had baseline F2-F3 fibrosis and FAST scores available at baseline and end of treatment (EOT). FAST combines liver stiffness measurement by vibration controlled transient elastography, controlled attenuation parameter and aspartate aminotransferase levels and provides the probability (between 0 and 1) for active NASH with significant fibrosis (NAS≥4 and F≥2): ≥0.65: high-risk, 0.35–0.65: intermediate-risk, ≤0.35 low-risk. FAST scores were compared between lanifibranor and placebo arms using a mixed model adjusted for baseline value; the correlation between changes in FAST scores at EOT and liver histology and biomarkers of metabolism, inflammation and fibrosis was also evaluated.
Results: Mean (SD) FAST score at baseline was 0.55 (0.22), similarly distributed in the 3 treatment arms, with 34% at high-risk NASH, 45% at indeterminate risk and 21% at low-risk. At EOT, FAST significantly decreased from baseline, with mean absolute changes of −0.22 and −0.23 for lanifibranor 800 and 1200 mg respectively (both $p < 0.01$), and −0.09 for placebo. Mean FAST score at EOT was 0.31 for both lanifibranor arms and 0.51 for placebo; 67% in both lanifibranor and 27% in placebo arms had FAST ≤0.35 (low-risk) at EOT. Decreases in FAST scores correlated with histological end point 'resolution of NASH and improvement of fibrosis', and with improvement in triglycerides, Apo-C3 and ferritin levels.
Conclusion: Treatment of NASH patients with F2/F3 fibrosis with lanifibranor for 24 weeks leads to a significant reduction of the FAST score compared to placebo and this decrease correlates with improvements in liver histology and biologically relevant biomarkers responses. These results not only support the histological efficacy data but also the potential of the FAST score as a NIT to monitor disease progression and response to therapy.

SAT121
Effect of smartphone-assisted lifestyle intervention in patients with metabolic-associated fatty liver disease (MAFLD): a preliminary analysis of a randomized controlled trial
Suraphon Assawasuwannakit[1], Apichat Kaewdech[1], Chaitong Churuangsuk[1], Naichaya Chamroonkul[1], Pimsiri Sripongpun[1]. *[1]Prince of Songkla University, Medicine, Hat Yai, Thailand*
Email: pim072@hotmail.com

Background and aims: Patients with metabolic-associated fatty liver disease (MAFLD) are on the rise globally. While therapeutic medications are being studied, the mainstay of treatment is lifestyle intervention (LSI), but adherence to LSI and weight loss are difficult to achieve. We hypothesized that providing LSI and MAFLD information, as well as encouraging LSI through a social media application, would improve clinical outcomes in MAFLD more than standard of care (SOC).
Method: This is a preliminary result of a randomized controlled study in noncirrhotic MAFLD patients (defined as an international expert consensus statement 2020) aged 18–65 years in Thailand. Patients with active malignancy, current pioglitazone treatment, coexisting other liver diseases, and unstable cardiovascular/neurological conditions were excluded. Eligible patients were randomly assigned to control (SOC) and intervention arm. In the control arm, patients receive standard LSI advice from a single hepatologist; whereas in the intervention arm, in addition to SOC, the investigator sent infographics about MAFLD and LSI information and reminded patients to do LSI every 3–7 days via a social media app popular in Thailand (LINE®) using the study's official account. The outcomes are changes in liver steatosis (measured by controlled attenuated parameter) and fibrosis (measured by liver stiffness) by Fibroscan® at 24 weeks, as well as weight loss, body composition, and serum alanine aminotransferase (ALT) level between the two groups.
Results: So far, 80 patients were enrolled. Of those, 49 patients had week12 follow-ups for weight, waist circumference, and ALT. The mean age of these patients was 51 ± 7 years, 69% were female, mean body mass index (BMI) was 28.3 ± 4.2 kg/m2, and 17% had diabetes. There were 25 and 24 patients in the control and intervention arm, respectively. Overall, the patients had a lower BMI at week12 compared to their baseline (median delta BMI −0.4 [IQR: −0.1, 0.04] kg/m2, $p = 0.003$). Figure 1 depicts the percentage weight loss, ALT,

and waist circumference change in each group. When compared to baseline, patients in the intervention group had a significant reduction in weight (−2.4%, p = 0.006) and ALT level (−8.5 U/L, p = 0.004); whereas patients in the control group had a significant decrease in weight (−1.2%, p = 0.034) but not ALT level (−6 U/L, p = 0.19). The intervention group had a greater reduction in percent weight loss and ALT than the control group, but the statistically significant levels were not reached.

	%weight loss	ALT change (U/L)	Waist circum. change (cm)
Control (n=25)	-1.2±2.5 (p=0.034)	-6 [-16.2,5] (p=0.19)	0 [-5,1.4] (p=0.2)
Intervention (n=24)	-2.4±3.9 (p=0.006)	-8.5 [-20.2,-0.8] (0.004)	-1 [-4.2,1] (p=0.12)

Conclusion: In this preliminary result, encouraging LSI and delivering MAFLD information via social media application to patients with MAFLD resulted in a significant reduction in weight and ALT level compared to baseline, and the results appeared to be better than SOC. However, the complete data of all eligible patients as well as change in liver steatosis and fibrosis is yet to be confirmed.

SAT122

Efficacy and mechanism of time-restricted fasting in non-alcoholic liver disease

Jiang Deng[1], Dandan Feng[1], Ning Gao[1], Juanjuan Shi[1], Shuangsuo Dang[1]. [1]*The Second Affiliated Hospital of Xi'an Jiaotong University, Department of Infectious Disease, Xi'an, China*
Email: dang212@126.com

Background and aims: Non-alcoholic fatty liver disease (NAFLD) lacks specific treatment drugs. The aims of this study were to analyze the efficacy and mechanism of time-restricted fasting (TRF) in the treatment of NAFLD.
Method: Thirty-two male rats were randomly divided into three groups: Normal group, which was given a standard diet; NAFLD group, which was given a 60% high-fat diet; and TRF group, which was given a 60% high-fat diet, eating was allowed for 6 hours per day. After 15 weeks, the liver lipidomics and other indicators were determined, detected, and compared.
Results: A total of 1062 metabolites were detected. Compared with the Normal group, weight, body fat ratio, aspartate aminotransferase, total cholesterol, low-density cholesterol, fasting blood glucose, uric acid and the levels of 317 lipids in the NAFLD group were higher, whereas 265 lipids were down-regulated ($p < 0.05$). Compared with the NAFLD group, weight, body fat ratio, daily food intake, and the levels of 253 lipids in the TRF group were lower; 82 lipids were up-regulated ($p < 0.05$), serum triglyceride level was increased, but there was no statistical significance ($p > 0.05$). Kyoto Encyclopedia of Genes and Genomes pathway enrichment was conducted according to the results of differential metabolites, and the results showed that the pathways involved mainly included metabolic pathways, regulation of lipolysis in adipocytes, fat digestion and absorption, etc. Reverse transcription polymerase chain reaction proved that TRF improved the abnormal expression of FAS and PPARα genes in the NAFLD group ($p < 0.05$).

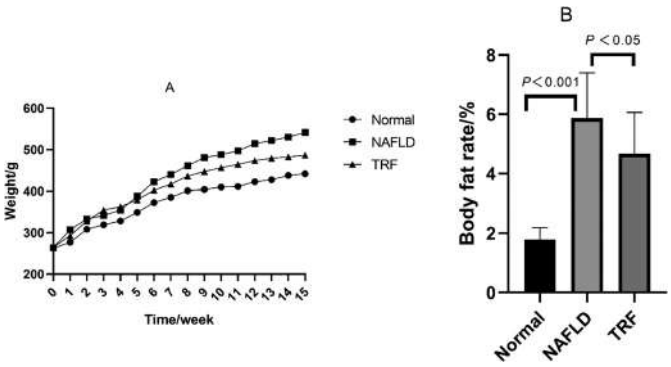

Figure 1: Physical characteristics of rats: (A) Body weight from 1 to 15 weeks (g); (B) body fat rate (%). The data are presented as means ± SD or the median.

Conclusion: Six hours of time-restricted fasting improves non-alcoholic fatty liver disease by regulating lipid synthesis and metabolism, without an excessive increase in triglyceride levels.

SAT123

Functionalizing novel cancer related genes in liver disease and liver regeneration

Nooshin Nourbakhsh[1,2], Torsten Wuestefeld[1,3,4], Agnes Bee Leng Ong[1], Rong Gao[1]. [1]*Genome institute of Singapore, In vivo genetics and gene therapy, Singapore, Singapore;* [2]*Yong Yoo Lin School of Medicine, National university of Singapore, Medicine;* [3]*National Cancer Centre Singapore, Singapore;* [4]*Nanyang Technological University, School of Biological Sciences, Singapore*
Email: nnourbakhsh@gis.a-star.edu.sg

Background and aims: Caloric abuse and an inactive lifestyle have led to a widespread obesity and metabolic syndrome epidemic. Non-alcoholic fatty liver disease (NAFLD) and non-alcoholic steatohepatitis (NASH) are considered to be the hepatic consequence of it. As NAFLD/NASH condition are highly prevalent and drives a growing incidence rate of HCC, it is considered to be an important and alarming health issue. The critical question how the combination of an inflammatory microenvironment, created by NAFLD/NASH, abnormal metabolism and ongoing liver regeneration contributes to DNA instability and as a consequence promotes cancer is still unanswered. By this project we aim to reveal new relevant biomarkers for early and easier detection, treatment stratification and monitoring as well as approaches to therapies for both prevention and treatment in people who are at high risk for presenting fatty liver associated HCC to improve human health border.
Method: We take advantage of *in vivo* functional genomics screen in a mouse model of progressive fatty liver disease (Choline deficient high fat diet) to address this question. We screened a mir30 based shRNA library targeting 1000 genes, which human orthologs showed dysregulation in cancer. Scoring shRNAs will be validated *in vitro* as well as *in vivo* for influencing cell proliferation, survival and transformation and further will investigate the underlying mechanism with the goal for therapeutic intervention in disease progression.
Results: Computational analysis of shRNA abundance comparing CDHFD vs normal chow group shows selective enrichment for a number for targets. *In vitro* Knockdown of target genes show significant increasing in cell proliferation compared to control group. Short listed targets proceed for *in vivo* validation in NASH mouse model as well as *in vivo* liver repopulation and regeneration assay.

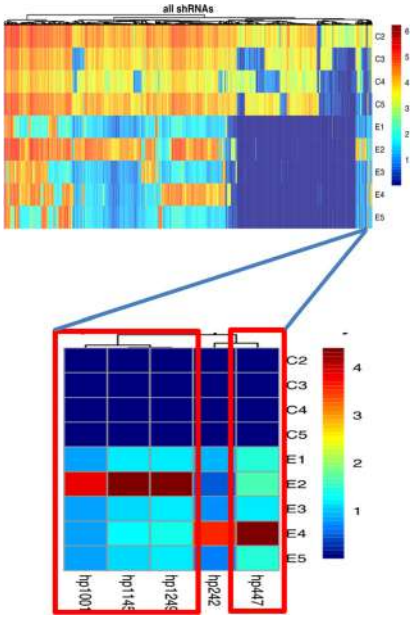

Figure: RNAi screen under CDHF diet, significant enriched shRNAs selected for in detail characterization.

Conclusion: In vivo functional genetic screen identifies new regulators of NASH related liver cancer development.

SAT124

Effect of long-term dietary intervention on liver pathology and markers of hepatocellular senescence in the GAN diet-induced obese mouse model of NASH

Kristoffer Voldum-Clausen[1], Denise Oró[1], Martin Rønn Madsen[1], Mathias Flensted-Jensen[2], Cecilie Holmegaard Andersen[2], Steen Larsen[2], Henrik B. Hansen[1], Michael Feigh[1]. *[1]Gubra, Hørsholm, Denmark; [2]Xlab, University of Copenhagen, Denmark*
Email: kristoffervc@gmail.com

Background and aims: Lifestyle change remains the first-line intervention for non-alcoholic steatohepatitis (NASH). This study aimed to evaluate long-term low-caloric dietary intervention on liver disease and markers of hepatocellular senescence in the GAN (Gubra-Amylin NASH) diet-induced obese (DIO) mouse model of NASH with hepatic fibrosis.
Method: Male C57BL/6 mice were fed the GAN diet high in saturated fat, fructose, and cholesterol for 34 weeks prior to study start. A liver biopsy was sampled 4-weeks prior to study start. Only animals with biopsy-confirmed steatosis (score ≥2) and fibrosis (stage ≥F1) were included and stratified into treatment groups. DIO-NASH mice were kept on the GAN diet or received dietary intervention by switching to chow feeding (chow-reversal) for 8, 16 or 24 weeks (n = 14–16 per group). Chow-fed C57BL/6J mice (n = 10) served as normal controls. Pre-to-post liver biopsy histology was performed for within-subject evaluation of NAFLD Activity Score and Fibrosis Stage. Terminal quantitative liver histology, RNA sequencing, blood and liver biochemistry was assessed. Liver senescence markers included p21 histomorphometry, mitochondrial respiratory capacity and gene expression signatures.
Results: Chow-reversal promoted substantial benefits on metabolic outcomes and liver histology, as demonstrated by robust weight loss, complete resolution of hepatomegaly, hypercholesterolemia, elevated transaminase levels and hepatic steatosis in addition to attenuation of inflammatory markers. Notably, all DIO-NASH mice demonstrated ≥2 point significant improvement in NAFLD Activity Score following dietary intervention. While not improving fibrosis stage, chow-reversal (≥16 weeks) reduced quantitative fibrosis markers (PSR, collagen 1a1, a-SMA). Notably, these changes were accompanied by improved liver mitochondrial respiration, complete reversal of p21 overexpression and partial reversal of hepatocellular senescence-associated gene expression signatures.
Conclusion: Chow-reversal substantially improved metabolic, biochemical, and histological hallmarks of fibrosing NASH. Interestingly, molecular signatures of hepatocellular senescence in GAN DIO-NASH mice were also improved following long-term low-caloric dietary intervention, making the model suitable for profiling emerging senotherapeutics targeting senescencent hepatocellular cells for the treatment of NASH.

SAT125

Fecal microbiota trasplant using endoscopic-placement hydrogel reduces liver fibrosis with no changes in steatosis in a rat model of steatohepatitis with fibrosis

Ramon Bartolí[1,2], Ignacio Iborra[1,3], Sandra Barbosa[4], Maria Doladé[5], Marta Fortuny[6], Helena Masnou[2,3], Rosa M Morillas[2,3]. *[1]Health Research Institute Germans Trias i Pujol (IGTP), Hepatology Unit. Gastroenterology Derpartment, Badalona, Spain; [4]Universitat Autònoma de Barcelona, Department of Cell Biology, Physiology and Immunology, Faculty of Veterinary Medicine, Bellaterra, Spain; [5]Hospital Germans Trias i Pujol, Clinical Analysis and Biochemistry Department., Badalona, Spain; [6]Hospital Germans Trias i Pujol, Gastroenterology Department, Badalona, Spain*
Email: rbartoli@igtp.cat

Background and aims: Intestinal microbiota (IM) has emerged as a key factor conditioning the development and progression of non-alcoholic fatty liver and although fecal microbiota transplant (FMT) has been proposed as a promising therapeutic strategy, effective colonization of the colon is difficult to achieve. Our group has developed an endoscopic placement hydrogel able to release substances (covergel) that used as a carrier could improve FMT. We aimed to assess the role of IM in the mechanisms leading to steatosis and fibrosis and to compare the efficacy of covergel for FMT delivery with single colonoscopy vs the standard-method, in a rat model of steatohepatitis with fibrosis.
Method: 24 rats were fed with a diet rich in fat/cholesterol/fructose throughout the study (15 weeks) and carbon tetrachloride was injected for 12 weeks (NASH rats). 6 rats (healthy controls) were standard chow fed. At week 12, feces were collected to: 1) assess microbiota phylogenetic profile, and 2) pooled and cryopreserved as "NASH feces" and "healthy feces" for FMT. At week 13, NASH rats were randomized in 3 groups and underwent FMT by single colonoscopy to receive: group 1: 0.5 ml of healthy feces in 3.5 ml of saline (standard method); group 2: 0.5 ml of healthy feces in 3.5 ml covergel (HF-covergel-FMT); group 3: 0.5 ml of NASH feces in 3.5 ml covergel.
Rats were euthanized at week 15 and fibrosis (Mason's Trichromic staining) and steatosis (Oil Red staining) degrees were assessed in liver samples. Plasma biochemical parameters were also quantified.

Results: In comparison to control rats, NASH rats didn't develop increased significant body weight gain but an increased in liver to body weight ratio was detected in NASH rats but not in HF-covergel-FMT rats. Levels of albumin, bilirubin, glucose, cholesterol and triglycerides were not altered in any group. ALT and phosphatase alkaline were significantly elevated whereas LDL and HDL-cholesterol significantly reduced in NASH rats. No differences were observed in phosphatase alkaline and LDL-cholesterol between HF-covergel-FMT and control rats.
Standard-FMT was not effective in reversing liver fibrosis, although a non-significant improvement was observed (group 1 vs group 3, p = 0.084). In contrast, HF-covergel-FMT was effective in reducing liver fibrosis (group 2 vs group 3; p = 0.001). Moreover, HF-covergel-FMT showed a significant improvement on fibrosis compared to standard-FMT (group 1 vs group 2; p = 0.034). FMT had no significant effect on steatosis.
Conclusion: HF-covergel-FMT significantly reduces liver to weight ratio, normalizes phosphatase alkaline and LDL-cholesterol and significantly reduces fibrosis without significant attenuation of the ongoing steatosis. The use of covergel would be an advantage, since the prolonged residence time of the hydrogel adhered to the mucosa would facilitate microorganism colonization with a single colonoscopy.

SAT126

Reversing diet-induced steatohepatitis and CCl4 induced fibrosis with AN1284 treatment

Rinat Abramovitch[1,2], Adi Yehezkel[2], Nathalie Nachmansson[1,2], Marta Weinstock[3]. [1]*Hebrew University-Hadassah Medical Center, The Wohl Institute for Translational Medicine, Jerusalem, Israel;* [2]*Hebrew University-Hadassah Medical Center, The Goldyne Savad Institute of Gene Therapy, Jerusalem, Israel;* [3]*Hebrew University, School of Pharmacy, Institute for Drug Research, Jerusalem, Israel*
Email: rinat@hadassah.org.il

Background and aims: Non-alcoholic fatty liver disease (NAFLD) is the leading cause of chronic liver disease that can progress to more aggressive non-alcoholic steatohepatitis (NASH). The molecular and metabolic changes occurring in the development and progression of NAFLD to NASH include oxidative stress, chronic hepatic inflammation and fibrosis. So far, there are no effective drug treatments for NASH. AN1284 is an indoline derivative that exhibits potent antioxidant and anti-inflammatory activities in mice with LPS-activated acute liver damage. The aim of the current study was to determine whether AN1284 could reverse steatosis and fibrosis in a mouse model of pre-existing NASH.
Method: The effect of chronic treatment with AN1284 (1 mg/kg/day) by mini-pumps on pre-existing hepatic steatosis and fibrosis, was examined in two mouse models: (I) western dietary (WD) induced NASH for 6 month and (II) CCl_4 induced liver fibrosis. RNA-Seq was used to assess whether changes in cellular processes that occur in human subjects with NASH exists in these mice, and whether they are reversed by AN1284 treatment.
Results: AN1284 treatment (1 mg/kg/day) significantly attenuated liver damage, reduced liver/body ratio, liver fat content and serum ALT levels in dietary induced NASH, and hepatic fibrosis in both models. RNA sequencing showed that the WD significantly elevated the hepatic pathways of steatosis, fibrosis, inflammation, oxidative stress and liver damage seen in human subjects. AN1284 reduced oxidative stress (iNOS) and fibrosis, in association with a decrease in collagen-4 and TGF-beta. RNA-Seq analysis revealed the altered pathways including FXR/RXR, fatty-acid synthase and inflammation (Fig).

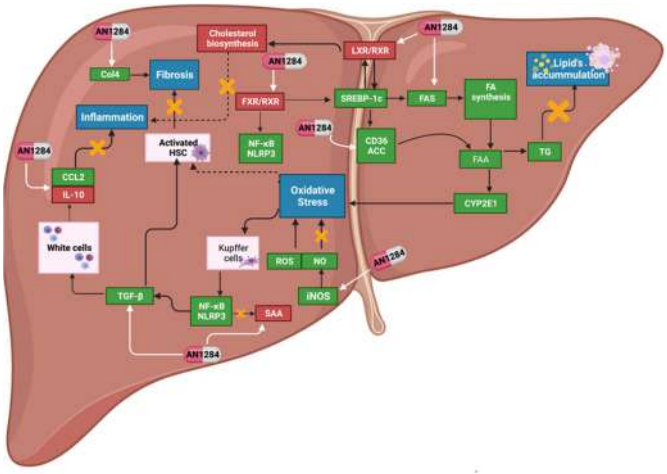

Figure: Summary of changes induced by AN1284 treatment to mice with WD-induced NASH. Up-regulated factors are shown in red and the down-regulated are shown in green.

Conclusion: The diet used in this study reproduced liver pathology in human subjects with NASH. Chronic AN1284 treatment reversed pre-existing steatosis and fibrosis by reducing several factors involved in disease development.

SAT127

Spontaneous and drug-induced histological changes in non-alcoholic steatohepatitis: an assessment by meta-analysis of trials

Grazia Pennisi[1], Ciro Celsa[1], Marco Enea[1], Marco Vaccaro[2], Vito Di Marco[1], Carlo Ciccioli[1], Giuseppe Infantino[1], Stefanie Parisi[1], Claudia La Mantia[1], Antonio Craxi[1], Calogero Camma[1], Salvatore Petta[1]. [1]*Section of Gastroenterology and Hepatology, Dipartimento Di Promozione Della Salute, Materno Infantile, Medicina Interna e Specialistica Di Eccellenza (PROMISE), Palermo, Italy;* [2]*2Dipartimento di Scienze Economiche, Aziendali e Statistiche, University of Palermo, 90133 Palermo, Italy*
Email: graziapennisi901@gmail.com

Background and aims: Non-alcoholic steatohepatitis (NASH) has a variable rate of progression, making the effect of investigational drugs difficult to assess and compare. In this study, we provide by meta-analysis a reference standard for histological progression of untreated NASH (patients receiving placebo), and perform a network meta-analysis to estimate the relative efficacy of investigational drugs for NASH.
Method: A comprehensive search of several databases was conducted to detect phase 2 and 3 randomized controlled-trials (RCTs) comparing pharmacological interventions in patients with non-cirrhotic NASH. Resolution of NASH without worsening of fibrosis or ≥1 stage reduction of fibrosis without worsening of NASH were evaluated as composite outcomes validated by Food and Drug Administration (FDA). Meta-analysis and meta-regressions were performed on placebo arms, and a network meta-analysis on interventions arms.
Results: A total of 15 RCTs met the eligibility criteria. The meta-analysis on untreated patients arms showed a pooled estimate rate of 17% (95% C.I. 12%-23%; I2 = 86%; p < 0.01) and of 21% (95% C.I. 13%-31%; I2 = 84%; p < 0.01) for resolution of NASH without worsening of fibrosis and ≥1 stage improvement of fibrosis without worsening of NASH, respectively. Phase 3 RCTs, older age and higher AST levels were associate to a lower rate of spontaneous improvement at univariate meta-regression analysis. By network meta-analysis, semaglutide and pioglitazone, alone or plus Vitamin E, had the highest ranking of effectiveness for NASH resolution without worsening of fibrosis (P-score 0.906, 0.890 and 0.826, respectively). Aldafermin, lanifibranor and obeticholic acid had the highest probability to achieve ≥1 stage of fibrosis improvement without

worsening of NASH (P-score 0.776, 0.773 and 0.711, respectively). When combining the two outcomes, lanifibranor, semaglutide and aldafermin were the most effective drugs.
Conclusion: Since semaglutide and pioglitazone appear to be more effective on NASH activity while aldafermin, lanifibranor and obeticholic acid perform better on the evolution of fibrosis, combination therapies should be assessed prospectively in subjects who are less likely to improve spontaneously over time, i.e. older patients with biochemically active disease.

SAT128

Synergistic activity of GLP-1 peptide analog XW003 and the long-lasting GIP receptor agonist XW017 in a diet induced obese mouse model

Xinle Wu[1], Haixia Zou[1], Bin Wang[1], Rui Zhu[1], Yan Li[1], Wanjun Guo[1], Catherine Jones[2], Martijn Fenaux[2]. *[1]Sciwind Biosciences, China; [2]Sciwind Biosciences, United States*
Email: catherine.jones@sciwindbio.com

Background and aims: Glucagon-like peptide-1 (GLP-1) and glucose-dependent insulinotropic peptide (GIP, also known as gastric inhibitory polypeptide) are small peptide hormones termed incretins. Incretins are produced by the gut following food intake and act to stimulate insulin secretion and lower blood sugar. Incretins have additional effects on the digestive tract, liver, pancreas, and central nervous system to maintain metabolic health. GLP-1 receptor agonists have shown promise for treating obesity, type 2 diabetes, and non-alcoholic steatohepatitis (NASH); GIP receptor agonists have the potential to work synergistically with GLP-1 agonists to enhance efficacy.
Method: We investigated GLP-1 peptide analog, XW003 (3 nmol/kg), alone or in combination with a long-lasting GIP peptide analog, XW017 (3, 10, 30, 100 nmol/kg), in the diet induced obese (DIO) mouse model. GLP-1 and GIP peptide analogs were dosed subcutaneously QD for 27 days (n = 6 animals per group). We also evaluated in parallel the activity of a dual GLP-1/GIP receptor agonist, tirzepatide (10 nmol/kg), in this mouse model.
Results: Treatment of mice with the GLP-1 analog XW003 alone resulted in mean body weight loss of 15.6% compared to baseline after 27 days of treatment. Treatment of mice with the GIP analog XW017 alone did not result in significant weight loss (0% compared to baseline at day 27). Combination of XW003 (3 nmol/kg) with XW017 showed an enhanced effect in inducing body weight loss compared to either peptide alone, with mean weight reductions of 24.6**%** (XW003 + 30 nmol/kg XW017) and 28.3% (XW003 + 100 nmol/kg XW017), respectively, at the end of treatment. In comparison to tirzepatide, combination of XW003 and XW017 showed comparable or higher levels of weight loss. At day 14, tirzepatide (10 nmol/kg) treatment resulted in a 25.8% weight reduction compared to baseline, while the animals treated with a combination of XW003 (10 nmol/kg) and XW017 (100 nmol/kg) produced a mean weight loss of 33.9%.
Conclusion: In conclusion, combinatory treatment of GLP-1 and GIP receptor agonists showed a synergistic effect on promoting weight loss in a mouse model of obesity.

SAT129

Preclinical pharmacology of low molecular weight GLP-1 receptor agonist XW014

Wanjun Guo[1], Xinle Wu[1], Haixia Zou[1], Bin Wang[1], Rui Zhu[1], Catherine Jones[2], Martijn Fenaux[2]. *[1]Sciwind Biosciences, China; [2]Sciwind Biosciences, United States*
Email: catherine.jones@sciwindbio.com

Background and aims: Glucagon-like peptide-1 (GLP-1) is a peptide hormone produced by the gut in response to food intake and then rapidly degraded. GLP-1 has multiple beneficial effects on metabolism, including delaying gastric emptying and increasing satiety, stimulating insulin secretion and lowering blood sugar, reducing liver fat, and promoting weight loss. GLP-1 peptide analogs have shown promise for treating obesity, type 2 diabetes, and non-alcoholic steatohepatitis (NASH). XW014 is a small molecule GLP-1 receptor agonist with improved oral bioavailability and cardiovascular safety. Here we evaluated XW014 in vitro and in vivo activity.
Method: GLP-1 receptor agonism was evaluated in vitro by assessing cAMP production in HEK-293 cells. cAMP production in cells treated for 30 minutes with XW014 or comparator was quantified by HTRF-based assay (Cisbio). C57BL/6 mice expressing humanized GLP-1 receptor were dosed with XW014 (50 mg/kg PO BID) or vehicle (n = 4 animals per group) for 4 days. Weight, cumulative food intake, post-prandial glucose, glucose tolerance, and insulin secretion were measured. Cynomolgus monkeys (n = 5) were given a single dose of XW014 (20 mg/kg PO). Intravenous glucose tolerance test (IVGTT) was performed 2 hours after oral dosing.
Results: XW014 showed potent GLP-1 receptor agonist activity in cell culture, with a mean EC_{50} value of 0.44 ± 0.2 nM. In mice expressing the human GLP-1 receptor, treatment with XW014 (50 mg/kg BID) for 4 days resulted in reduced blood glucose, food intake, and body weight. In cynomolgus monkey, treatment with a single dose of XW014 (20 mg/kg) resulted in improved blood glucose suppression and insulin response during IVGTT compared to baseline.
Conclusion: XW014 is a potent small molecule agonist of the GLP-1 receptor in vitro and induces effective target engagement in two preclinical models, humanized GLP-1 mice and cynomolgus monkeys. The results support the continued development of XW014 for the treatment of metabolic disease.

SAT130

Integrated transcriptomics of CRV431 treatment in a Phase 2a NASH trial confirms anti-fibrotic effect of pan-cyclophilin inhibition and identifies CRV431-specific biomarkers

Patrick Mayo[1], Stephen Harrison[2], Todd Hobbs[1], Daren Ure[1], Daniel Trepanier[1], Erin Foster[1], Caroline Zhao[1], Robert Foster[1]. *[1]Hepion Pharmaceuticals, Edison, United States; [2]Pinnacle Clinical Research, Austin, United States*
Email: pmayo@hepionpharma.com

Background and aims: The progression of liver fibrosis in Non-Alcoholic Steatohepatitis (NASH) has been directly linked to increased mortality and morbidity. To date, numerous drug candidates have failed to show a significant benefit in fibrotic end points for NASH patients enrolled in clinical trials. CRV431, a non-immunosuppressive pan-cyclophilin inhibitor has demonstrated pleotropic effects well-suited for the treatment of NASH and fibrosis. A new transcriptomic analysis was performed to further elucidate the action of CRV431 in subjects with biomarker defined F2/F3 NASH and explore transcriptomic markers for clinical responsivity.
Methods: RNA sequencing data was obtained from 27 patients with biomarker confirmed F2/F3 NASH participating in a 28-day, Phase 2a trial of CRV431 (NCT04480710). Subjects were administered CRV431 75 mg, 225 mg, or placebo orally once daily for 28 days. RNA was stabilized and isolated from whole blood on Day 1 and Day 28. RNA sequencing transcripts were evaluated using FastQC, with quantification in Salmon v1.4.0. Differential expression analysis (DEA) was performed using edgeR. Co-expression networks were constructed using weighted gene co-expression network analysis (WGCNA). DEA was combined with WGCNA to enhance the discriminating ability of highly related genes as potential biomarkers. Functional enrichment was performed using clusterProfiler and GeneWalk, followed by key hub gene selection.
Results: Consistent with pre-clinical models, CRV431 down-regulated several collagen genes including COL6A5 (log2Fold = – 2.2, p = 0.04), COL7A1 (log2Fold = – 4.7, p = 0.0052), COL8A2 (log2Fold = – 4.8, p = 0.00076), COL13A1 (log2Fold = – 2.4, p = 0.02), COL18A1 (log2Fold = – 3.1, p = 0.03). WGCNA analysis identified separate gene modules where CRV431 regulated C6M ($r = 0.72$, $p < 10^{-200}$), ProC3 ($r = 0.78$, $p < 10^{-200}$) and ALT ($r = 0.59$, $p = 8.9 \times 10^{-136}$) production. The ProC3 module demonstrated involvement in collagen

regulation (COL4A2, COL6A2) while the ALT-module demonstrated a mixture of collagen (COL13A1, COL18A1, COL7A1), anti-inflammatory (IL1RL2, IL17RB) and regulatory effects on cholesterol and ceramide biosynthesis. The C6M module included genes linked to inflammatory and immune responses (IL17RE, IL31RA, IL32, IL7R, LOXL2).
Conclusion: Integrated transcriptomic analysis confirmed anti-fibrotic and anti-inflammatory effects of CRV431 in NASH subjects and suggested regulation of cholesterol and ceramide biosynthesis. Potential biomarker panels were identified to predict ProC3, ALT, and C6M responsivity to CRV431. A paired biopsy Phase 2b study will be conducted to investigate the link of this biomarker panel to NASH histopathology.

SAT131

Pharmacokinetic (PK) and pharmacodynamics (PD) of BIO89-100, a novel glycoPEGylated FGF21, in non-alcoholic steatohepatitis (NASH) patients with compensated cirrhosis

Naim Alkhouri[1], Will Charlton[2], Hank Mansbach[2], Maya Margalit[3], Kemal Balic[2], Leo Tseng[2,4]. *[1]Arizona Liver Health; [2]89bio, Clinical Development, San Francisco, United States; [3]89bio, Clinical Development, Herziiya, Israel; [4]89bio, Clinical Development, San Francisco*
Email: leo.tseng@89bio.com

Background and aims: BIO89-100 is a long-acting glycoPEGylated analogue of fibroblast growth factor 21 (FGF21) in development for the treatment of non-alcoholic steatohepatitis (NASH) and severe hypertriglyceridemia. PK/PD of BIO89-100 was previously characterized in a multiple-ascending dose (MAD) study in noncirrhotic NASH patients (fibrosis stage F1-3). This phase 1 study was designed to characterize the PK/PD properties of BIO89-100 in adult patients with compensated cirrhosis from NASH (F4) and evaluate the effect of cirrhosis on BIO89-100 PK/PD.
Method: This Phase 1, open-label, single-center study in the USA enrolled a total of 8 adult patients with diagnosed compensated cirrhosis (F4) due to NASH based on Liver Forum criteria. Patients received a single 30 mg dose liquid formulation of BIO89-100 via subcutaneous (SC) injection on Day 1. Blood samples for PK and PD assessments were collected before and at predetermined timepoints after BIO89-100 administration. PK parameters were estimated using a non-compartmental approach. As part of exploratory objectives, PD end points from the lipid panel (i.e., triglycerides [TGs], total cholesterol, low-density lipoprotein cholesterol [LDL-C] and high-density lipoprotein cholesterol [HDL-C]) were evaluated as the absolute change and percent change from baseline to Day 8. PK/PD data were consequently compared to historic findings from the MAD study.
Results: A prespecified interim PK/PD analysis was conducted using data from the first 6 patients for PK and all 8 patients for PD. The majority of patients were female (62.5%); mean age was 53.3 years; mean BMI was 37.4 kg/m^2; mean VCTE was 28.9 kPa. Following a single 30 mg SC dose in patients with F4 fibrosis, BIO89-100 serum concentration declined in a monophasic fashion with the mean elimination half-life of 62 hours consistent with previous studies. PK exposure differences in F4 patients in this study vs. F1-3 patients in the MAD study were negligible and within a clinical PK variability. Simulated PK profiles using already developed popPK model based on F1-3 data adequately described the F4 PK (Figure). Moreover, BIO89-100 had a robust effect compared to baseline on serum TGs (up to 44% reduction), HDL-C (up to +55% increase), and LDL-C (up to 29% reduction) on Day 8 in patients with F4 NASH. A favorable safety and tolerability profile was observed in this study.

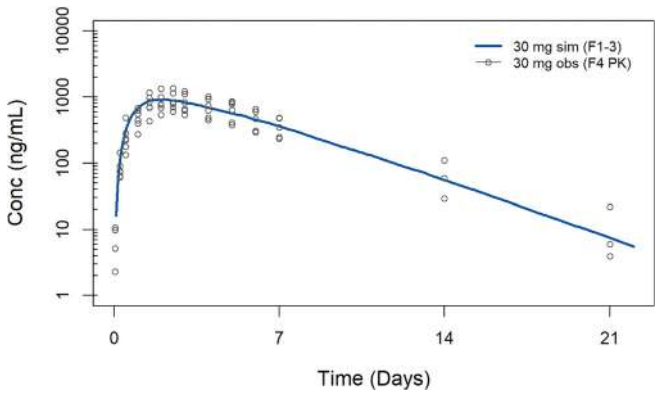

Figure: Simulated (F1-F3) vs. Observed PK Profiles from F4 Patients.

Conclusion: The interim PK/PD data indicate BIO89-100 elicits a robust PK/PD effect independent of NASH fibrosis stage. These findings highlight the feasibility of achieving favorable treatment outcomes in F4 patients with compensated hepatic function without requiring dose adjustment. Overall, these PK/PD properties warrant further investigation to allow assessments of effectiveness of BIO89-100 in a larger F4 population.

SAT132

HEC96719, a novel tricyclic farnesoid X receptor agonist for treatment of non-alcoholic steatohepatitis: results of preclinical study and phase I trial

Shengtian Cao[1,2], Xinye Yang[1], Liting Dai[1], Jing Li[1], Ying Jun Zhang[1], Xiaojun Wang[1], Yan Wang[2]. *[1]Sunshine Lake Pharma Co Ltd, HEC Pharm Group, HEC Research and Development Center, Dongguan, China; [2]Southern Medical University, Biomedical Research Center*
Email: yanwang@i.smu.edu.cn

Background and aims: Current options for therapeutic treatment of NASH are limited. FXR is an effective target modulating important pathways in NASH liver. Here we report the development, preclinical study and phase I trial of HEC96719 a novel tricyclic non-steroidal FXR agonist to identify its potential for NASH treatment.
Method: We designed a series of compounds with structural basis of a prior high-affinity nonsteroidal molecule GW4064. Among these compounds, we identified the ones with no toxicity and higher activity in *in vitro* and *in vivo* models. Then, we tested their distribution and bioavailability in animal models and determined their treatment effect on NASH mice. For the selected compound with the most favorable properties, *i.e.* HEC96719, we further analyzed its effect on FXR in terms of selectivity and efficacy, and determined its efficacy in various animal models of NASH and liver fibrosis in comparison with obeticholic acid. With supporting data, a phase I trial was then performed in 184 healthy participants at different centers to test the safety, tolerability, pharmacokinetics and surrogate activity of HEC96719 (NCT04546984, NCT04422496, NCT04194242).
Results: We successfully designed several compounds with potent activities and high efficacies on FXR. HEC96719 has a high selectivity for FXR according to the profiling assays with a panel of enzymes, ion channels, nuclear receptors, and G-protein coupled receptors. HEC96719 has a 150-fold higher agonistic potency on FXR than GW4064 and has a good bioavailability and stability. Its distribution in liver and ileum can be respectively 19-fold and 208-fold higher than that in plasma, indicating high effectiveness to sustain FXR activation and FGF15/19 expression. HEC96719 shows better therapeutic efficacy in NASH and liver fibrosis animal models than obeticholic acid. In the healthy participants, HEC96719 was well-tolerated at maximum dose and no severe adverse events were observed. Significant changes of FGF19 and bile acid synthetic intermediate were detected. Their levels were proportional to the increased exposure dosage of HEC96719.

Conclusion: These data on pharmacokinetic properties, efficacy and safety profiles overall indicate that HEC96719 is a promising drug candidate for NASH treatment. Planned clinical studies are warranted to further evaluate these effects.

SAT133

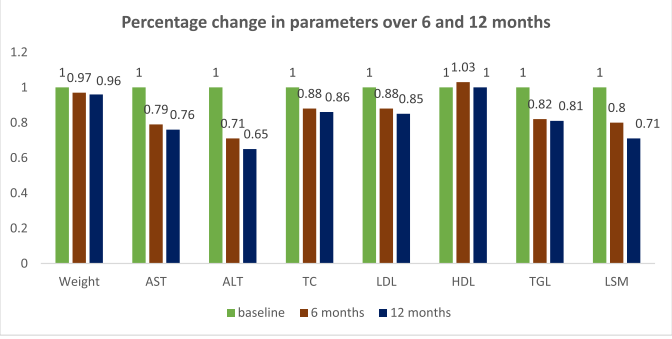
Effect of saroglitazar in reducing liver enzymes and liver stiffness in non-alcoholic fatty liver disease: a single arm prospective study

Avisek Chakravorty[1], Swetha Sattanathan[2], Krishnadas Devadas[2].
[1]Government Medical College Thiruvananthapuram, Medical Gastroenterology, thiruvananthapuram, India; [2]Government Medical College Thiruvananthapuram, Medical Gastroenterology, thiruvananthapuram, India
Email: avisek.doc@gmail.com

Background and aims: Non-Alcoholic Fatty Liver Disease (NAFLD) is fast becoming the leading cause of cirrhosis worldwide. But the pharmacotherapy of Non-Alcoholic Steatohepatitis (NASH)) remains elusive. This trial was conducted to study the effects of the dual peroxisome proliferator- activated receptor (PPAR) agonist Saroglitazar (approved by Drugs Controller General of India for NASH) on liver fibrosis, transaminases and lipid profile in NAFLD patients

Method: Investigator initiated single arm prospective observational study. Consecutive patients of NAFLD (2016 EASL Clinical Practice Guidelines) with raised transaminases and liver stiffness (LSM) ≥7 kPa (by Transient Elastography) were started on Tab Saroglitazar 4 mg daily. Patients with pregnancy and lactation were excluded. AST/ALT, Lipid profile and LSM were measured at baseline, 6 months and 1 year

Results: 90 patients were started on Saroglitazar. Data was analysed for all patients at 6 months and for the 57 patients who completed 1 year of therapy. At 6 months and 1 year, there was a significant reduction in transaminases (20.8% and 23.6% reduction for AST, 29.5% and 35.4% reduction for ALT, p = 0.00006). Mean liver stiffness reduced from 11.6 kPa at baseline to 9.4 at 6 months and 8.3 at 12 months (21.5% and 28.7% reduction, respectively, p = 0.000001). For those with advanced liver fibrosis at baseline (TE ≥9.9 kPa), the reduction in LSM was 28.2% and 36% at 6 and 12 months, respectively. Total cholesterol, Low density lipoproteins (LDL) and triglycerides reduced significantly (14.5%, 15.3% and 18.6% respectively at 1 year, p < 0.05). No significant difference in High density lipoproteins (HDL) could be found. Significant weight reduction was noted at 6 and 12 months compared to baseline (3.3% and 3.9% reduction respectively, p = 0.00004). No serious adverse effects were noted in any of the patients while on therapy.



Conclusion: Saroglitazar seems to be a promising option for reduction of liver stiffness and transaminitis in NAFLD. Whether there is similar effect on liver histology has to be proven by biopsy-based studies.

SAT134

Intrahepatic microcirculation disorders and hyperammoniemia and their correction at non-alcoholic steatohepatitis patients with initial stages of liver fibrosis

Tatiana Ermolova[1]. *[1]North-western state medical university named after I.I.Mecnnikov, Internal Medicine and Faculty, St.-Petersburg, Russian Federation*
Email: t.v.ermolova@mail.ru

Background and aims: Ammonia is new therapeutic target for chronic liver diseases. Some experimental studies demonstrated, that ammonia increases of activity of hepatic stellate cells, stimulating liver fibrogenesis, impairs liver microcirculation, and these processes are reversible after the using of hypoammoniemic medicines. Aims of our study are to estimate blood level of ammonia, intrahepatic microcirculation and efficacy of ornithine (Hepa-Merz) for correction of such disorders at the chronic liver diseases.

Method: We investigated 56 non-alcoholic steatohepatitis (NASH) and 45 HCV patients with initial fibrosis 0–1 stages. Level of ammonia was estimated by biochemical method (PocketChem BA, Arcray, Japan) in capillary blood at the patients and 37 healthy individuals (control), normal ammonia level is less than 60 umol\L. Intrahepatic hemodinamics are determined by polyhepatography (PHG)-modificated hepatic impedansometry, non-invasive method for integral estimation of intrahepatic blood flow by checking of tissue resistance to weak electric current. PHG registers a blood flow in projection of zone of hepatic right, left lobes and spleen, integral body impedansography. For correction of blood flow disorders we used hypoammoniemic drug ornithine (Hepa-Merz) in dosage 3 grams 3 times daily 4 weeks. Efficacy of LOLA we looked in 2 and 4 weeks via the control PHG and control of ammonia.

Results: Analysis of PHG demonstrated, that at all patients we revealed a liver microcirculation disorders- increased blood resistance, abnormal forms and amplitude of waves in sinusoidal level (out flow zone) at NASH patients and presinusoidal level (inflow zone) at viral patients. Level of ammonia in the NASH patients was 137.2 umol/L, in control group-49.3 umol/L (p <0.01). Hyperammoniemia was higher at the NASH patients, compared with viral patients higher (102.3 umol) (p <0.01). Analysis of efficacy of Hepa-Merz showed, that it was effective for correction of hepatic hemodinamic disorders at all patients, in 2 weeks of the treatment we observed normalization or improvement of the wave form, in 4 weeks-wave amplitude. Level of ammonia was decreased in 2 weeks.

Conclusion: NASH patients with initial stages of liver fibrosis are characterized by hyperammoniemia, which is more pronounced in comparison with viral hepatitis. NASH is accompanied by disorders of intrahepatic microcirculation disorders in out flow zone. LOLA improved liver microcirculation and decreases of blood ammonia level at the NASH and HCV patients.

SAT135

Ticagrelor, but not clopidogrel, attenuated hepatic steatosis in a model of non-alcoholic fatty liver disease

Hyunwoo Oh[1], Hyo Young Lee[1], Huiyul Park[2], Dae Won Jun[3], Eileen Yoon[3], Sang Bong Ahn[4], Chul-min Lee[5], Mi Mi Kim[5], Bo-Kyeong Kang[5], Joo Hyun Sohn[6]. *[1]Uijeongbu Eulji Medical Center, Department of Medicine, Gyeonggi-do, Korea, Rep. of South; [2]Uijeongbu Eulji Medical Center, Department of Family medicine, Gyeonggi-do, Korea, Rep. of South; [3]Hanyang University College of Medicine, Department of Medicine, Seoul, Korea, Rep. of South; [4]Nowon Eulji Medical Center, Eulji University School of Medicine, Department of Medicine, Seoul, Korea, Rep. of South; [5]Hanyang University College of Medicine, Department of Radiology, Seoul, Korea, Rep. of South; [6]Hanyang University Guri Hospital, Hanyang University College of Medicine, Department of Medicine, Gyeonggi-do, Korea, Rep. of South*
Email: bliss153@hanmail.net

Background and aims: Several studies have suggested that platelets are associated with inflammation and may play an important role in

hepatic inflammation. We tried to evaluate whether antiplatelet drugs could improve non-alcoholic fatty liver disease (NAFLD).
Method: Mice were fed a high-fat diet (HFD) to establish an NAFLD model, which was verified through pre-study liver biopsy at 18 weeks. Animals with an NAFLD activity score (NAS) ≥4 were randomized into HFD-only, clopidogrel (CLO; 35 mg/kg/day), and ticagrelor (TIC; 40 mg/kg/day) groups, which were then treated with the respective drug for an additional 15 weeks. Liver and blood samples were collected from all animals at 33 weeks.
Results: The TIC group, but not the CLO group, showed significantly lower degree of steatosis and NAS than the HFD group (HFD: 5.3 ± 0.9, CLO: 4.6 ± 0.7, TIC: 3.4 ± 1.2; p = 0.0047). Hepatic *de novo* lipogenesis markers (SREBP1c, FAS, SCD1, and DGAT2 expression) and mRNA expression of inflammatory markers only decreased significantly in the TIC treatment group. Endoplasmic reticulum (ER) stress markers (CHOP, Xbp1, and GRP78) also decreased significantly in the TIC group, but not in the CLO group. Nile red staining intensity decreased in HepG2 cells following TIC treatment. Hepatic *de novo* lipogenesis markers were decreased significantly in HepG2 cells after TIC treatment.
Conclusion: TIC, but not CLO, attenuated steatosis and NAS via inhibiting fat *de novo* synthesis as well as ER stress in the biopsy proven NAFLD animal model.

SAT136
Lemon balm extract ALS-L1023, an angiogenesis inhibitor, inhibits liver fibrosis in a non-alcoholic fatty liver disease model

Hyo Young Lee[1], Hyunwoo Oh[1], Eileen Yoon[2], Dae Won Jun[2], Sang Bong Ahn[3], Huiyul Park[4], Bo-Kyeong Kang[5], Mi Mi Kim[5], Chul-min Lee[5], Joo Hyun Sohn[6]. *[1]Uijeongbu Eulji Medical Center, Department of Medicine, Gyeonggi-do, Korea, Rep. of South; [2]Hanyang University College of Medicine, Department of Medicine, Seoul, Korea, Rep. of South; [3]Nowon Eulji Medical Center, Eulji University School of Medicine, Department of Medicine, Seoul, Korea, Rep. of South; [4]Uijeongbu Eulji Medical Center, Department of Family medicine, Gyeonggi-do, Korea, Rep. of South; [5]Hanyang University College of Medicine, Department of Radiology, Seoul, Korea, Rep. of South; [6]Hanyang University Guri Hospital, Hanyang University College of Medicine, Department of Medicine, Gyeonggi-do, Korea, Rep. of South*
Email: novabless@gmail.com

Background and aims: ALS-L1023 is an ingredient extracted from *Melissa officinalis L.* (Labiatae; lemon balm), which grows wild in Europe and the Mediterranean. ALS-L1023 is also known as a natural medicine that suppresses angiogenesis. Herein, we aimed to determine whether ALS-L1203 could alleviate non-alcoholic fatty liver disease (NAFLD).
Method: C57BL/6 wild-type male mice (age, 6-weeks-old) were fed a choline-deficient high-fat diet for 10 weeks to induce NAFLD. Two doses (a low dose, 8 g/kg/day; and a high dose, 12 g/kg/day) of the lemon balm extract, ALS-L1023, were selected and mixed with feed for administration. RNA sequencing was performed for the choline-deficient high-fat diet group, ALS-L1023 responder group, and ALS-L1023 non-responder group.
Results: There was no significant difference between the groups in mean final body weight or food intake. Biochemical analysis revealed that the ALS-L1023 low-dose group had significantly decreased alanine transaminase and aspartate transaminase compared to the choline-deficient high-fat diet group. Based on Sirius red staining, the area of fibrosis significantly decreased due to the administration of ALS-L1023, and the anti-fibrotic effect of ALS-L1023 was greater than that of obeticholic acid. RNA sequencing was performed after mice were divided into responder and non-responder groups. The responder group had lower expression of genes related to the hedgehog-signaling pathway than the non-responder group.
Conclusion: ALS-L1023 may exert anti-fibrotic effects in the NAFLD model.

SAT137
Hepatocyte-specific JNK signaling is protective during progression of NASH

Julia Piche[1], Ines Volkert[1], Marius Maximilian Woitok[1], Tobias Otto[1], Christian Trautwein[1]. *[1]Uniklinik RWTH Aachen, Aachen, Germany*
Email: jpiche@ukaachen.de

Background and aims: The prevalence of non-alcoholic fatty liver disease, ranging from steatosis to non-alcoholic steatohepatitis (NASH), is increasing in developed countries. Mechanism leading to progression towards end-stage cirrhosis and hepatocellular carcinoma (HCC) are incompletely understood.
The c-Jun N-terminal kinases (JNKs) play a crucial role in liver physiology and disease pathogenesis. In the present study, we aimed to investigate the relevance of hepatocyte-specific Jnk1 and Jnk2 inhibition in two experimental NASH models.
Method: NASH was induced by feeding animals a Western-style diet (WSD) or a Choline-deficient high fat diet (CD-HFD) to compare disease development between wild-type (WT) and mice with a hepatocyte-specific deletion of Jnk1 and Jnk2 (JNK1/2$^{\Delta hepa}$).
Results: WSD and CD-HFD triggered significantly increased serum transaminases, as well as enhanced steatosis in JNK1/2$^{\Delta hepa}$ compared to WT animals. Inflammation as evidenced by increased infiltration of immune cells, especially leukocytes and monocyte-derived macrophages, was significantly higher in JNK1/2$^{\Delta hepa}$ mice. This was further strengthened by strongly increased liver cytokine and chemokine levels as well as an increased oxidative stress response. Furthermore, fibrogenesis was strongly increased in JNK1/2$^{\Delta hepa}$ animals. Analysis of cell death mechanism revealed strongly increased apoptotic cell death, while necroptosis and pyroptosis was not changed. Thus, we generated JNK1/2$^{\Delta hepa}$/caspase 8 $^{\Delta hepa}$ animals and could show that the phenotype was rescued following WSD feeding.
Conclusion: Our results demonstrate that deletion of Jnk 1 and Jnk2 in hepatocytes increases NASH progression. Specifically, an increase in apoptotic cell death is crucial in mediating this effect. Thus, blocking caspase 8 in hepatocytes during an increased stress response may represent a promising therapeutic strategy for NASH.

SAT138
Semaglutide use in adjunct to multidisciplinary lifestyle interventions improves weight and body composition in NAFLD patients

Rochelle Wong[1], Steven Mathews[1], Carolyn Newberry[2], Sonal Kumar[2]. *[1]New York Presbyterian Hospital, Medicine, New York, United States; [2]Weill Cornell Medicine, Medicine, New York, United States*
Email: sok9028@med.cornell.edu

Background and aims: Non-alcoholic fatty liver disease (NAFLD) is an increasingly prevalent cause of liver disease as obesity rates continue to rise. Recent studies have shown that semaglutide in adjunct to lifestyle intervention is beneficial in treating weight and metabolic syndrome-related comorbidities such as type 2 diabetes (T2DM). Here we describe our single center experience with semaglutide in NAFLD patients.
Method: Patients with NAFLD per transient elastography seen in our multidisciplinary gastroenterology clinic between 2019 and 2021 who were initiated on semaglutide were included. All patients also underwent lifestyle counselling from a team of gastroenterologists, dietitians, and endocrinologists. Primary outcomes were measured by change in weight, body composition analysis via dual bioelectrical impedance analysis, liver chemistries such as alanine aminotransferase (ALT), and metabolic markers such as hemoglobin A1c (HbA1c) and lipid profile in patients on medication for >3 months. Paired t-tests were used for analysis.
Results: Seventy-two patients were prescribed semaglutide. Eleven discontinued due to side effects. Thirty-two were on semaglutide for <3 months at time of analysis. Thirty-three were maintained on semaglutide for at least 3 months and included in the analysis. Of this

cohort, 22 (66.7%) had T2DM, 7 (21.2%) had prediabetes, 5 (15.2%) were overweight, and 24 (72.3%) were obese with BMI >30. All 33 had follow-up labs, 20 with follow-up body composition analysis, and 10 with follow-up transient elastography. Median maximum semaglutide dose was 1.0 mg (IQR 0.5–1.0 mg) with median length of follow-up 281 days (range 92–921 days) after semaglutide initiation. Average weight loss achieved at follow-up was 8.45% ($p = 0.001$, Figure 1). Other body composition parameters such as visceral fat area (VFA) (-7.64%, $p = 0.01$), percent body fat (−3.46%, $p = 0.03$), and truncal segmental fat mass (−7.52%, $p = 0.01$) also significantly improved. ALT significantly decreased (−17.5 U/L, $p = 0.04$) along with other metabolic parameters HbA1c (−0.7, $p = 0.03$). Nausea was the most common adverse event.

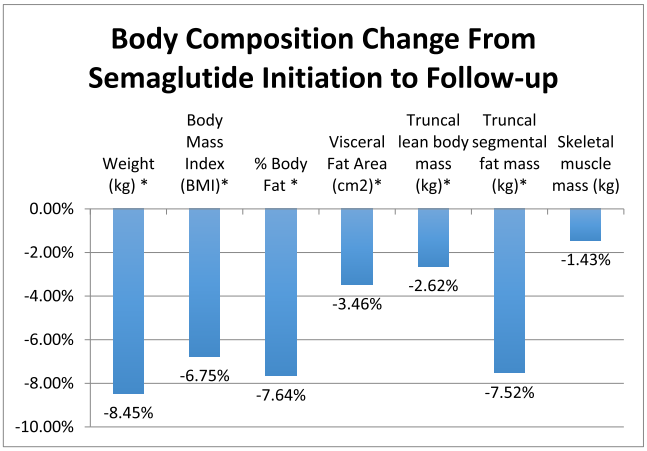


Figure: * indicates $p < 0.05$

Conclusion: Our study is consistent with prior findings of semaglutide achieving clinically significant weight loss when used in combination with lifestyle modifications, and overall being well-tolerated. Semaglutide was also associated with improved body fat distribution parameters, including VFA, which is most associated with cardiometabolic risk factors and metabolic syndrome, given its anatomic location around the internal organs and hyperlipolytic activity. Improving VFA with semaglutide may improve the dysmetabolic profile of NAFLD patients. Further investigation is needed to evaluate the impact of these weight and body composition improvements on cardiovascular outcomes and overall morbidity and mortality.

SAT139

Pegozafermin improved liver histology, liver-related non-invasive tests (NITs) and metabolic profiles in an open-label cohort of a Phase 1b/2a study in subjects with non-alcoholic steatohepatitis (NASH)

Rohit Loomba[1], Naim Alkhouri[2], Don Lazas[3], Pierre Bedossa[4,5], Linda Morrow[6], Shibao Feng[7], Leo Tseng[7], Germaine D. Agollah[7], Will Charlton[7], Hank Mansbach[7], Maya Margalit[8], Stephen Harrison[9]. [1]*UCSD NAFLD Research Center, La Jolla, CA, United States;* [2]*Arizona Liver Health, Tucson, AZ, United States;* [3]*Digestive Health Research/ ObjectiveHealth, Nashville, TN, United States;* [4]*Liverpat, Paris, France;* [5]*Newcastle University, Institute of Translational Research, Newcastle, United Kingdom;* [6]*Prosciento Inc., San Diego, CA, United States;* [7]*89bio Inc., San Francisco, CA, United States;* [8]*89bio Inc., Herzliya, Israel;* [9]*Pinnacle Clinical Research, San Antonio, TX, United States*
Email: maya.margalit@89bio.com

Background and aims: Pegozafermin (PGZ), a long-acting glycoPEGylated recombinant human FGF21 analog, had significant liver-related and cardiometabolic benefits, with favorable safety and tolerability, in a Phase 1b/2a study in NASH.

Method: In this open label cohort, 20 subjects with biopsy-proven NASH (NAS ≥4, fibrosis stage F2/F3) received SC PGZ 27 mg QW for 20 weeks. Key end points were histology [≥2-point improvement in NAS with ≥1 point improvement in ballooning or inflammation; NASH resolution without worsening of fibrosis, and ≥1 stage fibrosis improvement without worsening of NASH], and safety and tolerability at week 20 (W20). Change in liver fat and liver and metabolic markers were also assessed. Biopsies were read by one central reader.
Results: BL characteristics included (means): Age 58.4 years, BMI 37.0 kg/m^2, NAS 5.3 points, MRI-PDFF 21.1%, ALT 47.1 U/L, ProC3 19.3 ng/ml and Fibroscan™ VCTE score 14.3 kPa. 75% of subjects were female, 85% had T2DM, and fibrosis stage was F3 in 65% and F2 in 35% of subjects. 19/20 subjects completed treatment and had W20 biopsies. At W20, 74% of subjects had ≥2 pt reduction in NAS (mean absolute change −2.4 pts); 32% and 26% had NASH resolution without fibrosis worsening and improved fibrosis without NASH worsening, respectively. There was a consistent improvement in NITs that assess fibrosis compared to BL [VCTE score −4.6 kPa (-31%; $p < 0.001$), FAST score −0.47 (−76%; $p < 0.001$)), FIB4 −0.29 (−19%; $p < 0.01$) and ProC3 −4.3 ng/ml (−20%; $p < 0.001$). 88% of subjects with BL FAST scores in the 'rule-in' or 'indeterminate' range had 'rule-out' FAST scores (≤0.35) at W20. At W20, mean relative reduction in MRI-PDFF was 65% ($p < 0.001$), and 100% and 79% of subjects had ≥30% and ≥50% reductions, respectively. ALT decreased by 46% compared to BL ($p < 0.001$); mean absolute decrease in ALT was −27.8 U/L in subjects with elevated ALT at BL, and ALT decreased ≥17 U/L in 71% of these subjects. At W20, significant improvement in HbA1c and lipids, weight loss and increased adiponectin were observed in PGZ-treated subjects. PGZ was safe and well tolerated. There were no deaths, related SAEs or discontinuations due to AEs. Treatment related AEs reported in ≥10% of subjects included diarrhea, nausea, vomiting, injection site bruising, injection site erythema and decreased appetite; there were no reports of AEs grade ≥3, hypersensitivity, tremor or adverse effects on vital signs.
Conclusion: PGZ (27 mg QW for 20 weeks) led to meaningful changes in key histology end points and fibrosis-related NITs, reduction in MRI-PDFF and decreased ALT in a cohort of NASH subjects with advanced fibrosis. In addition to these benefits on liver health, PGZ significantly improved metabolic parameters, with good safety and tolerability. These results extend the growing evidence of PGZ's potential as treatment for NASH. PGZ is currently being evaluated in NASH in the ongoing Phase 2b ENLIVEN study.

SAT140

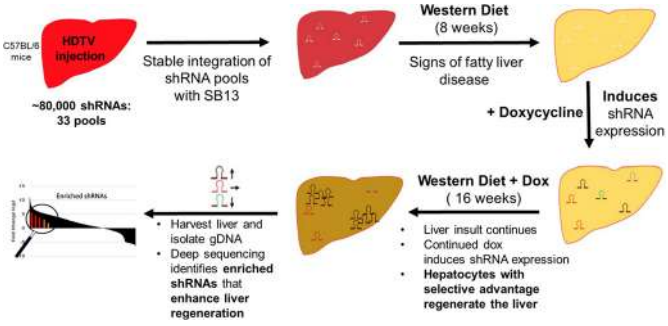
Identification of new therapeutic targets for hepatic regenerative medicine in Non-Alcoholic Fatty Liver Disease (NAFLD)

Shainan Hora[1], Rong Gao[1], Viktoriia Iakovleva[1], Agnes Bee, Leng Ong[1], Torsten Wuestefeld[1]. [1]*Genome Institute of Singapore, Laboratory of In vivo Genetics and Gene Therapy, Singapore, Singapore*
Email: Shainan_Hora@gis.a-star.edu.sg

Background and aims: Non-alcoholic fatty liver disease (NAFLD) has emerged as the most common cause of chronic liver disease in the recent years. The massive growth in NAFLD cases is being fueled by an increase in global over-nutrition and obesity. Despite this, NAFLD continues to be an underdiagnosed disease with no current approved treatment and only a handful of drugs in clinical trials. A number of strategies are being employed to reverse this end-stage liver disease, including our unbiased genome wide *in-vivo* functional genetic screen that aims to identify novel regulators of NAFLD and shed light on hepatic regenerative therapy.
Method: Western diet animal model that recapitulates NAFLD in conjunction with RNAi-based functional genetic screen was used to identify gene targets in NAFLD. Specifically, shERWOOD-UltramiR shRNA library targeting the whole mouse genome was shuttled into a transposon-based inducible vector system, followed by hydrodynamic tail vein (HDTV) injections into animal liver. To recapitulate the fatty liver phenotype, mice were fed western diet supplemented

with high fructose. Following diet treatment for 8-weeks, doxycycline was added to induce shRNA expression enabling gene knockdown, along-with western diet for another 16 weeks. Animal livers were harvested, primary NGS analysis was performed and abundance of each shRNA was determined using differential expression analysis method. Top enriched shRNAs were down-selected using a stringent criterion (95% confidence interval with a 4-fold change), validated using a series of experiments *in-vitro* and injected into fumarylacetoacetate hydrolase (FAH)-knockout animals to study liver repopulation following diet treatment.

Results: We have identified several shRNAs that confer a negative or positive effect on the regenerative capacity of hepatocytes when subjected to detrimental environment such as high fat diet. Top enriched shRNAs have been validated using various *in-vitro* assays followed by selection of top scoring shRNAs for their impact on fatty liver disease phenotype using *in-vivo* animal models. Furthermore, we have identified some of the known markers of NAFLD that further validates the authenticity of our screen.



Conclusion: RNAi-based functional genetic screen in combination with high-throughput sequencing will allow the identification of new gene targets and uncover new insights underlying NAFLD development and disease progression.

SAT141

The effects of dietary vitamin E intake on NAFLD and sex differences in serum metabolic profile

Eleonora Scorletti[1], Kate Townsend Creasy[2], Marijana Vujkovic[2], Daniel Rader[1,2], Kai Markus Schneider[3], Carolin Victoria Schneider[1].
[1]University of Pennsylvania, Department of Medicine, Philadelphia, United States; [2]University of Pennsylvania, Department of Genetics, Philadelphia, United States; [3]University of Pennsylvania, Department of Microbiology, Philadelphia, United States
Email: eleonora.scorletti@pennmedicine.upenn.edu

Background and aims: Non-alcoholic fatty liver disease (NAFLD) is characterised by the accumulation of lipid droplets in hepatocytes and affects approximately 20–30% of the general population. Currently, there are no approved pharmacological agents available to treat NAFLD. Growing evidence supports the potential benefits of vitamin E in reducing steatosis and lobular inflammation in nondiabetic patients with NAFLD. Despite previous trials tried to assess the efficacy of vitamin E supplementation in patients with NAFLD, there remains a lack of understanding on the effects of vitamin E. Further, there are reported sex differences in NAFLD etiology and severity, although they have been poorly described.

Method: We analyzed the UK Biobank (UKB) dataset and selected our study population based on the availability of nutritional assessment. We investigated the association between dietary vitamin E intake with various disease phenotypes, serum metabolites and NAFLD prevalence.

Results: Data from >210, 000 participants demonstrate that increased dietary vitamin E intake was associated with a lower prevalence of NAFLD and overall mortality. Each standard deviation (SD = 7 mg) vitamin E increase per kJ energy intake was associated with reduced the risk of NAFLD ICD-10 diagnosis by 12.5% ($p < 0.0001$) and a reduced risk of MRI diagnosis of NAFLD by 24.3% ($p < 0.0001$). Additionally, we found sex differences in the effect of dietary vitamin E on metabolic profiles. Analysis of serum metabolites showed a greater reduction in gamma-glutamyl transferase (GGT) ($p < 1 \times 10^{-92}$) and urate ($p < 1 \times 10^{-68}$) in males, and a greater increase in sex hormone binding globulin (SHBG) in females ($p < 1 \times 10^{-15}$) (Figure 1).

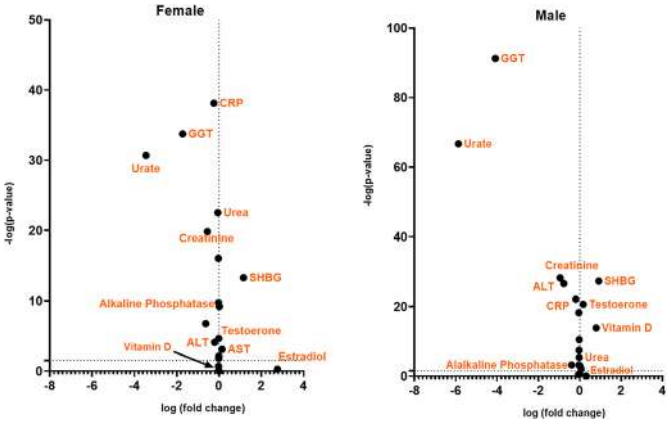


Figure 1: Volcano plot of serum metabolites in males and females.

Conclusion: Our study showed that increased dietary vitamin E intake may be beneficial for preventing NAFLD. Moreover, we found sex differences in the effects of dietary vitamin E on serum metabolic profiles. More randomized clinical trials are needed to identify suitable candidates for vitamin E supplementation in NAFLD patients. [UKB dataset reference number 71300]

SAT142

Favorable safety profile of TERN-201, a highly selective inhibitor of vascular adhesion protein-1, in the non-alcoholic steatohepatitis phase 1b AVIATION study

Mazen Noureddin[1], Eric Lawitz[2], Naim Alkhouri[3], Robert Jenders[4], Douglas Denham[5], Bal Raj Bhandari[6], Christopher Jones[7], Cara H. Nelson[7], Tonya Marmon[7], Swapna Shenvi[7], Hiba Graham[7], Daria Crittenden[7], Erin Quirk[7], Diana Chung[7]. *[1]Cedars-Sinai Medical Center, Cedars-, Sinai Fatty Liver Program, Los Angeles, United States; [2]Texas Liver Institute, San Antonio, United States; [3]Arizona Liver Health, Tucson, United States; [4]Velocity Clinical Research, La Mesa, United States; [5]Clinical Trials of Texas, LLC, San Antonio, United States; [6]Delta Research Partners, Monroe, United States; [7]Terns Pharmaceuticals, Foster City, United States*
Email: equirk@ternspharma.com

Background and aims: TERN-201, an irreversible inhibitor of vascular adhesion protein-1 (VAP-1) with >7000-fold selectivity over monoamine oxidase A or B, has demonstrated sustained target engagement in healthy human subjects. VAP-1 levels are elevated in non-alcoholic steatohepatitis (NASH) patients with fibrosis. Here we report results from Part 1 of the TERN-201, Phase 1b AVIATION trial in patients with NASH.

Method: Part 1 of the two-part AVIATION trial was a double-blind, placebo-controlled study (NCT04897594) in 30 adults with non-cirrhotic NASH phenotype evaluating 10 mg TERN-201 once daily (QD) for 12 weeks followed by off-treatment evaluation at Week 16. The prespecified Part 1 interim analysis primary end point was safety assessed by adverse events (AEs) and laboratory tests; percent change from baseline (BL) in plasma VAP-1 activity was a secondary end point. Exploratory imaging and blood-based biomarkers of liver inflammation and fibrosis were also assessed.

Results: Thirty patients, mean age 49.7 years, 22 (73.3%) women, 4 (13.4%) non-whites, mean (±SD) alanine aminotransferase (ALT)

67.25 (±31.25) U/L, liver stiffness (LS) 8.68 (±2.03) kPa by transient elastography, multiparametric magnetic resonance liver imaging (MRI) corrected T1 (cT1) 899.9 (±110.2) msec and proton density fat fraction 17.6% (±7.5%) were randomized 2:1 to receive 10 mg TERN-201 or placebo. Nearly all patients (28/30, 95% of TERN-201 and 90% of placebo) completed Part 1. No patient discontinued due to any AE. 10 mg TERN-201 was well-tolerated with a similar incidence of AEs as placebo. All AEs were mild or moderate with no serious AEs or trends in AEs or laboratory abnormalities reported. 10 mg TERN-201 resulted in >98% inhibition of plasma VAP-1 activity in most subjects by Week 2 and sustained suppression through Week 12. There were no statistically significant differences between placebo and 10 mg TERN-201 in change from BL cT1, liver fat fraction, liver enzymes, or cytokeratin-18. At Week 12, tissue inhibitor of metalloproteinase-1 (TIMP1), a marker of hepatic fibrogenesis, decreased by 29.58 (±9.26) ng/ml in the TERN-201 group and increased by a mean (± SE) of 13.56 (±14.22) ng/ml in the placebo group relative to BL ($p < 0.05$).

Conclusion: TERN-201 was well-tolerated with a safety profile similar to placebo in patients with BL multiparametric MRI and LS values indicating NASH with at least stage 2 fibrosis. While 10 mg TERN-201 led to near complete inhibition of plasma VAP-1 activity and decreased levels of the hepatic fibrogenesis marker TIMP1, no statistically significant differences were observed between TERN-201 and placebo on markers of liver inflammation and injury following 12 weeks of treatment. Overall, these data support further assessment of safety and activity of 20 mg TERN-201 in the ongoing Part 2 of the AVIATION Trial in phenotypic NASH.

SAT143

Pegozafermin led to significant metabolic benefits, in addition to robust beneficial effects on the liver, in an open-label cohort of a Phase 1b/2a study in subjects with non-alcoholic steatohepatitis (NASH)

Naim Alkhouri[1], Rohit Loomba[2], Juan P Frias[3], Linda Morrow[4], Shibao Feng[5], Leo Tseng[5], Germaine D. Agollah[5], Will Charlton[5], Hank Mansbach[5], Maya Margalit[6], Stephen Harrison[7]. *[1]Arizona Liver Health, Tucson, AZ, United States; [2]USCD NAFLD Research Center, La Jolla, CA, United States; [3]National Research Institute, Los Angeles, CA, United States; [4]Prosciento Inc., San Diego, CA, United States; [5]89bio Inc., San Francisco, CA, United States; [6]89bio Inc., Herzliya, Israel; [7]Pinnacle Clinical Research, San Antonio, TX, United States*
Email: maya.margalit@89bio.com

Background and aims: Metabolic derangements are key drivers of NASH and significant risk factors for cardiovascular (CV) morbidity and mortality in NASH patients, that increases with advancing fibrosis. While treatments for NASH would ideally address both liver injury and metabolic derangements in this population, metabolic liabilities have been a drawback in several NASH drug development programs. Pegozafermin (PGZ), a long-acting glycoPEGylated recombinant human FGF21 analog in development for NASH, significantly improved liver and cardiometabolic parameters, with favorable safety and tolerability, in a Phase 1b/2a study in NASH.

Method: In this open label cohort, 20 subjects with biopsy-proven NASH (NAS ≥4, fibrosis stage F2/F3) received SC PGZ 27 mg QW for 20 weeks. Key end points included histology, safety and tolerability. Change in hemoglobin A1c (HbA1c), body weight (BW), triglycerides (TG), non-HDL cholesterol (non-HDL-C), LDL cholesterol (LDL-C) and adiponectin was assessed at Week 20 (W20).

Results: Baseline (BL) characteristics (means) included age 58.4 years, HbA1c 6.6%, BW 104.6 kg, BMI 37.0 kg/m^2, TG 170.0 mg/dL, non-HDL-C 125.9 mg/dL, LDL-C 92.0 mg/dL, HDL-C 43.4 mg/dL and adiponectin 3.55 µg/ml. 75% of subjects were female, and 85% had T2DM. 16/19 (84%) subjects who completed treatment took ≥1 anti-diabetic agent (range 1–4 medications, including 15 on metformin and 5 on GLP-1 receptor agonists). 11/19 subjects were treated with statins. At W20, significant improvement in glycemic control, BW and lipid parameters were observed. HbA1c decreased by −0.5% ($p < 0.001$) in the overall population. In subjects with BL HbA1c ≥6.5% (N = 10; mean BL HbAlc = 7.3%), who were taking an average of 2 anti-diabetic agents, HbA1c decreased by −0.9%, to a mean of 6.4% ($p < 0.01$). BW decreased by −3.9% ($p < 0.001$). Adiponectin increased by 88.1% ($p < 0.001$). TG decreased by 26% in the overall population, and by 32% in subjects with elevated TG at BL (N = 11, mean BL TG 210 mg/dL; $p < 0.001$ for both comparisons). Non-HDL-C and LDL-C decreased by 18% ($p < 0.001$) and 13% ($p < 0.05$), respectively, and HDL-C increased by 23% ($p < 0.001$). Mean changes in serum lipids in subjects treated with statins were: TG-29.0%; non-HDL-C −22.1%; LDL −16.2% and HDL-C +35.4%.

Conclusion: PGZ (27 mg QW for 20 weeks) led to meaningful reduction in HbA1c and body weight and significant improvement in serum lipids in a cohort of mostly diabetic NASH subjects with advanced fibrosis and significant metabolic derangements, many of whom were already on treatment for diabetes, hyperlipidemia or both. These benefits were additive to robust beneficial effects on liver histology and favorable safety and tolerability, and suggest a potential of PGZ to protect subjects with NASH not only from liver related outcomes, but also from CV risk. PGZ is currently being evaluated in NASH subjects (NAS ≥4, F2-F3) in the ongoing Phase 2b ENLIVEN study.

SAT144

Novel thyroid hormone receptor-beta agonist TG68 safely induces hepatic fat reduction in a non-alcoholic steatohepatitis rat model

Andrea Marco Caddeo[1], Marta Anna Kowalik[1], Marina Serra[1], Simona Rapposelli[2], Amedeo Columbano[1], Andrea Perra[1]. *[1]Cagliari, Department of Biomedical Sciences, Monserrato, Cagliari, Italy; [2]University of Pisa, Department of Pharmacy, pisa, Italy*
Email: andrea.perra@unica.it

Background and aims: Non-alcoholic fatty liver disease (NAFLD) encompasses a broad spectrum of hepatic pathological conditions ranging from simple steatosis to non-alcoholic steatohepatitis (NASH), in absence of alcohol abuse or hepatic viral infections. Patients affected by NASH can develop fibrosis, cirrhosis and, eventually, hepatocellular carcinoma (HCC). Despite the raising interest in finding a strategy for this condition, no pharmacological approaches have been approved for the treatment of NAFLD. In this respect, thyroid hormones (THs) regulate hepatic lipid metabolism by binding thyroid hormones receptors beta (TRβ) in the liver. Alteration of the hepatic TH signaling takes part of the rise and development of liver-associated diseases, such as NAFLD and HCC. To date, the use of THs as therapeutic approach is hindered by the lack of selectivity and adverse extrahepatic side effects, mainly due to their affinity for extrahepatic TRα receptors.

Method: To selectively activate TRβ, we designed and synthesized a novel TRβ agonist, namely TG68. Rats were fed a high fat diet (HFD) *ad libitum* for 25 weeks, and then animals received orally TG68 (2.8 mg/kg) for three weeks. Blood serum and tissues, including liver, heart and kidney, were collected and analysed after sacrifice.

Results: Blood analysis showed reduced circulating glucose, triglycerides, and cholesterol. Three week-treatment of TG68 significantly reduced liver weight as well as the liver weight/body weight ratio due to an increased fatty acid beta-oxidation and hydrolysis rates highlighted by the overexpression of *Cpt1a* and *Pnpla2,* respectively. Furthermore, TG68 strongly reduced hepatic fat accumulation and ameliorates liver injury in the absence of extrahepatic toxic effects.

Conclusion: Rats fed a HFD and treated orally with TG68 for the last three weeks before sacrifice, ameliorated liver weight/body weight ratio and intrahepatic neutral lipid content. This study strongly suggests that TG68 is an innovative hepatospecific TRβ agonist, whichmight be used as a future therapeutic tool for the treatment of NAFLD.

SAT145

Safety and pharmacokinetics (PK) of single and multiple ascending oral doses of ALG-055009, a thyroid hormone receptor beta agonist for the treatment of non-alcoholic steatohepatitis (NASH), in healthy volunteers and subjects with hyperlipidemia

Hakim Charfi[1], Jean-Louis Pinquier[1], Benedetta Massetto[2], Kha Le[2], Christopher Westland[2], Kusum Gupta[2], Lawrence Blatt[2], Sushmita Chanda[2], John Fry[2], Matt McClure[3]. *[1]Biotrial, Rennes, France; [2]Aligos Therapeutics Inc, South San Francisco, United States; [3]Aligos Therapeutics Inc, South San Francisco, United States*
Email: bmassetto@aligos.com

Background and aims: Thyroid hormone receptor beta (THR-β) agonists rapidly reduce atherogenic lipids such as low-density lipoprotein cholesterol (LDL-C) and triglycerides in serum and the liver, decrease hepatic fat content and improve liver histology. Therefore, therapeutics targeting THR-β represent a promising mechanism of action to treat patients with NASH. ALG-055009, a novel oral thyroid hormone analogue with high THR-β selectivity and nanomolar potency, is being assessed in a first-in-human study (NCT05090111).
Method: In Part 1 of this multi-part, double blind, randomized, placebo-controlled study, multiple cohorts of 8 healthy volunteers (HV) received single ascending doses of ALG-055009 or placebo (3:1 ratio). In Part 2, multiple cohorts of 10 subjects with mild hyperlipidaemia (LDL-C >110 mg/dL) receive a daily (QD) dose of ALG-055009 or placebo (4:1) for 14 days. Adverse events (AE), vital signs, electrocardiogram (ECG), laboratory parameters, including thyroid stimulating hormones, lipids, sex hormone binding globulin (SHBG), and plasma and urine PK samples are collected. Reported here are the available preliminary blinded safety and PK data in HV from the first five cohorts in Part 1 and the first cohort in Part 2. Pharmacodynamic results and data from additional cohorts will be included at the time of the presentation.
Results: Forty HV and 10 subjects with hyperlipidaemia were enrolled in Part 1 Cohorts 1–5 (0.1 mg, 0.3 mg, 0.9 mg, 2.6 mg, 4 mg) and Part 2 Cohort 1 (0.3 mg), respectively. All HV were male with a mean age of 38 years and a mean body mass index (BMI) of 25 Kg/m^2. Subjects with hyperlipidaemia were mostly male (90%) with a mean age of 41 years, a mean BMI of 27 Kg/m^2, and a mean LDL-C of 143.1 mg/dL. All 50 participants completed the study. No serious AE has been reported and no AEs have resulted in premature study drug discontinuation. Seven HV (17.5%) and 3 subjects with hyperlipidaemia (30%) experienced at least one treatment emergent AE (TEAE). All TEAEs were mild or moderate in severity and without dose response. Overall, TEAEs observed in more than 1 subject were: headache (N = 2); rhinopharyngitis (N = 2); insomnia (N = 2). All treatment emergent lab abnormalities were Grade 1, except for two subjects (N = 1 in Part 1 Cohort 4; N = 1 in Part 2 Cohort 1) who experienced a transient asymptomatic Grade 2 lipase elevation that resolved spontaneously by the following visit. No clinically significant changes in thyroid hormones or SHBG were observed. There were no clinically significant changes in vital signs or ECGs. Plasma ALG-055009 exposures increased dose proportionally between 0.1 and 2.6 mg dose levels (4 mg PK pending), with low variability (CV<36%) and ~1.7-fold accumulation following 14 daily doses.
Conclusion: Single doses of ALG-055009 of up to 4 mg and multiple daily 0.3 mg doses for 14 days were well tolerated with a favourable PK profile.

SAT146

A meditarranean diet intervention has beneficial effects on biomarkers of cardiovascular risk and hepatic fibrosis in non-alcoholic fatty liver disease (NAFLD)

Background and aims: Lifestyle interventions are the mainstay of non-alcoholic fatty liver disease (NAFLD) management. We assessed the feasibility and effectiveness of a Mediterranean diet (MD) intervention on patients stratified according to *PNPLA3* rs738409 I148M carriage.
Method: 49 participants with NAFLD were recruited from a tertiary hepatology centre in the UK. In a cross-over design, participants completed Diet 1 (MD) and Diet 2 (control) for 4 weeks, in random order (1:1 allocation), separated by a 4-week washout period. Participants completed one-to-one diet and lifestyle consultations at baseline, end of diet phase 1, end of washout and end of diet phase 2. Participants were advised to maintain baseline levels of physical activity and body weight. At each of these time points we assessed; anthropometry; biochemistry, markers of cardiovascular risk (CVR) and biomarkers of hepatic fibrosis.

Changes in physical, biochemical and dietary intake measures after 4-weeks of a MD intervention (n=48)

Participant Characteristics	Baseline	Post-MD Intervention	P-Value
Age (years)	60.0 (52.3- 68.8)		
Sex (n, % male)	22 (45.8%)		
PNPLA3 rs738409 (n, %) CC CG GG	 21 (44.7%) 14 (29.8%) 12 (25.5%)		
Anthropometrics			
Weight (kg)	93.5 (83.5-109.5)	93.2 (82.0-109.1)	<0.001
BMI (kg/m^2)	35.3 ± 5.5	34.7 ± 5.4	<0.001
Waist circumference (cm)	114.6 ±13.8	112.7 ±13.3	0.002
Body composition (kg): Fat free mass	53.2 (46.8-63.4)	53.9 (45.8-63.1)	0.027
Cardiometabolic measures			
Blood pressure: Systolic (mmHg) Diastolic (mmHg)	138.9 ± 16.4 83.2 ± 9.8	132.8 ± 14.5 79.1 ± 8.5	0.013 0.004
Fasting glucose (mmol/L)	6.7 (5.7-9.6)	6.5 (5.5-7.8)	0.017
HOMA-IR	5.2 (3.6-10.3)	4.3 (3.1-6.8)	0.017
Total cholesterol (mmol/L)	4.5 ± 1.2	4.1 ± 1.2	<0.001
Triglycerides (mmol/L)	1.5 (1.1-2.1)	1.4 (1.1-2.1)	0.011
HDL (mmol/L)	1.3 (1.1-1.5)	1.2 (1.0-1.4)	0.044
TC:HDL ratio	3.2 (2.7-4.1)	3.1 (2.5-4.0)	0.006
Non-HDL (mmol/L)	3.2 ± 1.2	2.8 ± 1.2	<0.001
Liver function			
Albumin (g/L)	45 (43-48)	46 (44-48)	0.024
ALP (IU/L)	89 (77-113)	85 (71-101)	0.014
Hepatic fibrosis			
PRO-C3 (ng/mL)	15.5 (11.4-21.3)	13.5 (10.8-20.1)	0.032
Dietary intake			
MEDAS (0-14)	5.7 ± 1.9	9.0 ± 2.1	<0.001

Values are means (SD), medians (IQR), or numbers (percentages)

Results: Retention of participants was high (n = 48, 98%). At 4 weeks MD adoption significantly increased from low to moderate (mean increase, 3.3 points; from 5.7 ± 1.9 at baseline to 9.0 ± 2.1) as assessed by MD assessment score. There was no change in physical activity and

weight loss was minimal. However, increased MD adoption was associated with significantly improved CVR, minor improvements in liver biochemistry (as measured by albumin and ALP) and significantly improved biomarkers of hepatic fibrosis (as measured by PRO-C3). Effects on CVR were most evident in wildtype *PNPLA3* than carriers of the I148M variant.

Conclusion: We have demonstrated the preliminary feasibility and effectiveness of a MD intervention, which rapidly improved CVR profile with evidence of early benefits on hepatic fibrosis. Carriers of the I148M variant appear to gain less benefit in terms of CVR factors when prescribed a MD intervention. Further validation in larger experimental studies are planned.

Liver development, physiology and regeneration

SAT151

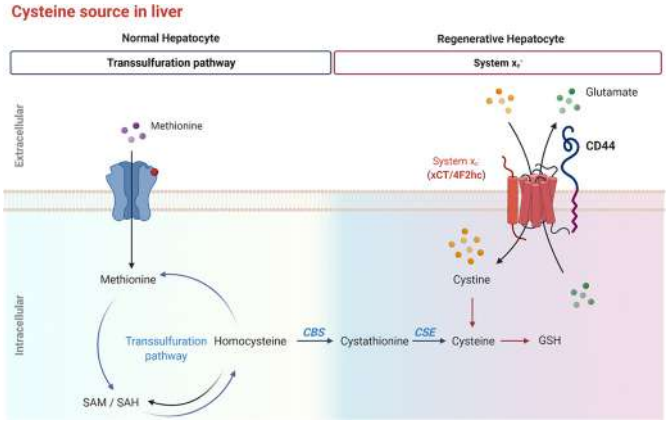
CD44 plays critical role in liver regeneration through enhanced redox balancing

Wan Seob Shim[1], Hyun Young Kim[1], Keon Wook Kang[1], Sang Kyum Kim[2]. [1]*Seoul National University, College of Pharmacy and Research Institute of Pharmaceutical Sciences, Seoul, Korea, Rep. of South;* [2]*Chungnam National University, Daedeok Campus, College of Pharmacy, Daejeon, Korea, Rep. of South*
Email: kwkang@snu.ac.kr

Background and aims: Liver regeneration triggered by fulminant liver damage accompanies proliferation of hepatic progenitor cells (HPCs). Thus, there has been considerable interest in identifying specific HPC markers. However, the physiological role of HPC markers during liver regeneration is not fully understood. Herein, we identify the mechanistic roles of cluster of differentiation (CD)44, a cell surface marker for hepatic regeneration, in HPC proliferation and redox homeostasis.

Method: Liver regeneration was induced by liver resection or injection of 250 mg/kg acetaminophen. The activity of the system x_c^- antiporter was measured using an extracellular glutamate assay and universal $^{13}C_6$-cystine isotope tracing. Lentiviral Albp-shCD44 (LV-GFP-Albp-mCD44-shRNA) delivery system (a construct comprising the gene encoding shCD44 from the albumin promoter) was used to produce hepatocyte-specific CD44 knockdown mice.

Results: After liver resection or exposure to acetaminophen, the CD44 expression level was elevated in mouse primary hepatocytes isolated from regenerative liver tissues. Flow cytometry data identified HPCs, a subpopulation of hepatocytes with a high CD44 expression level and proliferation rate. To elucidate the role of CD44 in HPC proliferation, we knocked it down in AML12 cells. Knockdown of CD44 decreased the expression of xCT as well as the uptake of extracellular cystine through system x_c^-. CD44 ablation resulted in a diminished intracellular cysteine, glutathione (GSH), and a decreased proliferation rate. The proliferation of HPC isolated on a hyaluronic acid-coated dish was highly sensitive to inhibition of system x_c^-. Administration of system x_c^- inhibitor abrogated liver regeneration after acetaminophen (N-acetyl-*p*-aminophenol; APAP)-induced liver injury. Moreover, liver regeneration following APAP injection was significantly inhibited in hepatocyte-specific CD44 knockdown mice.



Conclusion: The obtained results delineate the central role of CD44 in modulating liver-regenerative capacity. Specifically, CD44 contributes to the intracellular redox balance and cell proliferation by enhancing extracellular cystine uptake through system x_c^-.

Development of ECM mimicking 3D-hydrogel scaffolds for liver tissue engineering

Nathan Carpentier[1], Sara Campinoti[2], Luca Urbani[2], Peter Dubruel[1], Sandra Van Vlierberghe[1]. [1]*Ghent University-Campus Sterre-S4, Gent, Belgium;* [2]*Institute of Hepatology, King's College Hospital, United Kingdom*
Email: Nathan.carpentier@ugent.be

Background and aims: Annually, millions of people die because of liver failure, while the waiting duration for a donor liver is around 12 months. Herein, we target hybrid 3D-printed scaffolds to serve liver tissue engineering (LTE) applications.

As starting materials gelatin in combination with a polysaccharide was used to develop printable hydrogels. As polysaccharides dextran (Dex) and chondroitin sulphate (CS) were selected as mimics for the liver extracellular matrix (ECM) to explore their effect on the cell response. Methacrylated gelatin (GelMA) served as benchmark. The hydrogel materials were characterized on 2D-as well as on 3D-level. HepG2 cells were used to assess the in vitro biocompatibility of the developed hydrogels.

Method: Thiolated gelatin (GelSH) was crosslinked with the norbornene-functionalized polysaccharides DexNB and CSNB. Gelatin was methacrylated using methacrylic anhydride (GelMA) as reference material.

The different materials were characterized on both 2D- and 3D-level to assess the physico-chemical properties and the biocompatility. 3D-hydrogel scaffolds of the materials were developed by indirect 3D-printing.

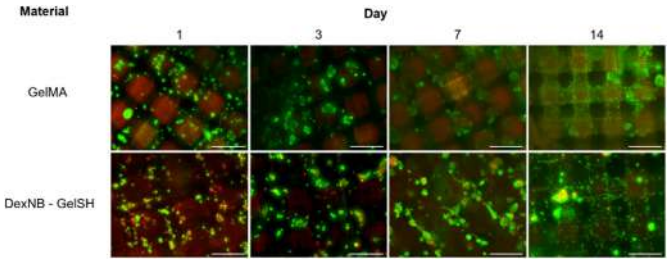
Results: DexNB-GelSH and CSNB-GelSH were superior over GelMA as their crosslinking kinetics were significantly faster and they mimicked natural liver tissue (NLT) to a greater extent with respect to physico-chemical properties. The swelling ratio of GelMA, DexNB-GelSH and CSNB-GelSH were all in line with NLT.

Atomic Force Microscopy (AFM) measurements revealed superior microscale mechanical properties of the DexNB-GelSH compared to the other materials that deviated more from NLT.

On a 3D-level, DexNB-GelSH scaffolds exhibited a compressive modulus of (4.8 ± 1.6)kPa which is in excellent agreement with that of NLT (i.e. 1–5kPa) as compared to GelMA which resulted in a modulus of (8.5 ± 1.9)kPa and CSNB-GelSH (12.6 ± 1.9)kPa.

So far, the biocompatibility of DexNB-GelSH and GelMA were compared. However, the in vitro biocompatibility of both materials was comparable based on the MTS assay. The live-dead staining showed that the cells grew more into clusters on the DexNB-GelSH

scaffolds compared to the more spread morphology which the cells exhibited on the GelMA material.



Conclusion: DexNB-GelSH and CSNB-GelSH scaffolds are promising hybrid materials to support LTE as they exhibit similar physico-chemical properties compared to NLT (cfr. microscale stiffness, compressive modulus, swelling ratio and chemical composition), while cell viability and proliferation of the hepatocytes were preserved.
In future research, different cell types such as primary hepatocytes and organoids will be included in the biological evaluation. Furthermore decellularized liver ECM will be incorporated into the hydrogel material in order to improve the cell interactivity and proliferation.

SAT153
Three-dimensional conditions in a perfusion bioreactor to support maturation of human amnion epithelial stem cells into functional hepatocyte-like cells

Sara Campinoti[1], Negin Goudarzi[1,2], Bruna Almeida[1], I. Jane Cox[1], Roberto Gramignoli[3], Luca Urbani[1,2]. *[1]The Roger Williams Institute of Hepatology, London, United Kingdom; [2]King's College London, Faculty of Life Sciences and Medicine, United Kingdom; [3]Karolinska Institutet, Department of Laboratory Medicine, Sweden*
Email: luca.urbani@researchinliver.org.uk

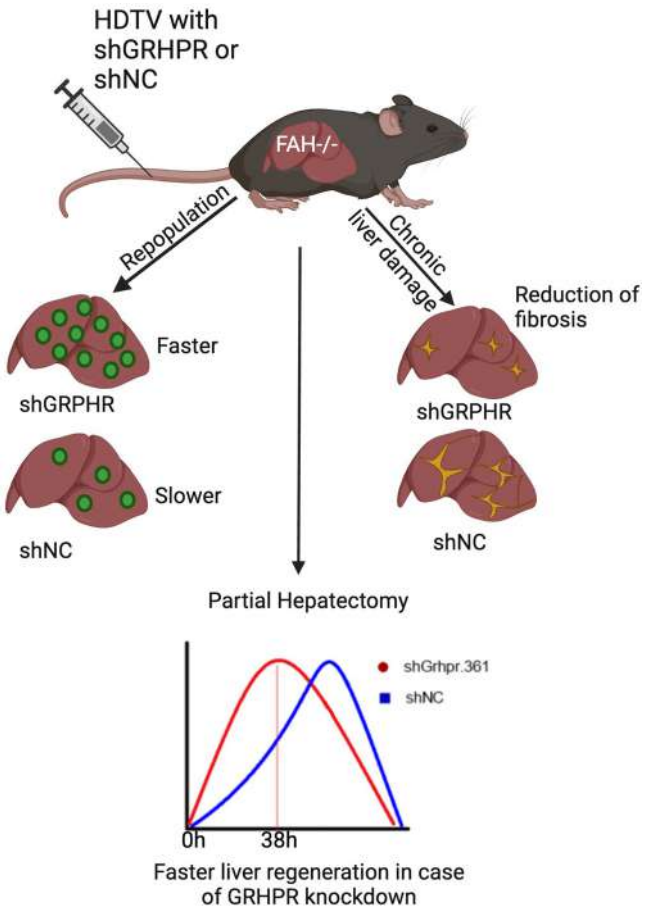
Background and aims: Organ or hepatocyte transplantation are efficient treatments for end stage liver disease, but limited by the shortage of donors. Bioengineered liver transplant is a promising approach, but requires functional liver cells. Perinatal stem cells are promising alternative source of somatic cells. We previously validated epithelial cells isolated from full-term amnion membranes (AEC) as therapeutic strategy to reverse congenital liver disorders or rescue subjects from hepatic failure. AEC cells can mature into hepatocyte-like cells in vivo, supporting their use in regenerative medicine. Decellularized liver extracellular matrix scaffolds (ECM-scaffolds) maintain matrix components and the 3D architecture and can be used to support hepatic maturation and function in vitro. We combined ECM-scaffold technology with primary human AEC and evaluated cell proliferation and functional maturation into hepatocyte-like cells.
Method: primary human AEC were isolated in accordance with current Good Manufacturing Practice (cGMP) and qualified by flow cytometric and biomolecular analysis. Approx. $30–40 \times 10^6$ AEC from every donor were seeded into rat ECM-scaffolds generated in our lab. The constructs were cultured in custom-made bioreactors both in continuous perfusion and static conditions for 40 days (10 in expansion and 30 in differentiation media). Metabolites and functional products generated by AEC differentiating into hepatocyte-like cells were quantified by NMR, ELISA and luminescent/fluorescent functional assays validated as release criteria for human hepatocyte in clinical use. Additional biomolecular analysis were performed at the end of experimental set.
Results: AEC maintained epithelial characteristics and developed hepatic markers upon maturation. After 2 weeks of hepatic differentiation, AEC expressed hepatoblast markers (AFP). At the end of differentiation, AEC were positive for hepato-specific markers such as CK18, albumin and CYP3A4, but negative for AFP. Albumin and urea quantifications supported hepatic maturation in bioreactor-cultured scaffolds. Phase 1 and 2 functional assays supported hepatic maturation and comparison with fetal/adult human hepatocytes. NMR analysis highlighted changes in the metabolite in the supernatant of differentiated AEC in ECM-scaffolds.
Conclusion: several groups/companies have proposed stem cells as alternative solution, bounded by genetic and epigenetic instabilities, and limited in hepatic maturation level. Here we show functional differentiation of primary human AEC into hepatocyte-like cells by 3D liver matrix support when maintained in a perfusion bioreactor. We conclude that innovative perfusion ECM-scaffold technology may support maturation for multipotent and eventually pluripotent stem cells, with important repercussion in therapeutic approaches and toxicological studies.

SAT154
Knockdown of Glyoxylate reductase/hydroxypyruvate reductase (GRHPR) accelerates liver regeneration and decreases chronic liver damage

Viktoriia Iakovleva[1,2], Anna Potapova[1], Agnes Bee, Leng Ong[1], Rong Gao[1], Yock Young Dan[2], Torsten Wuestefeld[1,3,4]. *[1]Genome Institute of Singapore (GIS), Laboratory of In vivo Genetics and Gene Therapy, Singapore, Singapore; [2]National University of Singapore, Medicine, Singapore, Singapore; [3]National Cancer Centre Singapore, Singapore, Singapore; [4]Nanyang Technological University, Singapore, Singapore*
Email: wustefeldt@gis.a-star.edu.sg

Background and aims: GRHPR dysfunction in humans causes primary hyperoxaluria type 2 (PH2). Excess oxalate leads to kidney stone formation and kidney damage. However, in an in vivo RNAi screen to identify potential modulators of liver regeneration and disease we recently conducted two independent shRNAs targeting GRHPR scored. In addition, GRHPR expression was described to be decreased or lost in a subset of HCC, associated with proliferation rate (Pan et al., Pathobiology 2013;80: 155–162). Intrigued by this, we went on and validated that knockdown of GRHPR in hepatocytes accelerates liver regeneration and protects against liver fibrosis under chronic liver-damaging conditions.
Method: RNAi screen was performed in C57BL/6JInv mice. shRNA pool contained 253 shRNAs and was delivered into the livers of C57BL/6JInv mice by hydrodynamic tail vein injections (HDTV). Thioacetamide (TAA) treatment was applied triweekly for 8 weeks (0.2 mg TAA per g bodyweight) to induce chronic liver damage. The abundance of each RNA was compared to the starting pool. Only enriched candidates were selected for further validation.
GRHPR was then validated in vitro and in vivo. For in vitro studies, a stable liver cell line with GRPHR knockdown was generated and knockdown efficiency was tested by Western Blot. Wound healing assay was performed to validate cell migration in two dimensions. For in vivo studies, we took advantage of the fumarylacetoacetate knockout mouse model (FAH-/-). We delivered an shRNA-expression construct (shGRHPR or shCTRL, non-targeting) into the livers of FAH-/- mice by HDTV, which leads to specific stable integration in hepatocytes. We investigated liver repopulation speed. Furthermore, liver regeneration upon Partial Hepatectomy (PH), and chronic liver damage (TAA model) was investigated on fully repopulated livers, where every hepatocyte expresses the shRNA of interest.
Results: We observed significantly faster cell migration in wound healing assay in case of the GRHPR knockdown. Furthermore, we observed faster clonal expansion in vivo in case of the GRHPR knockdown compared to a non-targeting control. Also, the PH model showed faster liver regeneration at 38 hours and 48 hours' time-points in the experimental group compared to the control group. Chronic liver damage model (TAA model) showed a significant reduction of fibrosis in case of GRHPR knockdown compared to

control. In addition, we observed that GRHPR knockdown in hepatocytes in vivo does not lead to tumor formation for 1 year.



Conclusion: Hepatocyte-specific knockdown of GRHPR improves liver regeneration and attenuates liver fibrosis. GRHPR knockdown in hepatocytes seems to be safe regarding liver cancer. We did not see any macroscopic impact on the kidney and mice survived for more than one year with hepatocyte-specific GRHPR knockdown. Nevertheless, kidney pathology has to be further evaluated.

SAT155

Expression and function of axon guidance genes in the developing portal tract

Lila Gannoun[1], Catalina De Schrevel[1], Sabine Cordi[1], Frédéric Lemaigre[1]. [1]*De Duve Institute UCLouvain, LPAD, Woluwe-Saint-Lambert, Belgium*
Email: frederic.lemaigre@uclouvain.be

Background and aims: The liver lobules consist of hepatocyte cords and sinusoids that radiate from the portal area to the central vein. The portal area contains a branch of the portal vein, a hepatic artery, a bile duct lined by cholangiocytes, lymphatics, nerves and a heterogeneous mesenchyme. During development, the portal mesenchyme instructs differentiation of cholangiocytes, and normal development of the bile ducts is required for hepatic arteriogenesis (Lemaigre, 2020). Yet, how portal mesenchyme, bile ducts and hepatic artery interact during development remains poorly understood. To address this issue, we hypothesize that the 3D morphogenesis of bile ducts and hepatic artery is guided by signaling interactions with mesenchymal cells in the portal tract.
Method: To investigate this hypothesis, we separately FACS-purified cholangiocytes and adjacent mesenchymal cells at various stages of liver development in mouse embryos, and subjected the cells to RNAseq analysis. We identified several ligand-receptor pairs where the ligand is differentially expressed in the mesenchyme and the receptor in the cholangiocytes, or vice versa, during duct morphogenesis. These included axon guidance genes, namely genes coding for Slit/Robo proteins, Eph receptors/Ephrins, Semaphorins/Plexins and Netrins/netrin receptors.
Results: We determined the cell-specific and spatial expression of selected genes, and focused our functional analyses on Slit/Robo and Netrin/Netrin receptor pairs due to their preferential location of expression near forming ducts (Fig. 1). Using a Cre-loxP strategy we inactivated selected genes in the developing mesenchyme or cholangiocytes. Functional assays, 2D and 3D imaging identified axon guidance genes required for normal development of bile ducts and hepatic artery.

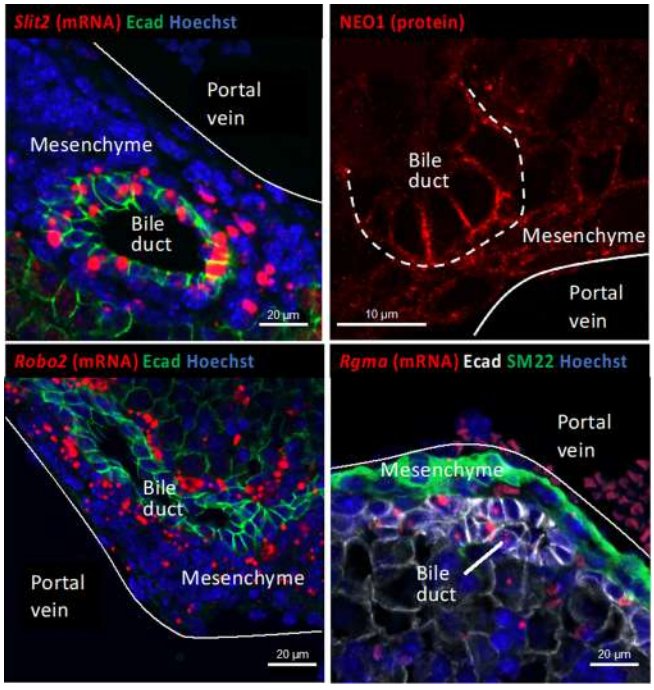


Figure: Expression of axon guidance genes (red) in developing mouse liver at E18.5.

Conclusion: We conclude that axon guidance pathways drive cell-cell interactions that control normal development of bile ducts and hepatic artery in the portal tract.

SAT156

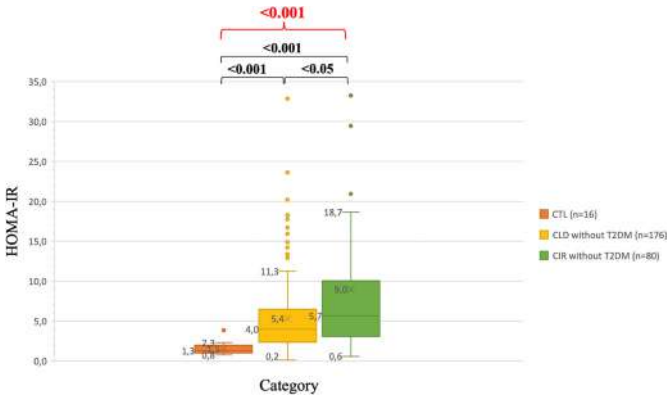
Patients with chronic liver diseases are at risk for diabetes even before development of cirrhosis

Georgia Bale[1], Frédéric Clarembeau[1], Peter Stärkel[1,2], Géraldine Dahlqvist[1], Yves Horsmans[1,2], Nicolas Lanthier[1,1,2]. [1]*Cliniques universitaires Saint-Luc, Service d'Hépato-gastroentérologie, Brussels, Belgium;* [2]*UCLouvain, Laboratory of Gastroenterology and Hepatology, Brussels, Belgium*
Email: nicolas.lanthier@saintluc.uclouvain.be

Background and aims: The prevalence of insulin resistance (IR) and type 2 diabetes mellitus (T2DM) is higher in patients with cirrhosis, compared to control patients without liver disease. The exact mechanism for this is unknown but could include liver inflammation. In this study, we investigate whether cirrhosis is the *primum movens* of IR or if impaired insulin sensitivity is already present in non-cirrhotic patients with chronic liver diseases.
Method: Patients were recruited and divided into three groups: control (CTL), active chronic liver disease without cirrhosis (CLD) and cirrhosis (CIR). In patients not taking pharmacological treatment for

T2DM, IR was quantified using the homeostasis model assessment of insulin resistance (HOMA-IR). The proportion of patients treated for T2DM was recorded in each group. Additionally, HOMA-IR levels among different disease etiologies were compared. The study was approved by the local ethics committee.

Results: 422 patients were included in our study, 16 were controls, 278 had a CLD and 128 were cirrhotic (CIR). The causes of liver disease were as follows: metabolic-dysfunction associated fatty liver disease (MAFLD, n = 206), alcoholic liver disease (ALD, n = 117), active chronic hepatitis C (HCV, n = 59), other cause (n = 24). IR, represented by a HOMA-IR value exceeding 2.5, is already present in patients with non-cirrhotic CLD (median HOMA-IR 4.0). HOMA-IR levels lie between those seen in CTL (median HOMA-IR 1.3) and CIR patients (median HOMA-IR 5.7), with a statistically significant difference between the three groups (p value <0.001) (Figure). Median glycemia in the CLD and CIR groups is the same (98 mg/dL and 99 mg/dL respectively) but insulinemia is different (101.5 pmol/land 132.3 pmol/lrespectively) resulting in distinct HOMA-IR values in CLD and CIR patients (p = 0.018). Compared to CLD patients, patients in the CIR group are also characterised by a higher age, higher AST levels and a lower platelet count consistent with portal hypertension. The number of patients with T2DM is the same in the CLD and CIR groups (36.7 and 37.5% respectively). Finally, HOMA-IR levels differ according to disease etiology (p value <0.001): MAFLD and HCV associated liver disease are associated with higher levels of IR compared to ALD and other causes of CLD.



Conclusion: Chronic liver disease is already a predisposing factor to T2DM, regardless of the presence of cirrhosis. Certain disease etiologies are associated with more severe IR. Cirrhosis is a factor which in itself elicits additional increase in insulin levels. The increased insulin levels in this group may be related to increased IR in this situation or to decreased insulin clearance due to portal hypertension.

SAT157

Characterization of bioengineered liver constructs using hepatoblast organoids (HBOs) and human liver extracellular matrix (ECM) 3D-platforms

Margarita Papatheodoridi[1], Katerina Zacharis[2], Carola Maria Morell[2], Elisabetta Caon[1], Luca Frenguelli[1], Andrew Hall[3], Ludovic Vallier[2], Krista Rombouts[1], Giuseppe Mazza[1], Massimo Pinzani[1]. [1]*University College of London, Royal Free Hospital, Institute for Liver and Digestive Health, London, United Kingdom;* [2]*University of Cambridge, Jeffrey Cheah Biomedical Centre, Welcome-MRC Cambridge Stem Cell Institute, Cambridge, United Kingdom;* [3]*University College of London, Royal Free Hospital, Academic department of Histopathology, London, United Kingdom*
Email: margarita.gpap@gmail.com

Background and aims: Primary fetal hepatoblast organoids (HBOs) derived from human fetal livers have self-renewal ability and can be consecutively passaged while retaining capacity to differentiate to both the hepatic and biliary lineages. We hypothesized that the environment provided by the decellularised healthy human liver extracellular matrix (ECM) will offer HBOs the natural acellular cues for growth and enhanced metabolic functionality and maturation. Thus, the aim of this study was to demonstrate proof of concept for survival and growth of HBOs in a bio-compatible healthy human liver 3D-platform and assess their functionality.

Method: Healthy human liver unsuitable for transplantation was decellularized. Acellular liver tissue was lyophilized ≥24 hours and comminuted to a particulate form. ECM powder was then solubilised, neutralized, sterilised, and mixed with Nanocellulose (Celllink) 70:30 in the resultant ECMgel. HBO cells that had been cultured and expanded on Matrigel were seeded on ECMgel (25 K cells/30 μL). Standard HBO Matrigel cultures (25 K cells/20μL) were used as controls. ECMgel (n = 36) and Matrigel (n = 36) samples for RNA extraction/gene expression, live/dead staining or ELISAs were collected up to day 14.

Results: HBOs repopulated the Matrigel and ECM gel and remained viable for 14 days in maintenance medium. HBO clusters on ECMgel had similar size but displayed a distinctively round shape compared to Matrigel where organoids have a characteristic budding morphology. Albumin gene expression in ECMgel was significantly higher compared to Matrigel samples and showed a significant increase from day 7 to 14. aFP gene expression showed a decreasing trend from day 7 to 14 in both materials. SERPINA and OTC gene expression of HBOs in ECMgel vs Matrigel was also higher on day 14, while CYP3A4 was higher in ECMgel on both timepoints. AURK gene expression in ECMgel was significantly higher than in Matrigel on day 14, suggesting higher proliferation. KRT19 expression was lower on ECMgel on day 7 compared to Matrigel and ranged in very low levels in all samples. Secreted albumin/aFP ratio significantly increased from day 5 to 14 in ECMgel indicating improved maturation but not in Matrigel samples.

Conclusion: Primary HBOs can grow in a healthy human liver ECM 3D-platform *in vitro* for at least 2 weeks and start differentiating towards a hepatocyte phenotype with the signals provided solely by the healthy human liver ECM. Overall, by combining two novel bioengineering technologies we showed the feasibility of constructing *in vitro* small implantable liver tissues that could be used for *in vivo* transplantation in future studies.

SAT158

Novel avenue towards liver regeneration and treatment of acute and chronic liver diseases: safety and PK profile from a first-in human (FIH) clinical trial for HRX-0215 as first in class MKK4 inhibitor

Birgit Jung[1], Markus Weissbach[1], Michael Lutz[1], Roland Selig[1,2], Stefan Laufer[2,3], Lars Zender[4,5], Michael Feigh[6], Matthias Berse[7], Jette Penski[7], Esther Kosmella[7], Wolfgang Albrecht[1]. Email: w.albrecht@heparegenix.com

Background and aims: Impaired liver regeneration is a hallmark of acute and chronic liver diseases and to date liver transplantation still represents the only ultimate treatment for acute liver failure and end stage chronic liver diseases. Recent reports validated Mitogen Activated Protein (MAP) Kinase 4 (MKK 4) as a novel target and demonstrated a role as a master regulator of liver regeneration (Wuestefeld et al., Cell 2013). Particularly striking efficacy results

accelerated liver regeneration and improved survival were recently obtained in 85% hepatectomy pig model upon treatment with the MKK4 inhibitor HRX-0215 (5 mg/kg i.v.) (Klotz et al., Hepatology, 2021). Here, we now report data from a FIH clinical trial for HRX-0215 related to safety, tolerability and pharmacokinetics.

Method: A FIH Clinical trial for HRX-0215 was conducted in 48 healthy volunteers to assess safety, tolerability and pharmacokinetics in a single-center, double-blind, randomized, placebo-controlled manner. In the Single Ascending Dose part volunteers were dosed from 5 to 500 mg, the Multiple Ascending dose part used daily doses between 100 and 500 mg. HRX-0215 was well tolerated at all doses, no relevant changes of any clinical or laboratory parameters were observed. Within a given dosing strength, PK analysis revealed a dose-proportional increase of exposure with very low interindividual variability. Concentration vs. time profiles of HRX-0215 supports a once-daily dose regimen during further clinical development.

Results: In the 4 wk GLP toxicity study in rats and dogs, a NOAEL of 300 mg/kg p.o. and 250 mg/kg p.o. was obtained, respectively. No organ toxicity was observed, which is in line with results from 12 mths ubiquitously, genetically suppressed MKK4 expression in mice. Most importantly, risk mitigation for liver tumor burden was achieved in a diet-induced obese mouse model with biopsy-confirmed NASH (non-alcoholic steatohepatitis) and advanced fibrosis, where HRX-0215 administered at a dose level of 30/kg once daily for 12 weeks attenuated progression in tumor numbers and growth.

Conclusion: Our FIH clinical trial demonstrates a favorable safety profile of HRX-0215 and confirms that pharmacological MKK 4 inhibition is well tolerated. PK characteristics indicate that therapeutic efficacy is achieved with a once-daily dose regimen This profile enables further clinical development and Phase 2 trials of HRX-0215 in patients with acute and chronic liver diseases.

SAT160

In vivo loss-of-function studies unravel protein tyrosine phosphatase delta as a regulator of liver regeneration during metabolic liver disease

Email: joachim.lupberger@unistra.fr

Background and aims: Signal transduction is tightly regulated by protein phosphatases and dysregulated in many diseases and cancers. Protein tyrosine phosphatase delta (PTPRD) is a STAT3 phosphatase, which was previously described as tumour suppressor. Since STAT3 signalling has a protective but also a pro-oncogenic role in the liver we aimed to study the impact of PTPRD expression on liver disease and development of hepatocellular carcinoma (HCC).

Method: To identify pathways responsive to PTPRD function, we analysed single-cell liver transcriptomics of healthy liver and transcriptomics and clinical data from patients with liver disease. We established a *Ptprd*-deficient mouse model, which was subjected to DEN and a choline-deficient diet enabling to study the role of PTPRD in NASH-associated liver cancer in vivo. The impact of PTPRD expression in the liver was validated using primary human hepatocytes and liver progenitor cells (LPCs) including the immortalized cell line HepaRG as well as in transcriptomes of regenerating liver after partial hepatectomy in rodents.

Results: In normal liver, single-cell transcriptomics identified hepatic PTPRD being expressed predominantly in EPCAM+ LPCs and in mature hepatocytes. Surprisingly, PTPRD-deficient mice with NASH developed significantly fewer HCC nodules although exhibiting higher fat inclusions compared to wild type mice. This suggests a dual role of PTPRD as a negative regulator of liver regeneration counteracting tumour formation and as a positive regulator hepatic fat metabolism. Indeed, PTPRD expression was strongly impaired after partial hepatectomy in rodent models, correlating with elevated STAT3 signalling in regenerating livers. Differentiated hepatocyte-like human LPCs express higher PTPRD compared to undifferentiated stem-cell like LPCs. Silencing of PTPRD or induction of STAT3 signalling in LPCs promoted de-differentiation and a stem-cell-like phenotype. Hepatocytes of the PTPRD-deficient mice exhibit impaired peroxisomal function, elevated STAT3 signalling and fat accumulation with elevated diabetic markers. Translating these observations to the clinic, obese patients with low hepatic PTPRD expression exhibited increased levels of clinical markers associated with metabolic disease.

Conclusion: Our results suggest a novel role of the STAT3 phosphatase PTPRD as regulator of hepatic regeneration in liver progenitor cells and fat metabolism in hepatocytes during metabolic liver disease.

SAT161

Integrated proteomics and metabolomics analysis reveals canonical and novel regulatory pathways linked to liver regeneration in living donor liver transplant (LDLT) Donors

Gaurav Tripathi[1], Adil Bhat[1,2], Manisha Yadav[1], Babu Mathew[1], Nupur Sharma[1], Vasundhra Bindal[1], Viniyendra Pamecha[3], Jaswinder Maras[1], Shiv Kumar Sarin[4]. *[1]Institute of liver and biliary science, Molecular and cellular medicine, New Delhi, India; [2]University of California, Los Angeles, Pathology and Lab Medicine, Los Angeles, United States; [3]Institute of liver and biliary science, hepatobiliary surgery, New Delhi, India; [4]Institute of liver and biliary sciences, hepatology, New Delhi, India*
Email: jassi2param@gmail.com

Background and aims: Living donor liver transplant (LDLT) in Donor's provides a unique opportunity to unravel novel biological networks associated to regenerative response. To explore more about liver regeneration, plasma proteomic, metabolomic and the clinical characteristic of LDLT Donors were integrated using network-based modelling with the final aim of uncovering novel biological processes associated to regeneration.

Method: Plasma proteomics and metabolomics were performed on (n = 10) healthy donors at baseline (pre-operative stage) and post-operative stages at Day1, Day3 and Day7. Proteome and metabolome data were analysed using weighted protein/metabolite correlation network analysis W[P/M]CNA to identify clusters of highly correlated proteins and metabolites modules differently expressed in donors at different days. Proteins and metabolites modules were cross correlated to form Multi-Modular Correlation Network (MMCN). Pathway analysis of MMCN identified regeneration linked proteins metabolite network which correlated with post-operative flare in liver enzymes (AST and ALT; $p < 0.05$).

Results: In comparison to baseline donor sample; post-operative day1 sample showed 232 differentially expressed proteins (DEP; Up-113, Down-119; $p < 0.05$) and 177 differentially expressed metabolites (DEM; Up-105, Down-72; $p < 0.05$). At day 1 VEGF, Hedgehog

signaling, Cell cycle, Tryptophan, Sphingolipid metabolism, Primary bile acid metabolism were increased and Calcium ion signaling, Apoptosis, Arachidonic acid metabolism were decreased ($p < 0.05$). At Day3; 264 DEP (Up-157, Down-107; $p < 0.05$) and 267 DEM (Up-136, Down-131; $p < 0.05$) associated to ILGF signaling, IL-12, NFK-B, MAP-K, JAK-STAT signaling, alanine aspartate metabolism and butanoate metabolism were increased whereas Rho-GTPases, interferon-gamma, Cytokine signaling, and fat metabolism were decreased ($p < 0.05$). Day7 showed 232 DEP (Up-97, Down-135; $p < 0.05$) and 299 DEM (Up-133, Down-166; $p < 0.05$) associated to autophagy, RHO-GTPases signalling and primary bile acid biosynthesis increased and Folate metabolism, N-glycan biosynthesis, Arachidonic acid metabolism, JAK-STAT, IL-12 signalling were decreased. Temporal integration performed using W [P/M] CNA identified MMCN clusters (r2>0.5). Correlation of these MMCN clusters with the clinical indicator of liver regeneration (liver functions) led to identification of day wise specificity of MMCN cluster e.g. (Day1 specific MMCN-direct correlates with AST and ALT levels (r2>0.5, $p < 0.05$)). Pathway enrichment of MMCN cluster identified canonical pathways involving haemostasis and regeneration but also enriched novel pathways linked to regeneration.

Conclusion: Multi-modular network analysis not only validates canonical pathways involving haemostasis and regeneration but also highlight novel pathways linked to liver regeneration.

SAT162

Regulation of extracellular Nicotinamide adenine dinucleotide in patients with liver fibrosis: new insights into conventional hepatobiliary parameters

Can Kamali[1], Alexander Arnold[2], Philipp Brunnbauer[1], Kaan Kamali[1], Karl Hillebrandt[1], Moritz Schmelzle[1], Johann Pratschke[1], Felix Krenzien[1,3]. [1]*Charité-Universitätsmedizin Berlin, Department of Surgery, Berlin, Germany;* [2]*Charité-Universitätsmedizin Berlin, Institute of Pathology, Berlin, Germany;* [3]*Berlin Institute of Health, Berlin, Germany*
Email: can.kamali@charite.de

Background and aims: The extension of liver resections represents a challenging surgical decision, depending on many factors, such as the patient's pre-existing conditions, oncological history and expected surgical outcome. A key limiting factor is the hepatic regenerative capacity, which we examined focusing on extracellular nicotinamide adenine dinucleotide (eNAD+) and its implications.
Method: Patients undergoing liver resection were recruited, tissue and blood samples were collected, and postoperative liver insufficiency was graded based on the 50–50 criteria. We utilized an assay that we established in our workgroup to measure concentrations of eNAD+ in the plasma samples. Finally we explored the impact of an eNAD+ treatment on 3D primary murine hepatocyte spheroids.
Results: Patients with low (grade 0 and 1 fibrosis, n = 56) and high (grade 2, 3 and 4 fibrosis, n = 39) grade fibrosis showed akin transaminase levels (AST, ALT) prior to surgery, while postoperative peak transaminase levels were significantly higher in the low grade fibrosis group (ALT: $p = 0.0008$, AST: $p = 0.0041$). Meanwhile, eNAD+ levels were significantly higher in the low grade fibrosis group (Grade 0 to 4, $p < 0.05$). Conversely, increased expression of catalyzing

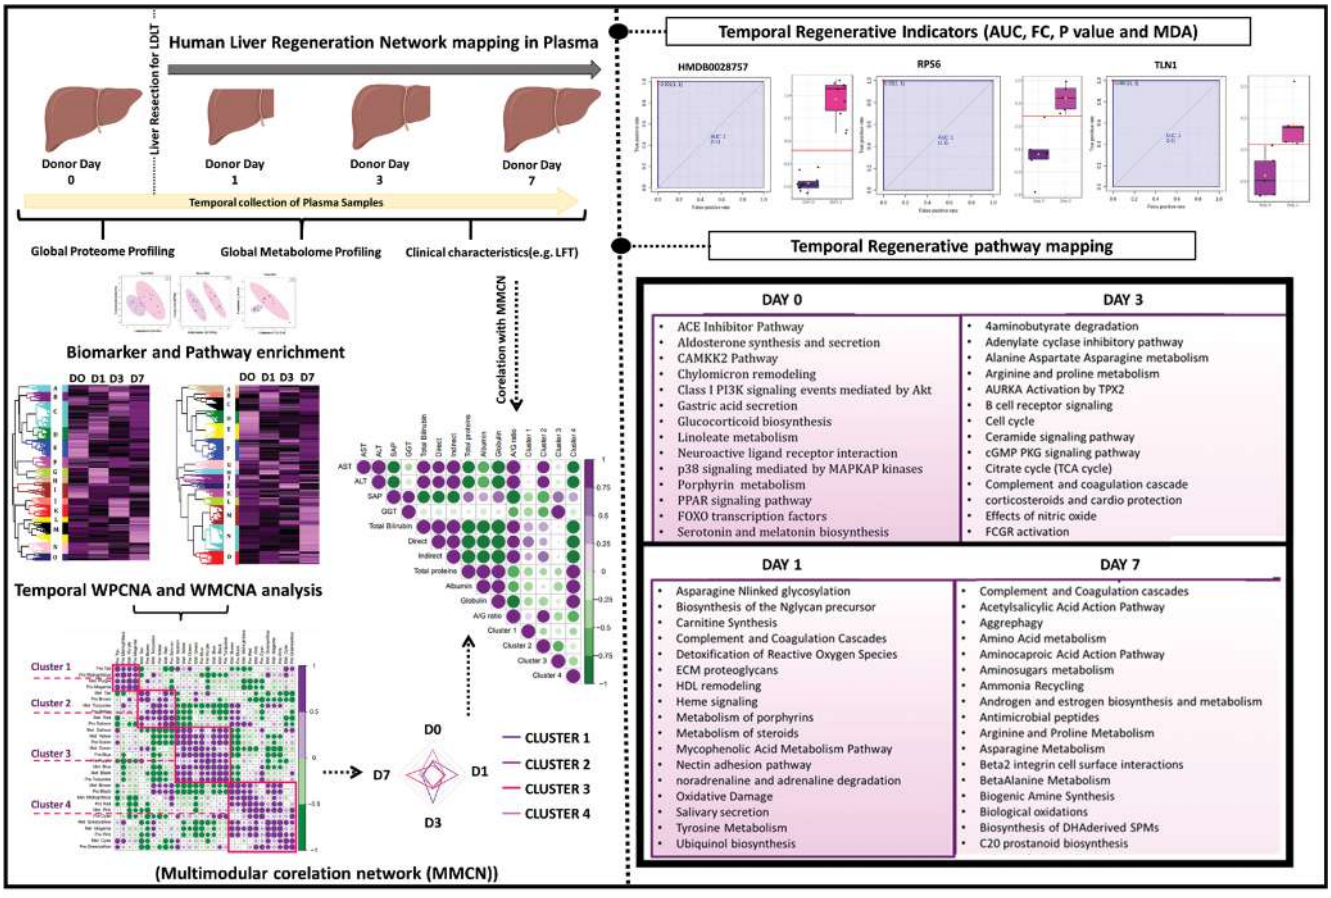

Figure: (abstract: SAT161)

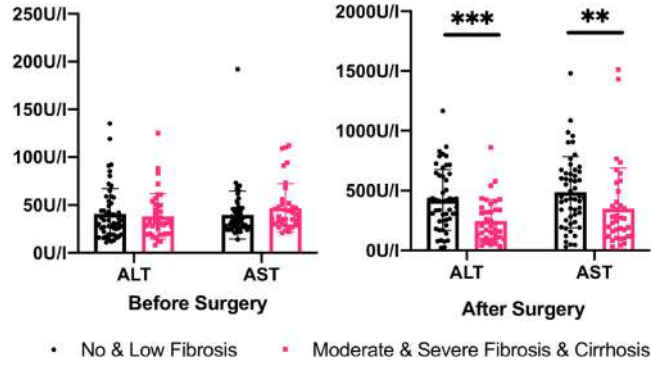
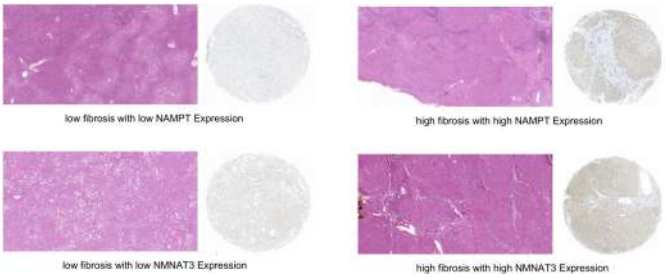
enzymes of NAD+ synthesis in liver tissue, nicotinamide mononucleotide adenylyltransferase (NMNAT) and nicotinamide phosphoribosyltransferase (NAMPT), were associated with higher fibrosis grade (p <0, 0001). Next, we tested whether eNAD+ was regulated following liver resection. Indeed, patients revealed a higher postoperative eNAD+ decrease than controls (p <0.0001). At the same time, patients who developed postoperative liver insufficiency (n = 8), exhibited significantly smaller eNAD+ decline than patients who did not develop liver insufficiency (n = 69, p = 0.0325). Next, 3D primary murine hepatocyte spheroids treated with eNAD+ for 12 days demonstrated the highest viability (p <0.0001) when compared to negative controls, TNF alpha treated or combined TNF alpha and eNAD+ treated hepatocytes. The eNAD treatment group was followed in superiority of viability in successive order by eNAD+ and TNF alpha treated, negative control and finally TNF alpha (lowest viability) treated cell cultures, respectively.





Conclusion: We demonstrated that low grade fibrosis was associated with higher eNAD+ levels and compensatory downregulation of catalyzing enzymes of NAD+ synthesis in liver tissue. Interestingly, eNAD+ was decreased following liver resection and linked to postoperative liver insufficiency. In conclusion, we provide evidence that eNAD+ is determined by the degree of fibrosis of the liver and is significantly regulated after liver resection with implications for future therapy targets.

SAT163

Hyaluronan in the prenatal extrahepatic bile duct increases in response to injury

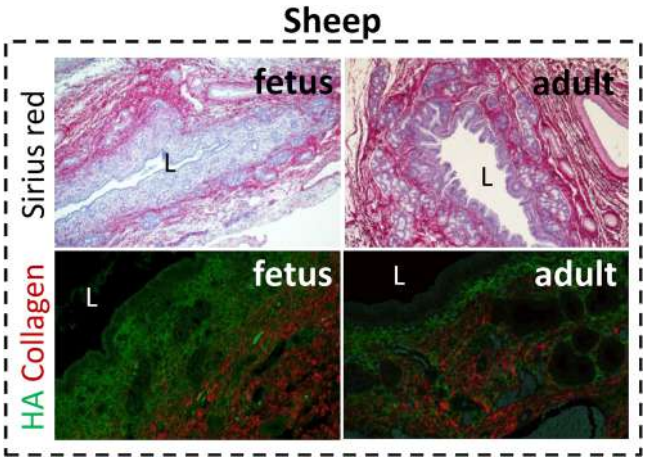
Email: i.e.m.de.jong@umcg.nl

Background and aims: Biliary atresia (BA) is a fibrosing obstructive cholangiopathy and represents the primary cause of obstructive jaundice in infants. The etiology is uncertain, but compelling evidence points toward a prenatal cause. Existing literature on BA focuses mainly on the post-natal period and the early response of the fetal extrahepatic bile duct (EHBD) to injury remains unknown. The objective of this study was to identify unique features of the fetal and neonatal EHBD injury response that had pathophysiological relevance.

Method: Mouse, rat, sheep, and human EHBD samples were studied at different developmental time points. Models included a fetal sheep model of prenatal 14- to 21-day injury, human BA EHBD remnant and liver samples taken at the time of the Kasai procedure, EHBDs isolated from neonatal rats and mice, and spheroids generated from primary neonatal mouse cholangiocytes that were cultured in either collagen, low or high molecular weight hyaluronan. A bile duct-on-a-chip device was used to study swelling of a collagenous matrix with and without hyaluronan.

Results: A thick layer of hyaluronan encircling the lumen was identified as a unique feature of the normal perinatal EHBD. This layer, which was surrounded by collagen, was significantly thicker in ducts subject to prenatal injury, in parallel with extensive PBG hyperplasia and mucus production, and increased serum bilirubin levels. BA remnants and liver samples similarly showed increased hyaluronan centered around ductular structures, compared with age-matched controls. High molecular weight hyaluronan has a positive effect on spheroid growth, supporting the pro-regenerative environment seen *in vivo*. Increased hyaluronan levels in the matrix lead to a decreased lumen diameter.



Conclusion: A dense layer of hyaluronan around the lumen that decreases rapidly after birth is a unique feature of the mammalian fetal and neonatal EHBD. Prenatal injury causes an increased thickness of the hyaluronan layer, with extensive PBG hyperplasia and mucus production, possibly leading to increased bilirubin levels and swelling and obstruction of the EHBD.

SAT164

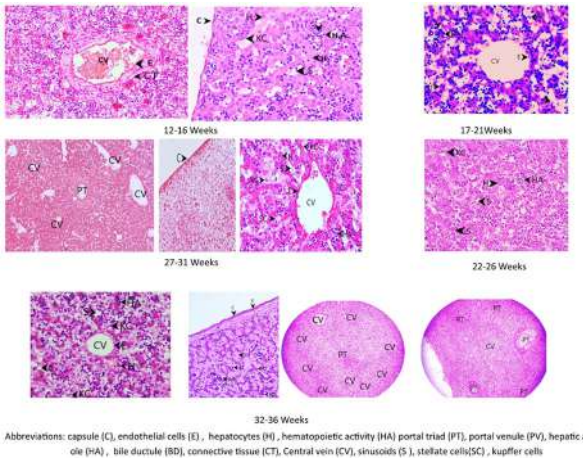
Embryogenesis of human fetal liver at various stages of gestation: a histomorphometric study

Pooja Bhadoria[1], Kavita Modi[1], Brijendra Singh[1]. [1]*All India Institute of Medical Science Rishikesh, Fetal Autopsy Lab Anatomy, Rishikesh, India*
Email: pooja.ana@aiimsrishikesh.edu.in

Background and aims: Correlation of general fetal morphometric parameters with liver dimensions and observation of microscopic features like kupffer cells, hematopoietic activity, stellate cells, glycogen granules, central vein, portal triad carries immense importance in estimation of fetal gestation age, detection of anatomical variations, and identification of congenital anomalies. Hence, we planned to assess prenatal development of human liver between 12 and 36 wks of gestation by evaluating both macroscopic and microscopic parameters using conventional autopsy and histotechniques.

Method: In 33 normal fetuses (gestation age 12–36 wks) were classified in 5 groups as 12–16, 17–21, 22–26, 27–31 and 32–36 wks. Liver parameters like weight, volume, transverse and sagittal diameter, vertical length, length and width of lobes of liver and general morphometric parameters of fetus like weight, crown- rump length, crown-heel length, bi-parietal diameter, head, chest and abdominal circumference, hand and foot length, inner and outer inter-canthal distance were measured. Hematoxylin and Eosin (HandE) sections were studied using Quasmo ISI microscope and image-pro express analyzer.

Results: Out of 33 fetuses (males 27: females 6) and maximum (n = 7) each were in group 17–21 and 27–31 wks. Correlation between gestational age and all general fetal and liver parameters except bi-parietal diameter were statistically significant ($p < 0.05$). Similarly, significant increase amongst all fetal and liver parameters was seen with increasing gestational age ($p < 0.05$). On HandE sections (Fig 1) during 12–16 wks, glisson's capsule, portal triad surrounded by fibrous capsule, central vein, kupffer cells and hematopoietic activity was observed. During 17–21 wks, hepatocytes were present in anastomosing radiating cords with organized hepatic sinusoids and parenchyma. During 22–26 wks, hematopoietic activity became focal, with clear demarcation of hepatic and portal lobule. During 27–31 wks, hepatic and portal lobule was clearly demarcated, hematopoietic activity reduced. Kupffer cells and capsule thickness increased with gestation age. During 32–36 wks, deposition of glycogen granules was observed. Hematopoietic activity became scanty and focal. Hepatic parenchyma became more structured with radiating cords of hepatocytes arising from distinct central vein.



Conclusion: Change in general fetal morphometric parameters and liver parameters except bi-parietal diameter are directly proportional with change in gestation age. Knowledge of morphological and histological features and normal limits of dimensions of liver with respect to gestation age is a reliable reference. Findings of studies can be used to better understand histology of normal liver and stages of development during fetal life to pick variations and anomalies.

SAT165

Generation of universal low-immunogenic human cholangiocyte organoids for treatment of cholangiopathies

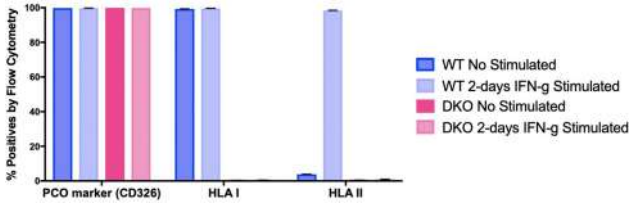
Sandra Petrus-Reurer[1], Adrian Baez-Ortega[2], Inigo Martincorena[2], Kourosh Saeb-Parsy[1]. [1]*University of Cambridge, Surgery, United Kingdom;* [2]*Wellcome Trust Sanger Institute, United Kingdom*
Email: sp2016@cam.ac.uk

Background and aims: Other than complex surgery or transplantation, there are no current curative therapies for cholangiopathies affecting the intra- or extrahepatic biliary tree such as Primary Sclerosing Cholangitis (PSC). We have previously shown that human bile duct epithelial cells can be cultured as 3D organoids to generate an unlimited supply of phenotypically- and functionally-mature primary cholangiocyte organoids (PCOs) for the treatment of bile duct disorders. We have used PCOs to generate bioengineered bile ducts to replace the extra-hepatic bile duct, and to treat intrahepatic cholangiopathy in human livers.

Since the generation of autologous PCOs is likely to remain logistically and economically prohibitive for the foreseeable future, immune rejection of allogeneic PCOs remains a key outstanding barrier to their clinical translation. We thus aimed to develop universal low-immunogenic cholangiocyte organoids for regenerative medicine applications.

Method: After systemic testing of numerous conditions, HLA I and II double KO (DKO) 'edited PCOs' (ePCOs) were generated using CRISPR/Cas9 by dissociating PCOs into single cells, electroporation with the guide-Cas9 complex and sorting for the specific double negative cells. Assessment comparing to parental wild-type (WT) cells was carried out by flow cytometry, functional readouts (e.g. Gamma-glutamyl Transferase and Alkaline Phosphatase analyses), and co-culture with $CD4^+$ and $CD8^+$ lymphocytes *in vitro*, as well as by engraftment under kidney capsule of immunodeficient mice. Mutational load and CRISPR-mediated off-target genetic mutations of parental vs ePCOs were quantified using whole genome sequencing and Nanoseq techniques.

Results: The HLA I and II DKO ePCOs generated maintain a mature PCO phenotype demonstrated by flow cytometry and functional analyses. Immune characterization *in vitro* by co-culture with $CD4^+$ and $CD8^+$ T cells experiments are ongoing to show that ePCOs have a reduced immunogenicity (Interferon-g secretion, IFN-g) compared to WT cells. Moreover, upon engraftment into the kidney capsule of immunodeficient mice, ePCOs survive and engraft expressing cholangiocyte markers (e.g. KRT-7, KRT-19) in a similar manner as WT cells. Finally, pilot data on off-target analysis and mutation burden of parental vs ePCOs do not show CRISPR-mediated off-target sites nor excess mutation in ePCOs. Additional experiments are ongoing to assess the immune response *in vivo* using humanised mouse models.



Conclusion: Human PCOs lacking HLA I and HLA II can be successfully generated using a CRISPR-Cas9 approach. ePCOs retain the phenotypic characteristics of mature PCOs both *in vitro* and *in vivo* upon engraftment in kidney capsule, but show reduced immunogenicity *in vitro* when co-cultured with $CD4^+$ and $CD8^+$ cells compared to

parental cells. Pilot data show no CRISPR-driven off-target mutational burden in ePCOs.

Opposite PAR2 roles in liver regeneration from autoimmune or direct damage. Solving the conflict

Gal Reches[1], Netta Rose Blondheim Shraga[1], Florent Carrette[2], Assaf Malka[1], Natalia Saleev[1], Yehuda Gubbay[1], Offir Ertracht[3], Linda M Bradley[2], Fred Levine[4], Ron Piran[1]. *[1]Bar Ilan University, The Azrieli Faculty of Medicine, Safed, Israel; [2]Sanford Burnham Prebys Medical Discovery Institute, Infectious and Inflammatory Disease Center, La Jolla, California, United States; [3]Galilee Medical Center, Eliachar Research Laboratory, Nahariya, Israel; [4]Sanford Burnham Prebys Medical Discovery Institute, Sanford Children's Health Research Center, La Jolla, California, United States*
Email: galreches@gmail.com

Background and aims: Liver inflammation will cause hepatic damage. In other cases, hepatic injury or poisoning will induce inflammation. Both scenarios will be defined as hepatitis. We chose two distinct hepatitis models that are typical for these two underlying causes. By doing so, we aimed to characterize the role of PAR2 in liver regeneration and inflammation, to reconcile PAR2 confusing role in many damage models, which sometimes aggravates the induced damage and sometimes alleviates it.
Method: WT and PAR2 knock out (PAR2KO) mice were injected with concanavalin A (ConA) for the immune-mediated model, or with carbon tetrachloride (CCl_4) for the direct hepatic damage. In order to separate the immune component from the liver regenerative response we conducted reciprocal bone marrow (BM) replacement of WT and PAR2KO mice and repeated the damage models.
Results: ConA injection caused limited damage in PAR2KO mice livers, while in the WT severe damage followed by leukocytes infiltration was evident. Reciprocal BM replacement of WT and PAR2KO showed that WT BM into PAR2KO displayed marked liver damage, while in PAR2KO BM into WT the tissue was generally protected. In the CCl_4 direct damage model, WT mice hepatocytes regenerated, while PAR2KO failed to recover. Reciprocal BM replacement did not show significant difference in hepatic regeneration comparing to the mice that were not transplanted. In PAR2KO hepatitis was significantly more apparent, while WT recovered regardless of the BM origin.

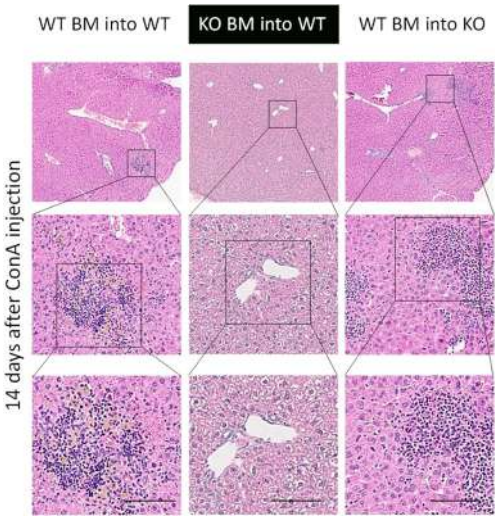

Figure: ConA induced hepatitis is controlled by PAR2 activation in the immune system

Conclusion: We conclude that when PAR2 is predominantly activated in the immune system, it aggravates hepatitis and when it is activated in the damaged tissue it promotes liver regeneration. When we incorporate this finding and revisit the literature reports, we were able to reconcile the conflicts surrounding PAR2 role in injury, recovery, and inflammation.

SAT167

Chronic injury induces plasticity between cholangiocytes and hepatocytes in the human liver

Vasileios Galanakis[1,2], Christopher Gribben[1], Alexander Calderwood[1], Ilias Moutsopoulos[1], Katarzyna Kania[3], Emmanouil Athanasiadis[4], Michael Allison[2], Irina Mohorianu[1], Ludovic Vallier[1]. *[1]Wellcome-MRC Cambridge Stem Cell Institute, Cambridge, United Kingdom; [2]Addenbrooke's Hospital, Cambridge, United Kingdom; [3]Cancer Research UK Cambridge Institute, Cambridge, United Kingdom; [4]Greek Genome Center, Biomedical Research Foundation, Academy Of Athens, Computational Biology Unit (CBU), Athens, Greece*
Email: vasilisgalan@gmail.com

Background and aims: Liver disease is on the rise, resulting in a huge health care burden. The liver's ability to regenerate is unique amongst the human organs. Liver regeneration is believed to mainly be driven by hepatocyte proliferation following acute liver injury or parenchymal volume reduction. However, in the presence of chronic liver injury the regeneration process is more complex and could involve several mechanisms. Indeed, animal studies suggest that 1) liver stem cells activation, 2) dedifferentiation/redifferentiation of cholangiocytes/hepatocytes, 3) transdifferentiation between cholangiocytes and hepatocytes, could be part of this regeneration process. Importantly evidences of regenerative process in human chronic liver diseases, such as in non-alcoholic fatty liver disease (NAFLD), are mainly indicative by histological observations and the underlying mechanisms remain to be fully uncovered.
Method: To define these mechanisms in vivo, we decided to combine state of the art single-nuclei transcriptional analysis (snRNAseq) with functional validations using cholangiocyte organoids. snRNAseq was performed on liver biopsies obtained from over 50 patients across the spectrum of NAFLD. Detailed computational analyses allowed the identification of factors and signalling pathways relevant for regenerative processes. The interest of these factors was further validated using a combination of cholangiocyte organoid system and multiome technology (single nuclei RNAseq and ATAC-Seq) on NAFLD derived cholangiocyte organoids, which were differentiated to hepatocyte like cells in vitro.
Results: Progression of liver disease towards decompensated cirrhosis is accompanied by transcriptomic changes, loss of liver architecture and zonation as well as expansion of ductular cells. Liver plasticity is also observed as evident by the presence of hepatocyte-cholangiocyte bi-phenotyping cells in the late stages of the disease. Similar bi-phenotyping cells can be observed by using the in vitro organoid system thereby suggesting that potential reciprocal plasticity.
Conclusion: Transcriptional analyses of patient biopsies and in vitro modelling suggest that cell plasticity is present in chronically diseased liver. Studying this plasticity may be key to understand the underlying regenerative mechanisms of the chronically injured human liver.

SAT168

In vivo characterization and functional effects of the NAD+ transporter, SLCA25A51

Sarmistha Mukherjee[1], Beishan Chen[1], Caroline E Perry[1], Melissa Lieu[1], Joseph A Baur[1]. *[1]Perelman School of Medicine, IDOM, Physiology, Philadelphia, United States*
Email: baur@pennmedicine.upenn.edu

Background and aims: SLC25A51 has recently been identified as the NAD+ transporter in mammalian mitochondria[1,2]. SLC25A51 (also known as MCART1) allows mitochondria to take up intact NAD+ from the cytoplasm and has previously been identified as a hit of unknown function in screens for essential genes. Although its function is now well established in cell lines, there is little information on SLC25A51

in intact tissues *in vivo*. Here, we are interested in characterizing and understanding the physiological role of hepatic SLC25A51.
Method: We used AAV vectors expressing *Slc25a51* or shRNA targeting under the control of the TBG promoter to overexpress or knock down *Slc25a51,* respectively, in the livers of mice.
Results: Preliminary data show that the *Slc25a51* knockdown mice have significantly higher fasting blood glucose and glucose intolerance, whereas overexpression has no effect. In contrast, overexpression lowers glucose in a pyruvate tolerance test whereas knockdown has no effect. As expected, mitochondrial NAD+ and NADH content and redox ratio are significantly higher in the over-expressors without a major change in total tissue NAD. Overexpression of SLC25A51 increased mitochondrial respiration and increased the rate of NAD+ uptake into isolated mitochondria. Conversely, loss of SLC25A51 impaired mitochondrial function. In addition, overexpression of SLC25A51 enhanced liver regeneration, significantly improved mitochondrial respiration and increased NAD+ uptake in post regenerative isolated mitochondria.
Conclusion: So far, our data suggest a direct enhancement of mitochondrial redox metabolism as the mechanism mediating improved regeneration in the over-expressors. Thus, the role of SLC25A51 appears to be conserved *in vivo* and impacts liver regeneration.

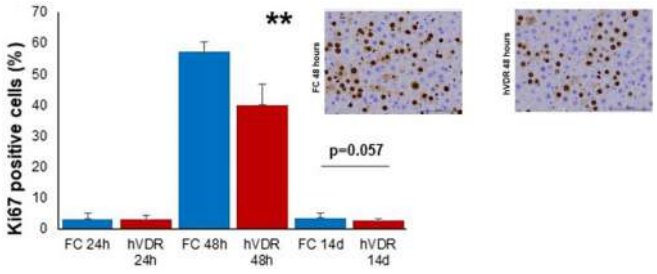
SAT169

The hepatocellular vitamin D receptor regulates liver regeneration after partial hepatectomy

Hari Elangovan[1,2], Jeremy Keane[1], Sarinder Chahal[1,2], Jennifer Chen[1], Christopher Liddle[3,4,5], Jenny Gunton[1,2,4,5]. *[1]Westmead Institute of Medical Research, The Centre for Diabetes, Obesity and Endocrinology Research, Westmead, Australia; [2]Garvan Institute of Medical Research, Darlinghurst, Australia; [3]The Westmead Institute for Medical Research, The Storr Liver Unit, Westmead, Australia; [4]Westmead Hospital, Westmead, Australia; [5]The University of Sydney, Faculty of Medicine and Health, Camperdown, Australia*
Email: harendran.elangovan@health.qld.gov.au

Background and aims: There is growing evidence to suggest a role for the vitamin D receptor (VDR) endocrine axis in the modulation of hepatic pathophysiology. However, normal hepatocytes express very low levels of the receptor, and the current dogma suggests that VDR mediates its hepatic functions through paracrine effects from non-parenchymal support tissue. We explored whether hepatocellular VDR (hVDR) might regulate liver regeneration following 2/3 partial hepatectomy (PHx) in a murine model. We hypothesized that hVDR null mice would experience worse regenerative outcomes after PHx.
Method: Hepatocyte-specific VDR null mice (hVDR null) and their floxed control (FC) littermates were bred via albumin promoter driven Cre-LoxP recombination. Utilizing Ki67 immunohistochemistry and polymerase chain reaction of cell cycle and apoptotic regulators, we comparatively analyzed the livers of hVDR null and their controls at 1-, 2- and 14-days post PHx.
Results: hVDR elimination blunted the hepatic regenerative response following pHx ((Ki67 positivity at 48 h hours, 57.1 ± 3.2% vs 40 ± 6.5%, p = 0.002) in hVDR null mice (see figure). This reduced cell proliferation appeared to persist into the 14-day mark with a diminution in gross regenerated liver weight (1.03 ± 0.02 g versus 1.11 ± 0.039 g, p <0.05) and a reduced liver-to-bodyweight ratio (3.6 ± 0.2% vs. 4.0 ± 0.4%, p <0.005) in hVDR null mice. Diminished cell proliferation was associated with reduced mRNA expression of cell cycle drivers Cyclin D (p <0.05), Cyclin E1 (p <0.01) and Cdk2 (p <0.05). We did not identify major differences in the expression of apoptotic regulators at the various time points examined.



Conclusion: hVDR supports liver regeneration following PHx and loss of function appears to stymie this process predominantly through impairment in cell cycle transition, consistent with VDR's function as a transcription factor. These results add further insight into the panoply of mechanisms by which VDR signaling supports hepatic homeostasis following tissue injury. VDR receptor ligands may have therapeutic utility in optimizing regenerative outcomes in the clinical setting.

SAT170

Selective induction of macrophage RNF41 stimulates liver regeneration in hepatectomized healthy and fibrotic mice

Email: pmelgar@ub.edu

Background and aims: Hepatectomy and liver transplantation are the standard of care in patients with liver tumours and end-stage liver disease, respectively. Macrophage RNF41 is an E3 ubiquitin-protein ligase that has been associated with muscle regeneration but its role in liver repair is unknown. We aimed to evaluate the regenerative effects of macrophage RNF41 induction in mouse models of partial hepatectomy.
Method: Fibrosis was induced with i.p. injections of CCl_4 (1/8 in corn oil) in BALB/c mice (n = 12) twice a week for 9 weeks. Partial hepatectomy was carried out in twelve healthy (70% resection, HP70) or fibrotic (40% resection, HP40) mice. Selective macrophage RNF41 induction was achieved with i.v. (50 μg/Kg) injection of a plasmid encoding RNF41 regulated by a CD11b promoter and linked to dendrimer-graphite nanoparticles (pRNF41-DGNP) every 3 days for 9 days. A scrambled pRNF41 composition served as control (pSCR-DGNP). Liver restoration rate, proliferating cell nuclear antigen (PCNA) immunostaining, hepatic function and the expression of growth factors were evaluated. *In vitro* assays were designed to assess hepatocyte proliferation under stimulation with conditioned media from RAW 264.7 macrophages treated with pRNF41-DGNP or pSCR-DGNP.

Results: Induction of macrophage RNF41 promoted higher hepatic restoration rate in HP70 mice treated with pRNF41-DGNP than in mice receiving pSCR-DGNP (6.3 ± 0.1 g/body weight, BW vs. 7.1 ± 0.1 g/BW, p <0.001). This effect was highlighted by the higher number of hepatic PCNA positive cells (3.2 ± 0.3% vs. 15.6 ± 0.9%, p <0.001). Induction of RNF41 did not affect hepatic function (AST, 511.8 ± 81.8 vs. 562.6 ± 59.2 U/L, ns; ALT, 117.3 ± 7.3 vs. 122.2 ± 13.3 U/L, ns). Fibrotic mice with HP40 treated with pRNF41-DGNP also showed a higher hepatic restoration rate (6 ± 0.1 g/BW vs. 7 ± 0.1 g/BW, <0.0001) and increased PCNA positive cells (2.6 ± 0.2% vs. 19.2 ± 2.4%, p <0.001) than fibrotic animals receiving pSCR-DGNP. In contrast to healthy mice with HP70, the selective macrophage RNF41 induction did improve liver function in fibrotic HP40 mice (AST, 742.1 ± 83.7 vs. 325.1 ± 72 U/L, p <0.01; ALT, 175.9 ± 15.15 vs. 65.17 ± 10.2 U/L, p < 0.001). The pro-regenerative effect of RNF41 that we observed in both animal models of partial hepatectomy was associated with an increased expression of liver insulin-like growth factor 1 (IGF-1) (HP70, 1 ± 0.1 vs. 4 ± 1 fold change (fc), p <0.05; HP40, 1 ± 0.1 vs. 2.8 ± 0.6 fc, p <0.05). Conditioned media from macrophages treated with pRNF41-DGNP stimulated hepatocyte proliferation (0.2 vs. 0.3 arbitrary units, ai, p <0.0001). This proliferative effect was reduced by IGF-1 blockade with a specific antibody (0.3 vs. 0.2 ai, p <0.0001).
Conclusion: Macrophage RNF41 plays a major role in hepatic regeneration after partial hepatectomy. This work provides a novel therapeutic target for the stimulation of liver regeneration after liver resection.

SAT171
Generation of functional ductal organoid with biliary tree network in decelluarized liver scaffold
Jiaxian Chen[1], Xi Liang[2], Heng Yao[1], Shiwen Ma[1], Hui Yang[1], Deying Chen[1], Jing Jiang[1], Dongyan Shi[1], Jiaojiao Xin[1], Lei Geng[3], Yun Li[4], Jun Li[1]. *[1]The First Affiliated Hospital, Zhejiang University School of Medicine, State Key Laboratory for Diagnosis and Treatment of Infectious Diseases, Hangzhou, China; [2]Taizhou Central Hospital (Taizhou University Hospital), Precision Medicine Center, Taizhou, China; [3]The First Affiliated Hospital, Zhejiang University School of Medicine, Hangzhou, China; [4]Zhejiang University*
Email: lijun2009@zju.edu.cn

Background and aims: Developing functional biliary tree organoids is essential for liver regenerative medicine. This study aims to construct a functional ductal organoid (DO) with biliary tree network in decelluarized liver scaffold (DLS) with primary cholangiocytes.
Method: Primary cholangiocytes isolated from mouse extrahepatic bile ducts were transplanted into the rat DLS to construct a functional DO. The developed DOs were dynamically characterized by bio-functions and the bio-processes with metabolomics.
Results: Functional DOs was generated in DLS retaining native structure and bioactive factors with mouse primary cholangiocytes expressing enriched biomarkers. The results of morphology assessment showed that the biliary tree-like structures gradually formed from day 3 to day 14. The cholangiocytes in the DOs maintained high viability and highly expressed 9 specific biomarkers (eg. cytokine 7, cytokine 19, EpCAM, aquaporin 1, prominin 1). The basal-apical polarity was observed at day 14 with immunostaining of E-cadherin and alpha-tubulin. The rhodamine 123 transport assay and active collection of cholyl-lysyl-fluorescein revealed that DOs exhibited functions of bile secretion and transportation at day 14, and without observed in monolayer and hydrogel culture systems. The metabolomics analysis with 1075 peak pairs showed that serotonin, as a key molecule of tryptophan metabolism pathway linked to the biliary functions, specifically expressed in functional DO during the period of whole culture process.

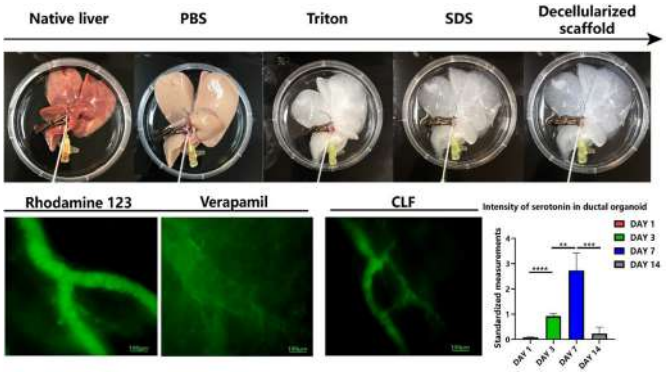

Figure: Primary cholangiocytes generated into functional ductal organoid with biliary tree network in decellularized whole liver scaffold.

Conclusion: A functional DO, with biliary tree network and differential expression of serotonin, was generated with primary cholangiocytes in DLS. It provides the feasibility for disease modeling and drug screening, and paves the way for future clinical therapeutic applications.

SAT172
Molecular basis of hepatic differentiation of human bone marrow mesenchymal stem cell in vivo
Dongyan Shi[1], Xi Liang[2], Jing Jiang[1], Lunzhi Yuan[3], Jiaojiao Xin[1], Suwan Sun[1], Beibei Guo[1], Xingping Zhou[1], Jiaxian Chen[1], Tong Cheng[3], Xin Chen[4], Ningshao Xia[3], Jun Li[1]. *[1]The First Affiliated Hospital, Zhejiang University School of Medicine, State Key Laboratory for Diagnosis and Treatment of Infectious Diseases, National Clinical Research Center for Infectious Diseases, Collaborative Innovation Center for Diagnosis and Treatment of Infectious Diseases, Hangzhou; [2]Taizhou Central Hospital (Taizhou University Hospital), Precision Medicine Center, Taizhou, China; [3]Xiamen University, State Key laboratory of Molecular Vaccinology and Molecular Diagnostics, National institute of Diagnostics and Vaccine Development in infectious Diseases, School of life Sciences and School of Public Health, Xiamen, China; [4]Zhejiang University School of Medicine, Institute of Pharmaceutical Biotechnology and the First Affiliated Hospital Department of Radiation Oncology, Hangzhou, China*
Email: lijun2009@zju.edu.cn

Background and aims: The human bone marrow mesenchymal stem cells (hBMSCs) derived hepatocytes are promising in liver regenerative medicine. This study aims to clarify the detailed molecular basis of the hepatocyte differentiation in vivo.
Method: The transcriptomics of hBMSCs-derived hepatocytes isolated from the liver-humanized mice were performed to reveal the differentiation basis.
Results: The cultured hBMSCs-derived hepatocytes isolated from the liver-humanized mice with hBMSCs transplantation exhibited the phenotypical characteristics of mature hepatocytes. Functional analysis of 2385 differentially expressed genes showed the implanted hBMSCs initiated hepatic differentiation at day-2 and gradually matured within 14 days. The bioprocesses of losing of stem cell characteristics, the hepatocyte differentiation and maturation (including glucose biosynthesis, drug metabolism, lipid transport, blood coagulation and complement cascades) were observed at day-1, day-2 and day-14, respectively. Engineering Evaluation by Gene Categorization analysis showed that the proportion of sufficient gene sets of hepatocyte differentiation increased from 4.6% at day-1 to 39.3% at day-14. The hepatocyte specific functional bioprocesses, including organic and carboxylic acid biosynthesis, and sulfur compound and fatty acid metabolism, appeared within 7 days. Transcription factor (TF) predictive analysis revealed that the liver specific TFs (including HNF4A, NR1H4 and FOXA3) initially expressed and regulated the hepatocyte functions from day-2. The increased

expressions of top 10 TFs confirmed their regulation during the hepatic differentiation periods.

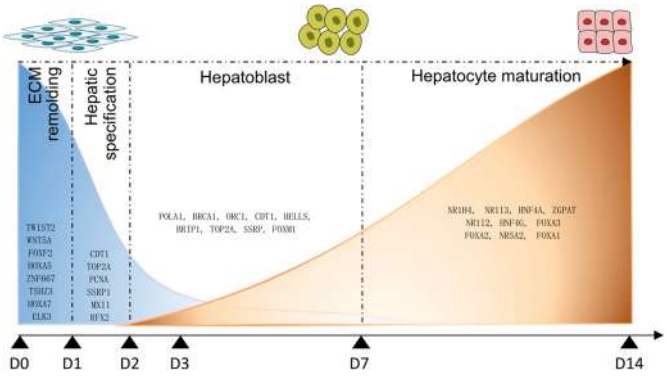

Figure: Process of hepatic differentiation of hBMSCs in vivo.

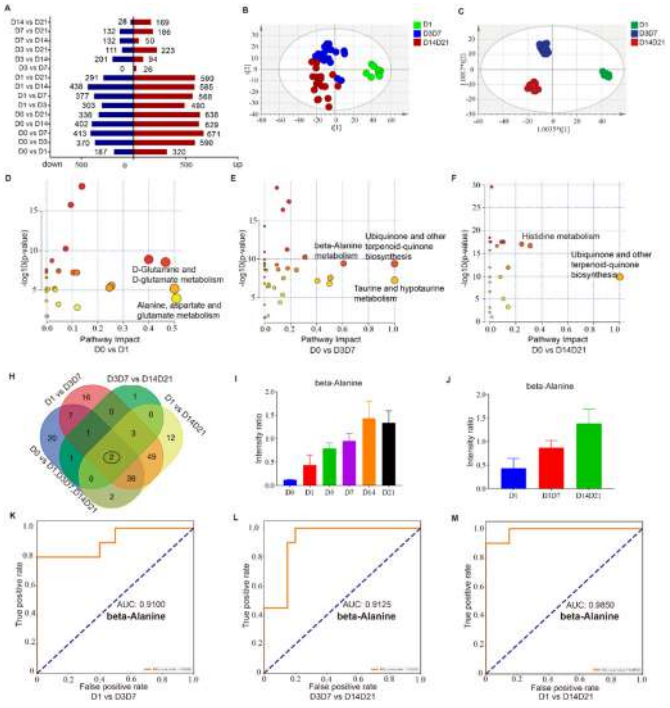
Conclusion: This study clarified the molecular basis of rapidly hepatocytic differentiation and maturation within 14 days in vivo, which may help for the clinical use of hBMSCs-derived hepatocytes in liver regenerative medicine.

SAT173

Dynamic alterations of metabolites revealed the vascularization progression of bioengineered liver

Qian Zhou[1], Beibei Guo[1], Deying Chen[1], Heng Yao[1], Xi Liang[2], Jiaojiao Xin[1], Dongyan Shi[1], Keke Ren[1], Hui Yang[1], Jing Jiang[1], Jun Li[1].
[1]*The First Affiliated Hospital, Zhejiang University School of Medicine, State Key Laboratory for Diagnosis and Treatment of Infectious Diseases, Hangzhou, China;* [2]*Taizhou Central Hospital (Taizhou University Hospital), Precision Medicine Center, Taizhou, China*
Email: lijun2009@zju.edu.cn

Background and aims: Vascularization is a critical but challenging process in developing functional bioengineered liver with the decellularized liver scaffolds (DLSs), in which, the process is accompanied by cell-specific metabolic alterations. The aims of the study were to explore the global change in the metabolic profile of human umbilical vein endothelial cells (HUVECs) during vascularization, and to identify the specific metabolites for evaluating the biological activities and cellular status, thereby providing a foundation for future research on the construction of a functionally vascularized bioengineered liver.
Method: Decellularize the whole rat liver with the most commonly used cocktail of detergents phosphate-buffered saline, 1% (v/v) Triton X-100 and 0.1% (w/v) sodium dodecylsulfate at a flow rate of 20 ml/min. The resulted DLSs were vascularized with HUVECs, and a liquid chromatography mass spectrometry-based metabolomics was performed on culture supernatants collected at 0, 1, 3, 7, 14 and 21 days during the 3 weeks of dynamic perfusion. The 309 positive metabolites were analysed with principal component analysis, partial least squares discriminant analysis and orthogonal partial least-squares discriminant analysis. MetaboAnalyst 5.0 database was then used for metabolic pathway and enrichment analysis.
Results: 1. A total of 1698 peak pairs were detected from the culture supernatant, with 309 metabolites being positively identified with high confidence using the dansyl library.
2. Principal component analysis showed a good separation of phase D1 (d0-d1), phase D3D7 (d3-d7), and phase D14D21 (d14-d21).
3. The biological processes of phase D1 were associated with alanine, aspartate and glutamate metabolism, D-Glutamine and D-glutamate metabolism. The metabolites that were activated in phase D3D7 mainly participated in ubiquinone and other terpenoid-quinone biosynthesis, taurine and hypotaurine metabolism, and beta-alanine metabolism. Meanwhile, the metabolites in phase D14D21 were more relevant to histidine metabolism, and ubiquinone and other terpenoid-quinone biosynthesis.
4. beta-Alanine discriminated any two phases with AUCs of 0.9100, 0.9125 and 0.9850. Its high expression on day 14 predicted the patency of vascularized bioengineered livers.



Conclusion: In this study, we revealed the metabolic alterations that occur during DLS vascularization and divided the vascularization process into 3 phases from metabolic perspective, including phase D1 (cell proliferation and migration), phase D3D7 (vascular lumen formation) and phase D14D21 (functional endothelial barrier formation). A high level of beta-Alanine on day 14 predicted the patency of vascularized bioengineered livers, which confirmed our previous finding that 14 days of in vitro dynamic culture is required for DLS vascularization.

Pharmacologic inhibition of HSD17B13 is hepatoprotective in mouse models of liver injury

Manuel Roqueta-Rivera[1], Mary Chau[1], Kelsey Garlick[1], Anand Balakrishnan[1], Archie C. Reyes[1], Jonathan Lloyd[1], Sourav Ghorai[1], Jiang Long[1], Joe Panarese[1], Bin Wang[1], Khanh Hoang[1], Tim Greizer[1], Lijuan Jiang[1], Guoqiang Wang[1], Yat Sun Or[1], Bryan Goodwin[1]. [1]*Enanta Pharmaceuticals, Inc., United States*
Email: mroqueta@enanta.com

Background and aims: Genome wide association studies identified a loss of function variant (rs72613567:TA) in HSD17B13 which confers protection against chronic liver diseases. As a result, HSD17B13 inhibitors may have clinical utility in non-alcoholic steatohepatitis and other liver diseases. Here we describe the identification and characterization of a novel, potent, and selective HSD17B13 inhibitor with hepatoprotective effects in preclinical models of liver injury.

Method: Multiple chemical series of HSD17B13 inhibitors were identified and optimized for potency, selectivity, and pharmacokinetic properties. Mass spectrometry was used to monitor HSD17B13 inhibition (HSD17B13i) of dehydrogenase activity in biochemical and cellular assays. *In vivo,* HSD17B13i was evaluated in a mouse model of acute (adenoviral) and chronic liver injury (choline deficient, L-amino acid defined, high fat diet; CDAHFD; A16092201). Markers of inflammation, injury and fibrosis were measured in plasma and liver. Transcriptomics and lipidomics suggested a potential hepatoprotective mechanism for HSD17B13i. Primary human hepatocytes (PHH) carrying the TA allele were used in gain of function studies.
Results: In biochemical assays, a tool compound (EP-036332) inhibited human HSD17B13 with a half-maximal inhibitory concentration (EC_{50}) of 14 nM. In cell based assays, EP-036332 inhibited human and mouse HSD17B13 with EC_{50}s of 47 and 55 nM, respectively. EP-036332 was selective for HSD17B13 over other HSD17B enzymes (>400 fold). In an adenoviral liver injury model, both HSD17B13i and a short hairpin RNA targeting mouse HSD17B13 were hepatoprotective. In addition to reduced plasma ALT and TNF-alpha, pharmacologic and genetic inhibition of HSD17B13 had overlapping transcriptional effects, including modulation of natural killer cell cytotoxicity (*Ifng*, *Gzmb)*, chemokines (*Cxcr6, Cxcl9, Ccl2*), and necroptosis (*Tnf, Fasl*). A similar gene expression profile was seen in a CDAHFD liver injury model (3 weeks of diet lead-in and 8 weeks of HSD17B13i). Within one week, HSD17B13i dose-dependently decreased ALT and favored an anti-inflammatory (*Nlrp3, S1pr4*), anti-fibrotic (*Tgfb2, Ctgf*) gene profile. After 8 weeks of HSD17B13i, liver hydroxyproline, plasma ALT and AST were significantly decreased. Lipidomics revealed HSD17B13i effects on lipid droplet composition (sphingolipids) and lower liver sphingosine-1-phosphate and cholesterol. Consistent with *in vivo* observations, rescue of HSD17B13 in PHH carrying the TA allele resulted in sphingolipid alterations.
Conclusion: Hepatoprotection by HSD17B13i in rodent injury models is characterized by a favorable bioactive lipid profile with a decrease in markers of cytotoxic immune cell activation, cell death, and fibrosis. Overall, these data provide preclinical pharmacologic validation of HSD17B13 inhibitors for the treatment of liver disease.

SAT178
Inhibition of NLRP3 inflammasome by GPR40 agonists

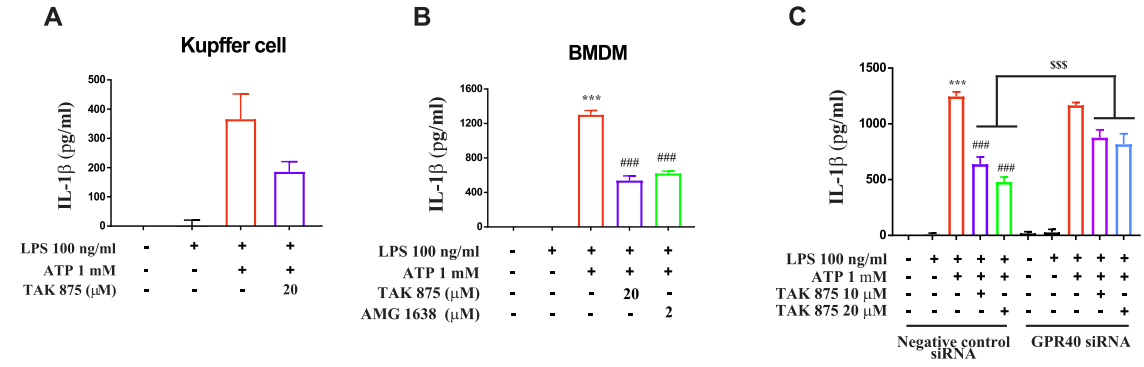
Jeongwoo Park[1], Moo-Yeol Lee[2], Yoon-Seok Seo[2], Sung-Chul Lim[3], Keon Wook Kang[1]. [1]*Seoul National University, College of pharmacy, Seoul, Korea, Rep. of South;* [2]*Dongguk University, College of pharmacy, Goyang, Korea, Rep. of South;* [3]*Chosun University, College of medicine, Gwangju, Korea, Rep. of South*
Email: kwkang@snu.ac.kr

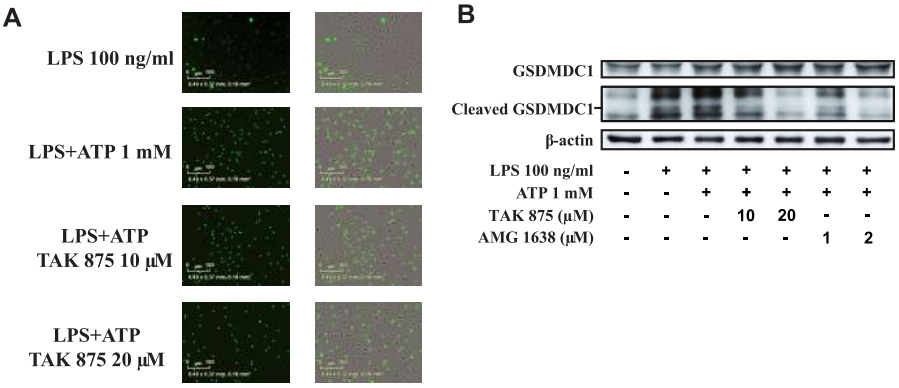
Background and aims: NOD-like receptor pyrin domain-containing protein 3 (NLRP3) inflammasome is a multi-protein intracellular complex that activates pro-inflammatory cytokines including interleukin (IL)-1β and IL-18. The activation of inflammasome is known to be related with metabolic inflammation such as the progression of non-alcoholic steatohepatitis. Fasiglifam (TAK875), a selective G-protein coupled receptor 40 (GPR40) agonist with high affinity, significantly improves glucose-dependent insulin secretion and weight gain without hypoglycemia. In this study, we evaluated the functional role of GPR40 agonists in the activation of NLRP3 inflammasome in bone marrow-derived macrophages (BMDMs), kupffer cells and an acute hepatitis mouse model.
Method: Primary BMDMs and kupffer cells were mainly used for cell-based analyses. For NLRP3 inflammasome activation, BMDMs were primed with LPS (100 ng/ml) for 4 h, and then pretreated with GPR40 agonists for 10 min, followed by incubation with ATP (1 mM) for 30 min. To test *in vivo* effects of TAK875, 9 weeks old C57BL/6J male mice were orally administrated with vehicle or 10 mg/kg TAK875 once a day for 4 days. The mice were intraperitoneally injected with 2.5 mg/kg LPS and 750 mg/kg D-galactosamine (D-GalN), and sacrificed after anaesthetization and blood and liver tissues were collected 4 h after LPS/D-GalN injection.
Results: TAK875 and AMG1638 suppressed activation of NLRP3 inflammasome in BMDMs. TAK875 inhibited the activation of inflammasome by blocking apoptosis-associated speck-like protein containing a CARD (ASC) formation which is a component of inflammasome. TAK875 also suppressed NLRP3 inflammasome-induced pyroptosis of BMDM. Moreover, nuclear factor-κB (NF-κB)-dependent priming signal of NLRP3 inflammasome was also partially inhibited by TAK875 and AMG1638. It has been known that intracellular Ca^{2+} increase by ATP, nigericin (pore forming toxin) or endoplamic reticulum (ER) stress activates NLRP3 inflammasome. Pre-exposure of BMDM to TAK875 suppressed ATP-induced intracellular Ca^{2+} increase, which was reversed by thapsigargin, a sarco/endoplasmic reticulum Ca^{2+}-ATPase (SERCA) inhibitor. Oral administration of mice with TAK875 decreased serum IL-1β increase in mice treated with lipopolysaccharide/D-galactosamine *in vivo*.
Conclusion: These findings provide an evidence that free fatty acid-sensing GPR40 plays a key role in NLRP3 inflammasome pathway.

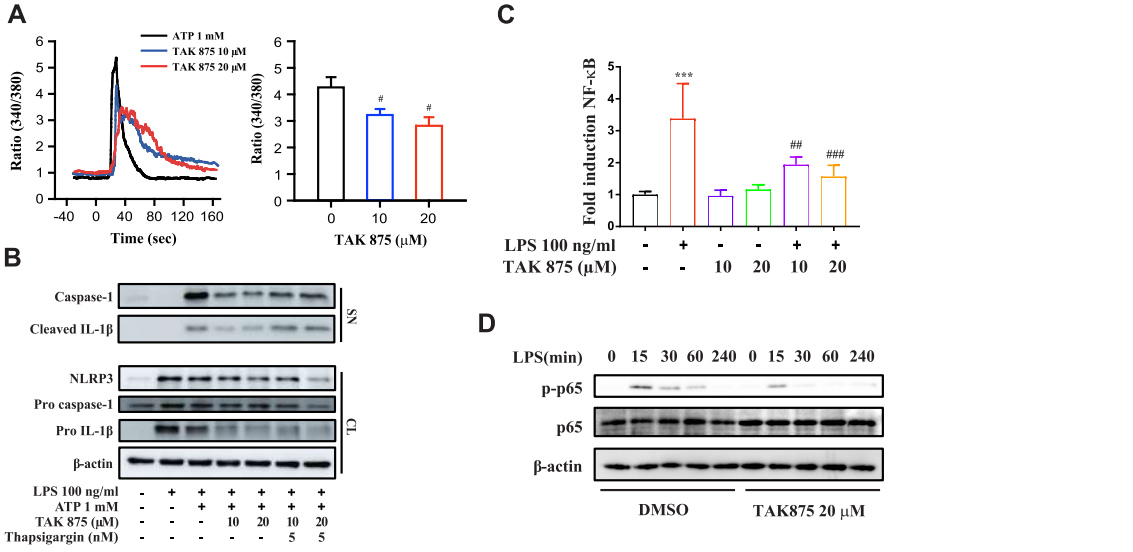
SAT179
Role of Monocyte chemoattractant protein-induced protein 1 in liver fibrosis and activation of hepatic stellate cells

Natalia Pydyn[1], Anna Ferenc[1], Justyna Kadłuczka[1], Piotr Major[2], Edyta Kus[3], Tomasz Hutsch[4,5], Andrzej Budzyński[2], Jolanta Jura[1], Jerzy Kotlinowski[1]. [1]*Faculty of Biochemistry, Biophysics and Biotechnology, Jagiellonian University, Department of General Biochemistry, Kraków, Poland;* [2]*2nd Department of General Surgery, Jagiellonian University Medical College, Poland;* [3]*Jagiellonian Centre for Experimental Therapeutics, Jagiellonian University, Poland;* [4]*Laboratory of Centre for Preclinical Research, Medical University of Warsaw, Department of Experimental Physiology and Pathophysiology, Poland;* [5]*Veterinary Diagnostic Laboratory ALAB Bioscience, Poland*
Email: natalia.pydyn@uj.edu.pl

Background and aims: Monocyte chemoattractant protein-induced protein 1 (MCPIP1) is a negative regulator of inflammation, acting through cleavage of transcripts coding for proinflammatory cytokines and by inhibition of NFκB activity. It was shown that Mcpip1 is involved in suppression of inflammatory response in liver macrophages. Moreover, overexpression of Mcpip1 reduces liver injury in septic mice, by inhibition of inflammatory reaction. On the other hand, Mcpip1 deletion in liver epithelial cells in $Mcpip1^{fl/fl}Alb^{Cre}$ mice resembles features of primary biliary cholangitis. In this study, we analyzed MCPIP1 level in human fibrotic livers and hepatic cells isolated from CCl_4-treated mice. We also investigated MCPIP1 impact on activation status of LX-2 hepatic stellate cell line.
Method: We analyzed liver biopsies isolated from 30 patients with fibrosis stage ranging from 0 to 4. To induce liver fibrosis during *in vivo* experiments, mice were injected with CCl_4 dissolved in corn oil (0, 2 mg/g), 3 times a week for 4 weeks. *In vitro* experiments were performed on LX-2 cells treated with TGF-β (5 or 10 ng/ml) to induce process of their activation.
Results: Analysis of patients' liver biopsies revealed that MCPIP1 level in liver tissue correlates with the development of fibrosis. To elucidate in which type of liver cells Mcpip1 level is induced during fibrotic changes, we analyzed its level in hepatocytes, HSCs and Kupffer cells isolated from fibrotic murine livers. We found that treatment with CCl_4 induces Mcpip1 expression in hepatocytes and hepatic stellate cells. On the other hand, Mcpip1 level in Kupffer cells from fibrotic livers is decreased. To evaluate role of MCPIP1 in activation of HSCs, we stimulated LX-2 cell line with TGF-β which resulted in increase of MCPIP1 level. Moreover, overexpression of MCPIP1 in LX-2 cells led to decreased mRNA expression of HSCs activation markers e.g. *Acta2, Tgfb, Col1a1* and α-SMA protein level. Contrary, MCPIP1 silencing in LX-2 cells resulted in their increased activation status.







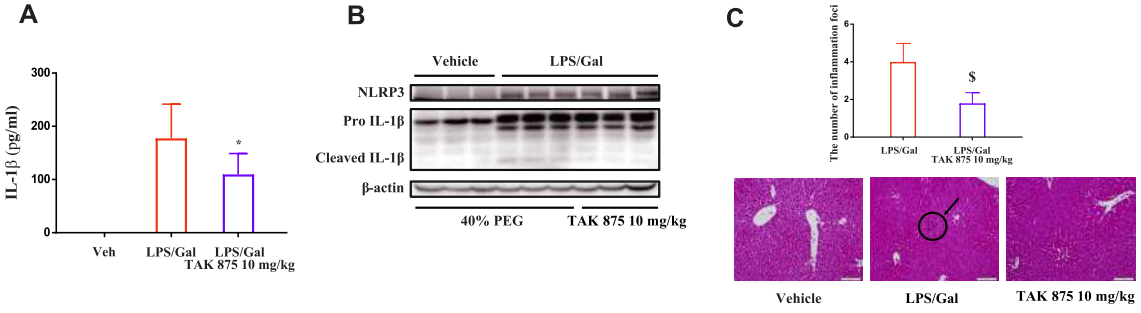


Figure: (abstract: SAT178)

Conclusion: In conclusion, we demonstrated a potent MCPIP1 role in liver fibrosis and activation of hepatic stellate cells. MCPIP1 presence in HSCs can be essential to prevent their excessive activation.
Acknowledgments: This study was supported by National Science Centre, grant number K/PBM/000672.

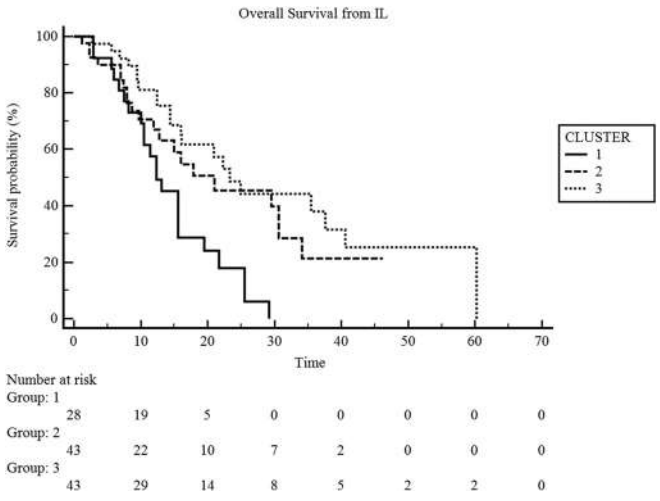
The genomic landscape of IDH1 mutant intrahepatic cholangiocarcinoma: a multicentre comprehensive analysis

Margherita Rimini[1], Teresa Mercade Macarulla[2], Valentina Burgio[1], Sara Lonardi[3], Monica Niger[4], Mario Scartozzi[5], Ilario Raposelli[6], Giuseppe Aprile[7], Francesca Ratti[1], Federica Pedica[1], Helena Verdaguer[2], Floriana Nappo[3], Federico Nichetti[4], Eleonora Lai[5], Martina Valgiusti[6], Alessandro Cappetta[7], Carles Fabregat[2], Matteo Fassan[3], Filippo De Braud[4], Marco Puzzoni[5], Giovanni Luca Frassineti[6], Francesca Simionato[7], Francesco De Cobelli[1], Luca Aldrighetti[1], Lorenzo Fornaro[8], Stefano Cascinu[1], Andrea Casadei Gardini[1]. *[1]Universitá Vita-Salute, IRCCS-San Raffaele Hospital; [2]Vall d'Hebron Institute of Oncology; [3]Veneto Institute of Oncology IOV-IRCCS; [4]Istituto Nazionale Tumori di Milano; [5]University Hospital of Cagliari; [6]Istituto Romagnolo per lo Studio dei Tumori "Dino Amadori"-IRST IRCCS; [7]Azienda ULSS8 Berica, Vicenza; [8]University Hospital of Pisa*
Email: margherita.rimini@gmail.com

Background and aims: The results obtained with new anti-IDH1 drugs in advanced cholangiocarcinoma (CCA) IDH1-mutant (IDH1m) patients, even if positive, didn't show durable responses. A better understanding of the biomolecular pathway, which could be involved in mechanisms of resistance to treatments, is an urgent need.
Method: We performed a retrospective analysis on 247 CCA patients (125 IDH1m and 122 IDH1 wilde type (wt)) tested with the FoundationOne platform. The primary end point was to perform a clustering analysis on IDH1m patients.
Results: From the clustering analysis, three main clusters resulted evident. The cluster 1 presented 84 mutated genes, including PI3K related genes (AKT, EGFR, ERBB2, FGFR2, FLT3, PDGFRA, PIK3CA, PIK3R1, PTEN, RET, SDHB, SDHC, SDHD and TSC1), and RAS related genes (BRAF, CIC, EGFR, ERBB2, FGFR2, FLT3, MAP2K1, MAP3K1, PDGFRA, PTPN11, RER, SSDHB, SDHC and SDHD). The cluster 2 presented 89 mutated genes, including chromatin modification related genes (ARID1A, ASXL1, CREBBP, DAXX, DNMT3A, KDM5C, MLL2, MLL3, NCOR1, PBRM1 and SETD2), DNA damage control related genes (ATM, BAP1, BRCA2, ERCC4, FANCA, MLH1, MSH2, MSH6 and TP53) and cell cycle related genes (ABL1, CASP8, CDK4, CDKN2A, DAXX, PPP2R1A and TP53). The cluster 3 presented 45 mutated genes, including cell cycle related genes (CDKN2A, MED12, NFE2L2, RB1 and TP53). At the univariate analysis for OS from the first line therapy, the inclusion in the cluster 1, 2 or 3 was highlighted to have a prognostic impact. In particular, the IDH1 m patients included in the cluster 1 showed a poorer OS compared with those included in the cluster 2 and 3 ($p = 0.0025$).
In the entire sample of patients (IDH1m and IDH1wt) the most frequently mutated or altered genes in our sample were: CDKN2A (27%), ARID1A (20%), CDKN2B (17%), PBRM1 (17%), KRAS/NRAS (16%), BAP1 (16%), TP53 (15%), FGFR2 (10%), BRCA2 (9%), PIK3CA (8.5%), ATM (7%), MTAP (7%) and MAP3K1 (7%). IDH1m patients showed more frequently alterations in CDKN2B ($p = 0.04$), and less frequently alterations in TP53, FGFR2, BRCA2, ATM and MAP3K1 ($p = 0.0006$, $p = 0.0013$, $p = 0.0015$, $p = 0.047$, $p = 0.0053$, respectively). In IDH1m cohort CDKN2A and CDKN2B resulted to negatively impact on DFS, while CDKN2A, CDKN2B and PBRM1 negatively impacted on OS from surgery; no genomic alterations resulted to impact prognosis in IDH1wt cohort. In IDH1m cohort alterations in KRAS/NRAS and TP53 resulted to negatively impact PFS while alterations in TP53 and PIK3CA negatively impacted on OS from I line; in the IDH1wt patients, MTAP negatively impact PFS while TP53 negatively impact OS from I line.



Conclusion: We identified three genomic clusters with prognostic value in IDH1m patients. This new insight in IDh1m CCA could help to identify mechanisms of resistance to treatments, including anti-IDH1.

SAT181

Isolation of hepatocytes from various liver tissues by a novel, semi-automated perfusion technology

Carsten Poggel[1], Timo Adams[1], Ronald Janzen[1], Alexander Hofmann[2], Olaf Hardt[1], Elke Roeb[3], Sarah K. Schröder[4], Carmen G. Tag[5], Martin Roderfeld[3], Ralf Weiskirchen[5]. *[1]Miltenyi Biotec B.V. Co. KG, Bergisch Gladbach, Germany; [2]Miltenyi Biotec B.V. Co. Email: carsten@miltenyibiotec.de

Background and aims: Primary liver cells represent a major tool in biomedical research. Presently, different protocols for the isolation of liver cell subsets have been introduced, which require trained staff to avoid considerable fluctuations in quality and yield. We aimed at establishing an easy workflow for the generation of hepatocytes.
Method: We developed a new semi-automated perfusion technology, which is suitable for the gentle, rapid, and efficient generation of single-cell suspensions from rodent livers. Tissue is clamped into a newly designed disposable (Perfuser) and enzymatically digested using optimized components. Afterwards, single-cells are liberated from the tissue by a short mechanical disruption of the perfused tissue and the sample is applied to a strainer to remove any remaining larger particles from the single cell suspension. Yield, viability and purity of cells were determined. Cells were stimulated with different cytokines and expression of target genes was analyzed by Western blot analysis.
Results: The new perfusion technology is suitable to generate single-cell suspensions from liver tissue. We have constructed a new tube format (Perfuser) which is run in combination with optimized reagents and newly designed sleeves on the gentleMACS instrument for optimal isolation of hepatocytes. The yield isolated from one liver lobule is $\sim 14 \times 10^6$ cells with ~83% viability. In culture, the cells take on the characteristic flattened, hexagonal appearance and can be grown for several days. After stimulation with IL-1β, the cells express and secrete large quantities of LCN2, previously shown to be a target of IL-1β. The elaborated protocol takes less preparation time than conventional protocols and also enables the isolation of hepatocytes from other sources such as rat, hamster, and human liver specimens.

Conclusion: The Perfusion Technology allows simple and reliable isolation of primary hepatocytes. Perfuser and appropriate reagents were optimized for parenchymal rodent liver cells but can be adapted to non-parenchymal cells. The semi-automated workflow enabling liver perfusion in a closed system is easy to apply and helps to implement the 3R principle because only one liver lobule is perfused, while others can be used for further experimentation. Nested processing allows simultaneous handling of up to 8 samples. The protocol does not require inconvenient perfusion in living animals avoiding the need of animal ethics approval.

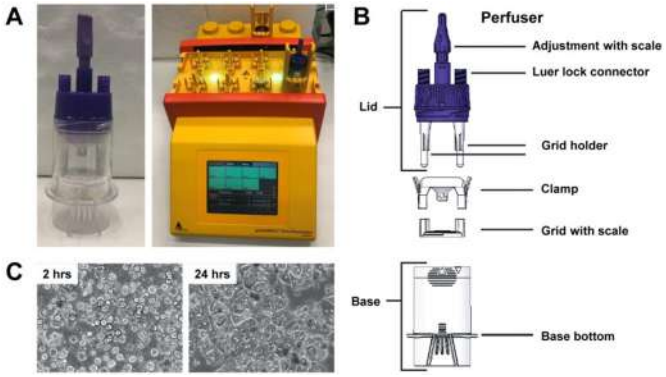

Figure: Semi-automated dissociation of liver tissue. (A) Overview of the Perfusion Technology. (B) Structure of the Perfuser used for generation of single cell cultures from rodent livers. **(C)** Hepatocytes isolated with optimized reagents after seeding for 2 hours (*left*) or 24 hours (*right*).

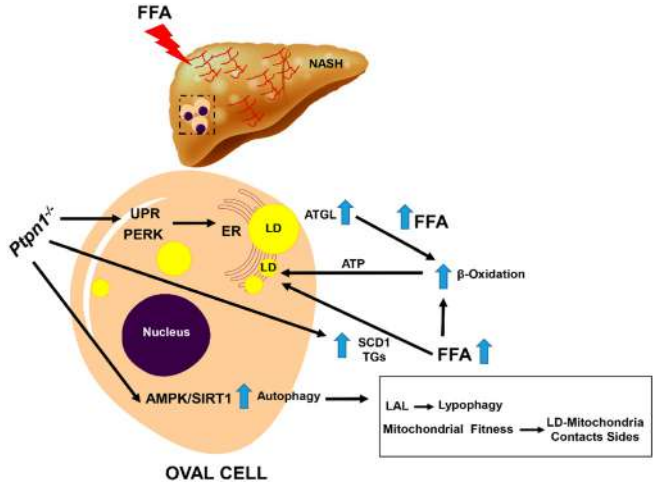
Email: pvaldecantos@iib.uam.es

Background and aims: Activation of oval cells has been related to hepatocyte injury during chronic liver diseases including non-alcoholic fatty liver disease (NAFLD). However, oval cells plasticity can be affected by the pathological environment. We previously found a protection against hepatocyte cell death by inhibiting protein tyrosine phosphatase 1B (PTP1B). Herein, we investigated the molecular and cellular processes involved in the lipotoxic susceptibility in oval cells expressing or not PTP1B.

Method: Palmitic acid (PA) induced apoptotic cell death in wild-type (*Ptpn1*$^{+/+}$) oval cells in parallel to oxidative stress and impaired autophagy. This lipotoxic effect was attenuated in oval cells lacking *Ptpn1* that showed up-regulated antioxidant defences, increased unfolded protein response (UPR) signaling, higher endoplasmic reticulum (ER) content and elevated stearoyl CoA desaturase (*Scd1*) expression and activity.
Results: These effects in *Ptpn1*$^{-/-}$ oval cells concurred with an active autophagy, higher mitochondrial efficiency and a molecular signature of starvation, favoring lipid droplet (LD) formation and dynamics. Autophagy blockade in *Ptpn1*$^{-/-}$ oval cells reduced *Scd1* expression, mitochondrial fitness, LD formation and restored lipoapoptosis, an effect also recapitulated by *Scd1* silencing. Importantly, oval cells with LDs were found in livers from *Ptpn1*$^{-/-}$ mice with NAFLD.



Conclusion: *Ptpn1* deficiency restrained lipoapoptosis in oval cells through a metabolic rewiring towards a "starvation-like" fate, favoring autophagy, mitochondrial fitness and LD formation. Dynamic LD-lysosomal interations likely ensured lipid recycling and, overall, these adaptations protect against lipotoxicity. The identification of LDs in oval cells from *Ptpn1*$^{-/-}$ mice with NAFLD opens new therapeutic perspectives to ensure oval cells viability and plasticity under lipotoxic liver damage.

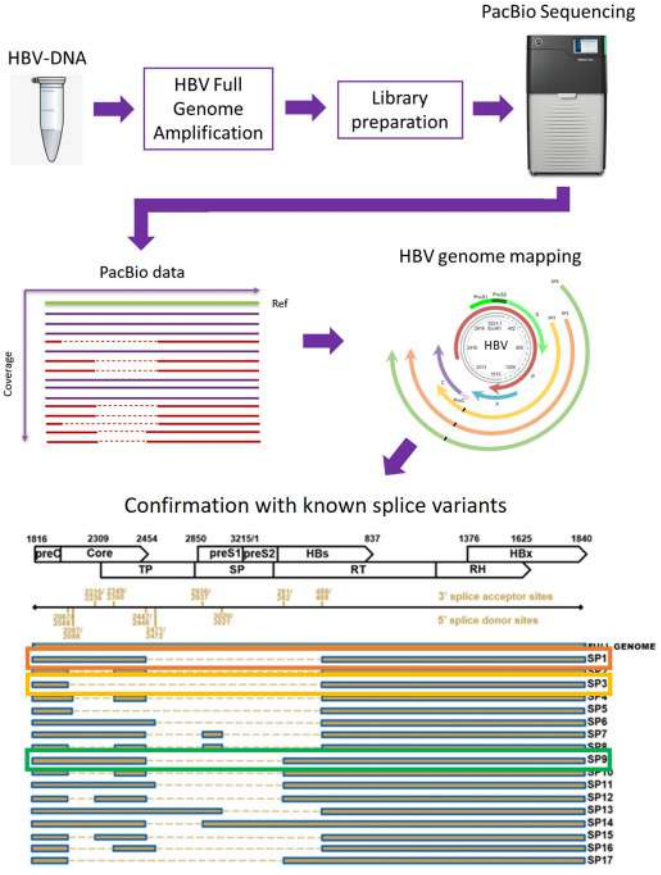
Accurate detection of HBV splice variant DNA by using long-read sequencing

Sanne Hulspas[1], Cornelis Knetsch[1], Michiel Weber[1], Anne Hout[1], Leen-Jan van Doorn[1]. [1]*Viroclinics-DDL, Rijswijk, Netherlands*
Email: sanne.hulspas@ddl.nl

Background and aims: Hepatitis B virus (HBV) RNA splice variants might play an important role in the HBV life cycle and pathogenesis. Although the biological and clinical significance of splice variants remains to be defined, some studies have linked HBV spliced variants to impaired response to interferon-α therapy. In depth HBV genome analysis may help to understand the role of splice variants in disease pathogenesis. With long-read sequencing, a spliced HBV genome can be covered by a single read, in contrast to short reads where the spliced genome is sequenced by multiple fragmented shorter reads. In a mixed population sample with both splice variant and full genomes, these shorter reads may originate either from the spliced template or the original full length genome template. In this study, we report our findings on the accurate detection of HBV splice variant DNAs in plasma (derived from RNA splice variants generated in the liver) with PacBio long-read sequencing.

Method: Starting material for the analysis were plasma sample from HBV-infected patients. Nucleic acid extraction was performed by using the QIAamp MinElute Virus Spin Kit (QIAGEN). The isolated DNA was amplified for HBV full genome by PCR and nested PCR, using the Expand high-fidelity PCR kit (Roche Molecular Systems). Sequencing libraries were prepared using the SMRTbell Express Template Prep Kit 2.0 (Pacific Biosciences). All sequencing reactions were performed on the PacBio Sequel System with the Sequel Sequencing Kit 3.0 chemistry (Pacific Biosciences). Sequencing was performed by using the circular consensus sequencing (CCS) mode, creating HiFi consensus reads. Splice variant analysis was done by using our in-house bioinformatics pipeline Athena.
Results: A first indication of the presence of splice variants is obtained by visualizing the amplification products on gel and looking at the read length distribution after sequencing. In our samples we observed multiple amplicons with varying lengths. After sequencing the read length distribution showed samples with full length HBV genome CCS reads (~3200 bp) and shorter CCS reads of varying size (~1600, ~2000, ~2400 bp). CCS reads were bioinformatically mapped against an HBV reference sequence using minimap2. Consequently, the read mapping was parsed with separate scripting on individual read level, resulting in read counts for each unique start and end splice junction combination. The read counts for potential splice variants were summarized in a table and the most prevalent ones were compared with literature. All identified dominant splice variants were virtually identical to the splice variants described in literature. In the example shown, we specifically identified DNAs, derived from SP1, 3 and 9 (Figure 1).



Conclusion: HBV splice variant DNA can be accurately detected with PacBio long-read sequencing.

SAT185

The identification and characterization of novel bile acid-derived Farnesoid X Receptor agonists

Dannielle Kydd-Sinclair[1], Kimberly A. Watson[1], Alex Weymouth-Wilson[2], Gemma Packer[3]. [1]*University of Reading, United Kingdom;* [2]*ICE Group, Italy;* [3]*NZP UK Ltd., United Kingdom*
Email: dannielle.kydd-sinclair@reading.ac.uk

Background and aims: Since its deorphanisation in the early 2000s, the farnesoid X receptor (FXR) has attracted significant attention due to its role in regulating genes involved in bile acid, lipid, glucose metabolism and inflammation. With these metabolic pathways underlying the aetiology of various liver diseases, it is unsurprising that pharmaceutical efforts have targeted FXR also for their treatment. While several FXR agonists, such as obeticholic acid, have been studied in clinical trials, they have been associated with adverse effects arising from the promiscuity of systemic FXR activation and efforts to limit or selectively modulate FXR downstream effects are now being investigated.
Method: *In silico* molecular modelling was performed using Surflex-dock (SYBYL, Tripos) to screen a library of bile acid-derived compounds. Lead compounds were tested further in Lantha screen coactivator recruitment assays (Invitrogen) and in biolayer interferometry assays (Sartorius) using biotinylated, recombinant FXR ligand binding domain. Compounds were added to cultured HepG2 and Huh7 cells for 6 hours, or given to C57BL/6 mice by oral gavage daily for 5 days. After respective treatment, cells or left lobe liver tissue were harvested and total RNA extracted for gene expression analysis by RT-qPCR.
Results: We have identified 2 novel compounds as potent and selective FXR agonists. Docking results, confirmed by the co-crystal structures of FXR LBD complexed with each compound, demonstrates a unique binding mode for each compound, not observed with classic bile acids, including occupancy of a receptor sub-pocket associated with allosteric activation. Both compounds had higher affinities for FXR and were more efficacious than obeticholic acid by up to ten times, and coactivator recruitment assays identified potential differential recruitment dependent on the compound complexed with FXR. In vitro, both compounds were more effective than obeticholic acid at regulating FXR target genes, whereas *in vivo*, there appeared to be compound-dependent differential regulation of these genes.
Conclusion: Work here suggests that novel compounds 1 and 2 may be able to achieve gene-specific FXR regulation due to their proposed differential coactivator usage and thus may be promising candidates worthy of further research.

SAT186

SARS-CoV-2 induces pericyte procoagulant response associated with portal vein microthrombosis and intrapulmonary vascular dilations in fatal COVID-19

Alberto Lasagni[1], Massimiliano Cadamuro[2], Claudia Maria Radu[3,4], Arianna Calistri[2], Matteo Pilan[2], Clarissa Valle[5], Pietro Angelo Bonaffini[5], Adriana Vitiello[2], Sandro Sironi[5], Maria Grazia Alessio[6], Previtali Giulia[6], Michela Seghezzi[6], Andrea Gianatti[7], Mario Strazzabosco[8], Alastair J Strain[9], Elena Campello[1,3], Luca Spiezia[3], Giorgio Palu[2], Cristina Parolin[2], Aurelio Sonzogni[7], Paolo Simioni[1,3], Luca Fabris[1,2,8]. [1]*Padua University-Hospital, Division of General Medicine, Padova, Italy;* [2]*University of Padua, Department of Molecular Medicine, Padova, Italy;* [3]*University of Padua, Department of Medicine, Thrombotic and Hemorrhagic Diseases Unit, Padova, Italy;* [4]*University of Padua, Department of Women's and Children's Health (SDB), Padova, Italy;* [5]*ASST Papa Giovanni XXIII Hospital, Department of Diagnostic Radiology, Bergamo, Italy;* [6]*ASST Papa Giovanni XXIII Hospital, Clinical Chemistry Laboratory, Bergamo, Italy;* [7]*ASST Papa Giovanni XXIII Hospital, Department of Pathology, Bergamo, Italy;* [8]*Yale University, Digestive Disease Section, Liver Center, New Haven, United States;* [9]*University of Birmingham, School of Bioscience, Birmingham, United Kingdom*
Email: luca.fabris@unipd.it

Background and aims: Alterations in portal microvasculature have been reported in lethal cases of COVID-19, but underlying mechanisms and clinical significance are unclear. Intrapulmonary vascular dilations (IPVD) arising during chronic or acute liver disease may contribute to hypoxemia. We hypothesize a link between portal vein microthrombosis and persistent hypoxia in patients with severe COVID-19.
Method: Patients who died from COVID-19 (n = 93) and underwent autopsy, were retrospectively analysed for presence of portal vein microthrombosis and IPVD at the capillary level (histology), and hypoxemia (arterial blood gas analysis). Peripheral IPVD was also evaluated by chest-computed tomography (CT), when performed. Hepatic vascular lesions were phenotyped by endothelial (vWF) and pericyte (αSMA or PDGFR-β) markers, tissue factor (TF) and viral nucleoprotein (NP). In-vitro, pericytes were infected with SARS-CoV-2 to measure TF expression and effects on endothelial cell (EC) phenotype.
Results: In 15 patients (12 males), portal vein microthrombosis was associated with diffuse IPVD (tissue involvement >75%). They were younger (62 vs 75 years), had a longer illness (27 vs 14 days) with persistent hypoxemia (median $PaO_2/FiO_2 = 106$) needing more mechanical ventilation (67% vs 24%), than patients with absent or focal lung vascular abnormalities (n = 78, all p < 0, 01). In 13 patients, a significant enlargement of the peripheral intrapulmonary artery diameter unrelated to pulmonary embolism was confirmed by chest-CT (mean = 5, 1 mm, 95% CI 4, 6–5, 5). The small intrahepatic portal veins showed more extensive thrombosis (median = 85 vs 67, 5%, p < 0, 05), with a thicker wall of αSMA^+ pericytes (median = 10, 63 vs 4, 98%, p < 0, 01), expressing NP around an intact endothelium compared with the other group of deceased COVID-19 patients. The αSMA^+ area correlated with percentage of thrombosed portal veins (r = 0, 284, p < 0, 05), whereas TF, the initiator of the coagulation cascade, was expressed by pericytes rather than by portal EC. Infection of pericytes *in-vitro* with SARS-CoV-2 induced increased expression of TF in pericytes, whose conditioned medium induced a pro-coagulant phenotype in ECs, characterized by overexpression of vWF.
Conclusion: SARS-CoV-2 infects liver pericytes, eliciting a prothrombotic response and the subsequent hemodynamic changes result in IPVD contributing to the long-lasting respiratory failure. Liver involvement may therefore play a crucial role in a subset of fatal COVID-19.

SAT187

Dual ileal/renal-liver bile acid transporter inhibitors with different transporter selectivity in vitro differentially increase faecal and urinary bile acid excretion in organic anion transporting polypeptide 1a/1b knockout mice in vivo

Ellen Strängberg[1], Per-Goran Gillberg[1], Ivana Uzelac[1], Ingemar Starke[1], Britta Bonn[1], Jan Mattsson[1], Peter Akerblad[1], Runa Pal[2], Ashwani Gaur[2], Ramesh Kangarajan[2], Shivendra Singh[2], Santosh Kulkarni[2], Paul Dawson[3], Erik Lindström[1]. Email: ellen.strangberg@albireopharma.com

Background and aims: Bile acids (BAs) play an important role in hepatobiliary injury. The apical sodium-dependent BA transporter (ASBT) and Na^+-taurocholate cotransporting polypeptide (NTCP) play key roles in maintaining BA homeostasis, and their selective inhibition has shown efficacy in liver diseases. ASBT inhibitors block intestinal and renal BA reuptake and increase faecal BA

excretion, whereas NTCP inhibitors block hepatocyte BA uptake, thereby increasing serum BA levels and urinary BA excretion. Dual-acting ASBT/NTCP inhibitors may increase BA excretion via both elimination routes. We aimed to determine the ability of potent dual ASBT/NTCP inhibitors with different transporter selectivity to increase faecal and urinary BA excretion in organic anion transporting polypeptide 1a/1b (OATP) knockout (KO) mice.

Method: Half-maximal inhibitory concentration (IC_{50}) values for inhibition of mouse ASBT and NTCP were determined using transfected cells. Male OATP KO mice (n = 5/group) were dosed orally once daily for 7 days at 30 mg/kg. Serum BAs were measured 1 h post-dosing on days 1 and 7. Measurements of plasma 7α-hydroxy-4-cholesten-3-one (C4), a marker of hepatic BA synthesis, and faecal and urinary BA excretion were performed on day 7.

Results: Systemically bioavailable ASBT/NTCP inhibitors with selective potency toward mouse NTCP (AS0909, AS0918) or ASBT (AS0826, AS0893) were compared (Table). On days 1 and 7, AS0909/AS0918 and AS0826/AS0893 increased serum BAs 20–50-fold and 2–8-fold, respectively, vs vehicle. On day 7, urine BAs increased 2–3-fold in response to AS0909/AS0918 and less than 2-fold with AS0826/AS0893. In contrast, faecal BA excretion was not significantly elevated with AS0909/AS0918 but increased 4–8-fold with AS0826/AS0893. Serum C4 levels were increased 2–3-fold with AS0826/AS0893 and unaffected with AS0909/AS0918.

Table: Mouse potency values (IC_{50} [nM])

Compound	NTCP	ASBT
AS0909	22	183
AS0918	17	438
AS0826	30	16
AS0893	30	2

Conclusion: ASBT-selective dual inhibitors significantly increased hepatic BA synthesis and faecal excretion while modestly increasing serum BA levels and urinary BA excretion. Conversely, NTCP-selective dual inhibitors caused pronounced elevations in serum and urine BAs without significantly affecting BA synthesis or faecal excretion. Dual ASBT/NTCP inhibitors with different selectivity may have a role as part of precision medicine strategy to reduce the BA burden in forms of hepatobiliary disease.

Integrated bile lipidome and meta-proteome analysis classifies lipid species and microbial peptides predictive of carcinoma of the gall bladder

Nupur Sharma[1,2], Manisha Yadav[1], Gaurav Tripathi[1], Babu Mathew[1], Vasundhra Bindal[1], Hamed Hemati[1], Sadam Hussain Bhat[1], Jaswinder Maras[1]. [1]*institute of liver and biliary sciences, Molecular and cellular medicine, New Delhi, India;* [2]*Institute of liver and biliary sciences, Molecular and cellular medicine, New delhi, India*
Email: jassi2param@gmail.com

Background and aims: Histopathological examination is gold standard for detection of gall-stone (GS) or gall bladder carcinoma (CAGB). Bile concentrated in the gall bladder, is expected to recapitulate metagenomics/molecular changes associated to development of CAGB.

Method: Bile samples were screened for lipidomics and metaproteome (microbiome) signatures capable of early detection of cancer. Analysis of training cohort (n = 87) showed that meta-stability of bile was reduced in CAGB patients ($p < 0.05$).

Results: Our results showed that CAGB was associated with the alteration of bile lipidome and microbiome as indicated by multivariate PLS-regression analysis and alpha, beta diversity indexes. Significant reduction of lipid species and increase in bacterial taxa were found associated to development of CAGB with gallstone and without Gallstone ($p < 0.05$, Log FC>1.5). Multimodular correlation network (MMCN) created using weighted lipid/Meta-proteomic correlation network analysis (W [L/MP] CNA) showed striking associations between lipid modules and meta-proteomic functionality. A significant and direct correlation of Meta-proteomic modules/functionality and inversely correlation of lipid modules and species with the clinical parameters and bile acid profile was observed in CAGB patients ($p < 0.05$). Signifcant increase in bacterial taxa; Leptospira, Salmonella enterica, Mycoplasma gallisepticum and their functionality showed direct correlation with lipid classes; Lysophosphatidylinositol, Ceramide 1-phosphates, Lysophosphatidylethanolamine, others and development of CAGB (r^2>0.85). Lipid/metaproteomic signature based probability for CAGB was>90% whereas probability for gall-stone was>80% ($p < 0.05$). Finally, we identified 8 lipid species of diagnostic capability for

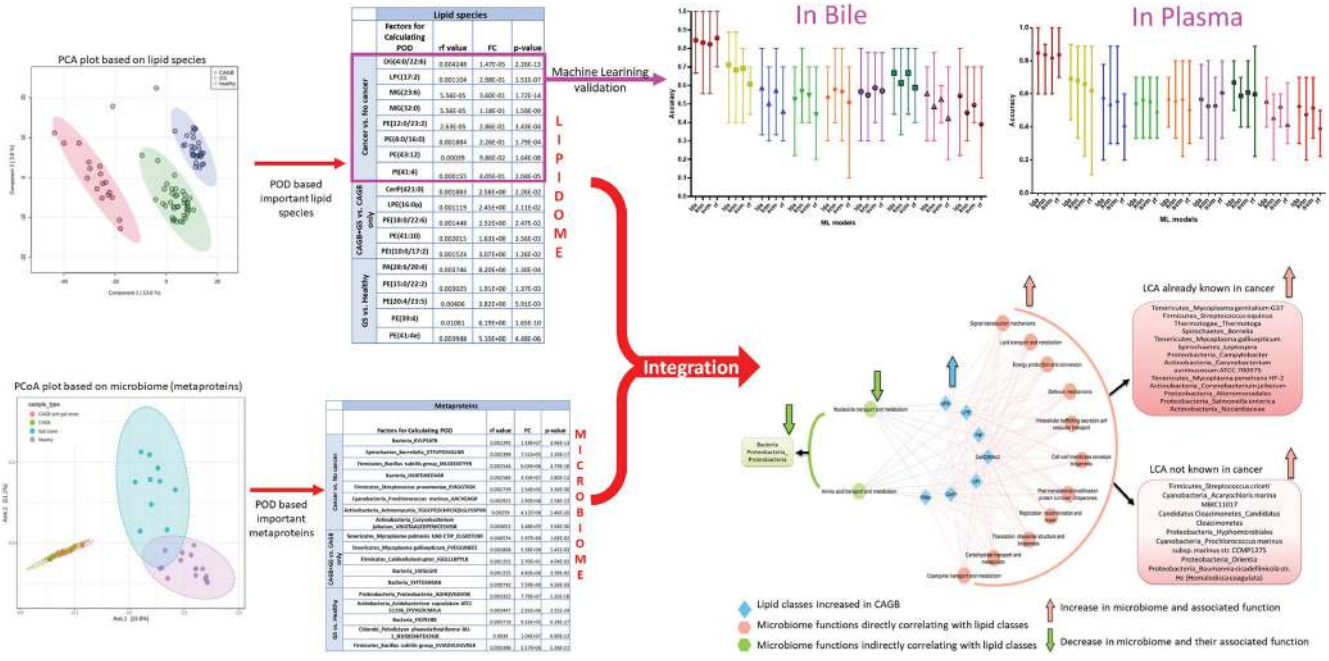

Figure: (abstract: SAT188)

CAGB and cross-validated, using 4 machine learning approaches in two separate test cohorts (n = 38; bile (T1) and paired plasma (T2) cohort, which jointly showed highest accuracy (99%), sensitivity (98%) and specificity (100%) with random forest model for CAGB detection.

Conclusion: Deep and integrated analysis of bile lipidome and metaproteome identify a panel of lipid species/meta-proteome capable of segregating patients predisposed to carcinogenesis of the gall bladder.

SAT189

The effects of apurimic/apirimidinic endonuclease 1 as a sensitizer to sorafenib in hepatocellular carcinoma

Mahzeiar Samadaei[1], Daniel Senfter[2], Sibylle Madlener[2], Karolina Uranowska[3,4], Christine Hafner[3,5], Michael Trauner[1], Nataliya Rohr-Udilova[1], Matthias Pinter[1]. *[1]Medical University of Vienna, Internal Medicine III, Gastroenterology and Hepatology, Vienna, Austria; [2]Medical University of Vienna, Department of Pediatrics and Adolescent Medicine, Vienna, Austria; [3]University Hospital St. Poelten, Department of Dermatology, St. Poelten, Austria; [4]Medical University of Vienna, Institute of Pathophysiology and Allergy Research, Center for Pathophysiology, Infectiology and Immunology, Vienna, Austria; [5]Karl Landsteiner Gesellschaft, Karl Landsteiner Institute of Dermatological Research, St. Poelten, Austria*

Email: nataliya.rohr-udilova@meduniwien.ac.at

Background and aims: Sorafenib, an oral multikinase inhibitor, was the first-generation targeted therapy for patients with hepatocellular carcinoma (HCC). Apurinic/apyrimidinic endonuclease 1/redox factor-1 (APE1/Ref-1) is a protein with dual function in redox regulation and DNA repair. APE1/Ref-1 plays a role in development and metastasis but is also linked to inflammation, hypoxia, autophagy and oxidative stress. APE1/Ref-1 also interacts with PI3K/Akt pathway which, in turn, induce sorafenib resistance. Here, we aim to deziffer the specific contribution of APE1/Ref-1 repair and redox functions to sorafenib sensitivity of human HCC cells.

Method: Impact of APEX1 expression on overall survival of HCC patients was evaluated by an *in silico* approach using Human Protein Atlas dataset. To check the effects of bifunctional APE1/Ref-1 in five human HCC cell lines (Huh7, SNU398, AKH12, AKH13, 3P), we introduced domain-specific mutations and applied selective inhibitors to block either the repair or the redox function of this protein. These treatments were combined with sorafenib. Neutral red assay was used to evaluate cell viability. To evaluate cytotoxicity, we quantified loss of membrane integrity by LDH release. Clonogenic and invasion ability of HCC cells were measured by colony formation assay and hanging drop method, respectively. Cell cycle distributions as well as characterization of apoptosis were performed by flow cytometry.

Results: *In silico* approach revealed that HCC patients with lower expression of APEX1 reveal longer overall survival: 6.0 ± 0.5 years (low) vs 3.8 ± 0.4 years (high), p = 0.01, n = 365. APEX1 knock down by siRNA per se-as well as in combination with sorafenib-reduced HCC cell viability. All five cells lines which overexpressed either APE1/Ref-1 wild-type or N212A mutants with abrogated DNA repair activity showed cosistently delayed response to sorafenib when compared to cells overexpressing mutant redox domain C65S. In line, an inhibitor of APE1/Ref-1 redox function E3330 in combination with sorafenib significantly reduced colony formation (Fig. 1) and invasion of HCC cells.

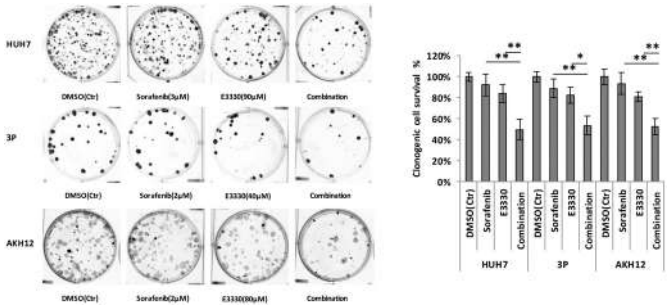

Figure: Impact of E330, an inhibitor of APE1/Ref-1 redox function, and sorafenib on colony formation in HCC cell lines.

Conclusion: Redox function of APE1/Ref-1 seems to be a promising target in HCC. APE1/Ref-1 redox inhibitor E3330 enhances the anti-tumor effects of sorafenib *in vitro*.

Soluble guanylyl cyclase expression and signaling in different types of liver fibrosis

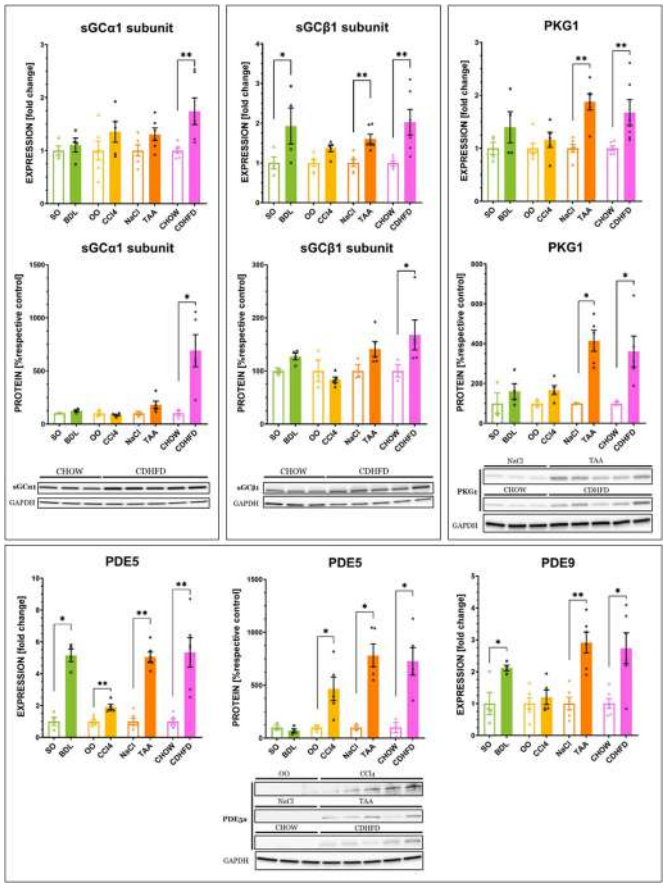
Ksenia Brusilovskaya[1,2,3,4], Philipp Königshofer[1,2,3,4], Benedikt Hofer[1,2,3], Oleksandr Petrenko[1,2,3,4,5], Kerstin Zinober[1,2,3], Martha Seif[1,2,3], Stefan Günther Kauschke[6], Larissa Pfisterer[6], Philipp Schwabl[1,2,3,4], Thomas Reiberger[1,2,3,4,5]. *[1]Medical University of Vienna, Division of Gastroenterology and Hepatology, Department of Medicine III, Vienna, Austria; [2]Medical University of Vienna, Vienna Hepatic Hemodynamic Lab (HEPEX), Division of Gastroenterology and Hepatology, Department of Medicine III, Vienna, Austria; [3]Medical University of Vienna, Christian-Doppler laboratory for portal hypertension and liver fibrosis, Vienna, Austria; [4]CeMM Research Center for Molecular Medicine of the Austrian Academy of Sciences, Vienna, Austria; [5]Ludwig Boltzmann Institute for Rare and Undiagnosed Diseases (LBI-RUD), Vienna, Austria; [6]Boehringer Ingelheim Pharma GmbH and Co.KG, Biberach, Germany*

Email: thomas.reiberger@meduniwien.ac.at

Background and aims: In cirrhosis, impaired NO-soluble guanylyl cyclase (sGC)-cyclic guanosine monophosphate (cGMP)-protein kinase G (PKG-1) signaling contributes to increased intrahepatic vascular resistance and fibrogenesis. We investigated the expression of sGC subunits and the downstream signaling pathway in healthy and diseased liver tissue.

Method: Liver tissue samples of cholestatic (bile duct ligation, BDL-4 weeks), toxic (8 weeks-CCl4 and 12 weeks-TAA), and metabolic (12 weeks-choline-deficient high fat diet, CDHFD) rat fibrosis models were used. Healthy control tissues were derived from sham-operated (SO), vehicle-injected (OO/NaCl), and normal-diet-fed (CHOW) animals. Gene and protein expression of sGC subunits and key downstream molecules were analyzed by RT-PCR and Western blot.

Results: All models presented severe fibrosis assessed by collagen-proportionate area (CPA: BDL: 13.4%; CCl4: 4.0%; TAA: 8.0%; CDHFD: 8.5%). The expression of sGC subunits alpha1 and beta1 (sGCa1/b1) increased in all fibrosis models, with the most pronounced upregulation in CDHFD (sGCa1: 1.7 ± 0.3-fold, p < 0.01; sGCb1: 2.0 ± 0.3-fold, p < 0.01). Accordingly, 6.9-fold sGCa1 (p = 0.04) and 1.7-fold sGCb1 (p = 0.04)-higher protein levels were detected in CDHFD group. The expression of PKG-1 was significantly increased in TAA and CDHFD models both on gene (TAA: 1.9 ± 0.2-fold, p < 0.01; CDHFD: 1.7 ± 0.2-fold, p <0.01) and protein (TAA: 4.1-fold, p = 0.04; CDHFD: 3.6-fold, p = 0.04) levels. Moreover, upregulation of the cGMP degrading phosphodiesterase enzymes PDE5 (BDL: 5.1 ± 0.4-fold, p <0.01; CCl4: 1.9 ± 0.2-fold, p <0.01; TAA: 5.1 ± 0.3-fold, p <0.01; CDHFD: 5.3 ± 0.9-fold, p <0.01), and PDE9 (BDL: 2.1 ± 0.1-fold, p = 0.05; CCl4: 1.2 ± 0.2-fold, p = 0.79; TAA: 2.9 ± 0.3-fold, p <0.01; CDHFD: 2.7 ± 0.5-fold, p = 0.03) was observed in cirrhosis. PDE5 protein levels also increased in CCl4 (4.7-fold, p = 0.04), TAA (7.8-fold, p = 0.04), and CDHFD (7.2-fold, p = 0.04) models-but remained similar in BDL (p = 0.23).



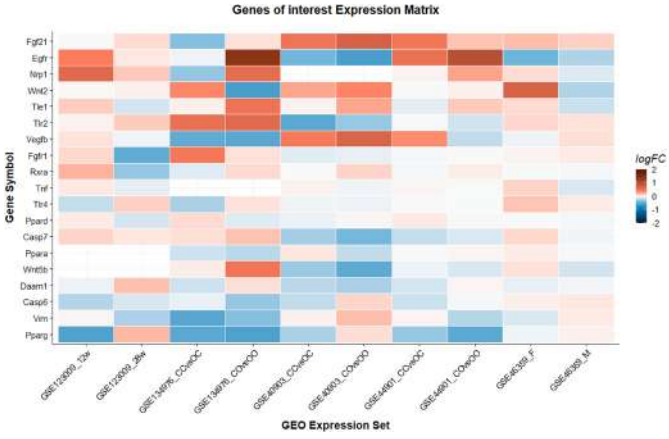
Conclusion: Expression of sGC alpha1/beta1 subunits increases in liver cirrhosis in different rat models, paralleled by upregulated cGMP-dependent PKG-1 in toxic and CDHFD cirrhosis. In contrast, overexpression of PDE5/9 across all models may indicate insufficient cGMP-related signaling effects in cirrhosis. The functionality of sGC-cGMP signaling in cirrhosis and the impact of pharmacologic activation requires further mechanistic studies.

SAT192

Impact of maternal obesity on liver disease in the offspring: a comprehensive transcriptomic analysis and validation of results

Beat Moeckli[1,2], Vaihere Delaune[1,2], Julien Prados[3], Matthieu Tihy[4], Andrea Peloso[2], Graziano Oldani[1,2], Thomas Delmi[1], Nicolas Goossens[5], Laura Rubbia-Brandt[4], Stéphanie Lacotte[1], Christian Toso[1,2]. *[1]University of Geneva, Faculty of medicine, Geneva, Switzerland; [2]Hôpitaux Universitaires de Genève (HUG), Chirurgie, Genève, Switzerland; [3]University of Geneva, Bioinformatics Support Platform, Geneva, Switzerland; [4]Hôpitaux Universitaires de Genève (HUG), Department of clinical pathology, Genève, Switzerland; [5]Hôpitaux Universitaires de Genève (HUG), Hepatology and gastroenterology, Genève, Switzerland*
Email: beat.moeckli@gmail.com

Background and aims: The global obesity epidemic is a major public health concern and particularly affects women of reproductive age. Offspring of obese mothers suffer from an increased risk of liver disease but the molecular mechanisms involved remain unknown. With this study, we uncover new pathways and genes involved in the transmission of liver disease and validate previously identified targets.
Method: We performed an integrative genomic analysis of datasets that investigated the impact of maternal obesity on the hepatic gene expression profile of the offspring in mice. Furthermore, we developed our own murine model of maternal obesity and validated the top deregulated genes by quantitative real time polymerase chain reaction (qPCR) in our model. Our data is available for interactive exploration on our companion webpage: (https://genebrowser.unige.ch/maternalobesity).
Results: We identified five publicly available datasets pertinent to our research question. Pathways involved in metabolism, the innate immune system, the clotting cascade and the cell cycle were consistently deregulated in offspring of obese dams. Concerning genes potentially involved in the development of liver disease, we found *Egfr, Vegfb, Wnt2* and *Pparg* deregulated in multiple independent datasets (Figure). In our own model, we observed higher tendency towards the development of non-alcoholic liver disease (60 vs 20%) and higher levels of alanine amino transferase (41.0 vs 12.5 IU/l, p = 0.008) in female offspring of obese dams. Male offspring presented higher levels of liver fibrosis (2.8 vs. 0.8% relative surface area, p = 0.045). Of the top deregulated genes deregulated in the integrative genomic analysis, we validated the deregulation of *Fgf21, Pparg* and *Ppard* by qPCR in our own model of maternal obesity.



Conclusion: Maternal obesity represents a looming threat for the liver health of future generations. Our comprehensive transcriptomic analysis discovered new pathways and molecular targets. This will help to better understand the mechanisms of the development of liver disease in the offspring of obese mothers.

SAT193

Liver directed in utero AAV gene therapy for maple syrup urine disease in a neonatal lethal murine model

Kate Mullany[1,2], Ian Alexander[1,3], Susan Siew[2]. *[1]Children's Medical Research Institute, Gene Therapy Research Unit, Westmead, Australia; [2]The Children's Hospital at Westmead, Gastroenterology, Westmead, Australia; [3]The Children's Hospital at Westmead, Westmead, Australia*
Email: kmullany@cmri.org.au

Background and aims: MSUD is a genetic metabolic autosomal recessive condition caused by a deficiency of the mitochondrial enzyme branched chain keto-acid dehydrogenase. Severely affected individuals present in the neonatal period with elevated branched chain amino acid (BCAA) levels leading to encephalopathy and muscle weakness which if untreated progresses to permanent brain injury and/or death. Dietary protein restriction or liver transplantation are current mainstays of therapy, however neither are curative. Liver directed adeno-associated viral (AAV) gene therapy represents a novel potential treatment for MSUD. Our aim is to determine if liver directed AAV gene therapy can rescue the phenotype of a neonatal lethal murine model of MSUD ($DBT^{-/-}$).
Method: A murine hepatotrophic gene addition vector rAAV8.hDBT (5 × 10^11 vector genome copies per mouse) was administered on D0 of life in 9 homozygous knockout pups. Outcome measures included

pup growth, serum BCAA levels through mass spectrometry, DBT protein expression via immunoblotting and vector genome copy via digital droplet PCR. Immunohistochemistry was used to assess presence of DBT protein in liver sections. As neonatal vector administration improved survival but did not rescue all pups, the timing of vector delivery was suspected to be critical, and the same vector was administered *in utero* to pups on E15. Equivalent studies are being initiated to compare outcomes following *in utero* treatment.
Results: Gene addition with a codon optimised DBT human transgene significantly improved survival, growth and BCAA levels ($p < 0.05$) compared to untreated knockout pups when administered on D0 of life. DBT protein in vector treated homozygous knock out pups was expressed at 2.5 times higher than untreated wild type pups. Immunohistochemistry demonstrated presence of DBT protein in vector treated pups (Figure 1). We will also present the results from the *in utero* vector administration.

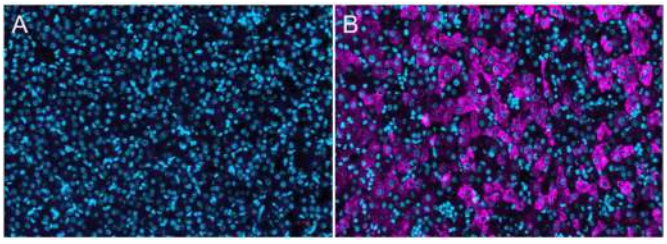


Figure 1. Presence of DBT protein (purple) in murine liver cells in A) untreated $DBT^{-/-}$ and B) D0 vector treated $DBT^{-/-}$ mouse pups. Hepatocyte nuclei were co-stained (blue, DAPI).

Conclusion: Neonatal murine liver transduction with a human DBT transgene significantly improves the disease phenotype in a murine neonatal lethal model of MSUD. Liver directed AAV mediated gene therapy represents a potential novel treatment for MSUD.

SAT194
Patient-derived hepatocellular carcinoma organoids as predictors of Treatment Response

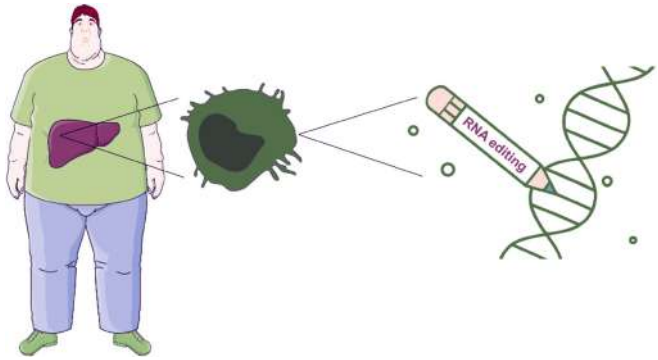
Jun Yong Park[1,2,3,4], Kyung Joo Cho[2,4], Hye Won Lee[1,3,4], Hye Jung Park[4], Sang Hoon Ahn[1,3,4], Hee Seung Lee[3], Chul Hoon Kim[2,5]. *[1]Yonsei University College of Medicine, Institue of Gastroenterology, Seoul, Korea, Rep. of South; [2]Yonsei University, Brain Korea 21 PLUS Project for Medical Science, Seoul, Korea, Rep. of South; [3]Yonsei University College of Medicine, Division of Gastroenterology, Department of Internal Medicine, Seoul, Korea, Rep. of South,; [4]Severance Hospital, Yonsei Liver Center, Seoul, Korea, Rep. of South; [5]Yonsei University College of Medicine, Department of Pharmacology, Seoul, Korea, Rep. of South*
Email: drpjy@yuhs.ac

Background and aims: Organoid models using patient-derived cancer tissues has allowed a better understanding of human cancer as well as development of precision medicine. For advanced HCC treatment, the proper models and the pivotal pathways of cancer stem cells (CSCs) are needed. In this study, we evaluate the sensitivity to anti-cancer drugs using HCC organoids (HCOs) and analyze the relationship between drug resistance group and CSCs-related signal for improving the drug response.
Method: Patient-derived tumor tissue was digested at 37 °C and mixed with Matrigel. After polymerization of Matrigel, medium was added and changed twice a week. To evaluate whether HCO exhibit different sensitivity to drugs, we tested its sensitivity and analyzed the sensitivity in HCO lines with the difference in gene expression.
Results: We successfully established 10 HCOs obtained from 16 HCC patients among. HCOs exhibited heterogeneous morphological features, forming compact structures with or without thick-layered cyst-like structures. HCOs shared somatic mutations and showed high concordance of somatic mutation between primary tumor and organoids. Through the different gross morphology of HCO showed the differential gene expression. Notably, Wnt pathway was significantly enriched in the compact spherical shape of HCO compared to combined shape ($p < 0.05$). We compared the growth of compact shape of HCOs with and without Wnt pathway-related components, however, they failed to form organoids without Wnt. Also, compact shape of HCOs was resistant to treatment with Lenvatinib in vitro.
Conclusion: Our results demonstrated that HCOs with specific structural features provide platform to identify the relationship between drug response and CSC-related signal in HCC.

SAT195
Dissecting A-to-I RNA editome of liver macrophages in non-alcoholic fatty liver disease

Achilleas Fardellas[1], Myriam Aouadi[1], Sebastian Nock[1], Ping Chen[1], Cecilia Morgantini[2]. *[1]Karolinska Institute, Department of Medicine, Center for Infectious Medicine, Huddinge, Sweden; [2]Karolinska Institute, Department of Medicine, Cardio Metabolic Unit (CMU), Huddinge, Sweden*
Email: myriam.aouadi@ki.se

Background and aims: RNA editing is an epitranscriptomic process referring to modifications in the chemical structure of RNA molecules. Adenosine-to-Inosine (A-to-I) editing is the most common RNA editing event catalysed by a family of enzymes called ADARs (adenosine deaminases acting on RNA). While aberrant RNA editing profiles have been associated with many diseases including neurological disorders and cancers, it has not been previously studied in the setting of non-alcoholic fatty liver disease (NAFLD).
Method: We used RNAseq datasets (GSE135251, GSE126848), which liver biopsies from lean, "healthy" obese and NAFLD patients. Global levels of RNA editing activity were estimated in this cohort using the Alu editing index (AEI), a robust signal with a minimal false-positive rate. Human monocyte-derived macrophages were treated with phRodo-labelled Escherichia. coli bioparticles for 2 hours and analyzed via flow cytometry after a 48hour ADAR1-knockdown.
Results: We have recently discovered that IGFBP7 transcripts in liver macrophage (LMs) of insulin resistant patients underwent A-to-I RNA editing at a high frequency leading to the production of a variant isoform with a higher capacity to regulate insulin signalling. Consistently, preliminary results from RNAseq analysis of 266 liver biopsy samples from two independent studies indicate that the RNA editing rate of NAFLD patients is considerably higher compared to lean and "healthy" obese. However, analyses of the overall RNA editome of LMs revealed that the RNA editing rate is unexpectedly decreased in obesity. To investigate the functional relevance of RNA editing in human macrophages, ADAR1, the key RNA editing enzyme, was silenced and an improved phagocytic capacity of particles was found.



Conclusion: These data suggest that the RNA editome of the liver changes dynamically in the setting of metabolic diseases and interestingly, in a cell-specific manner. Understanding the

epitranscriptomic landscape of NAFLD and its role in the disease development may lay the foundation for the development of novel therapeutic strategies and new disease biomarkers.

SAT196

Restoring bone marrow hematopoietic stem cells (BM-HSC) reserve augments regression of fibrosis and regeneration in animal model of cirrhosis

Nidhi Nautiyal[1,2], Deepanshu Maheshwari[1], Pranshu E Rao[3], Sujata Mohanty[3], Anupama Parasar[1], Chhagan Bihari[4], Subhrajit Biswas[2], Rakhi Maiwall[5], Anupam Kumar[1], Shiv Kumar Sarin[1,5]. *[1]Institute of Liver and Biliary Sciences, Molecular and Cellular Medicine, New Delhi, India; [2]Amity University Noida, Amity Institute of Molecular Medicine and Stem Cell Research, Noida, India; [3]All India Institute of Medical Sciences, Center of Excellence for Stem Cell Research, New Delhi, India; [4]Institute of Liver and Biliary Sciences, Department of Pathology, New Delhi, India; [5]Institute of Liver and Biliary Sciences, Department of Hepatology, New Delhi, India*
Email: shivsarin@gmail.com

Background and aims: Bone marrow (BM) is a reservoir for hematological and immune cells, plays a central role in resolution of damage and tissue repair. Exhaustion of BM-HSC reserve has been shown to be associated with increased susceptibility to infection, hematological dysfunction and early graft dysfunction post liver transplant in cirrhosis. Whether the loss of BM stem cell (BMSC) reserve in cirrhosis is the cause or a consequence of liver failure is not known. We aim to understand the relation between BM and liver regeneration, and potential therapeutic effect of restoring BM-HSC reserve in the management of chronic liver injury.

Method: C57BL/6 (J) mice were used to develop chronic liver injury through intraperitoneal administration of carbon tetrachloride for 15 weeks (0.1–0.5 ml/kg). Animals were culled at different time points (N = 10 each group; week 3/6/10/15) to study the changes in liver injury, regeneration, BM-HSC and mesenchymal stem cell (MSC) reserve. To restore the BMSC reserve, approximately 4 million healthy whole BM cells (hBM), isolated from GFP-C57BL/6 mice were infused intrafemoral (IF) after 12 weeks of chronic liver injury. Control animals were infused with saline. Animals post BM infusion were sacrificed (N = 10 each group; 24 hours/day 11/day 21) to study the changes in liver injury, regeneration and BMSC reserve.

Results: Histological analysis of liver tissue (figure 1A) showed progressive increase in fibrosis and hepatocyte proliferation till week 10 with development of portal fibrosis at week 3, bridging fibrosis at week 6 and nodular fibrosis (cirrhosis) at week 10. From 10–15 weeks, while the fibrosis was comparable, there was a significant increase ($p < 0.0001$) in TUNEL+ hepatocyte and loss of hepatocyte regeneration with hepatic decompensation {ascites (SAAG 1.4 (1.1–1.7) g/dL), jaundice and rise in ammonia ($p < 0.001$)}, suggesting increased hepatocyte injury without compensatory regeneration in development of decompensated cirrhosis. Interestingly, BM studies showed that during the course of chronic liver injury loss of BM MSC occurs between week 3 to 6 followed by loss of LT-HSC between week 6 to 10 followed by regeneration failure (figure 1B). Infusion of hBM in cirrhosis animals (figure 1C) showed that while donor cells disappear by day 21, there was significant increase in total BM LT-HSC reserve by day 11 (figure 1D). hBM recipients showed significant reduction in fibrosis and increased hepatocyte proliferation (figure 1E).

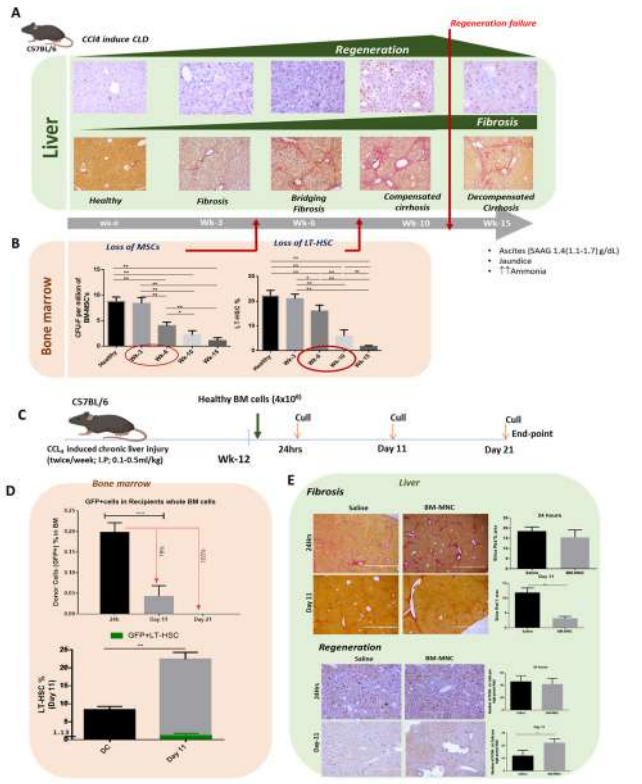


Figure- 1: **Restoring bone marrow hematopoietic stem cells (BM-HSC) reserve augments regression of fibrosis and regeneration in animal model of cirrhosis**. (A) Representative micrograph showing Sirius red staining (bottom) and IHC staining of PCNA+ hepatocyte (top) in liver sections at given time points. (B) Graph showing changes in number of BM-MSC colony forming unit (CFU) (Left) and percentage of long term hematopoietic stem cells (LT-HSC) (right) with progression of chronic liver injury (C) Study layout of BM-cell infusion in cirrhosis animals (D) graph showing change in percentage of total donor cells (top) and percentage of total LT-HSC {bottom; recipient (gray) and donor (green)} post BM-cell infusion in cirrhosis animals. (E) Representative micrograph (left) and bar graph (right) change in liver fibrosis and hepatocyte regeneration in cirrhotic animals with and without BM infusion

Conclusion: Loss of BM-HSC reserve precedes hepatic regeneration failure indicating seminal role of BM during chronic hepatic injury. IF infusion of hBM induces repopulation of native LT-HSC, accelerates fibrosis resolution and potentiates hepatocyte regeneration in cirrhosis. Hence, restoring BM-HSC reserve can serve as a novel therapeutic approach to augment resolution of fibrosis and native liver regeneration in cirrhosis.

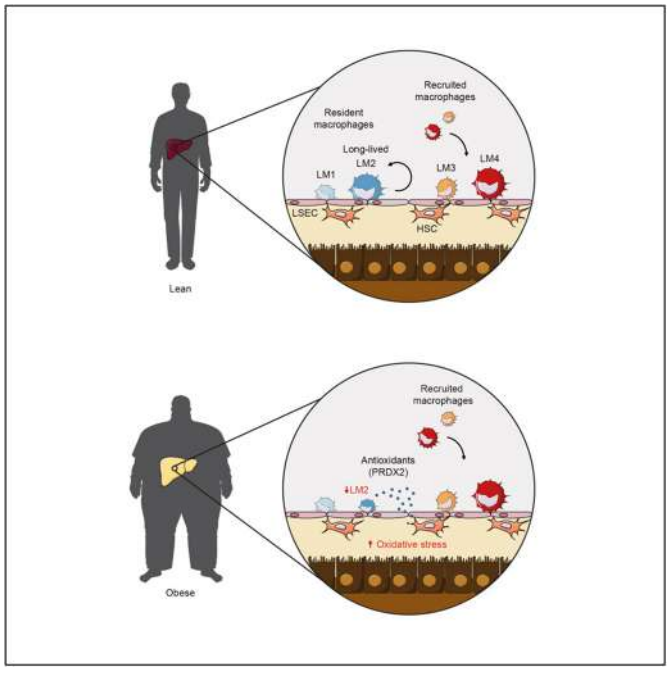
SAT197

Human resident liver macrophages protect against metabolic stress in obesity

Emelie Barreby[1], Benedikt Strunz[1], Valerio Azzimato[1], Joanne X. Shen[2], Léa Naudet[1], Isabella Sönnerborg[1,3], André Sulen[1,4], Sebastian Nock[1], Laura Levi[1], Cecilia Morgantini[1,5], Achilleas Fardellas[1], Helene Johansson[3], Greg Nowak[3], Per Stal[6], Ewa Ellis[3], Erik Naslund[7], Volker Lauschke[2,8], Niklas Björkström[1], Ping Chen[1], Myriam Aouadi[1]. *[1]Karolinska Institutet, Center for Infectious Medicine, Huddinge, Sweden; [2]Karolinska Institutet, Section of Pharmacogenetics, Stockholm, Sweden; [3]Karolinska Institutet, Division of Transplantation Surgery, Huddinge, Sweden; [4]University of Bergen, KG Jebsen Center for Autoimmune Diseases, Norway; [5]Karolinska Institutet, Cardio metabolic unit, Sweden; [6]Karolinska Institutet, Gastroenterology and Rheumatology Unit, Huddinge, Sweden; [7]Danderyd Hospital, Karolinska Institutet, Division of Surgery, Department of Clinical Sciences, Stockholm, Sweden; [8]Dr Margarete Fisher-Bosh Institute of Clinical Pharmacology, Germany*
Email: myriam.aouadi@ki.se

Background and aims: Non-alcoholic fatty liver disease has become the most common chronic liver disease, being associated with an increasing prevalence of obesity and type 2 diabetes. Macrophages contribute to the development of these metabolic disorders in

obesity. However, while multiple macrophage populations have been described in the human liver, little is known about their functional role in response to metabolic changes associated with obesity. In this study we characterized liver macrophages (LMs) during the development of metabolic disease in obese individuals.
Method: Liver biopsies from lean and obese individuals undergoing bariatric surgery were characterized by single cell RNA sequencing and flow cytometry. Macrophage ontogeny was examined by studying the replacement of LM subpopulations by monocytes in individuals undergoing liver transplantation, using markers of donor-recipient mismatch. Functional validation was then performed in primary human 3D *in vitro* cultures in which lipid accumulation and oxidative stress was induced as to mimic obese livers.
Results: Here, we identified multiple macrophage populations distinguished by their transcriptomic profiles and origin, rather than their inflammatory status in lean and obese individuals. Interestingly, by studying the dynamics of liver macrophages in individuals undergoing liver transplantation using markers of donor-recipient mismatch, we discovered that liver macrophage turnover differs dramatically in humans and in mice. While the majority of macrophages were monocyte-derived, human livers also contained a distinct population of resident 'long-lived' macrophages. This LM population, denoted LM2, expressed high levels of genes regulating oxidative and metabolic stress in obesity, in particular the antioxidant Peroxiredoxin-2. Moreover, the proportion of these long-lived LM2 decreased during obesity. Finally, removal of LM2 from primary liver 3D cultures reduced PRDX2 levels and increased extracellular ROS.



Conclusion: We discovered a liver resident macrophage population with a protective role that could reduce oxidative stress induced by lipid accumulation. Targeting specific LM populations could thus represent a promising therapeutic strategy for both liver and metabolic disease.

SAT198

Reversal of epithelial-mesenchymal transition in a cholangiocarcinoma cell line by genetic targeting of sulfatide synthesis

Lin Chen[1,2], Montserrat Elizalde[2,3], Steven Olde Damink[1,2,4], Frank Schaap[1,2,4], Gloria Álvarez-Sola[1,2]. [1]*Maastricht University Medical Center, Surgery, Maastricht, Netherlands;* [2]*Maastricht University, School of Nutrition and Translational Research in Metabolism, Maastricht, Netherlands;* [3]*Maastricht University Medical Center, Division of Gastroenterology-Hepatology, Department of Internal Medicine, Maastricht, Netherlands;* [4]*University Hospital Aachen, Department of General, Visceral and Transplant Surgery, Aachen, Germany*
Email: glalvare@gmail.com

Background and aims: Cholangiocarcinoma (CCA) or biliary tract cancer is the second most common liver malignancy with an increasing incidence in Western countries. CCA is a heterogeneous malignant disease with different epidemiological trends among different subtypes of CCA that may reflect genetic and environmental risk factors involved in the incidence of CCA. The lack of effective treatments due to late diagnosis associated with the absence of symptoms highlights the need to search for new therapeutic targets for CCA. A recent study demonstrated the presence of sulfatides, a class of sulfoglycosphingolipids, in the biliary tract in the liver. These lipids are involved in protein trafficking and cell adhesion, showing a protective role in different epithelial cells. Previous work has shown that sulfatides are adhesive molecules related to malignancy, since these lipids induce the binding of platelets to cancer cells promoting immune evasion. Our aim is to study the role of *GAL3ST1*, the gene that encodes the enzyme involved in sulfatide synthesis, in CCA.
Method: We analysed the expression of *GAL3ST1* in 16 non-tumors, 13 tumor tissue specimens of iCCA patients and different CCA cell lines. We used the CRISPRi-Cas9 system in the extrahepatic CCA cell line TFK1 to generate *GAL3ST1* Knockout (KO) cells, and small interfering RNAs to obtain Knockdown (KD) cells. We evaluated the cell proliferation, metabolic activity, epithelial identity and barrier function in these *GAL3ST1* deficient cells.
Results: *GAL3ST1* was up-regulated in CCA cell lines relative to H69 cholangiocyte cells, as well as in iCCA versus non-tumor liver tissue. *GAL3ST1* KO cells showed less proliferative and clonogenic activity in vitro. *GAL3ST1* deficient cells displayed a reduction in HIF1 alpha mRNA levels, lower expression of genes involved in glycolysis (e.g., *HK2* and *PGK1*) and less cell viability. Polarized *GAL3ST1* KO cells had increased transepithelial resistance (1.5-fold) and reduced permeability to FITC-dextran (-0.7-fold). Different epithelial markers (Occludin, ZO-1 and E-cadherin) were increased in *GAL3ST1* KO and KD cells. *GAL3ST1*-deficient cells showed reduced basal activation of ERK1/2 MAPK.
Conclusion: *GAL3ST1* was highly expressed in iCCA. The aggregated findings indicate that the modulation of *GAL3ST1* reversed the epithelial-mesenchymal transition in TFK1 cells, thereby reducing their tumorigenic capacity. It will be worth exploring whether targeting GAL3ST1 has potential in the treatment of CCA.

SAT199

Unravelling the circadian transcriptome and epigenome of the human liver

Atish Mukherji[1], Frank Jühling[1], Laurent Mailly[1], Carla Eller[1], Katharina Herzog[1], Cloé Gadenne[1], Clara Ponsolles[1], Alexandre Haller[2], Philippe Baltzinger[2,3], Hiroshi Aikata[4], Michio Imamura[4], Catherine Schuster[1], Xiaodong Zhuang[5], Jacinta Holmes[6], Jane McKeating[5], Irwin Davidson[2], Patrick Pessaux[7], Joachim Lupberger[1], Thomas Baumert[8]. *[1]Université de Strasbourg, Inserm, Institut de Recherche sur les Maladies Virales et Hépatiques Inserm, UMR_S1110, Strasbourg, France; [2]Institut de génétique et de biologie moléculaire et cellulaire, Illkirch, France; [3]CHU de Strasbourg, Internal Medicine, Endocrinology and Nutrition, Strasbourg, France; [4]Institute of Biomedical and Health Sciences, Hiroshima University, Department of Gastroenterology and Metabolism, Applied Life Sciences, Hiroshima, Japan; [5]Nuffield Department of Medicine, University of Oxford, Oxford, United Kingdom; [6]University of Melbourne, St Vincent's Hospital, Melbourne, Australia; [7]Université de Strasbourg, Inserm, Institut de Recherche sur les Maladies Virales et Hépatiques Inserm, UMR_S1110, Institut Hospitalo-Universitaire, Pôle Hépato-digestif, Nouvel Hôpital Civil, Strasbourg, Strasbourg, France; [8]Université de Strasbourg, Inserm, Institut de Recherche sur les Maladies Virales et Hépatiques Inserm, UMR_S1110, Institut Hospitalo-Universitaire, Pôle Hépato-digestif, Nouvel Hôpital Civil, Strasbourg and Institut Universitaire de France, Paris, Strasbourg, France*
Email: mukherji@unistra.fr

Background and aims: The role of the circadian clock (CC) as a major regulator of physiology has been well established in the last two decades. Indeed, murine models and epidemiological studies have implicated the disruption of CC-function in several pathologies including liver disease and hepatocellular carcinoma (HCC), which are global health challenges. However, in the human liver, the identity and the epigenetic landscape of CC-regulated gene networks remains largely unknown. Uncovering the identity and transcriptional regulation of circadian genes in human liver is therefore essential to comprehend the molecular understanding of chronic liver disease and HCC.
Method: To identify genes in human liver displaying a circadian expression pattern as well as their associated epigenetic changes under physiological conditions, we performed RNA- and ChIP-sequencing of livers from humanized liver chimeric mice (HM mice) sampled at six timepoints within a 24-hour period. This allowed us to determine temporal transcriptomic and epigenetic changes on a genome-wide level in human hepatocytes. Subsequently, we applied *MetaCycle* and *dryR* to analyze and identify the rhythmic genes and biochemical pathways in human liver cells. Our H3K27ac ChIP-sequnecing analyses revealed the kinetics of enhancer activation in human liver in a 24-hour cycle.
Results: Here, we discovered the identity of numerous genes and biochemical pathways which show a rhythmic expression in human liver under physiological conditions. We found that many master transcription factors and associated crucial cellular processes which display circadian rhythmicity uniquely in human liver cells. Importantly, our combined transcriptome and epigenomic analyses uncovered the molecular basis of human liver-specific rhythmic gene networks. Crucially, many of these rhythmically expressed genes and pathways are well-known to get deregulated in chronic liver disease and HCC. These rhythmic genes show a strong correlation between enhancer activation and gene expression.
Conclusion: We have unraveled the identity of circadian genes and gene regulatory networks in human liver cells. This work represents a milestone in understanding the physiology of human liver. Moreover, our findings provide novel opportunities for understanding the molecular relationship between CC in the normal liver but also serve as a reference to understand the perturbation and role of circadian genes in chronic human liver disease and HCC.

Scott[1], Ann-Britt Marcher[1], Janusa Vijayathurai[1], Sönke Detlefsen[2], Kim Ravnskjaer[1], Philip Hallenborg[1], Blagoy Blagoev[1]. *[1]University of Southern Denmark, Odense, Denmark; [2]Odense University Hospital, Odense, Denmark*
Email: ravnskjaer@bmb.sdu.dk

Background and aims: Non-alcoholic steatohepatitis (NASH) is an obesity-related disorder caused by extensive fat accumulation in the liver parenchyma. The outcomes are chronic hepatic inflammation and deposition of extracellular matrix (fibrosis) that over time alter the hepatic architecture and function. Disease progression is driven by highly complex interactions between various cell types including hepatic mesenchymal cells and infiltrating immune cells.
Method: To better understand the liver plasticity during NASH development, we performed single-cell RNA sequencing on livers from mice fed a Western diet for 52 weeks and age-matched healthy controls. A single-reference dataset was established through Seurat 3-based integration.
Results: Here, we confidently annotated 11 cell populations including hepatocytes, hepatic stellate cells (HSC), mononuclear phagocytes (MP), and B- and T-cells. The MP-composition showed an expansion of the Kupffer cell-like cell population in NASH and infiltration of monocytes leading to an increase in macrophage heterogeneity. This we confirmed by analysis of RNA velocities predicting profoundly altered MP plasticity in NASH. Also activated HSCs were present to a higher degree in NASH livers exhibiting enhanced extracellular matrix production. Using SCENIC, we identified subpopulation-specific transcriptional networks likely to underlie HSC activation. Combining gene expression levels from individual subpopulations of HSCs and MPs using NicheNet predicted ligand-receptor interactions reflecting possible cross-talk in healthy and diseased livers. Ongoing spatial and loss of function studies will map relative cell locations and function to validate these interactions.
Conclusion: Our results expose dynamical cellular interactions at a hitherto unprecedented resolution, and contribute to the elucidation of hepatic tissue plasticity during NASH development.

Dysregulated glutamine metabolism in intrahepatic cholangiocarcinoma: a perspective for targeted therapy

Michela Anna Polidoro[1], Laura Brunelli[2], Cristiana Soldani[1], Barbara Franceschini[1], Matteo Zampini[3], Alessio Aghemo[4,5], Matteo Donadon[4,6], Guido Torzilli[4,6], Roberta Pastorelli[2], Ana Lleo[4,5]. *[1]Humanitas clinical and research center IRCCS, Hepatobiliary immunopathology lab, Rozzano, Italy; [2]Istituto di ricerche farmacologiche Mario Negri IRCCS, Mass spectrometry laboratory, Milano, Italy; [3]Humanitas clinical and research center IRCCS, Haematological malignancies genomic lab, Rozzano, Italy; [4]Humanitas University, Department of biomedical sciences, Pieve Emanuele, Italy; [5]Humanitas clinical and research center IRCCS, Department of gastroenterology, Rozzano, Italy; [6]Humanitas clinical and research center IRCCS, Department of surgery, Rozzano, Italy*
Email: michela_anna.polidoro@humanitasresearch.it

Background and aims: Intrahepatic cholangiocarcinoma (iCCA) is a deadly cancer arising from biliary epithelial cells (BECs) lining the biliary tree. iCCA is a highly chemoresistant tumor and pharmacological therapies are generally unsuccessful. Furthermore, due to the complexity of the *in-vivo* cellular interactions, metabolic activation pathways are largely unknown. We herein aim to elucidate the metabolic asset of BECs and iCCA cells.
Method: BECS and iCCA cells were isolated from patients resected at the Division of Hepatobiliary and General Surgery, Humanitas Clinical Institute. BECs and iCCA surnantants were analysed by using mass

spectrometry-based untargeted and targeted metabolomic approaches. RNA-seq and Reverse transcriptase-polymerase chain reaction (RT-PCR) analyses were performed to identify altered metabolic pathways in iCCA cells. Moreover, iCCA cell proliferation was assessed at different time points post glutaminase-1 (GLS-1) inhibition (CB-839) and immunofluorescence staining for mitochondria was performed.

Results: iCCA cells were characterized by enhanced mitochondrial activity compared to BECs, resulting in an increased glutamine and glucose uptake. RNA-seq analysis revealed several altered metabolic pathways in iCCA cells attributed to the Warburg effect and glutamine metabolism. To explore the importance of glutamine metabolism, we further evaluated the mRNA expression of ASCT1 and ASCT2, two glutamine transporters, and GLS1, resulted to be significantly upregulated in iCCA cells. CB-839 treatment revealed that GLS1-high iCCA cells were more susceptible to GLS-1 inhibition compared to GLS1-low cells, along with changing in mitochondrial morphology.

Conclusion: Experimental data suggest an impairment of mitochondrial activity of iCCA cells. Resensitizing iCCA cells to metabolic treatments could make them more susceptible to cytotoxic drugs, opening new possibility to improve the outcomes of the iCCA patients.

SAT202

Microfluidic 3-dimensional bioprinting and 2-dimensional micropatterns as tools to bioengineer biliary ducts

Lorena Loarca[1], Cyrille El Khassis[1], Afshan Iqbal[2], Latifa Bouzhir[1], Alexandra Fuchs[3], Erin Bedford[4], Jean-Charles Duclos-Vallée[5], Emma Andersson[2], Pascale Dupuis-Williams[1,6]. *[1]Université Paris-Saclay, Physiopathogenèse et traitement des maladies du foie, Villejuif, France; [2]Karolinska Institutet, Cell and Molecular Biology, Solna, Sweden; [3]Université de Paris, INSERM, CEA, U 976 HIPI, Paris, France; [4]Aspect Biosystems, Vancouver, Canada; [5]FHU Hepatinov, Centre Hépato-Biliaire, Villejuif, France; [6]ESPCI Paris, Université PSL, Paris, France*

Email: pascale.dupuis-williams@universite-paris-saclay.fr

Background and aims: There is currently an unmet need of 3D *in vitro* tubular biliary models that replicate the physiopathogenesis of cholestatic disorders to test for novel therapeutic targets.

We are developing several methodologies for the construction of bile tubes:

by microfluidic co-extrusion bioprinting, with the aim of obtaining perfusable tubes of 300 to 500 µm in diameter orby self-organogenesis allowing the development of 3D hollow, polarized, and functional biliary trees grown on 2D micropatterns

Alagille Syndrome (ALGS) is a genetic disorder that affects various organs including the liver. Liver damage in ALGS occurs as a result of defects in the biliary system due to mutations on the JAG1 gene. A mouse model of ALGS (*Jag1*$^{Ndr/Ndr}$) with a missense mutation in *Jag1* was previously developed showing heart, eyes, and liver abnormalities.

The aim of our study is to show our progress on the construction of 3D bioprinted perfusable human biliary ducts and on the application of our biliary tree model to investigate the organogenesis features observed in ALGS using organoids from the *Jag1*$^{Ndr/Ndr}$ mouse model.

Method: Alginate-collagen I and human primary cholangiocytes were utilized to bioprint tubes of 3 cm in length and 300 µm inner diameter using the RX1 bioprinter and microfluidic printheads (Aspect Biosystems).

Collagen I-coated glass micropatterns and organoids from the *Jag1*$^{Ndr/Ndr}$ mouse model were employed to engineer 3D biliary trees of physiologically relevant geometry and dimensions.

Results: Perfusable human biliary tubes were fabricated via the microfluidic 3D bioprinting technology as assessed by confocal microscopy images of the polarized biliary epithelium.

3D biliary trees from WT and *Jag1*$^{Ndr/Ndr}$ mouse organoids were bioengineered from 2D micropatterns. The *Jag1*$^{Ndr/Nd}$ biliary trees exhibited thinner branches with impaired polarity and smaller lumens (Fig 1).

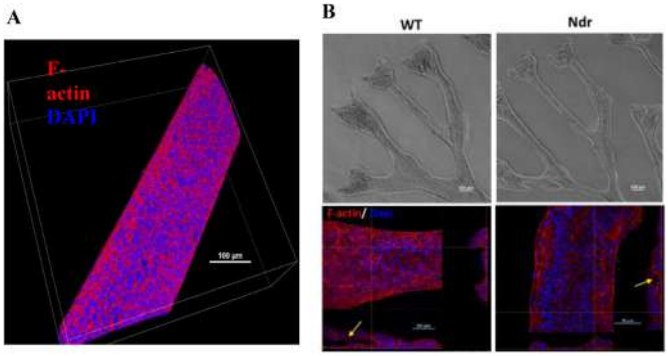

Figure 1. Biliary structures fabricated via microfluidic 3D bioprinting and 3D self-organogenesis on 2D micropatterns (A) 3D reconstruction of confocal Z-stacks of a bioprinted human tube showing F-actin and nuclei labelling (20X). (B) Branches from *Jag1*$^{Ndr/Ndr}$ biliary trees grown on 2D micropatterns are thinner (top panel, phase contrast, 10X) and with smaller lumens, (bottom panel, orthogonal views, confocal microscopy (40X)). Yellow arrows pointing at lumens.

Conclusion: Microfluidic 3D bioprinting and 2D micropatterns are two technologies that allow for bioengineering of 3D tubular biliary structures that recapitulate *in vivo* states of health and disease. These models open up opportunities to study organogenesis and physiopathological cues.

The bioprinted tubes could be connected to microfluidic perfusion systems to investigate questions related to bile flow and detoxification. Self-organogenesis of 3D structures on 2D micropatterns is a promising tool to mimic ALGS.

SAT203

Mcpip1 fl/fl LysM Cre mice as an animal model of TNFa-dependent liver endothelial cell dysfunction in humans with chronic inflammation

Dariusz Zurawek[1], Natalia Pydyn[1], Piotr Major[2], Edyta Kus[3], Stefan Chlopicki[3], Andrzej Budzyński[3], Ewelina Pośpiech[4], Jolanta Jura[1], Jerzy Kotlinowski[1]. *[1]Faculty of Biochemistry, Biophysics and Biotechnology, Jagiellonian University, Department of General Biochemistry, Kraków, Poland; [2]2nd Department of General Surgery, Jagiellonian University Medical College, Poland; [3]Jagiellonian Centre for Experimental Therapeutics, Jagiellonian University, Poland; [4]Malopolska Centre of Biotechnology, Jagiellonian University, Human Genome Variation Research Group, Poland*

Email: j.kotlinowski@uj.edu.pl

Background and aims: Mcpip1 is an RNase involved in a negative regulation of inflammation, which is tightly linked to the function of endothelial cells. Under such pathological state, endothelium is characterized by increased expression of adhesion molecules, enhanced permeability, diminished production of NO, or increased extravasation of leukocytes to the surrounding tissue. The aim of this work was to verify whether Mcpip1 deletion leads to endothelial activation.

Method: We used C57BL6/J mouse strain with a knock-out of Mcpip1 gene in leukocytes of myeloid lineage (Mcpip1$^{fl/fl}$LysM^{Cre}) as a model of endogenous, sterile inflammation. Multiplex Luminex assay was used to determine serum cytokine profile in these mice. Then, we performed differential expression analysis of genes in CD146^{+} endothelial cells (ECs) isolated from livers of 3 and 6-months-old control (Mcpip1$^{fl/fl}$) and Mcpip1$^{fl/fl}$LysM^{Cre} mice by using next generation sequencing (NGS) and RT-PCR method. NGS was followed by gene ontology enrichment analysis (GO) and signaling pathway impact analysis. Activation of hepatic ECs was analyzed by immunohistochemical (IHC) staining. Finally, results observed in mice were compared to ECs liver histology of a group of 40 patients.

Results: Depletion of Mcpip1 protein in myeloid leukocytes led to development of sterile and endogenous inflammation in 6-month-old Mcpip1$^{fl/fl}$LysM^{Cre} animals. Mcpip1$^{fl/fl}$LysM^{Cre} mice were characterized by increased serum levels of interleukins (IL-5, IL-6Rα, IL-10), chemokines (MCP-2, MCP-5, MIP-3β, MARC), markers of endothelial damage and TNFa. NGS analysis revealed 1094 differentially expressed genes (fold change >2 or <0.5) in ECs isolated from livers of Mcpip1$^{fl/fl}$LysM^{Cre} mice as compared to control Mcpip1$^{fl/fl}$ animals. GO analysis pointed out that 'antigen processing and presentation' and 'cell adhesion molecules' were the mostly affected biological pathways in liver ECs of Mcpip1$^{fl/fl}$LysM^{Cre} mice. Further, RT-PCR and immunohistochemical analysis confirmed significant upregulation of P-selectin, Vcam1 and Icam1 in hepatic ECs of Mcpip1$^{fl/fl}$LysM^{Cre} mice as compared to control littermates. Moreover, we observed significant reduction of the level of liver glycocalyx what was followed by increased serum TNFs levels observed in Mcpip1$^{fl/fl}$LysM^{Cre} mice. Finally, patients with high serum levels of TNFa (>14 pg/ml) showed significant decrease in the levels of glycocalyx in the liver.

Conclusion: Mouse genetic model of endogenous, sterile inflammation (Mcpip1$^{fl/fl}$LysM^{Cre}) has good translational potential in studies of liver ECs activation and damage observed in patients with chronic inflammation.

Acknowledgments: This work was supported by research grant from National Science Centre, Poland grant number 2017/27/B/NZ5/01440 to JK.

SAT204

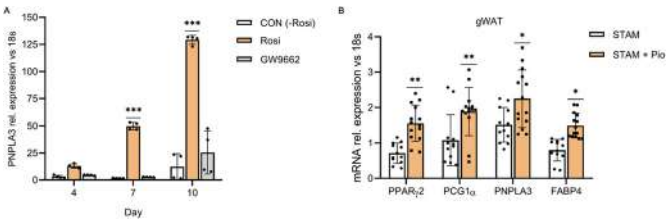
Peroxisome proliferator activated receptor gamma regulates patatin-like phospholipase domain-containing protein 3 in adipocytes in vitro and in vivo in a mouse model of non-alcoholic steatohepatitis

Emmanuel Dauda Dixon[1], Thierry Claudel[1], Alexander D Nardo[1], Veronika Mlitz[1], Claudia Fuchs[1], Michael Trauner[1]. [1]*Medical University of Vienna, Hans Popper Laboratory of Molecular Hepatology, Division of Gastroenterology and Hepatology, Department of Internal Medicine III, Wien, Austria*
Email: michael.trauner@meduniwien.ac.at

Background and aims: The patatin-like phospholipase domain-containing protein 3 (PNPLA3) is expressed highly in the liver and adipose tissue. Despite its unknown metabolic function, the PNPLA3 mutant I148M is associated with non-alcoholic fatty liver disease development and progression. Hence, there is a growing interest in understanding the role of PNPLA3 in adipose tissue and liver biology, the two main organs/tissues responsible for maintaining metabolic flexibility. Peroxisome proliferator-activated receptor gamma (PPAR gamma) binding activity was shown to be reduced in LX2 cells overexpressing the PNPLA3 I148M variant. Therefore, we explored whether PPAR gamma transcriptionally regulates PNPLA3 in vitro and in vivo in STAM mice as a model of NASH.

Method: A 1 kb DNA fragment of the human PNPLA3 promoter was cloned in front of a luciferase reporter gene and co-transfected into COS-7 cells with a PPAR gamma expression plasmid. Four potential peroxisome proliferator response elements (PPREs) predicted sequences were mapped using NUBIscan and Genomatix softwares. The predicted PPREs sequences were subjected to gel shift to report the direct interactions between PPAR gamma and PNPLA3. To explore the regulation of PNPLA3 independent of insulin, we investigated the STAM (diabetic and hyperlipidemia condition) model and fed 8 weeks old STAM mice an HFD supplemented with 0.01% pioglitazone for 2 weeks.

Results: Rosiglitazone induced PNPLA3 mRNA expression (+88%) and significantly increased the luciferase activity in co-transfected cells (+50%), demonstrating PPAR gamma-mediated induction of PNPLA3 promoter activity. Interestingly, two PPREs at positions 713–707 (+92%) and 790–780 (+93%) were bound by the PPAR gamma nuclear protein in the differentiated adipocytes. The introduction of two base-pair mutations into the identified 707mut (-40%) and 780mut1 (-60%) reduced PPAR gamma binding activity, but not 780mut2. Likewise, incubation with an antibody against PPAR gamma also reduced binding (-40%) to the PNPLA3 enhancer regions. In the STAM mouse, pioglitazone treatment increased markedly the expressions of PNPLA3 (+31%) and PPAR gamma (+50%) mRNA and its downstream target genes such as FABP4 and PGC1 alpha in the gonadal white adipose tissue (gWAT). In the liver (with lower PNPLA3 expression compared to white adipose tissue), however, pioglitazone treatment did not significantly increase PNPLA3 (p = 0.56) and PPAR gamma (p = 0.06) gene expression.



Conclusion: This study demonstrates that in the presence of PPAR gamma, PNPLA3 is up-regulated transcriptionally independent of insulin-SREBPs mediated effect. This data suggests that PNPLA3 is a PPAR gamma target gene. However, the pathogenetic and therapeutic relevance of this association with regards to adipose tissue and liver function remains to be determined.

SAT205

Animal variants of sodium-taurocholate co-transporting polypeptide permitting hepatitis B virus infection

Fuwang Chen[1], Jochen Wettengel[1], Florian Gegenfurtner[1], Yi Ni[2,3], Stephan Urban[2,3], Ulrike Protzer[1,4]. [1]*Institute of Virology, Technical University of Munich/Helmholtz Zentrum München, Munich, Germany;* [2]*Department of Infectious Diseases, Molecular Virology, University Hospital Heidelberg, Heidelberg, Germany;* [3]*German Center for Infection Research (DZIF), partner site Heidelberg, Heidelberg, Germany;* [4]*German Center for Infection Research (DZIF), partner site Munich, Munich, Germany*
Email: Fuwang.chen@tum.de

Background and aims: Evaluation of new therapies to cure chronic hepatitis B virus (HBV) infection is limited by the lack of suitable animal models. Identification of sodium-taurocholate co-transporting polypeptide (NTCP) as a species-specific key factor for HBV entry and infection may allow expanding the HBV host range. Key objective of this study was to analyse species-specific NTCPs for HBV binding and infection in order to advance our knowledge and to discover potential HBV animal models.

Method: NTCPs from various animal species were selected based on their sequence similarity within the human NTCP binding domain (amino acid 157–165). These NTCPs were expressed in HepG2 cells by DNA-plasmid or mRNA transfection. Subsequently, NTCPs expression, bile acid uptake and moreover their capability to support HBV binding and infection were analyzed by luminescence, radiometry, myristoylated HBV-preS1 peptide (MyrB-atto488) staining, flow cytometry and HBeAg-specific ELISA, respectively.

Results: Eighteen animal NTCP variants expressed at comparable levels revealed varying levels of bile acids uptake as physiological function of NTCP. MyrB-atto488 staining and subsequent flow cytometry analysis indicated that all NTCP variants except those from macaque and dolphin were able to bind HBV. Furthermore, HBV infection experiments showed that NTCPs from various species including aardvark, rabbit, whale, big brown bat, cat, rhinocerose and horse support *de novo* HBV infection when expressed on HepG2 cells. In addition, introducing minimal genetic changes into hamster, cow and goat NTCP at amino acid position 82–87 restored the capability to

mediate HBV infection. Notably, cells expressing horse NTCP were even more susceptible to HBV infection compared to the cells expressing all the other NTCP variants including human NTCP. Moreover, horse NTCP localization at the plasma membrane was two-fold increased compared to human NTCP, consequently leading to more HBV particles binding and enhanced HBV infection. In addition, HBcore staining and cccDNA quantification revealed that expression of horse NTCP increased total numbers of HBV infected cells and average viral load.

Conclusion: The evaluation of selected NTCP variants highlights the importance of two functional domains at aa 82–87 and aa 157–165 to support HBV infection. In addition, modification of cow and goat NTCPs suggested that additional unknown motifs also play a role to accomplish NTCP function in mediating HBV infection. Through our screening, we identified rabbits, cats and horses as potential HBV hosts if restriction factors downstream of HBV uptake can be overcome. HBV infection could be increased by expressing horse NTCP instead of human NTCP on HepG2 cells. Thus, horse NTCP is a promising candidate to create new *in vitro* and *in vivo* models and help to clarify NTCPs mode of action during HBV entry.

Email: michela_anna.polidoro@humanitasresearch.it

Background and aims: Intrahepatic cholangiocarcinoma (iCCA) is a deadly cancer of biliary epithelium with very limited therapeutic options. This highlights the importance of decipher iCCA mechanisms for effective therapeutic strategies. Nevertheless, *in-vivo* cellular interactions complexity has hindered an effective recapitulation of *in-vitro* human milieu through 2D culture systems. We aim to develop an *in-vitro* 3D microfluidic device with patient-specific co-cultures of the main cells involved in iCCA.

Method: Primary iCCA cells were isolated from patients surgically resected at the Hepatobiliary Surgery Department, Humanitas Clinical Institute. A PDMS microfluidic device, composed by three adjacent microchannels separated by pillars and with independent accesses, was fabricated at Polytechnic of Milan.

Results: Firstly, proliferation assays, morphology assessments and RT-PCR were performed for three cell types to verify the phenotype retaining with an *ad-hoc* medium composition. After medium optimization, to recapitulate iCCA microenvironment, iCCA cells and primary fibroblasts were co-cultured in the central channel embedded in an optimized fibrin/collagen hydrogel, displaying an high cell viability and 3D organization after 96 h in culture. Endothelial cells were seeded in one lateral channel forming a tubular vessel, corroborated by fluorescence microscopy with specific antibodies. Dextran diffusion assays and COMSOL simulations were performed to assess the hydrogel diffusion ability to molecules and the endothelial barrier functional integrity within the chip.

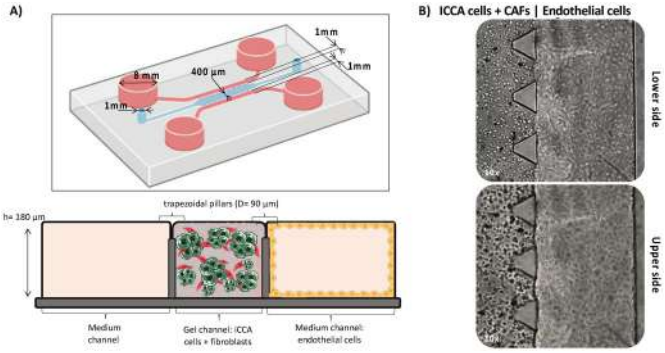

Figure 1: Cholangiocarcinoma-on-chip

Conclusion: Our results showed that we were able to recreate a reliable iCCA microenvironment in a 3D microfluidic device. This system will make it possible to elucidate the biological mechanisms involved in iCCA progression and may provide an efficient clinical tool for personalized drug testing.

Regulation of cholangiocyte ciliogenesis by soluble adenylyl cyclase

Hang Lam Li[1], Arthur Verhoeven[1], Simei Go[1], Jung-Chin Chang[1], Ronald Oude-Elferink[1]. [1]*Tytgat Institute for Liver and Intestinal Research, Amsterdam, Netherlands*
Email: r.p.oude-elferink@amsterdamumc.nl

Background and aims: Sec61 subunit beta (SEC16B) is involved in endoplasmic reticulum (ER) import of a selected group of N-linked glycosylated proteins Mutations in SEC61B and Polycystin 1 (PC1) are both causative for polycystic liver disease (PCLD), which is characterized by disturbed ciliogenesis and disturbed cyclic adenosine monophosphate (cAMP) homeostasis. Soluble adenylyl cyclase (sAC) is highly expressed in H69 cholangiocytes. Therefore, we investigated the role of sAC in ciliogenesis of H69 cells.

Method: Phosphoproteomics, western blotting and immunofluorescence staining were performed in H69 cholangiocytes in the presence and absence of the sAC-specific inhibitor LRE1 or by knockdown of sAC with lentiviral shRNA. Deglycosylation of H69 lysates was performed with PNGase F and endo H.

Results: Phosphoproteomic analysis of H69 cells incubated with the sAC-specific inhibitor LRE1 acutely and drastically reduced phosphorylation of SEC61B at serine 17. The function of this phosphorylation site is unknown. Since mutations in Sec61B are known to disturb the maturation of PC1, a primary ciliary protein, we studied the effect of sAC knockdown on PC1. Chronic sAC knockdown by lentiviral shRNA led to impaired glycosylation of PC1, while no difference was observed in protein levels (as determined by deglycosylation with PNGase F). Conversely, knockdown of sAC did not affect the protein level, nor the glycosylation of GLUT1, which is a strongly glycosylated plasma membrane protein that is not associated with the primary cilium. We also studied the effect of sAC knockdown on ciliogenesis. Immunofluorescence staining of cilia (with ADP-ribosylation factor-like protein 13B (ARL13B) as a marker) revealed disappearance of cilia upon sAC knockdown. This was accompanied by intracellular accumulation of ARL13B.

Conclusion: These data suggest that sAC-dependent phosphorylation is essential for proper co-translational glycosylation of a specific set of proteins that travel through the ER, including PC1. As a consequence, ablation of sAC expression leads to the absence of cilia in cholangiocytes. Our observations suggest that sAC may be a regulator of ciliogenesis.

Background and aims: Activation of hepatic stellate cells (HSC) by inflammatory cytokines plays a central role in the progression of fibrosis. We aimed to: (i) define the interplay between NF-kappa-B and TGF-beta pathways using induced pluripotent stem cell (iPSC)-derived hepatic stellate cells (iHSCs); and (ii) discover insights that align with non-alcoholic steatohepatitis (NASH) progression.
Method: We developed an iHSC model that showed evidence of cellular maturation and extracellular matrix production. We employed Cas9-engineered cells and barcoded guide RNAs to execute pooled optical screening in human cells (POSH); and single-cell RNA-seq to analyze cytokine-treated iHSCs. For characterization of NASH phenotypes, we used 4, 641 whole-slide images of liver biopsies from multiple trials. We trained end-to-end deep convolutional neural networks (CNN) to predict histological features [Casale et al, EASL 2020]. RNA-seq was performed on matched samples. For each clinical end point, we assessed the (multiple-hypothesis corrected) enrichment of TNF-alpha and IL1-beta response genes at multiple cutoffs using GSEA as implemented in the *gseapy* prerank module.
Results: Using a 400-guide RNA CRISPR library, we characterized the genes critical for TNF-alpha and IL1-beta-mediated activation of NF-kappa-B p65 response in iHSCs (Figure 1A **and not shown**). Molecular characterization of gene expression changes demonstrated that NF-kappa-B induces type I interferon response genes in iHSCs, constituting a distinct activation state as compared to TGF-beta (Figure 1B). Supporting the disease relevance of these signatures, we observed that TNF-alpha and IL1-beta signatures were enriched for genes associated with the CNN fibrosis stage and progression, as well as the serum fibrosis biomarker ELF score at FDR 5%.
Conclusion: This work constitutes an advancement above the state-of-the-art methodology, with optimized protocols and cell lines for genetic editing of iHSCs. Notably, this constituted the first time that POSH with image-based phenotyping has been achieved in iPSC derived cells. These studies also revealed a model of cytokine-driven fibrosis that aligned with clinical histological and biomarker features of NASH progression. Finally, we highlight the identification of NF-kappa-B p65 induced type I interferon in iHSCs. These results provide insights that will support the development of new therapeutic approaches for NASH.

SAT209

Regulation of cholangiocyte ciliogenesis by soluble adenylyl cyclase

Hang Lam Li[1], Simei Go[1], Jung-Chin Chang[1], Arthur Verhoeven[1], Ronald Oude Elferink[1]. [1]*Amsterdam UMC, Tytgat Institute, Amsterdam, Netherlands*

Background and aims: Sec61 subunit beta (SEC61B) is involved in endoplasmic reticulum (ER) import of nascent plasma membrane, secreted and vacuolar proteins. Mutations in the genes for SEC61B and PC1 are (amongst others) causative for polycystic liver disease

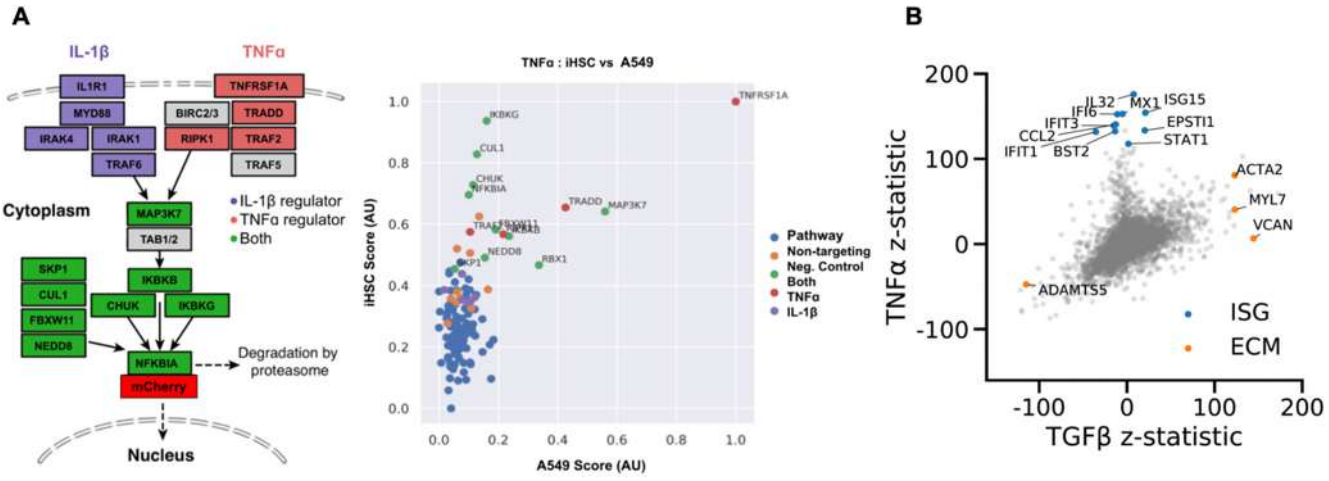

Figure 1 | TNF induced type I interferon stimulated genes mark a unique activation state in iHSCs.
(**A**) POSH targeting recovered genes responsible for image-based p65-mCherry translocation. iHSC scores were similar in rank to those found in the A549 reference tumor line. IL1-beta specific genes, purple; TNF-alpha specific genes, red; Common NF-kappaB genes, green; and Control genes, orange and blue (pathway modified from Feldman et al., 2019). (**B**) Scatter plot depicting gene expression levels in iHSCs reveals distinct TNF-alpha-induced type I interferon stimulated gene (ISG) signature, versus common TNF-alpha and TGF-beta cytokine-driven extracellular matrix (ECM) genes.

Figure: (abstract: SAT208)

(PCLD), which is characterized by disturbed ciliogenesis and disturbed cyclic adenosine monophosphate (cAMP) homeostasis. Soluble adenylyl cyclase is highly expressed in H69 cholangiocytes. Therefore, we investigated the role of soluble adenylyl cyclase (sAC, ADCY10) in ciliogenesis of H69 cells.

Method: Phosphoproteomics, western blotting and immunofluorescence staining were performed in H69 cholangiocytes in the presence and absence of the sAC-specific inhibitor LRE1 and by knockdown of sAC with lentiviral shRNA. Deglycosylation of H69 lysates was performed with PNGase F and endo H.

Results: H69 cells incubated with sAC-specific inhibitor LRE1 acutely and drastically reduced phosphorylation of SEC61B at serine 17. The function of this phosphorylation site is currently unknown. We therefore studied the effect of sAC knockdown by lentiviral shRNA on ciliogenesis. Immunofluorescent staining of cilia, with ADP-ribosylation factor-like protein 13B (ARL13B) as a marker, revealed disappearance of cilia upon sAC knockdown. This was accompanied by an intracellular accumulation of ARL13B. Polycystin-1 (PC1), which is largely expressed at the primary cilium of cholangiocytes, was also investigated. sAC knockdown led to impaired glycosylation of PC1, while no difference was observed in its protein levels (as determined by deglycosylation with PNGase F). Conversely, neither protein level, nor glycosylation state of GLUT1, a strongly glycosylated plasma membrane protein that is not associated with the primary cilium, were affected by knockdown of sAC

Conclusion: These data suggest that sAC-dependent phosphorylation of SEC61B is essential for proper cotranslational glycosylation of a specific set of proteins that travel through the endoplasmic reticulum, including PC1. As a consequence, ablation of sAC expression leads to absence of cilia in cholangiocytes. Our observations suggest that sAC may be a regulator of ciligenesis.

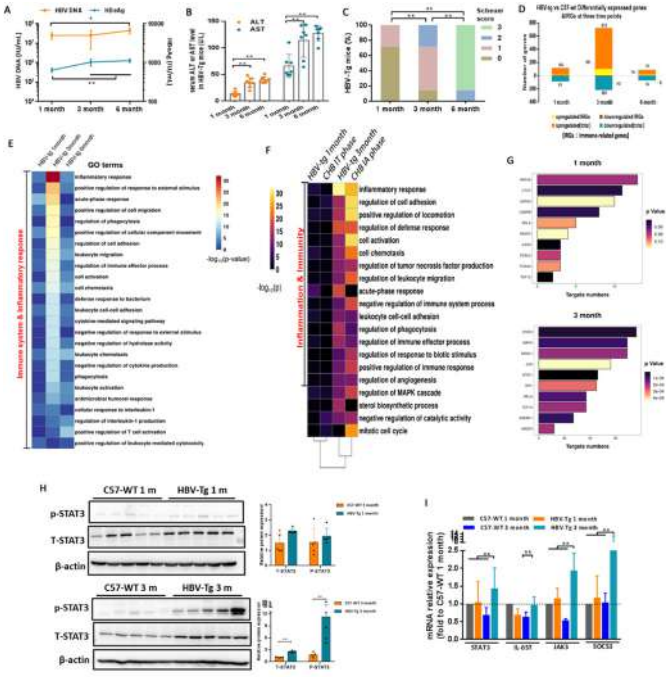
Email: mchen@hospital.cqmu.edu.cn

Background and aims: Various immune cells and mediators were reported to be significantly changed in immune activation stage during chronic HBV (CHB) infection. However, it is still unknown what key upstream regulators drive these numerous changes in gene expression, especially during the transition from immune tolerance to immune activation.

Method: A HBV transgenic (HBV-Tg) mice model with spontaneous development of hepatic immune activation was applied to comprehensively investigate the dynamic changes in hepatic gene expression and immune cells by RNA sequencing, flow cytometry and immunohistochemistry. The transcriptomic and immunologic characterizations were analyzed by Gene Set Enrichment Analysis (GSEA) and ImmPort, and upstream transcriptional factors (TFs) were predicted by ENCODE CHIP-seq library in immune tolerance and immune activation phases both in HBV-Tg mice and CHB patients (GSE83148 and GSE65359 from GEO datasets). Expression and activation of predicted transcriptional factors and the signal pathway components were identified and confirmed by western blot and quantitative real time PCR.

Results: Compared to 1-month-old HBV-Tg mice (in immune tolerance phase), a number of inflammatory and immune-related genes and pathways were significantly up-regulated in 3-month-old HBV-Tg mice (in early immune activation phase). Similar hepatic gene expression patterns were found between HBV-Tg mice in 1 month or 3 month and CHB patients in immune tolerance or immune activation phase respectively. STAT3 was predicted to be the top-ranking transcription factor in early immune activation phase of HBV-Tg mice (3 month). Furthermore, expression of total and phosphorated STAT3, and several genes involving STAT3 pathway was significantly enhanced in 3-month-old HBV-Tg mice.



A,B,C,D, serum HBV DNA and HBeAg levels (A), serum ALT and AST levels (B), histologic grading of inflammation by Scheuer scoring system (C), and the number of hepatic differentially expressed total or immune-related genes (D) in HBV-Tg mice at 1, 3, or 6 month. E, inflammation and immune-related pathways (GO terms) were significantly up-regulated in 3-month-old HBV-Tg mice by GSEA analysis. F, similar biologic processes between HBV-Tg mice in 1 month or 3 month and CHB patients in immune tolerance or immune activation phase separately by cluster analysis. G, STAT3 was the top-ranking transcription factor in 3-month-old HBV-Tg mice predicted by ENCODE tools. H, enhanced protein expression of hepatic total (T) and phosphorated (P) STAT3 in 3-month-old HBV-Tg mice. I, elevated mRNA expression of several components involving STAT3 signal pathway in 3-month-old HBV-Tg mice.

Conclusion: Activation of STAT3 with enhanced expression of immune- and inflammation-related genes indicated a shift from immune tolerance to immune activation in chronic HBV infection.

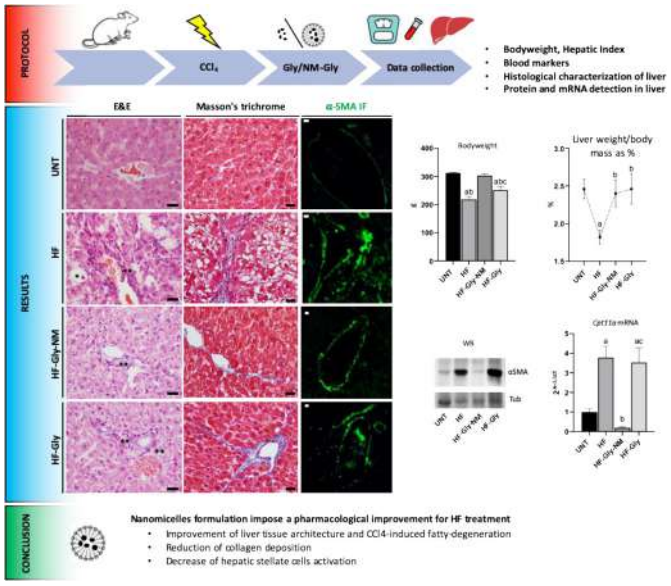
Email: luciana.dini@uniroma1.it

Background and aims: A major cause of liver-related disorders is hepatic fibrosis (HF). TGFb1, a cytokine, is one of the profibrotic mediators and it affects specific liver cells, including hepatic stellate cells and portal fibroblasts which participate in the overproduction of extracellular matrix. There have been promising results against chronic liver progression in animal models using the TGFb1 receptor inhibitor LY2157299 (Galunisertib, Gly), despite its low

bioavailability. Here, we evaluate in a rat model the possible benefit against HF of encapsulated Gly in polymeric nanomicelles based on polygalacturonic acid and polyacrylic acid (Gly-NMs) previously characterized and known to increase drug bioavailability.
Method: Gly and Gly-NMs role against fibrosis were tested in a CCl4-induced HF rat model. Morphological, hematic and hepatic data were collected to monitor disease progression.
Results: In terms of body weight, liver weight, and serum parameters of hepatic function, Gly-NM appeared to provide better recovery from hepatic fibrosis than Gly. Molecular markers and histopathological analysis showed that Gly-MN demonstrated marked antifibrotic properties, reducing collagen deposition in liver tissue and decreasing the activation of hepatic stellate cells. Furthermore, we remarked an improved CCl_4-induced fatty-degeneration following Gly-MNs treatment. The latter was associated with a gene downregulation of carnitine palmitoyl-transferase 1A *(Cpt1a)* which can impose a protective action against CCl_4 insult as reported in the literature for mice lacking the enzyme.



Conclusion: Our results show that encapsulated Gly reduces fibrosis and related disease markers and improve the fatty degeneration better than free drug in a *in vivo* rat model.

3D bioprinted hepatocyte and mesenchymal stem cell spheroids as a cell therapy for liver disease

Christopher Dickman[1], Stephanie Campbell[1], Haley Tong[1], Reza Jalili[1], Simon Beyer[1], Tamer Mohamed[1], Sam Wadsworth[1], Spiro Getsios[1].
[1]*Aspect Biosystems, Vancouver, Canada*
Email: chrisd@aspectbiosystems.com

Background and aims: Individuals with severe liver failure or metabolic liver disease, often have limited treatment options aside from transplantation. Liver transplantation is a complex and invasive surgery with limited availability of donor organs. Furthermore, recipients require life-long immune suppression, increasing the risk of infection and cancer. Recently, isolated hepatocytes have been transplanted into pediatric patients with acute liver failure with improvements in survival. Long term function of transplanted hepatocytes remains a challenge for treatment of chronic disease. The goal of this study is to demonstrate the ability of our unique bioprinting technology to generate hepatocyte implants capable of long term viability and function *in vitro* as well as *in vivo* in the intraperitoneal space of transplanted mice.
Method: Primary human hepatocytes (PHHs) were formed into spheroids with the addition of CD166 positive mesenchymal stem cells (MSCs). These spheroids were manufactured into a 3D bioprinted implant using Aspect Biosystems' RX1 bioprinter. Spheroids were embedded in a hydrogel core and surrounded by an immune isolating shell in a core-shell micro-architecture. Live/Dead; albumin, and alpha-1 antitrypsin (A1AT) production as well as ammonia detoxification assays were used to confirm *in vitro* function of printed implants. Hepatocytes were then implanted into the IP space of NOD-*scid* IL2Rgamma^{null} mice. Function was examined over 28 days by monitoring the levels of plasma albumin and A1AT. At day 28 fibers were retrieved to analyze function and viability.
Results: When cultured *in vitro* 1 million cell hepatocyte and MSC implants were able to synthesize >20 ug/million PHH/day. When implanted into mice plasma levels of albumin remained steady for 28 days and reached levels ≥2000ng/ml. The hepatocytes retained function and the ability to detoxify ammonia when retrieved from mice at the study end point.
Conclusion: Our hepatocyte and MSC bioprinted implants demonstrate promise for the treatment of liver disease. We aim to build upon our research with studies demonstration efficacy of these implants in a small and large animal model of acute liver failure.

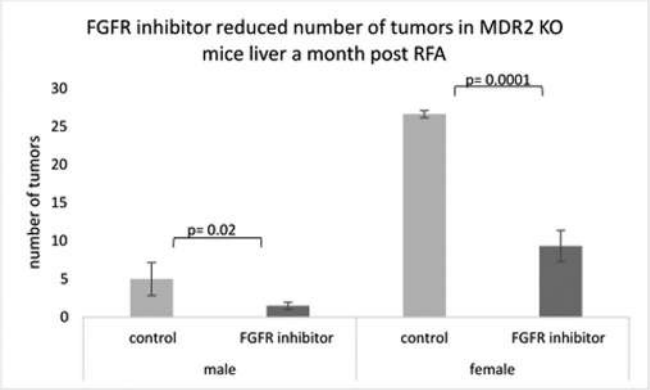
SAT213

Fibroblast growth factors are therapeutic targets for radiofrequency ablation induced tumorigenesis

Aurelia Markezana[1], Mor Paldor[1], Haixing Liao[1], Muneeb Ahmed[2], Elina Zorde-Khavlevsky[1], Nir Rozenblum[1], Salome Ganizate[1], Eithan Galun[1], S. Nahum Goldberg[1]. [1]*Hadassah Hebrew University Hospital, Goldyne Savad Institute of Gene Therapy, jerusalem, Israel;* [2]*Beth Israel Deaconess Medical Center (BIDMC), Harvard Medical School, Laboratory for Minimally Invasive Tumor Therapies, Boston, United States*
Email: aureliahakoune@gmail.com

Background and aims: Radiofrequency ablation (RFA) is an image-guided method used commonly to treat focal primary and metastatic tumors in the liver and other organs. Despite the advantages of RFA over surgery, the 5-year survival rate of patients treated with RFA remains approximately 50%, with 70%-81% new tumor recurrence in hepatocellular carcinoma (HCC). There is evidence, that local hepatic RFA can promote tumor growth even at a distance from the ablational site. Several potential pro-tumorigenic cytokines and factors, including IL-6, HGF, STAT3, and VEGF, increase following RFA, as we have shown. Additionally, following liver ablation, an increased inflammatory response is observed including recruitment of neutrophils, macrophages, and activated myofibroblasts to the ablated zone. Thus, strategies to identify and suppress local and systemic pro-oncogenic effects of RFA are urgently required to further improve the therapeutic effect.
Method: The proliferative effect of plasma of HCC or Colorectal carcinoma (CRC) patients post liver RFA on several HCC cell lines was tested. Multiplex ELISA protein analysis was performed on these plasmas to identify secreted cytokines and growth factors post RFA and may induce proliferation. Additionally, primary mouse hepatocytes and immortalized human hepatocytes were subjected to moderate hyperthermia in-vitro, to mimic the thermal stress induced during ablation in normal parenchymal cells. The medium of these cells was analysed by an unbiased manner protein array and a multiplex ELISA to detect factors secreted to the medium post heating. Next, since we observed increase in the fibroblast growth factors (FGF) post heating in vitro and in plasma of human and mice post RFA treatment we used an FGFR inhibitor to inhibit the proliferation observed post RFA in vivo and post heating in vitro.
Results: Plasma of HCC and CRC patients, 90 min post RFA, induce significant proliferation in HCC cell lines. Multiplex ELISA screening analysis of patient's plasma shows that RFA induced secretion of pro-tumorigenic growth factors and cytokines. Medium of in-vitro heated

mouse and human hepatocytes induced significant proliferation of multiple cancer cell lines. Protein analysis shows that hepatocytes subjected to moderate hyperthermia in vitro excrete a wide spectrum of growth factors. A proteomic non-biased array analysis revealed additional growth factors involved in tumorigenesis post RFA, specifically the FGF protein family, which were elevated and secreted from heated hepatocytes and post RFA in human and mouse. In an effort to further substantiate these observations, FGFR inhibitor reduced significantly liver tumor load post RFA in an MDR2 KO inflammation induced HCC mouse model.



Conclusion: Our results indicate that liver RFA, can induce tumorigenesis via the FGF signalling pathway, and its inhibition suppress HCC development.

SAT214

Glycine ameliorates paracetamol-induced liver injury in non-alcoholic fatty liver disease by supporting glutathione biosynthesis

Alia Ghrayeb[1], Shani Drucker[1], Bella Agranovich[1], Daniel Peled[1], Oren Rom[2,3], Ifat Abramovich[1], Sara Fernandes[1], Natan Weissman[1], Jonatan Fernandez Garcia[1], James Traylor[3], Chen Eugene[2], Eyal Gottlieb[1], Inbal Mor[1]. *[1]The Ruth and Bruce Rappaport Faculty of Medicine, Cell Biology and Cancer Science Department, Haifa, Israel; [2]University of Michigan, Internal Medicine Department, Ann Arbor, United States; [3]Louisiana State University Health Shreveport, Pathology and Translational Pathobiology Department, Shreveport, United States*
Email: aliaghrayeb81@gmail.com

Background and aims: Non-alcoholic fatty liver disease (NAFLD) is the most common chronic liver disease worldwide. NAFLD patients are more susceptible to drug-induced hepatotoxicity compared to healthy individuals, yet a clear understanding of the predisposing factors and dedicated therapeutic interventions are still lacking. Overdose of paracetamol, a common analgesic drug, is one of the leading causes of acute liver injury in general. Paracetamol is oxidized in the liver to N-acetyl-*p*-benzoquinone imine (NAPQI), a highly reactive metabolite, which is detoxified by the cellular antioxidant, glutathione (GSH). In toxic doses, GSH levels cannot eliminate NAPQI, leading to reactive oxygen species (ROS)-induced damage. Glycine, a substrate of GSH synthesis, is lower in plasma of NAFLD patients and mouse models. It has recently been shown that in mice, administration of glycine can elevate GSH in the liver. We examined the mechanistic link between steatosis and paracetamol toxicity and the role of glycine in glutathione replenishment as therapeutic intervention.
Method: AML12 mouse hepatocyte cell line was incubated with palmitate (PA), which induced an increase in lipid droplets and ROS levels as detected by BOIDPY and DHE staining, respectively. Metabolomics analysis of PA treated cells by liquid chromatography and mass spectrometry demonstrated a decrease in glycine and GSH levels, which was further exacerbated by exposure to paracetamol. Cell viability analysis showed paracetamol toxicity and PA lipotoxicity were synergistic, indicating lipid accumulation increases oxidative stress and paracetamol toxicity. Glycine supplementation elevated cellular levels of glycine and GSH, even in the presence of paracetamol.
Results: C57BL/6J mice fed western diet (WD) for 8 weeks, demonstrated liver steatosis and decreased circulating glycine compared to mice on standard chow diet (CD). Unbiased metabolomic profiling of liver tissue followed by pathway analysis, exhibited significant changes in GSH and glycine metabolism in WD compared to CD. Following the 8 week diet, mice received a single dose of paracetamol. WD-paracetamol treated mice displayed higher ALT levels and more severe liver histopathology compared to CD-paracetamol treated mice, demonstrating steatosis increased sensitivity to paracetamol hepatotoxicity. Metabolomic analysis of the livers 6hrs following paracetamol administration showed significantly lower GSH and glycine levels in WD compared to CD. Glycine administration to WD-paracetamol treated mice increased hepatic levels of GSH. Indices of liver injury: ALT levels, liver pathology and tissue marker for oxidative stress, were all improved following glycine administration.
Conclusion: These results indicate that decreased glycine in the plasma and the liver in NAFLD lead to lower hepatic GSH synthesis and increase paracetamol sensitivity which can be alleviated by glycine administration.

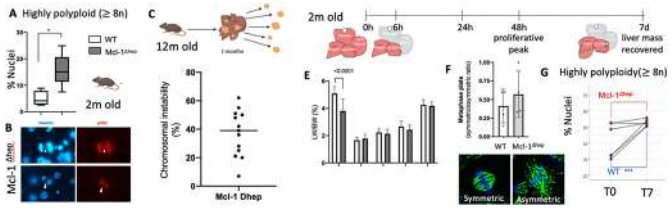
SAT215

Hepatocyte-specific deletiton of the anti-apoptotic Mcl-1 in mice induces polyploidization, mitotic erros and chromosomal instability.

Laure-Alix Clerbaux[1,2], Pierre Cordier[3], Nina Desboeufs[1,2], Kristian Unger[4], Gabriel Semere[2], Lap Kwan Chan[2], Chantal Desdouets[3], Massimo Lopes[1], Achim Weber[1,2]. *[1]Institute of Molecular Cancer Research, University of Zürich, Zurich, Switzerland; [2]Department of Pathology and Molecular Pathology, Zürich Hospital, Zurich, Switzerland; [3]Team Proliferation, Stress and Liver Physiopathology, INSERM, Paris, France; [4]Research Unit of Radiation Cytogenetics, Helmholtz Zentrum München, Germany*
Email: laure.alix.clerbaux@gmail.com

Background and aims: Mcl-1 is a widely recognized pro-survival protein and a promising target for cancer therapy. We previously showed that hepatocyte-specific deletion of Mcl-1 (Mcl-1^{Dhep}) triggers apoptosis and proliferation in livers of young mice, and found that higher apoptotic levels at early age correlate with spontaneous HCC development later on. Aiming to characterize further non-apoptotic roles of Mcl-1, we here investigated its role in ploidy and mitosis *in vivo*.
Method: Mcl-1^{Dhep} livers of 2 months old mice were analyzed for ploidy profile, formation and polarization of mitotic spindles. Whole exome sequencing (WES) of tumors of 12 months old Mcl-1^{Dhep} mice was performed to assess extent of chromosomal instability (CIN) via SNVs and indels frequency. To evaluate the impact of Mcl-1 loss in livers upon induced hyperproliferation, 2 months old Mcl-1^{Dhep} and WT mice were subjected to two-third partial hepatectomy (PHx). Ploidy contingent, mitotic figures and chromosome segregation were analyzed at the peak of proliferation (48 h post-PHx). WES was performed in regenerated livers when hepatocytes stop proliferating (7d post-PHx) to monitor associated genetic alterations.
Results: Mcl-1^{Dhep} livers of young mice displayed a high proportion of polyploid hepatocytes (Fig. A), which were associated neither with higher apoptosis, nor with higher proliferation, age or oxidative stress. Moreover, Mcl-1^{Dhep} hepatocytes entered into mitosis, thus excluding endoreplication. Gene set enrichment analysis showed an association between genes upregulated upon Mcl-1 deletion and genes of the mitotic spindle assembly checkpoint (SAC), which ensures correct chromosomes segregation during mitosis. Around

50% of the mitotic events in Mcl-1^{Dhep} livers were aberrant (Fig. B), with abnormal chromosome segregation. WES of Mcl-1^{Dhep} tumors of 12 months old mice showed a mean CIN of 33.8% (Fig. C). Following PHx, liver weight to body weight ratios were similar in Mcl-1^{Dhep} and WT mice during liver regeneration, while Mcl-1^{Dhep} livers were smaller prior to PHx (Fig. E). Mcl-1^{Dhep} hepatocytes progressed faster through G2/M. At the proliferative peak, abnormal mitotic figures were observed with similar frequency in Mcl-1^{Dhep} and WT livers (Fig. F). After regeneration, the ploidy profile was comparable in WT and Mcl-1^{Dhep} livers (Fig. G). Both WT and Mcl-1^{Dhep} livers harbored very low level of SNVs and indels.



Conclusion: In 2 months old mice, hepatocytes lacking Mcl-1 exhibit nuclear polyploidy, mitotic errors and abnormal chromosome segregation leading to CIN. Surprisingly, similar rates of aberrant mitosis were observed in WT and Mcl-1^{Dhep} livers upon hyperproliferation. And after hyperproliferation, WT and Mcl-1^{Dhep} livers exhibited similar levels of abnormal nuclear morphology, of low mutational burden and of high proportion of polyploid nuclei.

SAT216

Hepatic inflammation elicits production of proinflammatory netrin-1 through exclusive activation of translation

Romain Barnault[1,2,3,4], Claire Verzeroli[1,2,3,4], Carole Fournier[5], Michelet Maud[2,3,4,6], Anna-Rita Redavid[2,3,4,7], Ievgeniia Chicherova[2,3,4,6], Marie-Laure Plissonnier[2,3,4,6,8], Annie Adrait[9], Olga Khomich[2,3,4,6], Fleur Chapus[10], Mathieu Richaud[2,4,7,8], Maëva Hervieu[2,4,7,8], Veronika Reiterer[11], Federica-Grazia Centonze[11], Julie Lucifora[2,4,7,8], Birke Bartosch[2,4,7,8], Michel Rivoire[2,4], Hesso Farhan[11], Yohann Couté[9], Valbona Mirakaj[12], Thomas Decaens[5], Patrick Mehlen[2,3,4,7,8], Benjamin Gibert[2,3,4,7], Fabien Zoulim[2,3,4,6,13], Romain Parent[2,3,4,6]. *[1]Centre de Recherche en Cancerologie de Lyon, Inserm U1052-LabEx DEVweCan, France; [2]Université de Lyon, France; [3]CNRS UMR 5286, France; [4]Centre Léon Berard, Lyon, France; [5]Institute for Advanced Biosciences, La Tronche, France; [6]Pathogenesis of Chronic Hepatitis B and C Laboratory-Centre de Recherche en Cancerologie de Lyon, Inserm U1052-LabEx DEVweCan, France; [7]Apoptosis, Cancer an development Laboratory-Cancer research Center of Lyon, Inserm U1052-LabEx DEVweCan, France; [8]Centre de Recherche en Cancerologie de Lyon, Lyon, France; [9]University of Grenoble-Alpes, Inserm, CEA, UMR biosanté U1292, Grenoble, France; [10]The National Institute of Environmental Health Sciences, Durham, United States; [11]Medizinische Universität Innsbruck, Institute of Pathophysiology, Innsbruck, Austria; [12]Universitätsklinikum Tübingen Anaestesiology and Intensive care Medicine, Tübingen, Germany; [13]Service of Hepato-Gastroenterology, Hospice civils de Lyon, Lyon, France*

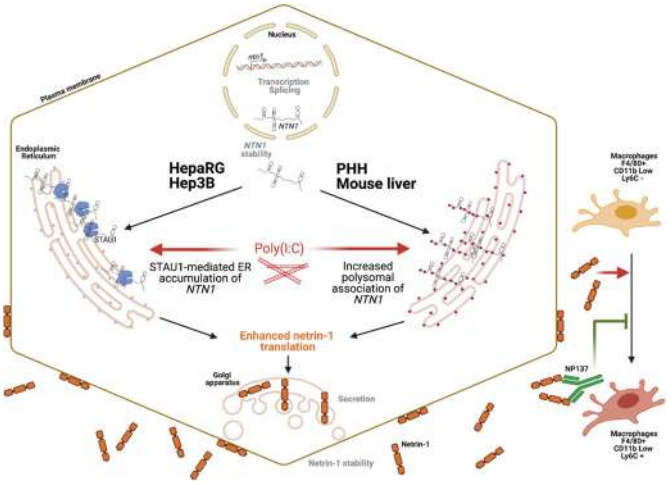
Background and aims: Chronic liver diseases (CLDs) affect more than 1 billion people worldwide. Though CLDs exhibit a high degree of diversity in terms of causal effects, including infectious (HBV and HCV), metabolic, toxic, and genetic, they all converge toward hepatic inflammation and represent a pertinent model for its study. Inflammation in turn drives hepatocyte turnover, extracellular matrix (ECM) accumulation, histological worsening, and the long-term induction of tumorigenic mediators such as IL-6, eventually leading to the development of HCC. Hence, the identification of factors involved in the harmful consequences of inflammation may lead to its clinical improvement.

Netrin-1 is well known for preventing cellular apoptosis through its binding to "dependence receptors," and we demonstrated that it is HBV- HCV induced and endowed hepatocytes with resistance to apoptosis during the unfolded protein response (UPR), a hallmark of CLDs and cirrhosis. Owing to the causal link between inflammation, cancer in general, and HCC, we hypothesized that hepatic inflammation and netrin-1 may be reciprocal influencers in the liver. This prompted us to test its inducibility and inflammatory contribution in the liver in the context of previous descriptions in inflammatory bowel disease and colorectal cancer.

Method: A panel of cell biology and biochemistry approaches (RT-qPCR, reporter assays, run-on, polysome fractionation, CLIP, filter binding assay, subcellular fractionation, western blotting, IP, stable isotope labeling by amino acids in cell culture) on in vitro- grown primary hepatocytes and liver cell lines from mouse samples and clinical samples was used

Results: We identify netrin-1 as a hepatic inflammation- inducible factor and decipher its mode of activation through an exhaustive eliminative approach. We show that netrin-1 up- regulation relies on a hitherto unknown mode of induction, namely its exclusive translational activation. This process includes the transfer of NTN1 mRNA to the endoplasmic reticulum and the direct interaction between the Staufen-1 protein and this transcript as well as netrin-1 mobilization from its cell- bound form. Finally, we explore the impact of a phase 2 clinical trial-tested humanized anti-netrin-1 antibody (NP137) in two distinct, toll- like receptor (TLR) 2/TLR3/TLR6-dependent, hepatic inflammatory mouse settings. We observe a clear anti-inflammatory activity indicating the proinflammatory impact of netrin-1 on several chemokines and Ly6C+ macrophages.



Conclusion: These results identify netrin-1 as an inflammation-inducible factor in the liver through an atypical mechanism as well as its contribution to hepatic inflammation.

SAT217

A meta-analysis to identify novel candidate genes in the development of hepatocellular carcinoma

Andrew Walakira[1], Cene Skubic[1], Nejc Nadižar[1], Miha Mraz[2], Miha Moskon[2], Tadeja Rezen[1], Damjana Rozman[1]. *[1]University of Ljubljana, Centre for Functional Genomics and Bio-Chips, Ljubljana, Slovenia; [2]University of Ljubljana, Faculty of Computer and Information Science, Ljubljana, Slovenia*
Email: andrew.walakira@mf.uni-lj.si

Background and aims: Hepatocellular carcinoma (HCC) is a major health problem worldwide. In 2020, there was about 900,000 new

cases of liver cancer, which is the third-highest number of cancer-related deaths (8.3% of 9.9 million) in the same year. Hepatitis B and C infections are still the major risk factors but with vaccination and effective treatment, these are steadily being overtaken by other factors, such as metabolic associated fatty liver disease and diabetes. Prevention efforts have been useful but the HCC burden is on the rise. To alleviate this problem, there is an urgent need for new tools, such as non-invasive diagnostics and effective treatments. We aim to unravel novel candidate genes that are important in HCC.

Method: We did a meta-analysis using 8 transcriptomics datasets (GSE19665, GSE39791, GSE41804, GSE57957, GSE64041, GSE84402, GSE84598, and HCCDB15/TCGA-LIHC). These datasets were from tumour and surrounding non-tumour tissue biopsies of the liver. First, we did differential gene expression analysis on each of the datasets individually by fitting linear models using the Limma package. This was followed by a meta-analysis by fitting random effects models using log fold change (LogFC) as effect size. Genes were considered significant if their p value was less than 0.05. Significant genes from the meta analysis were further analysed for KEGG pathway enrichment, network analysis in STRING database and searched DisGeNET to discover gene-disease associations. All statistical analyses were done in R software.

Results: After the meta-analysis, 690 genes were significantly differentially expressed. Thirty pathways were enriched with the majority (28) associated with metabolism. The two other enriched pathways were the cell cycle and p53 signalling pathways. Genes in the cell cycle and p53 signalling pathways were generally upregulated, while the genes in metabolism related pathways were generally downregulated. When searched DisGeNET database, 128 genes (of the 690 genes) were found not to be associated with HCC or other forms of liver cancer. Some of these genes like *KIAA0101, SERPINA10* and *RDH5* have been associated with HCC in smaller studies. Searching in STRING database revealed several important protein-protein interactions and hubs that are worth further investigation.

Conclusion: Four genes namely; *C8A, HAO1, PIPOX and PROZ* were identified as key hub genes and will be studied further in the laboratory.

SAT218

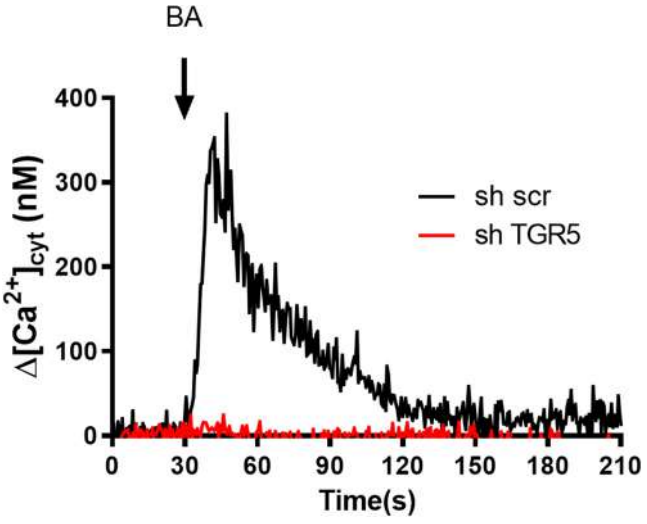
Characterization of TGR5-mediated Ca2+ signaling in cholangiocytes

Xuanmeng Chen[1], Amr Al Shebel[1], Thibault Pebrier[1], Thierry Thordjmann[1], Olivier Dellis[1]. [1]*University of Paris-Saclay, INSERM U1193, Orsay, France*
Email: olivier.dellis@universite-paris-saclay.fr

Background and aims: The Bile acid (BA) receptor TGR5 is known to be coupled with cyclic-AMP signaling in cholangiocytes, allowing Cl- and bicarbonate secretion in parallel with water, making a fluid and alkalinized bile. Our aim was to decipher TGR5-dependent bile acid-induced Ca2+ mobilization in cholangiocytes, a previously overlooked pathway.

Method: using spectrofluorimetry, we measured cytosolic calcium concentration variations in normal human cholangiocytes and cholangiocarcinoma cell lines loaded with the Ca2+ dye Indo1, using the BA taurolithocholate (TLCA) and RO5527239 (RO) as TGR5 agonists. Specific inhibitors for G proteins, P2Y2 receptors and Ca2° transporters like SERCA were used. TGR5 expression was also suppressed using shRNAs.

Results: TLCA and RO5527239 (100 and 300 µM respectively for cell lines and normal cholangiocytes) induced dose dependent Ca2+ signals in both normal human cholangiocytes and cholangiocarcinoma cell lines. TGR5-dependent cytosolic Ca2+ mobilization occurred through a complex pathway involving: Gαq/11 engagement, Ca2+ release from the endoplasmic reticulum and a strong Ca2+ influx from the extracellular medium. Furthermore, TGR5-dependent Ca2+ increase was dependent on an ATP release and on the activation of P2Y2 receptors (which are also able to induce Ca2+ release and Ca2+ influx), as revealed by using P2Y2-specific inhibitors and apyrase. In the lack of TGR5 expression (TGR5 shRNA treatment), BA-induced Ca2+ mobilization was totally impaired (Figure).



Conclusion: Beside the well-known cAMP pathway that stimulates CFTR-dependent Cl- ions secretion, TGR5 stimulation also induces Ca2+ signals through a pathway involving ATP release and purinergic P2Y2 stimulation. This new signaling pathway in cholangiocyte may have potential CFTR-independent impact on Cl- ions secretion in bile, and possibly other pathophysiological consequences to be further explored.

Liver transplantation and hepatobiliary surgery: Clinical aspects

SAT229

Outcomes of living liver donors are worse than those of matched healthy controls: nationwide cohort study

Jong Man Kim[1], Jin Yong Choi[2], Jae Heon Kim[3], Hyun Jung Kim[4], Jae-Won Joh[1]. [1]*Samsung Medical Center, Sungkyunkwan University School of Medicine, Department of Surgery, Seoul, Korea, Rep. of South;* [2]*Myongji Hospital, Goyang-si, Korea, Rep. of South;* [3]*Soonchunhyang University Seoul Hospital, Korea, Rep. of South;* [4]*Korea University, Korea, Rep. of South*
Email: jongman94@hanmail.net

Background and aims: Donor death is the most serious complication of living liver donation, but is reported rarely. We investigated the actual mortality of living liver donors (LLDs) compared with matched control groups based on analysis of the Korean National Health Insurance Services (NHIS) database.

Method: This cohort study included 12, 372 LLDs who donated a liver graft between 2002 and 2018, and were registered in the Korean Network for Organ Sharing. They were compared to three matched control groups selected from the Korean NHIS and comprising a total of 123, 710 subjects: healthy population (Group I); general population without comorbidities (Group II); and general population with comorbidities (Group III).

Results: In this population, 78.5% of living liver donors were 20–39 years old, and 64.7% of all donors were male. Eighty-nine donors (0.7%) in the LLD group died (68 males and 21 females), a mortality rate (1000 person/year) of 0.91 (0.74–1.12). Mortality rate ratio and the adjusted hazard ratio of the LLD group was 2.03 (1.61–2.55) and

1.71 (1.31–2.25) compared to Control Group I, 0.75 (0.60–0.93) and 0.63 (0.49–0.82) compared to Control Group II, and 0.58 (0.46–0.71) and 0.49 (0.39–0.60) compared to Control Group III. LLD group, depression, and lower income were risk factors for adjusted mortality. The incidence of liver failure, depression, cancer, diabetes, hypertension, brain infarction, brain hemorrhage, and end-stage renal disease in the LLD group was significantly higher than in Control Group I.

Conclusion: Outcomes of the LLD group were worse than those of the matched healthy control group despite the small number of death and medical morbidities in this group. LLDs should receive careful medical attention for an extended period after donation.

Lay summary: The incidence of mortality, liver failure, depression, cancer, diabetes, hypertension, brain infarction, brain hemorrhage, and end-stage renal disease in the LLD group was significantly higher than in the matched healthy group even though few cases. Careful donor evaluation and selection processes can improve donor safety and enable safe living donor liver transplantation.

SAT230

Pretransplant changes in serum protein glycosylation relate to risk of HCC recurrence after liver transplantation and provide a potential prognostic biomarker: a proof-of-concept study

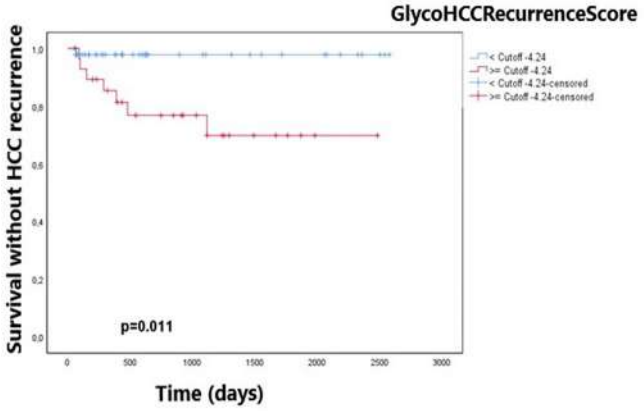
Xavier Verhelst[1,2], Heleen Engels[1], Anja Geerts[1,2], Aude Vanlander[3], Luis Abreu de Carvalho[3], Helena Degroote[1,2], Leander Meuris[4,5], Frederik Berrevoet[3], Nico Callewaert[4,5], Hans Van Vlierberghe[1,2].
[1]Ghent University Hospital, Gastroenterology and Hepatology, Gent, Belgium; [2]Ghent University, Liver Research Center Ghent, Gent, Belgium; [3]Ghent University Hospital, General, hepatobiliary and transplant surgery, Gent, Belgium; [4]VIB-Ugent, Center for Medical Biotechnology, Gent, Belgium; [5]Ghent University, Department of Biochemistry and Microbiology, Gent, Belgium
Email: xavier.verhelst@uzgent.be

Background and aims: Hepatocellular carcinoma (HCC) recurs after liver transplantation (LT) in 10% of patients. Changes in protein glycosylation have been described during the development of HCC. Study goal was to assess the risk of HCC recurrence after LT, according to changes in serum protein glycosylation before LT.

Method: A prospective study was performed in patients receiving LT between July 2011 and September 2018. A whole serum protein N-glycan profile was assessed using DNA sequencer assisted fluorophore assisted capillary electrophoresis, using a validated high-throughput protocol. For every sample, 13 glycans were quantified. Patients were followed until HCC recurrence or death. Specific changes in serum protein glycosylation profiles were analysed in patients with HCC recurrence compared to patients without.

Results: Amongst 225 consecutive liver transplant patients, 76 patients suffered from HCC before LT. Main indications were related to alcoholic cirrhosis (47.4%), HCV infection (21.1%) and NASH (15.8%). Eight patients (10.5%) developed HCC recurrence after a median follow-up time of 9.5 months after LT. Seventy-four patients (97%) fulfilled Milan criteria.

Significant differences in the relative abundance of 5 serum glycans were present in patients with HCC recurrence compared to patients without (Cox regression analysis). Based on these changes, a composite biomarker was developed (GlycoHCCRecurrenceScore). This score integrates an increased presence of triantennary glycans with and without branch and core fucosylation (NA3, NA3Fc and NA3Fbc) and a decreased presence of undergalactosylated glycans NGA2F and NGA2FB in patients with HCC recurrence. This biomarker panel shows an AUC of 0.855 (p = 0.001; 95% CI 0.731–0.979) for association with HCC recurrence. Using an optimized cut-off (-4.24), sensitivity fwas 87.5% and specificity 67.6%. Only 2.1% of patients with a value below this cut-off showed HCC recurrence, compared to 24.1% of patients with values above this cut-off (p = 0.011). PPV was 72.98% and NPV 84.39%. Figure 1 illustrates the discriminative value of this biomarker. In a univariate cox regression analysis other factors related to HCC recurrence in this cohort were diameter of the largest lesion before LT and the presence of perineural or lymphovascular invasion in the explant liver. In a multivariate analysis, the biomarker showed an independent relation with HCC recurrence (HR 1.931; p = 0.008:1.184–3.149).



Conclusion: A glycomics based serum biomarker panel is strongly associated with tumor recurrence in a cohort of LT patients with HCC, even if adhering to Milan criteria. In a multivariate analysis, this biomarker was the only pretransplant discriminative parameter of HCC recurrence in this cohort. The biomarker could potentially increase the prediction of HCC recurrence and improve allocation strategies in LT candidates with HCC.

SAT231

Liver transplantation for complications of hepatoportal sclerosis

Andrew Keaveny[1], Nadia Khatoon[2], Murli Krishna[2], Jason Lewis[2], Raouf Nakhleh[2]. *[1]Mayo Clinic, Transplantation, Jacksonville, United States; [2]Mayo Clinic, Pathology, Jacksonville, United States*
Email: keaveny.andrew@mayo.edu

Background and aims: Hepatoportal sclerosis (HPSc) is a rare, often unrecognized condition that leads to non-cirrhotic portal hypertension (PHT). Refractory complications of PHT may necessitate consideration of liver transplantation (LT). There are very limited data on the outcomes post-LT for this condition in the current era of transplantation. In this study, we sought to determine the patient and allograft outcomes of patients transplanted for HPSc at our large volume center.

Method: A 20-year retrospective search for the diagnosis of HPSc was conducted in our surgical pathology files. Twenty-one cases were identified and verified by slide review. The respective patient charts were reviewed for: clinical presentation, background history, biochemical and other laboratory studies, radiographic investigations, histology, treatment, and outcomes.

Results: Of the 21 cases, 12 were male. The age at histological diagnosis ranged from 18 to 83 years, with a median age of 61. Two patients had been referred with and were confirmed to have a diagnosis of HPSc. Six and 4 patients had been documented with ascites and esophageal varices, respectively; 4 patients had a history of hepatic encephalopathy. Relevant history included 5 patients with a prior malignancy treated with chemotherapy, 12 patients with autoimmune disorders, 4 patients with congenital abnormalities related to vascular anomalies, and 2 with HIV. Nine patients underwent LT for decompensated disease not controlled by medical management. One patient required simultaneous liver and kidney transplant. One patient required retransplantation for hepatic artery thrombosis 4 days after the original surgery. Four patients died post-LT. The causes of death at mean of 3.75 years (range: immediate-5 years) post-transplant were intra-operative death at the time of the transplant surgery (1), respiratory failure (1), and multi-organ failure

(2). The remaining 5 patients are alive at a mean of 4 years (range: 2–9 years) post-transplant. One patient was documented to have an occlusive thrombus in an inferior branch of the right portal vein 4 months post-LT and another patient developed a main portal vein thrombosis 3 years post-LT.
Conclusion: Patients presenting with complications of HPSc usually have an underlying risk factor that likely contributed to its development. LT may be required to treat refractory complications, with acceptable long-term outcomes.

SAT232

Discordance in categorization of acute-on-chronic-liver-failure in the national transplant database

Brian Lee[1], Giuseppe Cullaro[2], Aidan Vosooghi[3], Frederick Yao[2], Sarjukumar Panchal[4], David Goldberg[5], Norah Terrault[3]. *[1]University of Southern California, Los Angeles, United States; [2]University of California San Francisco; [3]University of Southern California; [4]University of Pennsylvania; [5]University of Miami*
Email: brian.lee@med.usc.edu

Background and aims: Studies regarding acute-on-chronic liver failure (ACLF) among liver transplant (LT) candidates from the United Network for Organ Sharing (UNOS) database are being used to inform LT policy changes worldwide. We assessed the validity of identifying ACLF in UNOS.
Method: We performed random probability sampling among 3 US LT centers between 2013 and 2019 to obtain a representative patient sample across ACLF grades. We compared the concordance of ACLF classification by UNOS vs. blinded manual chart review, according to EASL-CLIF. We compared the association of ACLF by UNOS and chart review with waitlist dropout within 90 days of listing.
Results: Among 481 sampled LT registrants, 250 (52%) had no ACLF, 75 (16%) had ACLF grade 1, 79 (16%) had ACLF Grade 2, and 77 (16%) had ACLF Grade 3 per UNOS categorization. Concordance of ACLF grade by UNOS vs. chart review was: 72%, 64%, 56%, and 64% for no ACLF, Grade 1, Grade 2, and Grade 3, respectively, with overall Cohen's kappa coefficient 0.48 (95%CI 0.42–0.54). Absence of acute decompensation was the most common reason for overestimation, and discordant brain and respiratory failure categorization were the most common reasons for underestimation of ACLF by UNOS. In multivariable analysis, ACLF by chart review was independently associated with waitlist dropout (Grade 1: p = 0.44; Grade 2: p = 0.003; Grade 3: p = 0.004), but this association was not present by UNOS classification (Grade 1: p = 0.68; Grade 2: p = 0.69; Grade 3: p = 0.63).

Concordance Metrics for ACLF Grade and Organ Failure by UNOS vs. Chart Review

		Sensitivity (95% CI)	Specificity (95% CI)	NPV (95% CI)	PPV (95% CI)	AUC (95% CI)
ACLF	None	0.96 (0.91-0.98)	0.72 (0.67-0.77)	0.59 (0.53-0.66)	0.98 (0.95-0.99)	0.84 (0.81-0.87)
	Grade 1	0.64 (0.44-0.81)	0.87 (0.84-0.90)	0.24 (0.15-0.35)	0.98 (0.96-0.99)	0.76 (0.67-0.85)
	Grade 2	0.56 (0.40-0.72)	0.87 (0.84-0.90)	0.28 (0.18-0.39)	0.96 (0.93-0.98)	0.72 (0.64-0.80)
	Grade 3	0.64 (0.53-0.75)	0.93 (0.90-0.95)	0.64 (0.52-0.74)	0.93 (0.90-0.96)	0.79 (0.73-0.84)
Organ Failure	Liver	0.96 (0.92-0.99)	0.98 (0.95-0.99)	0.94 (0.89-0.98)	0.99 (0.97-1.00)	0.97 (0.95-0.99)
	Coagulation	0.93 (0.88-0.97)	0.96 (0.94-0.98)	0.90 (0.83-0.94)	0.98 (0.96-0.99)	0.95 (0.93-0.97)
	Kidney	0.94 (0.89-0.97)	0.98 (0.96-1.00)	0.97 (0.93-0.99)	0.96 (0.94-0.98)	0.96 (0.94-0.98)
	Brain	0.13 (0.09-0.18)	0.92 (0.88-0.95)	0.63 (0.48-0.76)	0.51 (0.46-0.56)	0.53 (0.50-0.55)
	Respiratory	0.36 (0.21-0.53)	0.99 (0.97-1.00)	0.74 (0.49-0.91)	0.95 (0.92-0.96)	0.67 (0.60-0.75)
	Circulatory	0.15 (0.08-0.25)	0.98 (0.96-0.99)	0.52 (0.30-0.74)	0.86 (0.83-0.89)	0.56 (0.52-0.60)

Conclusion: In this retrospective multi-center study, ACLF categorization by UNOS showed weak agreement with manual chart review. We confirmed the independent association of ACLF with waitlist outcomes. These findings are informative for ongoing allocation policy discussions and highlight the importance of prospective studies regarding ACLF in LT and UNOS reform.

SAT233

Humoral response to 2-dose BNT162b2 mRNA vaccine for COVID-19 in liver transplant recipients

Maria Guarino[1], Ilaria Esposito[2], Giuseppe Portella[3], Valentina Cossiga[1], Ilaria Loperto[4], Luca Pignata[1], Raffaella Tortora[2], Maria Rosaria Attanasio[1], Michele Cennamo[3], Mario Capasso[1], Daniela Terracciano[3], Francesco Maria Cutolo[1], Alfonso Galeota Lanza[2], Raffaele Lieto[1], Sarah di Somma[3], Francesco Paolo Picciotto[2], Filomena Morisco[1]. *[1]University of Naples "Federico II," Department of clinical medicine and surgery, Gastroenterology and hepatology Unit, naples, Italy; [2]Hepatology Unit, AORN A. Cardarelli, Naples, Italy; [3]Department of translational medical science, University of Naples "Federico II," Naples, Italy; [4]UOC Epidemiologia e prevenzione e registro tumori, ASL Napoli 1 Centro, Naples, Italy*
Email: maria.guarino86@gmail.com

Background and aims: In the context of the Italian SARS-CoV-2 vaccination program, liver transplant (LT) recipients were prioritized for vaccine administration, although the lower response to vaccines is a well known problem in this population. We aimed to evaluate immunogenicity of BNT162b2 mRNA vaccine in LT recipients and healthy controls and to identify factors associated with negative response to vaccine.
Method: We prospectively evaluated a cohort of adult LT patients the humoral response (with anti-Spike protein IgG-LIAISON SARS-CoV-2 S1/S2-IgG chemiluminescent assay) at 1 and 3 months after 2-dose vaccination. A group of 307 vaccinated healthcare workers, matched by age and sex, served as controls.
Results: Overall, 492 LT patients were enrolled (75.41% male, median age 64.85 years). Detectable antibodies were observed in the 75% of patients with a median value of 73.9 AU/ml after 3 months from 2-dose vaccination. At multivariable analysis, older age (>40years, p = 0.016), shorter time from liver transplantation (<5 years, p = 0.004), and immunosuppression with antimetabolites (p = 0.029) were significantly associated with non-response to vaccination. Moreover, the LT recipients showed antibody titers statistically lower than the control group (103 vs 261 AU/ml, p <0.0001) (figure). Finally, both in controls and LT patients we found a trend of inverse correlation between age and antibody titers (correlation coefficient: –0.2023 and –0.2345, respectively).

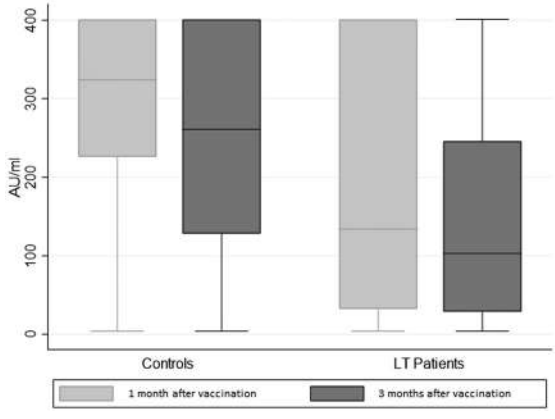


Figure: Humoral response to 2-dose BNT162b2 vaccine after 1 and 3 months in LT patients and healthcare workers (controls).

Conclusion: Three months after vaccination, LT recipients showed humoral response in 75% of cases. Older age, shorter time from transplantation and use of antimetabolites were factors associated with non-response to vaccination and needed to be kept under close monitoring.

SAT234

A predictive model for mortality within one year of liver transplantation at the time of wait-listing for transplant: a novel approach using machine learning algorithms in a large US multi-ethnic cohort

Sripriya Balasubramanian[1], Megha Bhatnagar[2], Jian Wang[2], Lisa Edelman[3], Malou Valencia[3], Aaron Rosenberger[2], Robert Freed[4], Amandeep Sahota[5], Varun Saxena[5,6], Nizar Mukhtar[5], Suk Seo[5], Brock McDonald[5], Joanna Ready[5]. *[1]Kaiser Permanente, Gastroenterology and Hepatology, Roseville, United States; [2]Kaiser Permanente, Information Support for Care Transformation, United States; [3]Kaiser Permanente, National Transplant Services; [4]Kaiser Permanente, Vascular and Interventional Radiology; [5]Kaiser Permanente, Gastroenterology and Hepatology, United States; [6]University of California, San Francisco, Hepatology, United States*
Email: priya.b.manian@gmail.com

Background and aims: Pre-liver transplant (LT) sarcopenia, malnutrition and frailty are implicated in increased mortality following LT. Tests for these entities are expensive (CT for sarcopenia assessment) or require one-on-one testing not readily available at all centres (frailty testing), limiting widespread use. A predictive tool using readily available clinical data at waitlisting would be valuable to identify patients at risk, allowing for targeted evaluation and intervention.

Method: All Kaiser Permanente adult members nationally who underwent a first LT between 2010 and 19 for indication other than hepatocellular carcinoma were included. Data extracted from the electronic medical record included demographics, laboratory values and diagnoses by ICD 9/10 codes. Frailty was assessed by previously published associated ICD codes; malnutrition by ICD codes and calculated Nutritional Risk Index. One year mortality was calculated from the day of transplant. Vote-based approach was used to identify variables of interest derived from six different machine learning algorithms. Variables with two or more votes were included. Cohort was split 80:20 for model training and validation. Models were developed with repeated iterations and hyperparameter tuning using cross-validation for maximal improvement. Model assessments done with ROC curves, confusion matrix and decile plots with KS statistic.

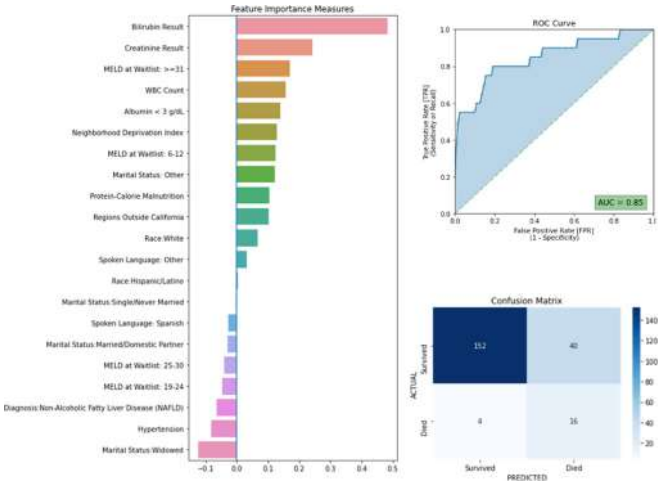

Figure: Combined Feature Importance plot, ROC curve and Confusion matrix for final predictive model: Linear SVC.

Results: A total of 1, 056 patient were included, of whom 98 (9.3%) died within one year of surgery. Variables deemed important by the "vote-based approach" included pre-LT bilirubin, creatinine, WBC count, albumin, MELD at Waitlist ≥31 and more (figure). Random forest, decision tree with bagging classifier and linear support vector classifier (SVC) performed best. Linear SVC model was selected as the final model based on sensitivity/recall, specificity, AUC statistic and F1 score. With a threshold of 50%, model had high sensitivity (80%), specificity (79%) and accuracy (79%) in identifying patients with poor outcome. Linear SVC Model performance assessed with KS statistic and decile plots achieved a value of 55 in the 3rd decile with the validation cohort, indicating excellent performance.

Conclusion: We have identified a model that predicts one year mortality after liver transplantation at the time of waitlisting with excellent performance. This enables early detection of patients at risk; studies on targeted interventions to improve post-transplant outcomes are planned.

SAT235

Monitoring patients with anti HBs trough levels can minimise hepatitis B immune globulin therapy after liver transplant

Erica Nicola Lynch[1], Stefania Petruccelli[2], Claudia Campani[1,3], Gabriele Dragoni[1,4], Tommaso Innocenti[1], Paolo Forte[5], Stefano Milani[1], Andrea Galli[1]. *[1]Gastroenterology Research Unit, Department of Experimental and Clinical Biomedical Sciences "Mario Serio," Florence, Italy; [2]Hepatobiliary Surgery and Liver Transplantation, University of Pisa Medical School Hospital, Pisa, Italy; [3]Department of Experimental and Clinical Medicine, University of Florence, Florence, Italy; [4]Department of Medical Biotechnologies, University of Siena, Siena, Italy; [5]Division of Gastroenterology, University Hospital "Careggi," Florence, Italy*
Email: ericanicola.lynch@unifi.it

Background and aims: Hepatitis B virus (HBV) is still among the most frequent causes of liver transplantation (LT) in Europe. Combined prophylaxis with anti-HBs immunoglobulins (HBIg) and nucleos (t)ide analogues (NUCs) has virtually eliminated the risk of a disease relapse, although there is growing evidence that HBIg therapy could be safely withheld in most patients. The aim of our study was to evaluate the effectiveness of a combined HBV prophylaxis with a minimised and personalised fixed-dose HBIg therapy and a target anti-HBs trough level of 50–100 UI/L.

Method: All patients transplanted for HBV-related diseases (at least 12 months post LT) who attended our tertiary referral centre between January 2019 and June 2021 were prospectively included in our study. All patients received a combined HBV prophylaxis with NUCs (tenofovir, entecavir, or lamivudine) and intramuscular HBIg therapy administered at individualised multiple-week intervals, aiming at obtaining anti-HBs trough levels of 50–100 UI/L.

Results: Out of a total of 40 patients, there were no cases of HBV-DNA or HBsAg recurrence. The median (IQR) interval between 1000 UI HBIg doses was 5 weeks (4–6 weeks), with a maximum of 9 weeks and a minimum of 4 weeks. No patient characteristic-including LT indication (cirrhosis, hepatocellular carcinoma, or acute hepatitis), HDV coinfection, and type of NUC-was significantly associated with HBIg dosage, nor did the latter correlate with body mass index, estimated glomerular filtration rate, or follow-up duration after LT. The mean anti-HBs trough level reduction per one week increase in inter-HBIg dose interval was 40 UI/L (95% CI 32.96–47.04 UI/L).

Conclusion: Our data support the use of a minimised HBIg for the prevention of HBV recurrence in LT recipients who should prudently continue combined prophylaxis (e. g. HDV coinfection). Anti-HBs trough levels rather than random assessments are rationally a more effective tool to lower the anti HBs level cut-off and therefore minimise HBIg dosage and costs. Individual HBIg consumption

profiles are highly variable and can be as low as <500 UI/month to maintain anti-HBs trough levels of 50–100 UI/L, thus treatment should be personalised.

SAT236

Formal referral networks optimise patient selection for liver transplantation

Oliver Tavabie[1], Victoria Kronsten[1], Talal Valliani[2], Deepak Joshi[1], Johnny Cash[3], Abid Suddle[1], Matthew Cramp[4], Andreas Prachalias[1], Krishna Menon[1], Kosh Agarwal[1], Michael Heneghan[1], Varuna Aluvihare[1]. [1]*King's College Hospital, United Kingdom;* [2]*North Bristol NHS Trust, United Kingdom;* [3]*Royal Victoria Hospital, United Kingdom;* [4]*Derriford Hospital, United Kingdom*
Email: oliver.tavabie@nhs.net

Background and aims: In the United Kingdom, liver transplant (LT) referral pathways for patients (PTs) with chronic liver disease (CLD) are not standardized. This is unlike other conditions with high mortality such as hepatocellular carcinoma (HCC). King's College Hospital (KCH) developed a network of satellite LT centres (SLTCs) with standardized referral pathways to improve access to LT. We aimed to evaluate the impact of SLTCs in LT candidacy evaluation in CLD PTs and those within the established HCC pathway.
Method: All PTs discussed at the KCH LT meeting between 10/2014–10/2019 were included. Second opinions from other LT centres and non-CLD/non-HCC PTs were excluded. Geographic, referral (KCH, SLTC or conventional referrer (CR)), clinical, demographic and laboratory data were retrospectively recorded. HCC PTs had tumor related variables recorded. CLD and HCC PTs were analyzed separately. Univariate (UVA) and multivariate analyses (MVA) were utilized to evaluate the effectiveness of SLTCs in PT selection for LT.
Results: 1102 assessments from CLD PTs (CR = 512 SLTC = 299 KCH = 291) and 240 assessments from HCC PTs (CR = 110 STLC = 72 KCH = 58) were included. HCC PTs were not more likely to be; referred from any centre, listed or have a contraindication to LT than CLD PTs. 725 CLD PTs were listed and 216 had contraindications to LT. Variables associated with listing were; younger age, autoimmune liver diseases (AILD), biliary atresia (BA), previous LT, higher CLD prognostic scores, shorter referral to decision time and SLTC referral. Variables negatively associated with listing were; non-alcoholic fatty liver disease (NAFLD), alcohol related liver disease (ARLD), hepatitis C and CR referral. MVA including significant and variables of interest was utilized to demonstrate that SLTCs referrals were independently associated with listing (adjusted odds ratio (aOR) 2.92 (95% confidence interval (CI) 2.07–4.17)). This was confirmed on sensitivity analyses excluding KCH and ARLD PTs. Variables associated with contraindication to LT were; older age, ARLD, NAFLD, higher CLD prognostic scores and CR referral. Variables negatively associated with contraindication to LT were; AILD, BA, previous LT or SLTC referral. MVA including significant and variables of interest was utilized to demonstrate that SLTC referrals were independently negatively associated with contraindications (aOR 0.33 (95%CI 0.21–0.50)). This was confirmed on sensitivity analyses excluding KCH and ARLD PTs. 168 HCC PTs were listed and 55 had contraindications to LT. No variables were significantly associated with listing including SLTC referral on UVA or MVA. Older HCC PTs were more likely to have a contraindication to LT but SLTC referral did not influence likelihood on UVA or MVA.
Conclusion: Formal referral pathways through SLTCs improve PT selection and access to LT for PTs with CLD but do not impact on the established HCC pathway.

SAT237

Efficacy and safety of SARS-CoV-2 vaccination in liver transplant recipients

Lucy Meunier[1], Mathilde Sanavio[1], Magdalena Meszaros[1], Stéphanie Faure[1], José Ursic Bedoya[1], Maxime Echenne[1], Antoine Debourdeau[1], Georges-Philippe Pageaux[1]. [1]*CHU Montpellier, St Eloi, Montpellier, France*
Email: lucy.meunier@chu-montpellier.fr

Background and aims: Liver transplant recipients have a poorer vaccine responses than the general population (1), so a booster dose is now recommended for these patients. Real-life data on SARS-CoV-2 vaccination in liver transplant recipients are limited. The objective of this study was to evaluate the efficacy and safety of the vaccine and identify factors associated with vaccine response.
Method: This was a retrospective observational study of consecutive liver transplant recipients attending CHU de Montpellier. Inclusion criteria were patients who had received at least one vaccine dose and serological assessment of SARS-CoV-2 spike protein antibody titers. Data on the transplantation indication, immunosuppression, vaccine type, and serology 28 days after the last vaccine dose were collected. Serology below 30 BAU/ml (WHO units) defined non-responders, 30–260 BAU/ml low responders, and >260 BAU/ml responders.
Results: 494 patients were included between 1 January and 15 March 2021. 366 (74%) patients were vaccinated: 280 with 3 doses, 63 with 2 doses, and 23 with 1 dose. 260 patients were excluded from the analysis: 128 (25.9%) unvaccinated, 130 without serology, and 2 with serology prior to the first dose. Complete data were available for 234 patients. 164 (70.1%) patients were male, with a mean age of 59 ± 12 years. Indications for transplantation were alcoholic (n = 92; 39.3%), viral (n = 37; 15.8%), NASH (n = 17; 7.3%), autoimmune (n = 14; 6%), and other cirrhosis (n = 74; 31.6%), with a mean time to transplantation of 4.9 ± 5.9 years. No serious adverse events were reported. Of 201 (85.9%) patients with complete vaccination and post-vaccination serology, 104 (51.7%) were responders, 45 (22.4%) poor responders, and 52 (25.9%) non-responders. In multivariate analysis, factors associated with no or low response were vaccination with Vaxzevria alone (HR 6.8 [1.46–31.67], p = 0.046), mycophenolate mofetil (MMF) therapy (HR 2.1 [1.1–3.9], p = 0.025), no previous SARS-CoV-2 infection prior to vaccination (HR 3.6 [1.025–12.89], p = 0.046), and female gender (HR 2.4 [1.15–4.99], p = 0.02).
Conclusion: Only half of our patients were vaccine responders after three injections. MMF, female gender, and Vaxzevria vaccination were associated with a poorer response, while previous SARS-CoV-2 exposure was associated with a better response. Even after three injections, serological responses were much lower than in the general population. It is now essential to determine the value of a fourth dose, the incidence of COVID-19 in transplant patients with poor serological responses after three doses, and the value of suspending MMF in liver transplant recipients to improve responsiveness.

Immunogenicity and safety of heterologous versus homologous prime-boost regimens with adenoviral vectored and mRNA SARS-CoV-2 vaccine in liver transplant recipients: a prospective study

Supachaya Sriphoosanaphan[1,2,3], Sirinporn Suksawatamnuay[1,2,3], Nunthiya Srisoonthorn[2], Nipaporn Siripon[2], Panarat Thaimai[1], Wanwisar Makhasen[2], Nawakodchamon Mungnamtrakul[2], Kessarin Thanapirom[1,2,3], Bunthoon Nonthasoot[4], Pokrath Hansasuta[5], Piyawat Komolmit[1,2,3]. *[1]Division of Gastroenterology, Department of Medicine, Faculty of Medicine, Chulalongkorn University, Bangkok, Thailand; [2]Center of Excellence in Liver Diseases, King Chulalongkorn Memorial Hospital, Thai Red Cross Society, Bangkok, Thailand; [3]Liver Fibrosis and Cirrhosis Research Unit, Chulalongkorn University, Bangkok, Thailand; [4]Department of Surgery, Faculty of Medicine, Chulalongkorn University, Bangkok, Thailand; [5]Division of Virology, Department of Microbiology, Faculty of Medicine, Chulalongkorn University and King Chulalongkorn Memorial Hospital, Thai Red Cross Society, Bangkok, Thailand*
Email: supachaya.sr@gmail.com

Background and aims: Data on immunogenicity of SARS-CoV-2 vaccination in liver transplant (LT) recipients is limited. Homologous vaccination protocol in a number of studies demonstrated variable responses. We aimed to explore SARS-CoV-2 specific humoral response in heterologous prime-boost immunization with ChAdOx1 nCoV-19 AstraZeneca (AZ) and BNT162b2 Pfizer-BioNTech (BNT) among LT patients.

Method: LT recipients receiving SARS-CoV-2 vaccine at King Chulalongkorn Memorial Hospital between April and October 2021 were enrolled. Patients received either heterologous prime-boost protocol (AZ/BNT) or homologous regimen (AZ/AZ) depending on national policies. Blood samples were collected before vaccine administration and 4 weeks after the second dose. SARS-CoV-2 spike receptor-binding-domain (RBD) IgG was measured using electrochemiluminescence immunoassay (Roche Diagnostics) with positive cut-off of ≥0.8 U/ml. The neutralizing antibody was detected by enzyme-linked immunosorbent assay-based surrogate virus neutralization test (sVNT) (GenScript) with positive cut-off of ≥30% inhibition. Adverse events following vaccination were recorded by questionnaires.

Results: Eighty LT recipients were enrolled; 68.8% male with mean age of 58.0 ± 14.6 years. Median time since transplant was 5.7 years (IQR 2.8–11.8). 58 (72.5%) and 22 (27.5%) patients received AZ/BNT and AZ/AZ, respectively. Comparable seroconversion rate of anti-RBD antibody and sVNT after vaccination were observed in both AZ/BNT and AZ/AZ group (89.7% vs 81.8%, p = 0.45 and 77.6% vs 59.1%, p = 0.10, respectively). However, median IgG titer was significantly higher in AZ/BNT group compared to AZ/AZ group (843.9 U/ml vs 147.1 U/ml, p = 0.014). LT patients receiving AZ/BNT also had significantly higher sVNT than those receiving AZ/AZ (91.2% vs 38.5%, p <0.001) (Figure 1). Use of prednisolone (OR 65.5, 95%CI 4.1–1055.5, p = 0.003), low body mass index (OR 1.7, 95%CI 1.1–2.5, p = 0.008), and leukopenia (OR 1.01, 95%CI 1.00–1.02, p = 0.014) were associated with lack of serological response. Reported adverse events were similar between both regimens.

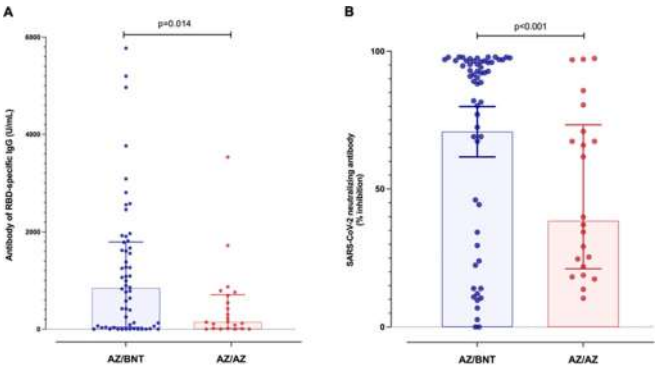

Figure 1. SARS-CoV-2 specific humoral response: A) Antibody of RBD-specific IgG B) Neutralizing antibody

Conclusion: Nearly 90% and 80% of patients had positive anti-RBD antibody and sVNT, respectively, following heterologous prime-boost immunization. AZ/BNT vaccination was well-tolerated and yields greater SARS-CoV-2 specific humoral response than AZ/AZ. Cell-mediated response and immune durability of this mix-and-match strategy among LT recipients are eagerly awaited.

Email: fl.veyre@gmail.com

Background and aims: Primary sclerosing cholangitis (PSC) is a rare indication of liver transplantation (LT). PSC can recur on the graft with a potential impact on graft survival. The factors associated with recurrence are poorly understood. The goals of our study were to describe the incidence of PSC recurrence (rPSC) and to identify its risk factors from a large cohort with long follow-up.

Method: Were included in a multicenter retrospective cohort study all adult patients transplanted for PSC between 1985 and March 2019, in all French LT centers. Overlap syndrome cases were included.

Results: A total of 571 patients (389 males, 68.1%) with a median age at listing of 42.0 years (IQR 31.5–52.0) were included. The median follow-up time after LT was 104 months (IQR 49.0–180.0).

During follow-up, 141 patients (24.7%) developed rPSC, at a median time of 60.0 months (IQR 28.0–107.0) after LT. The cumulative incidence of rPSC was therefore 15.6%, 27.8%, 37.9%, 48.3%, 52.6% at 5, 10, 15, 20, and 25 years after LT, respectively, with a median time to rPSC of 24 years.

In univariate analysis, risk factors associated with rPSC were age <30 years at LT (p = 0.03), inflammatory bowel disease (IBD) at inscription on LT waiting list (p = 0.001), maintenance steroid therapy (p < 0.0001), acute rejection after LT (p = 0.05), right liver transplant (p = 0.02). Maintenance treatment with mycophenolate mofetil (MMF) was protective (p = 0.02). History of CMV infection after LT was not associated with rPSC (p = 0.09). MELD score at enrolment, type of biliary anastomosis, year of LT, or "preventive" treatment with Ursodeoxycholic acid were not significantly associated with rPSC. In multivariate analysis, risk factors for rPSC were maintenance steroid therapy (HR = 1.70, CI95% [1.08–2.64]) and the presence of IBD at listing (HR = 1.61, CI95% [1.03–2.54]).

During follow-up, after exclusion of patients who died within the first year after LT, 87 patients (16.2%) underwent liver retransplantation (reLT), among whom 59 (68.0%) for rPSC, i.e. 41.8% of patients with rPSC. In the group of patients retransplanted for rPSC, the median time from first LT to rPSC was 59.0 months (IQR 28.0–107.0); this time was significantly shorter compared to patients with rPSC but without the need for reLT (80.5 months, IQR 49.5–144; p = 0.008). Fifteen patients underwent a third LT, among whom 12 (80%) due to rPSC, and 7 a fourth LT, among whom 5 for rPSC.

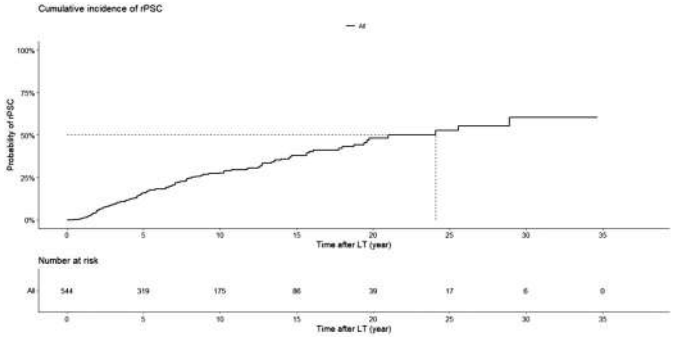

Figure:

Conclusion: Our large study with long follow-up strongly confirms that rPSC after LT for CSP is common, leading in a significant number of cases to one or more reLT. Independent risk factors were the presence of IBD at listing and steroid maintenance therapy. The type of biliary anastomosis had no impact on the risk of rPSC. "Preventive" treatment with AUDC after LT did not reduce the risk of rPSC.

SAT240

Impact of COVID-19 on the liver transplant activity in the US: variation by the region, etiology, and cirrhosis complications

Ashwani Singal[1], Yong-Fang Kuo[2], Paul Yien Kwo[3], Robert Wong[3].
[1]*University of South Dakota and Avera Transplant Institute, Medicine and Transplant Hepatology;* [2]*university of texas medical branch, Biostatistics;* [3]*stanford university school of medicine, Transplant Hepatology*
Email: ashwanisingal.com@gmail.com

Background and aims: To examine Covid-19 impact on liver transplant (LT) activity in the US.

Method: LT listings in UNOS registry stratified to 03/2020–05/2021 (Covid era) and 04/2018–02/2020. Monthly frequency of LT; percentage of etiology (HCV, ALD, NASH, HCC, and ACLF grade 2 or 3); and average MELD score were plotted. Regional analyses performed in northeast (UNOS regions 1, 2, 9), Midwest (regions 7, 8, 10), south (regions 3, 4, 11), and west (regions 5, 6). Joinpoint regression models assessed time trend had significant changes on a log scale.

Results: Of 23, 871 LT recipients (mean age 52 yrs., 62% males, 61% white, 32% ALD, 15% HCC, 30% ACLF grade 2–3, mean MELD score 20.5), 8995 were in Covid era. LT activity decreased since September 2020 by 3.4% every month for any transplant and 22% for HCC. LT activity increased by 4.5% for ALD since 11/2020 and 17% for ACLF 2–3 since 03/2021. LT activity decreased for NASH and HCV by 2.5% and 1% respectively every month and increased for alcoholic hepatitis by 4.5% without any joinpoint in Covid era. Monthly MELD score increased by 0.7 (Std. Error 0.17) and 0.36 (Std. Error 0.13) since 06/2020 for HCV and HCC respectively. Regional analysis showed Covid impact with 12.4–24.1% decrease in LT activity across the four regions. However, this was heterogeneous for overall number of LT, etiology, and for ACLF 2–3 (Table).

Conclusion: Covid-19 pandemic impacted LT activity in the US, with a decrease in LT for HCC, and increase for ALD and severe ACLF. Impact across regions is homogeneous for HCC, but not on other changes. Strategies are needed to reorganize cirrhosis patients in community to overcome after effects of Covid-19.

Table: (abstract: SAT240): Joinpoints in trends of monthly LT.

Perinatal outcomes in liver transplant patients-possible positive effect of aspirin prophylaxis

Marius Braun[1], Gil Zeevi[2], Eran Hadar[2], Arnon Wiznitzer[2], Alyssa Hochberg[2], Michal Cohen-Naftaly[1], Assaf Issachar[1], Orly Sneh Arbib[1], Yael Harif[1], Eviatar Nesher[3], Evelin Oxtrud[1], Amir Shlomai[1], Ran Tur-Kaspa[1]. *[1]Liver Institute, Petah Tikva, Israel; [2]Ob Gyn, Petah Tikva, Israel; [3]Transplant, Petah Tikva, Israel*
Email: m_braun_md@yahoo.com

Background and aims: To describe perinatal outcomes in liver transplanted (LT) women and evaluate the effect of low-dose aspirin treatment in these women.
Method: An observational retrospective study examining perinatal outcomes among liver transplant recipients, between 2016 and 2020 at a single university-affiliated tertiary medical center in Israel. Demographic, obstetric and clinical data were obtained from electronic health records. The role of aspirin was explored.
Results: Ten LT patients delivered 13 babies. All the patients received tacrolimus, 9 (69%) low dose prednisone and the liver kidney transplant (LKT) also received azathioprine. The 2 patients that were pregnant during the first year after LT had premature deliveries (week 31, 32) Regarding maternal outcomes, 2 women (16%) developed preeclampsia, 2 (16%) gestational diabetes, three (24%) postpartum infection, and one -postpartum hemorrhage. Median gestational age at delivery was 37 weeks (31–39 weeks), with 6 preterm births (31–36 weeks) and a median birthweight of 3072 g (1450–4100 g). All the babies had high Apgar scores and normal development, but the baby born at week 31 had to be ventilated for a week and is healthy with normal development at 2 year follow-up. Low-dose aspirin (100 mg daily) was administered to LT patients beginning 2018 and was given in 5 (38%) of the pregnancies. Of the women receiving low-dose aspirin, none developed hypertensive disease or suffered excessive bleeding during pregnancy.

Primary disease	Graft type	Week	Fetal weight g	Mode of delivery	Indication for cesarean section	Obstetric complications

Antibody response after a third dose of the mRNA-1273 SARS-CoV-2 vaccine in liver transplant recipients

Aitor Odriozola Herrán[1], María Del Barrio[1], Antonio Cuadrado[1], Jose Ignacio Fortea[1], Lidia Amigo[1], David San Segundo Arribas[2], María Rodríguez-Cundin[3], María Rebollo[3], Roberto Fernandez[4], Federico Castillo[4], María Achalandabaso[4], Juan Andrés Echeverri[4], Juan Carlos Rodríguez-San Juan[4], Marcos López-Hoyos[2], Juan Carlos Rodríguez Duque[1], Álex García Tellado[5], Javier Crespo[1], Emilio Fabrega[1]. *[1]University Hospital Marqués de Valdecilla, Gastroenterology and Hepatology Service, Santander, Spain; [2]University Hospital Marqués de Valdecilla, Immunology, Santander; [3]University Hospital Marqués de Valdecilla, Preventive Medicine, Santander, Spain; [4]University Hospital Marqués de Valdecilla, General Surgery, Santander, Spain; [5]University Hospital Marqués de Valdecilla, Internal Medicine, Santander, Spain*
Email: aodrihe94@gmail.com

Background and aims: Recent studies showed that antibody titers after vaccination against severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) in liver transplant recipients (LTR) are diminished as compared to the general population, suggesting the possible value of a third booster dose. We aimed to characterize the humoral response after three doses of the Moderna mRNA-1273 vaccine in LTR.
Method: The cohort comprised 129 adult LTR who received a third homologous dose of the mRNA-1273 SARS-CoV-2 vaccine. Humoral response was evaluated using plasma levels of anti-SARS-CoV-2 spike protein S1 immunoglobulin (Abbott® SARS-CoV-2 anti-spike IgG II assay, positive >50 AU/ml) measured a median of 30 days (IQR, 30–33.7 days) after the third vaccine injection.
Results: LTR (median age 63 [IQR, 56–68] years, 76.7% men) had a mean anti-S1 antibody level of 8, 388 [SD, ± 10, 836.9] AU/ml after the second dose, and 26, 134 [SD, 17, 136.4] AU/ml after the third dose. All 113 LTR (87, 6%) who had been seropositive before the third dose were still seropositive after the third vaccine injection; and their antibody titers increased significantly from 9426 [SD, 11, 057.5] AU/ml to 29, 449 [SD, 15, 460.5] AU/ml (p = 0.01).

3rd dose of moderna (129)	Seropositive (125)	Seronegative (4)	p
Age (years) (SD)	60.4 (± 10.4)	67.8 (± 1.7)	0.162
Sex (male) (%)	97 (75.2)	2 (1.6)	0.198
Previous medical history (%)			
Hypertension	75 (60)	3 (75)	0.546
Diabetes	44 (35.2)	3 (75)	0.103
Chronic Kidney disease	42 (33.9)	4 (100)	0.007
Cardiovascular disease	33 (26.4)	1 (25)	0.95
Inmunosupressive regimen (%)			<0.001
Without Mycophenolate	96 (76.8)	1 (25)	
With mycophenolate	29 (23.2)	3 (75)	
Monotherapy	6 (4.8)	2 (50)	
Association with CNI	23 (18.4)	1 (25)	
Inmunosupression (dose-mg) (mean; SD)			
Mycophenolate	1068.9 (± 394.7)	1666.7 (± 577.6)	0.022
Laboratory parameters (SD)			
Haemoglobin (g/dL)	14.9 (± 9.3)	12.7 (± 1.5)	0.635
Platelets (G/L)	169.9 (± 61.3)	150.0 (± 25.2)	0.518
Leukocytes (G/L)	5.9 (± 1.6)	6.5 (± 1.4)	0.474
Lymphocytes (G/L)	3.4 (± 1.8)	1.5 (± 0.8)	0.832
eGFR (ml/min/1.73 m^2)	69.4 (± 18.9)	32.3 (± 17.3)	<0.001

Sixteen patients (12, 4%) were non-responders after the second vaccine dose. After the third dose, twelve of the sixteen (75%) initial non-responders produced anti-spike antibody (3, 633 [SD, 8, 361.1] AU/ml). Non-response after third dose was associated with mofetil mycophenolate treatment (75% vs 23.2%) (p <0.001), a higher dose of this drug (1, 666.7 [SD, ± 577, 6] vs 1068, 9 [SD, ± 394, 7]) (p = 0.02), and lower estimated glomerular filtration rate (32.3 [SD, ± 17.3] vs 69.4 [SD, ± 18.9]) (p = 0.001).
Conclusion: our study showed that administration of a third dose of the mRNA-1273 SARS-CoV-2 to LTR improved the immunogenicity of the vaccine. Lower estimated glomerular filtration rate and inmunosupressive regimens with mycophenolate were associated with a poorer response to vaccination.

SAT243

Early post liver transplant rescue treatment with sofosbuvir/velpatasvir/voxilaprevir in patients experienced to NS5A-inhibitors

Margherita Saracco[1], Francesco Tandoi[2], Alberto Calleri[1], Donatella Cocchis[2], Giorgia Rizza[2], Renato Romagnoli[2], Silvia Martini[1]. *[1]AOU Città della Salute e della Scienza di Torino, Gastrohepatology Unit; [2]AOU Città della Salute e della Scienza di Torino, General Surgery 2U, Liver Transplantation Center*
Email: margherita.saracco@gmail.com

Background and aims: Direct acting antivirals (DAA) revolutionized the HCV treatment landscape. In patients (pts) who are HCV viremic at liver transplant (LT), early post-LT DAA therapy (tx) prevents graft damage and extrahepatic HCV involvement. Few data are available regarding pts who are HCV NS5B+NS5A inhibitors experienced at LT. We aimed to describe our first 6 pts treated early after LT with sofosbuvir/velpatasvir/voxilaprevir (SOF/VEL/VOX) for 12 weeks.
Method: From January 1th 2019 to November 1th 2021, 436 pts underwent LT in our Center. Among 46 pts who were viremic at LT, 6 were experienced to NS5A inhibitors. SOF/VEL/VOX was started as soon as graft function was optimal with stable immunosuppression tx (standard combination: steroid, tacrolimus, mycophenolate mofetil).
Results: At LT, the median age of our 6 pts was 54 years and median MELD 13. Median donor age was 70 years. Median cold ischemia time (CIT) 448 minutes. Pt #4 received a graft from a HBcAb-positive donor with 50% macrovescicular steatosis and pt #6 received a graft from a 82-year-old donor; both grafts underwent hypothermic oxygenated machine perfusion. Five pts were HCV genotype (GT) 3 and one 1a; the median post-LT HCV RNA was 618.180 UI/ml, before tx. Pt #6 (GT3) received HCV viremic donor (naïve GT2; Ishak: grading 3/18, fibrosis 1/6) and donor HCV strains replaced the recipient's (shift from GT3 to GT2). The median time from LT to DAA tx was 15 days. Four pts reached sustained virological response after 12 weeks by the end of tx (SVR12) and remained negative after a median follow-up of 587 days, range 42–831 days. Pt #6 is still on tx (week 3 with HCV RNA <15). Pt #3 interrupted the DAA tx at week 8 for cholestatic hepatitis (AST/ALT 62/56 UI/L, GGT/ALP 576/1294 UI/L, bilirubin 12 mg/dL); liver biopsy was consistent with drug-induced hepatitis. Bilirubin dropped to 4 mg/dL at day 7 after tx withdrawal and normalized within 28 days; HCV RNA remained negative from day 14 of tx (follow-up of 400 days). Immunosuppression levels were stable on DAA tx.
Conclusion: Early use of post-LT SOF/VEL/VOX was successful in pts who were HCV viremic at LT and experienced to NS5B+NS5A inhibitors. One pt developed cholestatic hepatitis which reverted after prompt interruption of tx. Early post-LT DAA tx prevented liver damage by HCV and allowed the use of suboptimal grafts (old donor, HCV viremic donor or with moderate macrovesicular steatosis).

SAT244

Inclusion of body composition parameters in MELD score leads to optimization of predictive performance in patients with cirrhosis

Maryam Ebadi[1], Rhonda J. Rosychuk[2], Elora Rider[1], Abha DunichandHoedl[3], Maryam Motamedrad[3], Rahima A. Bhanji[1], Aldo J Montano-Loza[1]. *[1]University of Alberta, Division of Gastroenterology and Liver Unit, Edmonton, Canada; [2]University of Alberta, Division of Infectious Diseases, Department of Pediatrics, Edmonton, Canada; [3]University of Alberta, Human Nutrition and Metabolism, Edmonton, Canada*
Email: montanol@ualberta.ca

Background and aims: Model for end-stage liver disease (MELD) score has been shown to estimate the risk of short-term mortality in patients awaiting liver transplant (LT). Given the decreasing predictive performance of MELD and the improved prognostication using body composition parameters in cirrhosis, inclusion of these parameters may lead to optimization of the organ allocation criteria in LT candidates. The aim of this study was to determine the performance of individual and combined body composition parameters by sex and to compare their performance with MELD in predicting pre-LT mortality.
Method: CT images, from LT evaluation of 860 patients with cirrhosis were used to determine height-normalized indices and radiodensity of muscle, visceral and subcutaneous adipose tissue (SAT) expressed by cm^2/m^2 and Hounsfield Unit (HU), respectively. Performance of body composition features and MELD score for mortality prediction was assessed at 3-, 6-, and 12-months by area under the receiver operating characteristic curve (AUROC) in the presence of competing risks.
Results: Sixty-six percent of the patients were male with the MELD score of 14 ± 8. Evaluated patients were followed for a mean time of 24 months. Performance of MELD and body composition features for mortality prediction is presented in Table. Among individual body composition features in male patients, SAT radiodensity outperformed other features when considering each time-point. Among various combinations in males, performance of combined skeletal muscle index and SAT radiodensity were superior to that of MELD. Addition of skeletal muscle index and SAT radiodensity to the MELD outperformed MELD at each time point in males. In females, inclusion

Table: (abstract: SAT243)

	RECIPIENTS							DONORS			AFTER-LT			
Pt #	Age, years	Sex	HCC	MELD at LT	HCV GT	Previous DAA	HCV RNA at LT (UI/ml)	Macrovesicular Steatosis	Age, years	CIT (min)	Days from LT to DAA	HCV RNA pre DAA	HCV RNA <15 UI/ml	SVR12
1	46	M	No	14	3	SOF/VEL	1370000	<5%	55	312	6	26500	Week 1	Y

of SAT and muscle radiodensity within MELD score improved the discriminative performance of MELD, but this was not significant.

	3-month	6-month	12-month
Male			
Skeletal muscle index (SMI)	66.5 (58.2–74.7)	66.5 (59.9–73.1)	62.3 (56.5–68.2)
Subcutaneous adipose (SAT) radiodensity	74.7 (68.0–81.5)	69.1 (62.9–75.3)	62.7 (56.9–68.6)
SAT radiodensity + SMI	76.4 (69.7–83.0)	72.7 (66.9–78.4)	66.1 (60.6–71.7)
MELD	75.3 (68.0–82.5)	68.8 (61.9–75.6)	62.3 (56.3–68.4)
MELD + SAT radiodensity + SMI	81.4 (75.1–87.6)	75.3 (69.3–81.2)	67.4 (61.7–73.0)
P value	0.004	0.001	0.009
Female			
Muscle radiodensity	65.9 (56.6–75.3)	64.8 (56.5–73.1)	63.2 (55.4–70.9)
SAT radiodensity	66.1 (58.3–73.8)	61.5 (53.6–69.5)	62.9 (55.6–70.3)
SAT radiodensity + Muscle radiodensity	72.0 (64.4–79.6)	69.4 (62.3–76.4)	68.7 (62.0–75.5)
MELD	76.9 (69.0–84.7)	71.2 (64.0–78.4)	68.5 (61.7–75.3)
MELD + SAT radiodensity +Muscle radiodensity	80.0 (72.3–87.0)	74.2 (67.3–81.1)	71.3 (64.4–78.1)
P value	0.32	0.23	0.24

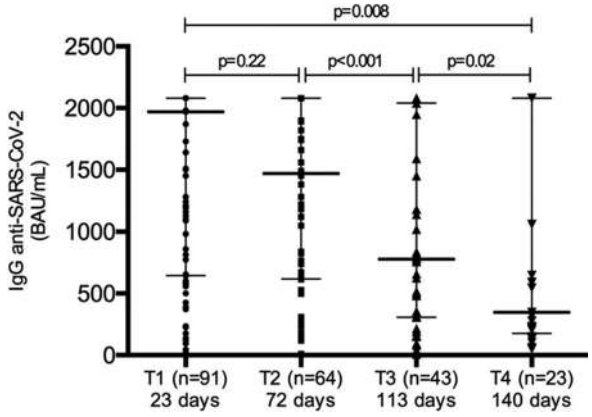
Conclusion: Inclusion of skeletal muscle index and SAT radiodensity within MELD was associated with an improvement in the prediction of mortality in male patients with cirrhosis.

SAT245

Long-lasting seropositivity after anti SARS-CoV-2 vaccination in pre liver transplant patients

Alberto Calleri[1], Margherita Saracco[1], Renato Romagnoli[2], Silvia Martini[1]. [1]*AOU Città della Salute e della Scienza di Torino, Gastrohepatology Unit, Turin, Italy;* [2]*AOU Città della Salute e della Scienza di Torino, General Surgery 2U, Liver Transplantation Center, Turin, Italy*
Email: alberto.calleri.md@gmail.com

Background and aims: Since the beginning of COVID-19 pandemic, global vaccination represents the goal to fight the virus spreading. Anti SARS-CoV-2 vaccines demonstrated a high rate of success in preventing severe COVID-19 and decreasing the infection rate, but few data are available about special population such as pre liver transplant (LT) patients (pts). Serological tests for IgG anti Spike reflect the humoral response to vaccination.
We aimed to evaluate the longevity of the humoral response to mRNA vaccine in pts listed for LT in our Center.
Method: From January 2021 to October 2021 we consecutively enrolled all pts on our LT waiting list who completed anti SARS-CoV-2 mRNA vaccination. Pts with previous COVID-19 received a single vaccine dose within 6 months after infection. All the other pts received 2 doses, administered 21 (Pfizer-BioNTech) or 28 days (Moderna) apart. Pts were tested for SARS-CoV-2 IgG antibodies (LIAISON® SARS-CoV-2 TrimericS IgG assay, positive value ≥33.8 BAU/ml) 1 month after mRNA vaccination and then every 2 months until LT. Mask wearing indoors and physical distancing measures were recommended for all pts.
Results: During the study period, 91 pre-LT pts completed the anti-SARS-CoV-2 vaccination: 80 pts received 2 vaccine doses, while 11 pts received only 1 dose, as per protocol. 94% of the pts received Pfizer-BioNTech and 6% Moderna COVID-19 vaccine. 69% were male, median age 56 years, BMI 25 kg/m^2, eGFR 95 ml/min, MELD 12 (IQR 8–15). 32% was affected by viral cirrhosis and 43% by hepatocellular carcinoma; 6 pts were treated with steroid and 1 with mycophenolate mofetil due to autoimmune cirrhosis and 1 pt was affected by common variable immunodeficiency.
After a median time of 23 days from the last vaccine dose (T1), 86/91 (95%) seroconverted (median titer 1970 BAU/ml, IQR 645–2080). During follow-up none of retested pts became IgG negative, however their titer progressively decreased:
-after a median time of 72 days from the last vaccine dose (T2), 61/64 (95%) tested again IgG positive (median titer 1480 BAU/ml, IQR 617–2080); -at T3 (113 days from vaccination) 42/43 (98%) pts remained positive and their titer significantly dropped (779 BAU/ml, IQR 307–2040); –23 pts were retested at T4 (140 days after vaccination) and all of them remained IgG positive (median titer 320 BAU/ml, IQR 148–2080). (T1 *vs* T2, paired p = 0.22; T2 *vs* T3 p < 0.001; T3 *vs* T4, p = 0.02; T1 *vs* T4, p = 0.008). (Figure 1).
At the end of a median follow-up period of 190 days (IQR 175–202) from vaccination, none of the patients developed COVID-19. No serious adverse events were registered following vaccination.



Conclusion: In our 91 pre-LT patients, mRNA anti-SARS-CoV-2 vaccination elicited a high rate of seroconversion (95%) within 1 month. We observed a progressive significant decrease in IgG titer during a median follow-up of 190 days after vaccination. Nevertheless, none of our pre-LT pts developed COVID-19.

SAT246

The outcome of living donor versus deceased donor liver transplantation for hepatocellular carcinoma: a systematic review and meta-analysis

Beshoy Effat Elkomos[1], Amr Abdelaal[1], Mostafa Abdo[1], Remon Mamdouh[1]. [1]*Faculty of Medicine, Ain Shams University, General surgery, cairo, Egypt*
Email: beshoy3ft@gmail.com

Background and aims: A potential solution to the deceased donor organ shortage is to expand the organ donor pool to include live donation and to identify patients with lower rates of HCC recurrence to fairly allocate liver grafts. our aims were to detect the long-term outcomes of living donor liver transplant (LDLT) versus deceased donor liver transplant (DDLT) for hepatocellular carcinoma (HCC) and the predictors of recurrence after transplantation.
Method: PubMed, Scopes, Web of science, Cochrane library were searched for eligible studies from inception to 1 July 2021 and a systematic review and meta-analysis were done to detect patient overall survival (OS), Intention to treat overall survival (ITT-OS), disease-free survival (DFS), and recurrence for LDLT vs DDLT recipients.

Outcomes			Studies (n)	Patients (n)	Effect Estimate [RR/HZ (95% CI)]	Favour group
OS	No. of years					
	1		21	6045	1.04 [1.01, 1.07]	LDLT
	2		14	4110	1.04 [0.96, 1.14]	None

	10		0		N/A	
Recurrence			16	3617	1.07[0.77, 1.48]	None
Predictors of recurrence	Recipient male sex		3	1491	1.02 [0.70, 1.48]	
	Recipient age, y		4	1647	0.99 [0.97, 1.01]	
	Beyond MC		4	1647	2.81 [1.69, 4.69]	within MC
	AFp >400		3	1019	3.70 [2.11, 6.47]	AFp <400
	Presence of VI	Microscopic	4	1647	3.73 [2.78, 5.01]	Absence of VI
		Macroscopic	3	1491	3.88 [2.64, 5.70]	
	Poor differentiation		2	840	2.69 [1.29, 5.61]	Well/mod. differentiation

Figure: (abstract: SAT246)

Results: 35 studies with total of 7822 patients were included. The 1-, 3-, 4 year-OS showed trivial improvement for LDLT recipients. However, LDLT and DDLT recipients had similar 5-, 6- and 10-year OS. Moreover, our subgroup analysis showed equal long term OS between LDLT and DDLT for those who were within Milan criteria (MC). Nevertheless, beyond MC, there was a better prognosis for the patients who underwent LDLT. In addition to that, a Significant improvement in the ITT-OS was observed for LDLT recipients. Regarding the DFS and recurrence, these studies showed no significant difference between LDLT and DDLT. Moreover, the pooled hazard ratio of the included studies showed that MC, level of alfa feto protein (AFP), presence of vascular invasion (VI), tumor differentiation were predictors of recurrence.

Conclusion: this study is in consonance with the view that the cancer biology (not the graft type) is the most important determinant of recurrence and survival after LT. However, LDLT provided a much better survival benefits to HCC patients especially in regions that suffer from low deceased organ availability.

SAT247

Impact of gender on survival of hepatocellular carcinoma

Chaonan Jin[1], Birgit Schwacha-Eipper[1], Jean-François Dufour[2], Pompilia Radu[2]. [1]*Department for BioMedical Research, Hepatology, University of Bern, Switzerland, Bern, Switzerland;* [2]*Department of Visceral Surgery and Medicine, Hepatology, Inselspital, Bern University Hospital, University of Bern, Switzerland*
Email: radupompilia@yahoo.com

Background and aims: Risk of hepatocellular carcinoma (HCC) is considerably higher in men compared to women; however, there is inconclusive evidence on the effect of gender on HCC prognosis. We aimed to evaluate whether gender influences overall survival (OS).

Method: A prospective cohort, consisting of 498 HCC patients included between 2010 and 2020 at University Clinic for Visceral Surgery and Medicine, Inselspital, Bern, was retrospectively analysed. Patients were grouped by gender and age (>65 and ≤65). The etiology was established based on histology, combined radiological and laboratory features. Treatments were divided into curative (orthotopic liver transplantation, radiofrequency ablation, microwave ablation, surgical resection), non-curative (stereotactic body radiation therapy, transarterial chemoembolization, transarterial embolization, target drugs) and best supportive care (BSC).

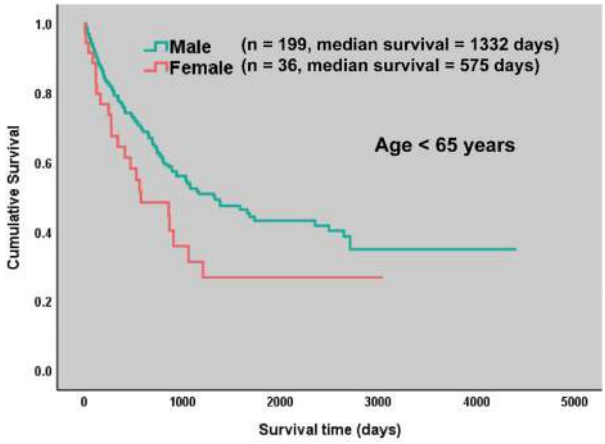
Cox multivariate regression analysis was performed to identify the risk factors for survival.

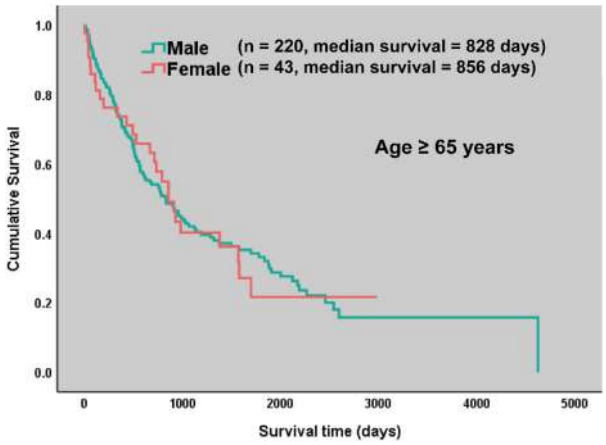
Results: The cohort consisted of 419 (84.1%) men, who had a higher median body mass index (26.8 vs 25.4, p = 0.037), more frequently both alcoholic and non-alcoholic fatty liver disease (12.9% vs 3.8%, p <0.05), cirrhosis (80.7% vs 70.9%, p = 0.050), and diabetes (35.8% vs 22.8%, p = 0.025) in comparison to women.

For the patients younger than 65 years of age, the median OS of female vs. male (<65 years) was 575 vs 1332 days (p = 0.037) while for the group >65 the median OS was 856 vs 828 days (p = 0.920).

In <65 group, men had more often both alcoholic and non-alcoholic fatty liver disease (11.6% vs 0.0%, p <0.05), and diabetes (29.2% vs 8.3%, p = 0.009). Men younger than 65 years of age were less frequently addressed to best supportive care than women (8.5% vs 22.2%, p <0.05) and frequently to curative therapy, particularly liver transplantation (27.6% vs 8.3%). Both curative and non-curative therapy (95% CI 0.031–0.121, p <0.001 and 95% CI 0.164–0.546, p <0.001, respectively) were independent protective factors.

In ≥65 group, no significant differences with respect to demographic, clinical, and tumor characteristics were observed between men and women. BCLC stage A (95% CI 0.196–0.758, p = 0.006), curative therapy (95% CI 0.173–0.525, p <0.001) and non-curative (95% CI 0.393–1.040, p <0.001) were independent protective factors.





Conclusion: Our single-center experience suggests that HCC females <65 years have inferior survival and a lower assignment rate to curative therapies, particularly liver transplantation than HCC males <65 years.

SAT248

Effectiveness of MRI methods in the assessment of hepatic steatosis in living liver donors

Digdem Kuru Öz[1], Zeynep Melekoğlu Ellik[2], Ayşegül Gürsoy Çoruh[1], Mehmet Adıgüzel[1,1], Mesut Gumussoy[2], Serkan Duman[2], Ramazan Erdem Er[2], Onur Kırımker[3], Deniz Balci[3], Hale Gokcan[2], Ramazan Idilman[2], Ayse Erden[1]. [1]*Ankara University School of Medicine, Radiology, Ankara, Turkey;* [2]*Ankara University School of Medicine, Gastroenterology;* [3]*Ankara University School of Medicine, General Surgery*
Email: digdem_k@hotmail.com

Background and aims: Liver biopsy is still gold standard diagnostic method for accurate quantification of steatosis. However, there is still no consensus in terms of which diagnostic methods to use for donor selection and which threshold value to acceptible. The aims of the present study, to determine utility of proton density fat fraction (PDFF) measurements for quantifying the liver fat content in potential donor candidates, and compare these results with liver biopsy findings.
Method: Between January 2017 and March 2021, a total of 134 living liver donor candidates imaged on a 1.5 tesla Magnetic Resonance Imaging (MRI) device were included. Magnetic resonance spectroscopy (MRS) was performed with a multiecho T2-corrected stimulated echo acquisition mode sequence. MRS fat fraction (FF) was calculated by placing an independent voxel in the right lobe of the liver. PDFF was calculated by 2 radiologists from the parametric FF map obtained with a multi-echo Dixon sequence using at least 4 regions of interest placed in the right lobe of the liver. The MRI measurement results were compared with pre- and/or intraoperative biopsy results. All liver biopsy specimens were evaluated by the Kleiner's method. Spearman correlation analysis was performed to determine the relationship between MRS and PDFF and histopathology. Receiver Operating Characteristic analysis was used for the diagnostic efficiency of the methods.
Results: Median age was 31 years. The gender was predominantly male (59.7%). On the liver biopsy evaluation, 25 (18.7%) had grade I steatosis, whereas 109 (81.3%) did not have steatosis. Median PDFF calculated with MRI was 3% (0.5–15%).
Signal fat fractions obtained by MRS and PDFF methods were statistically different in the groups with and without steatosis ($p < 0.001$, $p = 0.019$). There was a high degree of positive linear correlation between MRS and PDFF methods ($r = 0.819$, $p < 0.001$). The area under the curve was 0.848 and 0.824 ($p < 0.001$) at the cut-off of 5.05% and 3.25% for MRS and PDFF, respectively.
Conclusion: The present study indicates the MRS and PDFF measurements provided a non-invasive, accurate estimation of the presence and grading of hepatic steatosis in liver donor candidates. Such modalities can be used effectively in donor selection for living donor liver transplantation.

SAT249

Long-term outcomes of donation after cardiac death and living donor liver transplant for primary sclerosing cholangitis

Dilip Moonka[1], Toshihiro Kitajima[2], Tommy Ivanics[2], Kelly Collins[2], Michael Rizzari[2], Atsushi Yoshida[2], Marwan Abouljoud[2], Shunji Nagai[2]. [1]*Henry Ford Health System, Gastroenterology and Hepatology, Detroit, United States;* [2]*Henry Ford Health System, Transplant Institute, Detroit*
Email: dmoonka1@hfhs.org

Background and aims: The use of donation after circulatory death (DCD) grafts is reported to be a risk factor for worse outcomes after liver transplant (LT) for primary sclerosing cholangitis (PSC) due to a higher risk of biliary complications. However, long-term outcomes comparing DCD, donation after brain death (DBD) donors, and living donor LT (LDLT) have not been fully investigated in a recent cohort. This study aims to assess outcomes of LT for PSC with each graft type.
Method: Using OPTN/UNOS data, we analyzed adult LT patients with PSC or primary biliary cholangitis (PBC) between 2002 and 2020. Patients with exception scores, multi-organ or re-transplant were excluded. One, 5, and 10-year graft survival (GS) were compared between PSC and PBC groups (as control). Next, outcomes were compared between DBD-LT, DCD-LT, and LDLT in each group. In PSC, the three types of donor grafts were compared for cause of graft loss. Finally, transplant outcomes were analyzed in an early era (2002–2010) and late era (2011–2020). Risks were adjusted by recipient variables.
Results: 3, 946 PSC and 2, 675 PBC patients were eligible. Among PSC patients, 3, 099 (78.5%), 151 (3.8%), and 696 (17.7%) received DBD-LT, DCD-LT, and LDLT, respectively. One, 5, and 10-year GS were similar between PSC and PBC groups. In PSC, DCD-LT had significantly higher risks of 1, 5, and 10-year graft loss than DBD-LT (1-year: HR 1.87, $p = 0.007$, 5-year: HR 1.74, $p = 0.001$, 10-year: HR 1.60, $p = 0.003$) whereas LDLT had similar risks of 5 and 10-year graft loss. In contrast, outcomes were comparable between donor types in PBC. As a cause of graft loss, DCD-LT had a significantly higher incidence of both biliary complications and PSC recurrence than other graft types. 16.5% of DCD-LT lost grafts because of PSC recurrence or biliary issues vs 4.5% for DBD-LT and 5.1% for LDLT. Incidence of re-transplant was highest in DCD-LT (DCD-LT 18.5% vs DBD-LT 10.2% vs LDLT 10.6%, $p = 0.005$). This finding was more prominent in the early era, whereas risks of 3- and 5-year graft loss were similar among all graft types in the late era (Figure). When comparing profiles of DCD donors for PSC between eras, CIT was shorter in late era (6.5 vs 5.2 hours, $p = 0.001$)

		HR	lower	upper	P values
1-year	DCD	2.23	1.28	3.88	0.004
	LDLT	1.08	0.69	1.69	0.727
3-year	DCD	2.06	1.30	3.27	0.002
	LDLT	0.83	0.58	1.21	0.338
5-year	DCD	2.28	1.53	3.40	<0.001
	LDLT	0.83	0.60	1.15	0.267

		HR	lower	upper	P values
1-year	DCD	1.35	0.59	3.08	0.481
	LDLT	1.89	1.21	2.97	0.005
3-year	DCD	1.15	0.57	2.35	0.697
	LDLT	1.30	0.88	1.91	0.186
5-year	DCD	1.03	0.53	2.00	0.942
	LDLT	1.10	0.78	1.56	0.590

Figure: (abstract: SAT249)

whereas age and proportion of organ sharing were similar between 2 groups.

Conclusion: In PSC patients, the use of DCD grafts was associated with significantly worse post-transplant outcomes because of PSC recurrence and biliary complications. LDLT had similar outcomes to DBD-LT. However, the negative effect of DCD grafts was blunted in the more current era. The use of DCD grafts is an appropriate option for PSC with appropriate donor selection.

SAT250

Patients with acute-on-chronic liver failure have significantly greater healthcare resource utilization after liver transplantation

Vinay Sundaram[1], Christina Lindenmeyer[2], Kirti Shetty[3], Robert Rahimi[4], Atef Alattar[1], Gianina Flocco[2], Brett Fortune[5], Cynthia Gong[6], Suryanarayana Challa[3], Haripriya Maddur[7], Janice Jou[8], Michael Kriss[9], Lance Stein[10], Ross Vyhmeister[8], Ellen Green[8], Braidie Campbell[9], Josh Levitsky[11], Constantine Karvellas[12]. *[1]Cedars-Sinai Medical Center, Los Angeles, United States; [2]Cleveland Clinic Main Campus, Cleveland, United States; [3]University of Maryland, College Park, United States; [4]Baylor Scott and White Medical Center-Grapevine, Grapevine, United States; [5]Weill Cornell Medicine, New York, United States; [6]University of Southern California, Los Angeles, United States; [7]Tampa General Hospital, Tampa, United States; [8]Oregon Health and Science University, Portland, United States; [9]University of Colorado Denver, Denver, United States; [10]Piedmont Atlanta Hospital, Atlanta, United States; [11]Northwestern Medical Center, Chicago, United States; [12]University of Alberta, Edmonton, Canada*
Email: vinaysundaram@yahoo.com

Background and aims: Data is lacking regarding healthcare resource utilization after liver transplantation (LT) for patients with acute-on-chronic liver failure (ACLF).

Method: We retrospectively reviewed data from 10 centers in North America of patients transplanted from years 2018–2019, who required management in the intensive care unit prior to LT. ACLF was identified using the EASL-CLIF criteria.

Results: We studied 318 patients of whom 106 patients (33.3%) had no ACLF, 61 (19.1%) had ACLF-1, 74 (23.2%) had ACLF-2, and 77 (24.2%) had ACLF-3 at LT. Multivariable negative binomial regression analysis demonstrated a significantly longer LOS for patients with ACLF-1 (1.9 days, 95% CI 0.82–7.51), ACLF-2 (6.7 days, 95% CI 2.5–24.3), and ACLF-3 (19.3 days, 95% CI 1.2–39.7), compared to recipients without ACLF. Presence of ACLF-3 at LT was also associated with longer length of dialysis post-LT (9.7 days, 95% CI 4.6–48.8) relative to lower grades. Logistic regression analysis revealed greater likelihood of discharge to a rehabilitation center among recipients with ACLF-1 (OR = 1.79, 95% CI 1.09–4.54), ACLF-2 (OR = 2.23, 95% CI 1.12–5.01) and ACLF-3 (OR = 2.23, 95% CI 1.40–5.73). Development of bacterial infection post-LT also predicted LOS (20.9 days, 95% CI 6.1–38.5) and 30-day readmissions (OR = 1.39, 95% CI 1.17–2.25). (Table) Cost estimates based on post-LT LOS demonstrated that expenditures were significantly greater for patients transplanted with ACLF, and especially for ACLF-3 (No ACLF: $65, 359, ACLF-1: $102, 698, ACLF-2: $129, 893, and ACLF-3: $244, 406, p < 0.001).

Table: Multivariable negative binomial regression and logistic regression regarding predictors of post-LT healthcare resource utilization

	Post-LT length of stay (days) **(Coefficient, 95% CI)**	Post-LT length of dialysis (days) **(Coefficient, 95% CI)**	30-day readmission **(OR, 95% CI)**	Discharge to rehabilitation center **(OR, 95% CI)**
ACLF grade				
No ACLF (reference)	1.9 (0.8, 7.5)	2.1 (-22.4, 16.2)	1.27 (0.62, 2.57)	1.79 (1.09, 4.54)
ACLF-1	6.7 (2.5, 24.3)	5.8 (-1.4, 18.5)	1.37 (0.62, 3.04)	2.23 (1.40, 5.73)
ACLF-2	19.3 (1.2, 38.7)	9.7 (4.6, 48.8)	1.75 (0.87, 3.46)	2.12 (1.11, 5.01)
ACLF-3				
Age				1.05 (1.01, 1.09)
Braden score <16	13.2 (5.1, 44.0)			5.14 (1.89, 14.0)
In ICU at LT	7.7 (2.1, 18.1)			1.36 (1.12, 1.57)
Dialysis at LT	9.2 (2.0, 29.1)	4.9 (1.9, 18.6)		
Mechanical ventilation at LT				2.00 (1.17, 3.41)
Pre-transplant bacterial infection		5.5 (2.96, 16.0)		
Post-transplant bacterial infection	20.9 (6.1, 38.5)		1.39 (1.17, 2.25)	

Conclusion: Patients with ACLF at LT, particularly ACLF-3, have greater post-transplant healthcare resource utilization and costs.

SAT251

Use of statins after liver transplantation is associated with improved survival: results of a nationwide study

Chiara Becchetti[1], Melisa Dirchwolf[1,2], Jonas Schropp[3,4], Giulia Magini[5], Beat Müllhaupt[6], Franz Immer[7], Jean-François Dufour[1], Banz Vanessa[1], Annalisa Berzigotti[1], Jaime Bosch[1,8]. *[1]Inselspital, University Hospital, University of Bern, Department for Visceral Surgery and Medicine, Berne, Switzerland; [2]Hospital Privado de Rosario, Santa Fe, Argentina, Liver Unit, Argentina; [3]Open University of Cyprus, Cyprus, Department of Computer Science, Cyprus; [4]University of Cyprus, Cyprus, Department of Psychology, Cyprus; [5]Hôpitaux Universitaires de Genève, Geneva, Switzerland, Service de Transplantation, Geneve, Switzerland; [6]University Hospital Zurich, Switzerland, Swiss HPB (Hepato-Pancreato-Biliary) Center and Department of Gastroenterology and Hepatology, Zürich, Switzerland; [7]Swisstransplant, the Swiss National Foundation for Organ Donation and Transplantation, Bern, Switzerland, Berne, Switzerland; [8]University of Bern, Bern, Switzerland, Department of Biomedical Research, Switzerland*
Email: becchettichiara@tiscali.it

Background and aims: Statins are known to have pleiotropic effects that can act favorably on the liver, including protection from endothelial dysfunction and from ischemia reperfusion injury, as well as to increase cold preservation time in experimental grafts. However, there is limited data on the benefit that statins might confer in the liver transplant (LT) setting, either with regard to statin administration in LT recipients or its use in donors. This study aimed at analyzing the effect of statin exposure on recipient and on graft survival.

Method: We included all consecutive adult LT candidates nationwide who received a liver from a deceased donor. The statistical analysis adopted was a multistate modelling approach examining the effect of statin exposure (recipient under statin treatment or liver from donor exposed to statins) on the transition hazards between LT, biliary and/or vascular (B-V) complications, and death, while allowing for recurring events. The observation time was 3 years.

Results: Overall, 998 (696 male, 70%, mean age 54.5 ± 11.1 years) LT recipients were included. 19% of recipients were exposed to statins during the study period. Over the 3-year follow-up period, 141 patients died; there were 40 re-LT and 363 B-V complications. Recipient statin use protected from mortality after-LT (HR = 0.35; 95% CI 0.12–0.97; p = 0.039). However, it was not significantly associated with the occurrence of B-V complications (HR = 1.22; 95%CI = 0.83–1.78; p = 0.307) or re-LT (HR, 1.8e-7; 95%CI, 0-Inf; p = 1). In patients developing B-V complications, statin use significantly protected from mortality (HR = 0.10; 95%CI = 0.01–0.75; p = 0.023) and reduced recurrence of B-V complications (HR = 0.42; 95%CI = 0.18–1.00; p = 0.049). Donor' statins use prior LT had no significant influence on post-LT outcomes.

Conclusion: Our results show that statin use in recipients appears to confer a survival advantage. Statin administration should therefore be encouraged when indicated.

SAT252

Liver transplantation for hepatocellular carcinoma with extended criteria: performance and applicability of the AFP score after official adoption by the French Organ Sharing Organization ABM: 5-year outcomes

Background and aims: Composite scores for selection of patients who are candidates for liver transplantation (LT) for HCC with extended criteria are being considered by scientific societies (EASL), subject to a demonstration of the superiority of these models over the Milan criteria and to their audit. The first composite score developed, the AFP score, has been shown superior to Milan criteria and adopted by the French Organ Sharing Organization, ABM, in January 2013 as a selection tool. The aim of this study was to evaluate the applicability and performance of this new strategy.
Method: Adult patients listed and then transplanted for HCC in 15 French TH centers between March 1, 2013, and March 1, 2014, were studied. The primary end point was the incidence of recurrence at 5 years in patients with AFP score ≤2, or >2 or after down-staging. The secondary end points were 5-year survival rates in the same subgroups and the % of transplanted patients with an AFP score ≤2. Agreement for extraction of the centralized ABM data was obtained from each center and data were quality-controlled for recurrence and death. The statistical analysis was performed with cumulative incidence of recurrence functions and a competitive risk survival analysis taking into account death as a competitive event of recurrence.
Results: Over the enrolment period, 507 patients were consecutively listed, among whom 334 (65.9%) were transplanted and are the basis of this study. Median age at listing was 60 [55–63] and 84.7% were male. The median MELD was 10 [8; 15]; 74 patients (22.2%) were outside the Milan criteria. The AFP score was assessed in 331 patients (99.4%) at listing and in 333 patients (99.7%) within 3 months prior to LT. Overall, 297 (89.7%), 12 (3.6%) and 22 (6.7%) patients were transplanted with a final AFP score ≤2, >2, and after down-staging ≤2. The 5-year recurrence rates were 12.2% [8.9; 16.5], 50% [26.4; 79.2], and 22.7% [10.2; 46.3] in patients transplanted with an AFP score ≤2, >2 or after down-staging. Overall 5-year survival rates, or after listing and LT with an AFP score ≤2 or score >2, were 73.5% [95% CI: 63.4; 77.9%), **77.0%** (71.8; 81.4%) and 33.3% (10.3; 58.8%), respectively.
Conclusion: In this real-life prospective cohort study, including 22% of patients beyond Milan criteria, applicability of the AFP score was high with only 3.6% of patients transplanted with an AFP score >2. The 12%-observed recurrence rate in patients listed and transplanted with an AFP score ≤2 was in strict agreement with the prediction of the model, with a corresponding 77% 5-year survival rate. The AFP score complies with 2018 EASL requirements for an expansion of Milan criteria and can be proposed as a new selection tool for HCC patients.

SAT253

Tacrolimus drug exposure level in the first year after liver transplantation is an independant risk factor for de novo malignancy in patients transplanted for alcohol-related liver disease

Benedict Vanlerberghe[1,2,3,4], Hannah Van Malenstein[1,2], Mauricio Sainz-Barriga[5,6], Diethard Monbaliu[5,6], Schalk van der Merwe[1,2], Jacques Pirenne[5,6], Frederik Nevens[1,2], Jef Verbeek[1,2]. *[1]University Hospitals Leuven, Department of Gastroenterology and Hepatology, Leuven, Belgium; [2]KU Leuven, Department of Chronic Diseases and Metabolism, Leuven, Belgium; [3]Maastricht University Medical Center +, Department of Internal Medicine, Maastricht, Netherlands; [4]Maastricht University, NUTRIM School of Nutrition and Translational Research in Metabolism, Maastricht, Netherlands; [5]University Hospitals Leuven, Abdominal Transplantation Surgery, Leuven, Belgium; [6]KU Leuven, Department of Microbiology, Immunology and Transplantation, Leuven, Belgium*
Email: b.vanlerberghe@maastrichtuniversity.nl

Background and aims: De novo malignancy (DNM) is a major cause of mortality in patients undergoing liver transplantation (LTx) for alcohol-related liver disease (ALD). Immunosuppression protocol may influence the risk on DNM, but evidence is conflicting.
Method: We retrospectively analyzed all patients transplanted for ALD between 1990 and October 2016 at our center (n = 317). Patients with a post-LTx follow-up of <12 months (n = 22), a DNM in the 1st year post-LTx (n = 11) or switch of calcineurin-inhibitor type in the 1st year post-LTx (n = 20) were excluded. Total tacrolimus drug exposure level (TDEL) was calculated by area under the curve of trough levels in the 1st year post-LTx. Risk factors for DNM (excluding non-melanoma skin cancers) within 5 years after LTx were analyzed by Cox regression (presented as hazard ratio (HR) with 95% confidence interval).
Results: 264 patients were included. Median age at LTx was 59 years (interquartile range (IQR): 54–64), 206 (78%) patients were male and median follow-up post-LTx was 96 months (IQR: 65–152). 222 patients received tacrolimus and 42 cyclosporine in the 1st year post-LTx. TDEL was known for 212 patients, mean trough level was 7.44 ng/ml (95%CI: 7.22–7.66). 184 (69.7%) patients had a smoking history (ever smoking), of which 80 (30.3%) smoked untill LTx and 63 (23.9%) post-LTx. 35 patients developed 36 DNMs within 5 years post-LTx (lung (n = 9), oro-pharyngolaryngeal (n = 9), bladder (n = 3), esophageal (n = 3) and other (n = 12)). In multivariate analysis, type of immunosuppression (tacrolimus vs. cyclosporin and mycophenolic acid vs. azathioprine), any alcohol relapse and sex were not associated with a higher DNM risk, in contrast with age at LTx and smoking history. In patients on tacrolimus, TDEL was higher in those with than those without DNM (8.35 (95%CI: 7.73–8.97) vs. 7.32 (95%CI: 7.09–7.55), p = 0.003) and a higher TDEL was an independent risk factor for DNM (Table 1).

Table: DNM risk in patients on tacrolimus during the 1st year post-LTx (n = 212)

	Univariate	Sig.	Multivariate	Sig.
TDEL	1.417 (1.128–1.779)	.003*	1.540 (1.208–1.962)	.000*
Age at LTx	1.092 (1.028–1.160)	.004*	1.120 (1.054–1.190)	.000*
Smoking history	11.273 (1.525–83.365)	.018*	11.427 (1.541–84.715)	.017*

Legend: * statistically significant

Conclusion: Tacrolimus dose minimization in the 1st year after LTx might be an approach to lower DNM risk in ALD patients and should be investigated in prospective trials.

SAT254

SARS-CoV-2 vaccination in liver transplant recipients: factors affecting immune response and refusal to vaccine

Joanna Raszeja-Wyszomirska[1], Maciej K. Janik[1], Maciej Wójcicki[1], Piotr Milkiewicz[1,2]. [1]*Medical University of Warsaw, Liver and Internal Medicine Unit, Warszawa, Poland;* [2]*Pomeranian Medical University, Translational Medicine Group, Szczecin, Poland*
Email: joanna.wyszomirska@wum.edu.pl

Background and aims: The effectiveness of SARS-CoV-2 vaccination in liver transplant (LT) recipients varies between 47.5% to 81% with majority of reports focusing on the immune response assessed in the first month after the vaccination. Data on LT recipients willingness to receive vaccine is limited to only a few reports. Here, we analysed the immune response to the SARS-CoV-2 vaccination, factors affecting response and reasons for refusal to receive this vaccine.
Method: Among 300 consecutive LT recipients, 225 (75%) were vaccinated. Seventy-four (25%) subjects were not vaccinated, including 45 (15%) who refused to be vaccinated and 29 (10%) who did not get the vaccine due to medical reasons. The humoral response was assessed by quantitative determination of anti-trimeric spike-protein-specific-IgG antibodies to SARS-CoV-2 by LIAISON® SARS-CoV-2 TrimericS IgG assay (Diasorin, Italy), which is a chemiluminescence immunoassay (CLIA). Thirty-four vaccinated patients with prior COVID-19 infection were analysed separately.
Results: Among 192 LT recipients vaccinated without prior COVID-19, 69% of them had an immune response (median time of 125 days after the second dose). Older age, worse kidney function and dual immunosuppression negatively affected the humoral response. Mycophenolate mofetil increased the risk of non-response (OR 3.0, 95% CI 1.43–6.25). LT recipients with prior COVID-19 presented with a robust immune response (100%) and with significantly higher IgG antibodies (median 2080 vs 134 BAU/ml; p <0.001). The antibodies concentration was higher in the first 90 days from the second dose (p = 0.034) and stabile when compared between patients who received the vaccination within 90–150 or more than 150 days (Figure 1). Female gender, living in rural area, lower BMI (all p < 0.05) and younger age (p < 0.001) were associated with refusal of the vaccine due to non-medical reasons. In contrast, liver recipients with diabetes and impaired kidney function (both p <0.01) were more prone to get a vaccine.

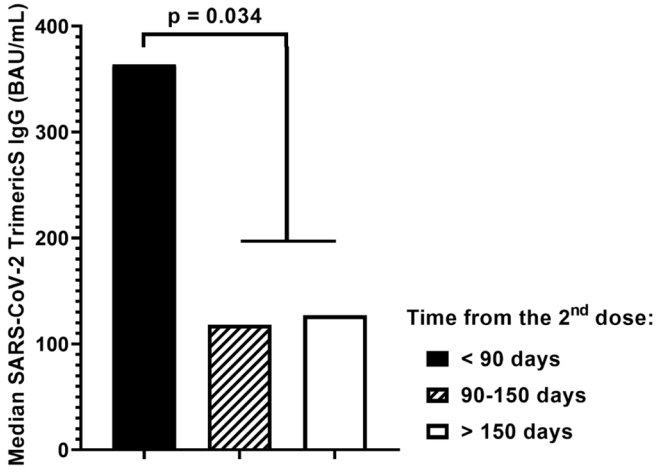

Figure: Median SARS-CoV-2 TrimericS IgG concentration among liver transplant recipients (without prior COVID-19) compared between time from the second dose of the vaccine: <90 days, 90–150 days and >150 days.

Conclusion: Lower immune response after the vaccine among LT recipients may support administration of a third dose. Previous COVID-19 infection dramatically improves response to vaccination in these patients. Sociodemographic factors may play a role in refusal of being vaccinated but this finding require further investigations in other cohorts of transplanted patients.

SAT255

The effect of clinicopathologic findings of hepatocellular carcinoma on posttransplant survival: a multcenter cohort from TASL liver transplantation special interest group

Email: akyildizmr@yahoo.com

Background and aims: The aim of the present study was to determine the effect of clinicopathological findings of hepatocellular carcinoma (HCC) on posttransplant survival.
Method: This was a multicenter retrospective study of patients with HCC undergoing LT from 10 tertiary center in Turkey between 2002 and 2020. Datas were retrieved from standardized electronic case report forms in each center.
Results: A total of 1428 patients with HCC underwent LT were included into the study. Viral hepatitis was the most common etiology accounting for 75.6% of patients. Hepatitis B infection was the most cause (58.6%) followed by hepatitis C (12.6%), and cryptogenic (13.8%). The mean overall survival (OS) was 178.2 months, whereas the mean progression free survival (PFS) was 44 months. The one and five-year estimated overall survival rate was found %89 and 80. Overall and disease-free survival did not significant differ between patients with Living Donor LT and patients with Deceased Donor LT (Log Rank for OS p = 0.148 and for PFS p = 0.137, respectively). In univariate analysis, serum AFP level, histologic differentiation, tumor size, Milan and UCSF criteria, the number of tumors, the presence of microvascular and macrovascular invasion were significantly associated with patient survival (p < 0.005). In multivariate analysis, serum AFP level, poor differentiation

microvascular invasion remained significantly associated with disease free survival (p < 0.05).

Table: The correspondance of Recurrence and Non-Recurrence groups

	Recurrence Group	Non-Recurrence Group	P value
Age	54.7 ± 9.8	56.1 ± 8.2	>0.05
Gender (Male)	87.9	84.2	>0.05
Cirrhosis (%)	95.4	93.7	P = 0.495
AFP	1825 ± 16311	135.2 ± 739.2	P < 0.001
0–9 (%)	35.9	52.3	P < 0.001
10–99 (%)	33.1	33.5	P < 0.001
100–499 (%)	18.2	10.2	P < 0.001
500–999 (%)	5.4	1.9	P < 0.001
>1000 (%)	7.4	2.1	P < 0.001
Transplantation Type: Living donor/ Cadaveric (%)	80.6/19.4	79.6/20.4	p > 0.05
MELD (0–14)%	69.1	67.2	p > 0.05
MELD >14%	30.9	32.8	
Total Tumor Diameter	79.7 ± 53.8	46.3 ± 37.4	P < 0.001
The Largest Tumor Diameter	53.8 ± 38.6	33.1 ± 24.4	P < 0.001
Total Tumor Number	4 ± 3.6	2.2 ± 2.2	P < 0.001
Milan (in/out) (%)	38.7/61.3	70.6/29.4	
UCSF (in/out) (%)	49/51	78.3/21.7	
Tumor Biology (%)			
Poor differentiated	25	9.4	
Mild differentiated	57.3	50	
Well differentiated	17.7	40.6	
Lymph node invasion (%)	42.9	24.4	P < 0.05
Microvascular invasion (%)	59.9	24.5	P < 0.001
Macrovascular invasion (%)	44.1	17.2	P < 0.001

Conclusion: Based on the results of the study, viral hepatitis remains the most frequent etiology of HCC in Turkey. High serum AFP levels, poor histologic differentiation and microvascular invasion significantly affect the posttransplant outcome. Donor type does not significantly affect posttransplant survival in patients with HCC.

SAT256

Utility and prognostic value of diagnosing metabolic dysfunction-associated fatty liver disease in patients undergoing liver transplantation for alcohol-related liver disease

Benedict Vanlerberghe[1,2,3,4], Hannah Van Malenstein[1,2], Mauricio Sainz-Barriga[5,6], Diethard Monbaliu[5,6], Schalk van der Merwe[1,2], Jacques Pirenne[5,6], Frederik Nevens[1,2], Jef Verbeek[1,2]. *[1]University Hospitals Leuven, Department of Gastroenterology and Hepatology, Leuven, Belgium; [2]KU Leuven, Department of Chronic Diseases and Metabolism, Leuven, Belgium; [3]Maastricht University Medical Center +, Department of Internal Medicine, Maastricht, Netherlands; [4]Maastricht University, NUTRIM School of Nutrition and Translational Research in Metabolism, Maastricht, Netherlands; [5]University Hospitals Leuven, Abdominal Transplantation Surgery, Leuven, Belgium; [6]KU Leuven, Department of Microbiology, Immunology and Transplantation, Leuven, Belgium*
Email: b.vanlerberghe@maastrichtuniversity.nl

Background and aims: Metabolic dysfunction-associated fatty liver disease (MAFLD) is a recently proposed term, which allows diagnosing liver disease associated with metabolic dysfunction in patients with alcohol-related liver disease (ALD). We assessed the prevalence of MAFLD in ALD patients undergoing liver transplantation (LTx) and its prognostic value on post-LTx outcome.

Method: We retrospectively analyzed all patients transplanted for ALD between 1990 and August 2020 at our center. MAFLD was diagnosed at LTx based on the presence or history of hepatic steatosis and a BMI ≥25 kg/m^2 or type II diabetes (DMII) or ≥2 metabolic risk abnormalities (dyslipidemia, hypertension, pre-diabetes). Overall survival and potential risk factors for recurrent liver steatosis (based on imaging or biopsy) and cardiovascular (CV) events were analyzed by Cox regression (presented as hazard ratio (HR) with 95% confidence interval).

Results: Of the 371 included ALD patients, 255 (68.7%) had concomitant MAFLD at LTx. Median follow-up post-LTx was 72 months (Table 1). Patients with ALD-MAFLD were older, more often male, and more frequently had hepatocellular carcinoma (HCC) at LTx (Table 1). Perioperative mortality and overall survival (HR: 0.991 (0.702–1.401); p = .960) did not differ between MAFLD and non-MAFLD ALD patients (Table 1). Multivariate analysis identified MAFLD at LTx (HR: 2.092 (1.412–3.098)), weight gain in the 1st year post-LTx (HR: 1.092 (1.043–1.143)) and any alcohol relapse (HR: 4.606 (3.097–6.850)) as independent risk factors for recurrent hepatic steatosis (p <.001). MAFLD at LTx was not associated with CV events post-LTx (HR: 1.519 (0.790–2.922); p = .210), in contrast with the traditional risk factors age (HR: 1.064 (1.016–1.114); p = .008) and DMII (HR: 2.068 (1.134–3.770); p = .018).

Table: Patient characteristics (at LTx)

	All (n = 371)	ALD-MAFLD (n = 255)	ALD-non-MAFLD (n = 116)	p value
Age (years) (IQR)	60.0 (56.0–66.0)	61.0 (56.0–76.0)	58.0 (52.5–64.0)	.001*
Male sex (%)	80.1	86.3	66.4	<.001*
HCC (%)	38.3	44.3	25.0	<.001*
Follow-up (months) (IQR)	72.0 (34.5–122.0)	68.0 (33.5–116.5)	82.0 (35.5–127.5)	.337
Perioperative mortality (%)	2.43	2.75	1.72	.553

Legend: * statistically significant/IQR: interquartile range

Conclusion: The presence of MAFLD in ALD is associated with a distinct patient profile at LTx and is a risk factor for recurrent hepatic steatosis irrespective of alcohol relapse. These novel findings demonstrate the utility and prognostic value of diagnosing MAFLD at LTx.

SAT257

Severe acute respiratory syndrome coronavirus type 2 (SARS-CoV-2) specific cellular and humoral immunity in Corovavirus Disease-2019 (COVID-19) convalescence after liver transplantation-a prospective six month follow-up

Theresa Kirchner[1], Hagen Sauer[1], Sophia Heinrich[1], Agnes Bonifacius[2], Ruhl Louisa[3], Isabell Pink[4], Bastian Engel[1], Emily Saunders[1], Joerg Martens[2], Marius M. Hoeper[4], Rainer Blasczkyk[2], Heiner Wedemeyer[1], Elmar Jaeckel[1], Christine Falk[3], Britta Eiz-Vesper[2], Richard Taubert[1]. *[1]Hannover Medical School, Department of Gastroenterology, Hepatology and Endocrinology, Hannover, Germany; [2]Institute of Transfusion Medicine and Transplant Engineering, Hannover, Germany; [3]Institute of Transplant Immunology, Hannover, Germany; [4]Department of Pneumology, Hannover Medical School, member of the German Centre for Lung Research (DZL), Hannover, Germany*
Email: kirchner.theresa@mh-hannover.de

Background and aims: Data on protective immunity against SARS-CoV-2 in liver transplantation recipients (LTR) after mild/moderate

COVID-19 are limited. The aim of the study was to analyse the immune response in LTR convalescents with ongoing immunosuppressive therapy in the first six month and to assess the impact of vaccination in LTR convalescents in comparison to matched convalescents without immunosuppression (non-IS).
Method: Immune response in LTR and non-IS was measured prospectively 1–2 (LTR: n = 15; non-IS: n = 14), 3–5 (LTR: n = 16; non-IS: n = 16) and ≥5 (LTR: n = 14; non-IS: n = 36) months after positive PCR test. Immunity after post-COVID-19 booster vaccination in convalescent LTR was measured in n = 11.
Specific T cell reactivity was detected by IFN-γ ELISPOT against 4 antigens (membrane, nucleocapsid, spike protein1/2). Specific antibodies (IgG and A) were detected against 4 different antigens (S1/2, receptor binding domain (RBD), nucleocapsid). Pre-pandemic samples were retrieved from our prospective LTR biorepository.
Results: The majority of LTR (93%) had a mild or moderate COVID-19 (outpatients: 87%). No T cell reactivity or IgG was detectable in pre-pandemic samples.
IgG antibodies in LTR were detectable in 62–85% (1–2month), 70–90% (3–5 month) and 56–100% (≥5 month and vaccination). Although IgG antibodies against nucleocapsid were reduced in LTR in comparison to non-IS, IgG and IgA antibodies against all other antigens including RBD of the spike protein of convalescent LTR were not reduced, neither in frequency nor in concentration.
In initial analysis convalescent LTR had no reduced IFN-γ production normalized to numbers of PBMCs compared to non-IS in the first 6 months. In addition, cellular and humoral immune response did not decline significantly over the first 6 months. However, booster vaccination non-significantly increases cellular (S1 p = .093, S2 p = .058) or humoral (S1 p = .065, S2 p = .096) reactivity against spike protein in convalescent LTR.
The prospective follow-up will be continued for 1 year after COVID-19.
Conclusion: In conclusion, LTR convalescents achieved cellular and humoral immune responses against SARS-CoV-2 comparable to non-IS, even after mild or moderate COVID-19. Cellular and humoral immunity showed no decline but could be booster with additional vaccination in the first months after COVID-19 in LTR convalescents. The development of a robust immunity without triggered rejection justifies the continuation of immunosuppression during infection.

SAT258

A third dose of the BNT162b2 mRNA vaccine significantly improved immune response among liver transplant recipients

Yana Davidov[1], Victoria Indenbaum[2], Keren Tsaraf[1], Oranit Cohen-ezra[1], Mariya Likhter[1], Gil Ben Yaacov[1], Rebecca Halperin[3], Itzchak Levy[3,4], Orna Mor[2,4], Nancy Agmon-Levin[4,5], Arnon Afek[4,6], Galia Rahav[3,4], Yaniv Lustig[2,4], Ziv Ben Ari[1,4]. *[1]Sheba Medical Center, Liver Diseases Center, Tel Aviv-Yafo, Israel; [2]Central Virology Laboratory, Ministry of Health, Tel-Hashomer, Tel Aviv-Yafo, Israel; [3]Sheba Medical Center, Infectious diseases unit, Tel Aviv-Yafo, Israel; [4]Tel Aviv University, Sackler School of Medicine, Tel Aviv-Yafo, Israel; [5]Sheba Medical Center, Clinical Immunology Angioedema and Allergy Unit, The Zabludowicz Center for Autoimmune Diseases, Tel Aviv-Yafo, Israel; [6]Sheba Medical Center, Tel Aviv-Yafo, Israel*
Email: y.davidov@gmail.com

Background and aims: Immune responses of solid organ transplant recipients to two doses of the BNT162b2 mRNA anti-SARS-CoV-2 vaccine is impaired. The immunogenicity and safety of a third dose among liver transplant (LT) recipients is unknown. This work aimed to evaluate the immune response of LT recipients to a third dose of the BNT162b2 mRNA vaccine.
Method: Consecutive LT recipients (n = 64) in follow-up at Sheba Medical Center were included. Receptor-binding domain (RBD) IgG and neutralizing antibody (NA) titers and T cells levels before (test 2) and 21–28 days a third vaccine dose (test 3) were determined and compared to their levels measured a median 38 days after the second vaccine dose (test 1). IgG antibody titers ≥1.1S/CO were defined as positive antibody. Adverse effects after the third dose were monitored.
Results: The LT recipients were of a median age of 64 years; 59.4% were male. The percentage of responders to the second vaccine (69.4%) decreased after a median time of 174 days (54%) and improved significantly after the third vaccine (97%). Geometric mean anti-RBD IgG levels, NA levels and T cell count also increased significantly after the third dose. Anti-RBD IgG and NA titers after the third vaccine negatively correlated with age (p > 0.0001), renal failure (p > 0.0001), mycophenolate mofetil treatment (p = 0.004), and combined immunosuppression vs. calcineurin inhibitors monotherapy (p = 0.001). After the third dose, adverse events were reported by 37% of recipients and were mostly mild (local pain and fatigue).
Conclusion: The immune response after a third BNT162b2 mRNA vaccine improved significantly among LT recipients, without serious adverse effect. Further studies are needed to evaluate immune response durability and to determine the optimal number and schedule of boost vaccines.

SAT259

Everolimus combined with low-dose tacrolimus controls histological graft injury and liver fibrosis as sufficiently as high-dose tacrolimus combined with mycophenolate after liver transplantation

Fabian Dranicki[1], Emily Saunders[1], Theresa Kirchner[1], Bastian Engel[1], Björn Hartleben[2], Heiner Wedemeyer[1], Elmar Jaeckel[1], Richard Taubert[1]. *[1]Hannover Medical School, Dept. Gastroenterology, Hepatology and Endocrinology, Hannover, Germany; [2]Hannover Medical School, Institute for Pathology, Hannover, Germany*
Email: dranicki.fabian@mh-hannover.de

Background and aims: After liver transplantation (LTx), there are multiple regimens for immunosuppression (IS). The combination of everolimus (EVR) and low-dose tacrolimus prevents T cell-mediated rejection (TCMR) of liver grafts as sufficiently as the standard of care (SOC) with high-dose tacrolimus (highTAC) and mycophenolate, but is associated with a preserved kidney function within the first years after liver transplantation (LT). However, none of the available studies assessed the histological pattern of graft injury or liver graft fibrosis in surveillance biopsies (svLbx), especially in the first year after LTx.
Method: All surveillance biopsies in our protocol biopsy program taken under at least 1 month of stable immunosuppression with either EVR (aim 3–8 ng/ml) and lowTAC (aim 3–5 ng/ml) or SOC with tacrolimus (aim 3–8 ng/ml) and mycophenolate (500–1500 mg/day) within the first 3–4 years after LTx at our center were included. Patients who were switched to EVR because of insufficient control of alloreactivity through SOC were excluded. Reasons for switches to EVR were malignancies before or after LT, chronic kidney injury, intolerance of SOC or CMV reactivations.
Results: So far, we could include 21 patients for the everolimus/low dose tacrolimus group, and 39 patients for the SOC/high dose tacrolimus group. The switch to EVR took place at a median of 119 days after LTx. EVR/lowTAC group exhibited lower TAC through levels at svLbx than SOC (p <.001). Histological graft injury quantified by the rejection activity index and hepatitis activity index according to Ishak were not significantly different between the EVR/lowTAC group and SOC. Similarly, liver graft fibrosis in all compartments (portal/periportal, sinusoidal, perivenular) was not significantly different between both groups. Likewise, patterns of TCMR, NAFLD/NASH and bile duct abnormalities exhibited similar frequencies in both treatment groups.
Conclusion: The combination of everolimus with low dose tacrolimus seems to control alloreactivity and histological graft injury as sufficiently as SOC with tacrolimus/mycophenolate within the first 3–4 years after LTx. These histological safety data suggest a broader application of this CNI-sparing regimen.

SAT260

The portrait of adult liver transplant recipients in the United States from 2002 to 2020

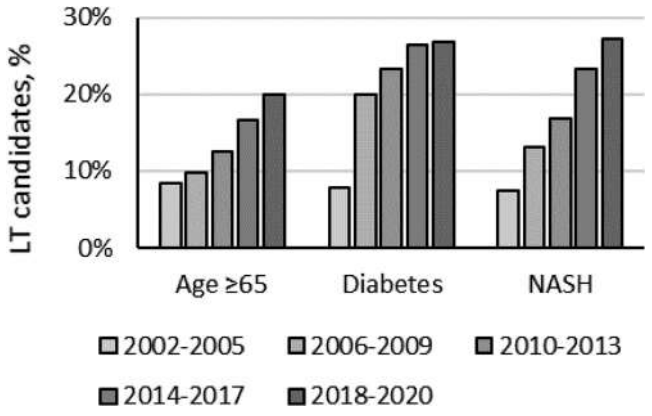
Zobair Younossi[1,2,3], Reem Al Shabeeb[1], Michael Harring[1], Janus Ong[4], Saleh Alqahtani[5,6], Linda Henry[1,7], Maria Stepanova[1,7]. [1]*Inova Health System, Medicine Service Line;* [2]*Betty and Guy Beatty Center for Integrated Research, IHS;* [3]*Center for Liver Disease, Inova Medicine;* [4]*University of the Philippines, College of Medicine;* [5]*King Faisal Specialist Hospital and Research Center;* [6]*Johns Hopkins University, Division of Gastroenterology and Hepatology;* [7]*Center for Outcomes Research in Liver Disease*

Email: zobair.younossi@inova.org

Background and aims: Aging population, the epidemics of obesity and metabolic syndrome, and decreasing burden of viral hepatitis are changing the portrait of liver transplant (LT) candidates in the U.S. We aimed to assess changes in demographics and clinical presentation of LT candidates in the U.S. over the last two decades.

Method: The Scientific Registry of Transplant Recipients (SRTR) data 2002–2020 was used to select adult candidates for LT. Patients with acute liver disease, hepatocellular carcinoma, or without known LT etiology were excluded. Trends in the proportions of common LT etiologies of chronic liver disease at the time of LT listing, such as chronic hepatitis B (CHB), chronic hepatitis C (CHC), non-alcoholic steatohepatitis (NASH, including cryptogenic cirrhosis if accompanied by obesity or type 2 diabetes), alcoholic liver disease (ALD) without and with CHC, autoimmune hepatitis (AIH), primary biliary cirrhosis (PBC), and primary sclerosing cholangitis (PSC), were assessed over time along with other clinico-demographic parameters

Results: There were 149, 910 LT candidates included in this study: n = 28, 581 in 2002–2005, n = 30, 158 in 2006–2009, n = 31, 824 in 2010–2013, n = 32, 925 in 2014–2017, and n = 26, 422 in 2018–2020. Over time, the mean ± SD age of LT candidates increased from 52 ± 10 years in 2002–2005 to 55 ± 11 years in 2018–2020, and the proportion of patients ≥65 years increased from 8% to 20% (trend $p < 0.0001$). The proportion of male candidates decreased from 65% to 60%, respectively, and so did the proportion of white patients: from 75% to 72%, respectively ($p < 0.0001$). During the same period, the proportion of liver re-transplants decreased from 6.0% to 3.5%, respectively ($p < 0.0001$). The rates of obesity (BMI >30 kg/m^2) and diabetes increased from 33% and 8%, respectively, in 2002–2005 to 40% and 27%, respectively, in 2018–2020 ($p < 0.0001$) (Figure). In 2002–2005, the most common etiology of chronic liver disease in LT candidates without HCC was CHC without or with ALD (total 45%), while NASH accounted for 7% of listings. In contrast, in 2018–2020, NASH was the second most common LT etiology at 27%, following ALD (38%), while CHC with or without ALD decreased to a total of 10%. Other common etiologies (CHB, AIH, PBC, and PSC) accounted for 2–7% listings each throughout the study period.



Conclusion: The portrait of LT candidates in the U.S. is changing to include more elderly patients, patients with metabolic syndrome, and diagnosis of NASH.

SAT261

Heterologous regimen viral-vector/mRNA produces significantly higher SARS-CoV-2 humoral response than homologous viral-vector and inactivated vaccines in liver transplant recipients

Manuel Mendizabal[1], Nicolas Ducasa[2], Paula Benencio[2], Maria Margarita Anders[3], Fernando Cairo[4], Adriana Alter[5], Patricia Etcheves[6], Giampaolo Scarton[6], Mirna Biglione[2], Ezequiel Mauro[7]. *[1]Hospital Universitario Austral, Hepatology and Liver Transplant Unit, Pilar, Argentina; [2]Instituto de Investigaciones Biomédicas en Retrovirus y SIDA (INBIRS), CONICET-Universidad de Buenos Aires, Argentina; [3]Hospital Aleman, Argentina; [4]Hospital El Cruce, Argentina; [5]Fundacion Hemocentro, Argentina; [6]Bioars, Argentina; [7]Liver Unit, Hospital Italiano, Buenos Aires, Argentina, Buenos Aires, Argentina*
Email: mmendiza@cas.austral.edu.ar

Background and aims: Knowledge of the immunogenicity of vaccines against SARS-CoV-2 in liver transplant recipients (LTR) is mainly limited to mRNA vaccines. We aimed to assess independent predictors of humoral response, in regimens based on homologous non-replicating viral vectors, inactivated vaccines, and heterologous combination.

Method: Multicenter and prospective study, in which consecutive and volunteering LTR and immunocompetent controls were recruited. COVID-19 Spike 1–2 IgG (S-IgG), neutralizing antibodies (NA) and nucleocapsid protein (N) were evaluated 21–90 days after receiving the second doses of vaccine ChAdOx1 (AstraZeneca), rAd26-rAd5 (Sputnik V), inactivated BBIBP-CorV (Sinopharm), and the heterologous combination rAd26/mRNA-1273 (Sputnik V/Moderna), according to the Argentinean immunization program. Vaccine side effects and clinical data was collected.

Results: After excluding 3 LTR for having a positive N protein test, 120 LTR and 27 immunocompetent controls were analyzed. No significant baseline differences were found between LTR and controls. Twenty-four (89%) controls and 74 (61%) LTR were positive for S-IgG ($p = 0.007$). NA titers were significantly higher in controls compared to LTR [64 (8–128) vs 16 (8–64); $p = 0.02$]. The correlation between S-IgG and NA titers was high [Pearson's correlation 0.89 (0.8–0.9); $p < 0.001$]. In a multivariate analysis, Increased BMI [OR 0.8 (0.8–0.9); $p = 0.004$] and the use of MMF [OR 5.1 (2.0–12.8); $p < 0.001$] were independently associated with a negative humoral response, while the use of the rAd26/mRNA-1273 combination [OR 0.11 (0.02–0.6); $p = 0.001$] was independently associated with a higher humoral response rate. No significant differences were detected regarding adverse effects between controls and LTR.

Variable	Detection of S-IgG		
	Negative N = 46	Positive N = 74	P
Age, years (median, IQR)	65 (55–72)	64 (53–70)	0.8
Female sex, n (%)	18 (39)	31 (42.5)	0.7
BMI, (median, IQR)	30 (26–31)	27 (24–31)	0.06
Diabetes, n (%)	20 (44)	23 (31)	0.1
Vaccine, n (%)			
ChAdOx1	19 (41.3)	16 (21.6)	0.02
BBIBP-CorV	13 (28.3)	12 (16.2)	0.1
rAd26-rAd5	12 (26.1)	25 (33.8)	0.3
rAd26/mRNA-1273	2 (4.3)	21 (28.4)	**<0.001**
Immunosuppression, n (%)			
CNI	44 (95.7)	63 (85.1)	0.1
Prednisone	10 (21.7)	12 (16.2)	0.4
mTOR	5 (10.9)	18 (24.3)	0.09
MMF	25 (54.3)	16 (21.6)	<0.001
Days 2nd dose-Extraction, (median, IQR)	61 (47–76)	52 (37–68)	0.3
Days between 1st and 2nd dose, (median, IQR)	67 (54–93)	92 (69–114)	0.001
Years since transplantation, (median, IQR)	3.5 (1.4–7.7)	5.6 (3.1–11.4)	0.09

Conclusion: LTR had a significantly lower humoral response than non-immunosuppressed controls. The use of MMF, and a higher BMI, were independently associated with a lower humoral response rate. In contrast, the heterologous combination rAd26/mRNA-1273 was significantly associated with higher S-IgG. New studies are needed in order to characterize the best vaccination scheme in LTR.

SAT262

Evolution of pretransplant cardiac risk factor burden and major adverse cardiovascular events in liver transplant recipients over time

Claire Harrington[1], Paul Levy[1], Elizabeth Cabrera[1], Jing Gao[1], Dyanna Gregory[1], Cynthia Padilla[1], Gonzalo Crespo[1], Lisa VanWagner[1]. *[1]Northwestern Memorial Hospital, Chicago, United States*
Email: claire.harrington@northwestern.edu

Background and aims: Non-alcoholic steatohepatitis (NASH) is associated with high cardiac risk factor burden in liver transplant recipients (LTRs). Major adverse cardiovascular events (MACE) are a major cause of complications in LTRs. The contemporary prevalence and temporal trends in pretransplant cardiac risk factor burden among LTRs are unknown. Therefore, the aim of this study is to evaluate the evolution of MACE and pre-LT cardiac risk factors in LTRs over time.

Method: This is a retrospective cohort of 1739 adult LTRs at a single, large U.S. academic transplant center (2003–2020) using the electronic health record. NASH was defined using primary or secondary listing diagnosis for NASH or cryptogenic cirrhosis plus one metabolic risk factor. MACE was defined as death or hospitalization for myocardial infarction (MI), revascularization, stroke, or heart failure (HF). Logistic regression analysis was used to assess factors *a priori* that are associated with 1-year MACE among LTRs.

Results: Figure 1 shows trends in pre-LT cardiac comorbid conditions. Comparing 2003 and 2020, there was a significant increase in pre-LT obesity, chronic kidney disease (CKD), atherosclerotic (ASCVD) and NASH ($p < 0.05$ for all). There was no significant change in proportion of LTRs with older age (≥65 years old), diabetes, or HF. The mean 1-year MACE rate was 18.7%. Higher 1-year MACE was observed in LTRs transplanted for NASH compared to other etiologies (26.4% vs 16.5%, $p < 0.0001$). There was a trend toward a decrease in MACE in 2020 vs 2003 (13.3% vs 25.0%, $p = 0.052$). In multivariable modeling, age, ASCVD, diabetes, HF, and CKD were significantly associated with MACE within 1 year of LT.

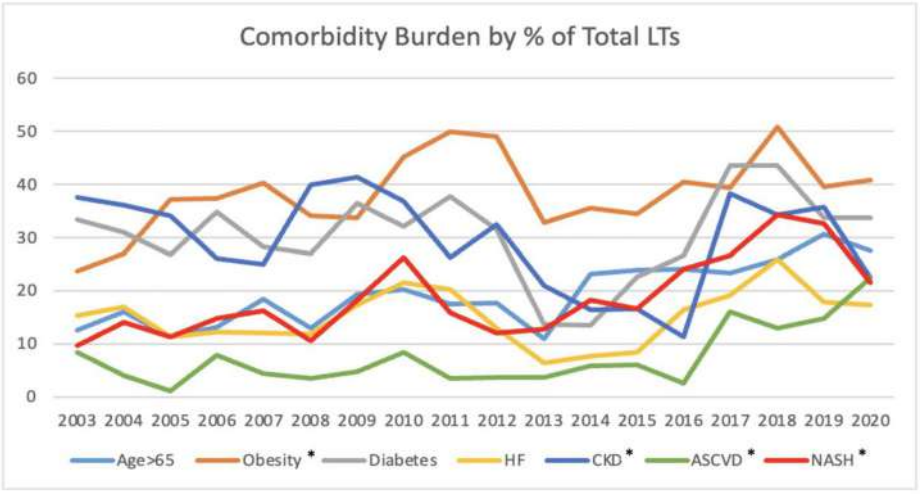


Figure 1: (abstract: SAT262): Comorbidity burden by percent of total LTs over time (2003–2020).

There was an increase in all cardiac risk factors over time. Factors marked with an asterisk had a significant increase between 2003 and 2020 ($p < 0.05$).

Conclusion: There has been an overall increase in cardiac risk factor burden among LTRs between 2003 and 2020 that are also significantly associated with MACE within 1 year of LT. Unexpectedly, overall MACE decreased in our cohort. This may reflect advancement in the identification and management of cardiovascular risk factors in LTRs. With projected continued increase in cardiac risk burden and the proportion of patients transplanted for NASH, it is critical for LT programs to develop and implement quality improvement efforts to improve cardiovascular care in LTRs.

SAT263

Retransplantation (reLT) outcomes of patients who were initially transplanted for ACLF

Gandhi Lanke[1], Feng Li[1], Paul J. Thuluvath[1,2]. [1]*Mercy Medical Center, Baltimore, United States;* [2]*University of Maryland School of Medicine, Baltimore, United States*
Email: thuluvath@gmail.com

Background and aims: The outcomes of early retransplantation (within 90-days of initial transplantation) of the liver (reLT) in those who initially underwent LT for acute on chronic liver failure (ACLF) are unknown.

Method: Using the national data from the United Network for Organ Sharing (UNOS) for all adult patients aged≥18 years who were listed for LT in the United States from Jan 11, 2016, to Aug 31, 2020, we identified those who had reLT. We defined organ failure (OF) and graded ACLF as described by EASL-CLIF. The primary outcomes of interest were 3-month mortality and all-time mortality after reLT in those initially transplanted with or without ACLF. Kaplan Meier survival analysis was used to compare survival probabilities.

Results: During the study period, 100 ACLF and 299 non-ACLF patients underwent reLT, and of those 47 ACLF and 159 non-ACLF underwent reLT within 90 days of initial LT. The mean age of ACLF and non-ACLF patients who underwent reLT was 48.6 ± 12.5 and 52.8 ± 11.8 years, respectively ($p < 0.001$). Alcoholic liver disease was the predominant etiology in ACLF patients (58% vs. 24% in non-ACLF, $p < 0.001$). Respiratory (7% vs. 0%, $p < 0.001$) and circulatory (18% vs. 0%, $p < 0.001$) were more common at the time of reLT in the ACLF group compared to non-ACLF group. The overall survival rates in ACLF and non-ACLF groups who underwent reLT within 90 days were similar (72.3% vs. 75.5%, $p = 0.66$). However, patients with 3 or more organ failures ($n = 71$) at the time of reLT (reLT within 90 days of initial LT) had worse outcomes (63.4% vs. 80.7%, $p = 0.006$) compared to those ($n = 135$) with less than 3 organ failures (Figure 1A). Irrespective of the interval between initial LT and reLT (anytime reLT), the survival was lower (68.6% vs. 81.8%, $p = 0.008$) in those with 3 or more organ failures ($n = 86$) at the time of reLT than those ($n = 313$) with less than 3 organ failures (Figure 1B). On multivariable logistic regression analysis, respiratory failure, circulatory failure, and ACLF grade were independent predictors of survival after reLT.

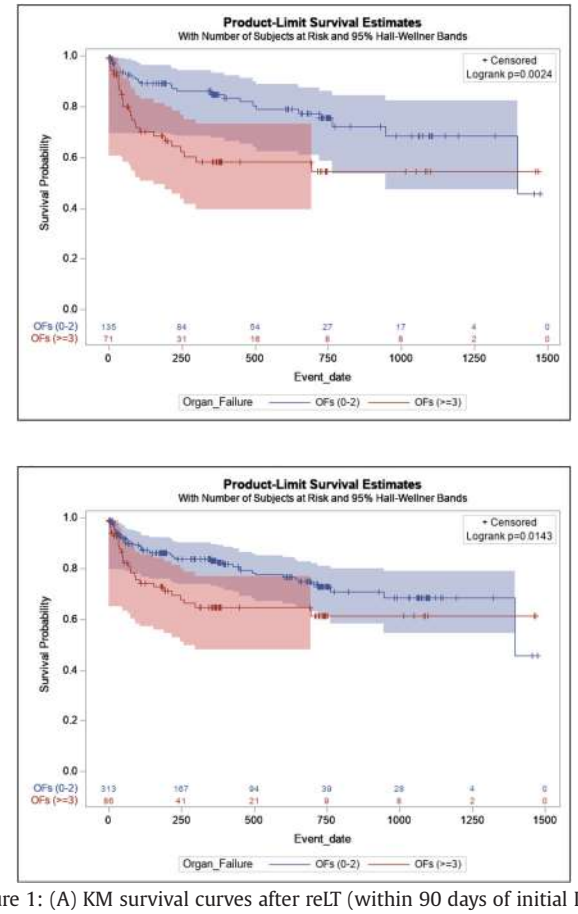

Figure 1: (A) KM survival curves after reLT (within 90 days of initial LT) in those with 0–2 OFs and ≥3 OFs at reLT. (B) KM survival curves after reLT (anytime reLT) in those with 0–2 OFs and ≥3 OFs at reLT.

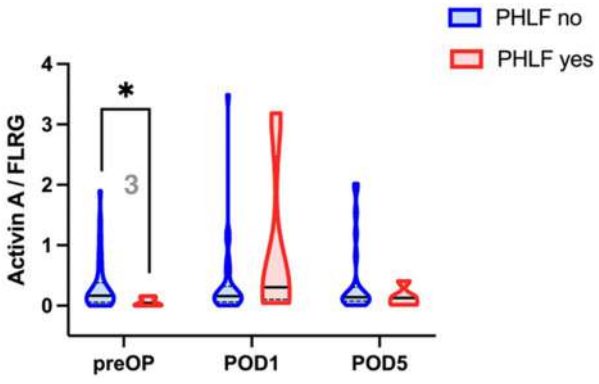
Conclusion: This large study showed that the post-LT survival outcomes after early or late reLT in patients initially transplanted with ACLF are excellent. Three or more organ failures at the time of reLT were associated with relatively poor outcomes.

SAT264

The ratio of Activin A and Follistatin-related gene allows prediction of posthepatectomy liver failure and postoperative morbidity in patients prior to liver surgery

Jonas Santol[1,2], David Pereyra[2], Steffanie Haegele[2], Daphni Ammon[2], Anita Pirabe[1], Philipp Jonas[3], Stefan Schuster[2], Sarang Kim[2], Toni Nguyen[2], Thomas Grünberger[3], Alice Assinger[1], Patrick Starlinger[2]. *[1]Medical University of Vienna, Physiology and Pharmacology, Wien, Austria; [2]Medical University of Vienna, General Surgery, Wien, Austria; [3]Klinik Favoriten, General Surgery, Wien, Austria*
Email: jonas.santol@gmail.com

Background and aims: Even though outcome after hepatic resection has improved, patient outcome is significantly worse if posthepatectomy liver failure (PHLF) develops. With no causal treatment available, research focusing on the prediction of PHLF and elucidating its potential causes, is of great importance. Here, we evaluate the predictive potential for PHLF of Activin A and its inhibitory protein Follistatin-related gene (FLRG) and examine their involvement in the development of PHLF.
Method: Activin A and FLRG were measured in plasma of 59 patients undergoing liver resection using commercially available ELISA kits. Plasma was prepared from blood taken prior to the operation (preOP), as well as on the first and fifth postoperative day (POD). Postoperative outcome was prospectively documented.
Results: We saw a significant decrease in plasma for Activin A and FLRG from preOP to POD1 ($p = 0.045$ and $p = 0.005$, respectively). Subsequently FLRG increased from POD1 to POD5 ($p = 0.004$). Interestingly, neither activin A nor FLRG differed between patients with and without PHLF at any timepoint. However, the ratio of Activin A/FLRG was significantly higher in patients without PHLF preOP ($p = 0.037$). There was no perioperative dynamic for Activin A/FLRG. PreOP Activin A, FLRG and Activin A/FLRG did not differ between patient in the context of underlying malign or benign liver primary or in the context of low-grade (grade 0–1) or high-grade (grade 2–4) fibrosis. Using Receiver operating curve analysis, we aimed to further investigate the predictive potential of preOP Activin A/FLRG for PHLF. The Activin A/FLRG ratio was able to significantly predict postOP PHLF (Area under the curve = 0.789, $p = 0.038$, 95%-CI: 0.609–0.969). Using the median of Activin A/FLRG ratio values, we further divided the cohort in a high and low Activin A/FLRG ratio group. When comparing the 2 groups, we could identify all patients with postOP PHLF in the low Activin A/FLRG ratio group, with none of the patients in the high Activin A/FLRG ratio group developing PHLF (5 of 21 [23.8%] vs 0 of 21 [0.0%], $p = 0.017$). Further, patients in the low Activin A/FLRG ratio group were found to suffer from a significantly higher risk for postoperative morbidity (14 of 21 [66.7%] vs 5 of 21 [23.8%], $p = 0.005$).



Conclusion: While the circulating dynamics of activin A and FLRG showed no association with PHLF, the preOP ratio of Activin A/FLRG was significantly decreased in patients suffering from PHLF. While further research into the patophysiology behind these results is needed, Activin A and the ratio of Activin A/FLRG show potential as possible predictors of PHLF and Morbidity.

SAT265

Derivation of a cardiac risk index for use in liver transplantation for non-alcoholic steatohepatitis

Paul Levy[1], Claire Harrington[1], Elizabeth Cabrera[1], Jing Gao[1], Dyanna Gregory[1], Cynthia Padilla[1], Gonzalo Crespo[1], Lisa VanWagner[1]. *[1]McGaw Medical Center of Northwestern University, Internal Medicine, Chicago, United States*
Email: paul.levy@northwestern.edu

Background and aims: Cardiovascular events (CVEs) are the most common cause of early mortality after liver transplant (LT). LT candidates with non-alcoholic steatohepatitis (NASH) are at highest risk for CVEs. The Cardiovascular Risk in Orthotopic LT (CAR-OLT) score quantifies risk for post-LT CVEs, but its accuracy in LT candidates with NASH is unknown. We propose a new prediction model for risk of CVEs among NASH LT candidates and compare its performance to the CAR-OLT score.
Method: All adults who underwent first LT at a large United States urban transplant center (2/1/2002–12/31/2020) were included. Data were drawn from the Organ Procurement and Transplant Network (OPTN) and linked to data from the electronic health record. Primary outcome was 1-year CVE, defined as death from a CV cause or hospitalization for myocardial infarction (MI), cardiac revascularization, heart failure, atrial fibrillation (AF), cardiac arrest, and/or stroke. NASH was identified based on OPTN primary or secondary listing diagnosis for LT or cryptogenic cirrhosis plus metabolic syndrome comorbidity. All pre-LT variables with $p \leq 0.15$ on bivariate analysis were considered for model inclusion. Akaike Information Criterion was used for model selection using backward selection. Receiver operating curve analysis was used to compare model discrimination.
Results: Among 1788 LT recipients, 330 (18.5%) were listed for NASH. Of these, 115 (34.9%) had 1 year CVE. Variables included in the final model were pre-LT recipient age, sex, functional status, hepatic encephalopathy, peritonitis, hepatorenal syndrome, MI, AF, hypertension, and venous thromboembolism. Only age, sex, history of AF and hypertension were shared risk factors within the CAR-OLT score. The discriminative performance of the new point based score (C statistic = 0.72) was superior to the CAR-OLT score (C statistic = 0.69) for 1-year post-LT CVEs in candidates with NASH (Figure 1).
Conclusion: Patients being considered for LT for NASH cirrhosis have a unique cardiovascular risk profile not captured by existing risk prediction models. This study proposes a novel point based risk prediction tool to guide future cardiac risk stratification in patients with NASH cirrhosis being considered for LT.

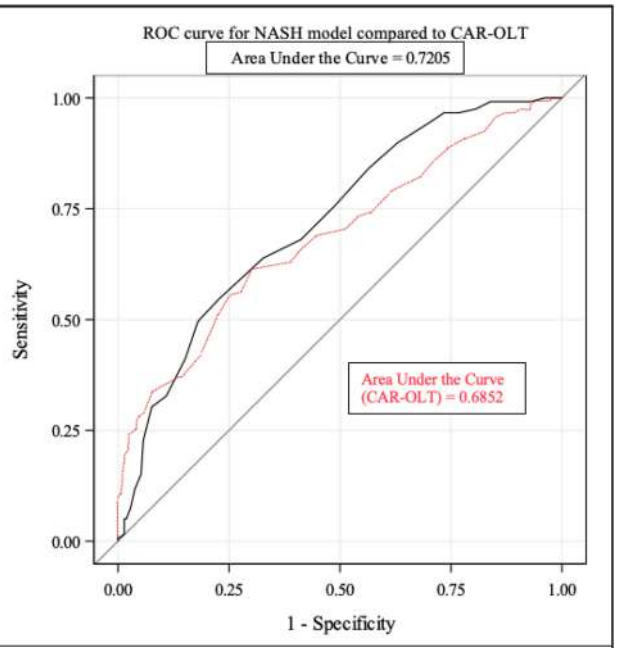


Figure 1: Discriminative performance of NASH scoring model compared to CAR-OLT
Variables selected for inclusion were age, sex, functional status, history of hepatic encephalopathy, peritonitis, hepatorenal syndrome, atrial fibrillation, hypertension, myocardial infarction, and venous thromboembolism.
The original CAR-OLT model (dotted red line) included age, sex, race, working status, education level, history of atrial fibrillation, respiratory failure requiring ventilator support, hepatocellular carcinoma, hypertension, diabetes, and heart failure.

The prognostic effect of adequate lymphadenectomy in clinically node-negative patients undergoing liver resection for intrahepatic cholangiocarcinoma

Carlo Sposito[1,2], Marianna Maspero[1], Francesca Ratti[3], Elena Panettieri[4], Stefano Di Sandro[5], Fabrizio Di Benedetto[5], Felice Giuliante[4], Luca Aldrighetti[3], Vincenzo Mazzaferro[1,2].
[1]Fondazione IRCCS Istituto Nazionale Tumori di Milano, HPB surgery and Liver Transplantation, Milano, Italy; [2]University of Milan, Oncology and Hemato-Oncology, Milano, Italy; [3]Ospedale San Raffaele, Hepatobiliary Surgery Division, Milano, Italy; [4]Fondazione IRCCS Policlinico Gemelli, General and HPB Surgery, Roma, Italy; [5]Policlinico di Modena, HPB Surgery and Liver Transplant Unit, Modena, Italy
Email: carlo.sposito@istitutotumori.mi.it

Background and aims: The prognostic effect of lymphadenectomy (LND) in the surgical treatment of intrahepatic cholangiocarcinoma (iCC) with no clinical evidence of lymph-node metastases (clinically node-negative, cN0) is still a matter of debate. The aim of this study is to assess the role of lymphadenectomy in cN0 iCC, and which patients might benefit most.
Method: Consecutive patients who underwent surgery for cN0 iCC at four Italian Centers between 2000 and 2020 were included. A multivariate analysis for factors associated with overall survival (OS) was performed. The cohort was divided into two groups according to LND adequacy, defined as at least 6 excised nodes, and survival analysis was carried out. An analysis of the subgroups of patients that benefited the most from LND was also performed.
Results: Out of 818 surgically resected iCC patients, 632 were cN0. In this cohort, 359 (57%) patients received adequate LND (AD-LND

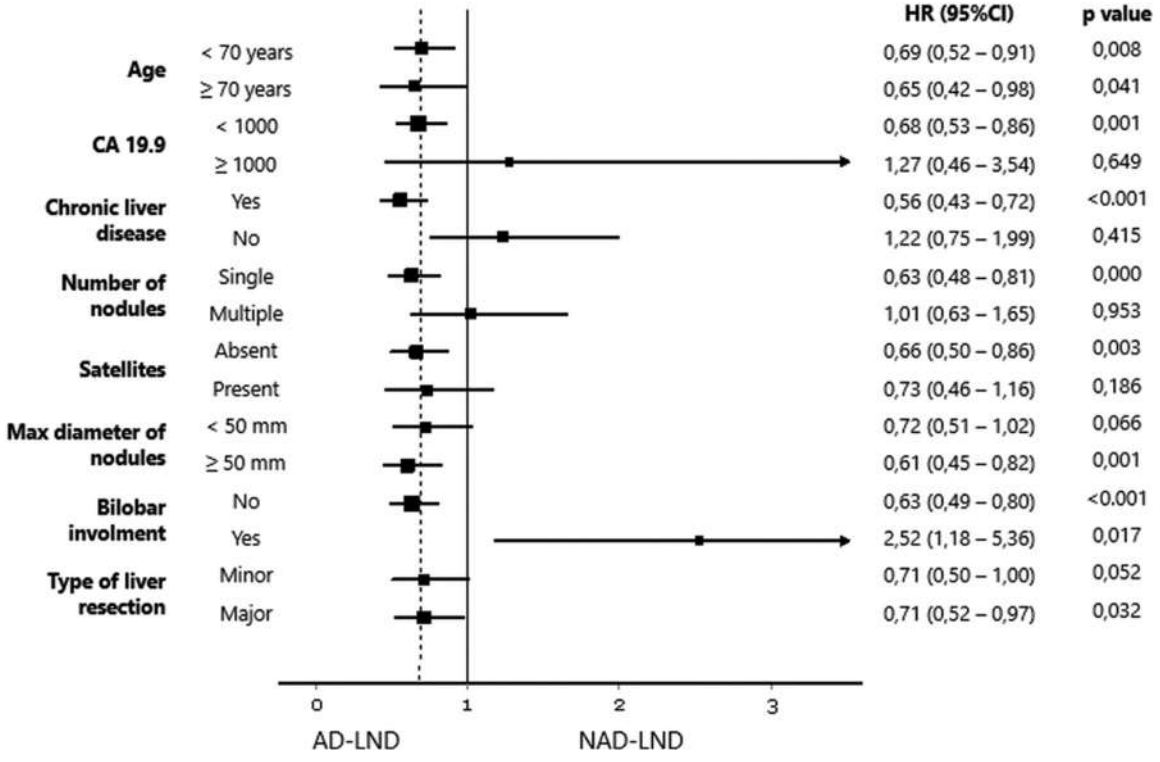

Figure: (abstract: SAT266)

group). Patient who did not receive adequate lymphadenectomy (NAD-LND group) were more likely to have an underlying chronic liver disease, a multifocal iCC and have received a major hepatectomy. Length of hospital stay, 90-day morbidity and mortality were comparable between the two groups. The AD-LND group had a higher number of patients with positive LNs at pathology (46% vs 15%, $p < 0.001$).
With a median follow-up of 57 months, OS and recurrence free survival (RFS) were significantly higher in the AD-LND vs. NAD-LND group (5-year OS 53.8% vs. 41.3%, $p < 0.001$; 5-year RFS 51.8% vs. 35.8%, $p < 0.001$). At multivariable analysis, NAD-LND was independently associated with worse OS together with CA19.9 >120, major hepatectomy, multifocal disease, grading >2, macrovascular invasion, and presence of positive lymph nodes at histology..
As shown in Figure 1, patients with age <70, single nodule or size >50 mm benefit most from AD-LND. Vice versa, in patients with cirrhosis or satellitosis or Ca19.9 > 1000, AD-LND did not seem to provide a survival advantage.
Conclusion: Adequate LND is associated with improved outcomes after surgical resection for iCC in patients with no preoperative evidence of lymph-nodal metastases. AD-LND does not seem to provide a survival advantage in patients with advanced disease or cirrhosis.

SAT267
Impact of MELD 3.0 Versus MELD-Na in patients with renal dysfunction

Allison Kwong[1], Ajitha Mannalithara[1], W. Ray Kim[1]. [1]*Stanford University, Gastroenterology and Hepatology, Redwood City, United States*
Email: allison.kwong@gmail.com

Background and aims: MELD 3.0 is a proposed model that improves upon MELD-Na, incorporating sex and albumin as additional variables, updating existing coefficients and adding relevant interactions, and resetting the upper bound of serum creatinine to 3.0 from 4.0 mg/dL. This analysis evaluates the impact of replacing MELD-Na with MELD 3.0 on waitlist priority among patients with advanced renal dysfunction.
Method: New adult waitlist registrations for liver transplantation from June 15, 2016 to June 30, 2021 were identified using OPTN data. MELD, MELD-Na, and MELD 3.0 scores from registration were calculated by the following equations:.
$MELD = 9.57*\log_e(\text{creatinine}) + 3.78*\log_e(\text{bilirubin}) + 11.20 \times \log_e(\text{INR}) + 6.43$;.
$MELD\text{-}Na = MELD + 1.32*(137\text{-}Na) - [0.033*MELD*(137\text{-}Na)]$;.
$MELD\ 3.0 = 1.33\ (\text{if female}) + 4.56*\log_e(\text{bilirubin}) + 0.82*(137\text{-}Na) - 0.24*(137\text{-}Na)*\log_e(\text{bilirubin}) + 9.09*\log_e(\text{INR}) + 11.14*\log_e(\text{creatinine}) + 1.85*(3.5\text{-albumin}) - 1.83*(3.5\text{-albumin})*\log_e(\text{creatinine}) + \mathbf{6.}$
Differences between MELD-Na and MELD 3.0 were evaluated by sex and serum creatinine at listing.
Results: There were 68, 111 new waitlist registrations for liver transplantation during the study period. The median serum creatinine at listing was 1.0 (IQR 0.7–1.5), with 1439 (2.1%) of listings with creatinine between 3 and 4 mg/dL and 6369 (9.4%) receiving maximum points for being on dialysis. On average, MELD 3.0 added 1.47 points for women and 0.14 for men compared to MELD-Na. For patients where the initial creatinine was between 3 and 4 mg/dL, MELD 3.0 added an average of 1.66 points for women and 0.50 for men compared to MELD-Na, whereas for patients on dialysis, MELD 3.0 added 0.16 points for women and subtracted 1.14 for men. Compared to MELD-Na, MELD 3.0 reduced the maximum number of potential creatinine-derived points from 13 to 12.
Conclusion: The MELD 3.0 scoring system increases the weight of the serum creatinine and thus the calculated MELD for patients with renal dysfunction — but not those with Cr ≥4 mg/dL or dialysis. If implemented in liver allocation, MELD 3.0 may increase waitlist priority for patients with acute kidney injury (e.g. hepatorenal syndrome); earlier access to liver transplant for this population could improve post-transplant renal outcomes including the need for kidney transplant.

SAT268
Sustainability of humoral immunity induced by the SARS-CoV-2 vaccine and response to booster dose among Liver Transplant recipients

Liane Rabinowich[1], Ayelet Grupper[2], Inbal Houri[3], Sharon Levy[3], Merav Ben-Yehoyada[3], Tami Halperin[4], Oren Shibolet[3], Helena Katzman[3]. [1]*Tel-Aviv Sourasky Medical Center, Department of Gastroenterology and Hepatology, Tel Aviv, Israel;* [2]*Tel-Aviv Sourasky Medical Center, Nephrology Department, Tel Aviv, Israel;* [3]*Tel-Aviv Sourasky Medical Center, Department of Gastroenterology and Hepatology, Tel Aviv, Israel;* [4]*Tel-Aviv Sourasky Medical Center, Department of infectious diseases, Tel Aviv, Israel*
Email: lianer@tlvmc.gov.il

Background and aims: Liver Transplant (LT) recipients were among the first to receive the BioNTech-BNT162b2 SARS-CoV-2 vaccine, with preliminary data indicating reduced humoral response compared to the general population. Our aim was to assess immunogenicity to the SARS-CoV-2 vaccine, durability over time and response to a third booster dose.
Method: LT recipients followed at the Tel-Aviv Sourasky Medical Center and healthy volunteers were tested for SARS-CoV-2 IgG antibodies against the Spike-protein (S) and Nucleocapsid-protein (N) at four time points: 10–20 days after the second Pfizer-BioNTech BNT162b2 SARS-CoV-2 vaccine dose, after 3 months follow-up, prior to (6 months follow-up) and 10–20 days after a third booster dose.

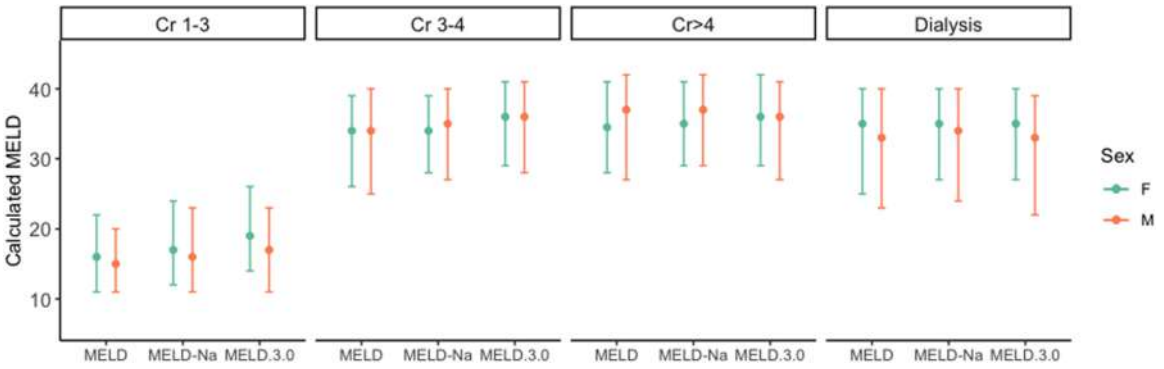

Figure: (abstract: SAT267): Median and interquartile range of calculated MELD using each scoring system (MELD, MELD-Na, and MELD 3.0), stratified by creatinine at listing and sex.

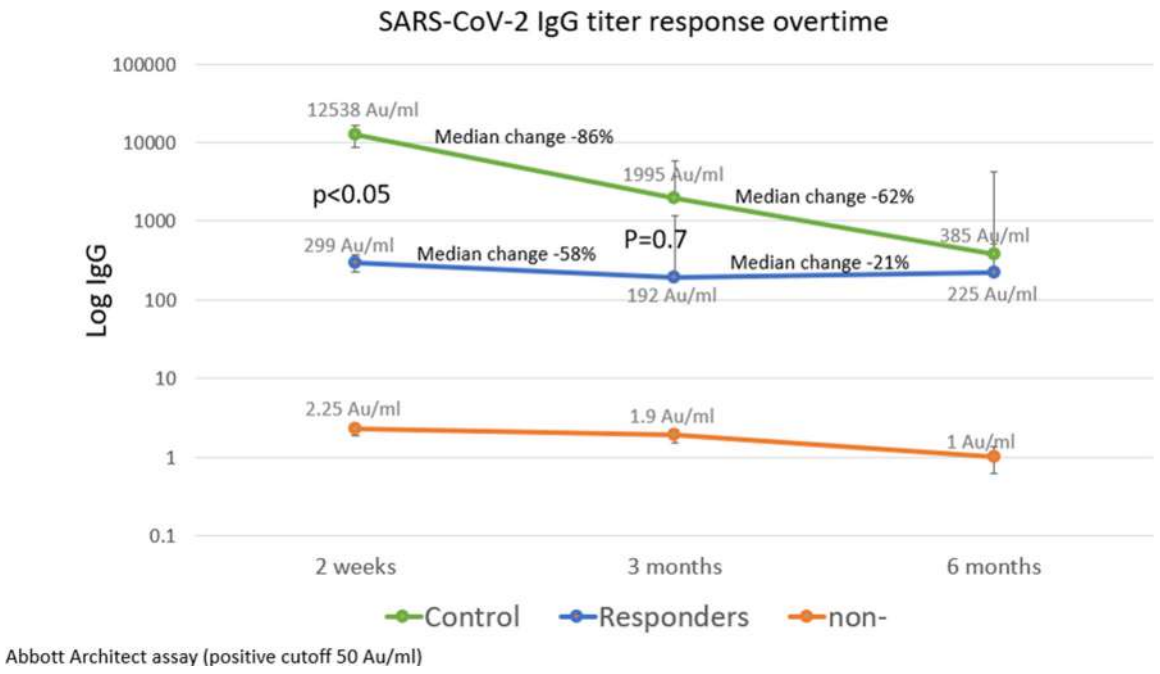

Figure: (abstract: SAT268)

Information regarding vaccine side effects and clinical data was collected from patients and medical records.

Results: Following the second vaccine dose, immunogenicity among 80 LT recipients was significantly lower compared to the control group, with positive serology in 52% compared to 100% among controls ($p < 0.001$). Antibody titer was also significantly lower among LT recipients (median 368.3 AU/ml vs. 12, 538 AU/ml in controls, $p < 0.001$). After 3 months follow-up, the antibody titer declined by 58% among LT compared to 86% decline in the controls (median titer 192 AU/ml vs 1, 995 AU/ml, $p = 0.7$). By 6 months the titers decreased by 21% and 62% in the LT and controls, respectively (median titer 225 AU/ml vs 385 AU/ml). Following a third dose given to 61 LT recipients received a third booster dose positive response rate increased to 85%. The median antibody titer significantly increased in both groups, but remained lower in LT recipients (3, 542 AU/ml vs. 28, 358 AU/ml among controls). Predictors for negative response among LT recipients were older age, lower eGFR, and treatment with high dose steroids and MMF.

Conclusion: LT recipients are at risk for lower humoral response to Pfizer-BioNTech SARS-CoV-2 mRNA based vaccine. The decline over-time is lesser in comparison to the general population. A booster dose was able to increase the response rate significantly, although antibody titers remained lower in comparison to control.

Email: christophe.duvoux@aphp.fr

Background and aims: The prognosis of severe sickle cell disease hepatopathy (SCDH) is dismal. Liver transplantation (LT) can be a salvage option but the worldwide experience, less than 70 reported LTs, is very limited and results controversial. The aim of this study was to describe presentation patterns and outcomes of LT for severe SCDH in a reference center for sickle cell disease.

Method: 24 patients, 16 men and 8 women, median age 37.4 years, transplanted between 1992 and 2020 were studied. Data on complications and management of SCD before LT, patterns of SCDH, liver explants, and post-LT outcomes were reviewed.

Results: SCD was SS, SC and S/β thal in 62, 8 and 30% of cases. The indications for LT were.

ACLF in 14 (58%) cases, triggered by severe intrahepatic vaso-occlusive (VOC).

in 11/14 (78.5%) cases, severe acute liver failure (ALF) in 5 cases, due to massive VOC in 4 cases and autoimmune hepatitis in 1 case. Five patients were transplanted electively: cirrhosis without ACLF in 3 cases (12.5%) (HCV 2, alcoholic hepatitis on cirrhosis 1), sclerosing cholangitis (SC) (8.5%) in 2 cases, with mild intrahepatic vaso-occlusive injury in 3 cases. Among patients with ACLF, 3 patients were ACFL grade 2, and 9 (64%) grade 3, with a median number of organ failures of 3; the underlying liver disease consisted of chronic SCD-related liver hepatopathy in 11/14 cases (71.5%).
The median MELD score at LT was 37.4, reaching 40 in ACLF patients. Median bilirubin was 700, 553, and 293 μmol/L, in ACLF, ALF and elective patients, respectively. 16 patients (67%) received induction immunosuppression. The incidence of acute cellular rejection was 13%. Six patients (25%) developed serious neurological complications (seizures 4 and/or PRES syndrome 3). Postoperative mortality was 0, 20% and 30% in elective patients, ALF and ACLF. The 5-year overall survival was 63%, ranging from 100% in elective patients to 60 and 50% in patients transplanted in ALF and ACLF. With a median post LT Fu of 6.4 years, a liver biopsy was performed in 10/19 patients beyond the 3rd month post LT because of liver lab tests suggestive of rejection. The recurrence of VOC injury was observed in 8/10 cases, significant graft fibrosis, F2/F3, in 4 cases (HCV 1 case). Recurrent SCD vaso-occlusive injury in the graft justified a preventive strategy combining transfusion exchanges and/or hydroxurea, with HbS target <30%.
Conclusion: This largest worldwide series of LT for SCDH shows that severe intrahepatic VOC causes ALF or ACLF in 75% of cases. Associated organ failures account for results inferior to those observed in other indications. In this rare indication, LT was associated with a reasonable 60% 5-year survival yet, transforming the prognosis of severe SCDH. LT should therefore be considered in expert multidisciplinary centers as a treatment option for SCDH. Identification of ACFL patients at high risk of post-operative death should be improved.

SAT270

Post-operative complications and short-term survival in obese cirrhotic patients undergoing liver transplantation

Javier Tejedor-Tejada[1], Carmen Alonso Martin[1], Samuel Juan Fernández Prada[1], Laura Juan[1], Violeta Mauriz[2], Abdelaleem Helal[3], Rifaat Safadi[4], Esteban Fuentes Valenzuela[1], Carolina Almohalla[1], Félix García Pajares[1]. *[1]Hospital Universitario Rio Hortega, Department of Gastroenterology, Hepatology and Liver Transplantation Unit, Spain; [2]Complejo Hospitalario Universitario de Santiago de Compostela, Department of Gastroenterology, Spain; [3]National Liver Institute, Menoufia University, Hepatology and Gastroenterology Department, Egypt; [4]Hadassah Medical Organization, Hadassah Hebrew University Medical Centre, The Liver Unit, Israel*
Email: jtejedor1991@gmail.com

Background and aims: Obesity is considered a risk factor for perioperative complications, but its effect on patients undergoing liver transplantation (LT) remains unclear. This study was conducted to analyze the impact of the body mass index (BMI) on morbidity and mortality risk following LT.
Method: A multicenter study of outcomes in patients submitted to LT between 2001 and 2019. Recipients were stratified in obese (BMI ≥30 kg/m^2) and non-obese patients (BMI <30 kg/m^2). The following exclusion criteria were considered: Patients with no BMI available, refractory ascites, polycystic liver disease or multiorgan transplantation. Post-LT outcomes and 1-year patient and graft survival were compared.
Results: A total of 1410 patients were included in the study, non-obese (989, 70.1%) and obese patients (421, 29.9%). There were not significant differences in Charlson comorbidity score, race, MELD, waiting time, total ischemia time, length of stay, ICU stay (Table 1). The rate of postoperative vascular and biliary complications were significantly higher in the obese recipients (23.3%, p 0.015 and 36.6%, p <0.01) versus the non-obese recipients (17% and 27.1%). There was a significantly increased risk for long-term graft failure. However, There was no difference in patient survival after LT.

	Non-obese N= 989	Obese N= 421	*P value*
Sex (male/female)	745/244	337/84	P= 0.063
Age (years), mean (SD)	53.9 (10.4)	55.4 (8.8)	P= 0.012
BMI (Kg/m2), mean (SD)	25.1 (3.1)	33.6 (3.2)	P < 0.001
Waiting list (days), mean (SD)	134 (323)	141 (345)	P= 0.718
Charlson comorbidity score, mean (SD)	2.4 (1.3)	2.7 (1.3)	P= 0.803
MELD score, mean (SD)	16.02 (6.7)	16.76 (6.6)	P= 0.884
Total ischemia time (minutes), mean (SD)	445.7 (136.5)	446.7 (142.8)	P= 0.909
Vascular complications (%)	168 (17%)	98 (23.3%)	P= 0.015
Biliary complications (%)	268 (27.1%)	154 (36.6%)	P= 0.002
Infectious complications (%)	257 (26%)	130 (30.9%)	P= 0.171
Postoperative bleeding (%)	121 (12.2%)	59 (14%)	P= 0.517
Ischemia-Reperfusion-Injury (%)	156 (15.7%)	47 (11.2%)	P= 0.08
Primary graft non-function (%)	91 (9.2%)	31 (7.4%)	P= 0.041
Acute rejection (%)	96 (9.7%)	54 (12.8%)	P= 0.178
Death			
• < 30 days	76 (7.7%)	33 (7.8%)	P= 0.251
• < 1 year	111 (12%)	46 (11.8%)	P= 0.505
Graft dysfunction			
• < 30 days	58 (6%)	27 (6.5%)	*P= 0.404*
• < 1 year	84 (9.7%)	53 (14%)	*P= 0.016*

Conclusion: Obese patients have significantly increased morbidity in terms of vascular and biliary complications after LT. They have a higher risk for worse 1-year graft survival in comparison to controls.

SAT271

Impact of comorbidities on liver transplantation: a prospective and multicentric study

Email: tserrano.aullo@gmail.com

Background and aims: Comorbidity plays an important role in the mortality of patients both on the waiting list and after liver transplantation (LT). To analyze the impact of comorbidities on LT, a prospective and multicentre study (HEPA_TIC) has been launched and the preliminary results are presented here.
Method: Analysis of 996 consecutive patients included in LT waiting list, in 18 Spanish hospitals, from October 2019 to October 2021. Retransplantation, multivisceral transplantation and patients younger than 16 years were excluded. Comorbidities at the time of

listing, and follow-up variables were collected. The analysis of comorbidities was disaggregated by sex.
Results: Patients were predominantly male (77.2%) with a median age of 61 years IQR (56–66); 60 years in females IQR (54–66) and 61 in males (56–66) (p = n.s). Median follow-up was 7.9 months IQR (4.9–12.1). Decompensated cirrhosis was the most frequent indication with no differences in both sexes. Hepatocellular carcinoma was significantly more frequent in males (45.9% vs. 24.6%; p < 0.001). The most frequent comorbidities were diabetes and arterial hypertension. Diabetes, chronic obstructive pulmonary disease and cardiovascular disease were significantly higher in men (p < 0.05), while chronic kidney disease was higher in women (p < 0.05). Only 11.7% of the listed patients had no comorbidities. The number of comorbidities was higher in males than in females (p < 0.001). 20.3% of the listed men and 15.1% of the women had more than three comorbidities. During follow-up, 4.8% of females and 2.5% of males died on the waiting list. Comorbidity was the cause of 13.3% of these deaths. In our cohort, 735 patients were transplanted during follow-up. Among all analyzed variables, only hyperuricemia was associated with a decrease in intention-to-treat survival (p = 0.02). Also, the presence of more than four comorbidities was related to a lower survival, although it did not reach statistical significance (p = 0.07).
Conclusion: Comorbidities are highly prevalent in patients with liver disease on the LT waiting list and are the second leading cause of waiting list mortality. Hyperuricemia is the only comorbidity associated with lower survival, although further follow-up is needed to determine the impact of other comorbidities on survival.

SAT272

Liver transplant patients infection rate with SARS-CoV-2 is lower but depend upon the infection rate in the general population and have a better outcome

Michal Cohen-Naftaly[1], Evelin Oxtrud[1], Orly Sneh Arbib[1], Assaf Issachar[1], Yael Harif[1], Amir Shlomai[1], Marius Braun[1]. [1]*Rabin Medical Center, Liver Institute, Israel*
Email: michal_c_n@yahoo.com

Background and aims: Conflicting results regarding the susceptibility to SARS-Cov2 infection and outcome in liver transplant (LT) patients (pts) were reported. Israel adopted early active policies to control the epidemic. Initially of severe travel restrictions and social distancing were enforced, followed by a lockdown. The relaxation of the restrictions led to 2 more severe waves, which triggered 2 new lockdowns. Israel was the first in the world to begin immunization with BNT162b2 on 20.12.2020, prioritizing first the elderly and immune compromised and rapidly extending to vaccination of the whole adult population. A fourth wave triggered the administration of booster doses in the same order. Guidelines encouraging social distancing, hygiene, and vaccination were disseminated to our pts and active follow-up was maintained using tele medicine. The immune suppression was not changed.
To assess the pattern of COVID19 pandemic among LT pts followed at Rabin Medical Center, compared to the general population in Israel.
Method: Retrospective study from2019 to 2021. Demographic data on 420 LT pts were collected from the electronic medical records, immunosuppressive therapy, dates of vaccination with BNT162b2, antibody levels after vaccination, data on SARS-COV-19 infection, severity of the disease, treatments and outcome. The data were compared to data reported on the Ministry of Health website: number of those infected in Israel, the vaccination rate. Comparison according to the waves of eruptions in Israel: 1st wave 2–5.2020, 2nd wave 6–11.2020, 3rd 11.2020–4.2021 and 4th wave 6–10.2021. 20.12.2020.
Results: 41 LT pts were diagnosed with Covid-19 out of 420 LT pts followed up : prevalence of 9.7%, significantly less than the 14.53% reported for the whole population (p < 0.05).
There were 4, 6, 19 and 12 COVID-19 cases respectively in waves 1 to 4. In waves 3 and four the number a COVID-19 patients that received 1, 2 and 3 vaccine doses was 2, 10 and 3 respectively, vs 16 unvaccinated. The vaccinated pts were infected at a median of 167 and 27 days after the second and third vaccine, respectively. The risk of infection was proportional to the risk in the population. (Fig 1).
Seven patient were hospitalized and treated with steroids, 3 of them died. All the other patients had mild disease, two pts received monoclonal antibodies.
Three pts died from COVID-19 while 4 pts died of unrelated causes. There was no increase in the mortality of LT pts due to the COVID epidemic.
Conclusion: In our LT cohort the outcome of COVID-19 was better than reported in the literature regarding both morbidity and mortality. Our data indicate that despite the population vaccination and the increase in the antibody titer after the third vaccine, there is still a considerable risk for LT recipients to develop COVID19, which is affected by the infection rate in the general population and not the immunization rate.

Sarcopenia predict complications after hepatic resection for primary hepatocellular carcinoma (HCC) in patients with advanced chronic liver disease (ACLD) and clinically significant portal hypertension (CSPH)

Federico Ravaioli[1], Giovanni Marasco[1], Elton Dajti[1], Vanessa Alemanni[1], Matteo Renzulli[1], Matteo Serenari[1], Matteo Ravaioli[1], Amanda Vestito[1], Giulio Vara[1], Davide Festi[1], Rita Golfieri[1], Matteo Cescon[1], Antonio Colecchia[1]. *[1]IRCCS Azienda Ospedaliero-Universitaria di Bologna, Department of Medical and Surgical Sciences, Bologna, Italy*
Email: f.ravaioli@unibo.it

Background and aims: Patients with advanced chronic liver disease (ACLD) complicated by early-stage hepatocellular carcinoma (BCLC-0/A) are the best candidates for surgical liver resection. Despite the latest improvements in clinical management and surgical techniques, hepatic resection is burdened with an incidence of major complications (MC) and post-hepatectomy hepatic failure (PHLF) with significant perioperative mortality and morbidity. Sarcopenia assessed by measuring skeletal muscle index (SMI) was associated with a higher risk of waiting list mortality and worse outcome after transplantation in patients with ACLD. In the absence of data on the role of sarcopenia in the post-hepatectomy setting, we aimed to investigate the prognostic role of SMI on the incidence of PHLF and surgical complications in patients with ACLD in a third-level European referral centre.

Method: All patients with available preoperative abdominal CT performed 3 months before surgery who underwent hepatic resection for primary HCC enrolled consecutively from 2014 to 2019 were included. Sarcopenia was defined according to the definition endorsed by the EASL as SMI, as measured by CT-images, <50 cm2/m2 in males and SMI <39 cm2/m2 in females. Surgical complications were assessed according to the Clavien-Dindo classification. The diagnosis of PHLF was performed according to the International Study Group of Liver Surgery (ISGLS) definition.

Results: 159 patients underwent hepatic resection for primary HCC, within inclusion criteria were included in the final analyses. Sarcopenia was present in 82 patients (51.6%). The median SMI was 39.2 (35.7–42.4) cm2/m2 and 48.9 (43–55.3) cm2/m2 in female and male patients, respectively. SMI values were significantly correlated with age (r = –0.229, p value = 0.004) and BMI (r = 0.369, p value <0.0001), but not with the of liver disease severity, as assessed by liver stiffness, platelet count, or MELD score. During the 30-days postoperative observation, 13 (8.2%) patients developed MC and 48 PHLF (30.2%; 34 PHLF-A; 14 PHLF-B/C). Overall, the presence of sarcopenia was not independently associated with post-hepatectomy and PHLF complications; however, in the group of patients with clinically significant portal hypertension (CSPH), SMI was independently associated with MC and PHLF B/C (OR 0.889 [0.798–0.990]; p value 0.032). Indeed, the MC rate was significantly higher in patients with (16.3%) than in patients without (0%) sarcopenia (p = 0.012).

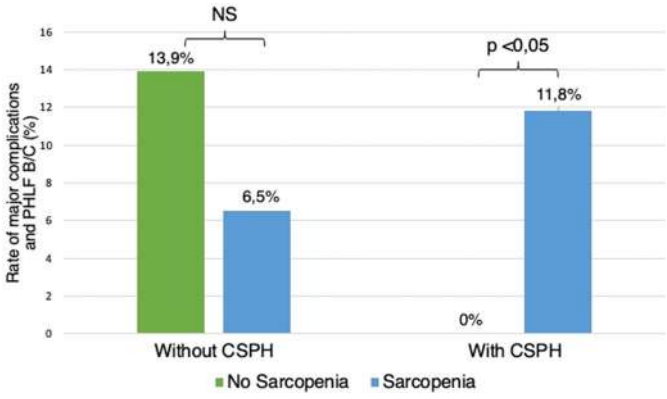

Figure:

Conclusion: The assessment of sarcopenia by SMI may aid physicians and surgeons in preoperative evaluation for hepatectomy for primary hepatocellular carcinoma in patients with advanced chronic liver disease complicated by clinically significant portal hypertension. However, further studies are still needed to evaluate the impact of perioperative nutritional and rehabilitation intervention.

SAT274

A comparison of hispanic living liver donor candidates approved and denied at a high-volume urban transplant center

Dana Toy[1], Brian Horwich[1], Ashwini Mulgaonkar[1], Ana Padilla[2], Jennifer Dodge[3,4], Navpreet Kaur[2,5], Hyosun Han[1,2,4]. *[1]University of Southern California, Medicine, Los Angeles, United States; [2]University of Southern California, Transplant Institute, Los Angeles, United States; [3]University of Southern California, Population and Public Health Sciences, Los Angeles, United States; [4]University of Southern California, Gastrointestinal and Liver Diseases, Los Angeles, United States; [5]University of Southern California, Surgery, Los Angeles, United States*
Email: dana.toy@med.usc.edu

Background and aims: Hispanics account for 20% of candidates waiting for liver transplantation (LT). Although living donor LT is comparable to deceased donor LT, minorities receive a disproportionately low percentage of living donor LT. From 2018–2019, living donor LT increased by one-third, while percentage of Hispanic living donors decreased. This study aims to compare Hispanic living liver donor candidates who were approved versus declined by a multidisciplinary selection committee at a large urban transplant center.

Method: The Living Liver Donor Referrals Database was reviewed between December 1, 2017 and August 31, 2021 for donor applicants (n = 195) who (1) completed a questionnaire and clinic evaluation, (2) were presented at a multidisciplinary selection committee, and (3) were formally approved/declined to serve as living liver donors. Statistical analysis was performed using Student's t-test and chi-squared test.

Results: Of 1, 689 living liver donor applicants, 11.5% (n = 195) were presented at a multidisciplinary selection committee. Half of those presented were approved (52.3%, n = 102), while the other half were declined (47.7%, n = 93). Hispanics who were approved (n = 55) and declined (n = 47) as living liver donor candidates had similar baseline demographics: mean age (34 v. 35 years, p = 0.71), mean body mass index (27.9 v. 28.8 kg/m^2, p = 0.40), female (61.8% v. 63.8%, p = 0.83). There was no significant difference in social history among Hispanics who were approved and declined: full time employment (62.3% v. 55.6%, p = 0.50), some college education (67.9% v. 68.9%, p = 0.92), married (47.2% v. 42.2%, p = 0.62), without alcohol use (20.6% v. 26.7%, p = 0.49). Both approved and declined Hispanic living liver donor candidates had nearly one-fourth who reported no medical insurance (28.3% v. 22.2%, p = 0.49) and no primary care doctor (25.5% v. 31.9%, p = 0.47). Hispanic living liver donor candidates were referred by intended transplant recipient or their friend/family (74.5% v. 83%, p = 0.30). Mean length of time from questionnaire to formal decision by a selection committee did not differ significantly when comparing approved and declined Hispanic candidates (165.4 v. 144.2 days, p = 0.55).

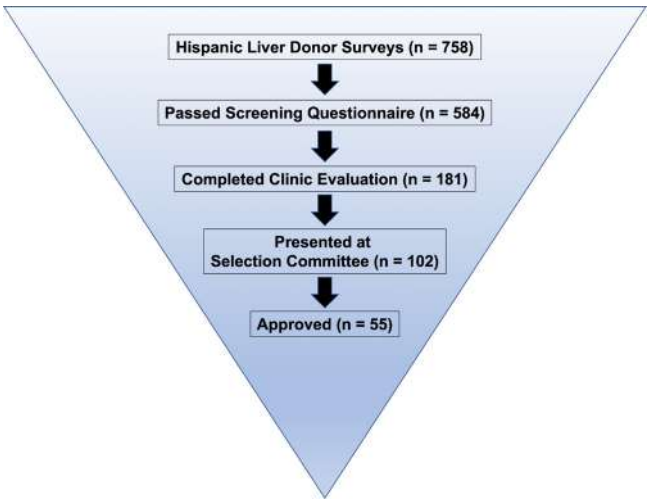

Figure: A schematic of the living liver donor evaluation process, which resulted in 55 approved Hispanic candidates.

Conclusion: The results of our study suggest that there is interest in living donor liver transplantation among Hispanics, given that nearly half (44.9%) of all living liver donor applicants were Hispanic. Our study suggests that the standard demographic and clinical data do not adequately capture factors that influence approval for living liver donor candidacy among Hispanics. There are ongoing efforts to establish comprehensive donor candidate registries that will better elucidate how the donor evaluation process may adapt to reduce racial and ethnic disparities in living donor LT.

SAT275

Liver transplantation in HIV infected subjects: a long-term single center experience

Gian Piero Guerrini[1], Noemi Gualandi[2], Giovanni Guaraldi[3], Paolo Magistri[1], Stefano Di Sandro[1], Nicola De Maria[2], Fabrizio Di Benedetto[1]. *[1]Policlinico di Modena, Hepatic-Biliary-Pancreatic Surgery and Liver Transplantation, modena, Italy; [2]Policlinico di Modena, Gastroenterology, modena, Italy; [3]Policlinico di Modena, Infectious Diseases, modena, Italy*
Email: gualandinoemi@gmail.com

Background and aims: Liver diseases, especially cirrhosis and hepatocellular carcinoma (HCC), represent one of the leading causes of death among HIV positive patients. Nowadays, liver transplantation (LT) is a well accepted option for end-stage liver diseases in this category of patients. The aim of the present study was to analyze the results of LT performed in our center comparing the outcome in HIV-positive and negative patients, in particular in HCC LT recipients.
Method: All patients with/without HIV infection who underwent LTs in our center between 2001 and 2020 were considered in the study. Cox regression analysis was used to determine prognostic survival factors, survival was calculated according to Kaplan-Meier method and compared using the log rank test. A subgroup analysis was performed in LT patients with HCC.
Results: 928 LTs were performed between 2001 and 2020, 63 of them in HIV positive recipients. HIV positive patients were younger than HIV negative (49.4 ± 6.6 yrs vs 53.3 ± 10.3, p = 0.001) while no difference was seen regarding MELD score at the time of LT (19 ± 9 vs 19, 1 ± 9.4). The mean follow-up was 58 ± 55 months. Five years overall survival in LT recipients HIV positive and negative was 65.3% and 72.7%, respectively (p = ns), whereas 5-year graft survival was 65% and 73.2% (p = ns). An improvement in survival was recorded in the second period of the study in the HIV-infected group, being 5 yrs survival 46.9% in Era I (2003–2011) and 80.6 in Era 2 (2012–2020, p < 0.001). The independent predictive factors of survival in the HIV infected group were: age of the donor (HR 1.07 p = 0.021), HCV-RNA detectable at time of transplant (HR 19.3 p = 0.011) and first Era of LT 2001–2010 (HR 12.7 p = 0.024). A total of 420 patients underwent LT for HCC, 34 of them were HIV positive and 386 were HIV negative. There were no significant differences between the two groups in terms of HCC macroscopic and histological characteristics. HIV positive subjects showed a better overall survival at 5 years and 10 years although the difference was not significant (71.6% vs 69.6% and 71.6% vs 61%, p = ns).
Conclusion: Our study shows that HIV positive LT patients have similar results to HIV negative in terms of survival; survival among HIV-infected LT subjects has improved over time, mainly because of DAAs introduction for HCV and better management of immunosuppression. Excellent results can be achieved for HIV-infected patients with HCC, even better than in HIV-negative patients in our experience, as long as a strategy of good selection of candidates and close surveillance of recurrence is adopted.

SAT276

SARS-CoV-2 infection in liver transplant recipients-a single center case series from Romania

Ioana-Alexandra Husar-Sburlan[1], Raluca Roxana Grigorescu[1], Elena Cristina Radu[1], Daniela Tabacelia[1], Madalina Florescu[1], Florina Nitu[2], Radu Dumitru[2,3], Ana Stanila[4], Alexandru Martiniuc[4], Nicolae Boleac[4], Dragos Chirita[4], Laura Popa-Dan[5], Cezar Stroescu[4], Narcis Copca[4]. *[1]Saint Mary Hospital, Gastroenterology, București, Romania; [2]Saint Mary Hospital, Radiology, București, Romania; [3]Fundeni Clinical Institute, Radiology, București, Romania; [4]Saint Mary Hospital, Surgery, București, Romania; [5]Saint Mary Hospital, Anesthesiology and Intensive Care Unit, București, Romania*
Email: sburlan.ioana@gmail.com

Background and aims: The COVID-19 pandemic has affected people and medical care and led to changes in solid organ transplant programs. Recipients of liver transplantation (LT) represent a special group of patients with chronic immunosuppression and frequently associated comorbidities that may present with different progression of the disease than the general population.
Method: We report a case series of patients undergoing post-liver transplantation evaluation, from a single centre in Romania, who were diagnosed with SARS-CoV-2 infection by RT-PCR from respiratory swaps. We analysed their clinical traits, prognostic factors, management and outcome.
Results: In this case series, we report 11 cases of SARS-CoV-2 infection in liver transplant recipients at different times after transplant, varying from 7 days to 77 months. 45% of patients included were asymptomatic, while in the symptomatic group dyspnoea was the most common manifestation (83.33%), followed by fever (50%), dry cough and gastrointestinal symptoms. COVID-19 therapies included antibiotics, antivirals, immunomodulators, steroids, low molecular weight heparin, antifungal, high dose vitamin therapy and Quercetine. Dyspnoea as a symptom, and neutrophil-to-lymphocyte-ratio (NLR) as biological marker were significantly associated with a severe clinical course. Other inflammatory markers like leucocytosis, platelet-to-lymphocyte-ratio (PLR), C-reactive protein (CRP), fibrinogen at diagnosis failed to show significant prognostic value. Patients who progressed to severe forms of the disease were often already hypoxic and tachypneic at presentation, highlighting once again that these patients may be presenting at a late stage of their infection, which limited their therapeutic options. In our study in 68% of patients immunosuppression was Tacrolimus, 9% had Tacrolimus with low dose corticoid, 9% had Sirolimus, and two patients were in the induction immunosuppression phase. Tacrolimus immunosuppression remained unchanged during COVID-19 infection in almost all cases. COVID-19-related mortality was 27.27%. No difference was observed in mortality between those infected within one-year vs after one year of liver transplantation.

No	Gender	Age	Time post LT-months	Comorbidities	Symptoms	NLR	PLR	CRP	LDH	TGO	TGP	Baseline imunosupression	Severity	Outcome
1	M	60	23 days	no	dyspnoea	28.82	517.65	279.63	424.22	76	112	Tacrolimus+corticotherapy	severe	dead
2	M	60	7 days	hypertension	fever, productive cough, dyspnoea, diarrhea	58.89	866.67	39.7	222.46	16	105	Syrolimus+corticotherapy	severe	alive

4	F	44	67	no	asymptomatic	2.09	82.78	2	222	12	7	Tacrolimus	mild	alive
5	M	50	65	type 2 diabetes	asymptomatic	1.88	145.20	1	313.96	42	39	Tacrolimus	mild	alive
6	M	47	59	no	asymptomatic	3.20	121.39	4	185.25	39	40	Tacrolimus	mild	alive
7	M	45	17	chronic obstructive pulmonary disease	asymptomatic	2.26	73.68	1	146.64	29	30	Tacrolimus	mild	alive
8	F	66	59	endometrial carcinoma	fever, chills, myalgia, asthenia, dyspnoea	3.90	240.28	25	354.7	35	25	Syrolimus	moderate	alive
9	F	48	66	no	dysphagia, dry cough	0.99	76.42	12.25	289	86	89	Tacrolimus	moderate	alive
10	M	66	77	type 2 diabetes, obesity, arterial hypertension	fever, dyspnoea	28.00	240.63	15	380	87	133	Tacrolimus+corticotherapy	severe	dead
12	F	66	75	type 2 diabetes, obesity, arterial hypertension	fever, myalgia, dyspnoea, severe asthenia	15.04	387.23	148.85	446.29	45	37	Tacrolimus	severe	dead

Figure: (abstract: SAT276)

Conclusion: In this case series, liver transplant recipients with COVID-19 disease, aged 60 years or older, who presented with dyspnoea and had diabetes mellitus had more severe outcomes. Neutrophil-lymphocyte ratio at diagnosis seems to be a prognostic factor for a more severe course of COVID-19 pneumonia. Other inflammatory markers had failed to show a significant prognostic role. Older liver transplant recipient patients with diabetes, that present dyspnoea related to COVID-19 pneumonia should be admitted and monitored because of the risk of severe course and high risk of mortality.

SAT277

Liver transplantation for hepatocellular carcinoma: outcome and prognostic factors for recurrence

Veronica Paon[1], Ilaria Normelli[2], Amedeo Carraro[3], Paola Violi[3], Andrea Dalbeni[2], Donatella Ieluzzi[1], Andrea Ruzzenente[4], Alfredo Guglielmi[4], David Sacerdoti[1]. *[1]Liver unit AOUI, medicine, Verona, Italy; [2]General medicine AOUI, medicine, Verona, Italy; [3]Liver transplant unit, surgery, Verona, Italy; [4]Hepatobiliary surgery, surgery, Verona, Italy*
Email: veronica.paon@aovr.veneto.it

Background and aims: Hepatocellular carcinoma (HCC) accounts for approximately 75% of primary liver cancers and is the fourth leading cause of death from malignancy worldwide. The 5 -year survival rate is around 10–15%, often due to late diagnosis with detection of advanced neoplastic disease. Liver transplant (LT) is a curative treatment in some patients. The post-transplant recurrence rate of HCC is very wide, between 5 and 30%, due also to different listing policies.
The aim of our study was to evaluate the recurrence rate of HCC after LT and to identify the main risk factors for recurrence.
Method: 230 patients (84% male, mean age 59 yr) with HCC transplanted between February 2007 and December 2020 were followed until recurrence or death. The majority of patients had Mayo End Stage Liver Disease (MELD) scores ≤19, while only 4.8% presented for transplant with MELD scores ≥30. Milan criteria were applied for listing. Etiology, biochemical data, comorbidities, pre-transplant treatments, and histological evaluation of the native liver were collected.
Results: 57% of patients had viral, 29.6% alcoholic, and 12.6% non-alcoholic fatty liver disease cirrhosis. 37% of patients had type 2 diabetes mellitus (T2DM) and 43.6% hypertension. 69% of patients had undergone pre-transplant treatments (percutaneous ethanol injection, radiofrequency ablation, transarterial chemioembolization, transarterial radioembolization, resection). The mean follow-up was 47 ± 39 months, with 77.4% survival. Average survival of patients without HCC recurrence was 48.6 ± 39.4 months, average survival of patients with recurrence was 23 ± 25.1 months. After LT, 9.1% of patients had HCC recurrence, and 22.6% died. Among those who had HCC recurrence, 57% of patients had recurrence within the first 12 months after transplantation; 19% at 24 months, 19% at 36 months and 5% at 60 months. In 66.6% of patients with relapsed HCC, the tumor started with extrahepatic localizations (lung, lymph nodes, mediastinum).
In the multivariate analysis the only factors that predicted the outcome (death or HCC relapse) were: extranodal microvascular invasion ($p < 0,001$), size of the largest nodule ($p < 0.005$) and number of pre-transplant local-regional treatments ($p < 0,04$). High pre LT MELD and T2DM identified patients with a worse overall outcome and poorer survival.
Conclusion: In our 13 years experience, recurrence of HCC after transplantation was low (9%). Number of pre-transplant treatments, size of nodules and microvascular invasion were the only predictors of recurrence of HCC after transplantation.

SAT278

The liver outcomes and equity (LOEq) index: neighborhood social determinants independently predict outcomes in liver transplantation

Kali Zhou[1], Leane Kuo[1], Jennifer Dodge[1], Laura Thompson[1], Norah Terrault[1], Myles Cockburn[1]. [1]*University of Southern California, Los Angeles, United States*
Email: kalizhou@usc.edu

Background and aims: The impact of social determinants of health (SDOH) at the neighborhood-level on patient outcomes in adult liver transplantation (LT) is unknown. We constructed the novel Liver Outcomes and Equity (LOEq) index to characterize area-based SDOH specific to the population with liver disease in the United States (US) and examined association with LT outcomes.

Method: The LOEq index was derived from 16, 713 unique ZIP codes (42% of all US ZIP codes) of adult waitlisted patients in the Scientific Registry of Transplant Recipients database between 6/18/2013–5/18/2018. We selected 38 ZIP code-level variables across five SDOH domains from the 2014–2018 American Community Survey as a comprehensive measure of neighborhood SDOH. Principal component analysis conducted with a structured and iterative process identified the most influential 13 variables to be included in the final index. Primary predictor was the LOEq index categorized into quintiles (Q1 = lowest to Q5 = highest SDOH). Outcomes were 1) waitlist (WL) mortality (= delisting for too sick/death) and 2) post-LT patient survival, examined with competing risk and Cox regression, respectively. Models were adjusted for transplant region and relevant demographic/clinical factors, with insurance tested as an effect modifier.

Results: Adult LT patients disproportionately resided in neighborhoods with higher SDOH, with 14.0% vs 30.3% of waitlisted patients (n = 59, 298) and 13.9% vs 30.2% of transplanted patients (n = 37, 598) in Q1 vs Q5, respectively. Lower LOEq quintiles had higher proportion minorities, public insurance, hepatitis C etiology, diabetes, and obesity. 47% in Q1 vs 17% in Q5 lived in transplant regions with a short wait time to LT; 5.6% in Q5 vs 2.4% in Q1 underwent living donor LT. The 3-year cumulative incidence of WL mortality was higher in Q1 (22.9%) vs Q5 (20.6%), while 3-year post-LT survival was lower in Q1 (85.8%) vs Q5 (87.4%). In the multivariable model of waitlisted patients, LOEq Q1–4 were associated with increased WL mortality compared to Q5 (all p < 0.01), with Q1 patients incurring 23% excess deaths compared to Q5 (HR 1.23, 95% CI 1.16–1.31). Among transplanted, risk of post-LT death was also elevated for LOEq Q1 (HR 1.14, 1.04–1.24) and Q3 (HR 1.12, 1.03–1.21) compared to Q5. There was a non-significant interaction between LOEq and insurance type: higher WL mortality for Q1 vs Q5 (HR 1.28 for private vs 1.15 for public; p = 0.08) and lower post-LT deaths for Q1 vs Q5 (HR 1.01 for private vs 1.17 for public; p = 0.09).

Conclusion: More LT patients living in higher LOEq quintiles highlights a neighborhood-level disparity in access to LT. Lower neighborhood SDOH predicted worse outcomes in LT independent of patient demographics and clinical characteristics. The liver disease-specific LOEq index might be leveraged to identify the most vulnerable patients for interventions in clinical settings to increase LT equity.

SAT279

Prevalence, prognosis, clinical, biological and histological features of incidentally found hepatocellular carcinoma after liver transplantation

Emilie Kerstens[1], Samuele Iesari[2,3], Eliano Bonaccorsi[1], Laurent Coubeau[1], Géraldine Dahlqvist[1], Olga Ciccarelli[1], Bénédicte Delire[1]. [1]*UCLouvain;* [2]*Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, General surgery and kidney transplantation, Milan, Italy;* [3]*Institut de Recherche Expérimentale et Clinique, UCLouvain, Pôle de Chirurgie Expérimentale et Transplantation, Brussels, Belgium*
Email: benedicte.delire@saintluc.uclouvain.be

Background and aims: An incidentally found hepatocellular carcinoma (iHCC) is an HCC diagnosed postoperatively after the analysis of the liver explant from patients who underwent liver transplantation (LT) for non-oncological indication. Data about the prevalence and prognosis of iHCC are scarce. The aim of this study is to evaluate the prevalence of iHCC in our LT patients and to compare the mortality, the risk of recurrence and the clinical, biological, and histological features between patients who underwent LT for preoperatively known HCC (pkHCC) and patients with a postoperative diagnosis of iHCC.

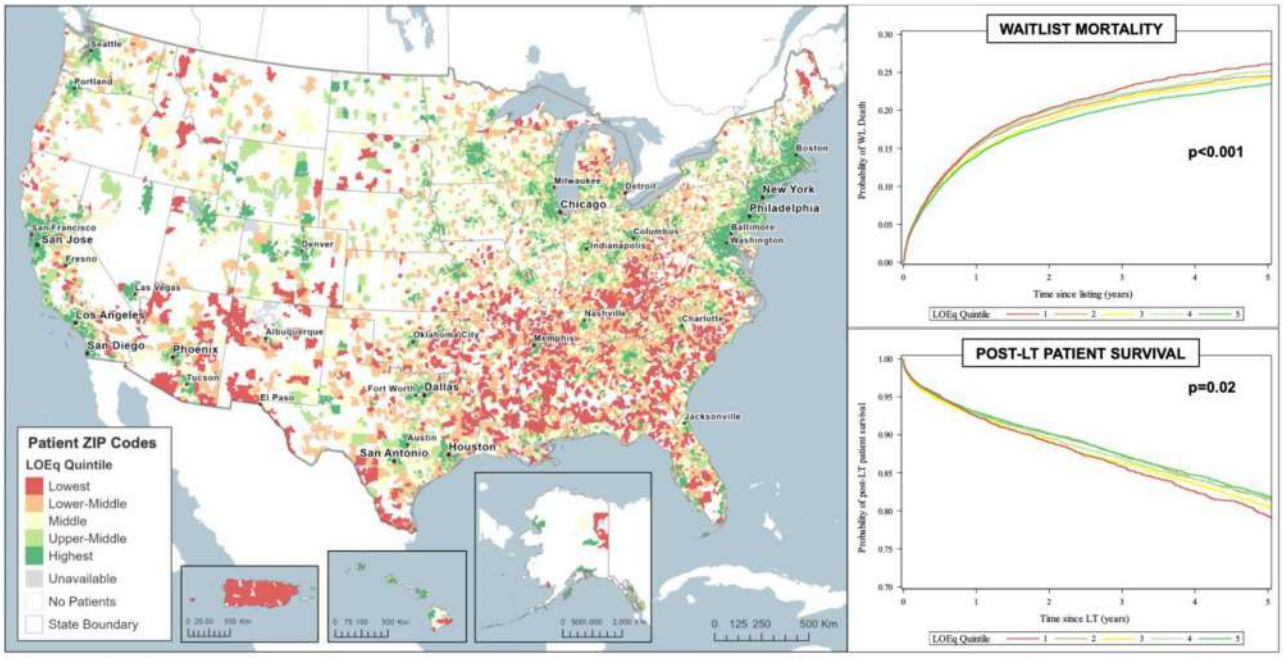

Figure: (abstract: SAT278)

Method: We retrospectively reviewed 268 adult patients who underwent LT at the Cliniques Universitaires Saint-Luc, Brussels, Belgium, from January 2010 to January 2020. Results were compared using Fisher's exact test or Mann-Whitney U test as appropriate. The Kaplan-Meier method was used to analyze the rate of death and graft loss. Log-rank tests were run to compare the survival curves. The significance of statistical tests was taken at a P value of <0.05. Analyses were run with SPSS Statistics.
Results: Among the 268 adult patients who underwent LT, 98 cirrhotic patients were transplanted for a pkHCC. Prevalence rate of iHCC was 12%. Alcoholic cirrhosis was predominant in the iHCC cohort (88.9% vs 48%, $p = 0.032$). As expected, the patients of the iHCC cohort had a higher MELD score (19.0 (17.0–20.0) vs 10.0 (8.0–13.0); p <0.001) both, at the registration on the waiting list and at LT. Value of Child-Pugh score was also higher for the iHCC cohort compared to pkHCC patients (10.0 (9.0–11.0) vs 5.0 (5.0–6.0); p <0.001). None of the iHCC patients got Child-Pugh A score vs 76, 3% of the patients with pkHCC (p <0.001). Child-Pugh class C cirrhosis at LT was mainly found in the iHCC cohort (55.6% vs 6.2%; p <0.001). No statistical difference was observed between the 2 cohorts for the level of alfa-fetoprotein, neither at time of registration nor at LT. However, des-carboxy-prothrombin level was significantly higher at time of LT in the iHCC cohort (273.8 (228.9–551.1) vs 42.0 (22.5–96.0); p = 0.022). The interval between the last imaging and LT was longer in iHCC cohort than pkHCC (2.7 months (1.9–3.7) vs 1.0 (0.5–1.7); p <0.004). Based on histological analysis, Edmondson grade II lesions were more frequently found in the iHCC cohort. However, there was no difference regarding the microvascular invasion rate. None of the 9 iHCC patients got recurrence of HCC post-LT. Cumulated recurrence at 1, 3 and 5 years post-LT for pkHCC patients were respectively 3%, 7% and 11%). No significant difference was observed for 1, 3 and 5-year survivals rates for iHCC patients compared to pkHCC patients (respectively 100%, 88% and 53% vs 90%, 87% and 65%; p = 0.565).
Conclusion: While the prevalence of iHCC is not negligible (12% in our patients), it impacts neither the neoplastic recurrence rate nor the survival rate compared to pkHCC patients.

SAT280

Survival benefit from liver transplantation for patients with and without hepatocellular carcinoma

Ben Goudsmit[1], Ilaria Prosepe[2], Maarten Tushuizen[1], Serge Vogelaar[3], Ian Alwayn[4], Bart Van Hoek[1], Andries Braat[4], Hein Putter[2]. *[1]Leiden University Medical Center (LUMC), Gastroenterology and Hepatology, Leiden, Netherlands; [2]Leiden University Medical Center (LUMC), Biostatistics, Leiden, Netherlands; [3]Foundation Eurotransplant International Foundation, Leiden, Netherlands; [4]Leiden University Medical Center (LUMC), Surgery, Leiden, Netherlands*
Email: b.f.j.goudsmit@lumc.nl

Background and aims: In the US, inequal liver transplantation (LT) access exists between patients with and without hepatocellular carcinoma (HCC). Survival benefit considers survival without and with LT and could equalize LT access. We calculated and compared LT survival benefit scores for patients with (out) HCC, based on longitudinal data in a recent US cohort.
Method: Adult LT candidates with (out) HCC between 2010 and 2019 were included. Waitlist survival over time was contrasted to posttransplant survival, to estimate 5-year survival benefit from the moment of LT. Waitlist survival was modeled with bias-corrected time-dependent Cox regression and posttransplant survival was estimated through Cox proportional hazards regression.
Results: Mean HCC survival without LT was always lower than non-HCC waitlist survival. Below MELD (-Na) 30, HCC patients gained more life-years from LT than non-HCC patients at the same MELD (-Na) score. Only non-HCC patients below MELD (-Na) 9 had negative benefit. Most HCC patients were transplanted below MELD (-Na) 14 and most non-HCC patients above MELD (-Na) 26. Liver function. (MELD (-Na), albumin) was the main predictor of 5-year benefit. Therefore, during five years, most HCC patients gained 0.12 to 1.96 years from LT, whereas most non-HCC patients gained 2.48 to 3.45 years.
Conclusion: On an individual level, transplanting patients with HCC resulted in survival benefit. However, on a population level, benefit was indirectly wasted, as non-HCC patients were likely to gain more survival due to decreased liver function. Based on these data, we now provide an online calculator to estimate 5-year survival benefit given specific patient characteristics. Survival benefit scores could serve to equalize LT access.

SAT281

Long-term outcomes of liver transplantation (LT) using grafts from donors with active and chronic hepatitis B virus (HBV) infection: multi-center cohort study

Sujin Gang[1], YoungRok Choi[1], Boram Lee[1], Kyung Chul Yoon[2], Su young Hong[1], Sanggyun Suh[1], Eui Soo Han[1], Suk Kyun Hong[1], Hae Won Lee[3], Jai Young Cho[3], Nam-Joon Yi[1], Kwang-Woong Lee[1], Kyung-Suk Suh[1]. *[1]Seoul National University College of Medicine, Department of Surgery; [2]Seoul National University Boramae Medical Center, Department of Surgery; [3]Seoul National University Bundang Hospital, Department of Surgery*
Email: choiyoungrok@gmail.com

Background and aims: We report the long-term outcome of liver transplantation (LT) using grafts from donors with active and chronic hepatitis B virus infection using Hepatitis B immunoglobulin (HBIG) and Nucleos (t)ide analogues (NA).
Method: Among 2260 LTs performed in Seoul National University Hospital, SNU Bundang Hospital, and SNU Boramae Hospital between January 2000 and April 2019, 26 (1.2%) grafts from donors with HBsAg (+), HBeAb (+) or HBV DNA (+) were referred as active and chronic HBV hepatitis grafts and reviewed retrospectively. Demographics and transplantation outcome were analyzed. HBV reactivation redefined as the increase of viral DNA for HBsAg (+) grafts and HBsAg positive seroconversion for chronic hepatitis grafts. Also, we adopted the stage of chronic HBV infection to evaluate and manage of recipients transplanted HBV infected grafts.
Results: Sixteen deceased donor LT were performed with active HBsAg (+) grafts. Ten living donor LT were performed with inactive HBV infected grafts; 8 patients in inactive hepatitis status; HBsAg (−), HBcAb (+) and HBV DNA (+), and 2 patients in chronic HBV hepatitis with seroconversion; HBsAg (−), HBsAb (+) and HBeAg (+). Average follow-up period was 82.6 ± 60.1 months. NA and HBIG were administered during perioperative period depending on donor and recipient's serology. Deaths (n = 8) were occurred 2.0–47.3 months after transplantation. Comparing LT using non-hepatitis virus-infected grafts, there was no difference in patient survival (30.8% vs. 18.6%, p = 0.247). Most common causes of death were infection (n = 4) and HCC recurrence (n = 3). HBV reactivation was identified in 1 patient but resolved spontaneously without additional management. All 10 LDLT recipients survived and were in good condition during follow-up. Survivors were in inactive or resolved status for HBV infection under the HBIG and NA. No graft failure was observed. Fourteen patients followed-up more than 5 years were stable and no increase in HCC recurrence rate was observed 5 years after transplantation.
Conclusion: Considering their long-term outcome, liver grafts with active and chronic HBV infection can be safely used in HBV endemic area.

SAT282

Safe use of hepatitis B surface antigen positive (HBsAg (+)) grafts in liver transplantation (LT): a nationwide study based on KOTRY (Korean Organ Transplantation Registry) data

Sujin Gang[1], YoungRok Choi[1], Kwang-Woong Lee[1], Bong Wan Kim[2], Dong-Sik Kim[3], Yang Won Nah[4], Jong Man Kim[5], Jae Geun Lee[6], Je Ho Ryu[7], Jaehong Jeong[8], Geun Hong[9], Shin Hwang[4]. [1]*Seoul National University College of Medicine, Department of Surgery;* [2]*Ajou University School of Medicine, Department of Surgery;* [3]*Korea University College of Medicine, Department of Surgery;* [4]*University of Ulsan college of medicine, Department of Surgery;* [5]*Sungkyunkwan University school of medicine, Department of Surgery;* [6]*Yonsei University College of medicine, Department of Surgery;* [7]*Pusan National University School of Medicine, Department of Surgery;* [8]*School of Medicine, Soonchunhyang University, Department of Surgery;* [9]*Ewha Womans University School of Medicine, Department of Surgery*
Email: choiyoungrok@gmail.com

Background and aims: In the era of nucleos (t)ide analogues (ANs), we investigate the outcomes of liver transplantation (LT) using HBsAg (+) grafts using Korean national registry database.
Method: Among 4265 LTs which were registered in KOTRY database between April 2014 and January 2020, 20 (0.5%) LTs using HBsAg (+) grafts were identified. We investigated the overall outcomes of LT using HBsAg (+) liver grafts (n = 4100, S (+) group) compared to those of HBsAg (−) liver grafts. S (+) group were compared to those for LT using HBsAg (−) and HBcAb (+) (n = 882, C (+) group) and HBsAg (−) and HBcAb (−) (n = 3132, SC (−) group) after propensity-score matching (1:1).
Results: Twenty HBsAg (+) grafts from deceased donors were transplanted to HBsAg (+) recipients. HBIG was maintained in 16 patients (80%). Most common NA was tenofovir. S (+) group showed comparable patient survival (26.5 ± 21.8 vs 22.8 ± 18.2 months, p = 0.332) and graft survival (26.5 ± 21.8 vs 21.3 ± 18.2 months, p = 0.152) compared to those of HBsAg (-) group.
Age (HR = 1.03, p = 0.016), HCC (HR = 4.61, p < 0.001), MELD score (HR = 2.82, p = 0.001), ascites (HR = 2.14, p = 0.002) and encephalopathy (HR = 2.53, p < 0.001) were the risk factors affecting patient survival. For graft survival, HCC (HR = 4.01, p = 0.001), pre-operative treatment to HCC (HR = 0.54, p = 0.006), MELD score (HR = 2.14, p = 0.012), ascites (HR = 2.52, p < 0.001), and encephalopathy (HR = 1.99, p < 0.001) were significant factors.
After PSM matching between S (+) and C (+), and S (+) and SC (−), there was no significant difference in patient survival (24.3 ± 20.7 vs 38.2 ± 23.0 months, p = 0.863, 24.3 ± 2.7 vs 38.2 ± 23.0 months p = 0.547), and graft survival (26.5 ± 21.8 vs 36.3 ± 17.4 months, p = 0.576, 26.5 ± 21.8 vs 36.3 ± 18.4 months, p = 0.327, respectively).
Conclusion: HBsAg (+) liver grafts can expand the donor pool without compromising the outcomes in the era of NA in the HBV endemic area.

SAT283

A panel of three micro RNAs allows robust prediction of overall survival after liver resection

David Pereyra[1,2], Hubert Hackl[3], Susanna Skalicky[4], Jonas Santol[1,2], Thomas Grünberger[5], Matthias Hackl[4], Alice Assinger[2], Patrick Starlinger[1]. [1]*Medical University of Vienna, Department of General Surgery, Division of Visceral Surgery;* [2]*Medical University of Vienna, Center of Physiology and Pharmacology, Institute of Vascular Biology and Thrombosis Research;* [3]*Medical University of Innsbruck, Division of Bioinformatics, Biocenter;* [4]*TamiRNA GmbH;* [5]*Clinic Favoriten, Department of Surgery, Hepatico-Pancreato-Biliary Center*
Email: david.pereyra@meduniwien.ac.at

Background and aims: Overall survival (OS) after liver resection (LR) is influenced by posthepatectomy liver failure (PHLF), disease recurrence, and chronic deterioration of liver function. We previously reported on a panel consisting of the three micro RNAs (miR) miR-122, miR-151a, and miR-192, summed up as the hepatomiR score, which allows accurate preoperative prediction of PHLF. Here, we aimed for investigation of the hepatomiR score in prediction of long-term OS.
Method: Blood was taken prior to LR in 175 patients followed by optimized plasma preparation. Plasma was used for evaluation of miRs using quantitative polymerase chain reaction, and hepatomiR was calculated. Patients were followed up for disease recurrence and mortality. Statistical analysis was carried out on SPSS version 26 and was based on receiver operating characteristic analysis (ROC), non-parametric tests, log-rank tests, and Cox-regression.
Results: HepatomiR showed a high predictive potential for PHLF with an area under the curve of 0.794 upon ROC. Further, hepatomiR was significantly associated with OS upon univariable Cox-regression (hazard ratio [HR] = 3.104, 95% confidence interval [95%CI] 1.177–8.184, p = 0.022), and remained significant in a multivariable model (HR = 6.326, 95%CI 1.994–20.066, p = 0.022). The previously evaluated cut-offs for hepatomiR (>0.59 and >0.68) were applied in order to divide the cohort into three risk groups. In Kaplan-Meyer analysis OS after LR was reduced in the intermediate-risk group (median OS = 44 months, 95%CI 0–96, p = 0.651), and patients in the high-risk group (hepatomiR >0.68) showed a significantly shorter OS (median OS = 11 months, 95%CI 5–18, p = 0.001) when compared to the low-risk group, respectively (median OS = 53 months, 95%CI 31–74). Accordingly, we focused on the high-risk group and observed a significantly higher incidence of 90-day mortality (3.7% vs 27.3%, p = 0.001), and mortality within 1 year (16.3% vs 63.6%, p <0.001), 3 years (42.9% vs 81.8%, p = 0.012), and 5 years (58.4% vs 90.0%, p = 0.048). An association with disease-free survival could not be observed. In order to evaluate the relevance of hepatomiR for PHLF independent prediction of OS, we further excluded patients with 90-day mortality. We observed that the high-risk cut-off was still able to identify patients with reduced OS (median OS ≤0.68 = 59 months, 95%CI 35–84; median OS >0.68 = 12 months, 95%CI 7–17, p = 0.040), and patients with mortality within 1 year (13.0% vs 50.0%, p = 0.004), 3 years (40.5% vs 75.0%, p = 0.055), and 5 years (56.5% vs 85.7%, p = 0.127).
Conclusion: We here present the hepatomiR score as a marker for risk stratification prior to LR. HepatomiR allows identification of patients at risk for PHLF, and patient with reduced OS after LR independently from PHLF. Accordingly, the evaluation of hepatomiR might improve patient selection and ultimately increase personalized outcome of liver surgery.

SAT284

Liver transplantation for primary sclerosing cholangitis and predictors of disease recurrence

Julie Zhu[1], Dennis Lim[2], Larry James[2], Eric Yoshida[3], Kevork Peltekian[2]. [1]*Dalhousie University, Atlantic Liver Transplant Program, Canada;* [2]*Dalhousie University, Medicine;* [3]*University of British Columbia, Medicine*
Email: julie.zhu@ualberta.ca

Background and aims: In liver transplantation (LT) for PSC, pre-transplant colectomy may lower the risk of PSC recurrence (rPSC), and well-controlled or lack of IBD may protect against rPSC, however, these findings are not consistent across all studies. It is unknown whether recipient/donor sex plays a role in rPSC. The aim is to study factors associated with PSC recurrence in the post-transplant population.
Method: This is a retrospective study on adults who received LT for PSC in Halifax NS from 1985 to 2020. Graft and patient outcomes are analyzed by logistic regression models.
Results: A total of 92 patients underwent deceased donor LT for PSC with a mean follow-up time of 9.2 yrs (SD 7.1). Fifty-three remain active in the program, 2 were lost to follow-up and 37 died. The mean age at transplant was 43 (SD13, range 18.9–67.8). Seven patients had a second transplant. The five- and 10-year patient survival rate of the entire cohort was 78.7% and 66% respectively. In the active cohort, the

prevalence of rPSC was 23.5% (12/51). Retransplantation for rPSC occurred in 8.3% (1/12). The prevalence of IBD was 82.4% (42/51), consisted of ulcerative pancolitis (64.7%, 33/51), ulcerative proctitis (3.9%), left-sided UC (2%) and Crohn's disease (9.8%). Males are much more likely than females to undergo a colectomy at any time (OR 5.5, 95% CI 1.07–28.22, p 0.041). Refractory IBD was the predominant indication for a colectomy (10/16), followed by dysplasia or colon cancer (6/16). In the post-transplant period, 69% had stable IBD without therapy escalation, 11.9% were escalated to a biologic, 19% underwent a colectomy for active IBD symptoms. Pretransplant colectomy negatively predicted rPSC, in this subgroup 0% (0/6) developed rPSC. Neither recipient sex (OR 1.14, 95% CI 0.26–5.0, p 0.86) or recipient age predicted the likelihood of rPSC. There was no association between donor sex on rPSC (OR 1.25, 95% CI 0.30–5.27, p 0.76). A trend towards increased rPSC was observed in male donors to female recipients versus female-to-female transplants (OR 6, 95% CI 0.33–107.42, p 0.224). Overall, having a post-transplant colectomy, subtotal or total, irrespective of timing, did not significantly impact rPSC (OR 0.389, 95% CI 0.09–1.66, p 0.20). Diagnosis of IBD was not associated with an increased risk of rPSC (OR 1.21, p 0.83).

Conclusion: Several factors were associated with rPSC after liver transplant in patients with PSC and IBD, pre-transplant colectomy was found to be protective, male donor to female recipient was a potential risk factor. It is important to study these factors in multi-centered cohorts to understand the pathogenesis of PSC. Pretransplant total colectomy may be beneficial for several reasons, reducing rPSC, controlling IBD activities, and lowering dysplasia and colon cancer rates in the post-transplant population.

SAT285

Predictive factors of antibody response after anti-SARS-CoV-2 vaccine in liver transplant recipients

Ilias Kounis[1], Bruno Roche[1], Lea Duhaut[1], Rodolphe Sobesky[1], Eleonora De Martin[1], Edoardo Poli[1], Alina Pascale[1], Gabriella Pittau[1], Oriana Ciacio[1], Jean-Charles Duclos-Vallée[1], Didier Samuel[1], Cyrille Feray[1], Audrey Coilly[1]. *[1]AP-HP Hôpital Paul-Brousse, Centre Hépato-Biliaire;, Inserm, Université Paris-Saclay, UMR-S 1193;, Université Paris-Saclay, Inserm, Physiopathogénèse et traitement des maladies du Foie;, FHU Hepatinov, Villejuif, France*
Email: ilias.kounis@aphp.fr

Background and aims: A weak immune response to 2 doses of anti SARS-CoV2 vaccine was observed in solid-organ transplant recipients, encouraging the authorities to recommend a third dose in immunosuppressed patients. The aim of our study was to search for predictive factors of an antibody response to the vaccines and describe their efficacy and tolerance in a large population of liver transplant (LT) recipients.

Method: This is retrospective monocenter study conducted at Paul Brousse Hospital in France. All adult LT recipients followed up in our transplant center and vaccinated with at least one dose of vaccine from January 2021 to September 2021 were included. A strong immune response to vaccination was defined as the presence of antibodies titration to SARS-CoV-2 spike protein up to 250 U/ml after 2nd or 3rd dose of vaccine.

Results: 745 patients were included. Of them, 642 (85.5%) had 2 doses and 343 (46%) patients had three. Mean age at vaccination was 59.1 (± 14.5) years and mean time from LT to vaccination was 12.1 (± 9.7) years. Immunosuppression was due to one immunosuppressive drug in 29.7% of patients, 2 drugs in 57.6% and 3 drugs in 12.5%. The prevalence of anti-SARS-CoV-2 antibodies was 11% (19 patients) before the first dose, 40.8% (53 patients) before the second dose, 66.2% (392 patients) before the third dose, and 72.5% (271 patients) after the third dose. 190 (36.7%) patients had a strong antibody titration after 2nd injection and 139 (47.6%) after 3rd injection. Patients who had strong antibody response had, in time of vaccination, lower Tacrolimus blood concentrations (p = 0.04), lower Mycophenolate (p < 0.001) and corticosteroid doses (p = 0.009), lower creatinine (p = 0.04), higher hemoglobin (p < 0.001) levels and longer time between LT and vaccination (p = 0.004). In multivariate analysis, predictive factors of strong response were time since LT >9.8 years (p = 0.001), while creatinine levels >95 µmol/l (p = 0.014), use of corticosteroids (p < 0.001) and high mycophenolate dose (p < 0.001) in time of vaccination were correlated with an absence of strong response to the vaccine. Fifteen (2%) patients had COVID after vaccination, 2 of them after 3 doses of vaccine. No serious adverse events were for 99.7% of patients.

Conclusion: A strong immune response was detected to less than a half of LT recipients after 3 doses of anti-SARS-CoV-2 vaccine. These patients remain at risk for Covid-19, especially if they had a recent LT or have high levels of immunosuppression.

SAT286

Immunotherapy before solid organ transplantation: an international transplant community-focused survey

Tommy Ivanics[1,2,3], Marco Claasen[1,4], David Al-Adra[5], Gonzalo Sapisochin[1]. *[1]University Health Network, Multi-Organ Transplant Program, Toronto, Canada; [2]Henry Ford Hospital, Department of Surgery, Detroit, United States; [3]Uppsala University, Department of Surgical Sciences, Akademiska Sjukhuset, Uppsala, Sweden; [4]Erasmus MC, Department of Surgery, Rotterdam, Netherlands; [5]University of Wisconsin-Madison, Division of Transplantation, Madison, United States*
Email: tommy.ivanics@uhn.ca

Background and aims: The use of immunotherapy for cancer has increased and is expected to continue to grow. The outcomes after solid organ transplantation (SOT) in patients having received immunotherapy before SOT remain unclear. We sought to evaluate the global transplant surgery community's attitude and experience with patients who have received immunotherapy for malignancy before SOT.

Method: An online-based survey was sent to North American transplant directors in December-2020 and to members of the International Liver Transplant Society (ILTS) in November-2021 to evaluate experiences with, and attitudes towards, SOT in recipients with previous immunotherapy for cancer. Descriptive summary statistics were reported.

Results: 134 respondents provided consent to participate in the survey and 91 completed the survey for a completion rate of 68%. Respondents represented center experience from North America, South America, Europe, Asia, and Australia. Most represented centers from the United States (n = 22, 24%), followed by India (n = 9, 10%), and Spain (n = 4, 4%). Fifty-eight (64%) respondents would consider offering a SOT to a patient with previous history of immunotherapy for cancer. Thirty (33%) respondents were aware of such recipients receiving immunotherapy for cancer before a SOT. The majority (n = 69, 77%) of respondents reported an absence of institutional clinical management policies in this setting.

Conclusion: Though this survey's response rate was relatively low, it provides preliminary insight into the attitudes and experiences with SOT after immunotherapy for cancer in the international transplant community. This represents a clinical scenario for which outcomes should be clarified and consensus guidelines established to inform future clinical management, especially as immunotherapy for cancer is likely to increase in coming years.

	Overall (N=139)

	UK	0.60 (0.60 to 0.60)	0.05 (0.05 to 0.05)
	US	0.63 (0.63 to 0.63)	0.06 (0.06 to 0.07)

Abbreviations: AUPRC: Area under precision-recall curve, AUROC: Area under receiver-operator characteristic, CA: Canada, UK: United Kingdom, US: United States

Figure: (abstract: SAT287)

three national registries and developed machine learning algorithm (MLA)-based models that were used to evaluate performance predictions both within and across these different countries.
Method: We studied adults (≥18-years) who underwent primary LT between Jan-2008 and Dec-2018 from United Network for Organ Sharing (UNOS-US), National Health Service Blood and Transplantation (NHSBT-UK), and the Canadian Organ Replacement Registry (CORR-Canada). MLA models for 90-day post-LT mortality were built firstly on each individual registry's capacity (based on variables inherent to the individual database) and then based on the overlapping variables available in all three registries (based on harmonized variables). The predictive abilities of the harmonized registry models were evaluated externally across countries using area-under-the-receiver-operator-curve (AUROC) and area-under-the-precision-recall-curve (AUPRC).
Results: The total number of patients were as follows: training (2008–2015) (Canada:n = 827;UK: n = 3, 388;US: n = 40, 454), validation (2016) (Canada:n = 126;UK:n = 621;US:n = 6, 128), and testing (2017–2018) (Canada:n = 261;UK:n = 1, 278;US:n = 12, 976). The best performing MLA-based model was the ElasticNet across both multiply imputed independent and harmonized datasets (best performance in the US:AUROC:0.70;Range:0.70–0.71). Model performance diminished from the independent to the harmonized (only using variables that were in common between the three registries) registries, especially in the UK (independent ElasticNet:AUROC:0.54; Range 0.52–0.56 to harmonized AUROC:0.48; Range:0.48–0.50) and the US (independent ElasticNet:AUROC:0.70;Range:0.70–0.71 to harmonized AUROC:0.65;Range:0.64–0.65). Model performance after external validation across countries was overall poor (Table 1).
Conclusion: MLA-based models can be constructed using international LT registries, with independent ElasticNet models demonstrating optimal predictive performance. While MLA-based model performance yields fair discriminatory potential, a diminishing number of variables and granularity results in decreased performance. Moreover, the external validity of such MLA-based models is poor when applied to other transplant registries. This is likely due to inherent limitations and variability within each dataset. As such, it is conceivable that these limitations may be overcome in the future by increasing the granularity of datasets (for example, with linkages to other administrative datasets), and placing an increased emphasis on consensus for variable standardization (such as with increased collaboration and communications across transplant data collecting organizations).

Liver transplant recipients have a higher incidence of lung cancer than general population

Paula Pujols[1], Fanny Meylin Caballeros[2], Mercedes Iñarrairaegui[3], Javier Zulueta[4], Gorka Bastarrika Alemañ[3], Jose Ignacio Herrero[3].
[1]University of Navarra, Pamplona, Spain; [2]Clínica Universidad de Navarra, Madrid, Spain; [3]Clinica Universidad de Navarra, Pamplona, Spain; [4]Mount Sinai Morningside, New York, United States
Email: iherrero@unav.es

Background and aims: De novo malignancies are frequent complications after liver transplantation. Liver transplant recipients (LTRs) have a higher risk of lung cancer than the general population, but it may be due to a higher frequency of smoking. Our aim was to compare the incidence of lung cancer in LTRs with respect to a matched group of control candidates.
Method: In this retrospective study, 124 LTRs and 496 controls participating in a lung cancer screening program with low-dose computed tomography (LDCT) were compared. Four controls were matched for each LTR according to gender, age (± 10 years), current smoking status, cumulative smoking (± 10 pack-years) and presence of emphysema on initial LDCT examination. The results of our lung cancer screening program in LTRs were also evaluated.
Results: Twelve LTRs (9.7%) and 28 controls (5.6%) were diagnosed with lung cancer. The actuarial risks of lung cancer at 3, 5, 7 and 10 years were 3.3%, 4.5%, 8.3% and 18.2% for LTR and 3%, 3.4%, 4% and 7.1% for controls, respectively (p = 0.038). The most important predisposing factors for lung cancer were a higher age and the presence of emphysema.
Ten of the12 LTRs with lung cancer were diagnosed with stage IA. At the end of the follow-up, six patients had died (two of them from lung cancer progression and one from chemotherapy-related sepsis). Nine patients were free of malignancy at their last follow-up.

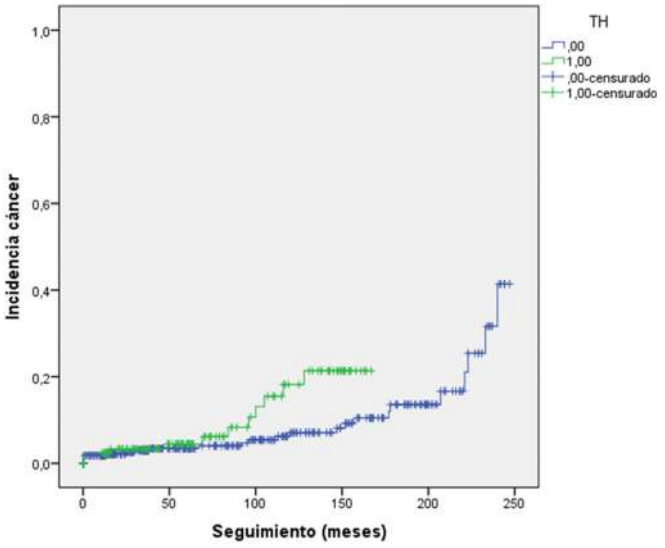

Figure: Comparison of the risk of lung cancer in LTR with respect to controls. (abstract: SAT288)

Conclusion: LTRs have a higher risk of lung cancer than the general population. LDCT allows early diagnosis of lung cancer in tyhis patient population.

SAT289

Survival benefit-based priority of liver transplantation in HBV-related acute-on-chronic liver failure

Peng Li[1], Xi Liang[2], Jinjin Luo[1], Jiaqi Li[1], Jiaojiao Xin[1], Jing Jiang[1], Dongyan Shi[1], Yingyan Lu[3], Hozeifa Mohamed Hassan[2], Qian Zhou[1], Shaorui Hao[1], Huafeng Zhang[1], Tianzhou Wu[2], Tan Li[1], Heng Yao[1], Keke Ren[1], Beibei Guo[1], Xingping Zhou[1], Jiaxian Chen[1], Lulu He[1], Hui Yang[1], Wen Hu[1], Shiwen Ma[1], Bingqi Li[1], Shaoli You[4], Shaojie Xin[4], Yu Chen[5], Jun Li[1]. *[1]The First Affiliated Hospital, Zhejiang University School of Medicine, State Key Laboratory for Diagnosis and Treatment of Infectious Diseases, Hangzhou, China; [2]Taizhou Central Hospital (Taizhou University Hospital), Precision Medicine Center, Taizhou, China; [3]Tongde Hospital of Zhejiang Province, Key laboratory of cancer prevention and therapy combining traditional Chinese and Western Medicine, Hangzhou, China; [4]The Fifth Medical Center of PLA General Hospital, Senior Department of Hepatology, Beijing, China; [5]Beijing Youan Hospital, Capital Medical University, Beijing Municipal Key Laboratory of Liver Failure and Artificial Liver Treatment Research, Fourth Department of Liver Disease, Beijing, China*
Email: lijun2009@zju.edu.cn

Background and aims: Acute-on-chronic liver failure (ACLF) is a life-threatening syndrome characterized by multiorgan failure and high short-term mortality rates. Liver transplantation (LT) is an effective therapy but is limited by organ shortages. Survival benefit-based priority for LT is important to decrease the risk of futile transplantation. This study aimed to identify an appropriate prognostic score for determining LT priority for ACLF patients who have a high survival benefit rate.

Method: Hospitalized patients with acute deterioration of hepatitis B virus-related chronic liver disease (n = 4577) from the Chinese Group on the Study of Severe Hepatitis B (COSSH) study cohort were enrolled between January 2015 and December 2020. The performance of five commonly used scores (COSSH-ACLF IIs, COSSH-ACLFs, CLIF-C ACLFs, MELDs and MELD-Nas) for predicting the outcome on the waitlist and post-LT at days 28/90/180/365 were evaluated. The survival benefit based on the extra lifespan derived from LT was calculated by the difference in the area under the survival curve between patients with and without LT.

Results: A total of 368 ACLF patients and 98 non-ACLF patients received LT. The 1-year survival probability of 368 ACLF-LT patients (77.2%) was significantly higher than that of non-LT patients in both the ACLF entire cohort (52.3%) and the propensity score matching (PSM) cohort (27.6%) (all p <0.001). However, 98 non-ACLF patients who underwent LT showed a lower survival probability than 2625 without LT (88.8%/92.3%, p = 0.20), and PSM analysis demonstrated no significant improvement in survival probability (88.8%/81.4%, p = 0.16). The receiver operating characteristic curve showed that the COSSH-ACLF II score had the highest performance (0.849) for identifying the 1-year risk of death on the waitlist and was also superior (0.864) for predicting 1-year outcome post-LT to the four other scores (COSSH-ACLFs/CLIF-C ACLFs/MELDs/MELD-Nas, 0.835/0.825/0.796/0.781; all p <0.05). Survival benefit rate analyses showed that 79.1% of ACLF patients with COSSH-ACLF IIs of 7–10 had a much higher 1-year survival benefit rate (39.2%-64.3%) than those with scores <7 or >10 (all p <0.001).

Conclusion: The COSSH-ACLF IIs not only identified the risk of death on the waitlist but also accurately predicted post-LT mortality and survival benefit rates for ACLF. Patients with COSSH-ACLF IIs of 7–10 should be prioritized for LT. Our findings can help to decrease the risk of futile transplantation and develop new clinical strategies for ACLF patients.

SAT290

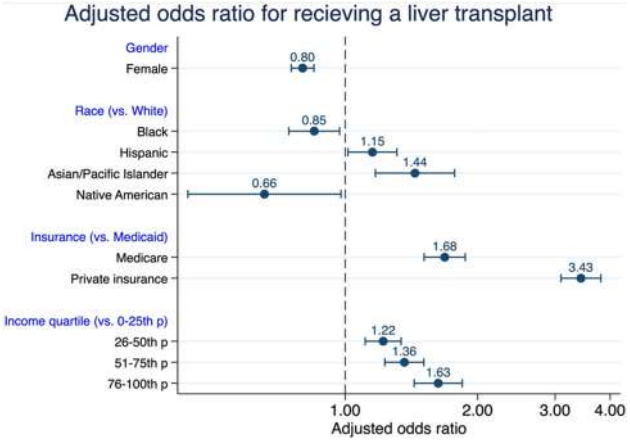
Social determinants of health and racial disparities in liver transplant: a nation wide analysis

Mahmoud Mansour[1], Adham Obeidat[2], Mohammad Darweesh[3], Ratib Mahfouz[4], Sanket Basida[5], Ahmad Ali[6]. *[1]University of Missouri Columbia, Internal Medicine, Columbia, Missouri, United States; [2]University of Hawaii, Internal Medicine, Honolulu, Hawaii, United States; [3]East Tennessee State University, Internal medicine, Johnson City, Tennessee; [4]Kent Hospital/Brown University, Internal Medicine, Warwick, Rhode Island, United States; [5]Upadhyay Medical College, Medicine, Gujarat, India; [6]University of Missouri Columbia, Hepatology, Columbia, Missouri, United States*
Email: aliah@health.missouri.edu

Background and aims: Liver transplantation is a life-saving treatment and standard of care for many forms of end-stage liver disease. Unfortunately, 20 percent of patients on liver transplant list die while on the waiting list, with several studies showing racial, gender and socioeconomic disparities among patients receiving a liver transplant. We sought to evaluate disparities amongst patients receiving liver transplant in the United States using the most recently available data from the National Inpatient Sample (NIS).

Method: We performed analysis of discharge data from the NIS between Jan 1st, 2016, to Dec 31st, 2019. We identified adult patients who underwent liver transplant using International Disease Classification of Disease 10th Procedure Coding System (ICD-10-PCS). Multivariate logistic regression was used to evaluate for differences in race, gender and socioeconomic status among those who received a liver transplant.

Results: A total of 29, 050 liver transplants were performed during the study period. Compared to White patients, Black and Native America patients had decreased transplant rates (adjusted odds ratio [aOR] 0.85, p = 0.017 and 0.66, p = 0.039; respectively) while Hispanic and Asian/Pacific Islander patients had increased transplant rates (1.15, p = 0.029 and 1.44 p = 0.001; respectively). The increase in income quartile was associated with an incremental increase in transplant rates. Additionally, patients with private insurance had much higher transplant rates compared to those with Medicaid (aOR 3.43, p < 0.001). Female gender was independently associated with decreased transplant rates (aOR 0.80, p < 0.001).



Conclusion: Our analysis showed that race and social determinants of health, including gender, income, and insurance status, are associated with the likelihood of receiving a liver transplant in the United States. Our study confirms, on a national level, previously described disparities in receiving liver transplantation. Patient-level studies are needed to understand better why disparities in liver transplant exist to achieve a more equitable distribution of this scarce resource.

SAT291

Reduced neutralization efficacy against SARS-CoV-2 Omicron variant after third boost of mRNA BNT162 vaccine among liver transplant recipients

Yana Davidov[1], Victoria Indenbaum[2], Michal Mandelboim[2,3], Keren Asraf[4], Tal Gonen[2,3], Keren Tsaraf[1], Oranit Cohen-Ezra[1], Mariya Likhter[1], Gil Ben Yaacov[1], Ital Nemet[2], Limor Kliker[2,3], Orna Mor[2,3], Ram Doolman[4], Carmit Cohen[5], Arnon Afek[3,6], Yitshak Kreiss[3,6], Gili Regev[3,5], Yaniv Lustig[2,3], Ziv Ben Ari[1,3]. *[1]Sheba Medical Center, Liver Diseases Center, Tel Aviv-Yafo, Israel; [2]Sheba Medical Center, Central Virology Laboratory, Ministry of Health, Tel-Hashomer, Tel Aviv-Yafo, Israel; [3]Tel Aviv University, Sackler School of Medicine, Tel Aviv-Yafo, Israel; [4]Sheba Medical Center, The Dworman Automated Mega Laboratory, Tel Aviv-Yafo, Israel; [5]Sheba Medical Center, Infection Prevention and Control Unit, Tel Aviv-Yafo, Israel; [6]Sheba Medical Center, General Management, Tel Aviv-Yafo, Israel*
Email: y.davidov@gmail.com

Background and aims: The immune response of solid organ transplant recipients to the two doses of the BNT162b2mRNA vaccine is impaired (72%). However, improved immune response was noted after the third boost. The durability and effectiveness of the

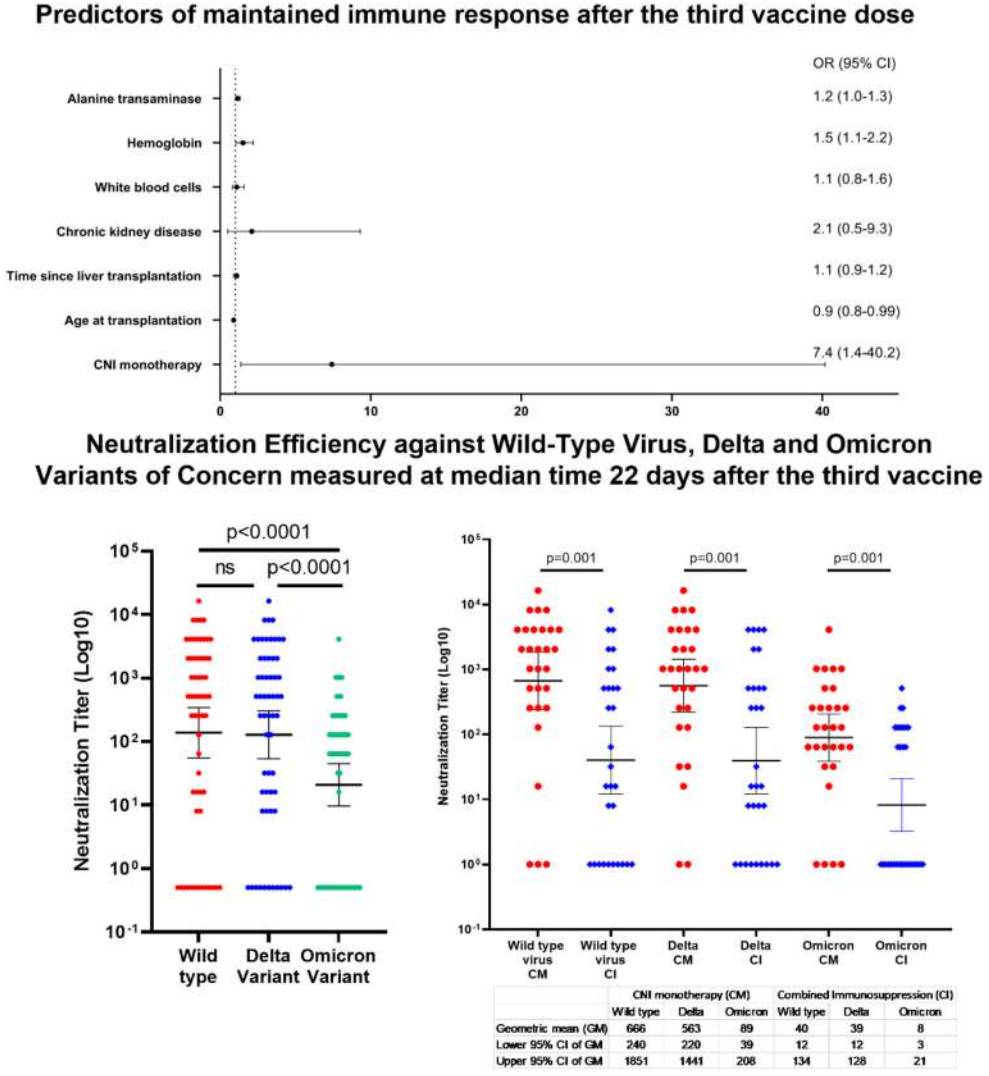


Figure: (abstract: SAT291)

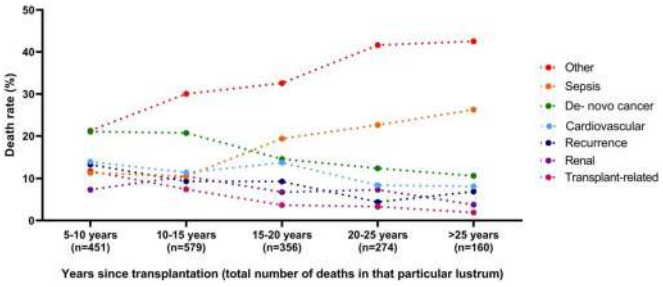
immune response after the third boost are unknown as well as the impact of the emergence of new variants. We aimed to evaluate for the first time, the durability of the response after the third BNT162b2mRNA vaccine among liver transplant recipients, its predictors, and the impact of emerged variants (VOC).
Method: Consecutive 59 liver transplant (LT) recipients, who received three doses of BNT162b2mRNA vaccine and followed-up at the Sheba Medical Center were included. Receptor-biding domain (RBD) IgG, pseudo-virus (pvSARS-2) neutralization antibody (NA) titers, and T cells levels were determined 4 ± 1 weeks and 19 ± 3 weeks after the third vaccine. IgG antibody titer above 21.4 BAU/ml was defined as a positive response. A comparison between the neutralization efficacy of the vaccine among wild type, omicron, and delta variants 4 ± 1 weeks after the third vaccine was conducted.
Results: The 59 LT recipients were of a median age of 61 years (ranges, 25–82); 53.5% were male. Four weeks after the third vaccine, a positive humoral immune response was detected in 81.4%. It decreased significantly 19 ± 3 weeks after the third boost to 76.1%, $p < 0.0001$. The geometric mean titers (GMT) of anti-RBD IgG decreased from 483 BAU/ml to 204 BAU/ml ($p < 0.0001$), pvSARS-2 NA 653 to 450 ($p = 0.2$), and T cell 223 to 30 cells per 10^6 PMC ($p < 0.0001$) four weeks and 19 weeks respectively. Following multivariate analysis, the independent predictors associated with maintaining a positive immune response 19 weeks after the third vaccine were CNI monotherapy ($p = 0.02$) and Hemoglobin >11.5 g/dl ($p = 0.02$). The GMT of omicron neutralization was significantly lower than wild-type, and delta virus and were 21.72, 140. 131, respectively ($p < 0.0001$). We evaluated the impact of CNI monotherapy vs. combined immunosuppression (combination of CNI with MMF or mTOR or prednisone) on neutralization efficacy of VOC. The GMT of the wild type, delta, and omicron variants were significantly higher among LT recipients who received CNI monotherapy than combined immunosuppression and were 666, 563, 89 and 40, 39, 8, respectively, ($p = 0.01$).
Conclusion: The immune response after the third BNT162b2mRNA boost vaccine decreased significantly and rapidly among LT recipients. CNI monotherapy was a predictor of durability. The neutralization efficacy against the omicron variant was reduced significantly. Further studies are needed to evaluate the efficacy of a fourth vaccine dose on the durability of the immune response and protection against symptomatic COVID 19 disease.

SAT292

Long-term outcomes (beyond 5 years) of liver transplant recipients-a transatlantic multicentre study

Naaventhan Palaniyappan[1], Emily Peach[1], Fiona Pearce[1], Amritpal Dhaliwal[2], Isabel Campos-Varela[3], Matthew Cant[2], Cristina Dopazo[3], Sapna Divani-Patel[2], James F. Trotter[4], Ayiesha Hatta[2], Laurence Hopkins[2], Giuliano Testa[4], Angela Bilbao[3], Zain Kasmani[2], Sarah Faloon[2], Darius F. Mirza[2], Goran Klintmalm[4], Itxarone Bilbao[3], Sumeet Asrani[4], Neil Rajoriya[2], Aloysious Aravinthan[1]. *[1]University of Nottingham, Nottingham, United Kingdom; [2]Queen Elizabeth Hospital Birmingham, United Kingdom; [3]Vall d'Hebron Hospital Universitari, Barcelona, Spain; [4]Baylor University Medical Center, Dallas, United States*
Email: naaventhan.palaniyappan@nottingham.ac.uk

Background and aims: Long-term (>5 year) outcomes following liver transplantation (LT) have not been extensively reported upon, in contrast to established short-term and medium-term outcomes. The aim was to evaluate survival outcomes of recipients who have survived the first 5 years following LT.
Method: A retrospective analysis of prospectively collected data from 3 high volume centres (Dallas, USA; Birmingham, UK; and Barcelona, Spain) was undertaken. Data were extracted of all adult patients, who underwent LT since the inception of the programme in the respective centres to 31 December 2010, and who survived at least 5 years since their first LT. Patient survival was the primary outcome measure. Age-standardised mortality rates stratified by sex were calculated for each centre and compared with respective jurisdiction mortality rates of the general population.
Results: A total of 3, 682 patients who survived at least 5 years following LT were included. Overall, median age at LT was 52 years (IQR 44–58); 53.1% were males; and 84.6% were Caucasians. 49.4% (n = 1, 820) died during a follow-up period of 36, 828 person-years (mean 10 years). 80.2% (n = 1460) of all deaths were premature deaths, defined as death before the age of 75 years (USA and UK) and 65 years (Spain). Age-standardised all-cause mortality as compared to general population was 3 times higher for males and 5 times higher for females. On adjusted analysis, besides older recipients (HR 2.09, 95%CI 1.44–3.04) and older donors (1.38, 95%CI 1.11–1.72), predictors of long-term mortality were pre-LT malignancy (HR 1.28, 95%CI 1.02–1.61), pre-LT CVD (HR 1.35, 95%CI 1.11–1.65) and post-LT dialysis (HR 2.40, 95%CI 1.56–3.68).



Conclusion: This study demonstrates an increased mortality rate in LT recipients even after 5 years of transplantation. It is likely that implementation of simple strategies such as non-invasive cancer screening measures, minimisation of immunosuppression and intensive primary/secondary cardiovascular prevention could further improve survival of organ recipients.

SAT293

Hepatic evaluation of patients with telomeropathies

Olivia Portolese[1], Isaac Ruiz[1], Julien Bissonnette[1], Julian Hercun[1], Helene Castel[1], Bernard Willems[1], Marc Bilodeau[1], Jeanne-Marie Giard[1], Catherine Vincent[1], Ziad Hassoun[1], Geneviève Soucy[2], Bich Ngoc Nguyen[2], Basil Nasir[3], Pasquel Ferraro[3], Julie Morisset[4], Charles Poirier[4], Genevieve Huard[1]. *[1]Centre hospitalier de l'Universite de Montréal (CHUM), Liver division, Montréal, Canada; [2]Centre hospitalier de l'Universite de Montréal (CHUM), Department of Pathology, Montréal, Canada; [3]Centre hospitalier de l'Université de Montréal (CHUM), Division of Thoracic Surgery; [4]Centre hospitalier de l'Université de Montréal (CHUM), Division of pulmonary medicine, Canada*
Email: isaac.ruiz@me.com

Background and aims: Telomeropathies arise from an inheritable genes mutations resulting in decreased telomere length and impaired telomere maintenance. The most frequent manifestation of telomeropathy in adults is interstitial lung disease (ILD) that can lead to consideration for lung transplantation. Liver and bone marrow involvement have also been described. Liver assessment in this population is not well described in the current literature.
The aim of this study was to describe the liver evaluation and findings of patients with telomeropathies and ILD that were evaluated for liver and lung transplantation.
Method: This is a retrospective analysis of a prospectively recruited real-world cohort including all patients between January 2020 and December 2021 who consulted the pulmonary and hepatology units at the Centre hospitalier de l'Université de Montréal (CHUM) for liver and lung transplantation. Diagnosis of telomeropathy was confirmed by sequence analysis and/or telomere length (flow-fish analysis). Demographic, clinical, biological, radiological and pathological data were collected. Liver fibrosis was assessed by elastometry (FibroScan,

Echosens, France) and/or histological analysis of a transjugular liver biopsy.

Results: For this analysis, 17 patients were included. Table 1 shows the main characteristics of the cohort. Mean age was 60 years (50–69) and 10 of 17 patients (58.8%) were male. The main raison for the hepatology consultation was pre-operatory evaluation for lung or liver transplantation. Sixteen of the 17 (94.1%) patients had at least one comorbidity. The biological evaluation showed a macrocytosis with a mean corpuscular volume of 95.1 fL (83.0–104.0). Mean platelet count was 203.3 x10^9L (62.0–485.0).

Transient elastography was available for 15 of 17 (88.2%) patients, mean elasticity was 8.9 kPa (3.7–28.0) and the mean CAP was 247 dB/m (168.0–358.0). Five of 17 (29.4%) patients had a transjugular liver biopsy following abnormal elastography result. Mean gradient was 9.4 (4.0–17.0). Steatosis was present in 4/5 cases (80.0%) and cirrhosis in 4/5 cases (80.0%).

One patient out of 17 (5.9%) had an isolated liver transplantation for decompensated cirrhosis and 10/17 (58.8%) had a lung transplantation. No patient underwent combined lung/liver transplantation.

Conclusion: In patient with telomeropathy undergoing liver/lung transplantation evaluation at least 4/17 (23.5%) had a cirrhosis. Transplantation evaluation should include a hepatology consultation, screening and management of comorbidities, a complete etiological assessment of liver diseases, assessment of the portal hypertension and non-cirrhotic portal hypertension and liver fibrosis via transient elastography and transjugular liver biopsy with hepatic venous pressure gradient measurement.

Third dose of SARS-COV2 mRNA-vaccine in liver transplant recipients: can it bridge the response gap?

Marzia Montalbano[1], Raffaella Lionetti[2], Ubaldo Visco Comandini[1], Silvia Meschi[3], Chiara Agrati[3], Federica Conte[4], Vincenzo Puro[3], Paola Piccolo[5], Giulia Matusali[3], Germana Grassi[3], Tiziana Mereu[1], Federica Angelone[3], Enrico Girardi[3], Giuseppe Maria Ettorre[6], Giampiero D'Offizi[1]. *[1]National Institute for infectious diseases Lazzaro Spllanzani, POIT; [2]National Institute for infectious diseases Lazzaro Spallanzani, POIT; [3]National Institute for infectious diseases Lazzaro Spllanzani; [4]Institute for Systems Analysis and Computer Science "Antonio Ruberti"; [5]San Giovanni Calibita, Fatebenefratelli Hospital; [6]San Camillo Hospital, POIT*

Email: raffaella.lionetti@inmi.it

Background and aims: Liver transplant recipients (LTRs) show reduced immunological response after 2-dose mRNA vaccine against SARS-CoV2: stronger immunosuppression, time from transplant (TFT) and mycophenolate mofetil (MMF) were related to non-response (NR; D'Offizi, Liver Int 2021). Some studies indicated an additional vaccine dose could improve response. Aim of our study is to assess the effect of a third dose on mRNA vaccine response in LTRs.

Method: 181 consecutive LTRs (median age 63 years, M/F 149/32) were tested for humoral response before first dose (T0), before second dose (T1), 2 weeks after second dose (T2), before third dose (T3), at 4 (T4) and 12 weeks (T5) after third dose; and for cellular response via Th1 production of interferon-γ (IFN-γ) at T3, T4, T5. Anti-spike IgG (RBD) and neutralizing antibodies (N-Ab) were measured and results expressed as median. NR was defined as titre <7.1 binding antibody units (BAU) for RBD; Micro-Neutralization Assay <5 for N-Ab. NR was defined as <10 pg/ml for IFN-γ. TFT groups were defined by a cut-off of more or less than 6 years.

Results: After 2-dose vaccine, 31 LTRs (17%) were non-responders for RBD and 74 (40.6%) for N-Ab. After third dose, a positive response for RBD and N-Ab was observed in 27 (87%) and 61 (82.4%) LTRs with previous NR, respectively.

Overall, MMF was a significant negative predictive factor for RBD ($p < 0.001$) and N-Ab ($p = 0.003$) response at T2, but not at T4 and T5.

Among responders, RBD titre was lower in LTRs receiving MMF at T2 (180 BAU vs. 278 BAU, $p < 0.05$) and at T4 (2331 BAU vs. 4009 BAU, $p < 0.05$), while N-Ab titre was lower only at T4 (160 vs. 320, $p < 0.05$).

Overall, we observed significantly higher response among LTRs with TFT >6 years vs. <6 years at all time points ($p = 0.0001$ and $p = 0.0004$; $p = 0.026$ and $p < 0.0001$; $p = 0.025$ and $p < 0.0001$ at T2, T4, T5 for RBD and N-Ab, respectively).

Among responders, RBD titre was higher among LTRs with TFT >6 years vs. <6 years at T2 (337 BAU vs. 113 BAU, $p < 0.05$), at T4 (3407 BAU vs. 1402 BAU, $p < 0.0001$), and at T5 (1927 BAU vs. 693 BAU, $p < 0.0001$). N-Ab titre was significantly higher only at T5 (160 vs. 80, $p < 0.05$).

IFN-γ production correlated with humoral response at all time points ($r = 0.4$, $p < 0.0001$ and $r = 0.32$, $p < 0001$ at T3; $r = 0.29$, $p = 0.0007$ and $r = 0.32$, $p = 0.0004$ at T4; $r = 0.3$, $p = 0.0006$ and $r = 0.35$, $p < 0.0001$ at T5 for RBD and N-Ab, respectively). None of the analysed variables influenced IFN-γ response.

Liver disease aetiology and comorbidities (diabetes, cancer, obesity, HIV positivity) did not influence response after third vaccine dose.

Conclusion: A third dose enhances antibody response in LTRs who had a poor response after an initial 2-dose mRNA vaccination to SARS-CoV2. However, MMF and TTF <6 years were associated with lower titres for RBD and N-Ab after the third dose. Further clinical studies should assess whether this enhanced response correlates to a favourable clinical outcome after breakthrough SARS-CoV2 infection.

SAT295

Protein-energy malnutrition is associated with worse outcomes in patients admitted for liver transplant: analysis of national inpatient sample

Mahmoud Mansour[1], Ratib Mahfouz[2], Mohammad Darweesh[3], Adham Obeidat[4], Nikolaos T. Pyrsopoulos[5]. *[1]University of Missouri Columbia, Internal Medicine, Columbia, Missouri, United States; [2]Kent Hospital/Brown University, Internal Medicine, Warwick, Rhode Island, United States; [3]East Tennessee State University, Internal Medicine, Johnson City, Tennessee, United States; [4]University of Hawaii, Internal Medicine, Honolulu, Hawaii, United States; [5]Rutgers-New Jersey Medical School, Gastroenterology and Hepatology, Rutgers, New Jersey, United States*
Email: pyrsopni@njms.rutgers.edu

Background and aims: Protein-energy malnutrition (PEM) is a common complication in liver cirrhosis patients, with an estimated prevalence of 25.1 to 65.5%. PEM among cirrhotic patients has been associated with increased morbidity and mortality. The data on the in-hospital outcomes of patients who underwent liver transplantation with co-existing PEM is limited. In this study we sought to evaluate the impact of PEM on patients who underwent liver transplantation.

Method: The United States Nationwide Inpatient Sample was used to search for patients who underwent liver transplantation between Jan 1st, 2016, to Dec 31st, 2019. Using International Classification of Diseases 10th revision codes, we divided patients into two groups based on the presence or absence of PEM. The NIS-provided discharge-level weights were used to reflect prevalence estimates. The primary outcome was in-hospital mortality. Secondary outcomes were intensive care unit (ICU) admission, length of stay (LOS), and hospital charges. Multivariate logistic regression was used to adjust for comorbidities and demographic variables.

Results: Among the 29, 050 patients who underwent liver transplantation, 7, 650 (26.33%) had the diagnosis of PEM. Patients with PEM had higher mortality, ICU admission, mean LOS, and hospital charges compared to those without PEM. After adjusting for potential confounders, PEM was an independent predictor of worse outcomes in patients undergoing liver transplantation. Adjusted odds ratio was 1.64, (p = 0.008) for mortality, and 1.88 (p <0.001) for ICU admission. Adjusted mean for LOS and total hospital charges increased by 14.49 days and $323, 270, respectively, for liver transplant patients with PEM compared to those without PEM.

Table: In-hospital outcomes of patients undergoing liver transplant with and without a diagnosis of protein-energy malnutrition (PEM).

Outcome	Without PEM	With PEM (p value)	aOR (95% CI)
In-hospital mortality (%)	2.50%	4.05% (<0.001)	1.64 (1.14–2.36)
ICU admission (%)	5.42%	9.76% (<0.001)	1.88 (1.58–2.24)
Mean length of stay (days)	16.40	30.75 (<0.001)	14.49* (12.15–16.82)
Mean hospital charges (US$)	513, 902	832, 365 (<0.001)	322, 270* (253, 832–392, 708)

*Adjusted mean difference
Abbreviations: PEM: protein energy malnutrition, CI: confidence interval, aOR: adjusted odds ratio

Conclusion: PEM is associated with increased morbidity, mortality, and hospital burden in patients admitted for liver transplantation. Timely nutrition assessment and intervention in liver transplant recipients may improve outcomes.

SAT296

COVID vaccination among liver transplant recipients: A EASL-ESOT/ELITA-ILTS multi society survey

Carmen Vinaixa[1,2], Francesco Paolo Russo[3], Luca Saverio Belli[4], Wojciech Polak[5], Manhal Izzy[6], Varvara Kirchner[7,8], Tommaso Di Maira[1,2], Ashwin Rammohan[9], Thomas Berg[10], Marina Berenguer[1,2,11]. *[1]Hospital Universitario y Politécnico La Fe, Hepatology and Liver Transplantation Section, Digestive Diseases Department, Valencia, Spain; [2]Instituto de Salud Carlos III, Madrid, Spain; [3]Azienda Ospedale-Università Padova, Gastroenterology and Multivisceral Transplant Unit Department of Surgery, Oncology and Gastroenterology, Padua, Italy; [4]Dipartimento Medico Polispecialistico, Milan, Italy; [5]Erasmus MC, Department of Surgery Division of HPB and Transplant Surgery, Rotterdam, Netherlands; [6]Vanderbilt University, Nashville, United States; [7]Minessota, United States; [8]Stanford University, Division of Abdominal Transplantation, Department of Surgery, Stanford, United States; [9]Dr Rela Institut and Medical Center, Chennai, India; [10]University Medical Center, Leipzig, Germany; [11]University of Valencia, Department of Medicine, Valencia, Spain*
Email: vinaixa.carmen@gmail.com

Background and aims: Liver transplant (LT) recipients have been prioritized for vaccination in most parts of the world.The aim of this multi-society survey was to explore and to describe the different policies and outcomes of vaccination in this population in a real-world setting.

Method: A web-based survey was available online from October 2021 to February 2022 to members of the EASL, ESOT/ELITA and ILTS. The survey was divided into 4 domains: (1)Vaccination policies, (2)Safety assessment, (3)Efficacy assessment, and (4)center data. No patient-related data were collected.

Results: 188 eight out of 470 centers responded to the survey. There was a wide geographic distribution: 41% Europe, 24% Asia and 23% North America (Fig 1).

The global response rate to the survey's section on vaccination policies was 90%. Most transplant patients (86%) were vaccinated after 12 months post-LT. Prioritization of transplant patients was very common (85% of centers), this was the case for co-habitants in only 29% of centers. mRNA vaccines were used in most centers (76%); with restrictions to use only these vaccines in transplant recipients in 43% of these centers, followed by viral vector vaccines in 27%. Barriers to vaccination were reported in 23% of cases, related to patient's fear (80%), public health policies (33%) and logistics (20%). Vaccination was ordered by health-care authorities or government in 56% of cases, and by the transplant provider in 30%.Other vaccines as flu were reported to be routinely recommended (92%).

The global response rate to the survey's section on safety assessment was 75.4%. Only 1/3 of centers implemented specific monitoring policies for liver function tests (LFT) and/or immunosuppression (IS) levels post-vaccination, with variable frequencies. Most patients (59%) were monitored in the outpatient clinic, via telemedicine (26%) or patient self-reporting (9%). Only 28% of centers responded to the IS section, and only a minority of them (9%) reported that changes in IS were implemented before vaccination, with variable strategies. Regarding adverse events (AE) post-vaccination, 27% of centers observed LFT elevation, 11% thromboembolic events, 9% acute graft rejection and 17% other AE.

83% of centers answered the vaccine efficacy assessment section: 1/3 of centers tested for SARS-CoV-2 antibodies post-vaccination. COVID-19 positive cases post-vaccination were observed in 65% of the centers, and 33% amongst these were severe.

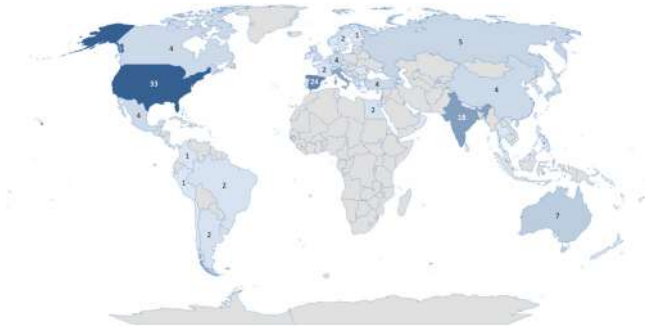

Figure: Geographic distribution of responding centers

Conclusion: COVID-19 vaccination is almost universal amongst LT recipients all over the world, with mRNA vaccines being the main type of vaccine administered. Monitoring for safety and efficacy purposes post-vaccination was only performed in one third of centers, probably reflecting the lack of recommendations. More than half of the centers reported post-vaccination COVID-19 cases.

SAT297

Does m-RNA vaccination protect from Sars-Cov2 (asymptomatic) infection in liver transplant recipients?

Ubaldo Visco Comandini[1], Marzia Montalbano[2], Raffaella Lionetti[2], Paola Piccolo[3], Daniela Nesticò[4], Silvia Meschi[4], Chiara Agrati[4], Chiara Taibi[4], Laura Vincenzi[2], Enrico Girardi[4], Giuseppe Maria Ettorre[5], Giampiero D'Offizi[2]. *[1]National Institute for infectious diseases Lazzaro Spllanzani, POIT, rome, Italy; [2]National Institute for infectious diseases Lazzaro Spllanzani, POIT; [3]San Giovanni Calibita, Fatebenefratelli Hospital; [4]National Institute for infectious diseases Lazzaro Spllanzani; [5]San Camillo Hospital*
Email: ubaldo.viscocomandini@inmi.it

Background and aims: Vaccination significantly reduces COVID-19 morbidity and mortality, as well as hospitalization, but it is less clear whether vaccination also prevents from asymptomatic infection. Liver Transplant recipients (LTRs) are less prone to develop severe COVID-19 compared to other solid organ transplant recipients (Trapani S, AJT 2021). A high frequency of asymptomatic Sars-CoV2 infections has been described in LTRs (Visco-Comandini, JLT 2021).
The study aim is to compare the vaccine-induced humoral response in LTRs who developed Sars-Cov2 infection during or after three dose of mRNA vaccination, with those who did not

Method: The LTRs cohort is composed by 246 subjects, 182 of whom completed a 3-dose vaccination program in 2021. Subjects with Sars-CoV2 infection prior to 1st dose were excluded.
All LTRs were regularly screened through telephone-based questionnaire or clinical visits to detect systemic, respiratory or gastrointestinal symptoms. LTRs reporting symptoms compatible with COVID-19 or close contact to a positive subject underwent nasopharyngeal swab (NPS) to detect active infection.
Sars-CoV2 Receptor Binding Domain antibodies (RBD-Ab, detection limit >7.1 BAU/ml) were prospectively measured at T0 [before 1st dose], T2 [4 weeks (W) after 2nd dose], T3 [before 3rd dose], T4 (4 W after) and T5 (12 W after) in all.
Anti-RBD and neutralizing antibodies (n-Ab, detection limit <1:5 for *alpha* and *delta*, <1:2.5 for *omicron*) were measured at T2, T3, T4 and T5. Neutralizing activity was measured toward *alpha* variant (T2), *alpha* and *delta* variants (T3 and T4), *delta* and *omicron* variants (T5)

Results: Twenty-seven of 164 LTRs were infected by Sars-CoV2 (14.8%) after the 1st dose: 9 between the 2nd and 3rd dose (group A), and 18 after the 3rd dose (group B). Their RBD-Ab and n-Ab titres measured at the last time point before infection, were compared to the remaining vaccinated LTRs who never developed a positive NPS or a positive non RBD-serology (controls, n = 137) (Figure 1).
Moderate to severe COVID19 cases were observed in 2/9 (22.4%) subjects infected after the first/second dose of vaccine (*alpha* or *delta* variant), and in 1/18 (5.5%) infected after the third dose (*delta* or *omicron* variant).
The rate of non-response to vaccination was 22.2% in group A and 22.1% in controls at T2; 0% and 2.9%, in group B and controls respectively at T4.
Absence of neutralizing activity was 77.8% in group A and 46.0% in controls at T2 (p = 0.09); 22.2% and 7.8%, at T4 in group B and controls (p = 0.07).
At T5 infected LTRs showed higher RBD-Ab compared to controls (median 2019, IQR 691–3845 BAU/ml vs 1281, IQR 452–2994 BAU/ml p < 0.05) but similar n-Ab titers

Conclusion: Sars-CoV2 infection between 1st and 3rd vaccination doses was associated with lack of anti-RBD response or lower neutralizing activity, while infection after the 3rd dose seemed to be independent of humoral response to vaccination

Email: llty24@gmail.com

Background and aims: Low dose interleukin-2 (LDIL-2) can expand endogenous circulating CD4+CD25+Foxp3+ regulatory T-cells (Tregs) in vivo, but its role in promoting allograft tolerance in humans has not been investigated. We conducted a clinical trial in stable liver transplant (LT) recipients 2–6 years post-transplant to determine the capacity of LDIL-2 to suppress allospecific immune responses and allow for the complete discontinuation of maintenance immunosuppression.
Method: The LITE trial is a phase IV, open-label, activity, safety and efficacy, prospective single arm clinical trial in which stable LT recipients <50 years old and 2–6 years post-LT receive 6 months of daily 1 million IU injections of LDIL-2. After 4 weeks of LDIL-2 treatment, those recipients in whom circulating Tregs expand >2-fold gradually discontinue their immunosuppressive medication over 3 months. Patients who maintain stable serum liver tests and normal histology 1 year after immunosuppression withdrawal are considered tolerant.
Results: Six patients were recruited with a median age of 34 years (range 22–49) and 38.5 months (range 31–45) post-LT. All patients achieved a marked and sustained increase in circulating Tregs, in keeping with previous studies. Significant increases in circulating eosinophils, basophils, CD56bright NK cells and a reduction in the absolute numbers of circulating B cells were also observed. However, these findings were not associated with the preferential expansion of donor-reactive Tregs and did not promote the accumulation of intra-hepatic Tregs. Furthermore, LDIL-2 induced a marked interferon-γ orchestrated transcriptional response in the liver even before immunosuppression weaning was initiated. The trial was terminated after the first six trial participants failed to reach the primary end point due to rejection requiring immunosuppression reinstitution.
Conclusion: Our trial provides unique insight into the mechanisms of action of immunomodulatory therapies such as LDIL-2 and their limitations in promoting alloantigen-specific effects and immunological tolerance.

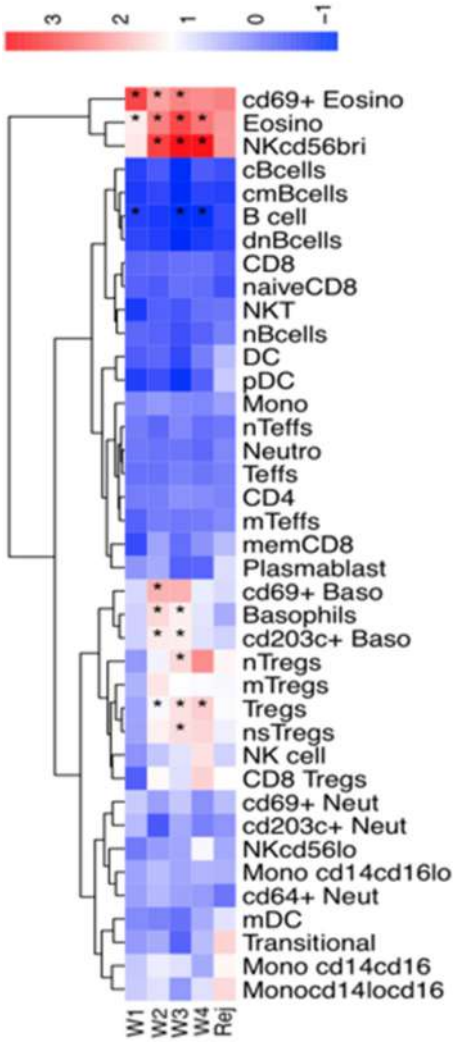

Figure: Sequential changes in mean absolute counts of each circulating immune cell subset following LDIL-2 treatment.

SAT299

Clinical significance of three-dimensional printing of the portal venous system in patients with extrahepatic portal hypertension

Binita Chaudhary[1], Utpal Anand[2], Rajeev Priyadarshi[3]. *[1]All India Institute of Medical Sciences, Patna, Anatomy, Patna, India; [2]All India Institute of Medical Sciences, Patna, Surgical Gastroenterology, Patna, India; [3]All India Institute of Medical Sciences, Patna, Radiodiagnosis, Patna, India*
Email: binitachaudhary18@gmail.com

Background and aims: Three-dimensional printing (3DP) is a novel technique that can generate 3D virtual image from multidetector computed tomography (MDCT) scan. The aim of the study was to investigate the feasibility of 3DP in visualization of portal venous system of patients with extrahepatic portal vein obstruction (EHPVO) to improve the surgical outcome (surgical time, blood loss).
Method: This retrospective study was performed in the Department of Anatomy in 24 patients of EHPVO who underwent shunt surgery from November 2018 to March 2022. The patients were divided into conventional planning group based on MDCT imaging (n = 12) and

planning with 3D printing group based on the 3D reconstruction of portal venous system (n = 12).
The image of MDCT was transferred to D2P software (dicom to print) and saved in a standard format DICOM (digital imaging and communication in medicine). Bone, soft tissue and blood vessels were semi-automatically segmented into separate areas. Segmented regions were combined to create a 3D object. These 3D objects were exported from D2P as STL files. STL files were repaired in 3D design software (Geomagic freeform plus) and a virtual 3D prototype was created. 3D virtual image prepared were used to see the exact location and depth of splenic and renal vein as well as surrounding collaterals.
Results: In conventional planning group, there were 12 patients (8 males and 4 females) with mean age of 24.00 ± 10.91. The time from day of surgery to the day of discharge from hospital was 7.08 ± 2.53 days. In planning with 3D printing group, there were 12 patients (10 males and 2 females) with mean age of 32.08 ± 16.57 years. The time from day of surgery to the day of discharge in 3D printing group was 7.16 ± 2.20 days.
The mean surgical time in planning with 3D printing group was 252.50 ± 11.579 min, which was significantly lower than that of conventional planning group (298.16 ± 12.87 min); *P* value<0.05. The intraoperative mean blood loss in planning with 3D printing group and conventional planning group were 441.25 ± 44.52 ml and 624.16 ± 123.13 ml respectively; (*P* valve <0.05).
The rate of complication in the planning with 3D printing group and conventional planning group was 16.66% (2/12) and 8% (1/12) respectively.
Conclusion: Presurgical planning in 3D printing reduces guesswork and thus it remarkably reduces surgical time, blood loss, minimizes complication and improves surgical outcome.

SAT300

Liver transplantation (LT) and ethnicity in the United States: the impact of non-alcoholic steatohepatitis

Zobair Younossi[1], Reem Al Shabeeb[2], Michael Harring[2], Dipam Shah[2], Janus Ong[3], Saleh Alqahtani[4,5], Linda Henry[1,6], Maria Stepanova[1,2,6].

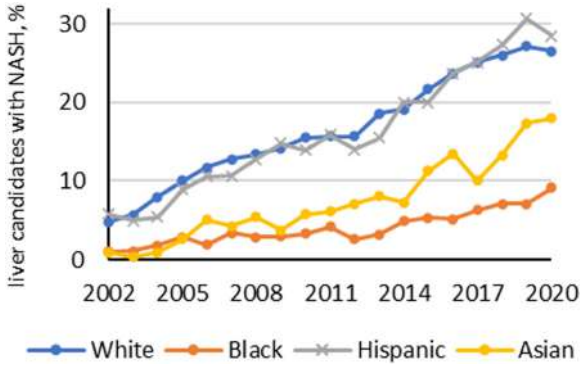
Email: zobair.younossi@inova.org

Background and aims: The burden of chronic liver disease (CLD) may vary by race and/or ethnicity. We aimed to assess distributions and trends of different CLD etiologies among liver transplant (LT) candidates from major racial/ethnic groups in the U.S. over the last two decades.
Method: The Scientific Registry of Transplant Recipients (SRTR) data 2002–2020 was used to select adult (≥18) candidates for LT. Patients without race/ethnicity data (white, black, Hispanic, or Asian) were excluded. Trends in the proportions of common LT etiologies, such as chronic hepatitis B (CHB), chronic hepatitis C (CHC), non-alcoholic steatohepatitis (NASH, including cryptogenic cirrhosis if accompanied by obesity or type 2 diabetes), alcoholic liver disease (ALD) were assessed over time.
Results: 204, 382 LT candidates with known race/ethnicity were included: n = 146, 535 non-Hispanic white (4.1 per 100, 000 per year with reference to the general U.S. population), n = 17, 653 non-Hispanic black or African-American (2.3 per 100, 000), n = 31, 086 Hispanic (2.7 per 100, 000), and n = 9, 108 Asian (2.4 per 100, 000). In whites, the most common etiologies were CHC (27% across all study years) followed by ALD (23%) and NASH (17%). In addition, in whites, there was a decreasing trend in CHC (34% in 2002–2005 to 12% in 2018–2020) but increasing trends in NASH (7% to 27%) (Figure) and ALD (17% to 35%) (all trend p < 0.0001). In blacks, CHC (41% in 2002–2005 to 25% in 2018–2020) decreased while ALD increased from 7% to 18% (all p < 0.0001). In Hispanics, the trends were similar to whites with CHC decreasing (40% in 2002–2005 to 13% in 2018–2020) while ALD (17% to 34%,) and NASH (6% to 29%) increasing (all p < 0.0001). Finally, in Asians, the most common etiologies of LT remained CHB and CHC (decreasing from 39% to 28% and from 28% to 11% in 2002–2005 to 2018–2020, respectively) while ALD (3% to 14%) and NASH (1% to 16%) increased (all p < 0.0001). The proportions of HCC remained substantially elevated in Asians (28% in 2002–2005, 39% in 2014–2017, and 36% in 2018–2020), and over time was increasing from 2002 to 2005 (7–8%) to 2014–2017 (21–27%) in all other ethnic groups but then decreased in 2018–2020 (17–24%). In multivariate analysis, older age, female gender, obesity and type 2 diabetes were associated with the etiology of NASH in LT candidates of all ethnic groups (all p < 0.0001). Higher post-transplant mortality was associated with older age, diabetes, higher MELD score and HCC in all ethnic groups (p < 0.01).



Conclusion: CLD etiologies of liver transplant candidates in the U.S. vary across racial/ethnic groups and over time in the U.S. The proportion of NASH among LT candidates increased at least 4-fold between years 2002–2005 and 2018–2020 in all major ethnic groups.

SAT301

Can endothelial biomarkers before liver transplantation together with classical cardiovasculat risk factors be useful to predict cardiovascular risk after liver transplantation

Julia Herreras López[1], Ângela Carvalho-Gomes[2], Tommaso Di Maira[1,1], Marina Berenguer[1], Victoria Aguilera Sancho[1,2]. *[1]La Fe University and Polytechnic Hospital, València, Spain; [2]Instituto de Investigación Sanitaria La Fe de Valencia, València, Spain*
Email: toyagui@hotmail.com

Background and aims: Cardiovascular (CV) disease is an important cause of morbidity and mortality after liver transplantation (LT). In the general population endothelial biomarkers have been associated to cardiovascular (CV) risk. Little is known about the relationship between endothelial biomarkers in LT candidates. To analyse pre-LT serum biomarkers (day 0) and to evaluate if they have an association with CV risk after LT alone or in combination with classical CV risk factors.
Method: Frozen plasma of 125 LT with a low FRS between 2014–2017 were analyze. At one year, patients with a high Framminghan Risk Score (FRS) or with metabolic syndrome (MS) were considered of high risk, as a surrogate marker for CV events. Endothelial biomarkers measured were: lpPLA2 measured by ELISA and adiponectine, VCAM1, IL6, TNF alfa and proBNP by Luminex. A multivariate analysis with clinical and endothelial biomarkers was done.
Results: Mean age was 56 years, 78% were men, HCV cirrhosis was the most frequent ethiology (36%) followed by alcohol (25%). Before LT, 20% had arterial hypertension and 19% diabetes. At one yr post-LT, 33% were considered to have a high CV risk by FRS or MS. Logistic regression showed that age before LT (OR = 1.06; p = 0, 025), DM before LT (OR = 5, 77; p < 0, 001) were associated with high CV risk. Plasma levels of LpPLA2, adiponectine, TNF alfa and ProBNP were associated with Liver function (MELD and Child) (p < 0, 05). LpPLA 2 showed a tendency through a high CV risk (OR = 2.82, p = 0, 089). A model with clinical and endothelial biomarkers was created. DM (OR 9, 6 3-31 p < 0, 001), obesity (OR 5, 1 IC 1.62–16 p = 0.005), tobacco use (OR 4.44 IC 1.26–15 p = 0, 02) and lpPLA2 (OR 8, 18 IC 1.5–44 p = 0, 015) were statistically significant associated with CV risk post-LT.
Conclusion: Clinical variables such as age, obesity, DM before LT and tobacco use in combination with endothelial biomarkers (LpPLA2) could be useful to predict CV risk after LT.

SAT302

Factors contributing to late evaluation in liver transplant candidates undergoing inpatient liver transplant evaluation

Katherine Cooper[1], Diana Liu[1], Alessandro Colletta[1,2], Deepika Devuni[1,2]. *[1]UMass Chan Medical School, Worcester, United States; [2]UMass Memorial Medical Center-University Campus, Worcester, United States*
Email: katherine.cooper@umassmed.edu

Background and aims: Timely referral for liver transplant evaluation (LTE) is critical in patients with chronic liver disease (CLD) due to the high mortality associated with decompensation. Unfortunately, CLD can be under recognized resulting in the need for urgent transplant evaluation. We aimed to identify the proportion of late referrals in patients undergoing inpatient LTE and potential causes of late LTE.
Method: Patients undergoing inpatient LTE for CLD at our centre between October 2017 and August 2021 were included in the study. Charts were extensively reviewed for liver history focusing on earliest signs of liver dysfunction, imaging evidence of cirrhosis, time of diagnosis, decompensation history and barriers to referral. Patients were considered to have late referrals if they had a Model of End Stage Liver Disease score (MELD) >15 or decompensation without a substance-related contraindication to transplant.
Results: One hundred fifty-nine patients, mean age 57.7 (SD 9.6) undergoing inpatient transplant evaluation were identified. About half could have been referred earlier for outpatient transplant evaluation. Two-thirds of these patients were diagnosed at least two years prior to their evaluation and had an average of 4.0 (SD 1.3) decompensations (Table 1). Almost all had a primary care physician or saw a health care provider regularly. The most common barriers to referral included failure to obtain MELD labs/calculate MELD and misconceptions about the sobriety period needed for transplant (Table 1).

Diagnosis relative to LTE	
Months since diagnosis	Median: 30 months [IQR: 12.25–60]
0–1 years since diagnosis	33.3%
2–5 years since diagnosis	48.7%
5+ years since diagnosis	17.9%
Decompensation history prior to LTE	
Total Decompensations (#)	4.0 ± 1.3
Jaundice	66.7%
Hepatic Encephalopathy	78.2%
Ascites	96.2
Hepatorenal syndrome	35.9%
Spontaneous bacterial peritonitis	20.5%
Large volume paracentesis	52.6%
Upper gastrointestinal/Variceal Bleed	35.9%
Hepatic hydrothorax	11.5%
Reason for late LTE	
Failure to obtain/calculate MELD	14.1%
Diagnosis missed or care delayed	12.8%
Misconception about sobriety cut off	12.8%
Understanding of LTE candidacy	5.1%
Insurance or Financial Barriers	10.3%
Care continuity	7.7%
Patient choice	10.3%
No clear reason	19.2%

Conclusion: Many patients are referred for liver transplant late in their clinical course causing unnecessary health care utilization. Efforts to increase timely referral for liver transplant include improving awareness about routine labs and indications for liver transplantation for non-transplant providers. Further, efforts to improve patient insight into their condition may facilitate the referral process.

SAT303

CMV reactivation is associated with lower hepatocellular carcinoma (HCC) recurrence after liver transplantation (LT)

Victoria Aguilera Sancho[1,2,3], Sarai Romero Moreno[1,3], Isabel Conde[1,3], Tommaso Di Maira[1,3], Ângela Carvalho-Gomes[1,4], Ángel Rubín[1,3], Laura Martínez-Arenas[1], F. Xavier Lopez-Labrador[5], Marina Berenguer[1,3,6]. *[1]Instituto de Investigación Sanitaria La Fe de Valencia, València, Spain; [2]CIBERehd Instituto de Salud Carlos III, Valencia, Spain; [3]La Fe University and Polytechnic Hospital, València, Spain; [4]Instituto de Salud Carlos III, CIBERehd; [5]Fisabio, València, Spain; [6]Ciberehd, Instituto Carlos II*
Email: toyagui@hotmail.com

Background and aims: There are data that link CMV reactivation (rCMV) with post-LT morbidity and mortality. Recent studies though suggest beneficial effects including a potential oncolytic effect

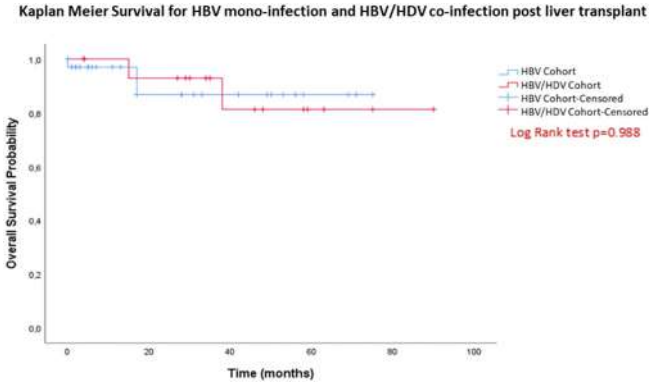
resulting in lower HCC recurrence after LT.To assess the effect of rCMV (before tumoral recurrence) in LT-patients with HCC.
Method: We included LT patients with HCC (2018–2020). Exclusion criteria were: late re-LT, early death <1month and combined Liver Kidney transplant. Variables: (i) Donor (D) and recipient (R) demographics, (ii) related with rCMV (defined if CMV viral load >400c/ml): DR CMV mismatch, preemptive therapy, CMV disease, (iii) related to HCC: bridging, downstage, vascular invasion, baseline AFP. Prophylaxis with valganciclovir was used in high-risk patients while a preemptive approach was used in the remainder. The retreat score was used to establish posttransplant follow-up (AFP and Tomography).
Results: Out of 266 LT, 122 (83% men, median age 59 yrs) fulfilled inclusion criteria; the main etiology was HCV (31%) followed by alcohol (25%) and the functional Meld was 10 (6–27). Most (80%) were intraMilan at LT; 16 (13%) were included after downstaging and 73% received locoregional therapy either for bridging or downstaging. On explant 11.5% had vascular invasion. Median AFP was 43 (1.1–748 ng/ml). A minority were considered high-risk due to CMV Mismatch (11% D/R ±). rCMV occurred in 50 patients (41%); 22 (18%) started early treatment and 5 (4%) developed CMV disease. Overall, 10 patients (8.2%) had HCC recurrence after a median of 288 days (Q1, Q3: 135–445). In multivariate analysis, vascular invasion [HR 11 (IC 3–44), p:0, 08] and absence of rCMV were associated with HCC recurrence [HR 0.12 [IC:0.0006–0.25, p:0.004]. Survival at 1, 3 and 5 yrs post-LT was 89%, 82% and 77%, respectively.
Conclusion: In our series, vascular invasion, and absence of rCMV were associated with higher risk of HCC recurrence after LT.

SAT304

Managing HBV/HDV co-infection post liver transplant-Exploring a decade of experience

Almuthana Mohamed[1], Lindsay Greenland[1], Maria Guerra Veloz[1], James Lok[1], Khin Aye Wint Han[1], Racquel Beckford[1], Deepak Joshi[1], Michael Heneghan[1], Varuna Aluvihare[1], Abid Suddle[1], Ivana Carey[1], Kosh Agarwal[1]. [1]*Institute of Liver Studies, King's College Hospital, Hepatology, London, United Kingdom*
Email: almuthana700@gmail.com

Background and aims: Liver transplantation is an important treatment modality for hepatitis B patients with delta co-infection (HBV/HDV), including those with hepatocellular carcinoma (HCC) or decompensated cirrhosis. Despite the judicious use of nucleos (t)ide analogues (NA) and hepatitis B immunoglobulins (HBIG), post-transplant management remains challenging, and there is an inherent risk of viral reactivation and graft failure. We describe ten years of experience in managing this patient cohort and explore their long-term clinical outcomes.
Method: In this retrospective study, all patients with HBV/HDV co-infection who underwent liver transplantation at King's College Hospital between 2012 and 2022 were identified. Baseline demographics, date and type of liver transplant, post-surgical management, clinical outcomes, and virological markers (HBV DNA and HDV RNA) pre-, 6- and 12-months post-transplantation were assessed, and Kaplan-Meier's survival curves were generated.
Results: Overall, 16 patients underwent liver transplant, including one individual with concomitant HBV, HDV and HIV infection. The median age was 51 years (Range 29–55, IQR 8), and dominant ethnic groups were Caucasian (n = 8, 50%), South Asian and Black African (18.8% each). The most common indication for transplantation was synthetic dysfunction from liver cirrhosis (87.5%). Prior to surgical intervention, 6 patients (37.5%) had detectable HBV DNA levels (Median = 229, Range 71–5.07E3 IU/ml) and 11 individuals (68.8%) had detectable HDV RNA (Median = 2.20E5, Range 1.00E4–3.11E7 IU/ml). In contrast, the vast majority (93.8%) had undetectable HBV DNA and HDV RNA titres at 6- and 12- months post-transplantation. There was also a significant difference in HBsAg levels Pre-transplant, 6- and 12- months post-transplant (p = 0.006). All patients were administered HBIG intra and post-operatively and continued on long-term HBIG and NA. 56% received Tenofovir disoproxil fumarate, 6 individuals (37.5%) were prescribed Entecavir due to underlying renal impairment, and one received tenofovir alafenamide as part of their concurrent HIV treatment. Survival post liver transplant was compared to a control group of HBV mono-infected individuals, the mean survival of HBV/HDV co-infection post liver transplant was 78.6 months, with two fatalities secondary to viral reactivation or transplant-related complications and a mean follow-up of 40.94 months (SD 24.07 months).



Conclusion: This study demonstrates that liver transplantation successfully controls HBV/HDV co-infection expression. Whilst NA and HBIG effectively prevent viral reactivation and are associated with favourable long term outcomes; further work is needed to establish a consensus approach across different transplant centres in this patient group.

SAT305

Durability of SARS-CoV-2 specific immune response following different primary prime-boost vaccine platforms and subsequent humoral response to booster dose among liver transplant recipients

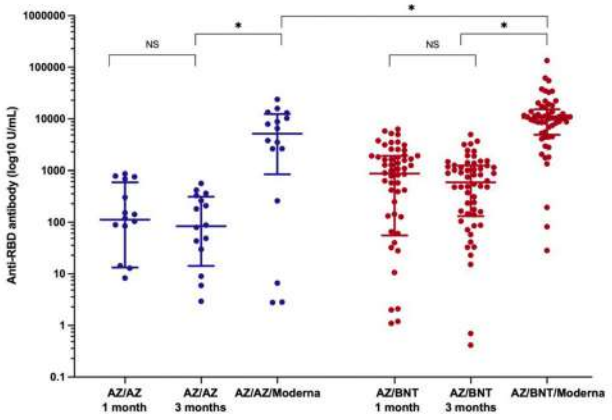
Supachaya Sriphoosanaphan[1,2], Sirinporn Suksawatamnuay[1,2,3], Nunthiya Srisoonthorn[2], Nipaporn Siripon[2], Panarat Thaimai[1], Wanwisar Makhasen[2], Nawakodchamon Mungnamtrakul[2], Kessarin Thanapirom[1,2,3], Bunthoon Nonthasoot[4], Pokrath Hansasuta[5], Piyawat Komolmit[1,2,3]. [1]*Division of Gastroenterology, Department of Medicine, Faculty of Medicine, Chulalongkorn University, Bangkok, Thailand;* [2]*Center of Excellence in Liver Diseases, King Chulalongkorn Memorial Hospital, Thai Red Cross Society, Bangkok, Thailand;* [3]*Liver Fibrosis and Cirrhosis Research Unit, Chulalongkorn University, Bangkok, Thailand;* [4]*Department of Surgery, Faculty of Medicine, Chulalongkorn University, Bangkok, Thailand;* [5]*Division of Virology, Department of Microbiology, Faculty of Medicine, Chulalongkorn University and King Chulalongkorn Memorial Hospital, Thai Red Cross Society, Bangkok, Thailand*
Email: supachaya.sr@gmail.com

Background and aims: Suboptimal immunogenicity among liver transplant (LT) recipients after primary SARS-CoV-2 vaccination has aroused concerns about the longevity of protection and urgent need of a booster dose. There is a paucity of information on antibody kinetics and response following a third dose vaccine in this population. We aimed to investigate the durability of humoral response after primary immunization induced by different prime-boost vaccine platforms and subsequent response to booster dose in LT recipients.
Method: LT recipients who were vaccinated with ChAdOx1 nCoV-19 (AZ)/AZ or AZ/BNT162b2 (BNT) as primary vaccine series at King Chulalongkorn Memorial Hospital, Bangkok, Thailand, between April and December 2021 were enrolled. The mRNA-1273 (Moderna) was

administered as the booster vaccine at 3 months following the second dose. SARS-CoV-2 spike receptor-binding-protein (RBD) IgG was assessed at 1 month, 3 months after the second dose, and 1 month following the booster vaccine. Anti-RBD antibody was tested using electrochemiluminescence immunoassay (Roche Elecsys). According to the basis of plasma-neutralizing capacity in patients with convalescent SARS-CoV-2 infection, anti-RBD titer of <0.8 U/ml, 0.8–50 U/ml, and >50 U/ml were defined as negative, low-positive, and high-positive, respectively.

Results: Of 74 LT recipients, 51 (68.9%) were male and median age was 61 (IQR 52–68) years. Median time from transplantation was 5.8 (IQR 2.2–10.8) years. Sixty-one (82.4%) patients were taking tacrolimus, 60 (81.1%) anti-metabolite, and 8 (10.8%) steroids. Fifty-eight (78.4%) patients received AZ/BNT as primary vaccine series. Overall, median anti-RBD titers at 1 month after primary immunization were 609.1 (IQR 38.2–1, 632) U/ml and the levels declined to 397.6 (IQR 77.7–1, 098.5) U/ml at 3 months (p = 0.54). Antibody reduction rate was comparable between two vaccine platforms (32.1% in AZ/AZ versus 43.8% in AZ/BNT, p = 0.25). After the booster dose, median anti-RBD titers significantly rose to 9, 597.0 (IQR 3, 935–13, 497.5) U/ml (p < 0.001). The proportion of LT patients with high-positive titers significantly increased from 78.4% at 3 months after primary immunization to 98.6% following the third vaccination (p <0.001). Patients who received heterologous prime-boost regimen as primary vaccine series had significantly greater anti-RBD levels after the booster (10, 346.0 U/ml in AZ/BNT/Moderna group versus 5, 134.0 U/ml in AZ/AZ/Moderna group, p = 0.04). (Figure 1)

Figure 1: Anti-RBD antibody levels at 1 month, 3 months after primary SARS-CoV-2 vaccination, and 1 month after a booster dose in LT recipients (Horizontal lines indicate the median and interquartile range; * p-value <0.05; NS, non-significant)



Conclusion: SARS-CoV-2 specific antibody among LT recipients waned over time after primary immunization regardless of vaccine platforms. The booster strategy substantially provided high protective antibody titers in almost all LT patients. Further studies evaluating duration of protection after the booster as well as clinical effectiveness against the variants of concerns are warranted.

SAT306

Outcome of choledochal cysts with intrahepatic involvement (type IV-A) after extrahepatic cyst excision and roux-en-Y hepaticojejunostomy in adults

Utpal Anand[1,1], Rajeev Priyadarshi[2], Ramesh Kumar[3]. [1]*All India Institute of Medical Sciences, Patna, Surgical Gastroenterology, Patna, India;* [2]*All India Institute of Medical Sciences, Patna, Radiodiagnosis, Patna, India;* [3]*All India Institute of Medical Sciences, Patna, Gastroenterology, Patna, India*
Email: utpalanand2@gmail.com

Background and aims: Type I and type IV-A choledochal cysts (CC) according to Todani's classification are the most frequent types. Unlike type I CC, in which the dilatation is confined to the extrahepatic bile duct, type IV-A affects both extra and intrahepatic ducts. The aim of this study was to evaluate outcomes in adult patients with type IV-A CC at least 2 years after resection of the extrahepatic bile duct cyst.

Method: Data was collected retrospectively from a cohort of 60 adult patients who underwent extrahepatic cyst resection for type IV-A CC from 2010 to 2020 in our institution. A total of 45 patients were included in the final analysis, with a minimum follow-up of two years

Results: Follow-up time ranged from 2 years to 10 years (median, 25 months). Thirty five patients remained asymptomatic; however, 5 patients had abnormal liver function tests (LFTs), requiring regular monitoring. Late complications in varying combinations were seen in 10 patients (16.6%), which included cholangitis and/or intrahepatic-hepatic stones in 9 (15%), intrahepatic bile duct stenosis with stones in 2, anastomotic stricture with or without stone formation in 6, and left lobar atrophy with intrahepatic stones in 3 patients.

Magnetic resonance cholangiopancreatography and/or Computed tomography scans was done to evaluate the causes of stricture which revealed anastomotic stricture in 6 patients and web like stenosis of the left intrahepatic bile duct in 2 patients. Percutaneous transhepatic biliary dilatation was done in 2 patients with anastomotic stricture without cystolithiasis. Re-do hepaticojejunostomy (HJ) required in the remaining 4 patients. The stenotic bile duct was incised and hepaticojejunostomy was performed in both patients with left intrahepatic web. The median time interval from primary surgery to reintervention was 24 months. The median follow-up period after reoperation was 5 years.

Out of 6 patients who required re-do HJ, three patients had left lobe atrophy with patent HJ anastomosis with recurrent attack of cholangitis on follow-up of 3, 8 and 10 years respectively. Two of them underwent left hepatectomy and refashioning of anastomosis and other was kept on conservative management.

Conclusion: Residual intrahepatic dilatation of type IV-A cyst in adults did adversely affect the postoperative outcome after a conventional surgical repair. A long term follow-up is necessary to recognize and address late complications.

SAT307

The impact of COVID-19 on the duration of the liver transplant process in patients presenting for inpatient liver transplant evaluation

Katherine Cooper[1], Arslan Talat[1,2], Diana Liu[1], Alessandro Colletta[1,2], Deepika Devuni[1,2]. [1]*UMass Chan Medical School, Worcester, United States;* [2]*UMass Memorial Medical Center-University Campus, Worcester, United States*
Email: katherine.cooper@umassmed.edu

Background and aims: The SARS-CoV-2 pandemic (COVID-19) adversely affected liver transplantation internationally. At its peak, COVID-19 was associated with decreased transplant rates and increased waitlist mortality. Though many centres have resumed normal transplant activities, there is concern that reduction in health care services may mean patients present later in their disease course resulting in need for more urgent transplant evaluations. We aimed to evaluate differences in the inpatient liver transplant process before and after the COVID-19 pandemic to understand the impacts on the overall transplant care pathway.

Method: Medical records for all patients undergoing liver transplant evaluation (LTE) from 10/2017–8/2021 were reviewed. Patients undergoing LTE for chronic liver disease (CLD) were included; patients with a history of liver transplant or in fulminant liver failure were excluded. Records were categorized as Pre-COVID if evaluation was before 3/15/2020 and post-COVID if after 3/15/2020. Demographic and clinical history were collected for patients undergoing inpatient LTE. Variables were compared using Fishers exact test and students t-tests; significance was evaluated at p = .05.

Results: One hundred and fifty-nine evaluations occurred (54% Pre-COVID, 46% Post-COVID). Time from referral to the first day of LTE tended to be longer in the Post-COVID period than the Pre-COVID period. Conversely, there was a significant reduction in days from transplant referral to liver transplant in patients who underwent inpatient LTE in the Post-COVID period (p = 0.0227). Time having elapsed There were no differences in age (p = 0.85), MELD-Na (0.81), months since diagnosis (p = 1.0). About 40%of patients who underwent inpatient LTE in the Post-COVID group had received a transplant at the time of data collection compared to 36.0% in the Pre-COVID group. Further, the rate of transplants performed per month has been about 70% higher for patients evaluated in the Post-COVID period compared to the Pre-COVID period (1.8 vs. 1.1 transplants per month, respectively).

	Pre COVID **(n = 86)**	Post-COVID **(n = 73)**	p value
Age (years)	57.6 ± 9.6	57.9 ± 9.7	0.845
Time since diagnosis (months)	49.0 ± 62.30	49.0 ± 77.7	1.0
MELD-Na (points)	27.3 ± 7.8	27.0 ± 8.3	0.81
Process Length			
Referral to Evaluation (days)	9.0 ± 17.9	14.4 ± 29.2	0.1552
Referral to Committee (days)	19.3 ± 26.3	22.9 ± 29.2	0.415
Referral to Transplant (days)	105.7 ± 176.6	55.4 ± 65.9	0.0227*

Conclusion: The COVID-19 pandemic appears to have had a negative impact on the ability to undergo evaluation for liver transplant in the outpatient setting. Despite this, patients seem to be receiving transplants at a faster rate despite no differences in time since diagnosis or MELD-Na at the time of work up. The reason for this is multifactorial and may include hospital capacity, varying disease progression, and clinical presentation.

SAT308

Patients with polcystic liver disease have longer waiting times but better clinical outcomes following liver transplantation in the UK

Matthew Gittus[1], Joanna Moore[2], Albert Ong[1]. *[1]The University of Sheffield, United Kingdom; [2]Saint James Hospital, United Kingdom*
Email: m.gittus@sheffield.ac.uk

Background and aims: Polycystic Liver Disease (PLD) can negatively impact a patient's quality of life with potentially debilitating symptoms secondary to hepatomegaly. Liver transplantation remains the only curative option. Liver transplantation rates and outcomes for people with PLD in the UK are not known. People with PLD are now often registered to the Variant Syndrome waiting list which is currently proportionally allocated liver allografts by NHS Blood and Transplant (NHSBT). Prior to this individual transplant centres allocated to their patients.
Method: Retrospective, national, cohort study using NHSBT data from 01/01/2010 and 31/12/2020. All adult recipients who received an elective liver or liver-kidney allograft in UK transplant centres. Data analysis was performed using SPSS 2020.
Results: There are 156 (2%) PLD recipients and 7686 (98%) non-PLD recipients with longer waiting time for PLD recipients compared to non-PLD recipients (mean 513.3, SD 491.8 vs 114.7 days, SD 199.6) but lower mortality (3.8% vs 8.1%) and graft failure (7.3% vs 14.9%) rates. Significant variation in PLD transplantation rates exists between the seven UK transplant centres (p <0.001, Chi^2 test); ranging from 0 to 54 over the 10-year period. 69.2% of all PLD liver transplantation were performed by two centres.

Recipient characteristics and outcomes	PLD n = 156 (2.0%)	Non-PLD n = 7530 (98.0%)	Total n = 7686	P value
Liver alone (L): Liver-Kidney (LK)	L:98, LK:58 (62.8%:37.2%)	L:7459, LK:71 (99.1%:0.9%)	L:7557, LK:129 (98.3%:1.7%)	0.289†
Male (M): Female (F): Not Reported (NR) Gender ratio-Male (M): Female (F): Not Reported (NR)	M:39, F:117 (1:3)	M:4908, F:2621, NR: 1 (1.87:1)	M:4947, F:2738, NR:1 (1.8:1)	0.154†
Mean age (range)	52.3 (20–69)	52.7 (18–76)	52.7	<0.001‡
Mean UKELD (range)	47.8 (40–60)	54.9 (39–83)	54.7	0.362‡
Mean MELD (range)	14.9 (6–60)	16.26 (6–40)	16.6	0.222‡
Mean Cr at registration (umol/l)	281.0	141.3	144.1	0.071‡
Total mean waiting time days (range, SD)	513.3 (0–2307, 491.8)	114.7 (0–2425, 199.6)	152.25	<0.001‡
Liver alone mean waiting time (range, SD)	142.2 (0–2425, 194.3)	426.7 (0–2307, 442.0)	145.9 (0–2425, 202.0)	<0.001‡
Liver-Kidney mean waiting time (range, SD)	656.4 (5–1875, 538.8)	400.9 (0–1759, 438.0)	544.8 (0–1875, 516.5)	0.000‡
Intraoperative death n (%)	1 (0.6%)	29 (0.4%)	30 (0.4%)	0.832†
Patient death* n (%)	15 (9.7%)	1128 (16.2%)	1143 (13.6%)	0.088†
Graft failure (excluding death as cause of failure)* n (%)	9 (12.5%)	936 (20.8%)	1037 (19.3%)	0.014†

*At time of data extraction 16/09/2021
†Chi^2 test for categorical variables
‡Independent t test for continuous variables 95% CI

Conclusion: People with PLD have a >4-fold longer waiting time to transplantation than other indications despite better graft and patient outcomes. Transplantation rates for people with PLD varied between centres and may be related to registration criteria interpretation. These disparities deserve further study.

SAT309

Missed referrals for liver transplant evaluation are associated with worse outcomes in patients needing inpatient liver transplant evaluation

Katherine Cooper[1], Daniella Gonzalez[1,2], Alessandro Colletta[1,2], Deepika Devuni[1,2]. *[1]UMass Chan Medical School, Worcester, United States; [2]UMass Memorial Medical Center-University Campus, Worcester, United States*
Email: katherine.cooper@umassmed.edu

Background and aims: Guidelines state individuals with chronic liver disease (CLD) should be undergo liver transplant evaluation (LTE) once MELD ≥15 or hepatic decompensation. However, CLD is often under-recognized and undertreated which delays referral for liver transplant evaluation (LTE). We aimed to evaluate the effect of late referral for LTE on outcomes in patients undergoing inpatient LTE.
Method: In this single centre retrospective study, we reviewed charts for all patients undergoing inpatient LTE for CLD between October 2017 and August 2021. Charts were extensively reviewed for history of liver dysfunction, imaging evidence of cirrhosis, liver decompensations, and cirrhosis management. Group 1 included patients with previously missed opportunity for outpatient referral (documented MELD >15 or decompensation without a substance-related contraindication). Group 2 included those referred in a timely manner based on previous history. Categorical variables were compared between groups using Fishers exact test and associations using logistic models.

Results: About one third (37.7%) of patients undergoing inpatient LTE have received a transplant since evaluation. Less than a quarter (15%) received a transplant during their index admission; with patients referred late tending to be transplanted less often (11.5% vs. 18.5%, p = 0.21). Overall, patients with missed referrals were more likely to die after approval (30.8% vs. 17.3% p = 0.05) and less likely to receive a transplant than those without missed referrals (28.2% vs. 48.1%, p = 0.016). Even when adjusting for MELD-Na, disease etiology, and age, patients not receiving timely LTE referral are 2.2 times less likely to receive a liver transplant.

	Missed (Group 1) (n = 78)	Not Missed (Group 2) (n = 81)	
Demographics			
Age	58.7 ± 10.0	56.8 ± 9.2	0.20
White	79.5%	81.3%	0.84
Non-Hispanic	80.8%	90.1	0.12
Male	59.0	55.6	0.75
MELD	27.2 ± 7.4	27.1 ± 8.7	0.938
Primary Diagnosis			
ETOH	43.6%	53.1%	0.93
NASH	26.9%	21.0%	
HCV	11.5%	8.0%	
PBC/PSC	1.3%	2.5%	
Autoimmune	5.1%	4.9%	
Genetic (A1AT, HH)	7.7%	4.9%	
Other/Cryptogenic	3.8%	3.7%	
Overall Outcome			
No Committee	6.4%	2.5%	0.22
Denied or Not Listed	11.5%	15.8%	0.41
Removed from list	9.0%	3.7%	0.17
Died After Approval	30.8%	17.3%	0.05
On Wait list	14.1%	13.6%	0.92
Transplanted	28.2%	48.1%	0.015

Conclusion: Failure to refer for LTE in a timely manner has an adverse effect on patient outcomes. It is crucial to improve education about liver transplant and for providers to remain up to date on liver transplant candidacy and the transplant referral process.

SAT310

Nutritional intake after liver transplant: systematic review with meta-analysis and meta-regression

Lynsey Spillman[1,2], Angela Madden[3], Holly Richardson[3], Fumiaki Imamura[4], Kirsten Rennie[1], Linda Oude Griep[4], Michael Allison[5], Simon Griffin[4]. *[1]University of Cambridge, MRC Epidemiology Unit, Cambridge, United Kingdom; [2]Cambridge University Hospitals NHS Foundation Trust, Nutrition and Dietetics, Cambridge, United Kingdom; [3]University of Hertfordshire, School of Life and Medical Sciences, Hatfield, United Kingdom; [4]University of Cambridge, MRC Epidemiology Unit, Cambridge, United Kingdom; [5]Cambridge University Hospitals NHS Foundation Trust, Cambridge Liver Unit, Cambridge, United Kingdom*
Email: lynsey.spillman@addenbrookes.nhs.uk

Background and aims: Diabetes, obesity, hypertension, dyslipidaemia and cardiovascular disease are prevalent after liver transplant (LT) and may be prevented by diet. Understanding dietary behaviours of LT recipients (LTRs) can inform the development of evidence-based behavioural interventions to improve outcomes after LT. We aimed to synthesise evidence on nutritional intake of LTRs and investigate causes of heterogeneity in reported intake between studies.
Method: We searched Cochrane Library, MEDLINE, Embase, AMED, CINAHL, PsycINFO, BNI, Web of Science and OpenGrey electronic databases from the earliest date until 04/07/21 for peer-reviewed original studies of any design that recruited LTRs ≥18 years old and assessed their nutritional intake. Two independent reviewers screened papers, extracted data and assessed risk of bias (ROB). Where necessary data were converted to means and standard deviations for energy (kcal/day) and macronutrients (percent energy/day). Meta-regression analyses were undertaken.
Results: We included 21 studies, and 19 provided dietary findings for meta-regression. Five studies were at low ROB. The pooled daily mean energy intake was 1, 998 kcal (Figure); 17% from protein, 48% from carbohydrate, 34% from total fat, 10% from saturated fat and 20 g fibre. Average fruit and vegetable intake ranged from 105 to 418 g/day. Daily energy intake was lower at <1-month post-LT compared to all later time periods: 1-<6 months (-609kcal mean difference (MD), p = 0.002), 6-<12 months (-251kcal MD, p = 0.003), and ≥12 months (-135kcal MD, p = 0.021). As age of LTRs increased, daily energy intake was estimated to be 49.7kcal higher (p = 0.018) and energy from carbohydrates was 1.0% lower (p = 0.022). Energy from saturated fat increased as proportion of male participants increased (0.2%, p = 0.001). Total energy intake was higher (201kcal, p = 0.042), energy from protein lower (-2.5%, p = 0.004) and energy from total fat higher (3.7%, p = 0.005) in European studies compared to other continents.
Conclusion: Diet quality is a potentially important area for post-operative intervention for LTRs. Compared to recommendations from the European Association for the Study of the Liver (35kcal/kg body weight (BW) and 1.5 g protein/kg BW per day), on average LTRs are unlikely to meet energy or protein requirements for recovery in the first month post-LT. For protein and saturated fat LTRs follow recommendations for a healthy diet, however they consume a diet high in total fat and low in fibre, fruits and vegetables. The high energy diet for recovery may continue for longer than required, leading to energy imbalance and excess weight and body fat.

SAT311

Impact of muscle mass on survival of patients with hepatocellular carcinoma after liver transplantation beyond the Milan criteria

Liver Transplantation Unit and Ciberehd and ISS La Fe, Valencia, Spain; [20]*Erasmus MC Transplant Institute, Department of Gastroenterology and Hepatology, Rotterdam, Netherlands*
Email: b.beumer@erasmusmc.nl

Background and aims: When listing for liver transplantation we can transplant as soon as possible or introduce a test of time to better select patients as the tumor's biological behavior is observed. Knowing the degree of harm caused by time itself is essential to advise patients and decide on the maximum duration of the test-of-time. Therefore, we investigated the causal effect of waiting time on post-transplant survival for patients with HCC.

Method: We analyzed the UNOS-OPTN dataset and exploited the natural experiment created by blood groups. Relations between variables were described in a causal graph. Inverse probability weighting was used to address selection bias. Confounding biases were avoided using instrumental variable analysis, with an additive hazards model in the second stage. The causal effect was evaluated as a contrast between a scenario in which all patients waited 2 months and one in which all patients waited 12 months. Upper bounds of the test-of-time were evaluated for probable scenarios by means of simulation.

Results: The F-statistic of the first stage was 86.3. The effect of waiting 12 months versus 2 months corresponded with a significant drop in overall survival of 5.07% 95%CI [0.277; 9.69] and 8.33% 95% CI [0.47; 15.60] at 5- and 10-years post-transplant, respectively. The median survival significantly dropped by 3.41 years from 16.21 years 95%CI [15.98; 16.60] for those waiting 2 months to 12.80 years 95%CI [10.72; 15.90] for those waiting 12 months. No significant effect modification by tumor size or number was found.

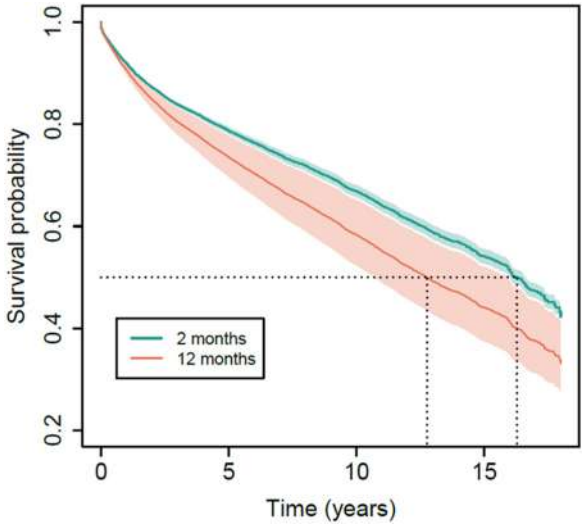

Figure 1: The survival probabilities if all listed HCC patients wait either 2 or 12 months.

Conclusion: From a patient's perspective the choice between ablate-and-wait versus immediate transplantation is in favor of immediate transplantation. From a policy perspective, the extra waiting time can be used to increase the utility of scarce donor livers, although the duration of the test-of-time is bound to be likely less than 8 months.

SAT312

Predictive factors of tumor recurrence after liver transplantation for hepatocellular carcinoma: analysis of a multicenter prospective study including 371 patients

Email: tdecaens@chu-grenoble.fr

Background and aims: Hepatocellular carcinoma (HCC) has become the first cause of liver transplantation (LT) in France but also in most countries of the world. Patient selection criteria are based on retrospective studies of cohorts of transplant patients. They are mainly linked to predictive factors of tumor recurrence. The aim of our work was to analyze the predictive factors of tumor recurrence at 24 months after liver transplantation, from a prospective study of patients registered on the LT list for HCC in France.
Method: Prospective multicenter study with 15 French LT centers (NCT01198704). Quantitative variables are presented as mean ± standard deviation or median with IQR25–75. The qualitative variables are presented in percentage. The overall survival analysis was carried out by the Kaplan Meier method and recurrence-free survival by competitive risk analysis (Fine and Grey) considering death as a competitive event.
Results: 371 patients were included in this study, 18 patients were wrongly included. Among the 353 patients, 72 patients left the list, including 48 (66%) for tumor progression. 281 patients were transplanted, 90% of them men. The median waiting time was 7.56 months (3.78–12.16). During the baseline freeze in October 2021, patients who had not died had a median follow-up of 60.1 months [95% CI: 58.8–61.2]. 45 patients showed tumor recurrence post-transplantation.
The 5-year overall survival was 72% (95%CI 66.2–77.0), the cumulative incidence rate was 16% (95%CI 12.2–21.0) and the median survival of relapsed patients was 16.1 months. (95%CI 13.0–24.0).
The multivariate analysis was divided into two for the construction of tumor recurrence scores based on the data accessible in pre-LT (registration and during the waiting time) and a model based on the data accessible after the transplant (pathology report, surgery data and clinical data within 6 months after LT). The remaining significant pre-LT parameters are the number of HCCs at enrollment >3 (HR = 2.67; p = 0.002) and progression of more than 7.5 ng/ml/month of AFP (HR = 2.25; p = 0.03). The progression of serum AFP level and the response to the waiting treatment disappear.
The remaining significant transplant and post-LT parameters are the number of viable HCC >3 (HR = 1.91; p = 0.039), the presence of satellite nodules (HR = 2.28; p = 0.01), and the presence of microscopic vascular invasion (HR = 2.41; p = 0.0006). The iron overload, the AFP rate at 6 months disappear.
Conclusion: This prospective multicenter study confirms the importance of the progression of the serum AFP level of more than 7.5 ng/ml/month as a predictive factor of tumor recurrence and underlines the importance of a low number of HCCs upon registration on listing. This study also shows the improvement in the prognosis of patients with tumor recurrence.

Evaluation of predictive factors for postoperative nausea and vomiting in hepatobiliary cancer patients

Juliana Fernanda Holanda Bezerra Pereira[1,2], Luciano Beltrão Pereira[3,4], Zoka Milan[1], Angela Sousa[2], Claudia Marquez Simões[2]. *[1]Kingś College Hospital, Anaesthesia and Critical Care, London, United Kingdom; [2]State of São Paulo Cancer Institute, Anaesthesia and Pain Care Department, São Paulo, Brazil; [3]Kingś College Hospital, Institute of Liver Studies, Liver Transplant and Surgery Department, London, United Kingdom; [4]Liver and Transplant Institute of Pernambuco-IFP, Recife, Brazil*
Email: julianafernanda@hotmail.com

Background and aims: Postoperative nausea and vomiting (PONV) is associated with prolonged stay in post anesthesia care unit, patient`s insatisfaction, dehydration, wound dehiscence, bronchoaspiration, acute hypertension, increased intracranial pressure, acid base and electrolyte disorders and delayed hospital discharge. Thus, PONV prophylaxis is mandatory for anesthesia good practice as it poses a significant medical risk. This work aims to validate a simple predictor model for nausea and vomiting in the first 24 postoperative hours in hepatobiliary cancer patients.
Method: This single center retrospective study included adults patients undergoing medium to large hepatobiliary cancer surgeries. It was approved by the Ethics and Research Committee at King`s College Hospital. We assessed the PONV incidence after 24 hours. To evaluate possible factors influencing the occurrence of PONV, logistic regression analysis was applied, regression coefficient B, odds ratio (OR), 95% confidence interval of the odds ratio (95% CI OR), and p value were reported. We constructed a receiver operation characteristic (ROC) curve with the area under with possible risk factors for PONV, including the Apfel Score (female sex, non smoking status, postoperative opioid use, history of PONV/sickness).
Results: Over a six months period, a total of 137 patients, predominantly non-smokers (91%), and British race (77%), with the mean age of 61.80 ± 14.41 years and almost equal ratio of males and females (53% vs. 47%), were included in the study. PONV was presented in 29.9% cases; 100% used opioids in the postoperative period; Apfel score ranged from one to four, and most patients had Apfel score two or three (94%). It was obtained that younger age, female gender, and higher Apfel score increased the probability for PONV, while ASA score 3 decreased it. None of the hepatobiliary surgeries was considered potential predictor for PONV. ROC curve for Apfel score as a predictor for PONV was 67.7% (p = 0.001) Figure 1.

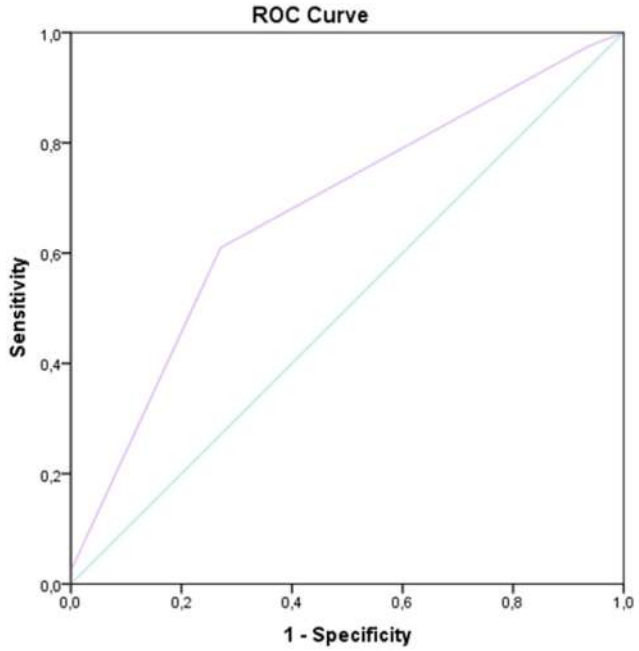

Figure 1. ROC curve for Apfel score as diagnostic marker for postoperative nausea and vomiting in hepatobiliary cancer patients.

Conclusion: We validated the Apfel Score in hepatobiliary cancer patients to guide the phophylaxis for PONV.

Liver transplantation and hepatobiliary surgery: Experimental and pathophysiology

Immune responses before and after liver transplantation: a cohort study of the induced immune response

Dina Leth Møller[1], Annemette Hald[1], Andreas Dehlbæk Knudsen[1,2], Ranya Houmami[1], Nicoline Stender Arentoft[1], Jens D. Lundgren[3,4], Allan Rasmussen[5], Sisse Rye Ostrowski[4,6], Susanne Dam Nielsen[1,4,5].
[1]Rigshospitalet, University of Copenhagen, Viro-immunology Research Unit, Department of Infectious Diseases 8632, Copenhagen, Denmark; [2]Rigshospitalet, University of Copenhagen, Department of Cardiology, Copenhagen, Denmark; [3]Rigshospitalet, University of Copenhagen, Centre of Excellence for Health, Immunity, and Infections, Department of Infectious Diseases, Copenhagen, Denmark; [4]University of Copenhagen, Department of Clinical Medicine, Copenhagen, Denmark; [5]Rigshospitalet, University of Copenhagen, Department of Surgical Gastroenterology and Transplantation, Copenhagen, Denmark; [6]Rigshospitalet, University of Copenhagen, Department of Clinical Immunology, Copenhagen, Denmark
Email: dina.leth.moeller@regionh.dk

Background and aims: Reliable methods to assess the immune function after liver transplantation (LTx) are needed to guide dosing of immunosuppression and thereby prevent infections and rejections. The TruCulture assay is a standardized immunoassay that assesses the induced immune response in whole blood following ligand-stimulation of toll-like receptors (TLR).
We aimed to investigate the induced immune responses using TruCulture in LTx recipients before and three months after LTx and explore associations between methylprednisolone-treated acute rejection and cytokine levels post-LTx.

Method: A prospective observational study including LTx recipients transplanted at Rigshospitalet, Copenhagen University Hospital, Denmark from February 2018 to December 2020.
The TruCulture analysis comprised 4 stimuli and a blank: A) Heat-killed Candida Albicans (HKCA, TLR1/2/4/6), B) Lipopolysaccharide (LPS, TLR4), C) Resiquimod R848 (R848, TLR7/8), D) Polyinosinic: polycytidylic acid (poly I:C, TLR3), and E) a blank containing only TruCulture media. After 22 hours of incubation, cytokine concentrations in the supernatants were measured by Luminex (TNF-α, IL-1β, IL-6, IL-8, IL-10, IL-12p40, IL-17A, IFN-α, and IFN-γ in pg/ml).
Differences in cytokine concentrations before and after LTx were assessed using Wilcoxon signed-rank tests with subsequent Benjamini-Hochberg corrections for multiple comparisons. Associations were assessed using logistic regression.
Results: We included 67 LTx recipients. Median age was 50 years (IQR: 23–70) and 41 were males (61%). Methylprednisolone-treated acute rejection occurred in 10 (15%) recipients a median of 8.5 days (IQR: 7–9) post-LTx.
Most of the stimulated cytokine levels decreased post-LTx (Figure 1). Methylprednisolone-treated acute rejection was significantly associated with an increased relative risk for a large decrease in HKCA-stimulated IL-10 (RR: 2.3 (1.1–5.0), p = 0.03), IL-1beta (RR: 2.5 (1.0–5.8), p = 0.04) and IL-8 (RR: 2.5 (1.1–5.5), p = 0.03), LPS-stimulated IL-10 (RR: 2.1 (1.1–4.1), p = 0.03), and Poly I:C-stimulated IL-1beta (RR: 2.1 (1.1–4.0), p = 0.03).

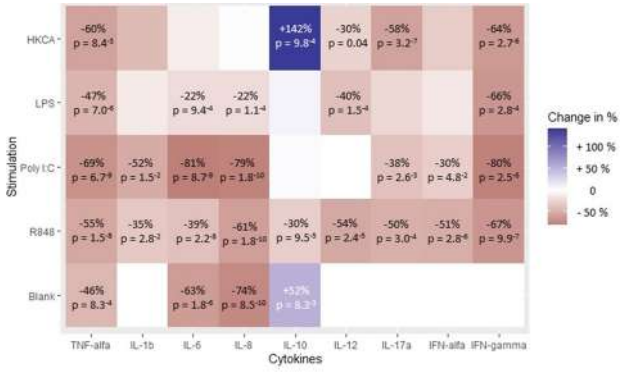

Figure 1: Differences in cytokine concentrations 3 months post-LTx compared to pre-LTx in percentages. Only significant differences are shown in the figure.

Conclusion: Most of the investigated induced immune responses decreased after liver transplantation. Treatment for acute rejection was associated with a larger decrease in a subset of the stimulated cytokines. Thus, TruCulture is feasible and seems promising. Further studies to determine utility for prediction of infections and rejections post-LTx are warranted.

SAT315

Andrographolide can potentially rescue unusable liver grafts by reducing fat content, enhancing mitochondrial function, and inhibiting Th1/Th17 immunity

Zhenlin Huang[1,2], Tengfei Si[2], Xiaohong Huang[2], Hanish Anand[2], Celine Filippi[2], Ragai Mitry[2], Anil Dhawan[2], Wayel Jassem[2], Zhengtao Wang[1], Nigel Heaton[2], Lili Ji[1], Yun Ma[2]. *[1]Shanghai University of Traditional Chinese Medicine, Institute of Chinese Materia Medica, Shanghai, China; [2]King's College London, Institute of Liver Studies, London, United Kingdom*
Email: yun.ma@kcl.ac.uk

Background and aims: There is a great shortage of good quality donor liver grafts to meet the increasing demand of patients with end-stage liver disease. A large proportion of donated livers are discarded due to suspected sub-optimal quality. One of the major reasons for low quality liver grafts is that the fat content in it being too high (>50%). Normothermic machine perfusion (NMP) is a novel

technique to preserve liver grafts which has been shown to improve marginal liver condition. Andrographolide (Andro), a newly defined active compound from traditional Chinese medicine (Chinese name: 穿心莲), has showed promising early results in vitro, so we are exploring using it in the NMP solution to reduce the fat content, improve the mitochondrial function, and inhibit the T cell induced immunity. This work is a deeper investigation of Andro's effects *in vitro* experiments to justify its use during NMP.

Method: Human hepatocytes were isolated from 9 donor fatty liver grafts which were unsuitable for transplantation due to their fat content >50%. Hepatic T cells were isolated from an additional 12 donors' liver perfusates. Hepatocytes and T cells were treated with sequentially increased dosage of Andro (5, 10, 25 μM) for 48 hours separately. After treatment, free and total cholesterol level in hepatocytes were detected using commercially available kits (Cholesterol Quantification Assay kit, CS0005, Merck); total DNA and RNA was extracted, mitochondrial DNA copy numbers and the expression of anti-oxidative genes was measured by qRT-PCR (SYBR™ Select Master Mix, 4472908, Thermo fisher); lipid droplets were stained using Oil Red (Lipid Staining Kit, MAK194, Merck). Cytokine levels in T cells including TNF-α, IFN-γ and IL-17 were

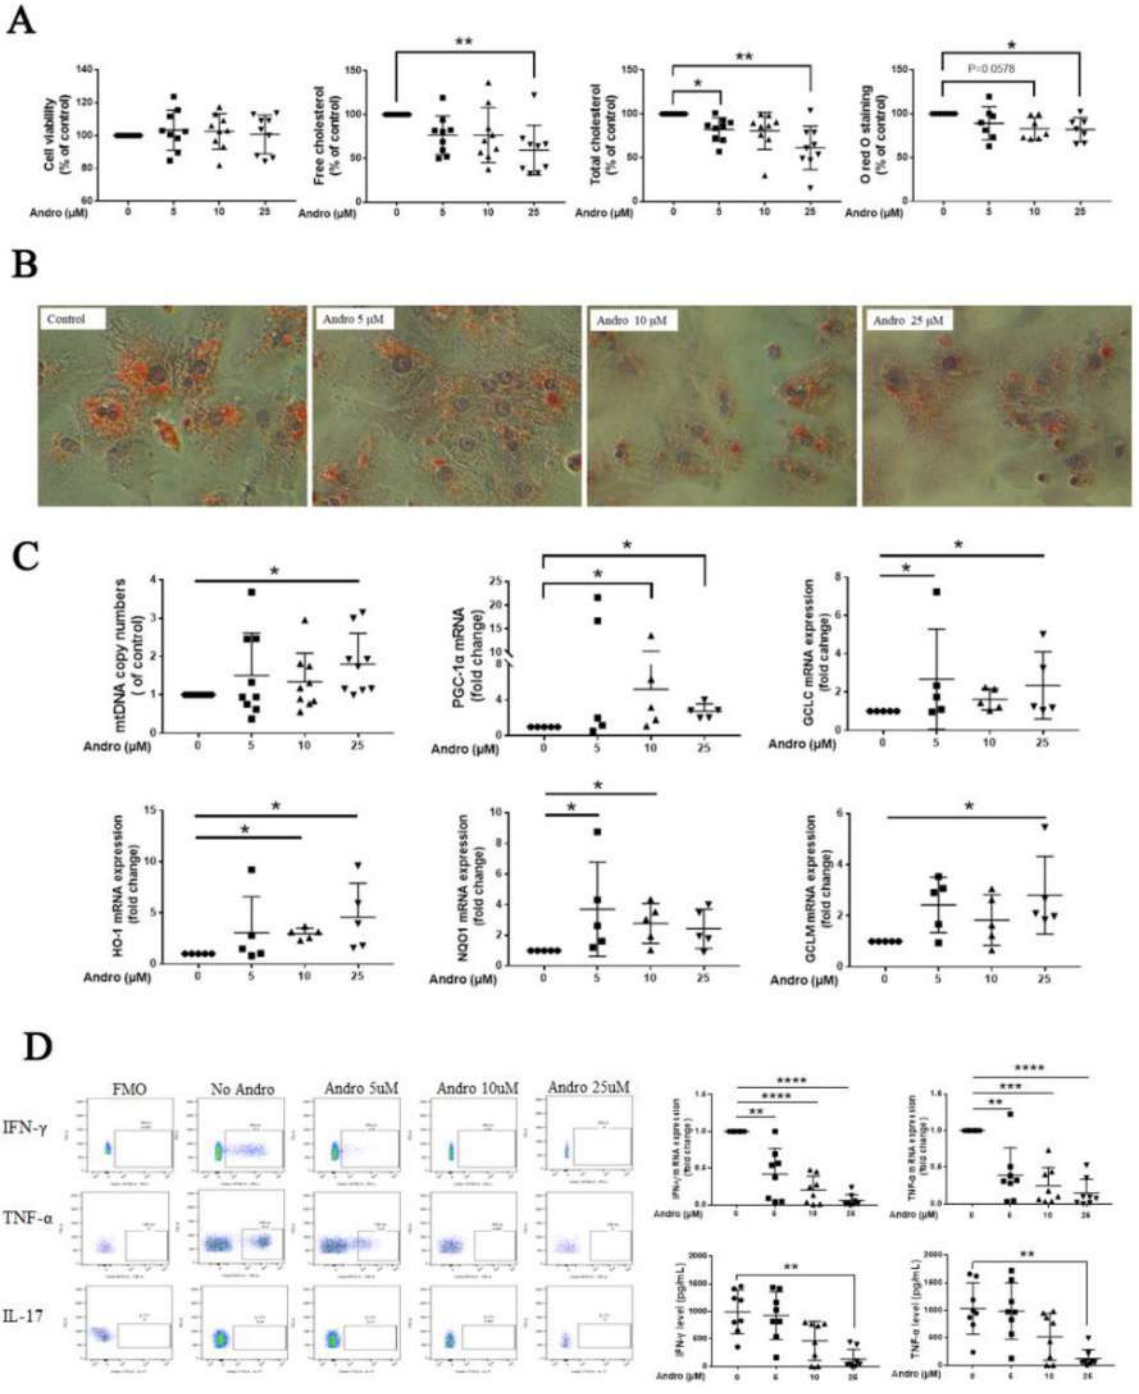

Figure: (abstract: SAT315)

measure using flow cytometry; qRT-PCR and ELISA (Human DuoSet ELISA, DY210/DY285B, RandD systems).
Results: In hepatocytes, different dosage of Andro (5, 10, 25 μM) caused no toxicity. High dosage of Andro (25 μM) reduced the level of free/total cholesterol (p <0.01) (Figure 1A), decreased amount of lipid droplets (Figure 1B), and increased the mitochondrial DNA copy numbers, mRNA expression of PGC-1α, GCLC, GCLM, HO-1 and NQO1 (p <0.05) (Figure 1C). Furthermore, Andro (5, 10, 25 μM) decrease the percentage of TNF-α, IFN-γ or IL-17-producing T cells and reduced mRNA expression of TNF-α and IFN-γ in T cells (p <0.05, $P < 0.01$, $P < 0.0001$). Andro (25 μM) also decreased the protein level of TNF-α and IFN-γ in T cell culture supernatant (p <0.01) (Figure 1D).
Conclusion: Andro is effective in reducing lipid content, promoting mitochondrial biogenesis and activating anti-oxidative system in hepatocytes. In addition, Andro inhibited Th1 and Th17 immunity. These results show that Andro has a great potential to rescue those marginal liver grafts to ease graft shortage in the setting of human liver transplantation.

Background and aims: The indications to liver transplantation (LT) are changing in western population over the years. The aims of the present study were to determine etiological trends in LT in Turkey.
Method: This is multicenter, retrospective study that evaluated the etiological factors of the patients with end-stage chronic liver disease who underwent LT between 2010 and 2020. A total of 5, 080 adult patients with LT was included into the study. The time frame was divided as January 1, 2010 to December 31, 2014 (first period) and January 1, 2015 to December 31, 2020 (second period) (Table 1).
Results: Mean age was 50.3 years; their gender was predominantly female (69.5%). Chronic viral hepatitis (46.4%) was the most common etiological factors leading to transplantation in the overall cohort. Hepatitis B virus (HBV) infection (35.2%) was the main etiology, followed by cryptogenic cirrhosis (CC) (23.5%), hepatitis C virus infection (8.2%), and ALD (6.2%). Hepatocellular carcinoma (HCC) was the LT indication for 939 patients (18.5%). In the second period, the proportion of viral hepatitis was decreased, whereas the proportion of NAFLD-related and ALD-related cirrhosis was increased (Table 1).

Table: Demographic data and etiologic changes in adult liver transplant patients

	Periods		
Demographic and etiologic parameters	2010–2014 (n:1677)	2015–2020 (n:3403)	p

Abbreviations: HBV (Hepatitis B Virus), HCV (hepatitis C Virus), HDV (hepatitis D Virus), AIH (Autoimmune Hepatitis), PBC (Primary Biliary Cholangitis), PSC (Primary Sclerosing Cholangitis), NAFLD (Non-alcoholic fatty liver disease), ALD (Alcoholic Liver Disease), CC (Cryptogenic Cirrhosis), WD (Wilson disease), BCS (Budd- Chiari syndrome), HC (Haemochromatosis), AAD (Alpha1-Antitripsin Deficiency)

Conclusion: The present study reports that chronic viral hepatitis as the main cause in indication of LT in Turkey and suggest that the proportion of viral hepatitis is beginning to decline, while the prevalence of fatty liver disease is increasing.

SAT317

A new avatar mouse model to predict the liver immune homeostasis and histologic inflammation of liver transplant patients

Soon Kyu Lee[1], Min-Jung Park[2], Ho Joong Choi[3], Young Kyoung You[3], Jeong Won Jang[1], Si Hyun Bae[1], Seung Kew Yoon[1], Pil Soo Sung[1], Mi-La Cho[2], Jong Young Choi[1]. *[1]College of Medicine, The Catholic University of Korea, Division of Hepatology, Department of Internal Medicine; [2]College of Medicine, The Catholic University of Korea, The Rheumatism Research Center, Catholic Research Institute of Medical Science; [3]College of Medicine, The Catholic University of Korea, Department of Surgery, Seoul St. Mary's Hospital*
Email: jychoi@catholic.ac.kr

Background and aims: Although liver transplantation (LT) patients have the possibility of rejection or tolerance, there have been no reliable models to predict the liver immune homeostasis of LT patients, which may give clinicians the chance to assess liver immunity and guide future treatment plans. Here, we developed a new patient-derived mouse model to predict the liver immune homeostasis of LT patients.
Method: The patient-derived avatar model was developed by injection of peripheral blood mononuclear cells from healthy controls (HCs) or LT patients with stable, rejection, or tolerance into NSG mice, followed by human hepatic stellate cells and CCl_4 injections. After seven weeks of transferring the cells, the patient's T-cell engraftment

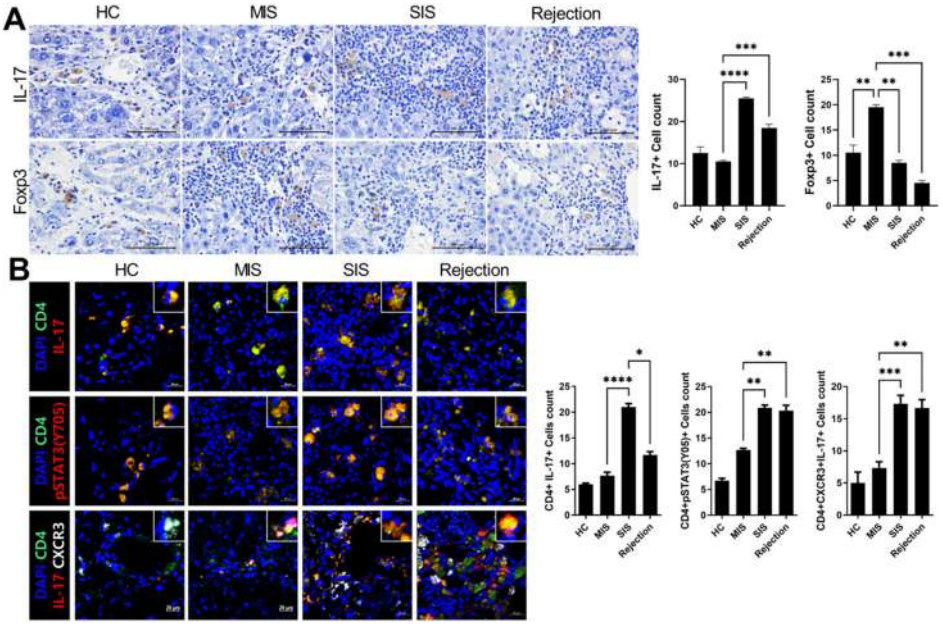

Figure: (abstract: SAT317): Comparative analysis of infiltrated T-cell subtypes in the liver of each avatar model group. (A) Representative images of IHC with anti-IL-17, FoxP3 antibodies. (B) Representative confocal microscopy analysis for Th17 cells localization in liver tissues. (×100, original magnification). $^{*}p$ <0.05, $^{**}p$ <0.01, $^{***}p$ <0.001, $^{****}p$ <0.0001. IHC, immunohistochemistry; MIS, mild inflammation with stable; SIS, severe inflammation with stable; NC, negative control; HC, healthy control.

and liver inflammation of the avatar model were evaluated and compared to the liver histology of LT patients.

Results: The CXCR3-dependently engrafted patient's T cells caused different liver inflammation in our model according to the status of the LT patients. The livers of avatar models from rejection patients had severe inflammation with more T helper 17 and fewer regulatory T cells compared to that of the models from tolerance and HCs showing only mild inflammation. Moreover, our model could classify stable post-LT patients into severe and mild inflammation groups, which correlated well with the liver immunity of these patients.

Conclusion: Using our new patient-derived avatar model, we could predict real liver immune homeostasis and histologic inflammation in stable LT patients without liver biopsy.

Conflict of Interest: All authors disclose no conflicts.

Email: sarahshalaby18@gmail.com

Background and aims: Patients with hepatocellular carcinoma (HCC) are at higher risk for post-transplant malignancies (PTM). Immune activation and senescence have been frequently implicated in cancer development, however, no data are available concerning their prognostic role in patients undergoing liver transplant (LT). The aim of the study was to analyze these profiles in patients transplanted for HCC (LT-HCC) and for other causes (LT-non-HCC).

Method: Patients who underwent LT between October 2016 and February 2021 at Multivisceral Transplant Unit, Padua University-Hospital were enrolled. Patients characteristics, HCC presence and features and immunosuppression were recorded. Exclusion criteria: ≤18 years old, follow-up shorter than 30 days or previous neoplastic history other than HCC. All PTM were registered. Markers of T (CD3+CD4/8+CD38+) and B (CD19+CD10-CD21-CD27+) cell activation, T (CD3+CD4/8+CD28-CD57+) and B (CD19+IgD-CD27-) cell senescence were evaluated by flow cytometry at transplantation (baseline).

Results: A total of 116 patients were included: 45 LT-HCC and 71 LT-non-HCC. LT-HCC patients were older than LT-non-HCC (median 60 vs 53 years, p = 0.011), but comparable for sex, liver disease etiology, immunosuppressive schedule. At baseline, levels of activated CD8, memory B-cells and senescent CD4, CD8 and B-cells were significantly higher in LT-HCC patients than LT-non-HCC ones. During 27.4 (7.7–41.7) months of follow-up, 6 PTM occurred: 4 in LT-HCC (8.9%) and 2 in LT-non-HCC (2.8%). Patients developing PTM showed significantly higher baseline levels of immune activation than patients without malignancies. Within LT-HCC group, levels of senescent cells were significantly higher in patients with PTM compared to the others [%CD8+CD28-CD57+: 22.45 (17.72–25.86) vs 10.82 (5.21–25.16), p = 0.098; %CD4+CD28-CD57+: 14.33 (10.23–21.12) vs 2.65 (1.10–13.11), p < 0.001].

Table: Differences of immunological parameters between LT-HCC and LT-non-HCC at baseline

Median (IQR)	LT-HCC (N = 45)	LT-non-HCC (N = 71)	p value*
%CD8 activation (CD8+CD38+HLA-DR+)	10.89 (5.61–18.52)	6.59 (4.26–9.25)	**0.003**
%CD4 activation (CD4+CD38+HLA-DR+)	7.23 (4.11–14.12)	6.21 (3.49–9.23)	0.092
%B activated memory (CD19+CD10-CD21-D27+)	10.97 (5.59–20.68)	7.60 (3.00–13.72)	**0.040**
%CD8 senescence (CD8+CD28-CD57+)	11.06 (6.24–25.16)	5.92 (3.54–10.97)	**0.006**
%CD4 senescence (CD4+CD28-CD57+)	3.80 (1.36–14.03)	1.80 (0.48–3.41)	**0.002**
%B senescence (CD19+CD27-IgD-)	12.20 (6.28–17.67)	6.59 (4.24–12.50)	**0.019**

*Adjusted by age.

Conclusion: Our findings suggest that patients undergoing LT for HCC have a higher immune activation and senescence profile compared to other recipients, possibly representing an additional risk factor for PTM. Moreover, immune activation and senescence may be prognostic factors for PTM occurrence regardless of the cause of transplantation.

SAT319

The crucial role of PARP [poly (ADP-ribose polymerase] on the post-ischemic liver injury and inflammation

Michitaka Ozaki[1], Sanae Haga[1], Naoki Morita[2]. [1]*Hokkaido University, Department of Biological Response and Regulation, Sapporo, Japan;* [2]*National Institute of Advanced Industrial Science and Technology (AIST)*
Email: ozaki-m@med.hokudai.ac.jp

Background and aims: Ischemia/reperfusion (I/R) of liver is an unavoidable event in liver surgery and transplantation, which sometimes causes serious post-operative liver failure/complications. The mechanism of I/R-induced liver injury, however, is complicated so that we have not elucidated yet. I/R-induced ROS, various types of programmed cell death and the following sterile inflammatory reaction seem to be crucial. In the present study, we investigated the roles of PARP [Poly (ADP-ribose) polymerase] on hypoxia/reoxygenation (H/R)-induced, ROS-mediated programmed cell death and inflammation in mouse liver cells and macrophages.
Method: AML12 cells and Raw264.7 cells were used for the experiments as hepatocytes and macrophages, respectively. Cells were cultured in high-glucose DMEM supplemented with 10% FBS. H2O2 were administered directly to the culture medium for oxidative stress. Cellular hypoxic conditions were created and maintained in a chamber by flushing with a 95% N2/5% CO2 gas mixture for 10 min and then sealing the chamber. Following 6 h of hypoxia, cells were reoxygenated by opening the chamber and replacing the hypoxic medium with oxygenated medium. Protein and gene expressions were measured by western blot analysis/capillary-based immunoassay and RT-PCR, respectively. Cell survival and death were determined by plating the cells in the xCELLigence System (Roche) and the LDH release.
Results: H/R-induced cell death was inhibited significantly by PJ34, a specific inhibitor of PARP. Because an oxidative stress is one of the major causes of H/R-induced cell death, we challenged 1 mM H2O2 to AML12 liver cells. H2O2 induced cell death, PAR [Poly (ADP-ribose)] production and nuclear translocation of AIF (apoptosis inducing factor), which were suppressed significantly by the pre-treatment of PJ34. H2O2 also induced Receptor-Interacting Protein (RIP)1/RIP3 binding, which indicates the involvement of necroptosis in H2O2-induced cell death. H2O2-induced RIP1/RIP3 binding was inhibited by PJ34. These facts indicate that H/R and ROS potentially induce parthanatos and necroptosis in hepatocytes. Furthermore, H/R-induced inflammatory reaction (proinflammatory gene expression) was inhibited by PJ34 both in AML12 cells and Raw264.7 cells.
Conclusion: PARP is potentially involved in H/R- and oxidative stress-induced cell death in mouse liver cells, by inducing programmed cell death (parthanatos and necroptosis) and inflammatory reaction.

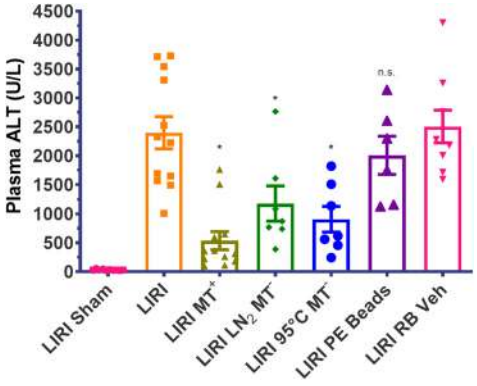
Background and aims: Liver ischemia/reperfusion injury (LIRI) is a disease process implicated in organ dysfunction following hepatic surgery, traumatic injuries, and liver transplantation. LIRI causes mitochondrial perturbations which lead to organ death. Stringent mitochondrial quality control is vital in reinstating organ integrity in LIRI. Mitochondrial transplantation (MT) has recently surfaced as a biotherapeutic option in IRI. The effect and mechanism of MT in IRI are poorly characterized. We hypothesized that MT, using mitochondria derived from mouse skeletal muscle tissue, is hepatoprotective following murine LIRI.
Method: We utilized an *in vivo* murine model of LIRI by occlusion of the hepatic artery leading to the left lobe for 1 h to achieve lobe-specific ischemia. Mitochondria were isolated from hindlimb mouse skeletal muscle tissue by differential filtration followed by characterization for particle size and number, ATP, membrane potential, ultrastructural morphology, and protein purity. Inactivation of mitochondria was conducted using liquid nitrogen (LN_2) immersion or incubation at 95°C. Active or inactive mitochondria were intrasplenically injected, to access the portal system, at the start of reperfusion. Mouse livers were reperfused for 2 h followed by sacrifice for blood and liver tissue collection for various molecular/histological analyses.
Results: Isolated active mitochondria (1–3um) retained membrane potential, cristae architecture and morphology, protein purity, and ATP content. LIRI animals had significantly greater circulating AST and ALT compared to sham animals. In addition, LIRI animals had extensive, left lobe-specific liver necrosis, congestion, and vacuolization, when compared to sham animals. Intrasplenic injection of 80 million active mitochondria into LIRI animals, significantly reduced plasma AST and ALT concentrations and normalized histology. Blinded Suzuki scoring of liver histology showed a significant attenuation of congestion, necrosis, and vacuolization as a result of MT in LIRI animals. Interestingly, inactivated mitochondrial particles (LN_2 or 95°C) also significantly reduced plasma AST and ALT, albeit to

a lesser degree. To rule out a confounding "particle effect" of MT, polyethylene beads (1–4um) were injected and showed no protective effect against LIRI. Treatment with active mitochondria in LIRI animals significantly increased plasma IL-10 and decreased plasma IL-6 compared to control animals.



Conclusion: MT attenuated LIRI regardless of whether injected mitochondria were active or inactive. Future studies will focus on understanding how MT confers protection from LIRI and how their use in clinical scenarios might be optimized. Future avenues of this research include exploring metabolic reprogramming and liver regeneration as potential explanations for the hepatoprotection afforded by MT.

Viral hepatitis B/D: therapy

Email: dietz.christopher@mh-hannover.de

Background and aims: Infection with hepatitis D virus (HDV) occurs as coinfection with hepatitis B virus. Chronic hepatitis D is the most debilitating form of viral hepatitis with a high risk of liver cirrhosis and hepatocellular carcinoma (HCC). Bulevirtide (BLV) is the first drug with a conditional approval for the treatment of chronic HDV infection in compensated liver disease. The aim of this project is the characterization of treatment response in terms of viral suppression and improvement of hepatic inflammation in a real-world setting.

Method: We collected anonymised longitudinal observational data from fourteen German centres treating patients with 2 mg of BLV. Individual case data from the participating centres were collected in a standardized data sheet. A paired t-test or Wilcoxon signed rank test was used for comparative data analysis. Analyses were carried out with R Studio. Statistical significance was assumed if p values were below 0.05.

Results: Baseline data was collected from 109 patients. In 103 cases BLV was given in combination with a nucelos (t)idanalogon. Currently, 47 and 26 patients reached treatment week 12 and 24 (Table 1). Elevated transaminases improved by 64 IU/ml at average with 24 cases reaching normal ALT levels (<45 U/l) at week 12. A 2log reduction in viral load was achieved by 4 (week 12) and 11 cases (week 24). Liver cirrhosis was present in 43 cases (FIB-4 >3.6) with 4 patients being initially decompensated. Observed improvements regarded the amount of ascites and levels of bilirubin. Hepatic decompensation occurred in two cirrhotic patients. No HCC or other drug-related SAE occurred. Fatigue was the most frequent AE reported (n = 7). A continuous improvement of FIB-4 was noted.

Table: Shown are key characteristics. p values were obtained from paired t-tests or Wilcoxon signed-rank test if medians were compared.

Parameter	Baseline (n = 109)	Week 12 (n = 47)	Week 24 (n = 26)
Log10 HDV-RNA Median	5.7	4.5 (p < 0.001)	3.5 (p < 0.001)
2log reduction	/	4/47	11/26
Viral non-response (<1log reduction)	/	20/47	4/26
ALT (U/l) Mean ± SD	116 ± 105	53 ± 30 (p < 0.001)	47 (p < 0.001)
AST (U/l) Mean ± SD	90 ± 64	49 ± 17 (p < 0.001)	37 (p < 0.001)
Albumin (g/l) Mean ± SD	41 ± 5.4	40 ± 6 (p = 0.36)	42 (p = 0.19)
Bilirubin (µmol/l) Mean ± SD	15 ± 10.4	17 ± 12 (p = 0.75)	14 (p = 0.83)
INR Mean ± SD	1.2 ± 0.1	1.2 ± 0.2 (p = 0.15)	1.1 (p = 0.55)
Platelets (10^3/µl) Median	125	115 (p = 0.42)	159 (p = 0.03)
Bile salts (µmol/l) (n = 15)	17 ± 19	60 ± 75 (p < 0.001)	49 ± 49 (p < 0.001)
FIB-4 Median	2.8	2.5 (p < 0.001)	1.9 (p = 0.006)

Conclusion: Decreased platelets and a median FIB-4 of 2.8 indicate advanced liver disease and portal hypertension in patients selected for BLV treatment. After 12 weeks of treatment a decline in viral load is accompanied by a significant improvement in hepatic inflammation and FIB-4. Updated results will be presented at the meeting.

SAT342

Challenges with the cascade of HDV care in Mongolia

Enkhjargal Altangerel[1], Nandintsetseg Tsoggerel[1], Suvd Batbaatar[1], Uyanga Bat-Osor[1]. [1]*Academy of Medical Professionals, Department of Research, Mongolia*
Email: ajargal8@gmail.com

Background and aims: Hepatitis D infection is highly endemic among individuals with chronic HBV infection in Mongolia. The anti-HDV prevalence among HBsAg-positive individuals, indicating likely HBV/HDV coinfection, ranged from 41% to 67% in the two major seroepidemiological studies. The study aimed to define the challenges within the care cascade among HDV patients.
Method: We conducted the cross-sectional survey designed with the inclusion and exclusion criteria for the selection among the patients diagnosed with a coinfection of HBV and HDV. The questionnaire covered topics of care cascade and linkage to the care. In total, 576 participants enrolled in the survey. Both online and paper modes were used to collect the questionnaire. The collected data was analyzed by SPSS 21.0 software.
Results: 65.0% of the participants were from urban areas. Most of the participants were women (59.8%), and the mean age was 43.57 ± 10.9. The duration of linkage to the specialized doctor varied: the most are within a month (33.3%), within 3–6 months (15.9%), 6–12 months year (17.9%) and more than a year (18.8%). More than half of the participants enrolled to fibrosis assessment within a month (35.0%) and within 3–6 months (26.7%) after linked to the specialized care. However, many (34.5%) didn't attend a specialist's periodic exam and monitoring service after the fibrosis stage was defined. Except for 22.7% of the participants, all were on the antiviral treatment for HBV, including entecavir (11.1%), TAF (36.4%), and the remaining (29.8%) were on a combination of entecavir and TAF. Almost all participants (97.1%) did not get treatment with Peg-interferon, while only (2.9%) underwent the treatment. Peg-interferon treatment patients had the injection at the hospital (70.6%), Family Health Centers (17.6%), and at home (11.8%). The treatment duration was between one months to 1.6 years. The main reasons for the treatment interruption are combination of two or three of the reasons including an inability to bear the side effects, stock out of the injection, and lack of the money to pay for the injection. At the same time, the doctors recommended the Peg-interferon treatment to only 8.7% of the participants.
Conclusion: The most of patients spent a month and more time for the linkage to the care for HDV patients. The patients experience delays in the further steps of the cascade of care, including defining the fibrosis stage and attending periodic monitoring exams. Most doctors do not recommend Peg-interferon treatment, and very few patients are under the treatment. Side effect impact, poor supply, and high cost for injection are the main reasons for treatment interruption. Antivirals treatment for HBV is well practiced.

SAT343

Safety, tolerability and pharmacokinetics of single ascending doses of ALG-020572, a GalNAc-conjugated antisense oligonucleotide, in healthy subjects

Edward J Gane[1], Man-Fung Yuen[2], Christian Schwabe[3], Min Wu[4], Kha Le[4], Jen Rito[4], Kusum Gupta[4], Christopher Westland[4], Felix Lai[4], Meenakshi Venkatraman[4], Megan Fitzgerald[4], Tse-I Lin[4], Lawrence Blatt[4], Sushmita Chanda[4], Matt McClure[4], John Fry[4], Kosh Agarwal[5]. [1]*University of Auckland, Faculty of Medicine, Auckland, New Zealand;* [2]*The University of Hong Kong, Hong Kong;* [3]*Auckland Clinical Studies, Auckland, New Zealand;* [4]*Aligos Therapeutics, South San Francisco, United States;* [5]*King's College Hospital, Institute of Liver Studies, London, United Kingdom*
Email: mwu@aligos.com

Background and aims: To evaluate the safety, tolerability, pharmacokinetics (PK) and antiviral activity of ALG-020572, an antisense oligonucleotide designed to reduce hepatitis B S-antigen (HBsAg) in subjects with chronic hepatitis B (CHB).
Method: This is a two-part, double-blind, randomized, placebo-controlled, single- and multiple ascending dose study. In Part 1, cohorts containing 8 healthy subjects, including at least 4 Asians, were randomized to receive a single ascending subcutaneous (SC) dose of ALG-020572 or placebo in a 3:1 ratio. In Part 2, planned cohorts will consist of 8 CHB subjects that are randomized 3:1 to receive multiple ascending SC doses of ALG-020572 or placebo. Safety assessments, viral markers (Part 2) and plasma/urine PK samples are collected throughout the study. Preliminary blinded results from the first 2 cohorts of Part 1 are reported here. Additional available data will be presented at the conference
Results: In Part 1, the first 2 cohorts of healthy subjects received a single 50 or 150 mg SC dose of ALG-020572 or placebo. Subjects were a mean age of 28 years, 94% male and 50% Asian. ALG-020572 was well tolerated; there were no serious adverse events (AEs) or dose limiting toxicities and all treatment-emergent AEs were mild in severity except one grade 2 injection site tenderness. All treatment-emergent laboratory abnormalities were Grade ≤2. No clinically significant physical examination, vital sign, or ECG abnormalities were reported. Plasma ALG-020572 exposures increased in a slightly greater than dose proportional manner between 50 and 150 mg, with low-to-moderate variability. ALG-020572 showed rapid absorption (t_{max} ~ 2hrs), high volume of distribution, high plasma clearance, and low urinary excretion. No differences in safety or PK were observed between Asian and non-Asian subjects. Based on observed exposures and nonclinical studies, ALG-020572 doses ≥150 mg are projected to have antiviral activity in CHB subjects.
Conclusion: ALG-020572 was safe and well tolerated with predictable PK properties when given to healthy subjects as single SC doses of up to 150 mg.

SAT344

Predictors of HBsAg loss after cessation of nucleo (s)tide analogue therapy in asian patients with low HBsAg levels

Email: m.j.sonneveld@erasmusmc.nl

Background and aims: HBsAg levels ≤100 IU/ml can be used to identify HBeAg negative patients most likely to achieve durable remission after cessation of nucleo (s)tide analogue (NUC) therapy. However, the majority of these patients will not achieve HBsAg clearance. We aimed to study predictors of HBsAg loss in patients with low HBsAg levels who discontinued NUC therapy.
Method: We identified Asian patients with low end-of-treatment (EOT) HBsAg levels (≤100 IU/ml) from a global database of HBeAg negative patients with undetectable HBV DNA who discontinued long-term NUC therapy. The primary end point for this analysis was HBsAg loss. Patients requiring re-initiation of antiviral therapy were considered non-responders. Determinants of HBsAg loss were explored using backward stepwise elimination in a multivariable Cox regression model considering the following variables: age,

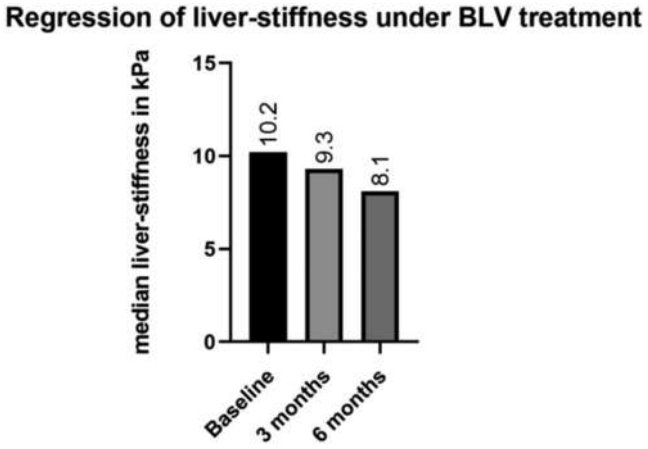
gender, baseline HBeAg status, HBV genotype, and EOT ALT, HBsAg and HBcrAg levels.
Results: We identified 243 patients, of whom the majority were treated with entecavir (62%) or tenofovir disoproxil fumarate (29%). Thirty (12%) patients had been HBeAg positive at start of NUC therapy (all were HBeAg negative at treatment cessation). Median HBsAg levels at EOT were 1.49 log IU/ml (IQR 1.0–1.8) and 172 (71%) had undetectable HBcrAg. HBV genotype B was detected in 107 (44%) patients, and genotype C in 43 (18%); the others had other or unknown genotypes. After therapy cessation, 83 (34%) patients were retreated and 52 (21%) patients cleared HBsAg after a median of 74 (IQR 48–179) weeks of off-treatment follow-up. Multivariable Cox regression identified HBV genotype C (aHR 2.769, p = 0.003), lower HBsAg (aHR 0.218, p < 0.001), lower HBcrAg (aHR 0.729, p = 0.010) and age (aHR 0.958, p = 0.015) as independent predictors of HBsAg loss.
Conclusion: Among Asian patients with EOT HBsAg levels ≤100 IU/ml, HBV genotype C, age and lower HBsAg and HBcrAg levels are associated with a higher probability of HBsAg clearance.

SAT345

Improvement of liver-stiffness after 6 months of therapy: real-life data for HBV/HDV co-infected patients treated with bulevirtide

Alexander Killer[1], Mahyar Ghavemi[1], Gliga Smaranda[1], Johannes Bode[1], Björn Jensen[1], Jan Köhler[1], Andreas Walker[2], Nadine Lübke[2], Jörg Timm[2], Tom Lüdde[1], Hans Bock[1]. *[1]Uniklinik Düsseldorf, Klinik für Gastroenterologie, Hepatologie, Infektiologie, Düsseldorf, Germany; [2]Uniklinik Düsseldorf, Institut für Virologie, Düsseldorf, Germany*
Email: Alexander.Killer@med.uni-duesseldorf.de

Background and aims: HBV/HDV coinfection is the most aggressive form of chronic viral hepatitis with a high risk for the development of liver cirrhosis and subsequent complications like hepatocellular carcinoma (HCC). In 09/2020 bulevirtide (BLV), a synthetic lipopeptide that blocks HBV/HDV uptake into hepatocytes by binding to the NTCP-receptor, has been approved for the treatment of HDV-related chronic hepatitis in Germany. So far, there is only limited data available on the efficacy of BLV treatment under real-life conditions. We present our single-centre clinical and virological data on 12 patients treated with BLV.
Method: From 11/2020 on, twelve HDV-infected patients with active chronic hepatitis were enrolled. Virological, biochemical and clinical parameters were measured at baseline and at monthly intervals thereafter. Furthermore, we measured liver stiffness by shear wave elastography.
Results: The median age of the 12 patients enrolled (4 female, all HDV-genotype 1) was 42.5. Five patients had compensated liver cirrhosis, ten received NUC-therapy and eight had a history of previous interferon treatment. Mean baseline parameters were: HDV-RNA 597, 000UI/ml, ALT 117U/l, AST64 U/l, bile acids 11.5umol/l, platelets 160/nl, HBsAg 23.074 IU/ml, liver stiffness 10.0kPa. Of note, shear wave elastography results revealed an improvement of liver stiffness to median values of 9.3kPa after 3 and 8.1kPa after 6 months. In total, 9 patients (75%) had improved by at least 1kPa in liver-stiffness. At the time of final analysis (median treatment duration: 8.5 months), no patient had undetectable HDV RNA, 6 patients (50%) had a normalization of ALT and 4 (33%) had reached a combined response of ALT normalization and ≥2Log IU/ml HDV decrease. Mean values of viral loads changed to HDV-RNA 27, 600IU/ml, bile acids 29umol/L, ALT 42U/l and AST 29U/l. Treatment was terminated for two patients, one because of non-response at week 48, and one for development of HCC.



Conclusion: BLV was well-tolerated and led to a biochemical and virological response in the majority of patients. Treatment led to an early and marked decrease of liver-stiffness, suggesting improvement in liver fibrosis in a setting of chronic viral infection. Therefore, an improvement in liver-stiffness could be a way to predict a clinically relevant response and benefit for patients treated with BLV, warranting additional studies in larger patient cohorts.

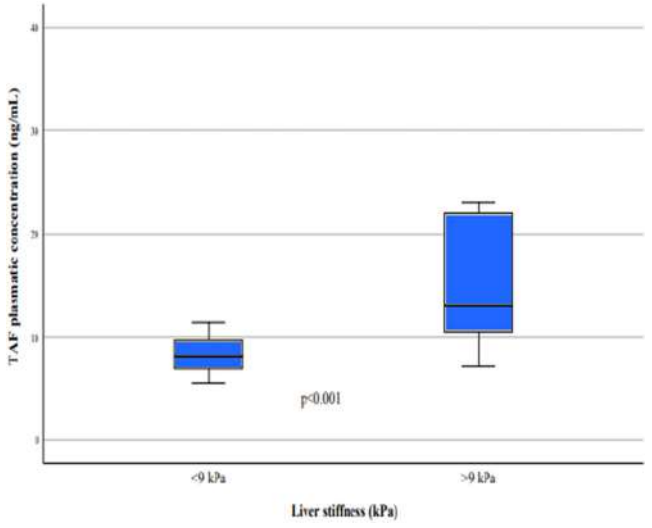
SAT346

Role of plasmatic and urinary TDF and TAF concentration in a cohort of HBV chronic hepatitis patients

Giacomo Stroffolini[1], Valentina Dodaro[1], Lucio Boglione[2], Giuseppe Cariti[1], Giovanni Di Perri[1]. *[1]Amedeo di Savoia Hospital, University of Torino, Medical sciences, Italy; [2]University of Piemonte Orientale, Italy*
Email: giacomo.stroffolini@unito.it

Background and aims: Tenofovir disoproxil fumarate (TDF) is the first-line therapy for chronic HBV infection. Currently, the proximal tubular kidney toxicity of the TDF is debated. Recently, tenofovir alafenamide fumarate (TAF) has been approved; virological and serological effectiveness are equal to TDF, but with lower kidney excretion and tubular toxicity. TAF is currently available for patients over sixty, pretreated with TDF or other NAs, with bone or kidney impairment; however, which categories of patients can benefit the most switching from TDF to TAF is still unclear.
Method: A cross-sectional study was conducted between November 2019 and January 2021. 42 patients were included (n = 42). At the baseline 17 patients who met the eligibility criteria were switched from TDF to TAF (n = 17), while the others continued treatment with TDF (n = 25). Patients were evaluated at baseline and aftersix months. The plasmatic and urinary dosage was performed for 16 patients treated with TAF (n = 16) and for 25 patients treated with TDF (n = 25).
Results: Patients treated with TDF were significantly younger than patients treated with TAF (38 vs 67 years). The plasmatic concentration of TAF was significantly lower for genotype E (27 vs 80 ng/ml) and higher for genotype C (114 vs 36.5 ng/ml) than other genotypes. Higher plasmatic concentration of TAF was found in patients whose liver stiffness was more than 9 kPa (8.20 vs 13.00 ng/ml, see figure). In the TAF group eGFR increased and urinary drug concentration reduced significantly compared to the TDF group (+9 vs 0 ml/min and – 4.5 vs +3 ng/ml. eGFR decreased and urinary TDF increased significantly for ADV-pretreated TDF patients compared to not-ADV-pretreated TDF patients (- 9 vs +2 ml/min and +9 ng/ml vs +1 ng/ml). The increase of eGFR and the reduction of excreted urinary TDF-TAF in ADV-pretreated TAF group were significant compared to not-ADV-pretreated TAF group (+6.50 vs +1 ml/min and-3.5 vs +2 ng/ml. At linear regression, in univariate analysis the variation of urinary tenofovir concentration was inversely related to age and pretreatment with ADV for TAF patients and directly proportional to eGFR and

pretreatment with ADV for TDF patients ($p < 0.005$). In the multivariate analysis only eGFR and pretreatment with ADV for TDF patients resulted significant and directly proportional to the variation of urinary tenofovir concentration (<0.005).



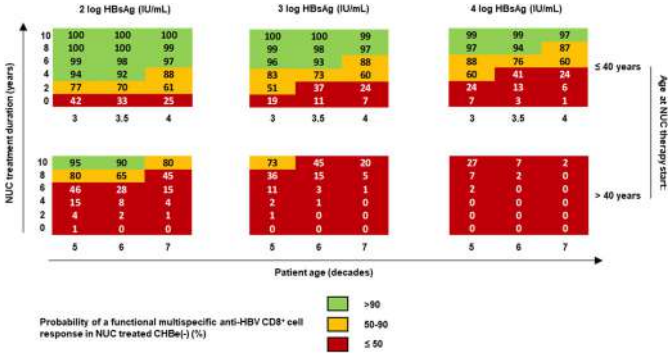
Conclusion: According to these results, ADV-pretreated patients have a benefit from switching TDF to TAF. The correlation of genotype with plasmatic TAF concentration suggests a possible key role of TDF/TAF transporter polymorphisms. Finally, further studies are needed for a better understanding of TAF pharmacokinetics in relation to liver stiffness

SAT347

Model to predict on-treatment restoration of functional HBV-specific CD8+ cell response foresees off-treatment HBV control in eAg-negative chronic hepatitis B

Julia Peña Asensio[1,2], Henar Calvo[1], Joaquin Miquel[1], Eduardo Sanz de Villalobos[1], Alejandro González Praetorius[1], Miguel Torralba[1,3], Juan Ramón Larrubia[1,3]. *[1]Guadalajara University Hospital, Translational Hepatology Unit, Guadalajara, Spain; [2]University of Alcala, Department of Biology of Systems, Alcala de Henares, Spain; [3]University of Alcala, Department of Medicine and Clinical Specialties, Alcala de Henares, Spain*
Email: hlnd.julia@gmail.com

Background and aims: Hepatitis B virus (HBV)-specific CD8+ cell response restoration during nucleos (t)ide analogue (NUC) treatment could lead to off-treatment HBV control in e-antigen-negative chronic hepatitis B (CHBe (-)). To predict this response with variables involved in T-cell exhaustion for use as treatment stopping tool.
Method: In NUC treated CHBe (-) patients, we considered a functional response in cases with HBV-specific CD8+ cells against core and polymerase able to proliferate and secrete type-I cytokines after antigen encounter. We performed a logistic regression model (LRM) to predict the likelihood of developing this response, based on patient age (subrogate of infection length) and, HBsAg level, NUC therapy starting point and duration (antigenic pressure). We discontinued treatment and assessed HBV-DNA dynamics, HBsAg loss and HBsAg decline during off-treatment follow-up, according to LRM likelihood.
Results: We developed a LRM that predicted the presence of a proliferative type-I cytokine-secreting cell response, which correlated positively with treatment duration and negatively with treatment initiation after 40-year age and with age adjusted by HBsAg level. We observed a positive correlation between LRM probability and intensity of proliferation, number of epitopes with functional proliferating response and type-I cytokine secretion level. Off-treatment, HBsAg loss, HBsAg decline >50% and HBV control were more frequent in the group with >90% LRM probability.



Conclusion: Short-term low-level antigen exposure and early long-term NUC treatment influence the restoration of a functional HBV-specific CD8+ cell response. Based on these predictors, high likelihood of detecting this response at treatment withdrawal associates with off-treatment HBV control and HBsAg decline and loss.

SAT348

Antiviral treatment cessation in HBeAg negative chronic hepatitis B: clinical outcome is associated with increase in specific pro-inflammatory cytokines

Marte Holmberg[1], Dag Henrik Reikvam[2], Olav Dalgard[3], Hans Christian Dalsbotten Aass[2], Ellen Samuelsen[3], Niklas Björkström[4], Asgeir Johannessen[1]. *[1]Vestfold Hospital Trust, Tønsberg, Norway; [2]Oslo University Hospital Ullevål, Oslo, Norway; [3]Akershus University Hospital, Lørenskog, Norway; [4]Karolinska University Hospital, Center for Infectious Medcine, Stockholm, Sweden*
Email: marte.holmberg@online.no

Background and aims: Patients with HBeAg negative chronic hepatitis B may experience an immune response after stopping nucleos (t)ide analogue (NA) therapy, which may potentially trigger functional cure (HBsAg loss) or off-therapy sustained viral control. The immunological mechanisms that determine clinical outcome after treatment stop remain poorly understood, and predictors of clinical outcomes are lacking. We hypothesized that markers of systemic inflammation could identify key inflammatory pathways that are associated with and can predict clinical outcome after NA therapy cessation.
Method: Plasma cyto- and chemokines from 57 patients from the ongoing Nuc-Stop study were analyzed by Bio-Plex Pro Human Cytokine 27-plex Assay at baseline and three months after stopping NA therapy. All patients were HBeAg negative, non-cirrhotic, and virally suppressed for at least 24 months prior to stopping NA therapy. Outcome at three months was classified as immune control (HBV DNA <2000 IU/ml and ALT <2x baseline), viral relapse (HBV DNA >2000 IU/ml and ALT <2x baseline), clinical relapse (HBV DNA >2000 IU/ml and ALT >2x baseline), or clinical relapse with restart of treatment. Statistical significance ($p < 0.05$) was determined using Kruskal-Wallis tests or one-way ANOVA followed by Bonferroni post-hoc tests.
Results: After three months, there was a significant increase in interferon gamma-induced protein 10 (IP-10) in patients with clinical relapse who restarted treatment ($p = 0.001$) (Figure). This group also had a stronger ALT flare compared with those who had a clinical relapse without restart (median peak ALT 216 vs. 103 U/L, $p = 0.025$). A significant, but less pronounced, increase in tumor necrosis factor (TNF) was observed in the same group ($p = 0.010$) (Figure). None of the other cyto- or chemokines were associated with clinical outcome at three months.

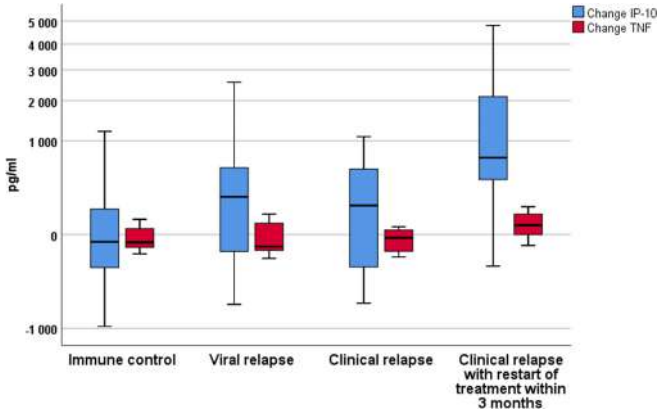


Figure: Changes in IP-10 and TNF 3 months after NA therapy cessation

Conclusion: Clinical relapse requiring restart of antiviral treatment after NA cessation was associated with specific increase in IP-10 and TNF.

SAT349

Tenofovir alafenamide for pregnant chinese women with active chronic hepatitis B: a multicenter, prospective, real-world study

Qing-Lei Zeng[1], Hongxu Zhang[2], Ji-Yuan Zhang[3], Shuo Huang[1], Wei-Zhe Li[1], Guangming Li[4], Ying-Hua Feng[5], Guofan Zhang[6], Jiang-Hai Xu[7], Wan-Bao Lin[8], Guang-Hua Xu[9], Guoqiang Zhang[10], Yan-Li Zeng[11], Zu-Jiang Yu[1], Fu-Sheng Wang[3]. *[1]The First Affiliated Hospital of Zhengzhou University, Department of Infectious Diseases and Hepatology, Zhengzhou, China; [2]Luohe Central Hospital, Department of Infectious Diseases, China; [3]The Fifth Medical Center of Chinese PLA General Hospital, Treatment and Research Center for Infectious Diseases, Beijing, China; [4]The Sixth People's Hospital of Zhengzhou City, Department of Hepatology, China; [5]The Sixth People's Hospital of Kaifeng City, Department of Hepatology, China; [6]The First Affiliated Hospital of Nanyang Medical College, Department of Infectious Diseases, China; [7]The Fifth People's Hospital of Anyang City, Department of Hepatology, China; [8]Xinyang Central Hospital, Department of Infectious Diseases, China; [9]The Affiliated Hospital of Yan'an University, Department of Infectious Diseases, China; [10]Luoyang Central Hospital, Department of Infectious Diseases, China; [11]Henan Provincial People's Hospital, Department of Infectious Diseases, China*
Email: zengqinglei2009@163.com

Background and aims: Data on long-term tenofovir alafenamide (TAF) therapy for pregnant women with active chronic hepatitis B (CHB, immune clearance and reactivation phases) are lacking. The aim of this study was to investigate the safety and effectiveness of TAF in pregnant women with active CHB and their infants.

Method: Pregnant women with active CHB treated with TAF and tenofovir disoproxil fumarate (TDF) were enrolled in this multicenter (a total of 11 hospitals) prospective study, and infants received standard immunoprophylaxis. The primary outcomes were rates of adverse (safety) events in pregnant women and defects in infants and fetuses. The secondary outcomes were virological responses in pregnant women, infants' safety, hepatitis B surface antigen (HBsAg) status, and growth conditions. Participants were assessed for eligibility from January 1, 2019, to March 31, 2020. The pregnant women and their infants were followed until at least 6 months after delivery and 7 months of age, respectively. The final follow-up date was the November 15, 2021.

Results: One hundred three and 104 pregnant women were enrolled, and 102 and 104 infants were born in the TAF and TDF groups, respectively. In the TAF group, 82 (79.6%) pregnant women were hepatitis B e antigen (HBeAg) positive, and the mean age, gestational age, alanine aminotransferase level, and viral loads at treatment initiation were 29.3 years, 1.3 weeks, 122.2 U/L, and 5.1 $\log_{10}$ IU/ml, respectively. TAF was well tolerated, and the most common adverse event was nausea (30.1%) during a mean of two years (101.1 ± 24.3 weeks) of treatment. Notably, 1 (1.0%) TAF-treated pregnant woman exposed to agricultural chemicals during early pregnancy who initiated TAF from 12 weeks plus 2 days of gestation underwent induced abortion at 23 weeks plus 4 days of pregnancy due to the diagnosis of cleft lip and palate for the fetus at 22 weeks of gestation, this fetus was regarded as a congenital defect (most likely not related to TAF, because the developmental processes of the lip and palate are completed by 6–10 weeks of embryogenesis). No infants in either group had birth defects. In the TAF group, the HBeAg seroconversion rate of mothers was 20.7% (17/82) at postpartum month 6, infants had normal growth parameters (weight, height, and head circumference) compared with Chinese and WHO standards, and no infants were positive for HBsAg at 7 months of age. As of November 15, 2021, 40 TAF-exposed mother-infant dyads completed the postpartum month 18 follow-up, the cumulative HBeAg seroconversion rate is 28.0% (23/82), and all infants have normal growth parameters compared with Chinese and WHO standards. The TDF group had comparable baseline characteristics, and safety and effectiveness profiles during therapy.

Conclusion: TAF administered throughout or beginning in early pregnancy is generally safe and effective for pregnant women with active CHB and their infants.

SAT350

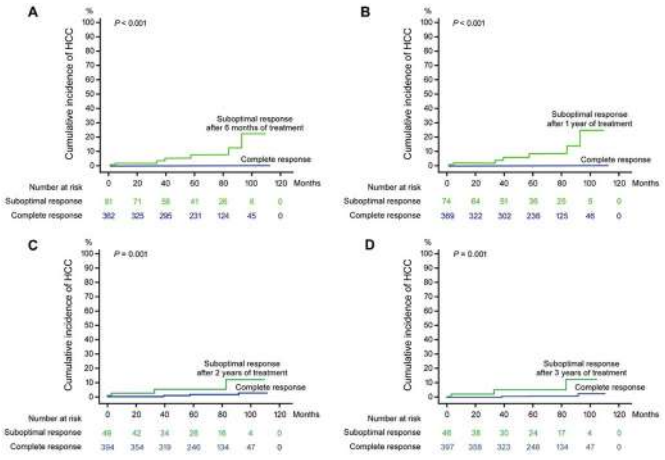
Suboptimal virological response to antiviral therapy in chronic hepatitis B as an independent predictor for occurrence of HCC and development of severe liver events

Chau-Ting Yeh[1], Chao-Wei Hsu[1]. *[1]Chang Gung Memorial Hospital, Liver Research Center, Taoyuan, Taiwan*
Email: chautingy@gmail.com

Background and aims: Although several potent antiviral drugs against chronic hepatitis B have been available worldwide with satisfactory virological suppression effect, incomplete virological suppression or suboptimal virological response can occur in a substantial proportion of patients. The definitions of suboptimal virological response varied among different international guidelines in terms of the remaining virological levels and the length of treatment periods. The suggested managements for patients experiencing suboptimal virological responses also varied, from continuation of the present antiviral drugs, switching to a more potent drug, to combination of two or more potent drugs. The long-term outcomes of these patients have never been interrogated.

Method: We retrospectively included 443 patients treated by entecavir in the Liver Clinic, Chang Gung Memorial Hospital, Taiwan, from 2008 to 2013. The HBV-DNA levels were assessed 6 months, 1 year, 2 years and 3 years after initiation of treatment. Suboptimal virological responses were defined as HBV-DNA levels above quantitative limit by Roche TaqMan Assay (>20 IU/ml) after the aforementioned treatment periods. The time-to-development of hepatocellular carcinoma (HCC) as well as the time-to-development of severe liver events (HCC or liver failure related death) were correlated with suboptimal responses and other clinical/virological factors. HBV X genes were sequenced from patients developing HCC.

Cell-based experiments were conducted to understand whether the HBV X mutants enhanced cccDNA accumulation.
Results: During the median follow-up period of 69 (range, 4 to 110) months, 6 patients developed HCC and 20 patients developed severe liver events. Kaplan-Meier analysis showed that suboptimal virological response detected at 6 months after treatment was an independent factor to predict HCC occurrence (p <0.001). Univariate and Multivariate Cox proportion hazard ratio analysis showed that suboptimal virological response detected at 6 months after treatment was an independent factor to predict development of severe liver events (unadjusted p = 0.006; adjusted p = 0.001). Novel HBV X mutations were identified in 5 of the 6 patients developing HCC during the suboptimal response period. These HBV X mutants were capable of enhancing cccDNA accumulation in HCC cells.



Conclusion: Suboptimal response detected at 6 months after antiviral treatment by entecavir was an independent predictor for HCC occurrence and development of severe liver events. Novel HBV X mutations could be selected during the period of suboptimal virological response and these HBV X mutants enhanced cccDNA accumulation in HCC cells.

Background and aims: Bulevirtide (BLV) is a novel first-in-class entry inhibitor for the treatment of chronic HDV infection (CHD) that was conditionally approved in the EU in July 2020. Patients treated with BLV alone have previously shown pronounced viral and biochemical responses (HDV RNA and ALT declines) in 2 phase 2 and 1 phase 3 trials (MYR202, MYR203 and MYR301). Here, we present an integrated efficacy analysis of 24-week data from these studies.
Method: A total of 281 patients with CHD without cirrhosis or with compensated cirrhosis were included in this pooled analysis including 92 and 95 patients treated with BLV at 2 mg or 10 mg given s.c. once daily, respectively, compared with 79 receiving no active anti-HDV treatment (Control) during the analysis period, and 15 patients treated with Peginterferon alfa (Peg-IFNα), the current standard of care (SOC) which is not approved for CHD. The primary efficacy end point assessed at week 24 was the combined response of undetectable HDV RNA or decrease by ≥2log$_{10}$ IU/ml from baseline and ALT normalization; additional end points included viral response (undetectable HDV RNA or decline by ≥2log$_{10}$ IU/ml), ALT normalization and change in HDV RNA levels.
Results: At baseline, demographics of all groups were well balanced. Characteristics of the BLV 2 mg group included: mean (SD) age 42 (9.0) years, 60.9% males, 83.7% White, 44.6% with compensated cirrhosis, 96.7% with HDV genotype 1, 64.1% were on nucleos (t)ide analogues therapy; mean (SD) HDV RNA was 5.2 (1.33) log$_{10}$ IU/ml and mean (SD) ALT was 107 (70.7) U/L. At Week 24, the combined response was achieved by 31.5% and 32.6% of patients in the BLV 2 mg and 10 mg groups, respectively. While the viral response rate was numerically lower in the BLV 2 mg group than in the BLV 10 mg group (53.3% and 71.6%), rates of ALT normalization were numerically higher for those treated with BLV 2 mg vs 10 mg (51.1% and 42.1%, respectively). For all efficacy end points, response rates were higher in the BLV groups compared to the Control or SOC groups.

Table. Efficacy at week 24.

	BLV 2 mg (N = 92)	BLV 10 mg (N = 95)	Control (N = 79)	Peg-IFNα (SOC) (N = 15)
Combined Response[1]: Responder at Week 24	29 (31.5%)	31 (32.6%)	0	0
95% CI	(22.2%, 42.0%)	(23.4%, 43.0%)	(0.0%, 4.6%)	(0.0%, 21.8%)
Viral Response[2]: Responder at Week 24	49 (53.3%)	68 (71.6%)	3 (3.8%)	4 (26.7%)
95% CI	(42.6%, 63.7%)	(61.4%, 80.4%)	(0.8%, 10.7%)	(7.8%, 55.1%)
Biochemical Response[3]: Responder at Week 24	47 (51.1%)	40 (42.1%)	5 (6.3%)	0
95% CI	(40.4%, 61.7%)	(32.0%, 52.7%)	(2.1%, 14.2%)	(0.0%, 21.8%)
Change from BL at week 24 in HDV RNA levels (log-10 scale): Mean (SD)	-2.07 (1.368)	-2.54 (1.209)	-0.14 (0.773)	-1.16 (2.048)

[1] Undetectable HDV RNA or decrease by ≥2log$_{10}$ IU/ml from baseline and ALT normalization.
[2] Undetectable HDV RNA or decrease by ≥2log$_{10}$ IU/ml from baseline.
[3] ALT normalization.
Undetectable HDV RNA defined as HDV RNA less than limit of detection (LOD), which was 14, 10, and 6 IU/mL in Studies MYR202, MYR203, and MYR301, respectively. Normalization of ALT was defined as an ALT value within the normal range, as defined by central laboratories (all sites in Studies MYR202 and MYR203 and Russian sites in Study MYR301: ≤ 31 U/L for females and ≤ 41 U/L for males; all other sites in Study MYR301: ≤ 34 U/L for females and ≤ 49 U/L for males).

Conclusion: In this integrated efficacy analysis of 24-week data from 281 patients, the combined response rates were comparable in the BLV 2 mg and BLV 10 mg groups; treatment with BLV was better than control or SOC groups. These results provide additional support for the use of BLV 2 mg once daily for treatment of compensated CHD.

SAT352

Integrated safety analysis of 24-week data from three phase 2 and one phase 3 clinical trials of bulevirtide monotherapy given at 2 mg and 10 mg dose level for treatment of chronic hepatitis delta

Email: pietro.lampertico@unimi.it

Background and aims: Bulevirtide (BLV) is a novel first-in-class entry inhibitor of the hepatitis D virus (HDV) that was conditionally approved for treatment of chronic hepatitis delta (CHD) in the EU in July 2020. BLV monotherapy was shown to be generally safe and well tolerated in three phase 2 and one phase 3 trials (MYR202, MYR203, MYR204 and MYR301). Here, we present an integrated safety analysis of 24-week data from these studies.

Method: A total of 355 patients with CHD were included in this pooled analysis: 92 and 145 patients treated with BLV alone at 2 mg or 10 mg given subcutaneous (s.c.) once daily, respectively, compared with 79 receiving no active anti-HDV treatment (Control) during the analysis period, and 39 patients treated with Peginterferon alfa (Peg-IFNα), the current standard of care (SOC) which is not approved for CHD. The assessed safety parameters included graded adverse events (AE) and laboratory abnormalities.

Results: At baseline, demographics of all groups were well balanced. Characteristics of the BLV 2 mg group included: mean (SD) age 42 (9.0) years, 60.9% males, 83.7% White, 44.6% with compensated cirrhosis, 96.7% with HDV genotype 1, 51.1% were Interferon experienced; mean (SD) HDV RNA was 5.2 (1.33) $\log_{10}$ IU/ml and mean (SD) ALT was 107 (70.7) U/L. By Week 24, the overall incidence of participants experiencing AEs was similar in BLV 2 mg and BLV 10 mg groups at 67.4% and 73.8%, respectively, compared to rates of 87.2% in the Peg-IFNα group and 49.4% in the control group. There were no serious AEs (SAEs) considered related to BLV and no AEs leading to discontinuation of BLV. The rates of grade 3–4 AEs and grade 3–4 laboratory abnormalities were similar in both BLV and control groups but were higher in the Peg-IFNα group. The AE profile was similar between the BLV groups and the control group, with a few exceptions. including higher rates of headache and total bile acids increased in the BLV treatment arms. Most AEs were mild or moderate in severity. Asymptomatic dose-dependent increase in serum bile acids is expected with BLV treatment based on its mode of action. Injection site reactions, considered as AEs of interest based on daily s. c. BLV administration mode, were more common in the BLV 10 mg group compared to 2 mg.

Number (%) of Participants With Any	BLV 2 mg (N = 92)	BLV 10 mg (N = 145)	Control (N = 79)	Peg-IFNα (N = 39)
AE	62 (67.4%)	107 (73.8%)	39 (49.4%)	34 (87.2%)
AE with Grade 3–4[a]	4 (4.3%)	10 (6.9%)	3 (3.8%)	17 (43.6%)
Grade 3 or 4 Laboratory Abnormalities	6 (6.5%)	11 (7.6%)	6 (7.6%)	16 (43.2%)
AE Related to BLV	45 (48.9%)	87 (60.0%)	0	0
SAE	0	1 (0.7%)	2 (2.5%)	2 (5.1%)
AEs of interest:				
Injection Site Reactions	7 (7.6%)	22 (15.2%)	0	1 (2.6%)

[a] Related to BLV: 2 (2.2%) participants in the BLV 2mg group and 5 (3.4%) participants in the BLV 10mg group
Adverse events were coded according to MedDRA Version 24.0.
Severity grades were defined by the CTCAE.
AE = adverse event; BLV = bulevirtide; CTCAE = Common Terminology Criteria for Adverse Events; Peg-IFNα = pegylated interferon alpha; SAE = serious adverse event

Conclusion: Over the 24-week treatment period, monotherapy with BLV at 2 mg and 10 mg dose was generally safe and well tolerated with a low frequency of grade 3–4 AEs, SAEs; and no AEs leading to BLV discontinuation or SAEs considered related to BLV.

SAT353

Virologic response to bulevirtide is delayed in cirrhotic HDV patients with clinically significant portal hypertension

Mathias Jachs[1,2], Caroline Schwarz[3], Marlene Panzer[4], Lukas Hartl[1,2], Simona Bota[5], Petra Munda[1], Albert F Stättermayer[1], Ivo Graziadei[6], Stephan Aberle[7], Michael Gschwantler[3], Heinz Zoller[4], Michael Trauner[1], Mattias Mandorfer[1,2], Peter Ferenci[1], Thomas Reiberger[1,2]. *[1]Medical University of Vienna, Division of Gastroenterology and Hepatology, Department of Internal Medicine III, Vienna, Austria; [2]Medical University of Vienna, Vienna Hepatic Hemodynamic Lab, Division of Gastroenterology and Hepatology, Department of Internal Medicine III, Vienna, Austria; [3]Klinik Ottakring, Division of Gastroenterology and Hepatology, Department of Internal Medicine IV, Vienna, Austria; [4]Medical University of Innsbruck, Department of Internal Medicine I, Innsbruck, Austria; [5]Klinikum Klagenfurt am Wörthersee, Department of Internal Medicine and Gastroenterology, Hepatology, Endocrinology, Rheumatology and Nephrology, Klagenfurt; [6]Landeskrankenhaus Hall, Department of Internal Medicine, Hall in Tirol; [7]Medical University of Vienna, Center for Virology, Wien, Austria*
Email: thomas.reiberger@meduniwien.ac.at

Background and aims: Bulevirtide (BLV) therapy is licensed for the treatment of hepatitis D virus (HDV)-infection in compensated patients in Europe. Patients with HDV-related advanced chronic liver disease (ACLD) and clinically significant portal hypertension (CSPH) are in urgent need of antiviral treatment due to a substantially increased risk of hepatic decompensation.

Method: The response to BLV therapy was assessed in HDV-related ACLD patients with evidence for CSPH, i.e., liver stiffness measurement (LSM) values ≥20 kPa by vibration-controlled transient elastography (VCTE), as compared to patients without evidence for CSPH.

Results: Twenty-one chronic HDV patients (median age: 47.6 years, sex: 10 male/11 female, baseline HDV-RNA: 100 to 21000000 copies/ml, HBV-DNA suppressed in all patients by NA therapy), were treated with BLV for ≥24 weeks and underwent pre-treatment VCTE-LSM. Median pre-treatment VCTE-LSM was 17.2 kPa (range: 5.4–48.0 kPa), and seven patients (33.3%) had CSPH by VCTE-LSM ≥20 kPa, further evidenced by thrombocytopenia (85.7%), splenomegaly (85.7%), or varices (66.7%).

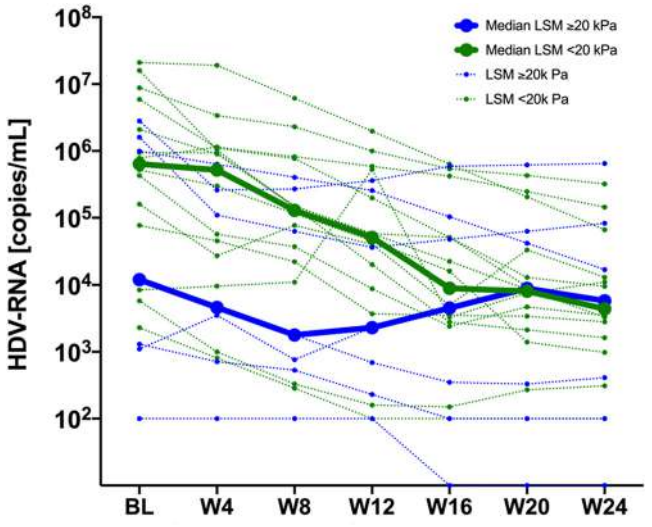
ALT levels ranged from 22 to 132 U/L in CSPH patients with 5 out of 7 showing ALT ≥50 U/L.

At week 24, virological response (VR, defined by ≥2-$\log_{10}$-decrease or undetectable HDV-RNA) was achieved by only one CSPH patient (14.3%), while five patients (71.4%) showed partial response, i.e. any HDV-RNA decrease (range: −0.63 to −1.77 $\log_{10}$); one patient experienced even an HDV-RNA increase (+0.72 $\log_{10}$). In the 14 HDV patients without evidence for CSPH, seven (50.0%) patients achieved VR at W24, partial response was seen in 6 (42.9%) and one patient showed an increase in HDV-RNA.

Interestingly, five (71.4%) CSPH patients achieved normal ALT levels at W24, as compared to 12 out of 14 (85.7%) non-CSPH patients. Four HDV-ACLD patients with CSPH have already reached W48; two (50.0%) achieved HDV-RNA undetectability and all (100%) showed normal ALT levels.

Of note, four out of seven CSPH patients underwent a follow-up VCTE-LSM after one year of BLV therapy (range 40–52 weeks), and three (75.0%) showed VCTE-LSM decreases of ≥20%, two patients even achieved a reduction to a final VCTE-LSM ≤20kPa (i.e. a clinically relevant decrease as by Baveno VII consensus).

BLV treatment in HDV-CSPH was well tolerated, and no significant adverse events were observed despite substantial increases in serum bile acids levels (median +829% at 4 weeks; maximum levels: 38.0–208.6 µmol/L).



Conclusion: Virologic response to BLV in cirrhotic HDV patients with CSPH seems delayed, however, a high rate of decreases in VCTE-LSM suggests a treatment benefit. BLV is safe in patients with CSPH. Data on changes in HVPG-as a potential surrogate for treatment efficacy-are awaited.

SAT354

Response-guided long-term treatment of chronic hepatitis D patients with bulevirtide-Results of a "real world study"

Mathias Jachs[1], Caroline Schwarz[2], Marlene Panzer[3], Teresa Binter[1], Elmar Aigner[4], Stephan Aberle[5], Albert Stättermayer[1], Ivo Graziadei[3], Petra Munda[1], Heinz Zoller[3], Michael Gschwantler[2], Michael Trauner[1], Thomas Reiberger[1], Peter Ferenci[1]. *[1]Medical University of Vienna, Internal Medicine 3, Gastroenterology and Hepatology, Wien, Austria; [2]Klinik Ottakring, Internal Medicine 4, Wien, Austria; [3]Medical University of Innsbruck, Internal Medicine 1, Innsbruck; [4]Paracelsus private University/SALK, Salzburg, Austria; [5]Medical University of Vienna, Center of Clinical Virology, Wien, Austria*
Email: peter.ferenci@meduniwien.ac.at

Background and aims: Bulevirtide (BLV) blocks hepatic uptake of the hepatitis D Virus (HDV) via the sodium/bile acid cotransporter NTCP. BLV was conditionally approved by EMA, but the optimal treatment duration is unknown. The aim of this real-world study was to define useful efficacy and futility end points.

Method: BLV was provided by MyrPharma (Leipzig/Germany) until 8/2020 and was subsequently prescribed and dosed at the discretion of the investigator. Based on the magnitude of HDV-RNA decline at week 24 patients were classified as responder (≥2log drop), partial responder (>1.0-<2log drop), or non-responder (<1log drop).

Results: 23 patients (m: 10/f:13; mean age: 47.9 years, cirrhosis: n = 15; median ALT:71 IU/ml (range 21–341); HDV-RNA: 9.5×10^5 [range:$1.0–2.1 \times 10^7$] copies/ml) received BLV (2 mg/d in n = 21; 10 mg/day in n = 2). 21 patients (84.6%) were on concomitant NUCs (ETV n = 3, TDF n = 16, TAF n = 2), 19 were previous Peginterferon-alfa2a (PEGIFN) non-responders. 22 patients completed at least ≥24 weeks of BLV treatment (range: 24–130 weeks), one dropped out at week 8.

Twelve patients (54.5%) were classified as BLV responders: in 2 treatment was terminated as HDV-RNA was undetectable for >6 months after 63 and 130 weeks, respectively. Both became HDV-RNA positive again after 60 and 4 weeks, respectively; in the latter BLV treatment was resumed. One patient underwent liver transplantation at week 25 and one was lost to follow-up after week 26. In 2 patients PEGIFN was added after 39 and 48 weeks, respectively, because of no further decline or re-increase of HDV-RNA. Thus, 7 are still on BLV monotherapy.

Four partial responders (18.2%) are still on BLV monotherapy (24–29 weeks).

Six patients (31.8%) were non-responders. (PEGIFN) was added in 5 except for one who dropped out after 24 weeks. In 4 patients HDV-RNA courses under BLV+PEGIFN are available showing a rapid decline of HDV-RNA within 12 weeks (-0, 97; – 1.19; – 1.23; and – 1.54 log-drop, respectively).

ALT levels normalized in 14/22 (63%) at week 24 and 8/10 (80%) at week 48, respectively. Treatment was well tolerated, bile acid levels increased without pruritus. HBsAg levels remained unchanged during BLV therapy.

Conclusion: Long-term BLV is safe and effectively decreases HDV-RNA and ALT. Responders likely require long-term treatment whereas in patients without virologic response response, the addition of PEGIFN seems to be of value. Our data indicate the need for an individualized approach for HDV treatment with BLV.

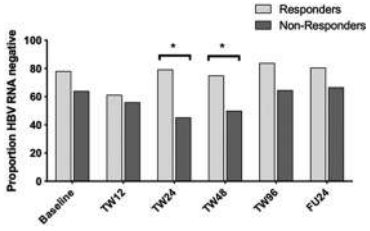
HBV RNA levels are associated with virological response to treatment with pegylated interferon alpha in patients with chronic hepatitis D virus infection

Lisa Sandmann[1], Birgit Bremer[1], Cihan Yurdaydin[2,3], Katja Deterding[1], Michael P. Manns[1,4], Markus Cornberg[1,4,5,6], Heiner Wedemeyer[1,4,6], Benjamin Maasoumy[1,4,5]. *[1]Hannover Medical School, Department of Gastroenterology, Hepatology and Endocrinology, Hannover, Germany; [2]University of Ankara Medical School, Department of Gastroenterology, Ankara, Turkey; [3]Koc University Medical School, Department of Gastroenterology and Hepatology, Istanbul, Turkey; [4]German Center for Infection Research (DZIF), Partner Site Hannover-Braunschweig, Germany; [5]Centre for Individualised Infection Medicin (CiiM), Helmholtz Centre for Infection Research, Germany; [6]German Center for Infection Research (DZIF), Partner Site HepNet Study House, Hannover, Germany*
Email: sandmann.lisa@mh-hannover.de

Background and aims: Chronic hepatitis D virus (HDV) infection causes severe liver disease with rapid progression to liver cirrhosis. Treatment with pegylated interferon alpha (pegIFNa) leads to viral response in approximately 25%, including patients with long-term virological control. Since IFN treatment is accompanied by severe side effects, on-treatment markers to identify patients with high chances of virological response are needed. HBV RNA, which reflects HBV cccDNA activity, may serve as a novel marker during antiviral treatment.

Method: The HIDIT-II study included 120 HBV/HDV co-infected patients. Patients were treated for 96 weeks with pegIFNa and either tenofovir or placebo. 99 patients with HDV RNA results 24 weeks after end of treatment (FU24) were included in this analysis, of whom 32 patients (32.3%) had undetectable HDV RNA at FU24. HBV RNA was measured at baseline, week 12, 24, 48, 96 and FU24 using the Roche Cobas 6800 system (LLOQ 10 cp/ml). Additional virological parameters (HBV DNA, quantitative HBsAg, HBcrAg and HDV RNA) were measured by appropriate assays (Lumipulse® G (Fujirebio-Europe)

for HBcrAg, Roche Cobas TaqMan system with an inhouse assay for HDV RNA).
Results: At baseline, mean HBV RNA levels were 1.71 ± 1.18 log cp/ml and HBV RNA levels were undetectable in 68.8% of patients. During treatment, mean HBV RNA levels did not differ between patients receiving either tenofovir or placebo. When separating between treatment responders (HDV RNA negative at FU24) and non-responders, mean levels of HBV RNA were significantly lower in responders at treatment week 24, 48 and end of treatment. Accordingly, the proportion of patients with undetectable HBV RNA was significantly higher in treatment responders at week 24 and 48 (79% vs. 50%, p = 0.0031; 75% vs. 50%, p = 0.0276) (Figure). However, HBV RNA levels of patients with viral relapse did not differ from those with maintained response at the end of treatment. No correlation between HBV RNA levels and HBV DNA, qHBsAg, HBcrAg or HDV RNA levels was detected at any time-point during the study. Interestingly, only 36% of patients with undetectable HBV RNA showed undetectable HBcrAg levels at baseline, whereas all but two patients with undetectable HBcrAg were HBV RNA negative (n = 24/26, 92%).



Conclusion: On-treatment HBV RNA levels differ significantly between responders and non-responders. Along with other virological parameters, HBV RNA could be a supportive marker to identify patients benefiting from treatment with pegIFNa. However, overall HBV RNA levels were low throughout the study population.

SAT356

Management of chronic hepatitis B virus infection within a large integrated health care setting: treatment patterns among kaiser permanente members in southern california, 2008–2019

Deborah Malden[1,2], Prabhu Gounder[3], Katherine Oh[1], Amandeep Sahota[1], Robert Wong[4], Amit Chitnis[5], Theresa Im[1], Vennis Hong[1], Ana Florea[6], Sara Tartof[1,7]. *[1]Kaiser Permanente Southern California Department of Research and Evaluation, Pasadena, United States; [2]Centers for Disease Control and Prevention, Epidemic Intelligence Service, Division of Scientific Education and Professional Development, Atlanta, United States; [3]Los Angeles County Department of Public Health, Los Angeles, United States; [4]Stanford University School of Medicine, Division of Gastroenterology and Hepatology, Stanford, United States; [5]Alameda, County Public Health, Tuberculosis Section, Division of Communicable Disease Control and Prevention, Oakland, United States; [6]Kaiser Permanente Southern California Department of Research and Evaluation, Research and Evaluation, Pasadena, United States; [7]Kaiser Permanente Bernard J Tyson School of Medicine, Department of Health Systems Science, Pasadena, United States*
Email: debbie.e.malden@kp.org

Background and aims: An estimated 1.89 million adults in the United States have chronic hepatitis B (CHB). Despite wide availability of treatment for CHB, many treatment-eligible patients remain untreated. To improve treatment rates, we investigated factors associated with receiving treatment among patients with CHB in a large, integrated health care setting in Southern California.
Method: Using data from Kaiser Permanente electronic medical records, we performed a retrospective cohort study among persons aged ≥18 years with CHB, defined as having two, positive hepatitis B surface antigen or hepatitis B virus (HBV) DNA tests >6 months apart during 2008–2019. Patients with HIV were excluded. CHB treatment eligibility was determined according to American Association for the Study of Liver Diseases guidelines based on hepatitis e antigen status, annual serum alanine aminotransferase levels, HBV DNA levels, and presence of fibrosis or cirrhosis. We used multivariate cox proportional hazards regression to estimate adjusted hazard ratios (aHRs) and corresponding 95% CI for treatment receipt among those eligible for CHB treatment during the study period, defined as receiving antiviral treatment according to electronic medical records.
Results: Of 5, 314 patients with CHB, 16% (n = 857) were eligible for treatment. Treatment-eligible patients were older (mean age 53 vs 48 years) and included a greater proportion of men (56% vs 48%) and persons with diabetes (15% vs 8%), compared with all CHB patients. Among patients eligible for treatment, 49% (n = 417) received treatment. Patients who received treatment were on average 4 years younger (mean age 51 vs 55 years), but did not differ greatly by comorbidity status or Body Mass Index than those who did not receive treatment. Women were less likely to receive treatment than men (aHR 0.69; 95% CI: 0.55–0.85). Relative to non-Hispanic Asian race/ethnicity, persons of non-Hispanic White race/ethnicity were less likely to receive treatment (aHR: 0.66; 95% CI: 0.43–0.99). Patients who were referred to a health care specialist (infectious disease, hepatology or gastroenterology) were almost twice as likely to receive treatment, compared with those who were not (aHR 1.85; 95% CI: 1.26–2.70).
Conclusion: Among a large cohort of CHB patients, fewer than half of patients who were eligible for treatment received treatment. Increasing referral of CHB patients to a health care specialist may improve treatment rates.

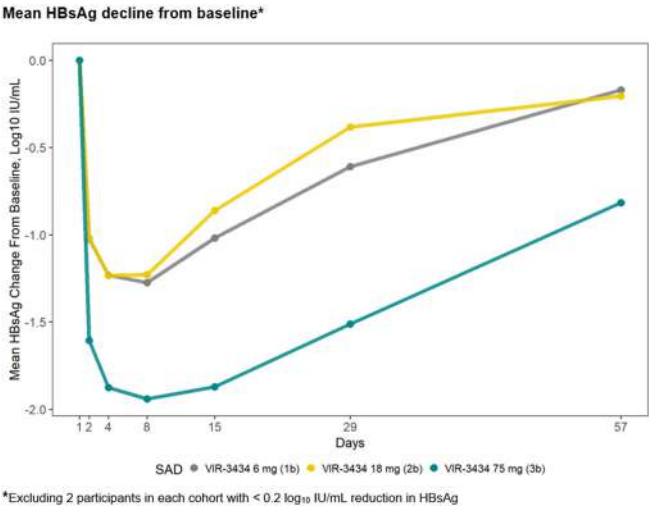
Dose-dependent durability of hepatitis B surface antigen reductions following administration of a single dose of VIR-3434, a novel neutralizing vaccinal monoclonal antibody

Kosh Agarwal[1], Man-Fung Yuen[2], Heiner Wedemeyer[3], Daniel Cloutier[4], Ling Shen[4], Andre Arizpe[4], Sneha V. Gupta[4], Marie C. Fanget[4], Lillian Seu[4], Andrea Cathcart[4], Audrey H. Lau[4], Carey Hwang[4], Edward J Gane[5]. *[1]King's College Hospital, Institute of Liver Studies, London, United Kingdom; [2]The University of Hong Kong, Queen Mary Hospital, Hong Kong, China; [3]Hannover Medical School, Department of Gastroenterology, Hepatology, and Endocrinology, Hannover, Germany; [4]Vir Biotechnology, Inc., San Francisco, California, United States; [5]University of Auckland, Faculty of Medicine, Auckland, New Zealand*
Email: kosh.agarwal@kcl.ac.uk

Background and aims: Chronic hepatitis B virus (HBV) infection is associated with significant morbidity and mortality and contributes substantially to the overall global health burden. VIR-3434 is an Fc engineered human monoclonal antibody targeting the conserved antigenic loop of hepatitis B surface antigen (HBsAg) currently in development for the treatment of chronic HBV infection. Here, we report preliminary data from an ongoing phase 1 study evaluating the safety, tolerability, and antiviral activity of VIR-3434 in participants with chronic HBV infection.
Method: This randomized, double-blind, placebo-controlled, phase 1, single ascending dose study included adults with hepatitis B e antigen (HBeAg)-negative chronic HBV infection without cirrhosis. Participants had HBsAg <3, 000 IU/ml at screening and had received nucleos (t)ide reverse transcriptase inhibitor (NRTI) therapy for ≥2 months. Eight participants in each cohort were randomized 6:2 to receive a single subcutaneous dose of VIR-3434 6 mg, 18 mg, 75 mg, or 300 mg, or placebo. Preliminary data through 8 weeks of follow-up are presented; dose escalation and follow-up are ongoing.
Results: Twenty-four participants were enrolled. Most participants achieved a ≥1 $\log_{10}$ IU/ml reduction from baseline in HBsAg within 1–3 days of dosing. The largest and most durable HBsAg reductions were observed in the 75 mg cohort. Among the 6 participants per cohort with >0.2 $\log_{10}$ IU/ml reductions in HBsAg, mean reductions in the

6 mg, 18 mg, and 75 mg groups were 1.30, 1.27, and 1.96 log_{10} IU/ml, respectively, at nadir and 0.17, 0.20, and 0.82 log_{10} IU/ml, respectively, at week 8 (Figure). Ten adverse events were reported, and all were grade 1 or 2 in severity. No clinically significant laboratory abnormalities or signs of immune complex disease were observed. Pending availability, data from participants receiving a single dose of 300 mg VIR-3434 will also be presented.



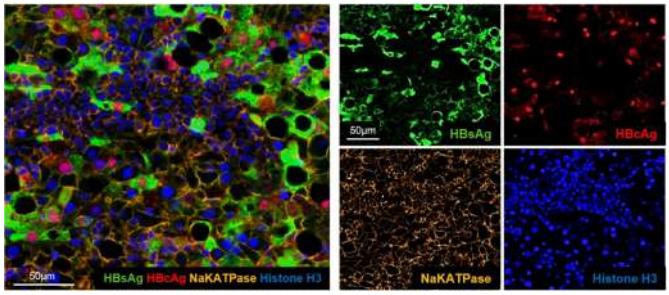
Conclusion: A single dose of 6 mg, 18 mg, or 75 mg VIR-3434 demonstrated a rapid reduction in HBsAg; the 75 mg dose level was associated with larger and more durable HBsAg reductions through week 8. Preliminary safety data suggest that VIR-3434 was generally safe and well tolerated. These preliminary data support the further evaluation of VIR-3434 for functional cure of patients with chronic HBV infection.

SAT358

Quantification of HBV hepatocyte burden using novel multiplex immunofluorescence staining and image analysis reveals substantial reduction in HBV liver burden with anti-viral treatment

Abhishek Aggarwal[1], Pamela Odorizzi[1], Jens Brodbeck[1], Nicholas Van Buuren[1], Christina Moon[1], Silvia Chang[1], MaryVic Adona[1], Torsten Trowe[1], Scott Turner[1], Patrick Marcellin[2], Maria Buti[3], Anuj Gaggar[1], Lauri Diehl[1], Becket Feierbach[1], Scott Balsitis[1]. *[1]Gilead Sciences, Inc., Foster City, United States; [2]Hospital Beaujon AP-HP, Clichy, France; [3]Hospital Universitari Vall d'Hebron, Barcelona, Spain*
Email: pamela.odorizzi@gilead.com

Background and aims: Patterns of Hepatitis B virus (HBV) infection and integration before and after nucleotide (NUC) therapy have been previously described, but accurate quantification of HBV-infected hepatocytes in a large liver biopsy collection has not been reported. We developed novel immunofluorescence and image analysis techniques to quantify HBV-positive cells and applied them to over 200 liver biopsies.
Method: A 4-plex immunofluorescence assay was developed with HBsAg, core, membrane (Na+/K+-ATPase), and nuclear (Histone H3) markers to assign HBV staining to individual cells. An image analysis algorithm was also developed to quantify the percentage of hepatocytes positive for HBV proteins. Biopsies from HBeAg-positive (n = 76) and HBeAg-negative (n = 129) patients before or during NUC (tenofovir disoproxil fumarate or adefovir) treatment for 48 or 240 weeks were analyzed from GS-US-174-0102/0103. When available, matched serum samples were evaluated for HBV DNA, HBsAg, HBcrAg, HBV RNA, and ALT. In fifteen cases, two biopsies were collected from different portions of the liver at the same timepoint and staining was compared to evaluate sampling effects.
Results: Two common and typically mutually exclusive staining patterns were observed: diffuse core staining and foci of HBsAg staining, thought to represent hepatocytes with cccDNA and integrated HBV DNA, respectively. Hepatocytes positive for both core and HBsAg were rare. Biopsies collected from the same patient and timepoint revealed enormous variability in HBV staining within individual patients, indicating that single biopsies are not representative of the entire liver. This intra-patient variability was confirmed in a liver resection sample. On a population level, NUC treatment was associated with >100-fold lower median frequency of core-positive cells (p <0.001), while reductions in HBsAg-positive cell frequency were modest and not statistically significant. HBeAg-negative Week 240 NUC-treated patients had the lowest HBV burden (median 3.8% hepatocytes positive for core and/or HBsAg). Positive correlations between serum viral biomarkers and liver HBV burden were only observed in HBeAg-positive patients prior to NUC treatment.



Conclusion: Using a novel multiplex imaging method for quantifying HBV burden in a large cohort of liver samples, we demonstrate 1) significant intra-patient variation in liver biopsies and 2) population-level reductions in HBV liver burden associated with HBeAg-negative status and NUC treatment.

SAT359

GST-HG141 inhibits de novo HBV cccDNA formation in cultured primary human hepatocytes

Dong Zhang[1], Wenqiang Wu[1], Shikui Chen[1], Zhou Yu[1], Vadim Bichko[1], John Mao[1], Jiang Zhigan[2], Haiying He[2], Li Jian[2], Shuhui Chen[2]. *[1]Fujian Cosunter Pharmaceutical Co., Ltd.; [2]Domestic Discovery Service Unit, WuXi AppTec (Shanghai) Co., Ltd.*
Email: vbichko@gmail.com

Background and aims: GST-HG141 is a novel, orally-bioavailable HBV capsid assembly modulator (CAM). It inhibits HBV pregenomic RNA packaging, leading to formation of "empty" capsids, devoid of genetic material. However, its mode of action and resistance profile appear to be distinct from other class I CAMs in development. GST-HG141 has an excellent antiviral potency in vitro, as well as efficacy in HBV mouse models. GST-HG141 was safe and well-tolerated in a first-in-man clinical study in healthy volunteers [Li et al, Antimicrob Agents Chemother. 2021; 65 (10)] and is currently under phase Ib evaluation in chronic HBV patients. Here we report antiviral properties of GST-HG141 in cultured primary human hepatocytes (PHH).
Method: Cryopreserved PHHs from a single donor were infected with HepG2.2.15 cell-derived HBV. Treatment with GST-HG141, GLS4, or Entecavir (ETV) started concurrently with infection, or 5 days post-infection. After 7 days of treatment, the effects on the secreted HBV DNA were determined using qPCR. Secreted HBsAg and HBeAg were quantified by ELISA. Southern blot was performed to detect and quantify the HBV covalently closed circular DNA (cccDNA). The identity of the cccDNA band was confirmed by EcoRI digestion.

Results: All three tested compounds reduced secreted HBV DNA levels in a concentration-dependent manner, regardless of when the treatment was started (GST-HG141 EC_{50} ~ 80 nM). The secreted HBsAg (EC_{50} ~ 1.5 microM) and HBeAg (EC_{50} ~ 1.6 microM) levels were also dose-dependently decreased by GST-HG141, but only if treatment started concurrently with infection. Similar observations were made with GLS4. ETV had no effect on HBeAg- and HBsAg levels in cell culture supernatants under neither condition. GST-HG141 potently and dose-dependently inhibited HBV cccDNA formation, but only when treatment started with the infection, and not at day 5 post-infection. No significant cytotoxicity was observed with neither compound in this study (CC_{50} >10 microM).
Conclusion: These data demonstrate that GST-HG141 prevents *de novo* synthesis of cccDNA, but has no effect on the established cccDNA pools in cultured PHH. It acts on different steps of the HBV life cycle, suggesting dual/multiple mechanisms of antiviral action. Further development of GST-HG141 for chronic HBV infections is warranted. Currently it is undergoing phase Ib-II clinical evaluations. The interim results from the ongoing phase Ib study show robust antiviral efficacy of GST-HG141 monotherapy and good safety/tolerability in chronic HBV patients.

Background and aims: BLV monotherapy as well as combination with PEG-interferon α 2a (PEG-IFNα) for 48 weeks induced HDV RNA declines in the French ATU early access program. The aim of this study was to evaluate 12-month predictive factors of virological response in HBV/HDV patients receiving 2 mg BLV with or without PEG-IFNα 2a (real-life study).
Method: 145 patients with chronic HBV/HDV co-infection, with cirrhosis or moderate fibrosis and elevated ALT levels, without liver decompensation, were included. Patients received 2 mg BLV qd sc alone in combination with PEG-IFNα once weekly for 12 months, according to physician's choice. Univariate analysis was performed to evaluate predictive factors of undetectable HDV-RNA after one year of treatment.
Results: Characteristics of the 145 patients were: 99 (68.3%) males, 41 years, cirrhosis N = 91/108 (62.8%), median viral load of 6.2 log_{10}IU/ml. At month 12, in the BLV monotherapy and in the BLV + PEG-IFN group, the median decrease of HDV-RNA was – 3.64 et – 5.56 log10IU/ml, respectively. Moreover, at month 12, HDV-RNA was undetectable in 39% and 85% of patients treated with BLV monotherapy and BLV + PEG-IFN group, respectively (per-protocol analysis). Factors associated with virological response are indicated in the table.

Table: Factors associated with undetectable HDV-RNA at month 12 (per-protocol analysis)

	Patients treated with BLV 2 mg alone		All patients (BLV with or without PEG-IFN)	
	HR (CI95%)	P	HR (CI95%)	P
Age	1, 00 (0, 95, 1, 05)	0.97	0.99 (0.96, 1.02)	0.62
Gender	2.71 (0.74, 9.95)	0.13	1.04 (0.55, 1.94)	0.91
BMI	0.97 (0.86, 1.09)	0.61	0.96 (0.9, 1.04)	0.31
Liver stiffness	0.96 (0.88, 1.04)	0.33	0.98 (0.95, 1.02)	0.30
FIB-4	0.87 (0.68, 1.12)	0.28	0.94 (0.82, 1.07)	0.31
Cirrhosis	0.39 (0.13, 1.17)	0.09	0.95 (0.52, 1.75)	0.88
HIV	2.49 (0.76, 8.21)	0.13	1.22 (0.48, 3.13)	0.68
HDV-RNA	**0.64 (0.42, 0.95)**	**0.03**	0.87 (0.68, 1.11)	0.26
HBe Ag+	2.39 (0.29, 19.73)	0.41	1.6 (0.38, 6.78)	0.53
HBV DNA	0.59 (0.32, 1.08)	0.09	0.96 (0.85, 1.07)	0.64
NUC	1.75 (0.22, 13.86)	0.59	1.11 (0.46, 2.66)	0.81
PEG-IFN	NA		**3.06 (1.64, 5.71)**	**<0.001**

Conclusion: In patients treated with BLV 2 mg alone, HDV-RNA is associated with virological response after one year of treatment. In patients treated with or without PEG-IFN, PEG-IFN treatment is associated with virological response. These preliminary results could help physicians for their clinical practice.

SAT361

Impact of baseline viral load on hepatocellular carcinoma risk during antiviral treatment in non-cirrhotic patients with HBeAg-positive chronic hepatitis B

Won-Mook Choi[1], Gi-Ae Kim[2], Jonggi Choi[1], Seungbong Han[3], Young-Suk Lim[1]. *[1]Asan Medical Center, Department of Gastroenterology, Liver Center, Seoul, Korea, Rep. of South; [2]Kyung Hee University School of Medicine, Department of Internal Medicine, Korea, Rep. of South; [3]Korea University College of Medicine, Department of Biostatistics, Seoul, Korea, Rep. of South*
Email: limys@amc.seoul.kr

Background and aims: Early initiation of anti-viral treatment with high viral load is highly controversial in HBeAg-positive patients with chronic hepatitis B (CHB). Here, we investigated the impact of hepatitis B virus (HBV) DNA levels at the onset of antiviral treatment on the on-treatment risk of hepatocellular carcinoma (HCC) in non-cirrhotic patients with HBeAg-positive CHB.
Method: We conducted a multicenter cohort study including entecavir- or tenofovir-treated non-cirrhotic patients with HBeAg-positive CHB and baseline HBV DNA levels ≥5.00 log_{10} IU/ml at three centers in Korea between January 2007 and December 2016. We compared the on-treatment risk of HCC between high viral load (HBV DNA levels ≥8.00 log_{10} IU/ml) and moderate viral load (5.00–7.99 log_{10} IU/ml) groups.
Results: Of 2, 073 patients, 1, 108 patients were classified as high viral load group and 965 patients were moderate viral load group. After propensity score (PS)-matching, 930 pairs of patients were generated with well-balanced baseline characteristics. In the entire cohort, HCC was developed in 10 patients (0.15 per 100 person-years) in the high viral load group compared with 37 patients (0.67 per 100 person-years) in the moderate viral load group, during a median 5.7 years of antiviral treatment. Patients with moderate viral load at baseline showed a significantly higher HCC incidence than those with high viral load in both the entire and PS-matched cohorts by Kaplan-Meier analysis (p <0.001 for both; Figure). By multivariable analysis, the moderate viral load group had a significantly higher risk of HCC (hazard ratio, 3.48; 95% confidence interval, 1.72–7.06; $P < 0.001$) than the high viral load group, which was also consistently observed in the PS-weighted, PS-matched, and competing risk analyses.

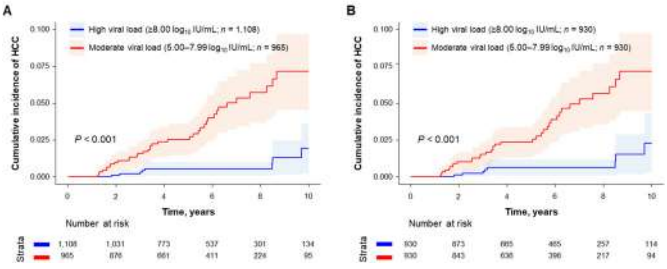

Fig.. **Cumulative incidence of HCC during treatment between high vs. moderate viral load groups. (A)** Entire cohort and **(B)** propensity score-matched cohort. High and moderate viral load groups were defined as those who had baseline serum HBV DNA levels ≥8.00 $\log_{10}$ IU/mL and 5.00–7.99 $\log_{10}$ IU/mL, respectively.

Conclusion: In non-cirrhotic patients with HBeAg-positive CHB, decreased HBV DNA levels at baseline was associated with a significantly high risk of HCC during antiviral treatment. Early initiation of antiviral treatment with a high viral load (≥8.00 $\log_{10}$ IU/ml) would retain a low on-treatment risk of HCC in HBeAg-positive CHB patients.

SAT362

Therapeutic vaccination with CLB-3000 in a mouse model of chronic hepatitis B induces anti-HBs responses associated with functional cure

Renae Walsh[1], Hans Netter[1], Chee Leng Lee[1], Rachel Hammond[1], Joan Ho[1], Stephen Locarnini[1], Ronald Farquhar[2], Bharat Dixit[2], Aileen Rubio[2]. [1]*Victorian Infectious Diseases Services, Parkville, Australia;* [2]*ClearB Therapeutics, Inc., CONCORD, MA, United States*
Email: arubio@clearbtherapeutics.com

Background and aims: Our therapeutic vaccine candidates previously achieved functional cure (FC) in a mouse model of chronic hepatitis B (CHB) [EASL 2021 poster 853, AASLD 2021 poster 829]. The vaccines consist of modified HBsAg displaying clearance profile (CP) associated epitopes identified from anti-HBs responses of FC clinical patients. CP-specific antibody responses are distinguished by the occupation of key loop 1 and 2 epitopes within HBsAg "a" determinant [Walsh, R et al 2019. Liver Int 39 (11) pp2066]. The vaccine candidate CLB-3000 consists of 2 modified HBsAg, expressed from *Pichia pastoris* and adjuvanted with Alhydrogel. Therapeutic vaccination with CLB-3000 achieved FC in CHB mice and were assessed for the presence of 'clearing' anti-HBs profiles consistent with those observed from clinical FC patients.
Method: CLB-3000 was subcutaneously delivered to CBA/CaJ mice with established CHB infection [Chou H-H et al 2015. PNAS 112 (7) pp2175]. Mice were monitored for FC by serological and liver immunohistochemistry (IHC). The quality of the anti-HBs immune response following FC was assessed for specificity to HBsAg CP epitopes defined clinically, HBsAg immune complexes to confirm serum clearance of HBsAg, and diagnostic anti-HBs titre.
Results: Therapeutic vaccination of CHB mice with CLB-3000 resulted in >2.5 log IU/ml reduction in serum HBsAg. Liver IHC confirmed clearance of HBV positive cells. Development of a vaccine-elicited CP-associated 'clearing' anti-HBs response was concomitantly detected in 80% of CLB-3000 treated CHB mice that achieved FC. Antibody specificity for CP-associated epitopes was detected, targeting both loops 1 and 2 of HBsAg, and mimicked that observed in FC patients. Immune complexes of residual HBsAg and anti-HBs were not typically detected following FC with an established 'clearing' anti-HBs response, indicative of complete HBsAg clearance. Placebo treatment resulted in no significant change in virological markers and no anti-HBs seroconversion.
Conclusion: CLB-3000 was highly efficacious in CHB mice as shown by rapid HBsAg decline, clearance from serum and liver, and seroconversion to CP-associated anti-HBs which mirrored clinical FC-associated anti-HBs responses. The data further support CLB-3000 development for the treatment of CHB.

SAT363

Evaluation of the disposition and mass balance recovery of vebicorvir, a first generation hepatitis B core inhibitor, in rats and humans

Katie Zomorodi[1], Luisa M Stamm[1], William Delaney[1], Michael Shen[1]. [1]*Assembly Biosciences, Inc., South San Francisco, United States*
Email: kzomorodi@assemblybio.com

Background and aims: Vebicorvir (VBR) is a first-generation hepatitis B virus (HBV) core inhibitor that targets multiple aspects of the viral replication cycle. VBR is in Phase 2 development for the treatment of chronic HBV infection (cHBV). Here we report the disposition and mass balance recovery of VBR in rats and healthy human subjects.
Method: 27 male rats were dosed with 30 mg/kg [^{14}C]-VBR radio-labeled with 5.5 MBq/kg. Three animals were placed in metabolism cages for up to 120 h post-dose. Total radioactivity was measured in urine, feces, cage rinse and carcass. Pharmacokinetic (PK) profiles were obtained in blood, plasma and liver samples collected at selected timepoints over 48 h post-dose from three additional terminal animals per timepoint. The human study (NCT04637139) was a single-arm, non-randomized, open-label Phase 1 trial. Following an overnight fast of ≥8 hours, 6 healthy subjects received a single oral dose of 300 mg VBR solution containing a microdose of approximately 2 μCi of [^{14}C]-VBR. Samples of blood, urine, and feces were collected for PK, metabolite, and radiolabel assessments for up to 240 h post-dose.
Results: In rats, 86% and 12% of the radio-labeled VBR dose were eliminated in feces and urine, respectively, with excretion of unchanged VBR in the feces accounting for the majority of the administered drug; unchanged VBR was the only radio-component detected in plasma. Total radioactivity showed very high distribution in the liver with partitioning ratios ranging from 18 to 30 over 48 h post-dose (calculated with respect to blood). Similarly, mean cumulative radioactivity recovery in humans was 88%, with 62% excreted in feces and 26% in urine (Figure 1), and unchanged VBR was the major component in both feces (50% of dose) and urine (10% of dose). Unchanged VBR was the predominant component in plasma with low overall circulating metabolite-related radioactivity. Plasma VBR concentrations reached peak by ~2.5 h and declined with terminal half-life of 27.7 h. Renal clearance of unchanged VBR (1.62 L/h) was a minor contributor to the total body clearance of VBR (17.9 L/h).

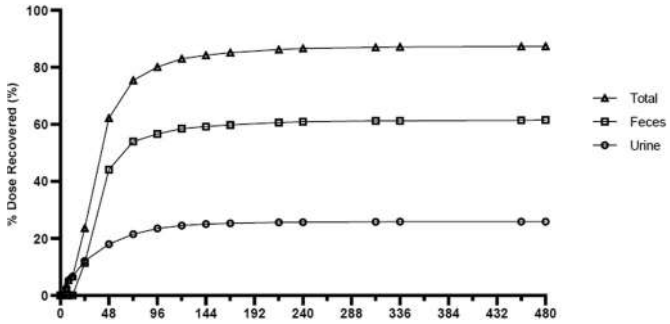

Figure: Mean Cumulative Percent Recovery of Radio-labeled VBR in Feces and Urine in Humans

Conclusion: Fecal excretion of unchanged drug is the primary route of VBR elimination in both rats and humans. VBR is the predominant component in the systemic circulation with low overall circulating metabolite-related radioactivity. VBR showed high liver loading in the rat indicating favourable distribution to the target organ for treatment of chronic HBV infection.

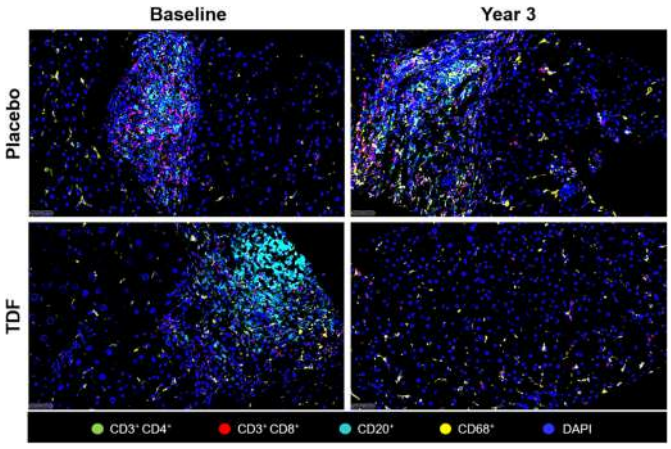
Email: abhishek.aggarwal5@gilead.com

Background and aims: Integrated analysis of the impact of nucleos (t)ide treatment on intrahepatic HBV antigen expression together with immune cell subset frequency is lacking. In this study, we performed concurrent analysis of the intrahepatic viral burden and the liver immune microenvironment in chronic hepatitis B (CHB) patients with minimally elevated serum alanine aminotransferase (ALT) before and after treatment with tenofovir disoproxil fumarate (TDF).
Method: CHB patients with serum viral load above 2000 IU/ml and mild ALT elevation between 1-2 folds the upper limit of normal were enrolled in a double- blind, placebo- controlled, randomized trial of either oral 300 mg TDF or placebo once daily for 3 years (NCT01522625). Paired core liver biopsies were collected at baseline and year 3 and analyzed by bulk RNA-Seq (n = 56 placebo and n = 64 TDF treated patients) as well as by a custom multiplex immunofluorescence (mIF) assay (Ultivue InsituPlex) in a subset of biopsies (n = 15 placebo and n = 15 TDF treated patients). Cell type proportions from RNA-Seq were calculated using the EPIC algorithm. Quantification of mIF images for immune cell subsets and viral burden was performed using Visiopharm software.
Results: Following 3 years of treatment, patients that received TDF showed significant reduction in serum ALT ($p < 0.05$) and HBV DNA levels ($p < 0.001$) compared to the placebo group. In line with RNA-Seq cell type estimates, mIF analysis revealed a decrease in $CD3^+$ T-cell ($p < 0.001$), $CD4^+$ T- cell ($p < 0.001$), $CD8^+$ T- cell ($p < 0.001$), $CD20^+$ B- cell ($p < 0.01$) densities and HBV $core^+$ hepatocyte frequency ($p < 0.001$) after 3 years of TDF vs. placebo treatment. PD-1 expression was also significantly reduced on both $CD4^+$ and $CD8^+$ T- cells ($p < 0.001$) with TDF treatment. Conversely, NK cell and monocyte gene signatures, as well as $CD68^+$ macrophage density and $HBsAg^+$ hepatocyte frequency did not significantly change with TDF treatment. mIF analysis also showed a reduction in periportal lymphoid aggregates (defined by dense $CD20^+$ B- cell clusters, $p < 0.05$) in TDF-treated vs. placebo patients.



Conclusion: Multiparametric analysis of the liver immune microenvironment revealed intrahepatic immune cell infiltration in patients with minimally elevated serum ALT. TDF treatment significantly reduced the number of HBV $core^+$ (but not $HBsAg^+$) hepatocytes, which was accompanied by a decrease in both intrahepatic T cells and B cells. These findings suggest that (i) CHB patients with minimally elevated ALT levels may benefit from nucleos (t)ide treatment and (ii) that intrahepatic T and B cell frequency is associated with the HBV $core^+$ cell burden.

Safety, pharmacokinetics, and antiviral activity of the class II capsid assembly modulator ALG-000184 in subjects with chronic hepatitis B

Man-Fung Yuen[1], Kosh Agarwal[2], Edward J Gane[3], Alina Jucov[4], Christian Schwabe[5], Junqi Niu[6], Jinlin Hou[7], Kha Le[8], Benedetta Massetto[8], Christopher Westland[8], Qingling Zhang[8], Felix Lai[8], Meenakshi Venkatraman[8], Lawrence Blatt[8], Tse-I Lin[8], Sushmita Chanda[8], Matt McClure[8], John Fry[8]. *[1]Hong Kong, University of Hong Kong, Hong Kong; [2]Institute of Liver Studies, Kings College Hospital, United Kingdom; [3]University of Auckland, New Zealand, New Zealand; [4]ARENSIA Exploratory Medicine, Republican Clinical Hospital and Nicolae Testemitanu State University of Medicine and Pharmacy, Moldova; [5]New Zealand Clinical Research, New Zealand; [6]The First Hospital of Jilin University, Jilin City, China; [7]Nanfang Hospital of Southern Medical University, China; [8]Aligos Therapeutics Inc, South San Francisco, United States*
Email: bmassetto@aligos.com

Background and aims: To evaluate the safety, pharmacokinetic, and antiviral activity of ALG-000184, an oral prodrug of ALG-001075, a novel, pan-genotypic class II capsid assembly modulator (CAM) with picomolar potency.
Method: This is an ongoing three-part, multicenter, double-blind, randomized, placebo-controlled study. In Parts 1 and 2, single and multiple doses of ALG-000184 were well tolerated in healthy volunteers (Gane et al, APASL, HBV TAG, 2021). Part 3 is evaluating untreated subjects with chronic hepatitis B (CHB) (N = 10/cohort; 8 active:2 placebo) receiving daily doses of ALG-000184 or placebo × 28 days. Reported here are preliminary blinded safety, PK, and antiviral data.
Results: To date, 36 subjects have completed dosing in Cohorts 1 (100 mg; N = 10 HBeAg neg), 2 (50 mg; N = 10 HBeAg neg), and 4 (100 mg; N = 10 HBeAg pos); enrollment in Cohort 3 (10 mg; N = 6 HBeAg neg) is ongoing. Most subjects were male (56%), Asian (58%), with a mean age of 40 years, a mean BMI of 24.6 Kg/m^2 and genotype B or D. At baseline, mean HBV DNA by cohort ranged from 4.4 to 8.1 $\log_{10}$ IU/ml and most subjects' (81%) baseline ALT concentrations were within the normal range. Study medication was well tolerated. There was 1 unrelated serious adverse event (hospitalization for back pain management). There were no treatment emergent adverse events (TEAEs) resulting in premature discontinuation. All TEAEs were Grade 1 or 2 in severity, except for three Grade 3 ALT elevations. These were asymptomatic, occurring post dosing and were associated with significant changes in HBV DNA and RNA. There were no changes in synthetic liver function. Plasma ALG-001075 exposures increased dose proportionally between 10, 50 and 100 mg dose levels, with low-to moderate variability and minimal accumulation. A similar magnitude of HBV DNA decline (~3–4 $\log_{10}$ IU/ml) was observed in all cohorts and a similar percentage (≥75%) of HBeAg negative subjects achieved HBV DNA below the lower limit of quantitation (LLOQ; <10 IU/ml). Mean HBV DNA level changes from baseline are shown in Fig 1. HBV RNA declined below LLOQ (10 copies/ml) in 100% of subjects in Cohorts 1 and 2 and by ~3.1 $\log_{10}$ copies/ml at day 28 in Cohort 4.

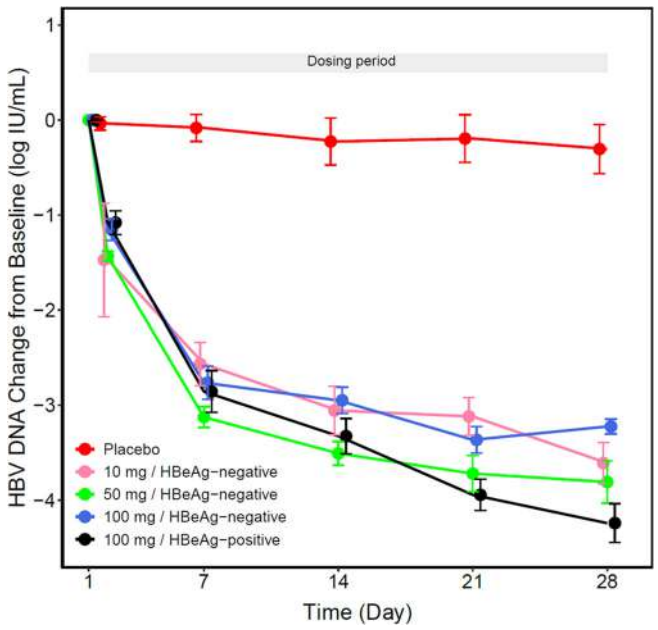

Figure: Mean (SEM) HBV DNA levels change from baseline through the end of the treatment period by Cohort

Conclusion: All dose levels of ALG-000184 were well tolerated, exhibited predictable PK, and resulted in similar, substantial antiviral activity in untreated CHB subjects, regardless of HBeAg status.

SAT366

Deeper virologic suppression with the addition of vebicorvir, a first-generation hepatitis B core inhibitor, to entecavir correlates with reduced inflammation and fibrosis-4 index in treatment naïve patients with HBeAg positive chronic hepatitis B

Email: msulkowski@jhmi.edu

Background and aims: The goal of NrtI therapy for chronic hepatitis B virus infection (cHBV) is suppression of HBV DNA. While NrtIs reduce HBV DNA in most patients (pts), low-level viremia remains which is associated with disease progression. Therapies providing deeper levels of virologic suppression may improve long-term clinical outcomes. Previous reports from Study 202 (NCT03577171) in treatment-naïve, HBeAg positive pts demonstrated deeper reductions in HBV DNA and pre-genomic RNA (pgRNA) and more rapid normalization of ALT when vebicorvir (VBR) was added to entecavir (ETV). This report explores associations between the reductions in viral parameters with Fibrosis-4 (FIB-4) index, an indicator of liver health.

Method: In Study 202, 13 pts received 300 mg VBR+0.5 mg ETV and 12 pts received PBO+0.5 mg ETV for 24 weeks. Entry criteria included ALT ≤10xULN, platelets ≥100, 000/mm^3, Metavir F0-F2/ Fibroscan≤8kPa. HBV DNA, pgRNA, and quantitative HBV antigens were measured at each visit. FIB-4 was calculated according to [(age*AST)/ (platelet count*$\sqrt{}$ALT)]. Correlation analyses were performed, and Pearson correlation coefficients (r) calculated to describe associations between viral parameters and FIB-4.

Results: At Week 24 reductions in ALT and AST were observed with VBR+ETV but not PBO+ETV: ALT – 47.2 U/L *vs* +1.6 U/L and AST – 25.3 U/L *vs* +8.4 U/L respectively. For platelet counts, the mean change from baseline (CFB) at Week 24 was +3.5 × 10^9/L for VBR+ETV and +23.2 × 10^9/L for PBO+ETV. Changes in these parameters were reflected in the mean CFB in FIB-4 index, which was significantly greater for VBR+ETV than PBO+ETV: – 0.21 *vs* +0.05, p = 0.034. For VBR+ETV but not PBO+ETV, significant associations were observed between FIB-4 and pgRNA (r = 0.70; p = 0.008) and HBcrAg (r = 0.78; p = 0.003). There were no significant associations between FIB-4 and HBV DNA for either group.

Conclusion: The addition of VBR to NrtI therapy provides deeper suppression of HBV DNA and pgRNA and more rapid normalization of ALT and AST than NrtI alone over 24 weeks of treatment. The deeper

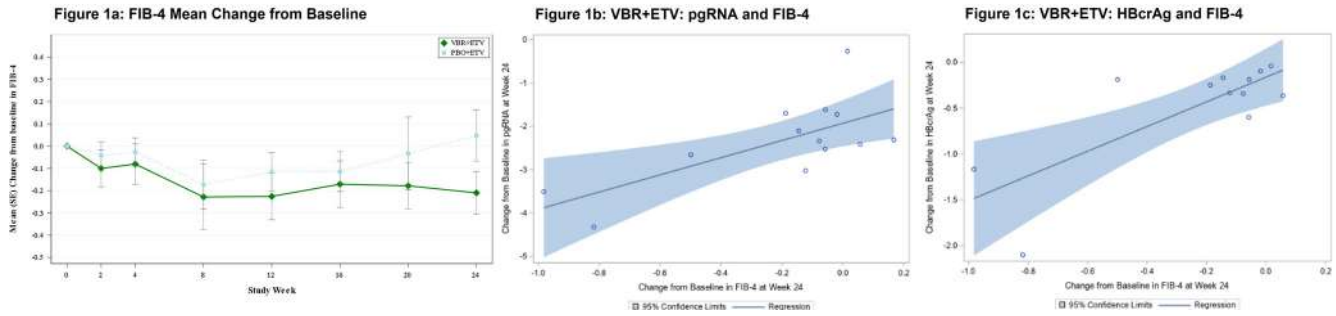

Figure: (abstract: SAT366)

level of viral suppression and reduced inflammation is reflected in greater reductions in FIB-4 for VBR+ETV compared to ETV alone. In post hoc analyses, reductions in pgRNA, a marker for cccDNA replicative activity, and HBcrAg are associated with improvement in FIB-4 over 24 weeks of treatment. Regimens providing deeper levels of viral suppression and reduced inflammation may further improve long-term clinical outcomes including fibrosis, cirrhosis and HCC.

Safety, tolerability, pharmacokinetics, and preliminary antiviral activity of the capsid assembly modulator (CAM) ZM-H1505R after multiple escalatiing oral dosed in patients with chronic hepatitis B virus (CHB) Infection

Jiajia Mai[1], Hong Zhang[2], Min Wu[2], Hong Chen[2], Yue Hu[2], Xiaoxue Zhu[2], Xiuhong Jiang[3], Bo Hua[3], Tian Xia[3], Gang Liu[3], Aiyun Deng[3], Bo Liang[3], Ruoling Guo[3], Hui Lu[3], Zhe Wang[3], Ming Ren[3], Huanming Chen[3], Zhijun Zhang[3], Junqi Niu[2], Yanhua Ding[2]. *[1]The First Hospital of Jilin University, Jilin, China, Phase I Clinical Research Center, Changchun; [2]The First Hospital of Jilin University, Jilin, China, Phase I Clinical Research Center, Changchun, China; [3]Shanghai Zhimeng Biopharma, Inc., Shanghai Zhimeng Biopharma, Inc., Shanghai, China*
Email: dingyanhua2003@126.com

Background and aims: ZM-H1505R is a newly discovered hepatitis B virus (HBV) capsid inhibitor with a novel pyrazole structure. It interferes with the assembly of HBV particles by inducing the formation of viral capsids devoid of genomic material. The safety, tolerability pharmacokinetics (PK), and preliminary antiviral activity of ZM-H1505R were evaluated in a double-blind, randomized, placebo-controlled, dose escalating study in treatment-naïve chronic hepatitis B (CHB) patients.

Method: Non-cirrhotic and treatment-naïve CHB patients were divided into three cohorts (10 patients each) and randomized within each cohort in a ratio of 4:1 to receive an ascending dose of 50, 100, or 200 mg of ZM-H1505R, or placebo once a day for 28 consecutive days.

Results: All results were analyzed in the blind state, because the blindness was still not uncovered. A total of 30 patients was randomized and completed the study. The cohorts were well matched and balanced with sex, age, baseline HBV DNA level and HBeAg status of the subjects. ZM-H1505R was safe and well tolerated from 50 to 200 mg qd oral administration, with most AEs being grade 1 or 2 and the symptoms being mild to moderate. No SAEs was observed and no withdrawal was caused due to AEs. The rates of AEs were 30%, 60% and 60% in the 50, 100, or 200 mg cohorts, respectively. The most common adverse reactions to ZM-H1505R were the elevation of alanine aminotransferase and aspartate aminotransferase in grade 1 or 2 severity (CTC-AE version 5.0), with the incidence of 10%-50% within a cohort. ZM-H1505R showed a linear pharmacokinetics proportional to the doses. ZM-H1505R reached mean plasma T_{max} at 2.5–3.5 hours postdose with mean terminal half-life of 11.975–12.999 hours after last dosage. A steady-state was achieved following 8 days of daily dosing (no samples were collected during days 2–7). The accumulation rate was similar among the different cohorts (0.941–3.454), which indicates that the accumulation is mild. At day 28, the mean plasma C_{min} were 2.7, 7.0, and 14.6 folds of its protein-binding adjusted HBV DNA EC_{50} for 50, 100, and 200 mg doses, respectively. The mean declines from baseline in HBV DNA were – 1.4, – 2.3 and – 2.5 log10 IU/ml, and in HBcrAg were – 0.14, – 0.34 and – 0.33 log10 IU/ml after 28 days treatment with ZM-H1505R at 50 mg, 100 mg and 200 mg, respectively. The mean decline from baseline in HBV pgRNA were – 0.76, and – 1.60 log10 IU/ml after 28 days treatment at ZM-H1505R 50 mg and 100 mg, respectively. Most patients experienced viral rebound after last treatment during follow-up period.

Conclusion: Once-a-day oral administration of ZM-H1505R for 28 days was safe and well tolerated. It produced a substantial decrease in HBV-DNA and HBV pgRNA levels in the serum of CHB patients. On the basis of these results, ZM-H1505R was recommended for further evaluation in phase II trials.

SAT368

Evaluation of renal and bone safety at 4 years in post-liver transplant patients with chronic kidney disease receiving Tenofovir Alafenamide for HBV prophylaxis

Edward J Gane[1], Rica Dagooc[1], Dominic Ray-Chaudhuri[1], Thomas Mules[1], Frida Abramov[2], Curtis Holt[3], Hongyuan Wang[4], Vithika Suri[2], Anu Osinusi[2], John F. Flaherty[2]. *[1]Auckland City Hospital and University of Auckland, New Zealand Liver Transplant Unit, Auckland, New Zealand; [2]Gilead Sciences, Inc., Clinical Development, Foster City, United States; [3]Gilead Sciences, Inc., Medical Affairs, Foster City, United States; [4]Gilead Sciences, Inc., Biostatistics, Foster City, United States*
Email: frida.abramov@gilead.com

Background and aims: Chronic HBV remains a leading indication for orthotopic liver transplantation (OLT) worldwide. Renal dysfunction and osteopenia are commonly observed long-term complications of maintenance immunosuppression in OLT recipients. In this at-risk population, tenofovir alafenamide (TAF) may have an advantage over tenofovir disoproxil fumarate (TDF) due to its improved renal and bone safety profile. We previously reported similar efficacy and improved safety with TAF vs TDF up to 192 weeks in this population. Presented here is a comprehensive analysis of long-term bone and renal safety.

Method: In this Phase 2 open-label study (NCT02862548), 51 liver transplant recipients on HBV prophylaxis with TDF-containing treatments and ≥Stage 2 chronic kidney disease were randomized 1:1 to TAF 25 mg/day or TDF for 48 weeks, after which all received TAF through Week 192 (i.e. TAF vs. TDF→TAF). Week 192 safety end points included changes in estimated glomerular filtration rate (eGFR) by CG, CKD-EPI, and Chromium-EDTA Renal Scan (Cr-EDTA) methods, serum creatinine (sCr), exploratory markers of renal tubular dysfunction, bone mineral density (BMD) at spine and hip by DXA, and markers of bone turnover.

Results: Baseline characteristics included: mean age 60 years, 75% males, 53% Pacific Islander, median eGFR 50 ml/min/1.73m^2 with 76% of patients at CKD stage 3 or greater, and median baseline surface area corrected GFRCr-EDTA was 58 ml/min/1.73^2. 46/51 (90%) patients completed 192 weeks of treatment. Overall safety results have been previously described. Renal parameters improved from baseline at Week 192 (Table). Increases from baseline in spine and hip BMD were observed with TAF (mean % change at Week 192: 3.4% and 1.1%, respectively) and TDF→TAF after switching to TAF (mean % change at Week 192: 3.8% and 2.1% for spine and hip, respectively); greater decreases in markers of bone turnover were observed in TAF vs TDF→TAF group (Table).

Table: Median (Q1, Q3) Change from Baseline at Week 192

	TAF 25mg **(N = 26)**	TDF→TAF **(N = 24)**
$eGFR_{CKD-EPI}$ (ml/min/1.73 m^2)	2.5 (−1.4, 8.2)	1.1 (−6.0, 9.3)
$eGFR_{CG}$ (ml/min)	2.8 (−1.5, 12.3)	0.2 (−9.0, 7.7)
sCr (mg/dL)	−0.08 (−0.19, 0.01)	−0.06 (−0.22, 0.09)
Cr EDTA (ml/min/1.73 m^2)*	0.1 (−7.1, 6.4)	−3.3 (−8.0, 5.6)
RBP:Cr ug/g (%)€	−40 (−85, −14)	−38 (−58, 88)
β2M:Cr ug/g (%)€	−54 (−87, 278)	−45 (−76, 223)
CTX ng/ml (%)¥	−39.0 (−60.5, − 14.3)	−26.9 (−60.3, 8.9)
P1NP ng/ml (%)¥	−36.98 (−55.13, −5.65)	−19.42 (−37.96, 12.75)

*Week 96 results presented
€markers of proximal tubular function (retinol-binding protein:Cr [RBP:Cr] and β2-microglobulin:Cr [β2M:Cr)
¥markers of bone formation (procollagen type 1 N-terminal propeptide [P1NP]) and resorption (C-type collagen sequence [CTX])

Conclusion: Long-term results after switching from TDF to TAF in an OLT recipient population with a high rate of renal dysfunction show sustained improvements in key bone and renal safety parameters.

Email: gaozhiliang_123@126.com

Background and aims: Add-on or switch to pegylated interferon alpha (PegIFN alpha) in nucleoside analog (NA) treated chronic hepatitis B (CHB) patients is effective strategies to improve functional cure (HBsAg loss) rate. We aimed to investigate the efficacy and safety of "add-on" or "switch to" therapy in large scale real-word and the predictors for HBsAg loss by pegIFN alpha.

Method: The Everest Project is a multicentre real-world study in China which focused on functional cure of CHB (NCT04035837). Patients who had NA therapy for more than one year, HBV DNA<100 IU/ml, HBeAg negative and HBsAg ≤1500 IU/ml were recruited since 2018. "Add-on" or "switch to" pegIFN alpha strategy for 48 weeks or up to 96 weeks was decided by doctor and patients. Data on those who have completed 48 weeks of treatment were analysed. mITT population included 5648 patients and PP population included 3988 patients.

Results: In the PP analysis, 81% patients were male, the mean age was 40.9 years and the mean baseline of HBsAg was 380.6 IU/ml. The HBsAg loss rate were 9.5%, 22.0%, 29.0% and 33.2% at 12, 24, 36 and 48 weeks, respectively (figure 1A). HBsAg baseline level, HBsAg decline level at12, 24 weeks and ALT flare are predictors for HBsAg loss at 48 weeks. 48-week HBsAg loss rate were 56.1%for patients whose baseline HBsAg was0.05–100 IU/ml. 48-week HBsAg loss rate was decreased with the increase of baseline HBsAg level (figure 1B). Patients achieved HBsAg < 500 IU/ml at 24 weeks had significantly higher 48-week HBsAg loss rate than those with HBsAg ≥500 IU/ml (36.7% vs. 1.3%, p <0.0001, figure 1C). For patients with HBsAg decline >1 log10 IU/ml from baseline to 24 weeks, the 48-week HBsAg loss rate was 58.6%, while 10.0% for those HBsAg decline ≤1 log10 IU/ml (p <0.0001) (figure 1C). Patients with higher ALT level at 12 weeks (≥5 × ULN) had a higher 48-week HBsAg loss rate (46.3%) (figure 1D). There are 1006 patients (68.4%, 1006/1470) achieved HBsAg ≤100 IU/ml at 48 weeks, although they did not achieved HBsAg loss. Those patients might achieve functional cure for further prolonged therapy of PegIFN alpha. There were no severe adverse events during this project.

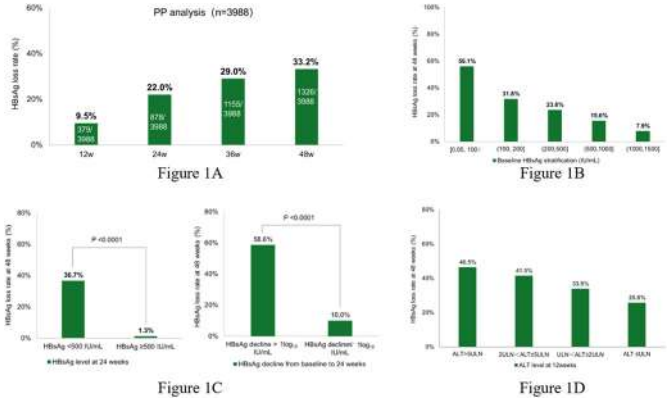

Figure: A. HBsAg loss rate at different time points in PP analysis. B. HBsAg loss rate at 48 weeks by baseline HBsAg stratification. C. HBsAg level or decline range at 24 weeks predicting HBsAg loss at 48 weeks. D. ALT level at 12 weeks predicting HBsAg loss at 48 weeks.

Conclusion: Functional cure could be well achieved in NA-suppressed HBeAg negative CHB patients by pegIFN alpha strategy. Lower HBsAg at baseline, lower HBsAg at 24 weeks, a rapid decline of HBsAg and ALT elevations at 12 weeks are predictors for functional cure at 48 weeks. There are still good chances of functional cure by prolonged treatment for patients who had not achieved HBsAg loss in 48 weeks course. PegIFN alpha therapy was well-tolerated.

SAT370

Understanding the dynamics of HBsAg decline through model-informed drug development (MIDD) of JNJ-3989 and JNJ-6379 for the treatment of chronic hepatitis B virus infection (CHB)

Huybrecht T'jollyn[1], Nele Goeyvaerts[1], Thomas Kakuda[1], Louis Sandra[1], Tetsuro Ogawa[1], Joris J Vandenbossche[1], Xavier Woot de Trixhe[1], Oliver Lenz[1], Ronald Kalmeijer[1], Michael Biermer[1], Juan Jose Perez Ruixo[1], Oliver Ackaert[1]. [1]*Janssen Research and Development*
Email: htjollyn@its.jnj.com

Background and aims: JNJ-3989 is an N-acetylgalactosamine-conjugated siRNA, consisting of 2 triggers JNJ-3976 and JNJ-3924, designed to target hepatitis B virus (HBV)-derived RNAs, thereby reducing all viral proteins. JNJ-6379 is a capsid assembly modulator inducing formation of 'empty' HBV capsids. The phase 2b study REEF-1 assessed the combination of 40, 100, and 200 mg JNJ-3989 as Q4W subcutaneous injections with or without 250 mg QD oral JNJ-6379 on a background of nucleos (t)ide analogue (NA) (AASLD 2021). The relationship between exposure to JNJ-3989 + NA ± JNJ-6379 and HBsAg decline was assessed using mechanism-based pharmacokinetic-pharmacodynamic (PK-PD) modeling (see Figure).

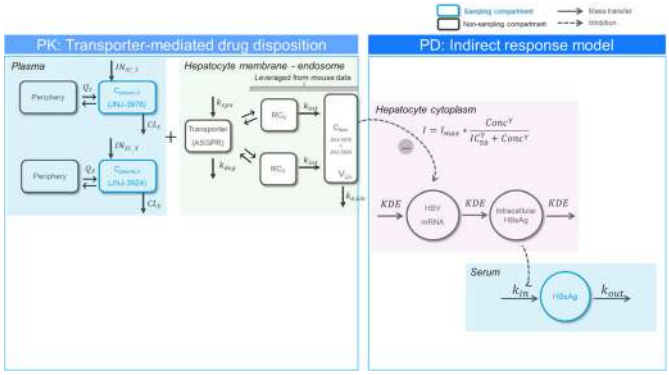

Figure: TMDD-IRM model developed based on Phase 1 and 2 PK and PD data for JNJ-3989.

Method: This PK-PD model, a Transporter-Mediated Drug Disposition (TMDD) with Indirect Response Model (IRM), was developed based on plasma PK of JNJ-3989 obtained from pooled Phase 1 and 2 studies in healthy, hepatically impaired, and CHB subjects, the latter also providing PD biomarker (HBsAg) data. Asialogylcoprotein (ASGPR)-mediated liver uptake was incorporated by leveraging information from plasma and liver JNJ-3989 concentrations collected in a HBV mouse study. The IRM described the relationship between estimated human liver concentrations and the inhibition of HBsAg production leading to observed HBsAg decline in patients, taking into account the treatment status at baseline [not currently treated (NCT) or virologically suppressed (VS)], and baseline HBeAg status (+ or -). A covariate analysis was performed to investigate treatment- and/or subgroup-specific HBsAg dynamics.
Results: JNJ-3989 liver uptake is saturable through ASGPR resulting in a decreased fraction of the dose that reaches the liver as the dose increases. The dynamics of HBsAg decline were governed by the accumulation of JNJ-3989 in liver, the exposure-dependent inhibition of HBsAg production, and the estimated HBsAg half-life. Covariate analysis indicated that (i) NCT HBeAg+ patients had faster and more pronounced HBsAg decline compared to other subgroups, (ii) combination treatment with JNJ-6379 led to a less pronounced decline in HBsAg, and (iii) JNJ-3989 activity is inversely associated to body weight.
Conclusion: JNJ-3989 showed a non-linear concentration-dependent liver uptake, mediated by ASGPR. HBsAg levels decreased in a dose-dependent manner up to 48 weeks of JNJ-3989 treatment in REEF-1. Covariate analysis identified that HBsAg dynamics display treatment- and subgroup-specific behavior.

SAT371

Serum HBsAg and ddPCR HBV-DNA as predictive parameters of HBsAg loss after nucleo (s)tide analogue (NA) treatment discontinuation in non-cirrhotic patients with chronic hepatitis B

Anna Francesca Guerra[1], Giovanni Tomassoli[1], Lorenzo Piermatteo[2], Stefano D'Anna[2], Romina Salpini[2], Valentina Svicher[2], Paolo Ventura[1], Gian Luca Abbati[1], Antonello Pietrangelo[1]. *[1]University of Modena and Reggio Emilia, Internal Medicine, Modena, Italy; [2]University of Rome "Tor Vergata", Italy*
Email: anna.f.guerra@hotmail.it

Background and aims: According to international guidelines, stopping nucleo (s)tide analogue (NA) treatment in selected non-cirrhotic Chronic Hepatitis B (CHB) patients may promote sustained serological and virological off treatment response. Nevertheless, this approach often leads to virus-induced flares, which may result to life-threatening liver failure. Therefore, in order to assure a safe discontinuation of treatment, reliable predictors of post-NAs remission need to be identified. Here, we aimed to identify predictive parameters of off-NAs response at the end of treatment and, specifically, their association with HBsAg loss or HBsAg <100 IU/ml (known to be predictive of subsequent HBsAg loss).
Method: 38 non-cirrhotic CHB patients, with complete virological suppression (>4 years), were prospectively monitored after suspending NA treatment for a median (IQR) time of 16 (10–19) months. For each patient, a plasma sample at suspension date (baseline, BL) was collected and used to quantify serum HBV-DNA by highly sensitive droplet digital PCR (ddPCR). HBsAg was quantified by the ARCHITECT HBsAg assay at BL, every 2 weeks from suspension in the first month, followed by every month until the sixth month, then every 3 months, in order to assess the achievement of HBsAg <100 IU/ml or HBsAg loss
Results: At BL, ddPCR revealed that 28 (73.7%) patients had detectable serum HBV-DNA (median [IQR] 5 [2–11] IU/ml), while 10 (26.3%) were completely negative to HBV-DNA. After NA suspension, 7 (18.4%) achieved HBsAg <100 IU/ml (median [IQR]: 43 [35–53] IU/ml) and 8 (21.1%) lost HBsAg at last follow-up.
As expected, patients achieving HBsAg loss had lower HBsAg levels at BL (140 [70–480] IU/ml with vs 1162 [439–3135] without HBsAg loss, p = 0.014).
Notably, the negativity to HBV-DNA by ddPCR at BL strongly correlated with the achievement of HBsAg <100 IU/ml or HBsAg loss after NA suspension (outcome observed in 70% [7/10] with vs 28.6% [8/28] without negative BL HBV-DNA; OR [95% CI]: 5.8 [1.3–23.6], p = 0.03). Even more, the combination of HBsAg <500 IU/ml + negativity HBV-DNA by ddPCR at BL was the best predictor for achieving HBsAg <100 IU/ml or HBsAg loss (outcome observed in 85.7% with vs 27.6% without this combination; OR [95% CI]: 15.8 (1.6–152.2; p = 0.008; PPV = 86%; NPV = 72%).
Conclusion: NA suspension can be an effective strategy to constrain or silence intrahepatic HBV reservoir in accurately selected patients. Residual HBV replicative activity at NA suspension, measured by highly sensitive assays, provides an added value in identifying patients more prone to achieve HBV functional cure.

SAT372

Exploring hepatitis B virus as an immunotherapeutic target for clinical trials of adoptively transferred T cells

Suhasini Lulla[1], Tsung-Yen Chang[1], Spyridoula Vasileiou[1], Manik Kuvalekar[1], Ayumi Watanabe[1], Yovana Velazquez[1], Jenny Stanton[2], Ann Leen[1]. *[1]Center for Cell and Gene Therapy, Baylor College of Medicine, Houston Methodist Hospital, Texas Children's Hospital, Houston, United States; [2]AlloVir Inc*
Email: AMLEEN@texaschildrens.org

Background and aims: Patients chronically infected with hepatitis B virus (HBV) have endogenous T cell deficits including dysfunctional and exhausted HBV-reactive cells, which may be addressed by the adoptive transfer of HBV-reactive T cells from healthy immune individuals. HBsAg-positive, allogeneic, hematopoietic cell transplant (HCT) recipients who received stem cells (and lymphocytes) from donors that were positive for HBc and HBs antibodies have shown high rates of functional cure post-transplant. We explored the feasibility of extending this benefit to all patients with chronic HBV infection by generating a bank of HBV-specific T cells (HBVSTs) from healthy donors that are suitable for off-the-shelf clinical use.
Method: HBVSTs were produced using peptide libraries spanning immunodominant antigens to expand reactive cells. Following a single in vitro stimulation, we achieved a 7.3 ± 0.6 (n = 9) fold increase, representing a >6000-fold enrichment of HBV-reactive T cells. The phenotypic profile of these cells was assessed by flow cytometry with antibodies to: CD3, CD4, CD8, CD25, CD69, CD45RO, CD16, CD62L and CD56. The effector profile of reactive cells was assessed using intracellular cytokine staining (ICS), luminex and/or IsoPlexis. In vitro cytolytic capacity was evaluated in a short-term killing assay using antigen-loaded autologous targets and partially HLA-matched HepG2.2.15 cells.
Results: Reactive cells were polyclonal and dominated by CD4+ T cells (mean 72 ± 4%) with a minor CD8+ (21 ± 2%) component. The cells expressed markers associated with central (CD45RO+/CD62L+: 58 ± 3%) or effector memory (CD45RO+/CD62L-: 30 ± 3%) potential and were activated based on expression of CD25 (59 ± 5%) and/or CD69 (21 ± 3%). Post-expansion, these HBVSTs were Th1-polarized and polyfunctional based on their ability to simultaneously produce multiple effector molecules including IFNγ, TNFα, GM-CSF, granzyme B, MIP-1α and MIP-1β. Finally, these cells were able to selectively kill virus-expressing autologous targets (40:1 E:T 36% specific lysis) and partially HLA-matched HBV-infected HepG2 cells (71%) with no reactivity against non-infected autologous or allogeneic targets (1% specific lysis each).
Conclusion: This study establishes the feasibility of developing banks of ex vivo expanded HBV-specific T cells that are suitable for clinical use. Further evaluation of these HBVSTs using in vivo models and in chronic HBV patients is warranted.

Treatment with Bulevirtide in patients with chronic HBV/HDV co-infection. Safety and efficacy at month 18 in real-world settings

Victor de Lédinghen[1], Sophie Metivier[2], Edouard Bardou-Jacquet[3], Marie-Noëlle Hilleret[4], Veronique Loustaud-Ratti[5], Nathalie Ganne-Carrié[6], Bruno Roche[6], Isabelle Fouchard Hubert[7], Anne Gervais[6], Anne Minello Franza[8], Tarik Asselah[6], Christiane Stern[6], Jérôme Dumortier[9], Xavier Causse[10], Dominique Roulot[6], Frederic Heluwaert[11], Leon Muti[12], Isabelle Rosa[13], Valérie Canva[14], Dominique Larrey[15], Caroline Lascoux-Combe[6], Juliette Foucher[1]. *[1]CHU Bordeaux; [2]CHU Toulouse; [3]CHU Rennes; [4]CHU Grenoble; [5]CHU Limoges; [6]APHP; [7]CHU Angers; [8]CHU Dijon; [9]CHU Lyon; [10]CHR Orléans; [11]CHG Annecy; [12]CHU Clermont-Ferrand; [13]CHI Créteil; [14]CHU Lille; [15]CHU Montpellier*
Email: victor.deledinghen@chu-bordeaux.fr

Background and aims: BLV monotherapy as well as combination with PEG-interferon α 2a (PEG-IFNα) for 48 weeks induced HDV RNA declines in HDV patients included in the French ATU early access program started in September 2019. To date, there is no data available evaluating the efficacy and safety of BLV 2 mg at 18 months. The aim of this study was to evaluate 18-month safety and virological response in HBV/HDV patients receiving 2 mg BLV with or without PEG-IFNα 2a included in the French BLV ATU (real-life study).
Method: 145 patients (male gender 99, mean age 41, 3 years, cirrhosis 90) with chronic HBV/HDV co-infection, with cirrhosis or moderate fibrosis and elevated ALT levels, without liver decompensation, were included in the French early access program. Patients received 2 mg BLV qd sc alone (group A) or in combination with PEG-IFNα once weekly (group B), according to physician's choice.
Results: Among these 145 patients, 19 patients switched BLV 2 mg to BLV 10 mg (reason: no response observed after at least 3 months of treatment with 2 mg), 43 patients stopped BLV for many reasons (lost to follow-up, no response, side-effects related to the disease, patient's wish) and 83 always received BLV 2 mg. At M12, HDV-RNA was undetectable in 39% and 85% of patients treated with BLV and BLV + PEG-IFN, respectively. In October 2021, M18 data were already available in 38 patients. Among them, no new severe side-effect was reported. Undetectable HDV-RNA and combined response (HDV-RNA decrease >2 $\log_{10}$ or undetectable and normal ALT <40 IU/L) were observed in 17 (44.7%) and 14 patients (36.8%), respectively. Details are indicated in the table. Among 7 patients treated with BLV 2 mg alone for at least 18 months, HDV-RNA was undetectable in 3 and HDV-RNA decrease >2 $\log_{10}$ or undetectable and normal ALT <40 IU/L was observed in 2.

Characteristics of patients according to response at month 18.

Undetectable HDV-RNA	YES (N = 17)	NO (N = 21)
Cirrhosis	10 (58.8%)	12 (57.1%)
BLV associated with PEG-IFN	12 (70.6%)	8 (38, 1%)
Stop BLV 2 mg before M13	2 (11.8%)	14 (66.7%)
Stop PEG-IFN before M13	8 (47.6%)	6 (28.6%)
Switched to BLV 10 mg during the first 12 months	1 (5.9%)	7 (33.3%)
HDV-RNA decrease ≥2 $\log_{10}$ or undetectable and normal ALT <40 IU/L	YES (N = 14)	NO (N = 24)
Cirrhosis	8 (57.1%)	14 (58.3%)
BLV associated with PEG-IFN	10 (71.4%)	10 (41.7%)
Stop BLV 2 mg before M13	3 (21.4%)	14 (58.3%)
Stop PEG-IFN before M13	7 (50%)	7 (29.2%)
Switched to BLV 10 mg during the first 12 months	0	7 (29.2%)

Conclusion: In this first real-world cohort and long-term follow-up, daily BLV 2 mg monotherapy is safe and well tolerated during 18 months. Strong antiviral responses against HDV in real-life were observed. Final results (month 18) will be presented during the meeting.

SAT374

Two-year safety and efficacy of tenofovir alafenamide in chronic hepatitis B: a HEllenic multicenter ReAl-life CLInical Study (HERACLIS-TAF)

Email: gepapath@med.uoa.gr

Background and aims: In the phase III trials in chronic hepatitis B (CHB), tenofovir alafenamide (TAF) compared to tenofovir disoproxil fumarate (TDF) had similar efficacy and improved safety in renal function and bone mineral density (BMD) parameters, but patients (pts) with significant renal or BMD disorders were not included. In Greece, TAF has been reimbursed since 02/2018 for CHB pts with estimated glomerular filtration rate (eGFR) <60 ml/min, serum phosphate <2.5 mg/dl or osteoporosis (T-score <-2.5). We assessed the safety and efficacy of 24-month (mo) TAF therapy in CHB pts treated at Greek tertiary liver centers.
Method: Adult CHB pts who started TAF between 02/2018–10/2019 at 13 clinics participating in the HERACLIS-TAF registry were included. Main exclusion criteria were HDV coinfection, active malignancy and biphosphates use in last 6 months. Clinical and laboratory characteristics were recorded at TAF onset and every 6 mos thereafter until mo-24. MDRD formula was used for eGFR (ml/min) estimation.
Results: TAF was initiated in 176 pts: age 64 ± 12 years, 71% males, 85% undetectable HBV DNA, 86% ALT<40, 45% eGFR <60, 94% nucleos (t)ide analogue (NA) experienced (91% directly switched to TAF from another NA-81% from TDF; 3% NA discontinuation >2 mos). There was no TAF-related serious adverse event. At mo-12 and – 24, HBV DNA was undetectable (<15 IU/ml) in 97% and 100% and ALT was ≤40 IU/L in 96% and 95% of pts. In pts switching to TAF from other NA, median ALT decreased from onset to mo-12 or – 24 of TAF (23 to 21 or 20 IU/L, p <0.001). Mean eGFR had decreased from previous NA onset (74 ± 28) to TAF onset (66 ± 26, p <0.001) and then increased at 6 (69 ± 26, p = 0.001) or 12 mos (71 ± 29, p <0.001) remaining stable at 24 mos (71 ± 31). eGFR difference between 24 mos and TAF onset was >0 in 56% and >10 in 36% of pts; eGFR difference >0 and >10 occurred more frequently in pts with baseline eGFR 30–60 (76% and 48%, p <0.030). In pts starting TAF with phosphate <2.5, mean phosphate levels increased from onset (2.1) to mo-12 or – 24 (2.7 or 2.9, p <0.001).

Mean BMD (Hip T-score) did not change significantly from TAF onset (-2.1) to mo-12 (-1.8, P = 0.164) but improved at mo-24 (-1.4, p = 0.016).
Conclusion: In most NA experienced CHB pts with renal and/or BMD disorders/risks, two-year TAF therapy is safe and effective achieving or maintaining virological suppression and improving ALT, eGFR and serum phosphate levels. eGFR improvement can be achieved in up to 60% of all pts and 75% of those with baseline eGFR 30–60.

Email: stian@orlien.no

Background and aims: The World Health Organization has set an ambitious goal of eliminating viral hepatitis as a major public health threat by 2030. In sub-Saharan Africa, however, antiviral treatment of chronic hepatitis B (CHB) is virtually unavailable in the public sector. Experiences from real-life CHB cohorts are needed to inform treatment guidelines and policy makers. Here we present 5-year results from one of the first and largest CHB treatment programs on the continent.
Method: Adults with CHB were enrolled in a cohort study at St. Paul's Hospital Millennium Medical College, Addis Ababa, from 2015. Liver function tests, viral markers and transient elastography was assessed at baseline and thereafter at 6-monthly intervals. Tenofovir disoproxil fumarate (TDF) was initiated based on the European Association for the Study of the Liver (EASL) criteria, with some modifications. Changes in laboratory markers were analyzed using Wilcoxon signed-rank tests. Adherence to therapy was measured by pharmacy refill data.
Results: In total, 1303 patients were included in the program; 533 (40.9%) were women and the median age was 31 years (interquartile range 26–40). Co-infections were rare: 29 patients (2.2%) were anti-HCV positive, and 19 (1.5%) were anti-HDV positive.
Overall, 294 individuals (22.6%) started TDF therapy within the first five years of follow-up. Thirty-nine (13.3%) of these patients died, of whom 36 (92.3%) had decompensated cirrhosis at baseline. Eight individuals (2.7%) developed hepatocellular carcinoma.
Liver stiffness declined steadily in patients on TDF therapy; median change from baseline after 1, 3 and 5 years was – 2.9 kPa, – 5.2 kPa and – 5.6 kPa, respectively. Among patients still in care, 141 of 149 (94.6%) had suppressed viraemia (<69 IU/ml). In patients with available pharmacy refill data, 253 of 290 (87.2%) had ≥ 80% adherence.
Conclusion: This pilot program demonstrated that CHB therapy is feasible in Ethiopia with excellent long-term clinical and virological results. Our findings support rolling out large-scale treatment programs in sub-Saharan Africa.

SAT376
Decrease in the burden of integrated hepatitis B virus DNA in chronic hepatitis B patients with minimally elevated alanine aminotransferase on tenofovir disoproxil fumarate as revealed by long-read DNA-sequencing
David Pan[1], Cameron Soulette[1], Dong Han[1], Ricardo Ramirez[1], Nicholas Van Buuren[1], Jaw-Town Lin[2], Cheng-Hao Tseng[3], Li Li[1], Simon Fletcher[1], Hongmei Mo[1], Becket Feierbach[1], Vithika Suri[1], Yao-Chun Hsu[4]. *[1]Gilead Sciences, Inc., Foster City, United States; [2]China Medical University, Digestive Medicine Center, Taichung, Taiwan; [3]E-Da Cancer Hospital, Division of Gastroenterology and Hepatology, Kaohsiung, Taiwan; [4]National Yang Ming Chiao Tung University, Institute of Biomedical Bioinformatics, Taipei, Taiwan*
Email: david.pan3@gilead.com

Background and aims: Treatment with tenofovir disoproxil fumarate (TDF) was recently shown to reduce the number of distinct, transcriptionally active hepatitis B virus (HBV) integrations in chronic hepatitis B (CHB) patients with mild alanine aminotransferase (ALT) elevation. This short-read RNA-Sequencing (RNA-Seq) analysis was limited to the identification of expressed HBV integrations and hence did not measure the complete burden of integrated HBV DNA. Here, we use targeted long-read DNA Sequencing (DNA-Seq) to enable comprehensive analysis of the effect of TDF treatment on HBV integrations.
Method: A phase 4, randomized, double-blind, placebo-controlled study was conducted to evaluate the efficacy of TDF in CHB patients with mild ALT elevation (>1 fold but <2-fold of the upper limit normal (ULN)) without hepatocellular carcinoma (HCC) (NCT01522625). Targeted long read DNA-Seq was performed on paired liver biopsies (baseline and year 3 post-treatment) from TDF (n = 28) and placebo (n = 27) treated patients. The average on-target read length for the long-read DNA-Seq was 5.5 kilobases (kb). The long-read DNA-Seq data was analyzed using the ViraAL Integrations ANd Translocations (VALIANT) bioinformatics workflow.
Results: All patients had evidence of integrated HBV DNA at baseline with integrations detected near (≤5 kb) 2, 165 genes including 13 genes in the Catalogue Of Somatic Mutations In Cancer (COSMIC) database. Of the patients with integrated HBV DNA, 98% (n = 54/55) had ≥1 integrated HBV sequence (s) flanked by the same human chromosome and 80% (44/55) of patients contained ≥1 integrated HBV sequence (s) flanked by two different human chromosomes, indicating an inter-chromosomal translocation. Consistent with our previous short-read RNA-Seq analysis, there was a significant decrease in integration burden at year 3 post-treatment in TDF-treated (p = 0.0076) but not placebo-treated (p > 0.05) patients.

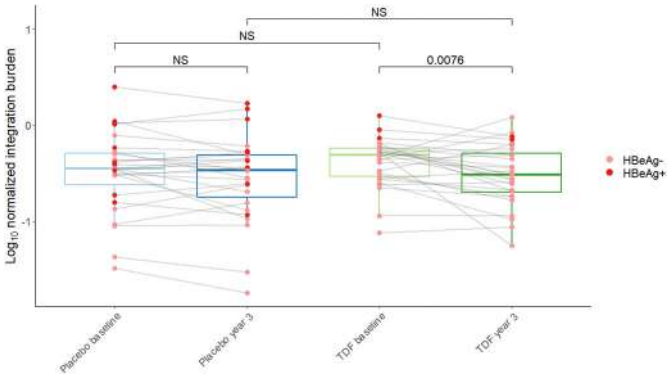

Figure: Normalized integrated HBV DNA burden shows decrease in TDF treated CHB patients but not in patients on placebo.

Conclusion: Targeted long-read DNA-Seq analysis revealed pervasive integrated HBV DNA in CHB patients with minimally elevated ALT, with ≥80% individuals having evidence of HBV-related chromosomal translocation. In line with our previous analysis, TDF treatment

significantly decreased the integrated HBV DNA burden in these patients. Together, these results suggest that early treatment of CHB patients with TDF may play a role in reducing the burden of integrated HBV DNA, which is commonly associated with hepatocarcinogenesis.

SAT377

Serum HBV RNA levels are associated with risk of hepatitis flare after stopping NA therapy in HBeAg-negative patients

Email: alexander.thompson@svha.org.au

Background and aims: Among HBeAg-negative chronic hepatitis B (CHB) patients on long-term nucelos (t)ide analogue (NA) therapy, treatment discontinuation has been associated with HBsAg loss and durable virological suppression, but also hepatitis flares requiring NA therapy to be restarted. The prediction of clinical outcomes after stopping NA therapy remains challenging. Quantification of circulating HBV RNA is a promising biomarker in CHB patients. We have evaluated the role of serum HBVRNA levels to predict clinical outcomes in a large cohort of patients enrolled in a prospective NA-STOP study.

Method: The Melbourne HBV-STOP study was a prospective multicentre study of NA discontinuation in 110 HBeAg-negative non-cirrhotic patients who had achieved long-term virological suppression on treatment. All patients were followed for 96 weeks. In a subset, we performed an exploratory analysis of serum HBVRNA levels for predicting clinical outcomes after stopping NA therapy. HBVRNA levels were measured at baseline and longitudinally using the automated Roche cobas® HBVRNA Investigational Assay. Clinical outcomes of interest included rates hepatitis flare (ALT>5xULN), disease remission (HBV DNA<2000 IU/ml and ALT<2xULN) and HBsAg loss, as well as rates of NA re-treatment.

Results: HBVRNA levels were tested at baseline and off-treatment in 65 patients. At baseline, the median age was 56 yrs, 54% were male, and 75% were Asian. Median HBsAg level was 701 (1.6–19912) IU/ml. Following treatment withdrawal, virological reactivation occurred in all participants, 38% experienced a hepatitis flare (ALT>5xULN), 26% restarted NA therapy and 6% (n = 4) lost HBsAg by 96 weeks. At baseline, serum HBV RNA was detectable in 16/65 (25%). The detection of HBVRNA in serum at baseline was positively associated with risk of hepatitis flare [ALT >5 xULN, 63% vs 31%, OR = 3.8, 95% CI = (1.2, 12.3), p value = 0.03], as well as lower likelihood of sustained disease remission as well as HBsAg loss. HBVRNA levels were undetectable at baseline in all patients who achieved HBsAg loss. Of patients HBVRNA negative at baseline, HBVRNA levels became detectable in 47/49 patients during follow-up. The time to detection of HBVRNA was shorter for patients stopping TDF than ETV (median 49 vs 90 days, p = 0.02). The detection of HBVRNA over time was associated with rising HBVDNA levels>10^4 IU/ml. HBVRNA levels>10^3 cp/ml off-treatment were associated with increased risk of hepatitis flare (ALT>5xULN).

Conclusion: Serum HBVRNA was detectable in a minority of HBeAg-negative patients on long-term NA therapy. The detection of any serum HBVRNA prior to stopping NA therapy, and rising HBVRNA off-treatment, were associated with risk of subsequent hepatitis flare, as well as lower likelihood of HBsAg loss. HBVRNA levels show promise as a biomarker for predicting clinical outcomes after stopping NA therapy in patients with HBeAg-negative CHB.

Efficacy and safety of tenofovir alafenamide versus tenofovir disoproxil fumarate in treatment-naive patients with chronic hepatitis B

Jihye Lim[1], Won-Mook Choi[1], Ju Hyun Shim[1], Danbi Lee[1], Kang Mo Kim[1], Young-Suk Lim[1], Han Chu Lee[1], Jonggi Choi[1]. *[1]Asan Medical Center, University of Ulsan College of Medicine, Gastroenterology, Korea, Rep. of South*
Email: jkchoi0803@gmail.com

Background and aims: We aimed to evaluate the efficacy and safety of tenofovir alafenamide (TAF) compared with tenofovir disoproxil fumarate (TDF) in treatment-naïve patients with chronic hepatitis B (CHB) based on real world data.

Method: We analyzed 2, 747 patients with CHB under TAF (n = 502) or TDF (n = 2, 245) treatments. Virological response (VR: HBV DNA <15 IU/ml), on-treatment ALT normalization, the incidence of HCC, renal function, and lipid profiles were compared between these groups. Propensity score matching of 495 pairs was also conducted for these comparisons.

Results: The mean age of the total cohort was 48.6 years and 58.2% were male. Cirrhosis had a 33.3% prevalence in this study population. VRs at 12-, 24-, and 36 months were achieved in 70.3%, 81.2%, and 83.3% of the TAF and 67.9%, 84.3% and 86.1% of the TDF cases, respectively (p >0.05 for all). Normalized ALT, as determined by local laboratory criteria (<40 U/L), occurred in 79.7%, 90.6%, and 86.2% of the TAF group and 78.2%, 85.8%, and 85.7% of the TDF group at 12-, 24-, and 36 months, respectively (p >0.05 for all). The HCC risk did not statistically differ across the entire cohort (TAF: 0.80/100 person-years [PYs] vs TDF: 1.45/100 PYs, P = 0.30) or in the PS-matched cohort (TAF: 0.82/100 PYs vs TDF: 0.90 PYs, P = 0.60). The TAF group showed a lower median increase in serum creatinine from baseline during the early study period. Compared with the TAF group, the TDF group showed significant decreases in total cholesterol, triglyceride, and HDL, but not in LDL.

Conclusion: Real-word data indicate that TAF has comparable efficacies to TDF in terms of VR and ALT normalization, with no higher risk of HCC.

Bulevirtide 2 mg/day monotherapy in patients with chronic hepatitis delta with or without cirrhosis: a multicenter european cohort real-life study

Alessandro Loglio[1], Peter Ferenci[2], Katja Deterding[3], Sara Colonia Uceda Renteria[4], Dana Sambarino[1], Mathias Jachs[2], Caroline Schwarz[5], Marta Borghi[1], Kerstin Port[3], Riccardo Perbellini[1], Floriana Facchetti[1], Elisabetta Degasperi[1], Benjamin Maasoumy[3], Thomas Reiberger[2], Markus Cornberg[3], Heiner Wedemeyer[3], Pietro Lampertico[1,6]. *[1]Foundation IRCCS Ca' Granda Ospedale Maggiore Policlinico, Division of Gastroenterology and Hepatology, Milan, Italy; [2]Medical University of Vienna, Division of Gastroenterology and Hepatology, Vienna, Austria; [3]Hannover Medical School, Germany; [4]Foundation IRCCS Ca' Granda Ospedale Maggiore Policlinico, Clinical Laboratory, Milna, Italy; [5]Klinik Ottakring, Department of Internal Medicine IV, Vienna, Austria; [6]University of Milan, CRC "A. M. and A. Migliavacca" Center for Liver Disease, Department of Pathophysiology and Transplantation, Milan, Italy*
Email: ale.loglio@gmail.com

Background and aims: Bulevirtide (BLV) has been recently approved for the treatment of HDV-related chronic hepatitis but its 'real-life' effectiveness and safety-especially in patients with cirrhosis-are still poorly known. This study aimed to describe the early virological and biochemical responses in a large European cohort.

Method: All consecutive HDV patients who started BLV 2 mg/day in three EU countries were enrolled in this study. Demographic, clinical and virological features were collected at baseline and during therapy. Primary end point was virological response (≥2 Log decline or undetectable HDV-RNA), secondary end points included virological non-response (<1 Log decline), biochemical response (normal ALT), combined response, and safety at week 24. HDV-RNA was quantified by Robogene 2.0 (LOQ 6 IU/ml), in-house RT-PCR (LOQ 100 cp/ml) and Robogene 1.0 (LOQ 80 IU/ml).

Results: 58 patients were enrolled: 47 (25–79) years, 62% males, 97% Caucasian, 78% cirrhotics, 67% varices, spleen diameter 17 (8–25) cm, platelets 88 (28–288)*10^3/mmc, transient elastography: 16.3 (1.7–57.8) kPa, CAP 203 (100–320) dB/m; 69% previous interferon therapy, 97% under NA therapy, 2 patients with HCC. At baseline (BLV start): ALT 80 (7–341) U/L (83% >ULN), albumin 4.1 (2.8–4.9) g/dL, HBsAg 3.7 (1.7–4.8) Log IU/ml, 91% HBeAg negative, 86% HBV-DNA undetectable. Baseline HDV-RNA levels were 4.9 (3.3–6.6) Log IU/ml, 4.7 (2.0–7.3) Log cp/ml and 5.8 (1.9–7.5) Log IU/ml, respectively in the three countries. By week 24, ALT levels declined to 34 (18–82) U/L and normalized in 77% of patients. HDV-RNA showed an overall 2.0 (0–3.9) Log decline: virological response was observed in 54% of patients (10% with HDV-RNA <LOQ), while 46% achieved a combined (virological and biochemical) response. A virological non-response (<1 Log decline at week 24) was observed in 27% of patients, even if 60% of them normalized ALT levels. HBsAg levels remained unchanged. BLV was well tolerated, with no significant injection site reactions, including in patients with active HCC or clinically significant portal hypertension.

Conclusion: This real-life multicenter EU cohort study demonstrated the early effectiveness and safety of BLV 2 mg monotherapy even in difficult-to-treat cirrhotic HDV patients. However, the rate of virological non-response at week 24 was higher than previously estimated. The week 48 data will be presented at the meeting.

SAT380

The orally available sodium/taurocholate co-transporting polypeptide inhibitor A2342 blocks hepatitus B and D entry in vitro

Britta Bonn[1], Ellen Strängberg[1], Ivana Uzelac[1], Michael Kirstgen[2], Nora Goldmann[3], Dieter Glebe[3], Joachim Geyer[2], Erik Lindström[1]. *[1]Albireo Pharma, Inc., Boston, MA, United States; [2]Institute of Pharmacology and Toxicology, Justus Liebig University of Giessen, Giessen, Germany; [3]Institute of Medical Virology, Justus Liebig University Giessen, Giessen, Germany*
Email: britta.bonn@albireopharma.com

Background and aims: A2342 is a novel small molecule, orally available, selective inhibitor of hepatic transporter Na^+/taurocholate co-transporting polypeptide (NTCP). NTCP mediates uptake of bile acids into hepatocytes and acts as a host receptor for hepatitis B and D viruses (HBV/HDV). The preS1 domain of the large envelope protein of HBV/HDV is essential for binding of these virus particles to NTCP. We previously demonstrated that A2342 lowers HBV DNA viral load in infected human hepatocytes in vitro and also attenuates HBV viral load and HBV antigens in infected humanized mice in vivo. Here, we aim to provide more detail on the NTCP inhibitory mechanism.

Method: Human NTCP-expressing HEK293 cells were used to evaluate inhibition of 1 µmol/L [^{3}H]taurocholic acid transport and [^{3}H]preS1 peptide binding as surrogate parameter for virus binding. Human NTCP-expressing HepG2 cells were used to evaluate entry inhibition of HDV and HBV via immunostaining against hepatitis D antigen (HDAg) and hepatitis B core antigen (HBcAg), respectively, and measuring hepatitis B e antigen (HBeAg) levels in supernatant of HBV-infected cells. Cryopreserved human hepatocytes infected with a clinical isolate of HBV were used for infection experiments; HBV DNA levels in supernatant were analysed. The peptides preS1 (genotype D) and myrcludex B or tenofovir disoproxil fumarate (TDF) were used as positive controls.

Results: A2342 inhibited [^{3}H]taurocholic acid uptake (half-maximal inhibitory concentration [IC_{50}], 186 nmol/L) and [^{3}H]preS1 peptide binding (IC_{50}, 149 nmol/L) in a concentration-dependent manner. In infection experiments, A2342 (range, 100–400 nmol/L) inhibited numbers of HBcAg-positive cells by 75%–90% and HDAg-positive cells by 40%–60%. HBeAg levels in supernatant were reduced with A2342 by >90% at all concentrations. In cryopreserved human hepatocytes, A2342 reduced HBV DNA levels in a concentration-dependent manner when given 18 h before infection. A2342 was not effective when given 18 h post-infection. Additive antiviral effects were evident when A2342 was given together with TDF. A2342 was devoid of cellular toxicity in hepatocytes and cell lines.

Conclusion: A2342 inhibits NTCP-mediated bile acid uptake and HBV preS1 peptide binding in similar manners and blocks entry of HBV and HDV. These data further support A2342 as the first orally bioavailable molecule able to inhibit HBV/HDV entry via NTCP in the nanomolar range.

SAT381

Comparative performance analysis between manual and automatic RNA extraction to quantify HDV RNA by RoboGene 2.0 kit in untreated and bulevirtide-treated HDV patients

Sara Colonia Uceda Renteria[1], Alessandro Loglio[2], Marta Borghi[2], Dana Sambarino[2], Riccardo Perbellini[2], Floriana Facchetti[2], Sara Monico[2], Elisabetta Degasperi[2], Ferruccio Ceriotti[1], Pietro Lampertico[2,3]. *[1]Foundation IRCCS Ca' Granda Ospedale Maggiore Policlinico, Clinical Laboratory, Milan, Italy; [2]Foundation IRCCS Ca' Granda Ospedale Maggiore Policlinico, Division of Gastroenterology and Hepatology, Milan, Italy; [3]University of Milan, CRC "A. M. and A. Migliavacca" Center for Liver Disease, Department of Pathophysiology and Transplantation, Milan, Italy*
Email: sara.ucedarenteria@policlinico.mi.it

Background and aims: Diagnosis and management of Chronic Delta Hepatitis (CHD) requires highly sensitive and reliable tests for HDV

RNA quantification coupled with automated lab procedures to optimize time and resources. Aim of the study was to compare two different extraction methods to quantify HDV RNA levels in untreated and Bulevertide (BLV)-treated HDV patients.
Method: This is a single-center retrospective study, evaluating frozen sera from consecutive untreated and BLV treated-HDV patients. HDV RNA levels were quantified by Robogene HDV RNA quantification kit 2.0 (Roboscreen GmbH, Leipzig, Germany; LOQ 6 IU/ml, linear range 5 to 10^9 IU/ml, pangenotypic) by using two different extraction methods: manual method, i.e. INSTANT Virus RNA/DNA kit (Analytik Jena AG, Jena, Germany) versus automatic method, i.e. EZ1 DSP Virus Kit (Qiagen, Hilden, Germany).
Results: 96 frozen sera collected from 18 Caucasians patients with CHD either untreated (baseline) or BLV treated were analyzed. The main baseline features of the patients were the following: 48 (29–77) years, 67% males, 100% HDV-GT1, 100% cirrhotics, all under TDF or ETV treatment, 67% previously interferon-exposed; ALT 106 (32–222) U/L, HBsAg 3.7 (2.5–4.3) Log IU/ml, 94% HBeAg negative, 72% HBV DNA undetectable. Overall, HDV-RNA levels were 3.61 (0.70–6.60) *vs* 2.66 (0.70–5.52) Log IU/ml, by manual vs automated extraction. Viremia tested undetectable in 0 (0%) *vs* 1 (1%), while <LOQ in 3 (3%) *vs* 14 (15%) patients, respectively. Compared to the automated method, manual RNA extraction reported higher HDV-RNA levels in 90 samples [median 0.80 (0.07–2.11) Log IU/ml], similar levels in 3 [two <LOQ samples, and one 197 IU/ml], and lower levels in 3 [0.11 (0.09–0.17 Log IU/ml]. In 15 samples tested "undetectable or <LOQ" by the automated method, HDV-RNA was <LOQ in 3, and positive low-titer [30 (7–92) IU/ml] in 12 samples tested with manual one. During the first 6 months of BLV monotherapy, HDV-RNA progressively declined using both manual [baseline 4.29→3.76→3.52→2.74→2.26 Log IU/ml] and automated extraction [3.59→3.41→2.64→1.61→0.85 Log IU/ml], achieving <LOQ result in 11% *vs* 47% at month six, respectively.
Conclusion: Quantification of HDV RNA by Robogene 2.0 is significantly influenced by the extraction method, the manual extraction being more sensitive although more time consuming. Therapeutic trials with new anti-HDV therapeutics should consider this important information.

SAT382

Combination therapy in HBeAg-negative chronic hepatitis B patients with low-level viremia to nucleos (tide) analogues

Xin-Yue Chen[1,2,3], Shan Ren[1,2,3], Junfeng Lu[2,2], Lina Ma[2], Sujun Zheng[2], Zhongjie Hu[2]. *[1]Beijing You'an Hospital, Capital Medical University, Beijing, China; [2]Beijing You'an Hospital, Capital Medical University, First Department of Liver Diseases, Beijing, China; [3]*
Email: chenxydoc@163.com

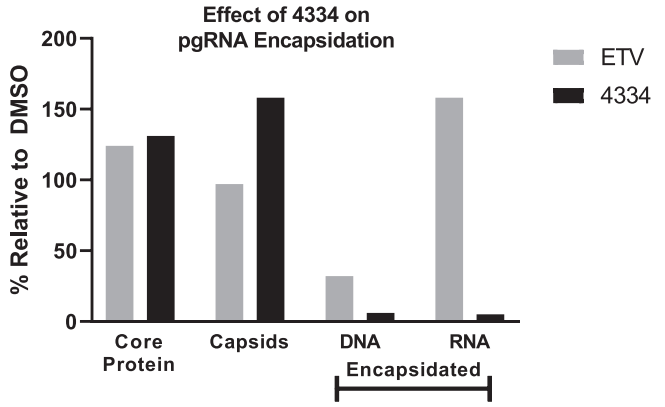
Background and aims: Considering that the ultimate goals of treatment are to decrease the morbidity and mortality related to chronic hepatitis B (CHB), the recently updated guidelines of liver disease recommend that people with low-level viremia (LLV) to nucleos (tide) analogues (NAs) should switch or add another drug for people with a suboptimal virological response.To compare and evaluate the efficacy and safety of pegylated interferon (peg-IFN)α in combination with NAs and NAs in combination with NAs in HBeAg-negative CHB patients with LLV to NAs, so as to investigate optimal treatment regimen with end point of therapy.
Method: Totally 240 HBeAg-negative CHB patients with LLV to NAs were enrolled in the study, and divided into 2 groups receiving Peg-IFN+NAs (IFN group) or NAs+NAs (NA group) according to administration of NAs. Complete virological response (HBV DNA concentration of less than 20 IU/ml or10IU/ml) rate, HBsAg loss/seroconversion rate at 48 weeks of treatment were compared between the 2 groups.
Results: There were 178 patients in IFN group and 89 patients in NA group, and 162 patients in the IFN group and 78 patients in NA group received 48-week treatment duration.At 12 weeks of treatment, the complete virological response rate was 51.1% (40/78) in the NA group, which was seemed higher than that in the PegIFN group (45.1%, 73/162), but the difference was not statistically significant ($X^2 = 0.52$, P = 0.47). At 48 weeks, the complete virological response rates of PegIFNα group and NA group were 97.50% (158/162) and 85.90% (67/78), respectively, with statistically significant differences ($X^2 = 10.56$, P = 0.001). There was no significant difference in HBsAg levels at baseline between the PegIFN group and NA group (823.97 vs. 988.50, t = 0.80, P = 0.43). In the PegIFNα group, HBsAg titer decreased significantly from baseline to week 12 (823.97 vs. 527.7, t = 2.31, P = 0.02), and then it decreased slowly from week 12 to week24 (399→324.9IU/ml). While in the NA group, HBsAg titer did not change significantly from baseline to week 48, there was no statistically significant difference (988.5 vs. 847.1, t = 0.84, P = 0.41). At week 48, the HBsAg loss/seroconversion rate in PegIFNα group (50/162, 30.9%) was higher than that in NA group (4/78, 5.1%), and the difference was statistically significant ($X^2 = 19.89$, P < 0.001).
Conclusion: The treatment regimens of Peg-IFN+NAs and NAs+NAs are effective in suppression of HBV replication in HBeAg-negative CHB patients with LLV to NAs, but Peg-IFN+NAs is superior to NAs +NAs in. Combination therapy with IFN as the basis will achieve reliable end point of therapy in HBeAg-negative CHB patients with LLV to NAs.
[Key words] hepatitis B; chronic; low-level viremia;Peg IFN α; HBsAg loss/seroconversion;complete virological response;

SAT383

ABI-4334, a novel inhibitor of hepatitis B virus core protein, promotes formation of empty capsids and prevents covalently closed circular DNA formation by disruption of incoming capsids

Nuruddin Unchwaniwala[1], William Delaney[1], Kathryn M Kitrinos[1]. *[1]Assembly Biosciences, Inc., South San Francisco, United States*
Email: kkitrinos@assemblybio.com

Background and aims: Core inhibitors (CIs) are a novel class of antivirals with the potential to improve cure rates in patients with chronic hepatitis B virus infection (cHBV). CIs have demonstrated potent antiviral activity in Phase 1 clinical studies and additive antiviral activity when combined with nucleos (t)ide reverse transcriptase inhibitors (NrtIs) compared to NrtIs alone in Phase 2 studies. CIs have multiple mechanisms of action, including inhibition of pre-genomic RNA (pgRNA) encapsidation, preventing assembly and release of infectious viral particles and disruption of incoming capsids, preventing covalently closed circular DNA (cccDNA) formation. ABI-4334 (4334) is a novel CI with single digit nM potency against pgRNA encapsidation and cccDNA formation. Here we further characterize the preclinical profile of 4334.
Method: CI binding pocket variants and NrtI-resistant mutants were assessed for 4334 sensitivity in a HepG2 transient transfection assay. Specificity of 4334 for HBV inhibition was assessed using a panel of 7 different viruses. Effects on pgRNA encapsidation were determined by inducing AD38 cells in the presence of 10x EC_{50} 4334 for 4 days. Intracellular levels of core protein, HBV DNA, and HBV pgRNA were measured by Western, Southern, and Northern blots, respectively. Intracellular capsid levels were measured by native gels. 4334 effects on cccDNA formation were determined by infecting HepG2-NTCP cells with HBV, treating with 4334 for 3 hours (capsid DNA) or 4 days (cccDNA), and then measuring HBV DNA species by Southern blot.
Results: 4334 demonstrated broad antiviral activity with activity comparable to wild-type for 14/16 CI binding pocket variants and 7/7 NrtI mutants. The antiviral activity of 4334 was specific to HBV, with no activity against any other viruses, including HIV and HCV. 4334 did not impact intracellular core protein levels but inhibited pgRNA encapsidation resulting in empty capsid formation, thus acting as a class II CI. Addition of 4334 also resulted in premature melting of incoming capsids during early infection stages, resulting in significantly lower levels of total HBV DNA deposition and cccDNA formation.



Conclusion: 4334 is a potent CI with broad coverage across CI binding pocket variants and NrtI mutants. The activity of 4334 against pgRNA encapsidation is consistent with a class II CI. 4334 treatment results in melting of cytoplasmic HBV capsids, which prevents cccDNA formation. A Phase 1a first-in-human study with 4334 is planned for 2022.

Real-word high adherence to hepatitis B antiviral treatment practice guidelines in Israel

Yana Davidov[1], Fadi Abu Baker[2], Ariel Israel[3], Ziv Ben Ari[1,4]. *[1]Sheba Medical Center, Liver Diseases Center, Tel Aviv-Yafo, Israel; [2]Hillel Yaffe Medical Center, Department of Gastroenterology and Hepatology, Hadera, Israel; [3]Leumit Health Services, Leumit Research Institute and Department of Family Medicine, Israel; [4]Tel Aviv University, Sackler School of Medicine, Tel Aviv-Yafo, Israel*
Email: y.davidov@gmail.com

Background and aims: Epidemiologic data regarding chronic hepatitis B virus (CHB) infections in Israel are limited as large population-based study have not been performed. This work aimed to evaluate adherence to European Association for the Study of the Liver (EASL) practice guidelines to antiviral treatment in Israel.
Method: Clinical and demographic data of HBsAg-positive patients registered in the Leumit-Health-Service database (one of the four major health maintenance organizations in Israel) between 2000-2019, were retrieved. Patients were compared according to eligibility to antiviral treatment, and type of nucleos (t)ide analogue (NA) treatment.
Results: In total, 1216 patients had documented HBsAg positivity (Israel born: 95.8%, males: 58.6%, mean age: 40.2 ± 14.2 years), 90.6% of whom were HBeAg negative. Cirrhosis was documented for 6% of the patients. Antiviral therapy eligibility was met by 37% of patients, among whom 89% received antiviral therapy. Antiviral therapies include NA with a high barrier to resistance (HBR) (64.5%) (entecavir 36.3% and tenofovir 28.2%) and NA with a low barrier to resistance (LBR) (35.5%) (adefovir 1.7% and lamivudine 33.8%). Compared to patients who received LBR NA, patients receiving HBR NA had shorter treatment (68.7 ± 50 months vs. 161.5 ± 42.6 months, $p < 0.0001$) and follow-up duration (125 ± 68 months vs. 188 ± 48 months, $p < 0.0001$); at the end of follow-up ALT levels and APRI score were higher among patients on LBR NA compared to patients on HBR NA.
Conclusion: Most of the patients infected with HBV were born in Israel and were HBeAg-negative. The majority of the patients received antiviral treatment according to the international practice guidelines. However, one-third of them were treated with a less potent NA probably due to their lower cost. These findings should encourage optimization of HBV care and full compliance with the professional practice guidelines recommendations.

SAT385

No detectable resistance to bulevirtide in participants with chronic hepatitis D (CHD) through 24 weeks of treatment

Julius Hollnberger[1,2], Yang Liu[3], Ross Martin[3], Savrina Manhas[3], Thomas Aeschbacher[3], Silvia Chang[3], Simin Xu[3], Bin Han[3], Tahmineh Yazdi[3], Lindsey May[3], Dong Han[3], Katrin Schöneweis[3], John F. Flaherty[3], Vithika Suri[3], Dmitry Manuilov[3], Roberto Mateo[3], Evguenia S Svarovskaia[3], Hongmei Mo[3], Stephan Urban[1,4]. *[1]University Hospital Heidelberg, Department of Molecular Virology, Heidelberg, Germany; [2]German Center for Infection Research (DZIF), Heidelberg; [3]Gilead Sciences, Inc., Foster City, United States; [4]German Center for Infection Research (DZIF), Heidelberg, Germany*
Email: stephan.urban@med.uni-heidelberg.de

Background and aims: Bulevirtide (BLV) blocks entry of HDV into hepatocytes via inhibition of the interaction between the HBV preS1 domain and the sodium taurocholate cotransporting polypeptide (NTCP) receptor. Previous studies show that treatment with BLV alone leads to a substantial HDV RNA reduction. Here, we present results from a comprehensive virologic analysis in HDV-infected participants who received BLV at doses of 2 mg, 5 mg, or 10 mg subcutaneously once daily for 24 weeks across two studies (MYR202 [Phase 2] and MYR301 [Phase 3]).
Method: Resistance analysis was performed for participants who experienced a suboptimal response to BLV (virologic non-responder [VNR]; defined as a decline in HDV RNA <1 $\log_{10}$ IU/ml from baseline ([BL] at week 24) or virologic breakthrough (VB, defined as two consecutive increases in HDV RNA of ≥2 $\log_{10}$ IU/ml from nadir or two consecutive HDV RNA values ≥LOD if previously <LOD). Virologic partial responder (VPR) and virologic responder (VR) were defined as HDV RNA decline ≥1 but <2 $\log_{10}$ IU/ml and decline ≥2 $\log_{10}$ IU/ml or HDV RNA <LOD at Week 24 respectively. Resistance testing included deep sequencing of the HBV PreS1 BLV region and HDV HDAg region. Additionally, *in vitro* phenotypic testing was performed for clinical isolates at baseline and Week 24 for VNRs and those with VB. For the analysis control, sequencing and/or phenotypic analysis were performed for all available BL samples in the two studies.
Results: Overall, resistance analyses were performed for 26 VNRs and 1 participant with VB representing 13/77 (17%), 9/32 (28%), and 5/80 (6%) participants receiving daily BLV at 2 mg, 5 mg, and 10 mg groups, respectively. No amino acid substitutions at HBV PreS1 BLV region or HDV HDAg associated with resistance to BLV were identified from any participants at BL and Week 24. Clinical isolates carrying the amino acid substitutions remained sensitive to BLV *in vitro*; all the amino acid substitutions were seen in the participants achieving a virologic response. Importantly, by phenotypic analysis, BLV medium EC_{50} values obtained from 117 baseline samples were similar across VNRs (EC_{50} = 0.42 nM), VPR (EC_{50} = 0.38 nM) and VR (EC_{50} = 0.27 nM) regardless of the presence of HBV and HDV polymorphisms.
Conclusion: This is the largest resistance analysis to date to demonstrate that no genotypic and phenotypic resistance to BLV has been detected through 24 weeks of treatment.

The HBV siRNA, ALG-125755, demonstrates a favourable nonclinical profile and significant and durable hepatitis B surface antigen reductions in the AAV-HBV mouse efficacy model

Megan Fitzgerald[1], Kusum Gupta[2], Kha Le[2], Sucheta Mukherjee[2], Jin Hong[3], Khiem Nguyen[4], Alfred Chen[5], Vivek Rajwanshi[4], Caroline Williams[4], Meenakshi Venkatraman[5], Matthew McClure[1], Sushmita Chanda[2], John Fry[1], David Smith[4], Julian Symons[6], Lawrence Blatt[7], Leonid Beigelman[8], Tse-I Lin[1]. *[1]Aligos Therapeutics, Inc., Clinical Development, South San Francisco, United States; [2]Aligos Therapeutics, Inc., TSS, South San Francisco, United States; [3]Aligos Therapeutics, Inc., Oligonucleotide Biology, South San Francisco, United States; [4]Aligos Therapeutics, Inc., Chemistry, South San Francisco, United States; [5]Aligos Therapeutics, Inc., CMC, South San Francisco, United States; [6]Aligos Therapeutics, Inc., Chief Scientific Officer, South San Francisco, United States; [7]Aligos Therapeutics, Inc., Chief Executive Officer, South San Francisco, United States; [8]Aligos Therapeutics, Inc., President, South San Francisco, United States*
Email: mfitzgerald@aligos.com

Background and aims: Currently approved therapies for chronic hepatitis B (CHB) infrequently achieve a functional cure in patients, which requires a sustained loss of hepatitis B surface antigen (HBsAg). In CHB patients, HBV targeted small interfering RNAs (siRNAs) have significantly reduced HBsAg, indicating a potential for their use in a curative therapeutic regimen. Here we evaluate the antiviral activity of ALG-125755, a N-acetylgalactosamine (GalNAc)-conjugated siRNA, in the adeno-associated virus (AAV)-HBV mouse efficacy model and its pharmacokinetic (PK) and safety profile in rats and monkeys.
Method: In the AAV-HBV mouse model, various doses of ALG-125755 or vehicle were administered subcutaneously (SC) once, biweekly for 10 weeks (6 doses), or monthly for 8 weeks (3 doses). For 24 weeks during dosing and follow-up, blood and liver samples were collected for plasma HBsAg and hepatitis B e antigen (HBeAg) assessments and liver ALG-125755 concentrations. The plasma samples were analyzed by LC-hybridization whereas the liver samples were analyzed by LC-MS for ALG-125755 concentration. For PK and toxicity studies, rat and monkey were given single or weekly subcutaneous doses of ALG-125755 and plasma, liver and kidney were collected at various timepoints and analyzed for ALG-125755 concentrations by LC-MS.
Results: A dose dependent inhibition of plasma HBsAg was observed with ALG-125755 in AAV-HBV mice dosed biweekly and monthly at 1.5 and 5 mg/kg/dose. Maximal HBsAg reductions of 1.7, 2.4 and 2.8 $\log_{10}$ IU/ml were observed one-month post-last dose in the 10 mg/kg single dose groups, and 5 mg/kg/dose monthly and biweekly treated groups, respectively. Furthermore, reductions in HBsAg levels were sustained for ≥70 days post-last dose in the single and 5 mg/kg/dose multiple dose groups. Plasma HBeAg was similarly reduced in a dose dependent manner, with reductions up to 1.2 $\log_{10}$ S/CO. Dose and dosing-regimen dependent exposures of ALG-125755 were observed in mouse liver which correlated with the pharmacodynamic effect. High liver exposure of ALG-125755 was observed following single or repeated doses in rats and monkeys. Further, ALG-125755 was well-tolerated in rats and monkeys with no toxicologically relevant findings up to 300 and 100 mg/kg/dose, respectively.
Conclusion: ALG-125755 demonstrated high liver concentrations across species, and significant and durable HBsAg knockdown in the AAV-HBV mouse model. Further development of ALG-125755 as a potential best-in-class HBV siRNA is ongoing.

SAT387

Hepatitis delta management in the United Status: an analysis of all-payer claims database

Robert Wong[1], Robert G. Gish[2,3], Joseph Lim[4], Ankita Kaushik[5], Yan Liu[5], Emily Acter[6], Ira M Jacobson[7]. *[1]Stanford University School of Medicine, Stanford and VA Palo Alto Healthcare System, Palo Alto, United States; [2]University of Nevada, Reno School of Medicine, Kirk Kerkorian School of Medicine at UNLV, Las Vegas, United States; [3]UC San Diego Skaggs School of Pharmacy and Pharmaceutical Sciences, Hepatitis B Foundation, La Jolla, United States; [4]Yale School of Medicine, New Haven, United States; [5]Gilead Sciences, Inc., Foster City, United States; [6]STATinMED, Plano, United States; [7]NYU Grossman School of Medicine, New York, United States*
Email: rwong123@stanford.edu

Background and aims: Hepatitis delta (HDV) infection runs a more progressive course than that of hepatitis B (HBV). If left untreated, HDV is associated with an earlier onset of hepatic disease such as cirrhosis, liver failure, and liver cancer compared to HBV. Pegylated-interferon (PEG-IFN) is used off-label as a standard treatment for HDV in the United States (US). Data evaluating HDV treatment patterns is limited. This study describes treatment rates and distribution of provider specialties in management of HDV in the US.
Method: Using the All-Payer Claims Database, adults (≥18 years) with ≥1 inpatient claim or ≥2 outpatient claims ≥30 days apart for HDV infection based on ICD-9/10-CM diagnosis codes were identified from 1/1/2015 to 12/31/2019. First date of HDV diagnosis was defined as the index date. Patients were required to have ≥12 months of continuous enrolment before and after their index date. Treatment patterns for antiviral therapies were assessed over the 12-month postindex period (follow-up). Physician specialty was assessed at diagnosis and during follow-up.
Results: Among the 9, 376 patients identified with HDV during the study period, 6, 719 met inclusion criteria; only 0.1% received treatment with PEG-IFN within the follow-up period. Additionally, only 8.8% were on HBV-specific antiviral therapy including tenofovir disoproxil fumarate (5.3%), entecavir (2.9%), and tenofovir alafenamide (1.0%). The majority (53.0%) of HDV patients were diagnosed by primary care physicians (PCPs), followed by gastroenterology (GI, 9.3%), obstetrics-gynaecology (OBGYN) (4.7%), infectious diseases (ID, 2.4%), and hepatology (0.6%) physicians. During the follow-up period, 62.1% of patients were managed by PCPs, while 12.1%, 4.4%, 2.9%, and 2.7% were seen by GI, OBGYN, ID, and hepatology physicians, respectively.
Conclusion: In a large national US cohort representing ~80% of the insured population, most patients with HDV were diagnosed and cared for by PCPs without specialty referral, and <20% were cared for by specialty providers. Rates of HBV-specific antiviral treatment among HDV patients were <10%, and very few patients were treated with PEG-IFN, the current standard of care for HDV. There is a critical need for greater awareness of the importance of ensuring HDV patients are appropriately treated, and for vigorous efforts to ensure that appropriate healthcare providers are made aware of new HDV therapies in a timely manner.

SAT388

Evaluation of the drug-drug interaction profile of vebicorvir, a first-generation hepatitis B core inhibitor: findings from phase 1 and phase 2a studies

Katie Zomorodi[1], Grace Wang[1], Steven J Knox[1], Julie Ma[1], Luisa M Stamm[1]. *[1]Assembly Biosciences, Inc., South San Francisco, United States*
Email: kzomorodi@assemblybio.com

Background and aims: Vebicorvir (VBR) is a first-generation hepatitis B virus (HBV) core inhibitor that targets multiple aspects of the viral replication cycle. VBR, administered in combination with nucleos (t)ide reverse transcriptase inhibitors (NrtIs) and other agents, is in Phase 2 development for the treatment of chronic HBV

infection (cHBV). In vitro, VBR is not a potent inhibitor of CYP450 s or drug transporters. Here we describe the clinical evaluation of VBR's drug-drug interaction (DDI) potential from Phase 1 and Phase 2a studies.

Method: Studies 201 (NCT03577171; N = 73) and 202 (NCT03576066; N = 25) were Phase 2a, double-blind, placebo-controlled studies evaluating VBR and NrtIs in patients with cHBV in which sparse PK samples were collected. Study 103 was a 3-part Phase 1 DDI study in healthy subjects. Part 1 (N = 20) investigated the potential of VBR to inhibit CYP2C9, 2C19, 2D6, and 2C8 through use of the index substrates tolbutamide, omeprazole, dextromethorphan, and repaglinide, respectively. Parts 2 (N = 18) and 3 (N = 20) evaluated CYP3A4 and 2B6 inhibition/induction, respectively, using midazolam and bupropion. Intensive PK samples were collected, and PK analysis was conducted by non-compartmental methods.

Results: In Studies 201 and 202, there were no clinically significant differences in mean trough VBR or NrtI concentrations following combination therapy in patients with cHBV (Figure 1a/1b). In Study 103 (Part 1), co-administration of VBR did not change the exposure of omeprazole, dextromethorphan, or repaglinide, suggesting VBR is not an inhibitor of CYPs 2C19, 2D6, or 2C8. Tolbutamide exposure was increased by approximately 30% with VBR co-administration, indicating VBR is a weak inhibitor of CYP2C9. In Part 2, midazolam exposure was reduced by 33% following co-administration with VBR, with no concomitant change in 1-hydroxymidazolam exposure, indicating VBR is not an inhibitor/inducer of CYP3A4. In Part 3, co-administration of VBR did not change the exposure of bupropion, indicating VBR is not an inhibitor/inducer of CYP2B6.

Figure 1A: Plasma VBR Trough Concentrations by NrtI I Patients with cHBV (Study 201)

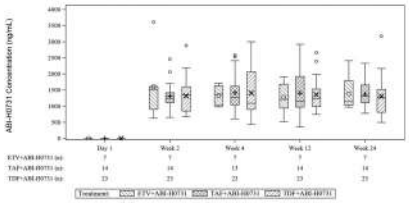

Figure 1b: Plasma Entecavir and Tenofovir Concentrations in Patients with cHBV (Study 201)

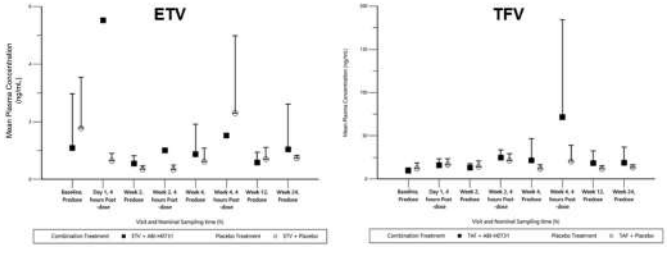

Conclusion: The results in Phase 2a studies suggest no clinically significant DDI between VBR and NrtIs. Based on the Phase 1 study, VBR is a weak inhibitor of CYP2C9, but is not an inhibitor of CYP2C19, 2D6, or 2C8, and is not an inhibitor/inducer of CYP3A4 or 2B6. Overall, VBR shows a favorable DDI profile for use in combination treatments including NrtIs and other concomitant medications.

SAT389

Improving the pharmacokinetic profile of the hepatitis B virus core inhibitor ABI-H3733 following oral administration: results from new formulation activities

Michael Shen[1], Zhixin Zong[1], Naqvi Mohammed[1], Katie Zomorodi[1], Luisa M Stamm[1], William Delaney[1], Nicole White[1]. [1]*Assembly Biosciences, Inc., South San Francisco, United States*
Email: mshen@assemblybio.com

Background and aims: ABI-H3733 (3733) is a novel orally administered inhibitor of the hepatitis B virus (HBV) core protein, a viral structural protein essential for HBV replication. 3733 targets multiple aspects of the viral replication cycle and has the potential to enhance cure rates for patients with chronic HBV infection (cHBV). 3733 is in Phase 1 development and has demonstrated favorable systemic exposure with a half-life of 21 hours using a liquid formulation (LF) in healthy subjects. An initial prototype tablet formulation (T1) only achieved 30% exposure compared to the LF with predicted trough concentrations (C_{min}) approximately 28- and 5.5-fold higher than the protein-adjusted EC_{50} ($paEC_{50}$) for pgRNA encapsidation and cccDNA formation, respectively, providing the opportunity to improve formulation for future clinical studies.

Method: The initial LF and T1 formulations of 3733 were tested in dog pharmacokinetic (PK) studies (at a dose of 50 mg) and assessed in healthy subjects at doses ranging from 100 to 500 mg. Due to the low exposure of T1 in both dogs and humans, a new tablet formulation (T2) was designed to improve the absorption and achieve comparable exposure as the LF. The pharmacokinetics of T2 and LF were evaluated in 6 male beagle dogs at 100 mg (3 dogs with T2 and 3 dogs with LF).

Results: In the initial dog PK study, T1 showed 36.7% AUC compared to the LF at 50 mg dose (human equivalent dose of approximately 150 mg). Human PK data were comparable with the dog PK data indicating the dog is a predictive model to evaluate the relative exposure for different formulations. T2 was subsequently tested in the dog PK model at 100 mg dose (predicted human equivalent dose 300 mg) and showed equivalent AUC compared to the LF.

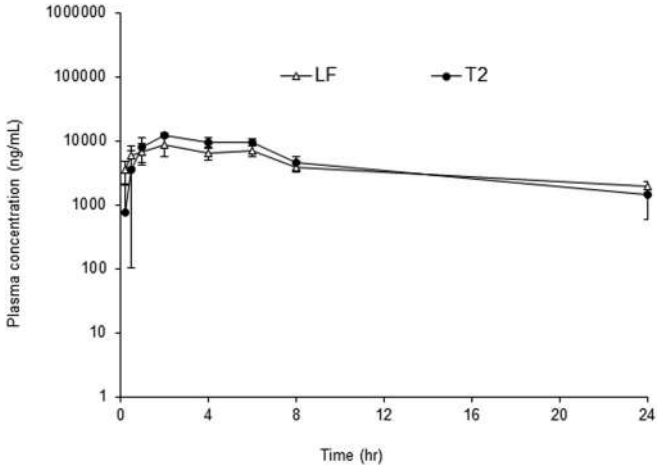

Figure: Mean Plasma Concentration-time Profiles of 3733 After Single Oral Doses of LF and T2 in Male Beagle Dogs

Conclusion: Based on the relative PK data in the dog model, T2 formulation is expected to have similar 3733 exposure as the LF in humans, with predicted C_{min} approximately 150- and 29-fold higher than the $paEC_{50}$ for pgRNA encapsidation and cccDNA formation, respectively. The improved T2 formulation will be used in an upcoming Phase 1b study conducted with cHBV patients.

SAT390

EDP-514, a novel pangenotypic class II hepatitis B virus core inhibitor: final results of a 28-day phase 1b study in nuc-suppressed chronic hepatitis B patients

Jordan Feld[1], Eric Lawitz[2], Tuan T Nguyen[3], Jacob P Lalezari[4], Tarek Hassanein[5], Paul Martin[6], Steven-Huy B Han[7], Douglas T Dieterich[8], Jeanne-Marie Giard[9], Guy De La Rosa[10], Alaa Ahmad[10], Ed Luo[10], Annie Conery[10], Nathalie Adda[10]. *[1]Toronto Centre for Liver Disease, University Health Network, Toronto, Canada; [2]Texas Liver Institute, San Antonio, Texas, United States; [3]Gastroenterology and Hepatology, San Diego, California, United States; [4]Quest Clinical Research, San Francisco, California, United States; [5]Southern California Research Center, Coronado, California, United States; [6]University of Miami, Gastroenterology, Miami, Florida, United States; [7]University of California, Los Angeles, Los Angeles, California, United States; [8]Icahn School of Medicine at Mount Sinai, Division of Liver Diseases, New York, New York, United States; [9]Centre Hospitalier Universitaire de Montréal, Montréal, Québec, Canada; [10]Enanta Pharmaceuticals, Watertown, Massachusetts, United States*
Email: gdelarosa@enanta.com

Background and aims: EDP-514, a novel class II HBV core inhibitor, demonstrated nanomolar potency in vitro, and a >4-log viral load reduction in an HBV mouse model. Here, we present the safety, pharmacokinetic (PK) and antiviral activity from a phase 1b study of multiple ascending doses (MAD) of EDP-514 in nucleot (s)ide (nuc)-suppressed chronic hepatitis B (CHB) patients.
Method: This phase 1a/b, randomized, double-blind, placebo-controlled study was conducted in two parts. In Part 1, healthy adult subjects received single or multiple ascending doses of EDP-514 or placebo. In Part 2, noncirrhotic, HBeAg (+) or (-) subjects virologically suppressed on nuc therapy received EDP-514 or placebo in a 3:1 ratio (24 subjects in 3 cohorts: 200 mg, 400 mg, 800 mg) for 28 days.
Results: The 24 subjects enrolled were mostly male (63%), Asian (67%), HBeAg (-) (88%), treated with tenofovir (92%), with a mean age of 45 years and a mean BMI of 27 kg/m^2. All TEAEs (n = 20) were mild except for 1 moderate event (200 mg) of abdominal pain that led to drug discontinuation, and 1 severe allergic reaction to aloe cream (800 mg). There were no other grade 3 TEAEs or any SAEs. No clinically significant laboratory abnormalities, liver function tests elevations or clinically relevant ECG or vital signs changes were observed. EDP-514 exhibited PK supportive of once daily (QD) dosing, with trough concentrations of up to ~21-fold above the paEC$_{50}$. HBV DNA remained undetectable and no virologic failures or breakthroughs were reported through 28 days of treatment. At Day 28, a maximum HBV RNA reduction of 2.3 log in HBeAg (-) and 2.8 log in HBeAg (+) patients was observed in EDP-514 arms compared to 1.2 log in placebo. There were no discernible changes in HBeAg, HBcrAg, and HBsAg.
Conclusion: EDP-514 was safe and well tolerated through 28 days of treatment in CHB nuc-suppressed patients, showed time-linear PK supportive of QD dosing with concentrations of up to ~21-fold above the paEC$_{50}$, and resulted in a higher log reduction in HBV RNA, up to a maximum of 2.8 log, was observed in HBeAg (+) patients receiving EDP-514.

SAT391

Preclinical activity of small-molecule oral PD-L1 checkpoint inhibitors capable of reinvigorating T cell responses from chronic hepatitis B patients

Emily P. Thi[1], Andrew G. Cole[1], Gavin Heffernan[1], Christina Iott[1], Seyma Ozturk[1], Sharie C Ganchua[1], Dan Nguyen[1], Ingrid Graves[1], Vijay Ahuja[1], Kim Stever[1], Kristi Fan[1], Jorge G. Quintero[1], Steven G. Kultgen[1], Maria Shubina[1], Boya Liu[1], Sunny Tang[1], Troy O. Harasym[1], Angela M Lam[1], Michael J. Sofia[1]. *[1]Arbutus Biopharma, Warminster, United States*
Email: ethi@arbutusbio.com

Background and aims: T cell tolerance is a critical driver in maintaining chronic hepatitis B (CHB) infection. The PD-1/PD-L1 checkpoint axis plays a key role in tolerization and inhibition of this axis by antibody approaches has been associated with loss of hepatitis B surface antigen and seroconversion in CHB patients. Oral small-molecule inhibitors of PD-L1 can enable tuneable on-target engagement with potential for better tissue penetration and improved efficacy. Here we report the preclinical *in vitro* activity of these compounds, as well as *in vivo* efficacy and ability to reinvigorate HBV-specific T cells from CHB patients.
Method: *In vitro* activity was assessed in a Jurkat T cell NFAT reporter assay and PD-L1 reduction was confirmed in CHO-K1 cells expressing human PD-L1 (CHO-K1-hPD-L1) and in peripheral blood mononuclear cells (PBMCs) from healthy donors. T cell activation assays were conducted with PBMCs from healthy donors and CHB patients. Non-specific cytokine release was evaluated in human whole blood. Pharmacokinetic (PK) evaluations were conducted in rodents and non-human primates (NHP). *In vivo* efficacy was evaluated in a MC38 tumor humanized PD-L1 and PD-1 mouse model.
Results: Two optimised PD-L1 inhibitor compounds were evaluated which mediated potent activation of T cells in a NFAT reporter assay (EC$_{50s}$ of 13 and 18 nM). Compound treatment resulted in reduction of PD-L1 expression on the cell surface through a novel internalization mechanism, with EC$_{50s}$ ranging from 1.9–24 nM in CHO-K1-hPD-L1 and primary human myeloid cells. Dose responsive elevations in IL-2 production occurred upon compound treatment of PBMCs stimulated with staphylococcal enterotoxin B. Compound treatment did not elicit non-specific cytokine release in human whole blood, supportive of favourable immune safety. PK profiles showed low systemic clearance in rodents and NHP. In a MC38 tumor model, oral administration of compounds at 10 and 30 mg/kg once daily resulted in profound tumor reduction with T cell activation comparable to anti-PD-L1 antibody. PD-L1 inhibitor treatment of PBMCs from CHB patients *ex vivo* resulted in HBV-specific T cell reinvigoration.
Conclusion: Novel oral small molecule PD-L1 inhibitors able to mediate activation and reinvigoration of HBV-specific T cells from CHB patients were identified. These compounds display *in vivo* anti-tumor efficacy comparable to anti-PD-L1 antibody and possess favourable preclinical profiles for further development.

SAT392

Safety, tolerability, pharmacokinetics (PK), and antiviral activity of the 3rd generation capsid inhibitor AB-836 in healthy subjects (HS) and subjects with chronic hepatitis B (CHB)

Edward J Gane[1], Alina Jucov[2], Liudmyla Kolomiichuk[3], Timothy Eley[4], Joanne Brown[4], Yele King[4], Elina Medvedeva[4], Maksym Chernyakhovskyy[4], Nagraj Mani[5], Andrew G. Cole[5], Steven G. Kultgen[5], Reddy Pamulapati[5], Emily P. Thi[5], Troy O. Harasym[5], Ravi Dugyala[5], Sachin Chaudhari[5], Michael J. Sofia[5], Michael Child[4], Gaston Picchio[4], Karen Sims[4], Man-Fung Yuen[6]. *[1]Auckland City Hospital, Auckland, New Zealand; [2]Arensia Exploratory Medicine, Chisinau, Moldova; [3]Arensia Exploratory Medicine, Kyiv, Ukraine; [4]Arbutus Biopharma, Clinical Development, Warminster, PA, United States; [5]Arbutus Biopharma, Research, Warminster, PA, United States; [6]The University of Hong Kong, Gastroenterology and Hepatology, Hong Kong, Hong Kong*
Email: teley@arbutusbio.com

Background and aims: AB-836 is a potent inhibitor of HBV pregenomic RNA encapsidation (a Class II capsid inhibitor). AB-836-001 is an ongoing 3-part study evaluating safety, PK and antiviral activity of AB-836 in HS (Parts 1 and 2) and CHB subjects (Part 3). Preliminary data from Parts 1, 2 and the first 2 cohorts of Part 3 are presented.
Method: In Part 1, HS enrolled into two 8-subject cohorts and were randomized to single doses of AB-836 or placebo (6:2) in 5 alternating dose panels from 10mg-175 mg fasted, and a 6th panel of 125 mg with food. In Part 2, 3 unique cohorts of 10 HS were randomized to 50 mg, 100 mg or 150 mg or placebo (8:2) once daily (QD) for 10 days. In Part 3, 2 ongoing cohorts of 12 HBV DNA+, HBeAg

(+) or (-) CHB subjects will randomize to 50 mg or 100 mg or placebo (10:2) QD for 28 days. Samples are collected for PK in all subjects and antiviral activity in CHB subjects. Safety and tolerability are monitored throughout.
Results: HS (N = 47) were mean age 29 years, mean BMI 24.7 kg/m^2, all male and 57% white. CHB subjects (N = 10) were mean age 44 years, mean BMI 23.5 kg/m^2, 60% male, 70% white, 60% HBeAg (-) with mean 5.2 $\log_{10}$ IU/ml HBV DNA at baseline (BL). Preliminary safety data showed AB-836 was well-tolerated in HS. No deaths or serious adverse events (AEs) were observed. One HS (50 mg QD) discontinued on Day 13 due to an AE of agitation. All but 3 AEs were mild (Grade 2 headache, agitation, and bronchitis); only 1 was assessed as related to AB-836 (Grade 1 rash). In ongoing Part 3, there have been no AEs; 1 CHB subject (100 mg) had a transient increase in ALT from BL Grade 1 to Grade 3 at a single visit that resolved with continued dosing. There were no clinically significant abnormalities in clinical laboratory tests in HS and no clinically significant abnormalities in ECGs, vital signs or physical exams in any subject. Single and multiple dose AB-836 PK in HS were dose proportional and support QD dosing with/without food. Mean (SE) HBV DNA $\log_{10}$ change from BL at Day 28 was –2.4 (0.3), –3.1 (0.8) and – 0.0 (0.19) at 50 mg, 100 mg, and placebo, respectively. Updated data will be presented.

Conclusion: Single and multiple doses of AB-836 in HS and up to 100 mg QD for 28 days in CHB subjects have been generally safe and well-tolerated. Robust antiviral activity was observed at Day 28 of treatment. These results support further evaluation of AB-836 alone and in combination with other agents, including the GalNAc siRNA AB-729, in CHB subjects.

Email: gdelarosa@enanta.com

Background and aims: EDP-514, a novel class II HBV core inhibitor, demonstrated nanomolar anti-HBV potency *in vitro*, and a >4-log viral load reduction in an HBV mouse model. Here, we present the safety, pharmacokinetic (PK) and antiviral activity from a phase 1b study of multiple ascending doses (MAD) of EDP-514 in viremic, chronic hepatitis B (CHB) patients.
Method: A phase 1b, randomized, double-blind, placebo-controlled study was conducted in noncirrhotic, viremic, HBeAg (+) or (-) CHB patients not currently on treatment. Patients received multiple doses of EDP-514 or matching placebo in a 3:1 ratio (24 planned patients in 3 cohorts: 200 mg, 400 mg, 800 mg QD) for 28 days.
Results: The 25 enrolled subjects were all Asian, mostly male (60%), HBeAg (-) (84%), with a mean age of 46 years, mean HBV DNA of 5.12 log IU/ml, and mean HBV RNA of 3.49 log U/ml at baseline. Overall, 9 subjects reported 22 treatment emergent adverse events (TEAEs), and all of which were mild except for 4 moderate events (n = 2, placebo [GI disorders and urinary tract infection] and n = 2, 200 mg [anaemia and aPTT prolonged], both unlikely related to study drug). No grade 3 TEAEs or SAEs, Grade 3/4 clinical laboratory abnormalities, liver function tests elevations or clinically relevant ECG or vital signs changes were observed in the EDP-514 groups. EDP-514 exhibited trough concentrations of up to ~24-fold above paEC50. At Day 28, mean HBV DNA reductions of 2.9, 3.3, 3.5 and 0.2 log IU/ml, and mean HBV RNA reductions of 2.9, 2.4, 2.0 and 0.02 log U/ml were observed, in the 200 mg, 400 mg, 800 mg and placebo groups, respectively. HBV RNA was undetectable on Day 28 in 11 subjects treated with EDP-514 as compared to none in placebo. HBV DNA was below the LLOQ in 7 subjects treated with EDP-514 as compared to none in placebo. EDP-514 led to a maximum HBV DNA reduction of 4.5 log vs. 0.5 log in placebo, and a maximum HBV RNA reduction of 4.8 log vs. 1.9 log in placebo. There were no discernible changes in HBeAg, HBcrAg, and HBsAg levels.
Conclusion: EDP-514 was safe and well tolerated through 28 days of treatment in viremic CHB patients, with a linear PK profile supporting QD dosing and trough concentrations up to ~24-fold above the paEC50. Profound antiviral activity was observed at Day 28 with mean HBV DNA reductions of up to 3.5 log, and mean HBV RNA reductions of up to 2.9 log with EDP-514 treatment. These results support further evaluation of EDP-514 in CHB patients.

SAT394

Increased HBsAg reduction and relapse outcomes in HBeAg negative patients with chronic hepatitis B after nucleos (t)ide analogue withdrawal: 4.5 year follow-up of the Toronto STOP Study

Arif Sarowar[1], Seng Liem[1,2], Scott K Fung[1], David Wong[1], Jordan Feld[1,3], Colina Yim[1], Seham Noureldin[1], Jenny Chen[1], Bettina Hansen[1,4], Harry Janssen[1]. *[1]Toronto General Hospital, Toronto Centre for Liver Disease, Toronto, Canada; [2]Erasmus University Medical Center Rotterdam, Department of Gastroenterology and Hepatology, Canada; [3]McLaughlin-Rotman Centre for Global Health, Canada; [4]University of Toronto, Institute of Health Policy, Management and Evaluation, Canada*
Email: arif.sarowar@uhnresearch.ca

Background and aims: Studies have found benefits in nucleos (t)ide analogues (NA) discontinuation in chronic hepatitis B (CHB) patients, but currently heterogenous outcomes are observed with little understanding of the long-term implications of stopping therapy. This study prospectively evaluates clinical outcome comparisons in HBeAg negative patients who stop or continue NA, and those with eventual retreatment.
Method: 67 HBeAg negative patients in a randomized control study were allocated to stopping (n = 45) or continuing (n = 22) NA therapy and were evaluated over 4.5 years. Patients were retreated based on standardized protocol if they had HBV DNA >20, 000IU/ml, HBeAg seroreversion, or HBV DNA>2000 with ALT>5xULN. Virological relapse (HBV DNA >2000 IU/ml), clinical relapse (HBV DNA >2000 IU/ml and ALT>1.5xULN), HBsAg decline >0.5 IU/ml, and HBsAg loss were compared.
Results: Mean duration of long-term follow-up (LTFU) was 227 weeks. 23/45 (51%) stop patients were retreated, with median time to retreatment of 36 weeks. HBsAg loss was achieved by 2/45 (4%) patients who stopped and 1/21 (5%) continue patients at LTFU. Virological relapse and clinical relapse in the stop group was observed in 41 (91%) patients and 32 (71%) patients, respectively. HBsAg decline >0.5 IU/ml at LTFU was achieved by 12/22 (55%) not

retreated stop patients, 10/23 (43%) retreated stop patients, and 3/22 (14%) continue patients. Incidence of HBsAg decline >0.5 IU/ml was higher in the stop group than those in the continue group ($p < 0.05$). Higher mean HBsAg decline was also observed in the stop group (-0.67 IU/ml) compared to continue group (-0.15 IU/ml, $p < 0.05$) by end of follow-up. No patients experienced adverse outcomes, liver decompensation, or death.

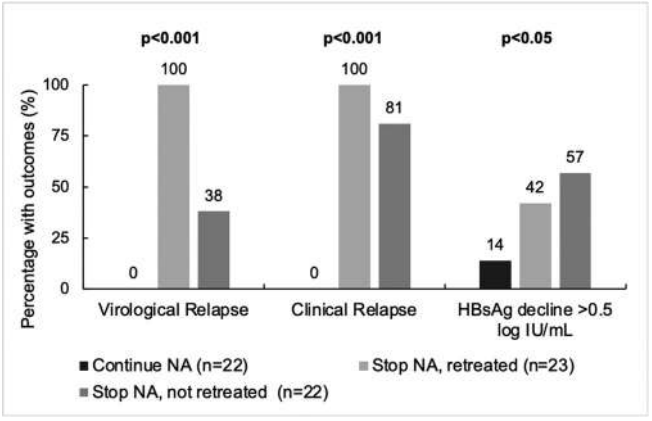

Figure: Clinical Outcomes of STOP Study patients (n = 67)

Conclusion: CHB patients that stop NA have high prevalence of virological relapse and clinical relapse. However, despite a limited HBsAg loss, those that stop therapy exhibited higher HBsAg reduction compared to continued NA treatment.

SAT395

Pharmacodynamics of durable HBsAg suppression by AB-729 short interfering RNA correlates with pharmacokinetics of RNA-induced silencing complex (RISC) loading within liver

Emily P. Thi[1], Maria Shubina[1], Ingrid Graves[1], Angela M Lam[1], Michael J. Sofia[1]. [1]*Arbutus Biopharma, Warminster, United States*
Email: ethi@arbutusbio.com

Background and aims: AB-729 is an *N*-Acetylgalactosamine (GalNAc)-conjugated short interfering RNA (siRNA), currently in Phase 2a clinical development in combination with other agents for treatment of CHB. AB-729 blocks all HBV RNA transcripts, resulting in durable suppression of viral replication and antigen production, including circulating HBV DNA and the hepatitis B surface antigen (HBsAg). This antiviral effect is mediated through association of AB-729 with the RNA-induced silencing complex (RISC), the RNA:protein complex responsible for mediating cleavage of HBV RNA. Here we investigate the mechanisms underlying the extent and duration of AB-729 activity through assessment of siRNA persistence in liver using an adenovirus-associated HBV (AAV-HBV) mouse model.
Method: Longitudinal serum, plasma and liver samples from AAV-HBV mice receiving a single dose of either a non-HBV targeting control GalNAc siRNA or a surrogate GalNAc siRNA containing the AB-729 siRNA trigger (HBV-siRNA) (1 or 3 mg/kg, n = 8) were assessed for HBsAg and total and RISC-loaded siRNA by chemiluminescent immunoassay, Ago2 immunoprecipitation and stem-loop quantitative reverse-transcription polymerase chain reaction.
Results: A dose responsive decline in serum HBsAg occurred following single doses of 1 and 3 mg/kg of HBV-siRNA, with mean maximum declines of 0.9 $\log_{10}$ and 1.9 $\log_{10}$ at Day 14, respectively. The kinetics of HBsAg decline did not correlate with that of total intrahepatic concentrations of HBV-siRNA, which peaked at 4-hour post dose and rapidly declined over time. Instead, maximal HBsAg reduction coincided with an increase in the number of RISC-loaded complexes. A decline in the number of RISC-loaded complexes was observed following day 14, mirroring a rebound in HBsAg. HBsAg subsequently returned to baseline 112 days after single doses of HBV-siRNA, which correlated with the detection of only trace amounts of RISC-loaded complex.
Conclusion: HBsAg suppression mediated by AB-729 in CHB patients is characterized by durable responses which persist up to 48 weeks post-dosing. The mechanisms driving this long duration of activity have not yet been assessed. Our preclinical data reveals that HBsAg reduction coincides with the pharmacokinetics of siRNA RISC-loading. These data suggest that the direct-acting antiviral activity of AB-729, mediated by RNA interference activity, may be a key driver of the prolonged HBsAg suppression observed in CHB patients administered AB-729.

SAT396

Inhibition of hepatitis B surface antigen by RNA interference therapeutic AB-729 is associated with increased cytokine signatures in HBV DNA+ chronic hepatitis B patients

Sharie C Ganchua[1], Bhavna Paratala[1], Christina Iott[1], Man-Fung Yuen[2], Edward J Gane[3], Timothy Eley[1], Karen Sims[1], Kevin Gray[1], Deana Antoniello[1], Angela M Lam[1], Michael J. Sofia[1], Gaston Picchio[1], Emily P. Thi[1]. [1]*Arbutus Biopharma, Warminster, United States;* [2]*Queen Mary Hospital, Hong Kong;* [3]*Auckland Clinical Studies, New Zealand*
Email: ethi@arbutusbio.com

Background and aims: Therapeutic strategies aimed at reducing antigenemia, particularly hepatitis B surface antigen (HBsAg), may result in HBV-specific immune reawakening in chronic hepatitis B (CHB). AB-729 is a single trigger *N*-Acetylgalactosamine (GalNAc)-conjugated siRNA targeting all HBV transcripts, currently in clinical development in combination with other agents for CHB treatment. Here we report immunological assessment of cytokines and other soluble immune biomarkers in CHB subjects not currently on nucleos(t)ide analog (NA) therapy (HBV DNA+) and compare these profiles to NA-suppressed (HBV DNA-) CHB subjects receiving a single dose of AB-729.
Method: Longitudinal plasma samples from subjects receiving a single dose of AB-729 (90 mg, n = 5 HBV DNA+, n = 6 HBV DNA-) were assessed for cytokines and other soluble immune biomarkers using multiplex Luminex assays.
Results: Following a single dose of AB-729, transient elevations of 2 to 38-fold over pre-dose baseline levels in at least one of IFNg, CXCL1, IP-10, sBTLA, sLAG3, sTLR2, sGITRL, sPD-1, sCTLA4, sPD-L1, sICOS, sCD80, and sCD86 were observed in 5/5 HBV DNA+ subjects. In HBV DNA- subjects, transient elevations of 2 to 7-fold over pre-dose baseline were observed in at least one of IFNg, IL-17a, CXCL9, CXCL13 and CD163 (3/6 subjects). In HBV DNA+ subjects, transient increases in IFNg (4/5 subjects) and CXCL1 (3/5 subjects) were associated with transient ALT elevations in the period up to 12 weeks post-dose. In contrast, in HBV DNA- subjects ALT elevation was accompanied by IFNg increase in only 1/6 subjects. All ALT elevations were mild (Grade 1) and no liver safety markers were considered adverse by the investigators.
Conclusion: We believe this is the first data comparing immunological responses of HBV DNA+ and DNA- CHB subjects undergoing HBsAg reduction following GalNAc-siRNA treatment. Our findings suggest that following AB-729 dosing, a greater breadth of cytokine and soluble immune biomarker responses with IFNg and T cell activation signatures are observed in HBV DNA+ subjects compared to NA-suppressed CHB patients. Transient elevations in checkpoint-related markers in HBV DNA+ patients were also observed, which were accompanied by mild ALT elevations. These results suggest that HBV DNA+ CHB patients are more immunologically responsive following AB-729 dosing. Assessment of responses following AB-729 repeat dosing in HBV DNA+ subjects with concomitant initiation of NA therapy is ongoing.

SAT397

Reduction of hepatitis B surface antigen mediated by RNA interference therapeutic AB-729 in chronic hepatitis B patients is associated with T cell activation and a decline in exhausted CD8 T cells

Sharie C Ganchua[1], Bhavna Paratala[1], Christina Iott[1], Edward J Gane[2], Man-Fung Yuen[3], Timothy Eley[1], Karen Sims[1], Kevin Gray[1], Deana Antoniello[1], Angela M Lam[1], Michael J. Sofia[1], Gaston Picchio[1], Emily P. Thi[1]. *[1]Arbutus Biopharma, Warminster, United States; [2]Auckland Clinical Studies, New Zealand; [3]Queen Mary Hospital, Hong Kong*
Email: ethi@arbutusbio.com

Background and aims: AB-729 is a GalNAc-conjugated RNA interference (RNAi) therapeutic, currently in Phase 2 clinical development in combination with other agents for the treatment of chronic hepatitis B (CHB). Reduction of antigenemia in CHB, particularly hepatitis B surface antigen (HBsAg), may result in HBV-specific immune reawakening. Here we report immunological assessments in CHB subjects receiving repeat doses of AB-729 after 48 weeks (wks) of treatment and 12 wks of follow-up.
Method: Longitudinal plasma and peripheral blood mononuclear cell (PBMC) samples from virologically suppressed subjects undergoing repeat dosing of AB-729 60 mg every 4 weeks (Q4W, n = 5 for PBMC; n = 6 for plasma assays) or every 8 weeks (Q8W, n = 7 for plasma assays; n = 2 for PBMC) were assessed using Luminex, IFN gamma (IFNg) T cell fluorospot, immunophenotyping by flow cytometry and thymidine-based T-cell proliferation assays.
Results: By EOT, 5/5 subjects receiving AB-729 Q4W exhibited increases in IFNg-producing HBV-specific T cells. 3/5 subjects had increases in IFNg-HBV-specific T cells between wks 16–28 which coincided with a plateau in HBsAg response, mild to moderate transient serum alanine aminotransferase (ALT) elevations (Grade 1–2), and was preceded by T cell proliferation. 2/5 subjects experienced pronounced increases in IFNg-HBV-specific T cells at EOT or at 12 wks follow-up. HBV-specific T cell IFNg production was also observed in subjects receiving AB-729 Q8W dosing (2/2). A decline in exhausted CD8 T cells was observed beginning at wk 28 and was present at EOT and at 8–12 wks of follow-up (AB-729 Q4W cohort; 4/6 subjects, Figure). This decline in exhausted CD8 T cells coincided with a plateau in HBsAg response. No significant increases in 41 plasma cytokine/chemokine levels were observed. Mild increases in sBTLA, sCD86, sCTLA-4, sPD-1 were noted in subjects receiving AB-729 Q4W and Q8W (sBTLA, sGITR, sCTLA4). No changes in adverse events related to liver safety markers were noted in either cohort.

Conclusion: Our findings suggest that HBsAg reductions, as a result of treatment with repeat doses of AB-729 every 4 or 8 weeks, is accompanied by HBV-specific T cell activation and proliferation with mild to moderate ALT elevations. A decline in exhausted CD8 T cells at the end of treatment and at 8–12 weeks of follow-up suggest that HBV-specific T cell immune restoration (reawakening) may be durable.

SAT398

Characterizing of hepatitis B virus serum RNA kinetics during TDF plus pegylated interferon alfa-2a with and without nucleic acid polymers

Leeor Hershkovich[1], Louis Shekhtman[1], Michel Bazinet[2], Mark Anderson[3], Mary Kuhns[3], Gavin Cloherty[3], Scott Cotler[1], Andrew Vaillant[2], Harel Dahari[1]. *[1]Program for Experimental and Theoretical Modeling, Division of Hepatology, Department of Medicine, Stritch School of Medicine, Loyola University Chicago, Maywood, United States; [2]Replicor Inc., Montreal, Quebec, Canada; [3]Abbott Diagnostics, Abbot Park, IL, United States*
Email: harel.dahari@gmail.com

Background and aims: Serum HBV RNA (RNA), and HBV core -related antigen (HBcrAg) are markers of cccDNA activity. Little is known about the serum RNA response during tenofovir disoproxil fumarate (TDF), and pegylated interferon alpha-2a (pegIFN) with and without nucleic acid polymer (NAP) treatment. Here we aim to characterize RNA kinetics under TDF and pegIFN with and without NAP combination therapies.
Method: Forty participants with chronic HBV in the REP 401 study (Gastro 2020; 158:2180–94) received 48 weeks of triple combination therapy with NAPs, pegIFN, and TDF. In the experimental group (n = 20), triple combination therapy (TDF+ pegIFN + NAPs) followed 24 weeks of TDF. In the control group (n = 20), triple combination therapy followed 24 weeks of TDF monotherapy and 24 weeks of dual therapy (TDF + pegIFN). Abbott RUO assay for RNA (LLOQ 1.65 $\log_{10}$ U/ml) was used every 4 weeks. The threshold for kinetic patterns was defined as a 3-fold change.
Results: Under dual therapy 10 (50%) participants experienced had RNA increase which was followed by a new elevated plateau (n = 6) or by a decline (transient increase, n = 4). All 6 participants establishing a new elevated RNA plateau level experienced a subsequent monophasic decline in RNA following the introduction of NAPs in the control group (Table 1). Under triple therapy in the experimental group 11 (55%) participants had a transient increase. The timing of RNA flares was significantly ($p < 0.02$) correlated with ALT flares.

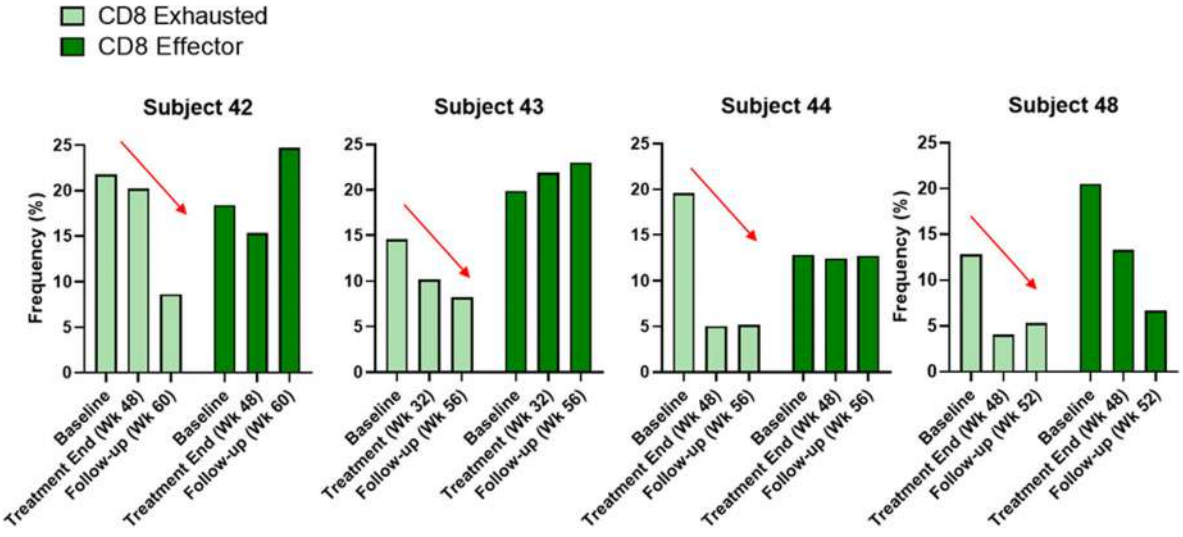

Figure: (abstract: SAT397)

Table 1: RNA kinetics during TDF + pegIFN + NAPs in the REP 401 study

Treatment phase, No. of patients (N)	Mean Pre-treatment RNA (log_{10} U/mL)	Kinetic Patterns				EOT median (IQR) Δ log RNA
		Remain unchanged, N [mean log RNA]	Transient increase, N [mean peak Δ* log RNA] (time of peak [w])	Increase / new elevated plateau, N [mean peak Δ* log RNA] (time of peak [w])	Immediate Decline, N [mean slope (log/wk)]	
pegIFN+TDF (20) †	1.6±0.7	6 [2.3±0.4]	4‡ [0.0±0.21] (5.0±1.7)	6¶ [1.9±0.61] (5.3±3.0)	4 [0.17±0.06]	-0.3 (1.7)
pegIFN +TDF + NAP Experimental (20)	1.9±0.4	4 [2.2±0.7]	11 [1.2±0.51] (4.4±1.1)	0	5 [0.26±0.16]	-0.7 (0.6)
pegIFN + TDF+ NAP Control † (20)	1.6±0.1	6§ [1.5±0.4]	4 [0.55±0.08] (5.0±1.7)	0	10¶ [0.22±0.14]	-0.6 (0.9)

*Peak Δ log RNA is relative to baseline RNA.
†Control group are the same participants who were treated with pegIFN+TDF.
¶All 6 participants with plateaus under pegIFN+TDF went on to have declines under pegIFN+TDF+NAPs.
‡All 5 participants with transient increases in pegIFN+TDF remained unchanged with transition to pegIFN+TDF+NAPs.

Conclusion: TDF + pegIFN induces transient increases in serum HBV RNA which either self-resolve or resolve in the presence of NAPs. The correlation of serum HBV RNA elevations with ALT flares suggests release of HBV RNA containing virus subsequent to cytolytic clearance of infected hepatocytes. The mechanism by which pegIFN or NAPs lead to an RNA increase may not indicate an increase in cccDNA activity and requires further research.

SAT399

Early antiviral efficacy of tenofovir alafenamide fumarate in the initial treatment of chronic hepatitis B patients with normal ALT

Huichun Xing[1], Xin Chi[1], Xiu Sun[1], Danying Cheng[1], Shunai Liu[2].
[1]Beijing Ditan Hospital, Capital Medical University, Center of Liver Diseases Division 3, Beijing, China; [2]Beijing Ditan Hospital, Capital Medical University, Beijing Key Laboratory of Emerging Infectious Diseases, Institute of infectious disease, Beijing, China
Email: hchxing@sohu.com

Background and aims: Patients were screened according to antiviral treatment indications recommended by China Guidelines for the prevention and treatment of chronic hepatitis B, some patients (over 30 years old or have a family history of liver cancer) will have ALT in normal range (An upper limit of normal for ALT is 50 U/L for males and 40 U/L for females).This study was designed to investigate the therapeutic effect of tenofovir alfenamide fumarate (TAF) on chronic hepatitis B (CHB) patients with normal alanine transaminase (ALT).
Method: A total of 79 treat-naive CHB patients treated with TAF antiviral therapy alone in Beijing Ditan Hospital, Capital Medical University from November 2018 to May 2021 were reviewed, including 39 patients in normal ALT group and 40 patients in abnormal ALT group. The clinical data of patients at baseline and 24 weeks after treatment were collected, and the changes of HBV DNA, serum hepatitis B virus e antigen (HBeAg) and hepatitis B virus surface antigen (HBsAg) were compared between the two groups before and after treatment.
Results: After 24 weeks of treatment, in the normal ALT group, HBV DNA decreased significantly from (5.0 ± 2.1) log10 IU/ml to (2.0 ± 1.5) log10 IU/ml (p = 0.000), in abnormal ALT group, HBV DNA decreased from (6.7 ± 1.9) log10 IU/ml to (1.8 ± 1.0) log10 IU/ml (p = 0.000). After 24 weeks of treatment, the rate of complete virological response (CVR) (HBV DNA <20 IU/ml) was 64.1% (25/39) in the normal ALT group, and 50.0% (20/40) in the abnormal ALT group. There was no significant difference between the two groups (p = 0.206). The CVR rates of normal ALT group and abnormal ALT group were 100% at baseline of low viral load (HBV DNA $<10^3$). At 24 weeks, the proportion of HBV DNA target not detected (TND) in the normal ALT group was 43.6% (17/39), significantly higher than that in the abnormal ALT group [12.5% (5/40)] (p = 0.003). Subgroup analysis was performed for the normal ALT group according to the reference upper limit of normal (ULN) recommended by AASLD 2016 (male ≤30 U/L, female ≤19 U/L). In normal ALT group (AASLD 2016), the CVR is 92.3% (12/13), in 30 U/L < ALT<50 U/L (male) and 19 U/L < ALT<40 U/L (female) group, the CVR at 24 w is 50% (13/26), respectively, the difference was statistically significant (p = 0.013).

Table: Baseline Demographics and Disease Characteristics

Variables	ALT Normal n = 39	ALT Abnormal n = 40	p values
Mean age, y (SD)	41 (8.4)	38 (8.7)	0.150
Men, n (%)	20 (51)	24 (60)	0.435
Mean ALT, U/L (SD)	30.4 (11.4)	194.3 (196.5)	0.000
Mean AST, U/L (SD)	24.7 (5.9)	101.5 (88.1)	0.000
Mean HBV DNA, log10 IU/ml (SD)	5.0 (2.1)	6.7 (1.9)	0.001
Mean HBsAg, log10 IU/ml (SD)	3.6 (1.2)	3.8 (0.6)	0.910
Mean HBeAg, log10 IU/ml (SD)	1.0 (1.7)	1.5 (1.6)	0.354
HBeAg positive, n (%)	14 (36)	22 (55)	0.088

Conclusion: Tenofovir alafenamide fumarate can obtain better antiviral efficacy in CHB patients with normal ALT, and the efficacy is not lower than that in CHB patients with abnormal ALT.

SAT400

Viral and ALT kinetics after nucleos (t)ide analogue withdrawal among patients who remain off-therapy: results from a global, multi-ethnic cohort of chronic hepatitis B patients (RETRACT-B study)

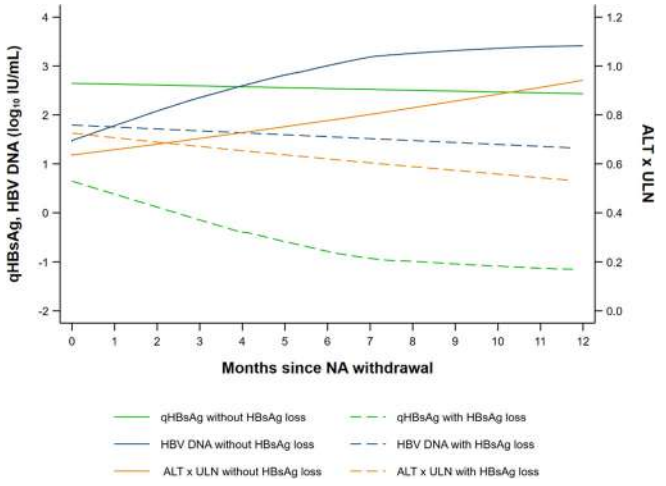
Email: grishma.hirode@gmail.com

Background and aims: Recent studies have analyzed the best candidates for nucleos (t)ide analogue (NA) cessation with respect to HBsAg loss. However, whether patients remain off-therapy is often dependent on local reimbursement policies. Patients who remain off-therapy, with/without HBsAg loss, have not been well characterized. We aim to describe this group and analyze early viral and biochemical kinetics after NA cessation.
Method: Virally suppressed, non-cirrhotic CHB patients who were HBeAg negative at NA cessation were included. Patients with coinfection, prior interferon therapy, or prior HCC diagnoses were excluded. We used mixed-effects regression to analyze HBsAg, HBV DNA, and ALT kinetics among patients who remained off-therapy at the end of 1 yr after NA cessation; only patients with follow-up ≥1 yr were included.

Results: Among 804 patients (mean age 52 ± 12yrs, 71% male, 84% pre-therapy HBeAg negative), 29 (3.6%) achieved HBsAg loss and 775 (96%) remained off-therapy without HBsAg loss at 1 yr. Patients with HBsAg loss (vs without) had a higher proportion of Caucasians (vs Asians) (31% vs 8.3%, p < .001), tenofovir-treated patients prior to cessation (vs entecavir-treated) (50% vs 32%, p = .04), and lower median HBsAg at end of therapy (0.4 [-0.6–1.6] vs 2.7 [2.2–3.1] log_{10}IU/ml, p < .001). Median ALT at end of therapy among the whole group was 0.6x (0.4–0.8) ULN. Patients with HBsAg loss showed a rapid decline in mean HBsAg in the first 6mos while those without HBsAg loss showed a modest decrease. There was a decreasing trend in mean HBV DNA among patients with HBsAg loss while HBV DNA increased steadily for the first 6mos among those without HBsAg loss; however, it stabilized thereafter. Patients with HBsAg loss (vs without) had a lower proportion of virological relapses (HBV DNA>2000 IU/ml: 21% vs 59%; p < .001) in the first year. Patients with HBsAg loss experienced a higher proportion of flares (ALT>5x ULN: 21% vs 10%, p = .07; ALT>10x ULN: 10% vs 4.5%, p = .15) in the first year but mean ALT decreased over time for that group and increased for those without HBsAg loss. Mean ALT remained normal in both groups. Among those without HBsAg loss, 4 had HBeAg reversions, and 1 decompensated in the first year.



Conclusion: Early kinetics were good indicators of outcomes following NA cessation among patients who remain off-therapy. Patients without HBsAg loss showed increases in HBV DNA and ALT with worse clinical outcomes and only nominal decreases in HBsAg compared to those who achieved HBsAg loss.

SAT401

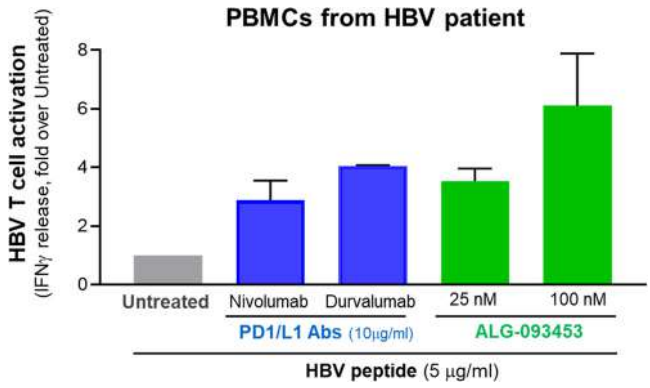
Discovery of oral PDL1 small molecule inhibitors specifically designed for the treatment of chronic hepatitis B

Tongfei Wu[1], Sarah Stevens[2], Cheng Liu[2], Kristina Rekstyte-Matiene[3], Elke Behaeghel[3], Sucheta Mukherjee[2], Sandra Chang[2], Ruchika Jaisinghani[2], Antitsa Stoycheva[2], Andreas Jekle[2], Qingling Zhang[2], Kusum Gupta[2], Jerome Deval[2], Julian Symons[2], Lawrence Blatt[2], Leonid Beigelman[2], Pierre Raboisson[1], Francois Gonzalvez[1]. *[1]Aligos Belgium BVBA, Leuven, Belgium, Belgium; [2]Aligos Therapeutics, Inc., South San Francisco, CA, Belgium; [3]Novalix, Leuven, Belgium*
Email: fgonzalvez@aligos.com

Background and aims: Chronic hepatitis B (CHB) is characterized by high viral replication and exhaustion of virus-specific T cells. In CHB patients, upregulation of PD1 on HBV-specific T cells and PDL1 on liver cells cause T-cell exhaustion and persistent viral infection. Therefore, inhibiting the PD1/PDL1 pathway has recently emerged as an attractive therapeutic strategy to restore a virus-specific T cell response and reverse immune tolerance. Seven PD1/PDL1 antibodies are currently approved as cancer therapies and nivolumab (anti-PD1) has demonstrated some clinical efficacy in CHB patients. However, the systemic immune-related adverse effects associated with antibodies limit their therapeutic window and therefore, there is a need to develop better tolerated PD1/PDL1 inhibitors for CHB patients. Here, we rationally designed oral PDL1 small molecule inhibitors to localize T cell activation to the liver and thereby mitigate systemic toxicity in CHB patients.

Method: Biochemical PD1/PDL1 interaction was assessed by AlphaLISA®. Cellular activity was measured using a co-culture reporter assay in which NFAT activity of Jurkat T cells is constitutively inhibited by the engagement of PD1 by PDL1-expressing CHO cells. In vivo pharmacokinetic analyses and efficacy were assessed in humanized-PDL1 MC38 subcutaneous xenografts and in the AAV-HBV mouse model. HBV-specific T cell activation assays were performed in PBMCs from an HBV-infected patient and assessed by measuring IFNg release.

Results: Using structure-based and rationale design, we identified a series of oral PDL1 small molecule inhibitors. In biochemical assays, our lead molecules inhibited PD1/PDL1 interaction with an IC_{50} value of 16 pM. In PD-1/PDL1 blockade cellular assays, these compounds increased TCR signaling with an EC_{50} value of 1.5 pM, a similar potency to nivolumab. In mice, our lead molecules displayed good oral bioavailability and high liver/plasma ratios. When dosed orally in MC38 tumor-bearing mice, our lead molecules were well tolerated. Importantly, these compounds showed similar in vivo efficacy to durvalumab in this tumor model that relies on systemic exposure. To test whether our compounds can release exhaustion of HBV-specific T cells, we stimulated PBMCs from an HBV-infected patient with HBV peptide antigens in presence of our lead compounds (Figure). ALG-093453 activated HBV-specific T cells in a dose dependent manner to similar or higher extend as nivolumab and durvalumab.



Conclusion: We designed oral PDL1 small molecule inhibitors specifically for CHB. Our lead molecules show similar in vitro potency and in vivo efficacy in systemic models to FDA-approved PD1/PDL1 antibodies, together with high liver/plasma exposure ratios. Our PDL1 small molecule inhibitors have the potential to activate HBV-specific T cells in the liver, while decreasing bystander T cell activation in the periphery.

SAT402

Incorporation of novel ASO chemistries significantly improves the potency and durability of HBV ASOs in the AAV-HBV mouse model

Jin Hong[1], Laxman Eltepu[1], Saul Martinez Montero[1], Hua Tan[1], Kang Hyunsoon[1], Vivek Rajwanshi[1], John Cortez[1], Dawei Cai[1], Cheng Liu[1], Elen Rosler[1], David Smith[1], Julian Symons[1], Lawrence Blatt[1], Leonid Beigelman[1]. *[1]Aligos Therapeutics*
Email: jhong@aligos.com

Background and aims: We applied proprietary chemistries to develop the best-in-class HBV ASOs, ALG-020572 and ALG-020576, with unique N-Acetylgalactosamine 4 (GalNac4) conjugation. These

ASOs target the open reading frames of the small HBsAg and the HBx protein respectively. Both ASOs contain next generation spirocyclopropyl Bridged Nucleic Acid (scp BNA) and nucleobase modified monomers that reduced hepatotoxicity while maintaining efficacy in AAV-HBV mouse model. In this study, we further explored additional BNAs such as guanidine-bridged nucleic acid (GuNA) and other proprietary BNAs in the sequences of ALG-020572 and ALG-020576. We demonstrated that further improvement of in vitro and in vivo activities could be achieved.

Method: ASOs with LNA and 3rd gen BNA chemistries were synthesized on MerMade 12 and MerMade 48 synthesizers. In vitro screening of ASOs was carried out in HepG2.2.15 cells or HBV infected primary human hepatocytes (PHH) using an HBsAg release assay. The AAV-HBV mouse model was used to test efficacy and hepatotoxicity of GalNAc-ASOs by analyzing HBsAg and ALT in mouse plasma.

Results: ALG-021682 and ALG-021639 are GalNAc 4 conjugated ASOs targeting the same site as ALG-020572. ALG-021682 contains GuNA and ALG-021639 contains a novel 3rd gen BNA. Unconjugated ALG-021682 showed a 5-fold lower EC_{50} than unconjugated ALG-020572 in HepG2.2.15 assay. In HBV infected PHH, the unconjugated ALG-021639 was 5-fold more potent than unconjugated ALG-020572. When tested in the AAV-HBV mouse model, both ALG-021682 and ALG-021639 exhibited a 2-fold lower HBsAg nadir than that of the ALG-020572 analog when dosed at a single dose of 5 mg/kg subcutaneously. None of the ASOs demonstrated ALT elevations. Finally, ALG-021618 is an ALG-020576 derived ASO with a novel structure. It was inactive in vitro due to the inability to be metabolically processed by HepG2.2.15 cells. However, in the AAV-HBV mouse model with 3 × 10 mg/kg repeat dosing on days 0, 3 and 7, ALG-021618 achieved a HBsAg nadir of – 1.8 $\log_{10}$ IU/ml vs. – 1.2 $\log_{10}$ IU/ml for ALG-020576. By day 60, ALG-020576 dosed animals reverted to baseline HBsAg levels but ALG-021618 still suppressed HBsAg by 1 $\log_{10}$ IU/ml.

Conclusion: GuNA and other novel BNAs improved the in vitro and in vivo activities of our lead ASO ALG-020572. Novel modifications of ALG-020576 significantly improved the in vivo depth and durability of HBsAg knockdown. Further investigations combining these chemistries are ongoing.

SAT403

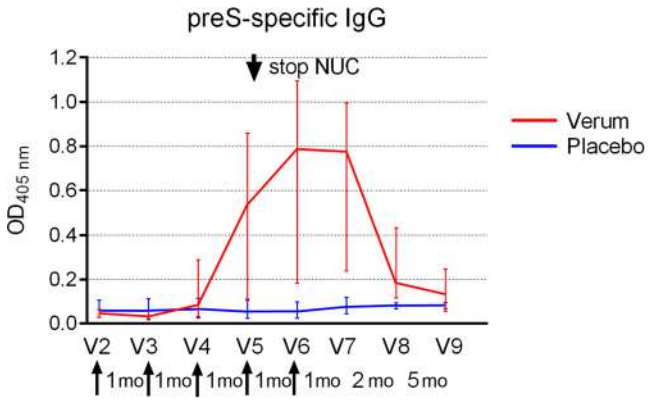
Induction of pre-s antobodies in HBeAg negative chronic hepatitis B patients by thereupatic vaccination with the pre-s based vaccine VVX001-interim analysis

Petra Munda[1], Ina Tulaeva[2], Rudolf E. Stauber[3], Pia Gattringer[2], Michael Trauner[1], Helmut Brunar[4,4], Rudolf Valenta[2], Peter Ferenci[2]. *[1]Medical University of Vienna, Internal Medicine 3, Gastroenterology and Hepatology, Austria; [2]Medical University of Vienna, Wien, Austria; [3]Medical University of Graz, Internal Medicine 1, Graz, Austria; [4]Vivaraxx AG, Austria*
Email: peter.ferenci@meduniwien.ac.at

Background and aims: VVX001 is an HBV vaccine candidate based on a HBV-derived preS fused to grass pollen allergen peptides. The aim of this prospective double-blind, placebo-controlled trial (NCT03625934) was to investigate if VVX001 can induce preS-specific antibody and T cell responses in 4 different cohorts including patients with chronic hepatitis B.

Method: This is an interim analysis of non-cirrhotic patients with HBeAg-negative chronic hepatitis B on long-term treatment (>3 years) with nucleo (t)side analogues (NUCs) (cohort 4a) treated either with 5 s.c. injections (visits 2, 3, 4, 5, 6) of either VVX001 or placebo in 4-week intervals (randomized 3:1), respectively Inclusion criteria: HBV DNA <20 IU/ml (detection limit); HBsAg<1000 IU/ml. After the third vaccination (visit 4) NUCs were stopped. After visit 6, patients were then followed for further 36 weeks (visits 7, 8, 9). preS-specific IgG and CD4+/CD8+ T cell responses were studied by ELISA and FACS analysis CFSE-labeled PBMCs

Results: All 20 patients (m/f:16/4; 19 Caucasians, 1 Asian, age:35–59 years) completed treatment and 17 of them reached visit 9 at this point. Five patients received placebo and 15 received VXX001. All patients in the verum group developed robust preS-specific IgG responses peaking one month after the last injection and declining at month 12. At visit 8 (12 weeks after the last injection) preS-specific IgG levels increased by 139% (median) compared to baseline ($p < 0.001$). HBsAg decreased from median 365 IU/ml (range: 100 to 1320) to 116 (0–340) (available in 9; $p = 0.04$) at end of follow-up (FU) in the verum group but did not change in the placebo group ($n = 4$).
During FU, HBV DNA became quantifiable in 6 verum patients; 2 patients developed ALT flare >10x the upper limit of normal (ULN) and were restarted on NUCs. One had transient ALT increase (7×ULN). In this and in 3 other patients HBV-DNA decreased again below 20 IU/ml. Thirteen verum patients (87%) remained HBV-DNA negative with normal ALT, and none of them required repeated NUC treatment.
Except local injection site-reactions, VVX001 was well tolerated in all participants and no SAEs were reported.



Conclusion: VVX001 is safe and well tolerated and induces a preS-specific immune response in patients with chronic HBeAg-neg hepatitis B. In 87% of vaccinated patients, no repeated treatment with NUCs was necessary after stopping NUCs. A longer follow-up is needed to evaluate the long-term impact of vaccination and stop of NUC therapy.

HEC121120, a novel allosteric modulator of HBV core protein demonstrates potent antiviral activities in vitro and in vivo

Qingying Lai[1], Pu Wang[1], Xinchang Liu[2], Qingyun Ren[2], Baohua Gu[1], Jing Li[1], Yunfu Chen[1]. *[1]State Key Laboratory of Anti-Infective Drug Development (NO. 2015DQ780357), Sunshine Lake Pharma Co., Ltds, Pharmacology and toxicology division, Dongguan, China; [2]State Key Laboratory of Anti-Infective Drug Development (NO. 2015DQ780357), Sunshine Lake Pharma Co., Ltds, Dongguan, China*
Email: chenyunfu@hec.cn

Background and aims: Capsid assembly modulators (CAMs) represent a clinically validated strategy for the treatment of chronic hepatitis B. Here, we report on HEC121120, a novel class I CAM with improved antiviral activities *in vitro* and *in vivo*.

Method: Antiviral activities on HBV DNA were determined in HepG2.2.15 cells and in HBV-infected primary human hepatocytes (PHH) both *in vitro* and *ex vivo* using quantitative PCR. *In vivo* antiviral efficacy was assessed in the AAV-HBV mouse model with 8 weeks of treatment and 4-week off-treatment follow-up period.

Results: HEC121120 showed potent antiviral activity on HBV DNA production ($EC_{50} = 5.03$ nM) in HepG2.2.15 cells with low cytotoxicity ($CC_{50} \geq 150$ μM), similar to that of GLS4 ($EC_{50} = 8.66$ nM, $CC_{50} \geq 150$ μM). However, significantly enhanced potency was demonstrated in HBV-infected PHH with EC_{50} 16.3 nM and 724 nM for HEC121120 and GLS4, respectively. In PHH isolated from chronically infected

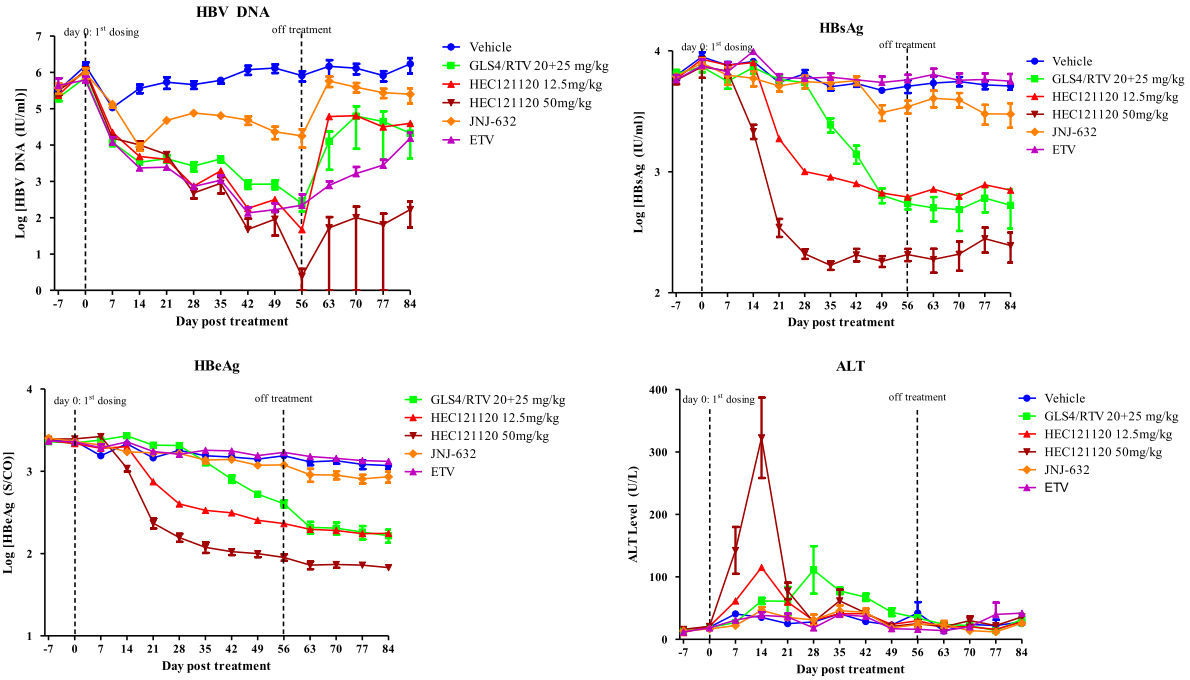

Figure: (abstract: SAT404)

humanized liver mouse, 14 days of GLS4 (5 μM) and HEC121120 (2 μM) treatment resulted in suppression of HBV DNA, HBsAg and HBeAg while entecavir (ETV) had no effect on either viral antigen. To compare with similar compounds in AAV-HBV mouse model, treatment with ETV (0.1 mg/kg, QD, p.o.) and JNJ-632 (200 mg/kg, QD, s.c.) resulted in potent reduction of serum HBV DNA but no significant impact on serum HBsAg and HBeAg level. In contrast, both GLS4/RTV (25/20 mg/kg, BID, p.o.) and HEC121120 (12.5 mg/kg or 50 mg/kg, BID, p.o.) potently suppressed HBsAg and HBeAg in addition to HBV DNA. At the end of treatment, HBV DNA declined 3.6, 1.7, 3.5, 4.2, 5.5 log10 for ETV, JNJ-632, GLS4/RTV, HEC121120 (12.5 mg/kg dose) and HEC121120 (50 mg/kg dose), respectively. The mean decline for HBsAg was 1.0, 0.9, 1.4 log10 and the mean decline of HBeAg was 0.6, 0.8, 1.2 log10 for GLS4/RTV, HEC121120 low dose and HEC121120 high dose. There was no significant rebound of viral antigens in GLS4/RTV and HEC121120 treated animals during the 4-week follow-up period. Furthermore, liver IHC showed HBcAg positive hepatocytes were significantly reduced in HEC121120 treated groups compared to control. Similar to GLS4, HEC121120 caused a dose dependent, self-limiting ALT elevations but at an earlier time and with increased magnitude in higher dose group of HEC121120. Concomitantly, the decrease of HBsAg correlated well with the timing and magnitude of ALT, indicative of ALT flare as a therapeutic effect.

Conclusion: HEC121120 is a novel class I CAM, which demonstrated improved antiviral properties both *in vitro* and *in vivo*, further clinical study will be conducted to evaluate the antiviral potency in CHB patients.

Evaluation of quantitative HBsAg levels in chronic hepatitis B-a targeted literature review

Anadi Mahajan[1], Saifuddin Kharawala[1], Nitesh Singh[1], Supriya Desai[1], Stuart Kendrick[2], Emily Lloyd[2], Vera Gielen[2]. [1]*Bridge Medical Consulting, London, United Kingdom;* [2]*GlaxoSmithKline, Research and Development, United Kingdom*
Email: anadimahajan@bridgemedical.org

Background and aims: A targeted literature review (TLR) was conducted in patients with chronic hepatitis B (CHB). **Objective 1:** Hepatitis B surface antigen (HbsAg) titres across disease phases, and their *cross-sectional* relationship with clinical, biochemical and treatment characteristics. **Objective 2:** Association between HBsAg titres and long-term disease outcomes (cirrhosis, hepatocellular carcinoma [HCC], liver transplant, mortality). **Objective 3:** *Change* in HBsAg titres and their relationship with the above characteristics.

Method: Structured searches were performed in MEDLINE® and Embase® (January 2000 to March 2021), with bibliographic searches, hand searches of relevant congress abstracts (2019–2021) and grey literature searches.

Results: Of all studies identified, 59 were selected for reporting, of which 46% were retrospective-cohort and 25% prospective-cohort. HBsAg titres were generally higher in initial Hepatitis B e-antigen (HBeAg)-positive phases than in later HBeAg-negative phases. Cross-sectionally, higher HBsAg titres were consistently associated with higher Hepatitis B Virus (HBV) DNA levels (moderate-to-strong in HBeAg-positive phases; weak-to-moderate in HBeAg-negative phases) and lower age (moderate). Greater decline in HBsAg was consistently associated with subsequent HBsAg seroclearance (hazard ratio [HR]: 1.95 to 43.83) and with lower HBV DNA levels (odds ratio [OR]: 2.82 to 26.52 for virological response). HBsAg titres predicted development of HCC and cirrhosis in treatment-naïve CHB patients by multivariate analysis. Data were limited for prediction of cirrhosis.

Conclusion: HBsAg titres are associated with HBV DNA and age across CHB phases. Decline in HBsAg titres is associated with HBsAg seroclearance and lower HBV DNA levels. HBsAg titres can predict the development of long-term outcomes.

Nucleoside/nucleotide analogoues monotherapy is safe and efficient for the prevention of HBV flare-ups after liver transplantion in the long term

Orly Sneh Arbib[1], Assaf Issachar[1,2], Marius Braun[1,2], Michal Cohen-Naftaly[1,2], Yael Harif[1], Evelin Oxtrud[1]. [1]*Beilinson, Petah*

Tikva, Israel; [2]Tel Aviv University, Tel Aviv-Yafo, Israel
Email: orlysneh@gmail.com

Background and aims: The recurrence rate of HBV after transplantation decreased dramatically due to prophylactic therapy including hepatitis B immunoglobulin (HBIg) and nucleoside/nucleotide (Nuc) analogues. Published data on cessation of HBIg after transplantation and treatment with Nuc analogues as monotherapy are scarce especially in western world
In 2013 we decided to stop HBIg in liver transplant patients with undetectable HBV DNA in serum during follow-up, more than 2y post LT with good compliance, normal liver function tests that were HBeAg negative and with viral load less than 2000IU/ml at transplantation. Lamivudine was switched to entecavir or tenofovir, before stopping HBIg.. Due to excellent results we decided in 2018 stop HBIg as soon as possible after transplantation in patients who fulfill the other criteria
We aimed to determine the long-term efficacy of Nuc analogues monotherapy for prevention of HBV seroconversion and flare-up of hepatitis. Overall graft and patient were assessed.
Method: This is a retrospective study on a prospectively maintained data base of transplanted patients in the largest transplant center in Israel. All patients that required LT due to HBV and its complications are followed up by biannual liver function tests, HBV serology, HBV DNA AFP and ultrasound.
Results: 630 liver transplants were performed in our center since 1995, 420 patients are in active follow-up. HBV related disease was the reason for LT in 84 patients, and 25 were eligible for monotherapy (Table 1). The patients were treated with dual therapy for an median time of 7.2 years (IQR 3.4–12.7 years). During a follow-up of median 6.8 years (IQR 4.2–7.4 years) after HBIG discontinuation there were no hepatitis flares, however, two patients treated with entecavir had detectable HBsAg in serum (one of them also temporarily exhibited low titre HBV DNA in serum during follow-up). Two patients had detectable HBsAb, two years after the HBIG was discontinued. There was no recurrence of HCC. There was no graft failure. Five patients received active immunization.

Patients	N
LT d/t HBV	84
Gender male	16
Age (mean)	46
Monotherapy with Nuc analogues	25
Anti HDV Ab prior to transplant	9
HCC prior to transplant	6
Treated with lamivudine before HBIg interruption	12
Treated with tenofovir after HBIg interruption	8
Treated with entecavir after HBIg interruption	17

Conclusion: The Long term follow-up reiterates the safety and efficacy of monotherapy with Nuc analogous in carefully selected Caucasian patients including HCC patients and HBV/HDV co-infected patients.

SAT407

A new method to identify co-variation in hepatitis B virus whole genome sequences identifies networks of polymorphisms associated with drug resistance

Sheila Lumley[1], Steven Lin[2], Louise Downs[1], Cori Campbell[1], Anna McNaughton[3], Azim Ansari[1], Philippa Matthews[4]. *[1]Peter Medawar Building for Pathogen Research; [2]Wellcome Trust Centre for Human Genetics; [3]University of Bristol; [4]The Francis Crick Institute*
Email: sheila.lumley@trinity.ox.ac.uk

Background and aims: We developed a model to identify coevolving amino acid (aa) sites within or between hepatitis B virus (HBV) proteins with the aim of identifying structural or functional protein interactions while accounting for the population structure among the isolates (founder effect). Here we present a computationally efficient method to identify co-varying sites across the HBV genome in the context of its phylogeny. We examine the trends in covariation across the genome and apply this to the study of drug resistance associated mutations (RAMs).
Method: We downloaded 9313 genotype A, B C and D whole genome HBV sequences from HBVdb. We aligned, deduplicated and translated them into a sequences. We built a phylogeny for each genotype and

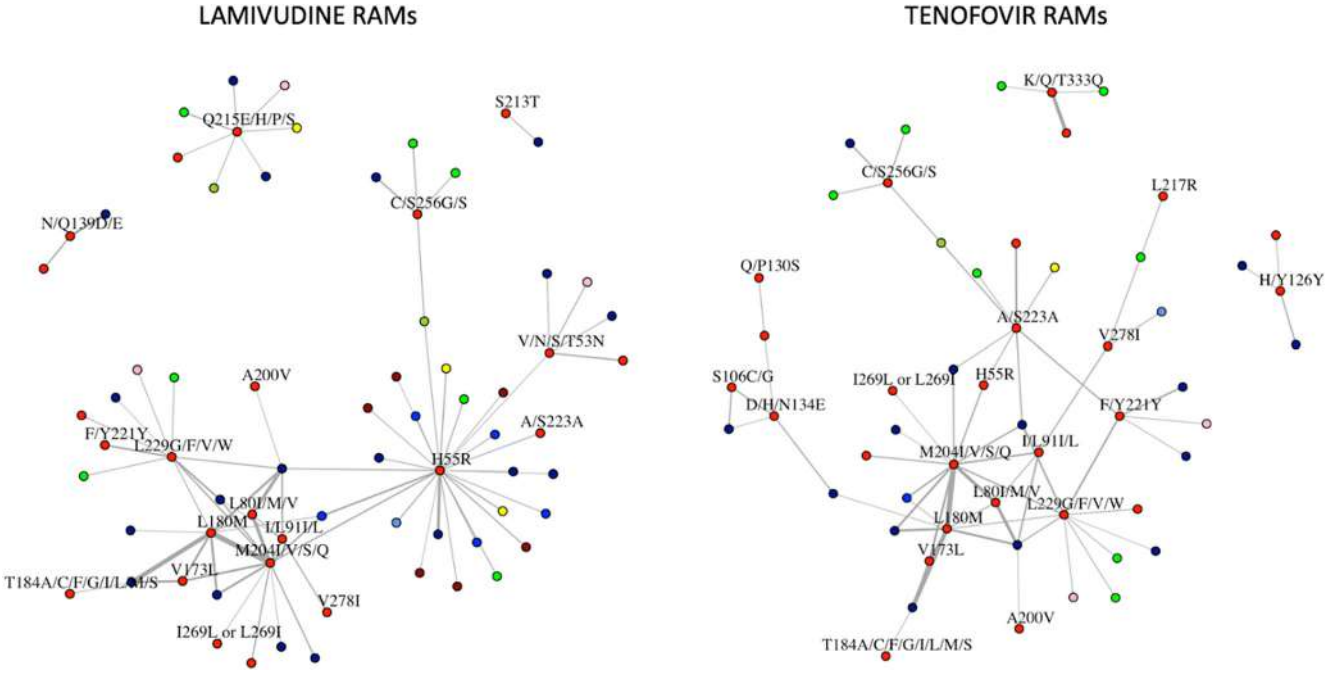

Figure 1: (abstract: SAT407): Network analysis highlighting covarying pairs in which one or more amino acids are Lamivudine or Tenofovir RAMs. Each node represents an amino acid. Node colour indicates the protein; p = reds, C = greens, S = blues, X = yellow. Line width is inversely proportional to the adjusted harmonic mean p value.

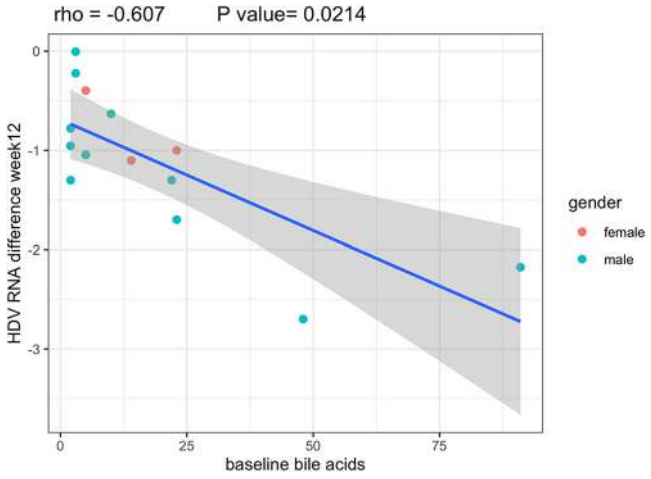
reconstructed the ancestral state for each polymorphic site. We used Fisher exact test to investigate covariance between a changes on the tree between two sites. We combined p values using harmonic mean p value and used false discovery rate to account for multiple testing.
Results: We identified 1066 co-varying aa pairs across the genotypes; 547 (51%) pairs involved core protein, 532 (50%) polymerase, 351 (33%) surface, and 87 (8%) X. Core protein was enriched in the proportion of covarying sites relative to other proteins. Within-protein covariations were enriched across all genotypes. Of the 615 within-protein covarying pairs, 53 (9%) were adjacent, and 60 (10%) were ≤3 a apart. For genotypes B, C and D, most co-varying sites were linked in a dominant network, the largest of which included 131/186 (70%) covarying amino acids (genotype B). Identification of known primary/secondary RAM pairs in this dataset validated our method; previously reported RAMs were enriched among the covarying sites (OR 2.1, p <0.05). 136 pairs were identified where one or more sites was a known RAM. RAMs co-varied in networks spanning all four proteins (Fig 1), demonstrating the global epistatic connectivity of RAMs.
Conclusion: Covariation analysis reveals a complex, genotype-specific network of a substitutions in HBV. We have shown how this method can describe networks of RAMs, and it could further provide evidence of sites of clinical relevance pertinent to understanding viral evolution and phylogeny, immune escape, and therapeutic vaccine design.

SAT408

Baseline bile acid levels but not bile acid increases during bulevirtide treatment of hepatitis D are associated with HDV RNA decline

Katja Deterding[1], Cheng-Jian Xu[1,2], Kerstin Port[1], Benjamin Maasoumy[1], Markus Cornberg[1,2], Heiner Wedemeyer[1].
[1]Hannover Medical School, Gastroenterology, Hepatology and Endocrinology, Hannover, Germany; [2]Center for Individualized Infection Medicine, CiiM, a joint venture between Hannover Medical School and the Helmholtz Center for Infection Research, Hannover, Germany
Email: deterding.katja@mh-hannover.de

Background and aims: Bulevirtide is an entry inhibitor blocking entry of HBsAg into hepatocytes by interfering with Na+-taurocholate cotransporting polypeptide (NTCP), the HBV/HDV receptor. As NTCP is a bile acid transporter, one would expect an increase of bile salts during bulevirtide treatment. Still, there is no data available if the increase in bile acids reflect antiviral efficacy.
Method: We studied 14 patients (11 male, 3 female) with compensated HDV infection receiving bulevirtide 2 mg subcutaneously once daily for at least 12 weeks. The median age of the patients was 48 years (± 12, 44) and all of the patients had liver cirrhosis or advanced fibrosis and 7 were previously treated with pegylated interferon alfa.
Results: ALT levels improved in all patients over time with 7/14 patients showing normal ALT values at treatment week 12. An HDV RNA drop of at least 50% was evident in 12/14 patients at week 12 including 8 patients with a more than 1log IU/ml and 2 patients achieving a fast response with more a than 2 log HDV RNA decline.
Total serum bile acids showed a heterogeneous pattern before and during treatment. Bile salts levels were above the limit of normal already before treatment in 6 patients and increased during bulevirtide administration with different kinetics in most patients. Of note, no patient reported systemic itching. Baseline bile acids were associated with higher transient elastography values ($p = 0.01$) but liver stiffness was not associated with bile acid changes during treatment.
Bile acid levels before the start of treatment were associated with HDV RNA declines at treatments weeks 2, 8 and 12 (rho = -0.70 and $p = 0.005$, rho = -0.75 and $p = 0.002$, rho = -0.61 and $p = 0.02$, respectively; see figure). However, bile acid increases during treatment were not associated with subsequent HDV RNA declines at neither time point ($p = 0.73$; $p = 1$, $p = 0.28$, respectively). Furthermore, bile acid changes during treatment were also not associated with subsequent ALT declines.



Conclusion: In conclusion, we demonstrate that the bulevirtide-induced increase in bile salts does not correlate with HDV RNA decline in patients with hepatitis D. Thus, blocking HBsAg entry and interfering with the bile acid transporter function of NTCP occur at different concentrations. Thus, in clinical practice, regular measurement of bile salts during bulevirtide treatment does not predict virological response to bulevirtide treatment.

SAT409

Low levels of qHBsAg and tenofovir therapy are associated with successful treatment withdrawal in HBeAg negative chronic hepatitis B: results from spanish multicentric study

Anna Pocurull[1,2,3,4], Elena Hoyas[5], Manuel Rodríguez[6], Mireia Miquel[7], Clara Amiama Roig[8], Sergio Rodriguez-Tajes[1,2,3,4], Francisco Javier Garcia-Samaniego Rey[8], Emilio Suarez[5], Sabela Lens[1,2,3,4]. *[1]Hospital Clínic de Barcelona, Liver Unit; [2]University of Barcelona; [3]IDIBAPS; [4]CIBEREHD; [5]Hospital Universitario Virgen de Valme, Sevilla; [6]Hospital Universitario Central de Asturias, Oviedo; [7]Hospital Parc Taulí, Sabadell; [8]Hospital La Paz, Madrid*
Email: pocurull@clinic.cat

Background and aims: Clinical guidelines suggest that nucleos(t)ide analogues (NA) discontinuation in HBeAg negative chronic hepatitis B (CHB) may increase functional cure rates. However, information about predictive factors in Caucasian patients is still limited also influenced by different re-treatment criteria. We aimed to analyze baseline factors and outcomes after NA withdrawal in 5 Spanish Centers with homogeneous re-treatment criteria.
Method: Prospective inclusion of 96 non-cirrhotic patients with HBeAg-negative CHB in complete viral suppression after >3 years. The re-treatment criteria after NA withdrawal were: ALT >10 upper limit normal (ULN) and bilirubin >2 mg/dl, ALT >5 ULN during 1 month, or ALT >2 ULN and DNA-VHB >2.000UI/ml >6 months.
Results: The median age of the cohort was 55 (IQR: 46–63) years old and 68% were male. Fibrosis values assessed by Fibroscan® were low in all cases (4, 9 (4–6) kPa). At the time of NA withdrawal, 72% received tenofovir and 28% entecavir [median treatment duration of 11 (7–15) years, similar in both groups]. qHBsAg levels (n = 89) were 904 (305–2416) UI/ml. After a median follow-up of 28 (24–47) months after NA withdrawal, Twenty-two patients (23%) achieved HBsAg loss. Previous treatment with tenofovir ($p < .05$) and low levels of qHbsAg (<1000 UI/ml) before stopping treatment ($p < .05$) were associated to a higher rate of functional cure. Twenty-six patients (27%) accomplished re-treatment criteria due to ALT >5 ULN (n = 5) or >10 ULN (n = 7) of which 5 also had bilirubin >2 mg/dl. One patient required liver transplantation due to a fulminant hepatitis.

	HBsAg loss n = 22	HBsAg Persistence n = 74	p
Sex (Male)	17 (77%)	48 (65%)	p = 0, 275
Age (years) (median;IQR)	57, 05; (46–64, 2)	54, 6; (47–63)	p = 0, 365
Genotype (D/A) n = 30	5/2 (16/7%)	18/5 (60/17%)	p = 0, 801
Tenofovir	22 (100%)	47 (64%)	**p = 0, 001**
LAM Resistence	13 (59%)	21 (28%)	p = 0, 015
ALT ≥5LSN peak without restart treatment	7 (32%)	7 (9%)	p = 0, 068
Baseline qHBsAg (median, IQR)	240 (72–584)	1500 (556–3455)	**p = 0, 011**
Baseline qHBsAg >1000 IU/L (n = 42)	3 (14%)	39 (53%)	**p = 0, 0001**
Treatment duration (years) (m; IQR)	12, 97 (9, 1–18, 48)	11, 01 (7, 1–13, 94)	p = 0, 132
Follow-up (months) (m;IQR)	35, 58 (24, 37–57, 6)	33, 36 (24, 39–45, 6)	p = 0, 58

Conclusion: NA withdrawal increases the chance to achieve functional cure also in Caucasian patients, specially those previously treated with tenofovir and very low levels of qHbsAg (<1000 UI/ml). However, a very strict follow-up is strongly recommended so that re-treatment is promptly started.

SAT410

Preliminary results of the effectiveness and safety of Tenofovir Alefenamide Fumarate prophylaxis in HBV-infected individuals, who received chemo/immunosuppressive therapy

Feyza Gunduz[1], Serdar Durak[2], Yasemin Unsal[3], Mehmet Demir[4], Zeynep Melekoglu Ellik[5], Abdullah Emre Yıldırım[6], Shahin Mehdiyev[1], Haydar Adanir[7], Coskun Ozer Demirtas[1], Enver Ucbilek[8], Yasemin Balaban[9], Elif Sitre Koç[10], Digdem Ozer Etik[11], Pinar Gökçen[12], Derya Ari[13], Hale Gokcan[5], Suna Yapali[10], Nergis Ekmen[3], Mehmet Arslan[2], Meral Akdogan Kayhan[13], Kamil Ozdil[12], Orhan Sezgin[8], Sedat Boyacioglu[11], Halis Simsek[9], Nurdan Tozun[10], Dinc Dincer[7], Ramazan Idilman[5]. *[1]Marmara University School of Medicine, Turkey; [2]Karadeniz Technical University School of Medicine, Turkey; [3]Gazi University School of Medicine, Turkey; [4]Mustafa Kemal University School of Medicine, Gastroenterology, Turkey; [5]Ankara University School of Medicine, Turkey; [6]Gaziantep University School of Medicine, Turkey; [7]Akdeniz University School of Medicine, Turkey; [8]Mersin University School of Medicine, Turkey; [9]Hacettepe University School of Medicine, Turkey; [10]Acıbadem University School of Medicine, Turkey; [11]Başkent University School of Medicine, Turkey; [12]Health Sciences University, Umraniye Training and Research Hospital, Turkey; [13]Ankara City Hospital, Turkey*
Email: drfgunduz@yahoo.com

Background and aims: There are very limited data regarding the efficacy and safety of tenofovir alafenamide fumarate (TAF) prophylaxis to prevent HBV reactivation in HBV-infected individuals undergoing chemo/immunosuppressive therapy. The aims of the present study were to determine the effectiveness and safety of TAF prophylaxis in HBV-infected individuals, who receive chemo/immunosuppressive therapy.
Method: This is a multicenter, observational study. Data were entered in a standardized electronic case report form (CRF) from each center and collected from the CRF. TAF was administered at a dose of 25 mg/day at the initiation of the chemo/immunosuppressive therapy. The mean follow-up period was 17.1 ± 7.8 months.
Results: A total of 326 HBV-infected individuals with benign and malign diseases received TAF prophylaxis. Among these patients, 158 patients (M/F:83/75) with at least 6 months of follow-up were included into analysis. Mean age was 59.55 ± 12.2 years. Thirty patients had detectable HBV DNA and 5% were HBeAg positive. Solid tumors were the most common primary disease (33.5%), followed by rheumatic diseases (32.9%) and myeloproliferative diseases (32.2%). Of these patients, 48% received cytotoxic chemotherapy, 17% received B cell depleting therapy, 13% received anti-TNF therapy, 8% were received glucocorticoid therapy, and 12% patients were received other treatments. During the follow-up period, none of the patients had clinical, biochemical, and serological evidence of HBV reactivation under TAF prophylaxis. No HBV-related morbidity and mortality was observed. HBV DNA became negative in 77% of the patients with detectable HBV DNA. All patients maintained their chemo/immunosuppressive therapy without interruption. TAF prophylaxis was well tolerated. The renal function tests and lipid profiles, except triglyceride level did not significantly change from the baseline to the end of the follow-up period (Table 1). No serious adverse events were reported.

Table 1. Laboratory changes during follow-up

n=158	Baseline mean±sd	6-months mean±sd	12-months mean±sd	18-months mean±sd	24-months mean±sd	p value (pairwise comparisons vs baseline) 6-months	12-months	18-months	24-months

Email: fehmitabak@yahoo.com

Background and aims: Tenofovir alafenamide (TAF) is a new prodrug of tenofovir used for the treatment of HIV-1 and HBV infections. It provides more efficient intracellular tenofovir concentrations at a relatively lower dose than provided by tenofovir disoproxil fumarate (TDF). TAF is expected to have efficacy similar to that of TDF with improved safety profile. TAF is commonly used in HBV treatment in

Turkey. We studied TAF use in chronic hepatitis B patients in a real life setting across the country.
Method: Treatment-experienced chronic HBV patients were included. Twenty-five sites from 15 cities were enrolled. Patients' demographics, laboratory studies before TAF and during TAF treatment were recorded. Data at baseline, in 6th month and in 12th month were compared.
Results: The study included 509 treatment-experienced patients. Among patients, median age was 53 years, male 302 (59.3%), HBeAg-negative 348 (86.1%), median ALT 23 U/L, median fibrosis score 2, and HAI 7. They were previously using TDF (83.9%), entecavir (6.8%), lamivudine (5.5%), telbivudine (3.0%), and adefovir (0.8%). Before TAF, teatment duration <6 months 13 (2.9), 6–12 months 29 (6.5), >12 months 403 (90.6). Indications to switch were osteoporosis 206 (40.5%), blood phosphate level 108 (21.2%), physicians decision 65 (12.8), glomerular filtration rate (GFR) 62 (12.2%), drug affecting bone mineral density 59 (11.6%), proteinuria/albuminuria 49 (9.6%), transplantation 11 (2.2%), steroids 6 (1.2%), fracture history 2 (0.4), and hemodialysis 2 (0.4%).
Among all patients with HBV-DNA <20 IU/ml was 76.0% at baseline (during switch), 88.0% in 6th month and 84.1% in 12th month ($p < 0.05$). ALT normalization was 72.3% at baseline, 76.9% in 6th month and 81.0% in 12th month ($p < 0.05$). Creatinine levels and estimated (eGFR) remained stable from baseline to 6th and 12th months (0.82 mg/dl, 0.86 mg/dl, and 0.88 mg/dl ($p > 0.05$); 95 ml/min, 84.45 ml/min, and 94.0 ml/min ($p > 0.05$), respectively). Change in HDL, LDL and total cholestrol at baseline, 6th month and 12th month are not significant.
Among all patients, TAF was tolerated well. Side effects were headache 7.7%, nausea 3.1%, fatigue 3.1%, and rash 1.0%.
Conclusion: Although the majority of the patients were using potent nucleos (t)ide analogs, switching to TAF was associated with improved virologic and biochemical responses. Renal functions and lipid parameters remained stable and the drug was well tolerated. Real life data confirmed the efficacy and safety of TAF in treatment-experienced chronic hepatitis B patients.

Mathematical modeling of HDV RNA kinetics suggests high peginterferon Lambda efficacy in blocking viral production: insights from the LIMT-1 study

E Fabian Cardozo-Ojeda[1,2], Sarah Duehren[1], Saeed Sadiq Hamid[3], Yoav Lurie[4], Edward J Gane[5], Anat Nevo-Shor[6], David Yardeni[6], Scott Cotler[1], Ingrid Choong[7], Jeffrey Glenn[8], Harel Dahari[1], Ohad Etzion[6]. *[1]Program for Experimental and Theoretical Modeling, Division of Hepatology, Department of Medicine, Stritch School of Medicine, Loyola University Chicago, Maywood, United States; [2]Vaccine and Infectious Disease Division, Fred Hutchinson Cancer Research Center, Seattle, United States; [3]Aga Khan University, Karachi, Pakistan; [4]Shaare Zedek, Jerusalem, Israel; [5]Auckland City Hospital, Auckland, New Zealand; [6]Soroka University Medical Center, Beer-Sheba, Israel; [7]Eiger BioPharmaceuticals, Inc., Palo Alto, United States; [8]Stanford University, Stanford, United States*
Email: harel.dahari@gmail.com

Background and aims: We previously reported 5 HDV RNA kinetic patterns under peginterferon-lambda (Lambda) monotherapy therapy (The Liver Meeting, AASLD 2019 #LP12). Here we sought to provide insights into HDV-host dynamics and Lambda efficacy using a mathematical modeling approach.
Method: Thirty-three chronic HDV infected patients participated in a randomized, open-label, Phase 2 clinical study (LIMT-1) of Lambda 120 µg (n = 19) or 180 µg (n = 14), administered once weekly by subcutaneous injections for 48 weeks, with 24 weeks of follow-up. All subjects were on tenofovir or entecavir. Kinetic data was obtained at Week 1 and every four weeks during and post Lambda therapy. HDV RNA was measured by Robogene®2.0 (limit of quantification of 14 IU/ml, horizontal dotted line in Fig. 1). Six patients were excluded from HDV kinetic analysis. The remaining 27 patients were previously categorized into 4 HDV kinetic patterns: monophasic, MP (Fig. 1a), biphasic, BP (Fig. 1b), flat-partial response, FPR (Fig. 1c) and triphasic/staircase, TP (Fig. 1d). We used a mathematical model of virus dynamics with or without proliferation of HDV-susceptible and HDV-infected hepatocytes to recapitulate the 4 HDV kinetic patterns and assess the impact of Lambda in blocking viral production. We fit the models to the HDV data using a population, nonlinear mixed-effects approach. HDV clearance rate was fixed to 0.43 day^{-1} as previously estimated under lonafarnib (Lancet Infect Dis 2015:15: 1167–74).

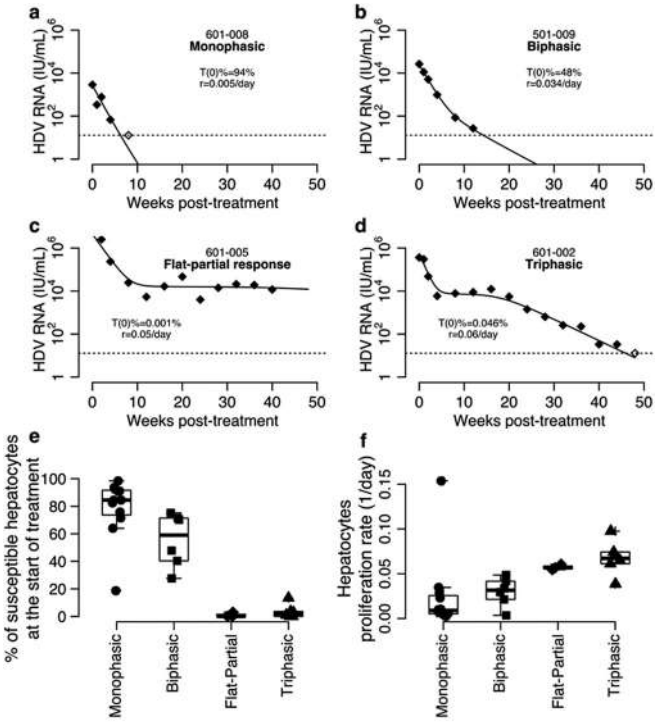

Figure 1. (a-d) Representative modeling calibration (curves) with patient's HDV RNA (symbols) during 48-week Lambda monotherapy. Horizontal lines represent HDV RNA limit of limit of quantification. 'T(0)%' is the estimated percentage of non-infected susceptible hepatocytes at the start of Lambda monotherapy and 'r' is the hepatocytes proliferation rate. Distributions of the estimated **(e)** T(0)% and **(f)** r using the best model fits.

Results: We found that only a model with hepatocyte proliferation of HDV-susceptible and HDV-infected cells is able to recapitulate all the 4 HDV kinetic patterns (Fig. 1a-d). The model predicts that population median half-life of HDV-infected hepatocytes is 9 days (equivalent to death/loss rate of 0.08 day^{-1} [%RSE = 38%]), and that Lambda blocks virus production with population median efficacy of 99% (%RSE = 0.5%). The model predicts that participants with monophasic (Fig. 1a) and biphasic (Fig. 1b) HDV kinetic patterns have a high fraction of noninfected hepatocytes at the start of treatment compared to those with TP and FPR (Fig. 1e). Those with BP kinetics had a ~3.5-fold faster hepatocyte proliferation compared to MP (Fig. 1f). However, hepatocyte proliferation in those with BP was ~2-fold slower than those in the TP and FPR (Fig. 1f).
Conclusion: This study provides, for the first time, a dynamic description of HDV response under Lambda monotherapy. Modeling results predict that Lambda blocks viral production (as estimated under pegylated IFN-α therapy) with high efficacy. The model predicts that the HDV kinetic patterns depend on Lambda efficacy, the fraction of noninfected hepatocytes at the beginning of treatment and their proliferation rates. Further theoretical and experimental efforts are needed to verify and/or refine our understanding of Lambda mode of action against HDV.

SAT413

Heterologous prime-boost immunotherapy circumvents tolerance and induces broadly neutralizing antibodies that protects against hepatitis B and D co-infection and hepatitis D super-infection

Lars Frelin[1], Panagiota Maravelia[1], Rani Burm[2], Yi Ni[3], Gustaf Ahlén[1], Lieven Verhoye[2], Freya Van Houtte[2], Anna Pasetto[1], Stephan Urban[3], Philip Meuleman[2], Matti Sällberg[1]. Email: lars.frelin@ki.se

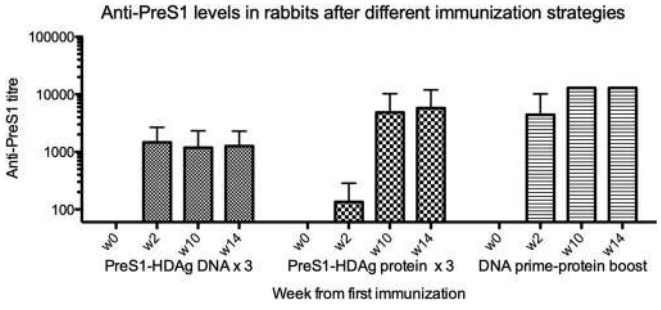
Background and aims: Chronic hepatitis B and D virus (HBV/HDV) infections are a major cause of severe liver disease and cancer that generally require lifelong therapy. A hallmark of chronic HBV infection is the profound T cell dysfunction/tolerance to viral proteins, and strategies to break this tolerance may therefore contribute to achieving functional cures. The HDV antigen acts as a heterologous antigen and supports HBV-specific immunactivation, leading to enhanced anti-HBV antibody and T cell responses. Its incorporation into an immunotherapeutic approach to enhance neutralizing antibody and T-cell responses to HBV preS1 is therefore being investigated.
Method: Plasmid DNA and fusion proteins containing HBV preS1 and HDAg sequences were expressed in E. coli. Antibody and T-cell responses directed against preS1 and HDAg after DNA-prime protein boost immunization were assessed in rabbits and in wild type and HBsAg-transgenic mice. Protection against HBV/HDV co-infection, and HDV super-infection was assessed in uPA-Scid mice repopulated with human hepatocytes against in vivo.
Results: A DNA prime protein boost immunization resulted in superior anti-preS1 and anti-HDAg antibody and T-cell responses in mice and rabbits compared to repeated immunization with DNA or protein alone (Figure 1). Antibody titres resulting from immunization were similar across HBV genotypes A-H. The induced antibodies also had broadly neutralizing activity against both HBV and HDV *in vitro*. Immunization of wild-type and HBsAg transgenic C57BL/6 mice resulted in equivalent antibody titres, supporting the role of HDAg in circumventing T cell tolerance to HBV. Passive transfer of antiserum from immunized wild-type mice resulted in protection against HBV/HDV co-infection in 3/3 mice with humanized livers compared to 0/4 control animals that received serum from un-immunized mice. Passive transfer of antiserum from immunized wild-type mice resulted in protection against HDV superinfection in 3/3 mice with humanized livers that had been infected with HBV 8 weeks previously, compared to 0/4 control animals that received serum from un-immunized mice.



Conclusion: This novel prime-boost immunotherapy circumvents immune tolerance and induces endogenous production of high levels of broadly neutralizing preS1 antibodies and T cells against preS1 and HDAg. Our results merits further investigation as a curative strategy for HBV mono-infection and HBV/HDV co-infection.

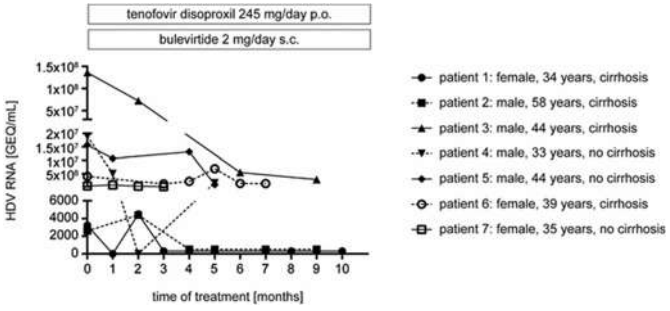
Email: florian.vanboemmel@medizin.uni-leipzig.de

Background and aims: The hepatitis B and D virus (HBV/HDV) hepatocyte entry inhibitor bulevirtide (BVL) is available in Europe since July 2020. Real-world data on efficacy and safety of BVL in patients with chronic hepatitis delta (CHD) are sparse. We report efficacy and tolerability of BVL treatment in patients with CHD.
Method: CHD patients were treated with BLV 2 mg/day in combination with tenofovir disoproxil fumarate (TDF) 245 mg/day. HDV RNA and HBV DNA were quantified by real-time PCR based assays (HDV: Roche Diagnostics, lower limit of detection (LLD) 150 genome equivalents (GEQ)/ml; HBV: Abbott Molecular, LLD 10 IU/m), and HBV surface antigen (HBsAg) by the ARCHITECT assay (Abbott Molecular, sensitivity 0.05 IU/ml).
Results: 7 patients were recruited (4 male, age 41 ± 8.1 years, 5 Caucasians, 2 Asians, 4 with cirrhosis Child-Pugh A). Before BVL treatment initiation, median serum HDV RNA levels were $3.9 \times 10^6 \pm 4.96 \times 10^7$ [range 1.36×10^8] GEQ/ml, median serum HBV DNA 27 ± 203 [range 600] IU/ml, median serum HBsAg 1100 ± 16230 [range 47470] IU/ml and median elevation of alanine aminotransferase (ALT) levels 2.27 ± 1.81 [range 5.13] above upper limit of normal (ULN). After a mean follow-up of 6.7 months, improvement >50% or normalization of ALT was observed in 5/7 patients, suppression of HDV RNA below the detection limit in 2/7, reduction of HDV RNA >2 log GEQ/ml in 2/7, reduction of HDV RNA <2 log GEQ/ml in 2/7 and HDV rebound in 1 patient. Complete virological responders (n = 2, both with cirrhosis) had low HDV RNA levels at baseline (3.22×10^3 and 3.24×10^3 GEQ/ml) and showed a normalization of ALT after 9 or 10 months of treatment. Partial virological responders >2 log GEQ/ml (n = 2, 1 with cirrhosis) presented with higher baseline HDV RNA (1.36×10^8 and 1.57×10^7 GEQ/ml) and showed a reduction of ALT >50% after 5 or 9 months of treatment. Virological non-responders <2 log GEQ/ml (n = 2, 1 with cirrhosis) presented with initial HDV RNA levels of 3.9×10^6 and 3.5×10^5 GEQ/ml, and showed no or <50% reduction of ALT after 3 or 7 months of treatment. 1 patient (no cirrhosis, baseline HDV-RNA 1.9×10^7 GEQ/ml) showed a rebound of serum HDV RNA to 1.48×10^6 GEQ/ml after initial complete response (5 months of treatment), while ALT normalized. HBV DNA was undetectable in 6/7 patients at the end of observation. No BLV related adverse effects were recorded in all individuals.



Conclusion: BVL is well tolerated and leads to a biochemical response in the majority of patients, but the virological response is variable, depending on the viral load at baseline. Further studies should evaluate BLV dose adjustments or peginterferon alfa-2a combination treatments in patients showing insufficient virologic responses.

SAT415

Higher rates of virological relapse after nucleos (t)ide analogue withdrawal in HBeAg-negative versus positive chronic hepatitis B patients: results from a global, multi-ethnic cohort of patients with chronic hepatitis B (RETRACT-B Study)

Email: sjchoi0731@gmail.com

Background and aims: Whether hepatitis B e antigen (HBeAg) status at the start of nucleos (t)ide analogue (NA) therapy is associated with differential outcomes following NA withdrawal remains unclear. We aimed to compare rates of virological and clinical relapse, ALT flares, and hepatitis B surface antigen (HBsAg) loss in chronic hepatitis B (CHB) patients who were HBeAg-positive versus negative at the start of the most recent NA therapy (SOT).
Method: We investigated outcomes in CHB patients who stopped NA therapy from centres across North America, Europe, and Asia. All included patients were HBeAg-negative and non-cirrhotic at NA discontinuation. Rates of virological (HBV DNA ≥2, 000 IU/ml) or clinical (HBV DNA ≥2, 000 IU/ml and ALT ≥2 × ULN) relapse, ALT flares (≥5 or 10 × ULN), and HBsAg loss were compared between SOT HBeAg-positive and -negative patients, using race-stratified Cox regression adjusting for age, sex, NA therapy duration, treatment history, and ALT and HBsAg levels at the end of therapy (EOT).
Results: Of 1, 360 CHB patients included, 1, 142 were HBeAg-negative and 218 HBeAg-positive at SOT. The HBeAg-negative group was older (54 vs 43 years) and had a higher proportion of males (73% vs 65%), fewer patients previously treated with interferon (8% vs 14%), and lower HBsAg levels at EOT (2.6 vs 3.1 $\log_{10}$ IU/ml), all $p < 0.05$. The duration of NA therapy and racial composition were comparable between the two groups. HBeAg-negativity versus positivity at SOT was significantly associated with a higher rate of virological relapse (adjusted hazard ratio [aHR] 1.9, $p < 0.01$) but not clinical relapse (aHR 1.2, $p = 0.14$). Other significant predictors of virological relapse included higher HBsAg levels at EOT ($\log_{10}$ IU/ml, aHR 1.7), TDF versus ETV treatment (aHR 1.6), and prior use of other NA (aHR 1.2), all $p < 0.05$. For clinical relapse, higher HBsAg ($\log_{10}$ IU/ml, aHR 1.9) and ALT (× ULN, aHR 1.4) levels at SOT, TDF versus ETV treatment (aHR 1.6), prior use of other NAs (aHR 1.5), and male sex (aHR 1.6) were identified as predictors, all $p < 0.01$. No differences in rates of ALT flares (≥5 or 10 × ULN) or HBsAg loss were observed.

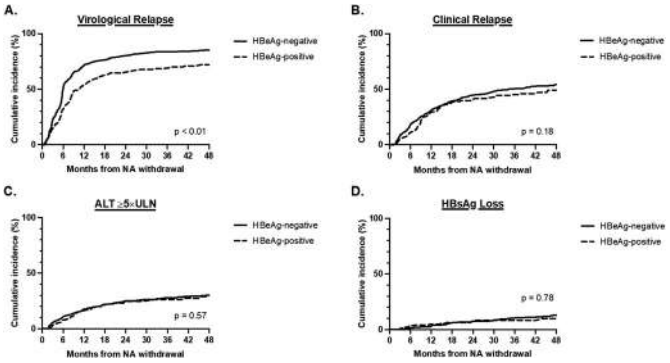

Figure: Unadjusted cumulative incidence of: A) virological relapse; B) clinical relapse; C) ALT flare ≥5 × ULN; D) HBsAg loss by HBeAg status at the start of nucleos (t)ide analogue therapy.

Conclusion: CHB patients who were HBeAg-negative versus positive at SOT experienced higher rates of virological relapse, despite having longer time spent in the HBeAg-negative phase of infection. Off-therapy ALT elevations and HBsAg loss were not associated with HBeAg status at SOT.

SAT416

Real life efficacy and tolerability of Tenofovir alafenamde fumarate in liver transplant recipients: a multicenter study

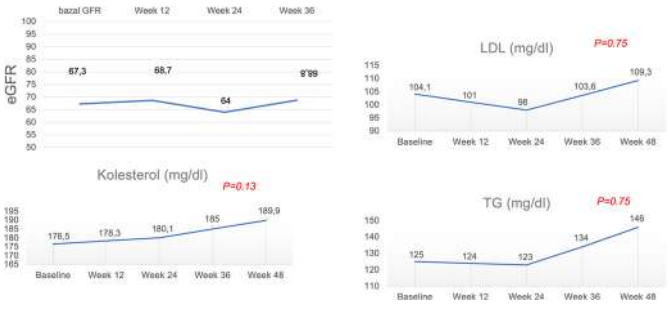
Email: sunayapali@gmail.com

Background and aims: We aimed to determine the real-life efficacy and tolerability of tenofovir alafenamide fumarate (TAF) in liver transplant recipients.
Method: This a multicenter retrospective study. A total of 196 recipients were enrolled into the study. The primary end points were virological and biochemical response at week 24 and 48 of the treatment, the secondary end point was tolerability of TAF. Median duration of the TAF treatment was 11.6 months (range: 6–60 months).
Results: A total of 108 recipients who had at least 6 months follow-up were included in the analysis. Mean age was 58 ± 10 years, 74% were male. Of these, 80% were on tacrolimus-based and 38% on everolimus-based treatments. Median duration from LT to TAF initiation was 24.5 months (range:0–252 months). Seventeen patients received TAF treatment as first-line therapy, whereas 91 patients switched to TAF treatment. Renal dysfunction and osteoporosis were the most common indications for TAF treatment.
Baseline median serum ALT level was 25 IU/L (range: 10–96 U/L) and baseline median HBV DNA level was 890 IU/ml, respectively. Virological and biochemical response were 90% and 71% at week

24, and 100% and 92% at week 48, respectively. From baseline to the last follow-up, improvement in ALT at every 24 weeks compared by linear mixed model was significant; –3.226 IU/ml [95% CI: (–5.62)-(–0.84); *p = 0.009*]. After the switch to TAF treatment, none of the patients experienced HBV reactivation.
TAF treatment was well tolerated. Renal functions and lipid profile remained stable during TAF treatment (Figure 1). No serious adverse events were reported. No graft rejection was observed.

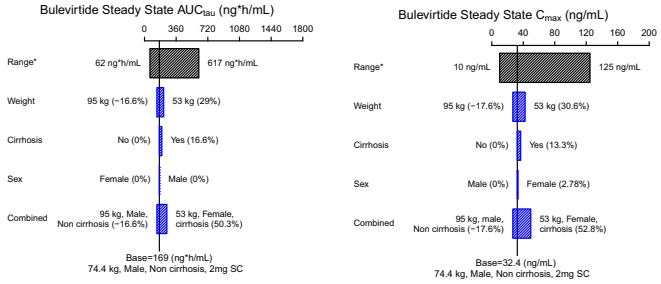


Conclusion: The present study indicates that TAF is effective and tolerable in liver transplant recipients.

SAT417
Impact of patient-related factors on the pharmacokinetics of Bulevirtide

Renu Singh[1], Parag Kumar[1], Rory Leisegang[1], Francesco Bellanti[2], Craig Comisar[2], Kishore Polireddy[2], Vithika Suri[1], Dmitry Manuilov[1], John F. Flaherty[1], Sandhya Girish[1]. [1]*Gilead Sciences, Foster City, United States;* [2]*Certara Inc, Princeton, United States*
Email: renu.singh16@gilead.com

Background and aims: Bulevirtide (BLV) is a novel, first-in-class, potent, highly selective hepatocyte entry inhibitor of the hepatitis delta virus (HDV) that binds to and inactivates sodium taurocholate cotransporting polypeptide (NTCP), an essential HDV entry receptor. BLV is a 47-amino acid lipopeptide, recommended at a 2 mg dose by daily subcutaneous (SC) injection. Our objective was to characterize the population PK of BLV in participants with or without HDV and evaluate the effect of covariates on its PK to characterize intrinsic/extrinsic factors that might affect BLV exposures.
Method: Comprehensive PK data from participants in 2 Phase 1 studies (N = 48), 3 Phase 2 studies (N = 314), and 1 Phase 3 study (N = 99) were analysed using nonlinear mixed-effects modeling (NONMEM®) software. Individual BLV PK parameter estimates were generated and the impact of patient-specific covariates (eg. baseline (BL) body weight (WT), age, sex, race, BLV dose, health status, BL HDV viral load, creatinine clearance, presence of anti-drug antibodies, liver function tests, comedications (oral antivirals and pegylated interferon alpha) were evaluated.
Results: Nonlinear PK was observed with greater than dose proportional increase in BLV exposure. The final BLV model was described by a 2-compartment model with sequential zero- first-order absorption and first-order elimination from the central compartment. An absolute SC bioavailability of 53.4% was estimated with a dose effect on clearance adequately characterizing the non-linear PK.
WT was the most influential covariate, with a change in BLV exposures ranging from – 17.6% to +30.6% (relative to exposures at the median WT) for participants with extreme covariate values (ie, 5th and 95th WT percentiles), respectively (Figure 1). Additionally, participants with compensated cirrhosis were found to have 17% higher exposure, as compared to participants without cirrhosis.

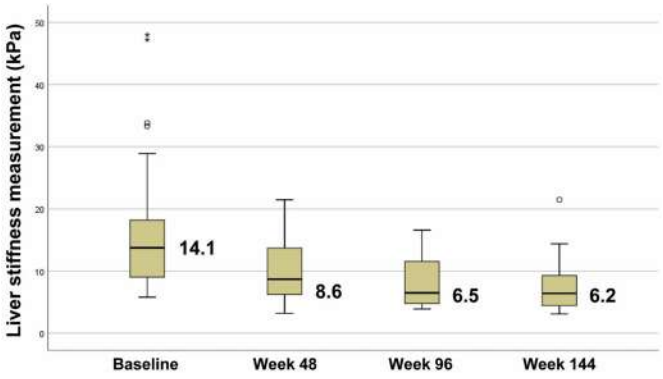


Conclusion: Across a wide range of participants, BLV exposures were inversely correlated with WT along with slightly higher exposures in participants with cirrhosis. These changes in BLV exposures were not considered clinically meaningful. These data support the use of the recommended 2 mg once daily dose across the spectrum of participants with varied patient-related factors.

SAT418
Reduction of liver stiffness in chronic hepatitis B patients treated with tenofovir disoproxil fumarate: a prospective observational study

Heejin Cho[1], Yun Bin Lee[1,2], Yeonjung Ha[2], Young Eun Chon[2], Mi Na Kim[2], Joo Ho Lee[2], Seong Gyu Hwang[2]. [1]*Department of Internal Medicine and Liver Research Institute, Seoul National University College of Medicine, Seoul, Korea, Rep. of South;* [2]*Department of Internal Medicine, CHA Bundang Medical Center, Seongnam, Korea, Rep. of South*
Email: yblee@snu.ac.kr

Background and aims: Regression of hepatic fibrosis during antiviral therapy in patients with chronic hepatitis B has been demonstrated, but data about influence of long-term treatment with tenofovir disoproxil fumarate (TDF) on liver stiffness (LS) measured by transient elastography are scarce. We aimed to investigate changes in LS values during 144-week antiviral therapy with TDF in patients with chronic hepatitis B.
Method: A total of 48 treatment-naïve patients with chronic hepatitis B who initiated TDF therapy were enrolled and followed up for 144 weeks. Laboratory tests and LS measurements were performed at baseline and repeated at weeks 12, 24, 48, 96 and 144. A significant decline of LS was defined as ≥30% drop of LS value from the baseline to week 96.
Results: Among the 48 enrolled patients, 11 patients were lost to follow-up before 96 weeks and 37 patients were included in the analysis (median age, 45 years [interquartile range, 35–55.5 years]; 20 men [54.1%]). During antiviral therapy with TDF, the median LS value decreased from 14.1 kPa to 8.6 kPa, 6.5 kPa, and 6.2 kPa at weeks 48, 96 and 144, respectively (all $P < 0.001$; Figure 1). At week 96, virologic and biochemical response were achieved in 34 patients (91.9%) and 33 patients (89.2%), respectively. Moreover, 21 of 36 patients (58.3%) in whom the 96-week LS values were measured showed a significant decline of LS and higher baseline LS value was a single independent predictor of a significant decline of LS (odds ratio, 1.212; 95% confidence interval, 1.027–1.431; $P = 0.023$).



Conclusion: During the long-term antiviral therapy with TDF, LS values declined significantly in treatment-naïve patients with chronic hepatitis B.

Toll-like receptor 8 agonism activates monocytes and induces antiviral cytokine production by T-cells in HIV and chronic hepatitis B coinfection

Lydia Tang[1,2], Natarajan Ayithan[1,2], Shyamasundaran Kottilil[1,2].
[1]University of Maryland, Baltimore, Baltimore, United States; [2]Institute of Human Virology, Baltimore, United States
Email: lydiatang@ihv.umaryland.edu

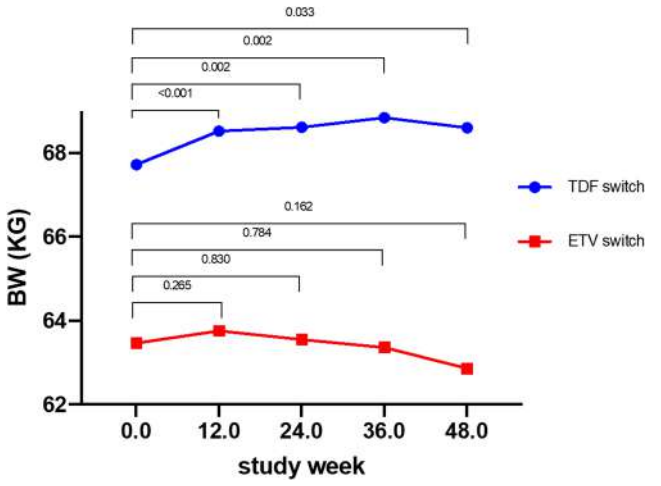
Background and aims: In people with HIV/CHB co-infection, progression and mortality from liver disease is worse than among people without HIV. There is no effective cure for CHB. Immune-targeting therapy aimed at recovering HBV-specific immunity is a strategy for CHB cure. Toll-like receptors (TLRs) are a group of pattern recognition receptors identified as immunomodulatory targets for CHB treatment. TLRs activate antigen presenting cells, priming the adaptive immune system. In clinical trial, TLR8 agonism was shown to induce antiviral cytokine production and enhanced HBV-specific B-cell responses in CHB. The aim of this study is to evaluate the effect of HIV co-infection with CHB on HBV-specific immune responses to TLR8 agonism.
Method: CD14+ monocytes and CD3+ T cells were isolated from autologous peripheral blood mononuclear cell samples by pan T cell negative selection (Miltenyi Biotec) or FACSAria sorting from people with CHB and HIV/CHB co-infection enrolled in an observational natural history study at the Institute of Human Virology, University of Maryland Baltimore. Monocytes were stimulated with ssRNA40, a TLR8 agonist, then pulsed with HBV peptide and co-cultured with autologous T cells. Activation of monocytes by TLR8 stimulation was evaluated by flow cytometry immunophenotyping and compared with unstimulated monocytes. Activation of HBV-specific CD8 T cells by TLR8 stimulated monocytes was then evaluated by measuring (by intracellular staining and flow cytometry) production of pro-inflammatory cytokines. For statistical analysis student's t-test was used with $p < 0.05$ considered significant.
Results: Samples from 7 patients with CHB and 7 with HIV/CHB were analyzed. At baseline, monocyte population was larger in CHB compared to HIV/CHB ($p = 0.03$) with higher HLA-DR, CD11c and IL6 expression and induced stronger HBV-specific CD8 T cell responses than HIV/CHB with higher induction of TNF alpha ($p = 0.01$), IFN gamma ($p = 0.002$), IL-2 ($p = 0.003$), and IL-21 ($p = 0.03$). *In vitro* treatment of monocytes with ssRNA40 was associated with increased CD40 ($p = 0.03$), CD86 ($p = 0.005$), CD69 and HLA-DR ($p = 0.008$) expression in CHB but not in HIV/CHB. Treatment of autologous T cells with TLR8-stimulated monocytes resulted in increased TNF alpha ($p = 0.02$), IFN gamma ($p = 0.04$), and IL-21 ($p = 0.03$) by CD8 T cells in the HIV/CHB patients. No significant changes were seen in the CHB T cells.
Conclusion: TLR8 agonism activated monocytes. These, in turn, were able to activate HBV-specific antiviral CD8 T cell functions. In HIV/CHB samples, this effect on T cells was seen despite the absence of significant changes in the monocytes with TLR8 treatment, supporting further study of toll-like receptor agonism for CHB treatment in people with HIV/CHB.

SAT420

Comparison of body weight and lipid profiles following tenofovir disoproxil fumarate or entecavir switching to tenofovir alafenamide-an interim analysis

Pin-Nan Cheng[1], Chun-Jen Liu[2], Jyh-Jou Chen[3], I-Cher Feng[4], Hsing-Tao Kuo[4], Pei-Lun Lee[3], Ming-Lung Yu[5], Yencheng Chiu[1], Chiu Hung-Chih[1], Shih-Chieh Chien[1], Pei-Jer Chen[2]. *[1]National Cheng Kung University Hospital, Department of Internal Medicine, Tainan, Taiwan; [2]National Taiwan University Hospital, Department of Internal MedicineT, Taipei, Taiwan; [3]Chi-Mei Medical Center, Liouying, Tainan, Taiwan, Department of Internal medicine, Tainan, Taiwan; [4]Chi-Mei Medical Center, Tainan, Taiwan, Department of Internal Medicine, Tainan, Taiwan; [5]Kaohsiung Medical University Hospital, Kaohsiung, Taiwan, Department of Internal Medicine, Kaohsiung, Taiwan*
Email: pncheng@mail.ncku.edu.tw

Background and aims: Body weight (BW) and lipid profiles changes have been reported in HIV infected patients treated with tenofovir alafenamide (TAF) containing regimens. Tenofovir disoproxil fumarate (TDF) treated chronic hepatitis B (CHB) patients exhibited lower lipid profiles in phase III study. The impact of TAF, as a new drug for CHB treatment, on BW and lipid profiles remains unclear and needs to investigate.
Method: This was a prospective, multi-center, observational study. CHB patients from five hospitals in Taiwan treated with TDF or entecavir for at least 1 years and then switched to TAF were enrolled. Measurement of biochemical, virological, and atherosclerotic cardiovascular disease (ASCVD) risk score at baseline and then at an interval of 12 weeks or 48 weeks by items. Primary end point was the body weight changes following switching to TAF or entecavir. Secondary end points included ASCVD score changes, and changes of lipid and sugar profiles following switching to TAF.
Results: At the end of October 2021, 99 patients, including 63 males with a mean age of 54.3 years, completed a 48 weeks follow-up were enrolled for analysis. Of them, 65 and 34 patients treated with TDF or entecavir before switching to TAF, respectively. At baseline, significantly lower TG, Chol, and LDL (all $p < 0.05$) in TDF switch group than entecavir switch group. Figure 1 shows the BW changes during 48 weeks of TAF treatment. Following switching to TAF, significant BW gain was present from12 weeks and maintained thereafter until 48 weeks in TDF switch group comparing with baseline BW. In contrast, BW remained unchanged in entecavir switch group during 48 weeks of observation. In TDF switch group but not entecavir switch group, all of the lipid profiles including TG (88.6 ± 48.3 vs. 104.4 ± 66.6 mg/dL, $p = 0.014$), Chol (160.3 ± 33.1 vs. 188.1 ± 38.9 mg/dL, $p < 0.001$), LDL (104.9 ± 28.9 vs. 121.9 ± 34.2 mg/dL, $p < 0.001$), and HDL (48.2 ± 11.7 vs. 58.2 ± 13.2 mg/dL, $p < 0.001$) were significantly increased following 48-week TAF treatment. ASCVD risk score had a trend toward a significant increase in TDF switch group (6.3 ± 9.5 vs. 7.0 ± 9.4, $p = 0.051$), but not in entecavir switch group (12.5 ± 16.7 vs. 13.2 ± 18.5, $p = 0.343$).



Conclusion: Following TDF switch to TAF, BW increased shortly and the lipid-lowering effects of TDF diminished. Combining BW gain and increase of lipid profiles, CVD risk may need to monitor closely.

Email: sunayapali@gmail.com

Background and aims: We aimed to determine the real-life efficacy and tolerability of tenofovir alafenamide fumarate (TAF) in patients with hepatitis B virus (HBV)-related cirrhosis
Method: This multicenter study included a total of 91 patients with HBV-related cirrhosis who received TAF treatment as first line treatment or switched to TAF. The primary end points were virological and biochemical response at week 24 and 48 of the treatment, the secondary end point was the assessment of safety and tolerability of TAF. Median follow-up on TAF treatment was 13.7 (range 6–26) months.
Results: Of the 91 patients with cirrhosis, 43 patients who had at least 6 months of follow-up were included in the analysis. Mean age was 64 ± 11 years and %63 was male. Baseline median MELD score was 10 (range: 9–14), and 4 (9.3%) were decompensated. Six (14%) patients received TAF treatment as first-line therapy. Baseline median serum ALT and HBV DNA levels were 25 IU/L (range: 10–96 U/L) and 51000 IU/ml, respectively. Thirty-seven (86%) patients switched to TAF treatment. Renal dysfunction and hypophosphatemia were the most common indications for TAF treatment.
Virological and biochemical responses were 67% and 67% at week 24 and 100% and 83% at week 48, respectively. Serum HBV DNA was undetectable at week 36 among all patients with detectable HBV DNA at baseline. From baseline to the last follow-up, improvement in ALT at every 24 weeks compared by linear mixed model was significant; −1.13 IU/ml [95% CI: (−1.8)- (−0.45), $p = 0.005$]. None of the patients experienced HBV reactivation. During TAF treatment, renal functions and lipid profile were stable (Figure 1). No serious adverse effect was observed.

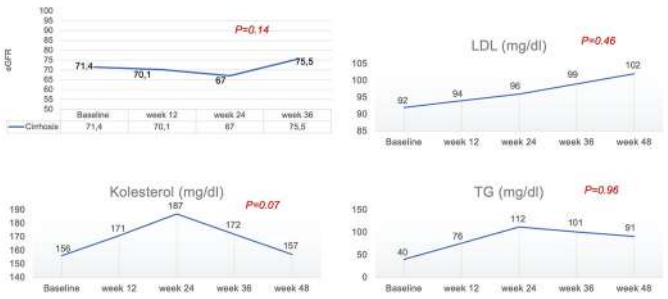

Figure: Changes in estimated glomerular filtration rate (GFR) and lipid profile

Conclusion: Based on the preliminary results of this study, TAF is effective and tolerable in patients with HBV-related compensated and decompensated cirrhosis

SAT422

Effects of the siRNA JNJ-3989 and/or the capsid assembly modulator (CAM-N) JNJ-6379 on viral markers of chronic hepatitis B (CHB): results from the REEF-1 study

Man-Fung Yuen[1], Tarik Asselah[2], Ira M Jacobson[3], Maurizia Brunetto[4], Harry Janssen[5], Tetsuo Takehara[6], Jinlin Hou[7], Thomas Kakuda[8], Tom Lambrecht[9], Ronald Kalmeijer[8], Carine Guinard-Azadian[10], Cristiana Mayer[8], John Jerzorwski[8], Thierry Verbinnen[9], Oliver Lenz[9], Umesh Shukla[8], Michael Biermer[11]. *[1]Queen Mary Hospital, Department of Medicine and State Key Laboratory of Liver Research, The University of Hong Kong, Hong Kong, China; [2]Université de Paris, INSERM UMR1149 and Hôpital Beaujon, APHP, Clichy, France; [3]New York University Grossman School of Medicine, New York, New York, United States; [4]University of Pisa, Pisa, Italy; [5]University of Toronto, Toronto, Canada; [6]Osaka University Graduate School of Medicine, Osaka, Japan; [7]Nanfang Hospital, Southern Medical University, Guangzhou, China; [8]Janssen Research and Development, United States; [9]Janssen Research and Development, Belgium; [10]Janssen Research and Development, France; [11]Janssen Research and Development, Germany*
Email: mfyuen@hku.hk

Background and aims: JNJ-3989 is an siRNA targeting all hepatitis B virus (HBV) RNAs thereby reducing viral proteins. JNJ-6379, a CAM-N, prevents the formation of infectious viral genome-containing capsids. The REEF-1 study (NCT03982186) assessed the efficacy and safety of monthly s.c. injections of JNJ-3989 (40, 100, and 200 mg) and/or 250 mg daily oral JNJ-6379 versus placebo in combination with daily oral NA in not currently treated (NCT) or virologically suppressed (VS) HBeAg positive (HBeAg+) or negative (HBeAg-) CHB patients.
Method: In this Phase 2b, multicenter, active-controlled study, CHB patients (N = 470) were randomized and dosed for a 48-week double-blind placebo-controlled treatment period. Changes in viral markers were assessed. Data from week 24 follow-up (FU W24) are presented.
Results: JNJ-3989 reduced HBsAg in a dose dependent manner with the greatest decline at the 200 mg dose (mean [SD] reduction of 2.6 [0.10] $\log_{10}$ IU/ml) at week 48 (W48) versus control (0.22 [0.85] $\log_{10}$ IU/ml; $P < 0.001$). By FU W24, 47.0% of patients in the JNJ-3989 200 mg group had HBsAg <100 IU/ml. HBsAg reduction from baseline (BL) remained ≥1 log for 84.3% and ≥2 log for 37.3% of patients in the JNJ-3989 200 mg group at FU W24. 19.1% and 29.7% of patients met NA stopping criteria (ALT <3x ULN, HBV DNA <LLOQ, HBeAg-, HBsAg <10 IU/ml) with JNJ-3989 200 mg at W48 and until FU W24, respectively. Only 3 of 66 (4.5%) patients who met NA stopping criteria met NA re-starting criteria during the follow-up.
Declines in HBeAg and HBcrAg were generally dose dependent and greater in patients with higher baseline (BL) levels, thus reductions were most pronounced in NCT HBeAg+ patients with mean (SD) change from BL at W48 of – 2.22 (1.14) $\log_{10}$ IU/ml for HBeAg and – 2.56 (0.93) $\log_{10}$ U/ml for HBcrAg in the 200 mg JNJ-3989 group

versus – 1.45 (1.67) and – 1.69 (1.41) for control; mean (SD) change from BL at FU W24 was – 2.52 (1.23) for HBeAg and – 2.74 (1.11) for HBcrAg with JNJ-3989 200 mg versus – 1.50 (1.70) and – 1.71 (1.57) for control. Despite lower BL HBeAg and HBcrAg levels in VS and/or HBeAg- patients, seroclearance of these markers was infrequent. In NCT HBeAg+ patients, mean (SE) HBV RNA change from BL at W48 was – 3.66 (1.11) $\log_{10}$ copies/ml for JNJ-3989 200 mg and – 4.68 (1.16) for JNJ-3989 100 mg+JNJ-6379+NA versus – 1.34 (1.40) for control. The respective HBV RNA undetectability rates at W48 were 29%, 100% and 0%. Off-treatment HBV RNA levels generally remained stable or declined in the JNJ-3989 arms, but increased in the JNJ-6379 arms consistent with the direct inhibition of HBV RNA release by JNJ-6379. Numerically greater decline in HBV DNA was seen with JNJ-3989 100 and 200 mg and JNJ-6379 containing arms versus control.
Conclusion: Treatment with JNJ-3989 reduced levels of HBV markers in a dose dependent manner. Reductions in viral markers were most pronounced in NCT HBeAg+ patients.

Email: vbichko@gmail.com

Background and aims: Hepatitis B virus (HBV) capsid assembly modulators (CAMs) are clinically validated agents for the chronic HBV drug development, with a potential for HBV cure. Safety, tolerability, and pharmacokinetics of GST-HG141, a novel CAM, in healthy subjects (NCT04386915) has been reported previously [Li et al., Antimicrob Agents Chemother. 2021:65 (10)]. The aim of this study was to evaluate safety, PK and antiviral activity of multiple doses of GST-HG141 in patients with chronic hepatitis B (CHB).
Method: A multi-center, randomized, double-blind, placebo-controlled multiple ascending-dose phase Ib study (NCT04868981). Patients with CHB, who were not treated with interferon or nucleosides (>12 or >6 months, respectively), HBeAg-positive or negative (serum HBV DNA $\geq 2 \times 10^5$ or $\geq 2 \times 10^4$ IU/ml, respectively) received oral BID doses of GST-HG141 (25, 50 and 100 mg) for 28 days. Ten patients in each cohort were randomized to receive a drug or placebo (4:1). A validated LC-MS/MS method was used to quantify GST-HG141 in plasma. The PK parameters were calculated with WinNonlin 8.3 software. Serum HBV DNA and HBV pgRNA were determined using Quantitative Real-Time PCR, serum HBV antigens-by ELISA methods.
Results: Administration of 25, 50 or 100 mg of GST-HG141 BID for 28 days was well tolerated. No SAEs or dose-related increase in number of AEs was reported. There were no TEAEs leading to discontinuation of treatment. A rapid and robust decline in serum HBV DNA was observed (median 2.9, 3.3 and 3.5 $\log_{10}$ IU/ml for 25, 50 and 100 mg dose cohorts, respectively). Serum HBV pgRNA levels decreased by median 2.2 $\log_{10}$ U/ml in all dose cohorts, with a maximum median decrease of 2.40 $\log_{10}$ U/ml in the 100 mg dose cohort at day 29 of treatment. No virus breakthrough was noted. No statistically significant decline in serum HBsAg, HBeAg or HBcrAg was observed. However, there was a trend of serum HBeAg and HBcrAg decrease in patients, receiving the drug. Plasma GST-HG141 exposure increased relatively proportionally with the dose. Moderate accumulation (mean values 1.67–2.38) was seen with dosing for 28 days.
Conclusion: Oral BID dosing with 25, 50 or 100 mg of GST-HG141 for 28 days was safe and well tolerated. It resulted in rapid, robust and dose-dependent decline in serum HBV DNA. Serum HBV pgRNA levels also decreased significantly. Plasma GST-HG141 exposure was nearly dose-proportional. Further clinical development of GST-HG141 for CHB is warranted. Pase II drug combination study with GST-HG141 and nucleoside analogs is underway.

SAT424

Predictors of sustained response in hepatitis B surface antigen-negative patients after peginterferon therapy: an observational study

Jun Chen[1], Yan Huang[1]. [1]*Xiangya Hospital Central South University, Department of Infectious Diseases, Changsha, China*
Email: drhyan@126.com

Background and aims: Hepatitis B surface antigen (HBsAg) clearance is considered the functional cure and recommended as the optimal end point of antiviral therapy for chronic hepatitis B (CHB) patients. Although patients could achieve HBsAg clearance after peginterferon treatment, HBsAg reversal occurred in some patients. This study aimed to investigate predictors of sustained response in HBsAg-negative patients after peginterferon therapy.
Method: CHB patients with HBsAg clearance after peginterferon therapy were enrolled from 2018 to 2021. Patients were followed up for 48 weeks after functional cure. Patients with sustained negative HBsAg were non-recurrence group and patients with HBsAg reversal were recurrence group.
Results: A total of 176 patients achieved HBsAg clearance after peginterferon treatment. 113 patients were included at the 48-week follow-up (104 in non-recurrence group, 9 in recurrence group). The cumulative rates of HBsAg reversion at 12 weeks, 24 weeks, 36 weeks, and 48 weeks after achieving functional cure were 2.89%, 3.85%, 6.72%, and 7.92%, respectively. HBsAb at the end of treatment was significantly higher in non-recurrence patients compared with recurrence patients at week 48 ($p < 0.001$).

Table: Analysis of potential predictors for sustained response

Variables	Non-recurrence (N = 104)	Recurrence (N = 9)	p value
HBeAg at baseline (S/CO)	0.36 [0.32, 0.42]	0.35 [0.27, 0.36]	0.171
HBsAb at baseline (mIU/ml)	4.53 [1.65, 18.76]	9.26 [7.24, 30.79]	0.359
HbcAb at baseline (S/CO)	7.64 ± 1.54	7.94 ± 1.27	0.567
HBeAg at the end of treatment (S/CO)	0.46 ± 0.60	7.51 ± 12.40	0.397
HBsAb at the end of treatment (mIU/ml)	416.50 ± 386.61	13.43 ± 8.32	<0.001
HbcAb at the end of treatment (S/CO)	7.89 ± 1.38	8.50 ± 0.65	0.382
Consolidation treatment time, n (%)			0.644
0–12 weeks	15 (14.42)	2 (22.22)	
12–24 weeks	29 (27.89)	1 (11.11)	
24–36 weeks	27 (25.96)	2 (22.22)	
36–48 weeks	33 (31.73)	4 (44.44)	

Conclusion: HBsAb level at the end of treatment is a potential predictor of sustained response. Evaluating HBsAb level when peginterferon discontinued can improve sustained functional cure.

Background and aims: Tenofovir Alafenamide (TAF) is a novel prodrug of tenofovir (TFV) with non-inferior efficacy and greater plasma stability resulting in enhanced delivery of TFV and reduced plasma concentrations leading to an improved bone and renal safety profile over tenofovir disoproxil fumarate (TDF).TAF is approved for use in adult patients with Chronic Hepatitis B (CHB). However, safety and efficacy data in pediatric CHB patients are lacking. In a multi-center, randomized, double-blind, placebo-controlled trial we evaluated the safety and efficacy of TAF in children 6 years and older weighing ≥25 kg.

Method: Males or females aged 12 to <18 years weighing ≥35 kg (Cohort 1), and 6 to <12 years weighing ≥25 kg (Cohort 2, Group 1), with HBV DNA $\geq 2 \times 10^4$ IU/ml, ALT ≥1.5 × ULN, and creatinine clearance (eGFR; Schwartz method) ≥80 ml/min were randomized (2:1) to TAF 25 mg or PBO daily for 24 weeks, after which all patients received open-label TAF for up to Week 240. The co-primary end points were the proportion with HBV DNA <20 IU/ml and safety (treatment-emergent [TE] serious adverse events [SAEs] and all TE adverse events [AEs]) at Week 24; other assessments included serological and biochemical responses, bone mineral density (BMD) (spine and whole body[minus head]), resistance surveillance and pharmacokinetics.

Results: 88 patients were randomized and treated (Cohort 1: TAF 47, PBO 23; Cohort 2 group 1: TAF 12, PBO 6). Baseline (BL) characteristics were similar; overall mean (range) age and mean (SD) weight were 14 (7–17) years and 50.9 (12.9) kg, respectively; 58% were male, 66% Asian, 68% had HBV DNA ≥8 log10 IU/ml and mean (SD) ALT 107 (118) U/L. 99% were HBeAg-positive, with genotypes D (44%), C (24%), and B (23%) being most common. Overall, at Week 24, 11/59 (19%) TAF and 0/29 PBO patients had HBV DNA <20 IU/ml (p = 0.0137); mean (SD) HBV DNA change from BL TAF vs PBO was – 4.98 (1.52) log10 IU/ml and – 0.10 (0.64) log10 IU/ml (p <0.0001), respectively. High BL viral load and genotype D were associated with lower rates of viral suppression. A higher proportion of TAF vs PBO patients had ALT normalization (TAF 67%, PBO 4%; p <0.0001), while the rate of HBeAg seroconversion was similar (TAF 7%, PBO 3%). Grade 3 or 4 AEs and SAEs related to study treatment were similar for TAF vs PBO. Slight fluctuations in eGFR were noted for both treatment groups during double blind treatment; however, no patient had eGFR <90 ml/min/1.73m^2 at Week 24. Mean % increases from BL to Week 24 in BMD were similar in the TAF vs PBO (spine: +1.6% vs. +1.9%; [p = 0.77]; whole body: +1.9% vs. +2.0%; [p = 0.83]). Viral resistance was not detected through Week 24. TAF and TFV plasma exposures were within range of adult reference cohorts

Conclusion: In pediatric CHB patients, viral suppression and ALT normalization were superior to placebo, while safety results, including changes in BMD, were similar for TAF and PBO at Week 24

SAT426

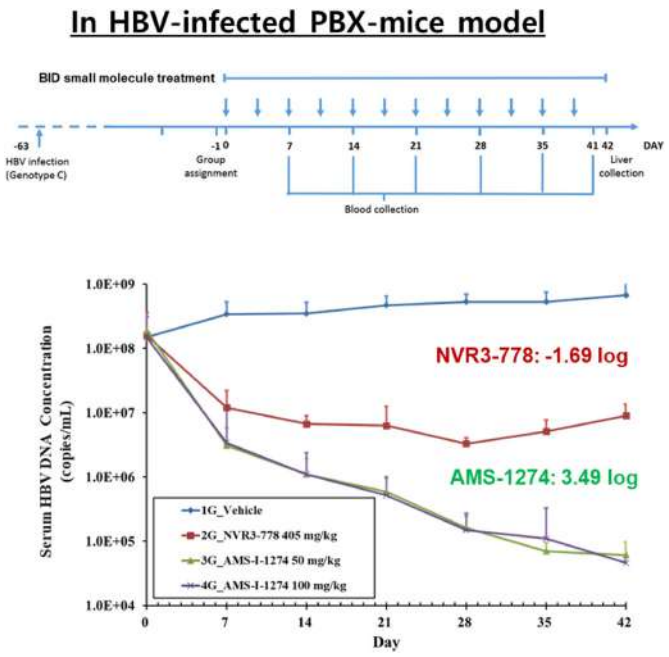
The discovery of AMS-I-1274, a high potent and orally active capsid-assembly modulator against hepatitis B virus

Nakcheol Jeong[1], Peppi Prasit[1], Jung-Hee Kim[1], Misun Lee[1], Heewoo Sim[1], Ryoon Ho Kim[1], Bo-Yeong Pak[1]. *[1]AM Sciences, Seoul, Korea, Rep. of South*
Email: njeong@amsciences.co.kr

Background and aims: Hepatitis B virus (HBV) infection leads to a wide spectrum of liver diseases ranging from acute to chronic hepatitis, cirrhosis, and hepatocellular carcinoma. New drugs that inhibit HBV replication are needed to enhance the treatment of chronic hepatitis B resulting in a higher number of durable responses and functional cures. Capsid-assembly modulators (CAM) are a novel class of HBV antivirals and they have been suggested to be effective anti-HBV agents in both preclinical and clinical studies. Here, we describe the discovery of a novel CAM through high-throughput screening. Lead optimization resulted in the identification of the clinical candidate, AMS-I-1274.

Method: HepAD38 cells were used for the investigation of efficacy including serum-shift assay and mechanism of action studies. HBV genotype (Gt), core-, and NA-resistant variants were evaluated in a HepG2/plasmid DNA transfection system. In vitro anti-viral activity and the effect on the cccDNA level were determined in HBV-infected HepG2-hNTCP cells and primary human hepatocytes (PHH). Pharmacokinetic (PK) properties were assessed in rodents and non-human primates. uPA/SCID mice with humanized liver (PXB-mice) were used for in vivo efficacy studies. Human hepatotoxicity was ascertained by in vitro model using Hurel micro liver.

Results: AMS-I-1274 inhibited HBV replication with an EC50 value of 6.2 nM. The presence of 40% of human serum albumin (HAS) caused a slight reduction in potency (EC50 = 15.6 nM, 2.5-fold increase). It also did not show any significant cytotoxicity (CC50 >100 μM). AMS-I-1274's anti-viral activity was 65-fold more potent compared to Novira 3–778 (EC50 = 5, 700 nM at 40% HSA). Capsid formation assay demonstrated that AMS-I-1274 induced the formation of empty capsid particles devoid of pgRNA and rcDNA (Class II capsid inhibitor). In a de novo HBV infection system, AMS-I-1274 inhibited viral replication with an EC50 value of 1.2 nM against HBV DNA, 8.4 nM against HBsAg, 13.8 nM against HBeAg, and 1.6 nM against intracellular HBV RNA, respectively, and reduced the level of cccDNA (EC50 = 772 nM). AMS-I-1274 showed pan-genotypic activity against isolates from Gt A to H. Most core variants showed no or modest decrease in potency; except for T33N (80-fold). NA-resistant variants remained fully susceptible to AMS-I-1274. PK results showed a good systemic exposure and high oral bioavailability in rodent and non-human primates. In HBV-infected PBX-mice, oral administration of AMS-I-1274 at 50 mg/kg twice daily resulted in robust multi-log reduction (-3.49 log10) of serum HBV DNA after 42 days of treatment.



Conclusion: Taken together, these data support that AMS-I-1274 is a novel class II capsid inhibitor with high anti-HBV potency and a favorable preclinical profile for clinical advancement.

Hoffmann-La Roche, Basel, Switzerland*
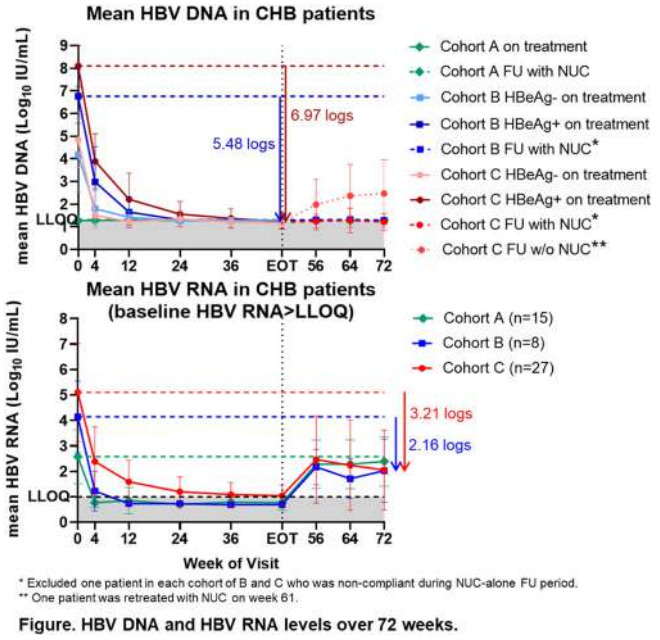
Email: qingyan.bo@roche.com

Background and aims: RO7049389 is a Class I HBV core protein allosteric modulator that induces abnormal capsid assembly, leading to depletion of functional core protein thereby inhibiting HBV DNA replication and cccDNA formation. Here we report antiviral and safety results following 48 weeks of RO7049389 plus NUC with/without Peg-IFN-alpha and 24 weeks of follow-up (NCT02952924).

Method: The ongoing open-label study enrolled NUC-suppressed patients to receive RO7049389+NUC (Cohort A, n = 32), and treatment naïve patients to receive RO7049389+NUC without (Cohort B, n = 10) or with (Cohort C, n = 30) Peg-IFN alpha for 48 weeks. At Week 48, all patients except for 5 Cohort C patients who met NUC stopping criteria (HBV DNA <LLOQ and HBsAg <100 IU/ml) entered a 24-week NUC-alone follow-up period.

Results: In Cohort A (11/32 HBeAg+; baseline HBV DNA <LLOQ), 30/32 patients completed the 72-week study with HBV DNA maintained <LLOQ. In all patients with quantifiable HBV RNA at baseline, HBV RNA declined to <LLOQ (10 copies/ml) by Week 4, but rebounded to approximately the baseline level during NUC-alone follow-up. In Cohort B (6/10 HBeAg+; mean baseline HBV DNA 5.7 log10IU/ml) and Cohort C (19/30 HBeAg+; mean baseline HBV DNA 6.9 log10IU/ml), a total of 37 patients (10 and 27 respectively) completed the 72-week study. All patients reached HBV DNA <LLOQ except for four Cohort C HBeAg+ patients who had detectable HBV DNA below 150 IU/ml by Week 48. During 24-week follow-up with NUC treatment, except for 2 patients with non-compliance issue, all other patients maintained HBV DNA <LLOQ or at low levels (below 250 IU/ml) and two further patients achieved <LLOQ by Week 72. In 30/33 treatment naive patients with quantifiable HBV RNA at baseline, HBV RNA decreased <LLOQ at Week 48, and remained an average of >2 log_{10}copies/ml below baseline at the end of follow-up. RO7049389+NUC ± Peg-IFN was safe and well tolerated up to 72 weeks. No RO7049389-related SAEs occurred; two early terminations in each cohort of A and C were due to non-safety reasons. Most common Grade 2–4 lab abnormalities (ALT elevations) were mainly observed in treatment-naïve patients and were accompanied by a decline in viral markers. ALT elevations resolved spontaneously and were not accompanied by significant changes in liver function.



* Excluded one patient in each cohort of B and C who was non-compliant during NUC-alone FU period.
** One patient was retreated with NUC on week 61.

Figure. HBV DNA and HBV RNA levels over 72 weeks.

Conclusion: RO7049389+NUC ± Peg-IFN demonstrated potent effect on viral nucleic acids suppression even in treatment naïve patients. HBV DNA was suppressed and maintained <LLOQ in the majority of treatment-naïve patients. Mean HBV RNA levels remained >2 log_{10}-copies/ml below baseline after the cessation of RO7049389, which may suggest a certain level of suppression in cccDNA level/transcriptional activity in treatment naïve patients. RO7049389 plus current standard of care for 48 weeks was safe and well tolerated, supporting further development in viremic patients.

Phase 1b/2a study of heterologous ChAdOx1-HBV/MVA-HBV therapeutic vaccination (VTP-300) combined with low-dose nivolumab (LDN) in virally-suppressed patients with CHB on nucleos (t)ide analogues

Tom Evans[1], Eleanor Barnes[2]. [1]*Vaccitech, Oxford, United Kingdom;* [2]*Oxford University, Nuffield Department of Medicine, Oxford, United Kingdom*
Email: tom.evans@vaccitech.co.uk

Background and aims: Induction of a CD8+ T cell response to HBV may be required to achieve a functional cure of chronic hepatitis B (CHB). The highest magnitude CD8+ T cell responses achieved to date in man have been induced by replication incompetent adenoviral vectors followed by attenuated poxvirus boosts.
Method: Vaccitech with Oxford University is developing a therapeutic HBV vaccine (VTP-300) using a chimpanzee adenoviral vector (ChAdOx1-HBV) and a Modified vaccine Ankara boost (MVA-HBV), that encode the inactivated polymerase, core, and the entire large S region from a consensus genotype C virus. A Phase 1b/2a trial is enrolling up to 52 patients (10–16 patients in each of 4 groups) with CHB, on antivirals for a minimum of one year with VL undetectable and HBsAg <4, 000 IU). Group 1, MVA-HBV (1 × 10*8 pfu) followed at d28 by homologous MVA-HBV; Group 2, ChAdOx1-HBV (2 × 10*10 viral particles) followed at d28 by MVA; Group 3, same as group 2 with low dose nivolumab (LDN) (0.3 mg/kg IV) at d28; Group 4 same as Group 2 with LDN at day 0 and day 28. HBV specific T cell responses are assessed using genotype C and D HBV peptides spanning the HBV immunogen in an IFNg ELISpot assay, before and after (days 7, 28, 35, 84, and 168) vaccination.
Results: As of March 1st 2022, 40 patients had been enrolled with no concerning safety signal or vaccine-associated SAEs reported. Transaminase flares have been observed, associated with SAg decline, in two patients. Groups 2 and 3 have shown reduction in SAg at month 3 In Group 2, only patient with low initial SAg have shown an effect, whereas almost all most patients in Group 3 have shown SAg decline (1 log10 at 6 months in first 6)
HBV genotype C T cell response were assessed in 20 patients to date, targeted HBV core (8/20), sAg (17/20) and pol (8/20) with a mean magnitude of 217, 213 and 118 × SFU/10^6 PBMC respectively (mean total magnitude 363 SFU) at baseline. After prime vaccination peak mean magnitude (day 7 or day 28) of total HBV specific T cell responses were 437, 244, 688, 332 SFU/10^6 in groups 1–4 respectively. After boost vaccination peak (day 35) total HBV specific T cell responses were 344, 689, 689, 277 SFU/10^6 in groups 1–4 respectively. Responses were enhanced from baseline in 13 patients after prime and in 16 patients after boost. Responses were sustained out to 3–6 months in the majority of patients. HBV inter-genotype cross reactive T cell responses were highly cross-reactive with genotype D peptides.
Conclusion: VTP-300 immunotherapy, either alone or combined with nivolumab at the boosting time point, has been immunogenic and shown reduction in SAg in well-controlled CHB patients, while exhibiting an excellent safety profile.

SAT429

Bulevirtide monotherapy for 48 weeks in HDV patients with compensated cirrhosis and clinically significant portal hypertension

Elisabetta Degasperi[1], Maria Paola Anolli[1], Colonia Sara[2], Uceda Renteria[2], Dana Sambarino[1], Marta Borghi[1], Riccardo Perbellini[1], Caroline Scholtes[3,4], Floriana Facchetti[1], Alessandro Loglio[1], Mirella Fraquelli[5], Andrea Costantino[5], Ferruccio Ceriotti[2], Fabien Zoulim[3,4], Pietro Lampertico[1,6].

M. and A. Migliavacca" Center for Liver Disease, Department of Pathophysiology and Transplantation, Milan, Italy*
Email: elisabetta.degasperi@policlinico.mi.it

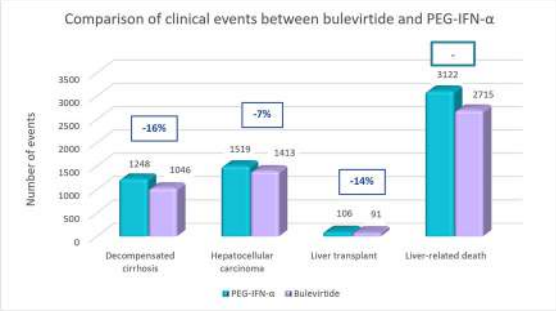
Background and aims: Bulevirtide (BLV) has been recently approved for the treatment of chronic hepatitis Delta (CHD) in Europe but its long-term effectiveness and safety in patients with compensated cirrhosis and clinically significant portal hypertension (CSPH) are unknown.
Method: Consecutive HDV patients with compensated cirrhosis and CSPH who started BLV 2 mg/day were enrolled in this single-center longitudinal study. Clinical and virological characteristics were collected at baseline, weeks 4, 8 and every 8 weeks thereafter. HDV RNA was quantified by Robogene 2.0 (LOD 6 IU/ml), HBcrAg by LUMIPULSE® G (LOQ 3 Log U/ml), HBV RNA by cobas® 6800 (LOQ 10 cp/ml).
Results: 18 Caucasian patients with compensated cirrhosis and CSPH under nucleos (t)ide analogue (NUC) treatment were enrolled: 48 (29–77) years, 67% males, 2 active HCC; platelets 70 (37–227) x10^3/mm^3, liver stiffness measurement 16.4 (7.8–57.8) kPa, ALT 106 (32–222) U/L, HBsAg 3.7 (2.5–4.3) log IU/ml, HDV RNA 4.9 (3.3–6.6) log IU/ml. During 48 weeks of BLV monotherapy, HDV RNA declined by 3.1 (0.2–4.6) log IU/ml, becoming undetectable in 6 (33%) patients and <100 IU/ml in 9 (50%). A virological response, defined as HDV RNA undetectability or ≥2 log IU/ml decline, was observed in 14 (78%) patients, while 2 (11%) were non-responders. Median ALT declined to 34 (15–76) U/L; a biochemical response (ALT normalization) was observed in 89% of patients while a combined response (virological and biochemical) was observed in 72%. AST, GGT, AFP, albumin, IgG and gammaglobulin levels improved ($p < 0.001$), while HBsAg, HBV RNA, HBcrAg, platelets and bilirubin did not significantly change. While Child-Pugh Turcotte (CPT) score remained unchanged in all patients with CPT A5 at baseline, 4 out of 5 patients with baseline CPT A6 improved their liver function to CPT A5. No liver-related complications occurred during treatment. BLV was well tolerated: the only adverse event observed was a fully asymptomatic increase of serum bile acids; no site injection reactions were observed. No patient discontinued treatment.
Conclusion: A 48-week course of BLV 2 mg/day monotherapy is safe and effective even for difficult-to treat HDV patients such as those with compensated cirrhosis and CSPH. Virological response is associated with an improvement of liver function tests and CPT score.

SAT430

Bulevirtide avoids future clinical events and related costs compared to pegylated-interferon alpha in chronic hepatitis D in Spain

Maria Buti[1], José Luis Calleja Panero[2], Miguel Ángel Rodríguez Sagrado[3], Helena Cantero[4], Ana de las Heras[5], Raquel Domínguez-Hernández[5], Miguel Ángel Casado[5]. *[1]Hospital Universitari Vall d'Hebron, Hepatology and Internal Medicine, Barcelona, Spain; [2]Puerta de Hierro Majadahonda University Hospital, Gastroenterology and Hepatology, Majadahonda, Spain; [3]Hospital Ramón y Cajal, Pharmacy, Madrid, Spain; [4]Gilead Sciences, Market Access, Madrid, Spain; [5]Pharmacoeconomics and Outcomes Research Iberia (PORIB), Pozuelo de Alarcón, Spain*
Email: rdominguez@porib.com

Background and aims: Chronic Hepatitis D (CHD) is the most severe form of all chronic viral hepatitis. Although it is not approved, pegylated-interferon alpha (PEG-IFN-α) is the most used treatment for patients with CHD. Bulevirtide (Hepcludex®) is a novel, first-in-disease and first-in-class entry inhibitor with the European Medicine's Agency conditional approval to treat adults with compensated CHD. The aim of the study was to evaluate the avoided clinical events and their costs of bulevirtide compared to PEG-IFN-α, in patients with CHD in Spain.
Method: The course of the disease was simulated, for a lifetime horizon, through a decision-tree model integrated into a Markov model in order to predict the number of clinical events and derived costs of using bulevirtide in comparison to PEG-IFN-α in CHD patients. A cohort of 3, 882 patients was assumed (national prevalence figures), from which 46.90% were cirrhotic at baseline. "Response to bulevirtide" was defined as achieving the combined response end point (hepatitis D virus-RNA undetectable or ≥2log decline and alanine aminotransferase normalisation) at 24–48 weeks, and "non-response" was considered when the combined response end point was not reached. For bulevirtide, responders remained under treatment beyond 48 weeks, except for patients with HBsAg seroclearance or progression, whereas non-responders stopped treatment at week 48. For PEG-IFN-α, patients were treated until week 48. The parameters of the analysis (patient characteristics, efficacy of bulevirtide and PEG-IFN-α, disease progression and unitary event costs) were extracted from the literature. Only clinical event direct costs were evaluated in the model, from the National Health System perspective (€, 2021). Results were described as avoided events of decompensated cirrhosis (DC), hepatocellular carcinoma (HCC), liver transplant (LT) and liver-related death, and their avoided costs.
Results: In a cohort of 3, 882 patients during a lifetime period, treatment with bulevirtide could avoid 202 DC events, 105 HCC, 15 LT and 407 liver-related deaths in comparison to PEG-IFN-α, resulting in a 16%, 7%, 14% and 13% event reduction, respectively. This would imply a total cost reduction related to events of 12.5 million € with bulevirtide vs PEG-IFN-α (2.3 million € for DC, 1.3 million € for HCC, 7.5 million € for LT and 1.4 million € for liver-related deaths).



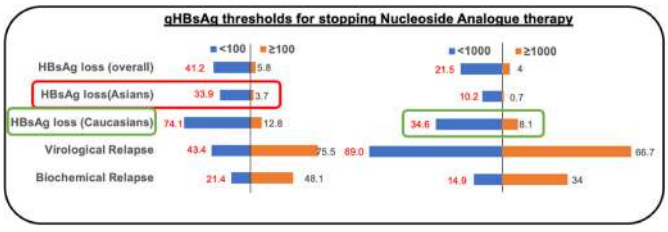
Conclusion: Bulevirtide for CHD could avoid a significant number of clinical events compared to PEG-IFN-α, leading to a slower disease progression and cost savings originated by the reduction in the number of negative liver-related events.

SAT431

Quantitative HBsAg (qHBsAg) as an end point to stop nucleos (t) ide analogues in chronic hepatitis B: a meta-analysis with meta-regression

Seng Gee Lim[1], Ada Ee Der Teo[1], Edwin Shih-Yen Chan[2], Wah Wah Phyo[1], David Hsing Yu Chen[2], Carol Anne Hargreaves[3]. *[1]National University Health System, Division of Gastroenterology and Hepatology, Singapore, Singapore; [2]Singapore Clincal Research Institute, Singapore; [3]National University of Singapore, Data Analytics Consulting Centre, Faculty of Science, Singapore*
Email: mdclimsg@nus.edu.sg

Background and aims: Guidelines differ on recommendations for stopping nucleoside analogue (NA) therapy in HBeAg-negative Chronic Hepatitis B (CHB) as the risk-benefit trade-off is unclear. An end-of-treatment quantitative HBsAg (EOTqHBsAg)<100IU/ml or <1000IU/ml has been proposed as criterion to stop NA. We assessed this by meta-analysis and meta-regression.
Method: We searched PubMed, EMBASE and abstracts of major liver conferences for studies of HBeAg-negative CHB NA discontinuation. Risk of bias was assessed by Newcastle-Ottawa tool (modified). Random-effects meta-analysis and meta-regression was performed with covariates of ethnicity (ETHN), EOTqHBsAg (<100≥IU/ml [EOT_100], <1000≥IU/ml [EOT_1000] and as an ordinal variable [EOT_ORD]), duration of NA therapy (TDUR); dichotomised at 24months[EOT_24] and 36 months[EOT_36]) and duration of follow-up (FUP) after stopping NA. We assessed pooled risk, with 95% confidence intervals (95%CI) of HBsAg loss, virological (VR) and biochemical relapse (BR). Heterogeneity was reported as I^2. Multivariate meta-regression models examined covariates to explain the heterogeneity.
Results: A total of 42 studies were included (34papers, 8 abstracts). The pooled risks of HBsAg loss, VR and BR for stopping therapy at EOTqHBsAg<100IU/ml were 41.2% (95% CI30.6–52.7%), 43.4% (95% CI30.6–57.2%) and 21.4% (95% CI14.3–30.9%) respectively compared 5.8% (95% CI3.6–9.4%), 75.5% (95% CI64.7–83.8%) and 48.1% (95% CI35.9–60.6%) respectively for those with EOTqHBsAg≥100IU/ml. The pooled risks of HBsAg loss, VR and BR for stopping therapy at EOTqHBsAg<1000IU/ml were 21.5% (95% CI 11.8–36.0%), 69.0% (95% CI43.2–86.8%) and 14.9% (95% CI7.6–27.1%) respectively, compared to 4.0% (95% CI1.8–8.9%), 66.7% (95%CI41.8–84.8%) and 34.0% (95% CI20.3–51.1%) respectively for those with EOTqHBsAg≥1000IU/ml. ETHN significantly contributed to HBsAg heterogeneity. In Asians, EOTqHBsAg<100IU/ml had HBsAg loss of 33.9% while in Caucasian studies, EOTqHBsAg<1000IU/ml had HBsAg loss of 34.6%, hence a difference in threshold between ethnicities is advocated. Multivariate analysis showed TDUR (continuous) was significant for VR and BR but subgroup analysis of TDUR_24 or TDUR_36 showed no difference.



Conclusion: This meta-analysis provides level 1 evidence to adopt EOTqHBsAg as a criterion to stop NA in HBeAg-negative CHB patients; in Asians EOTqHBsAg<100IU/ml can be advocated, while in Caucasians, EOTqHBsAg<1000IU/ml is appropriate.

SAT432

Low level of HBcrAg is beneficial to functional cure obtained with pegylated interferon therapy in inactive HBsAg carriers

Hong Li[1], LiLi Liu[1], Ling Qin[2], YaLi Liu[1], Zhang Jing[1], Xin-Yue Chen[3], Zhenhuan Cao[1]. *[1]Beijing Youan Hospital, Capital Medical University, The Third Unit, Department of Hepatology, Beijing, China; [2]Beijing Youan Hospital, Capital Medical University, Biomedical Information Center, Beijing, China; [3]Beijing Youan Hospital, Capital Medical University, The First Unit, Department of Hepatology, Beijing, China*
Email: caozhenhuanyu@mail.ccmu.edu.cn

Background and aims: HBsAg clearance, represented functional cure, is extremely difficult to obtain clinically. Our and other recent studies have shown that IHCs treated with pegylated-interferon (PEG-IFN) results in high HBsAg clearance rates of 44.7% to 65%. Recent study showed that hepatitis B core-related antigen (HBcrAg) could be used as a valuable marker for HBV replication. However, the predictive value of HBcrAg for HBsAg clearance is unclear. This study aims to identify HBcrAg associated with functional cure in IHCs with PEG-IFN therapy.

Method: IHCs received PEG-IFN 135 ug weekly for 96 weeks. Subjects who achieved clearance of HBsAg were considered as responders (R group), and those who did not were considered as non-responders (NR group). To evaluate the factors in predicting HBsAg clearance, univariate and multivariate logistic regression analyses were performed. The receiver operator characteristic curves and the area under the receiver operator characteristic curve (AUROC) were used to evaluate prognostic values.

Results: Our results showed that 39 cases obtained HBsAg clearance (group R), while 21 cases did not (group NR). There was no significant difference in age, ALT, and AST levels between two groups. HBcrAg were all significantly lower in R group than NR group at baseline, 12 and 24 weeks. HBsAg quantification were lower in the R group than in the NR group at 12 and 24 weeks (Table 1). Univariate logistic regression analysis showed that HBcrAg at baseline (OR 10.763, p = 0.001), and at 12 weeks (OR 12.511, p <0.001), and 24 weeks (OR 6.955, p = 0.008) were all strong predictors of functional cure as well as HBsAg levels at 12 weeks (OR 8.147, p = 0.004) and 24 weeks (OR 9.743, p = 0.002), HBsAg changes from baseline at 12 weeks (OR 5.468, p = 0.019) and 24 weeks (OR 10.719, p = 0.001). A multifactor logistic analysis was performed with Y = 219.227–1.269*BaselineHBcrAg-0.994*12weekHBcrAg-0.825*24weekHBcrAg. AUROC was up to 0.916 with 93.5% sensitivity and 85.7% specificity.

Table: Characteristics of R and NR groups at baseline, 12 and 24 weeks of treatment

Parameter	R group n = 39	NR group n = 21	p
Gender (M/F)	27/12	16/5	0.568
Age (years)	38.05 ± 11.25	40.62 ± 11.26	0.368
Baseline			
ALT (U/L)	30.88 ± 14.62	33.17 ± 14.36	0.570
AST (U/L)	27.97 ± 6.89	28.17 ± 8.32	0.946
Lg HBsAg (IU/ml)	1.61 ± 0.97	2.08 ± 0.73	0.067
HBcrAg (mU/ml)	5.45 ± 1.09	6.71 ± 1.16	<0.001
12week			
ALT (U/L)	82.56 ± 89.52	66.05 ± 49.14	0.681
AST (U/L)	64.89 ± 74.50	47.71 ± 28.05	0.545
Lg HBsAg (IU/ml)	0.67 ± 1.21	1.70 ± 0.98	0.001
HBcrAg (mU/ml)	5.79 ± 0.95	7.17 ± 1.31	<0.001
24week			
ALT (U/L)	54.77 ± 50.70	54.45 ± 48.95	0.728
AST (U/L)	46.39 ± 28.24	46.65 ± 45.28	0.636
Lg HBsAg (IU/ml)	−0.29 ± 1.14	1.22 ± 1.27	<0.001
HBcrAg (mU/ml)	5.53 ± 0.93	6.63 ± 1.61	0.003

Conclusion: This study provides evidence supporting serum HBcrAg, as a clinical predictor of HBsAg clearance, which has a higher predictive value compared to the conventional predictors of HBsAg and ALT.

SAT433

Comparative risk of hepatocellular carcinoma in patients with chronic hepatitis B receiving tenofovir- or entecavir-based regimens: a meta-analysis using individual patient data

Email: limys@amc.seoul.kr

Background and aims: Chronic hepatitis B (CHB) is associated with a long-term risk of hepatocellular carcinoma (HCC), which can be mitigated by nucleo (s)tide analogue therapies such as tenofovir disoproxil fumarate (TDF) and entecavir (ETV). Aggregate data meta-analyses have been unable to reach a consensus on the relative effectiveness of TDF and ETV to reduce the risk of HCC due to challenges with heterogeneity and different methodologies of included studies. To account for these challenges, this meta-analysis used individual patient data (IPD) to compare the risk of HCC in patients receiving TDF or ETV and identify any subgroup of patients who may benefit more from one treatment than the other.

Method: A literature review identified 20 observational studies from East Asia reporting HCC incidence in patients receiving TDF or ETV, 11 agreed to participate in this study. Eligible patients were adults with CHB who were treatment-naïve before receiving TDF or ETV monotherapy and completed at least 1 year of treatment. After adjustment for potential confounding variables and multiple imputation to account for missing data, a one-stage IPD meta-analysis

evaluated the hazard ratio (HR) of treatment with TDF versus (vs) ETV to reduce HCC risk using a multivariable Cox proportional hazards model. Subgroup analyses for age, sex, HBeAg positivity, cirrhosis status and diabetes status were also conducted.

Results: Data from 42, 939 eligible patients (6, 979 TDF and 35, 960 ETV) were included. The treatments were similar in terms of baseline age (TDF: 48.32 years [yrs] vs ETV: 52.26 yrs), sex (female: 38.64% vs 34.13%), follow-up time (3.71 yrs vs 3.97 yrs) and presence of cirrhosis (38.01% vs 33.69%). Patients receiving TDF were associated with a significantly lower risk of developing HCC: adjusted HR (95% confidence interval [CI]) = 0.77 (0.61–0.98), p = 0.03. In all subgroup analyses, TDF showed a lower risk of HCC than ETV (HR <1.0), with the risk difference most pronounced in the HBeAg positive subgroup (Figure).

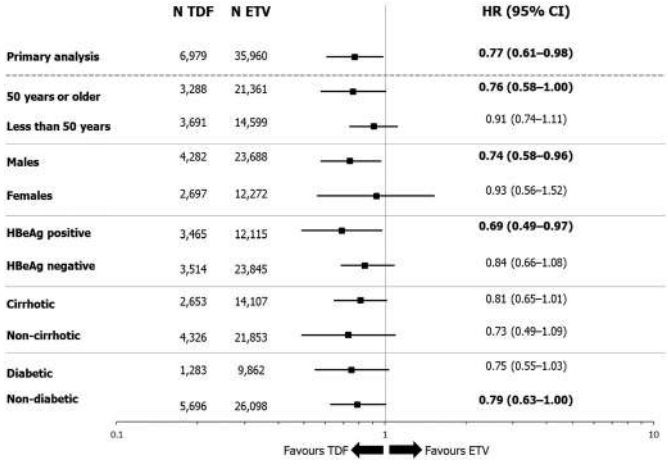

Figure: Analyses for cumulative incidence of HCC in patients with CHB treated with TDF or ETV

*Statistically significant results are in bold. For the '50 years or older' and 'non-diabetic' subgroups, the upper bound of each CI is <1.00, but each has been rounded up to 1.00 when reported to two decimal places.

CHB, chronic hepatitis B; CI, confidence interval; ETV, entecavir; HBeAg, hepatitis B e-antigen; HCC, hepatocellular carcinoma; HR, hazard ratio; TDF, tenofovir disoproxil fumarate

Conclusion: The risk of developing HCC was significantly lower in CHB patients receiving TDF than ETV. TDF was consistently associated with lower HCC risk across all subgroups, but most notably in HBeAg positive patients.

SAT434

VIR-2218 plus VIR-3434 combination therapy reduces hepatitis B virus surface antigen levels in vivo

Julia Noack[1], Jonathan Gall[1,2], Hasan Imam[1], Yesseinia Anglero-Rodriguez[3], Vasant Jadhav[3], Michael A. Schmid[4], Anna Bakardjiev[1,5], Lisa A. Purcell[1], Christy Hebner[1], Florian Lempp[1]. *[1]VIR Biotechnology, San Francisco, United States; [2]Genentech, South San Francisco, United States; [3]Alnylam Pharmaceuticals, Cambridge, United States; [4]Humabs Biomed SA, a subsidiary of Vir Biotechnology, Bellinzona, Switzerland; [5]Denali Therapeutics, South San Francisco, United States*

Email: jnoack@vir.bio

Background and aims: Ribonucleic acid (RNA) interference (RNAi) therapeutics targeting hepatitis B virus (HBV) RNAs and monoclonal antibodies (mAbs) targeting HBV surface antigen (HBsAg) represent compelling strategies for potentially enabling a functional cure in chronic HBV patients. VIR-2218 is an investigational siRNA therapeutic that targets a highly conserved region within the HBV X open reading frame and demonstrates potent *in vitro* and *in vivo* antiviral activity. VIR-3434 is an investigational neutralizing monoclonal antibody targeting the antigenic loop of HBsAg with pan-genotypic neutralizing activity *in vitro,* and inhibits viral spread, leading to elimination of HBsAg *in vivo*. VIR-2218 and VIR-3434 are currently in clinical trials as monotherapy and in combination.

Method: To evaluate the combination activity of VIR-2218 and VIR-3434 versus monotherapy, two *in vivo* studies were conducted using well-established mouse models of HBV infection: C57BL/6 mice transduced with AAV8-HBV (genotype D) or human liver-chimeric PXB-mice infected with HBV (genotype C). The mice were treated with VIR-2218, VIR-3434, entecavir (ETV, AAV8-HBV study only), or a combination of agents at different concentrations. Antiviral activity was determined by evaluation of viral serum/plasma markers including HBV DNA, HBsAg, and HBeAg.

Results: In the AAV-HBV mouse model, VIR-2218 led to a significant reduction of plasma HBsAg, HBeAg and HBV DNA levels (0.89 log, 0.51 log, and 0.65 log maximum mean reduction, respectively), while VIR-3434 monotherapy significantly reduced plasma HBsAg (0.79 log). The combination of VIR-2218 and VIR-3434 further reduced plasma HBsAg and HBV DNA levels when compared to VIR-2218 monotherapy (2.11 log and 2.05 log additional maximum reduction, respectively). The triple combination of VIR-3434, VIR-2218, and ETV significantly enhanced reductions of plasma HBsAg and HBV DNA when compared to ETV monotherapy (2.39 log and 1.26 further maximum reduction, respectively). In HBV-infected PXB mice, VIR-3434 monotherapy resulted in a substantial decrease in serum HBsAg (1.46 log); treatment with the combination of VIR-2218 and VIR-3434 showed an additional ~1 log reduction (2.51 log). VIR-2218 and VIR-3434 combination also showed a clear reduction in serum HBV DNA levels (1.47 log) when compared to the vehicle group, whereas treatment with VIR-3434 alone led to a 0.72 log decrease.

Conclusion: Monotherapy with either the RNAi therapeutic, VIR-2218, or the mAb VIR-3434 is effective in reducing plasma/serum levels of HBsAg in two HBV mouse models. Combined treatment provided improved suppression of HBsAg over monotherapy and represents a promising strategy for HBV functional cure. These data support further clinical development of combination therapy with VIR-2218 and VIR-3434 for the potential treatment of chronic HBV patients.

SAT435

Safety, pharmacokinetics, and antiviral activity of the S-antigen Transport Inhibiting Oligonucleotide Polymers (STOPS) drug candidate ALG-010133 in subjects with chronic hepatitis B

Edward J Gane[1], Kosh Agarwal[2], Man-Fung Yuen[3], Alina Jucov[4], Christian Schwabe[5], Kha Le[6], Stanley Wang[6], Christopher Westland[6], Kim Steel[7], Qingling Zhang[6], Vikrant Gohil[6], Felix Lai[6], Meenakshi Venkatraman[6], Lawrence Blatt[6], Leonid Beigelman[6], Tse-I Lin[6], Sushmita Chanda[6], Matt McClure[6], John Fry[6]. *[1]University of Auckland, Auckland, New Zealand; [2]King's College Hospital, Institute of Liver Studies, London, United Kingdom; [3]The University of Hong Kong, Queen Mary Hospital, Department of Medicine, School of Clinical Medicine, Hong Kong, Hong Kong; [4]ARENSIA Exploratory Medicine, Republican Clinical Hospital and Nicolae Testemitanu State University of Medicine and Pharmacy, Chisinau, Moldova; [5]New Zealand Clinical Research, Auckland, New Zealand; [6]Aligos Therapeutics, Inc.; [7]SARPO Consulting, Melbourne, Australia*

Email: swang@aligos.com

Background and aims: To evaluate the safety, pharmacokinetics (PK) and antiviral activity of ALG-010133, a STOPS molecule designed to reduce hepatitis B S-antigen (HBsAg) in chronic hepatitis B (CHB) patients.

Method: This was a 3-part, multicenter, double-blind, randomized, placebo-controlled study. In Parts 1 and 2, single and multiple subcutaneous (SC) doses of ALG-010133 were generally well tolerated in healthy volunteers (Gane et al, EASL 2021). Part 3 evaluated weekly SC doses of ALG-010133 or placebo × 12 weeks in virologically suppressed Hepatitis B e-antigen (HBeAg) negative CHB subjects (N = 10/cohort; 8 active:2 placebo). Reported here are preliminary

blinded Part 3 safety, PK, and antiviral data; unblinded data will be presented at the conference.

Results: 31 CHB subjects completed dosing and follow-up in Cohorts 1 (120 mg; N = 10), 2.
(200 mg; N = 10), and 3 (400 mg; N = 11). Most subjects were male (61%) and 48% were white, with mean age 48 years, mean BMI 26.1 kg/m^2 and baseline HBsAg across cohorts of 3.6 to 3.7 $\log_{10}$ IU/ml. There was 1 unrelated serious treatment emergent adverse event (TEAE) (hospitalization for orchitis) and 1 unrelated TEAE (COVID-19 infection) resulting in premature study drug discontinuation. All TEAEs were Grade 1 or 2 in severity, except for 1 Grade 3 TEAE of injection site erythema (severity based only on surface area criteria of ≥100 cm^2; required no treatment and resolved despite continued study drug dosing) and the aforementioned TEAE of orchitis (Grade 3). There was no dose relationship to severity or frequency for any TEAE. The most common (≥3 subjects) TEAEs were injection site erythema (n = 5), increased ALT (n = 4), injection site bruising (n = 4), increased AST (n = 3), and injection site pruritus (n = 3); none were assessed as clinically concerning. Although treatment-emergent ALT and AST elevations (n = 13) were observed, all were Grade 1 (<2.5x upper limit of normal [ULN]) or 2 (≥2.5 to <5x ULN) and none led to premature study drug discontinuation or were associated with symptoms or evidence of liver dysfunction. There were no other clinically significant lab abnormalities. No clinically significant physical examinations, vital signs, or ECG abnormalities were reported. Plasma ALG-010133 exposures increased more than dose proportionally between the 120 to 400 mg dose levels, with moderate variability and minimal accumulation. Compared to baseline, the magnitude of HBsAg decline at Week 12 was <0.1 $\log_{10}$ IU/ml for placebo and across all ALG-010133 dose levels, including the projected efficacious dose level of 400 mg (estimated to maintain total liver exposures >3x EC_{90} for HBsAg inhibition).

Conclusion: ALG-010133 was safe and well tolerated with predictable PK properties when given to CHB subjects as multiple SC doses of up to 400 mg. No meaningful HBsAg reduction was observed across all cohorts. Further clinical development of ALG-010133 has been discontinued.

SAT436

Costimulation of CD40 and type-I interferon immune pathways by a bifunctional molecule in HBV infection models and healthy non-human primates

Xavier Marniquet[1], Marion Dajon[1], Julie Montegut[1], Maria Elena Giusepponi[2], Michela Pecoraro[2], Elena Vicentini[2], Francesca Morandini[2], Floriana Zanderigo[2], Denise Federico[2], Odile Bonnin[1], Gregory Neveu[1], Charlotte Blanc[1], Christelle Marcou[1], Juliette Lavaux[1], Michel Didier[3], Galina Boldina[3], Jacques Dumas[3], Thomas Bouqin[3], Annabelle Milla[1], Hugh Watson[1], Kara Carter[1], Antoine Alam[1]. *[1]Evotec ID (Lyon), Antiviral Research Unit, Lyon, France; [2]Aptuit (Verona) Srl, Verona, Italy; [3]Sanofi, Vitry-sur-Seine, France*
Email: xavier.marniquet@evotec.com

Background and aims: Type-I interferons (IFN-I) have shown limited ability to cure patients with chronic hepatitis B (CHB), thus more effective treatments are needed to achieve cure in a larger proportion of patients. We aimed to investigate the simultaneous stimulation of CD40 and IFN-I pathways in HBV infection models and non-infected non-human primates (NHP).

Method: HBV-infected primary human hepatocytes (PHH) were used to characterize the effects of IFN-I and CD40 ligand separately and in combination. AAV/HBV-infected mice were subsequently used to confirm these effects in vivo. A single bifunctional molecule with both activities was investigated using reporter cells, HBV-infected PHH and non-infected NHP. Pro-inflammatory cytokine release was assessed in vitro with NHP and human white blood cells (WBC).

Results: The combination of IFN-I and CD40 ligand, on primary human hepatocytes (PHH) and in AAV/HBV-infected mice, showed a significant increase in anti-HBV activity when compared to either CD40L or IFN-alpha alone. Fusion of IFN-I molecules to an anti-CD40 agonistic mAb yielded a bifunctional molecule active on both CD40 and IFNR expressed in reporter cells. This fusion molecule reduced pgRNA and HBeAg release from HBV-infected PHH treated at picomolar concentrations starting 4 days after infection, without cytotoxicity. Stimulation of CXCL10 release and anti-HBV activity in infected PHH treated for 1 day was maintained after a washout period of 3 days. Stimulation of WBC in vitro led to low or undetectable release of pro-inflammatory cytokines. Treatment of non-infected NHP with the fusion molecule produced dose-dependent elevation of serum CXCL10, 2′5′OAS and neopterin and stimulated the CD40 pathway without significant systemic release of unwanted pro-inflammatory cytokines.

Conclusion: Target engagement of CD40 and IFN-I receptors with a single bifunctional molecule results in potent activity in HBV-models and stimulates CD40 and type-I IFN immune pathways in vivo.

SAT437

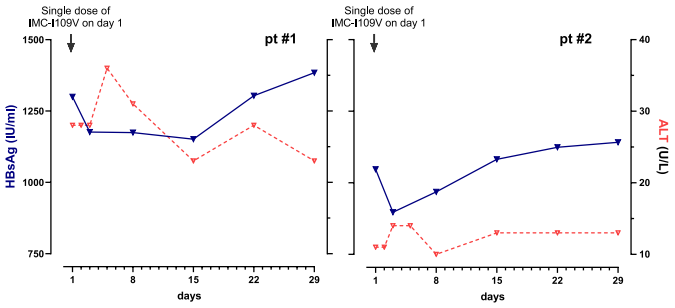
IMC-I109V, a novel T cell receptor (TCR) bispecific (ENVxCD3) designed to eliminate HBV-infected hepatocytes in chronic HBV patients: initial data from a first-in-human study

Stefan Bourgeois[1], Young-Suk Lim[2], Edward J Gane[3], Hyun Woong Lee[4], Wendy Cheng[5], Jeong Heo[6], Won Kim[7], Maria Buti[8], Alexander Thompson[9], Gail Matthews[10], Ewa Janczewska[11], Stephen Ryder[12], Raul J. Andrade[13], Yuan Yuan[14], Adel Benlahrech[15], Jay Wustner[14], Lucy Dorrell[16], Man-Fung Yuen[17]. *[1]Ziekenhuis Netwerk Antwerpen, Belgium; [2]Asan Medical Centre; [3]University of Auckland; [4]Gangnam Severance Hospital; [5]Royal Perth Bentley Group; [6]Pusan National University Hospital; [7]SMG-SNU Boramae Medical Centre; [8]Hospital Universitario Valle Hebron; [9]St Vincent's Hospital Melbourne; [10]St Vincent's Hospital Sydney; [11]ID Clinic Arkadiusz Pisula; [12]Nottingham University Hospitals NHS Trust; [13]Hospital Universitario Virgen de la Victoria-IBIMA; [14]Immunocore plc; [15]Immunocore Ltd; [16]Immunocore Ltd, United Kingdom; [17]The University of Hong Kong*
Email: lucy.dorrell@immunocore.com

Background and aims: HBsAg clearance is the treatment goal for chronic hepatitis B (CHB). New strategies that enable safe elimination of hepatocytes harbouring HBV genomes are needed. Immune-mobilising monoclonal TCR against viruses (ImmTAV®) are unique bispecific soluble proteins designed to redirect polyclonal T cells, regardless of their specificity, to eliminate virus-infected cells. IMC-I109V is an affinity-enhanced HBV-specific TCR fused to an anti-CD3 scFv T cell activating moiety, that redirects non-exhausted effector T cells to eliminate hepatocytes presenting HLA-bound HBsAg (Env)-derived peptide. Since the mechanism results in hepatocyte lysis, transient liver enzyme increases are expected, necessitating a conservative dosing schedule in our first-in-human study.

Method: IMC-I109V-101 is an open-label Phase 1/2 study evaluating IMC-I109V in HLA-A*02:01 positive patients with CHB who are non-cirrhotic, HBeAg-negative and virally suppressed on nucleos (t)ide analogues. Part 1 is a single ascending dose to identify a safe and pharmacologically active dose. Part 2 is a multiple ascending dose to evaluate safety and anti-HBV activity of repeated doses over 24 weeks. Secondary objectives include PK and effects on serum HBsAg, HBcrAg and HBV RNA levels.

Results: Three patients each received a single dose of 0.8 mcg, based on the minimum anticipated biological effect level (MABEL). Doses were well tolerated and not associated with adverse events in any subject. Preliminary PK, HBsAg and liver enzymes were available for the first two participants. PK analysis showed that the maximum serum concentrations were consistent with the dose level. By 12 hours, serum concentrations declined below the lower limit of quantification. Serum HBsAg levels transiently decreased by 11–15% during Days 3–15 post infusion, before returning to baseline within 3 weeks (Figure 1). The decreases coincided with small, transient elevations in ALT, albeit within the normal range.



Conclusion: The concomitant HBsAg declines and ALT elevations indicate that a single, very low dose of IMC-I109V elicited on-target activity consistent with the TCR bispecific (ENVxCD3) mechanism of action, without adverse events. These results are encouraging for the prospect of identifying a tolerable and active treatment regimen with higher and repeat dosing. Enrolment in Part 1 dose escalation continues to evaluate this novel mechanism designed to eliminate HBV-positive hepatocytes. (Eudract no. 2019–004212-64).

Long-term outcomes after cessation of antiviral therapy in HBeAg negative patients

Rachel Wen-Juei Jeng[1,2], Yen-Chun Liu[1,2], Chien-Wei Peng[1,2,2], Rong-Nan Chien[1,2,3], Yun-Fan Liaw[2,3]. *[1]Linkou Chang Gung Memorial Hospital, Gastroenterology and Hepatology, Taoyuan, Taiwan; [2]Chang Gung University, College of Medicine, Taoyuan, Taiwan; [3]Linkou Chang Gung Memorial Hospital, Liver Research Unit, Taoyuan, Taiwan*
Email: rachel.jeng@gmail.com

Background and aims: We reported a cohort of 691 HBeAg negative chronic hepatitis B patients who had stopping Nuc (Hepatology 2018) with a median follow-up duration about 3 years. We have extended the follow-up to a median of 6.6 (Q1-Q3: 5–8.2) years and to examined the long-term outcome of these patients.
Method: The 691 HBeAg negative CHB patients were followed-up till Dec 2021. Virological relapse (VR) was defined as HBV DNA >2000IU/ml and clinical relapse (CR) as VR plus ALT >2X ULN. Retreatment decision was made according to the Taiwan reimbursement criteria: cirrhosis with detectable HBV DNA or non-cirrhosis with CR prolonged over 3 months or CR with serum bilirubin level >2 mg/dL or INR >1.5 or by joint physician/patient discussion. According to the clinical outcome and management, these patients were categorized into 4 groups: A: no CR and no retreatment (retx); B: no CR but retx; C: CR and no-retx; D: CR and retx.
Results: During a median of 6.6 years follow-up of this observational cohort, 180 (26%) were group A, 27 (4%) were group B, 103 (15%) were group C and 381 (55%) were group D. The cumulative VR, CR, retreatment rate are listed in table. The annual HBsAg decline in group A-D was: – 0.304, – 0.144, – 0.277, – 0.205 $\log_{10}$IU/ml, respectively. Among the 691 patients, 343 (49.6%) achieved HBsAg <100IU/ml (group A-D: 72.8%, 38.5%, 56.3%, 37.8%, respectively) and 112 (16.2%) achieved HBsAg loss by the end of follow-up. The 5 and 10-year cumulative HBsAg loss rate are: group A: 27%, 57%; group B: 0%, 6%; group C: 13%, 38%; group D: 3%, 11%, respectively. Among the retreatment group (N = 407), 251 patients (61.7%) had completed additional course of finite therapy with a 10-year cumulative HBsAg loss rate (from the first EOT) of 15%, >2 times higher than 6% in those still under continued treatment. The incidence of HCC and liver related mortality was very low, mostly occurs in cirrhotic patients (Table).

Table: Summary of cumulative events of these 691 HBeAg negative CHB patients

Event	1-year	2-year	3-year	5-year	10-year
Virological relapse	72%	84%	86%	88%	89%
Clinical relapse	42%	60%	65%	70%	72%
Retreatment	21%	39%	48%	57%	63%
HBsAg loss	1%	3%	6%	10%	27%
No CR/no Retx	4%	11%	18%	27%	57%
CR/no Retx	0%	2%	3%	13%	38%
No CR/Retx	0%	0%	0%	0%	6%
CR/ Retx	0%	1%	1%	3%	11%
HCC				4%	6%
Non-cirrhosis				1%	2%
Cirrhosis				8%	11%
Liver-related mortality (due to HCC, hepatic decompensation or cirrhotic complication)				2%	3%
Non-cirrhosis				0%	0%
Cirrhosis				3%	6%

Conclusion: The finite therapy does much increase the functional cure rate, especially in those remain untreated. The HBsAg loss rate accelerated along with follow-up time, especially after year 3.

SAT439

Bepirovirsen, antisense oligonucleotide (ASO) against hepatitis B virus (HBV), harbors intrinsic immunostimulatory activity via Toll-like receptor 8 (TLR8) preclinically, correlating with clinical efficacy from the Phase 2a study

Shihyun You[1], Jared Delahaye[1], Megan Ermler[1], Jennifer Singh[1], William Jordan[1], Avijit Ray[1], Nicholas Galwey[2], Daren Austin[3], Dickens Theodore[4], Melanie Paff[1]. *[1]GlaxoSmithKline, Collegeville, PA, United States; [2]GlaxoSmithKline, Stevenage, United Kingdom; [3]GlaxoSmithKline, Brentford, United Kingdom; [4]GlaxoSmithKline, Research Triangle Park, NC, United States*
Email: shihyun.k.you@gsk.com

Background and aims: Bepirovirsen (BPV) is a modified ASO targeting HBV RNAs including pregenomic RNA; GSK3389404 (GSK404) is GalNac conjugated BPV. Phase 2a studies (NCT02981602 and NCT03020745) showed more robust dose-related HBsAg reductions and ALT flares with BPV than GSK404, prompting a hypothesis that preferential distribution of BPV to nonparenchymal cells may confer immune activity. To investigate the mechanism of BPV immunostimulatory effect, this post-hoc analysis evaluated changes in soluble proteins measured in study NCT02981602; preclinical models were used to validate the activity.
Method: This study analyzed plasma and serum from 30 patients receiving placebo (PBO) or BPV administered on Days 1, 4, 8, 11, 15 and 22 (treatment naïve: PBO n = 6, BPV 150 mg n = 6, 300 mg n = 12; nucleos[t]ide-treated: PBO n = 2, BPV 300 mg n = 4). Soluble proteins from plasma (only treatment-naïve groups) collected at 0.5, 4, 6 and 24 hours post dose were evaluated with the Olink 1536 Explore panel for pathway analysis; soluble proteins from serum on Days 1, 2, 8, 15, 22, 23, 29, 36, 57 and 85 were evaluated with the Olink 96 Inflammation panel for correlation analysis. A generalized linear mixed effects model compared changes from baseline at each time point. Mean fold changes and p values were used to select analytes for pathway analyses (Enrichr). A subset of proteins was used in principal component analysis (PCA). BPV was tested in a panel of pattern recognition receptor (PRR)-overexpressing cell lines (InvivoGen) in vitro and TLR8 activity was validated in human TLR8 (hTLR8) transgenic mice in vivo.
Results: Within 6- and 24-hour post BPV dosing, the most significant change was observed in the epithelial mesenchymal transition pathway (p = 2.75E-10) and in the inflammatory response pathway (p = 4.13E-8), respectively. Notably, induction of IL12B, IFNg, and IL1Ra, but not type I IFNs were detected, suggestive of TLR8

activation. PCA of TLR8 signature cytokines from longitudinal serum analysis showed that elevation of these cytokines was correlated with reduction of HBsAg in addition to BPV exposure and ALT flare. Transfected BPV showed weak activation of TLR8 among other PRRs in vitro. In hTLR8 mice, BPV elevated cytokines in plasma and livers, in a similar pattern to a TLR8 agonist; lesser effects were observed in wild type. In addition, the IL12B plasma response to BPV was greater than that by scrambled ASO or GSK404, indicating a specificity of BPV activating TLR8 in hTLR8 mice.

Conclusion: TLR8 agonism of BPV was confirmed preclinically. Cytokines/chemokines changed by BPV treatment in the Phase 2a study indicate that an immunostimulatory activity of BPV via TLR8 may be correlated with ASO-mediated HBsAg reduction. These findings support further investigation of a combination of HBsAg reducing agent and TLR8 agonist for treating HBV.

M. and A. Migliavacca" Center for Liver Disease, Department of Pathophysiology and Transplantation, University of Milan, Milan, Italy*

Email: harel.dahari@gmail.com

Background and aims: Bulevirtide (BLV) was recently approved for treatment of hepatitis D in Europe. Theory predicts that drugs like BLV that block virus infection should lead to a monophasic viral decline that is driven by the rate of loss/death of HDV-infected cells (Shekhtman et al. PMID: 34995688). The current study is the first to characterize HDV and ALT kinetics under BLV monotherapy in patients with advanced compensated cirrhosis.

Method: Eighteen patients with HDV-related advanced compensated cirrhosis were treated with BLV 2 mg/day monotherapy. All were receiving TDF or ETV for HBV. Blood samples were collected at treatment initiation, weeks 4 and 8, and every 8 weeks thereafter. HDV RNA was measured by Robogene 2.0 (lower limit of quantification, LLoQ = 6 IU/ml). ALT normalization was defined as 41 U/L and 59 U/L for women and men, respectively.

Results: Median baseline HDV and ALT were 4.9 log IU/ml [IQR 4.4–5.8] and 106 U/L [IQR 81–142], respectively. During therapy, patients fit into 6 interim HDV kinetic patterns (Fig. 1): monophasic, MP (n = 3, Fig. 1a), biphasic, BP (n = 7, Fig. 1b), flat-partial response, FPR (n = 4, Fig. 1c), FPR followed by decline (n = 1, Fig. 1d), FPR followed by breakthrough (n = 1, Fig. 1e), and non-responder, NR (n = 2, Fig. 1f). MP patients had significantly ($p = 0.039$) longer median HDV $t_{1/2}$ of 46 days [range:41–60] compared to BP/FPR patients (26 days [range:11–49]) during the first viral decline phase, suggesting two distinct HDV-infected cell population turnovers. There was no difference ($p > 0.18$) in HDV $t_{1/2}$, length (median 11 weeks [range 3–22]) and magnitude (median 2.0 log IU/ml [range 1.1–3.3]) of first viral decline phase from baseline between BP and FPR patients. The 2nd slower phase slope of viral decline in BP patients was not significantly different ($p = 0.18$) than the first phase slope of viral decline in MP patients, suggesting similar HDV-infected cell population turnover. ALT normalization was achieved in 14 (78%) patients at a median of 8 weeks (range: 4 to 16) from initiation of BLV therapy. MP patients had a significantly ($p = 0.048$) lower median ALT decline slope of 1.4 U/wk [range:0.6–8.9] compared to BP/FPR patients (10.1 U/wk [range:4.5–28.5]), supporting, in part, the theory that HDV decline under BLV reflects the loss/death rate of HDV-infected cells.

Conclusion: While theory predicts a MP viral decline under BLV, this pattern was only identified in 3 patients (17%). In 7 patients (39%) the first rapid phase observed in patients with BP suggests that an additional HDV-infected cell population with a shorter $t_{1/2}$ might exist compared to patients with MP decline. Six patients (33%) experienced a FPR kinetic pattern suggesting suboptimal BLV dosage, which should be further investigated. The current findings will help to develop theoretical models to explain the observed viral dynamics and develop response guided therapy strategies.

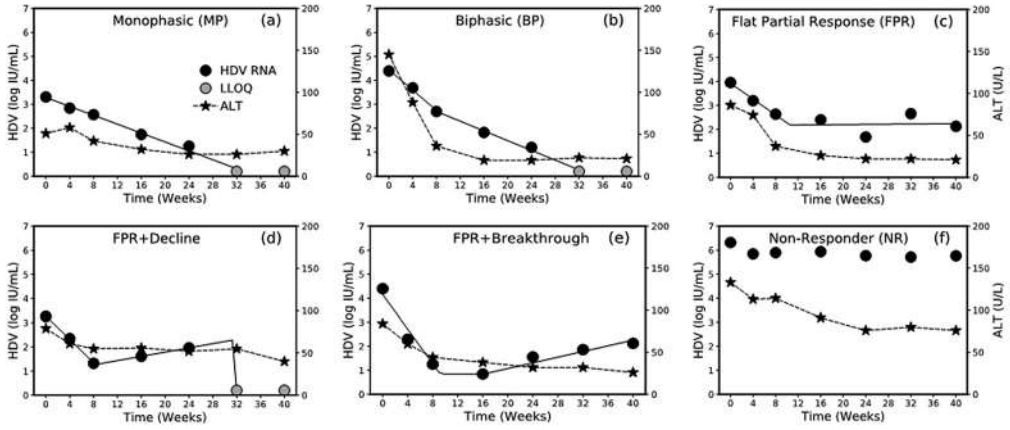

Figure 1. HDV kinetic patterns under BLV monotherapy in patients with advanced liver disease. **(a)** monophasic, MP, i.e., a single phase of viral decline (n=3), **(b)** biphasic, BP, viral decline consisting of a first phase decline that was 2-fold larger than the second phase decline rate (n=7), **(c)** flat-partial response, FPR, defined as a first phase viral decline followed by a plateau that was not significantly (p>0.05) different from slope=0 (n=4), **(d)** FPR followed by decline (n=1), **(e)** FPR followed by breakthrough (n=1), and **(f)** non-responder, NR, defined as having < ~1.0 log IU/mL decline from baseline (n=2). Solid lines for HDV reflect modelling using piecewise linear regression and dashed lines between ALT markers are shown only to highlight the trajectory.

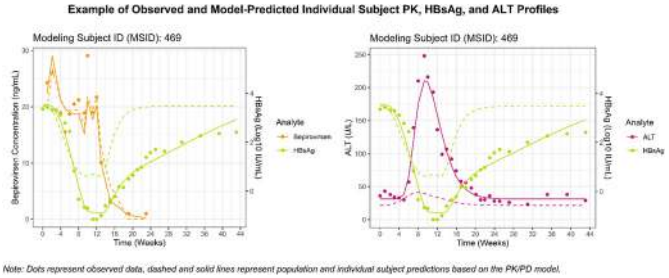
Email: amir.s.youssef@gsk.com

Background and aims: Bepirovirsen (BPV), an antisense oligonucleotide that inhibits production of HBsAg, is currently being developed for the treatment of Chronic Hepatitis B (CHB) with the goal of achieving functional cure (i.e., sustained viral suppression after stopping treatment). Following treatment with BPV, decreases in HBsAg were often observed prior to or in parallel with transient increases in alanine transaminase (ALT); suggesting an increase in immune-mediated clearance of infected hepatocytes and subsequent release of ALT. A mechanistic Pharmacokinetics (PK)/Pharmacodynamics (PD) model was developed to describe the time course of BPV systemic exposures and its effect on changes in HBsAg and ALT and to identify patient characteristics that may be predictors of exposure and response to treatment.

Method: PK, HBsAg and ALT data were pooled from a Phase 1 study (GSK 213725) (n = 28, dose range 75–450 mg) in healthy volunteers, Phase 2a (GSK 205695) and Phase 2b (GSK 209668) studies (n = 31 and 455, respectively, doses of 150 or 300 mg) in participants with CHB. BPV was administrated subcutaneously for up to 4 weeks in the Phase 1 and 2a studies and 12 or 24 weeks in the Phase 2b study. In the developed PK/PD model, HBsAg levels below the lower limit of quantification (LLOQ, <0.05 IU/ml) were estimated using a likelihood-based approach in order to predict a complete HBsAg profile during on- and off-treatment periods. A threshold for continued viral suppression was implemented to reflect an increased probability of participants achieving and maintaining HBsAg levels below LLOQ (BLQ) at end of study if their predicted HBsAg levels fall below the threshold. Direct and indirect drug effects on ALT were explored to describe ALT increases. The indirect effect was driven through reduction of HBsAg, resulting in immune-mediated hepatocyte senescence and subsequent ALT release. Using the developed PK/PD model, effects of BPV loading dose (LD) as well as baseline patient characteristics (e.g. demographics, HBsAg, HBeAg, genotype) on the response to bepirovirsen treatment were evaluated.

Results: The model accurately captured the time-course of BPV exposure, HBsAg and ALT changes as well as the percentage of subjects achieving and maintaining BLQ HBsAg levels at end of treatment and end of study, respectively. The increase of ALT was primarily driven by HBsAg suppression rather than a direct drug effect and baseline HBsAg was identified as a significant predictor of response to treatment. Model results indicate no significant efficacy benefit with inclusion of LD in the first two weeks of treatment; nor a difference in exposure-response relationship based on nucleos(t)ide coadministration.



Conclusion: The developed PK/PD model provides a useful tool for informing key decisions regarding Phase 3 design, dose selection, treatment duration, and patient population.

Background and aims: Prior studies comparing TAF with TDF have shown similar efficacy and improved renal/bone safety, but outcome data for patients switched to TAF after other nucleos(t)ide analogues (NA) are limited. We aimed to assess treatment and safety outcomes of CHB patients switched to TAF after at least 1 year of another NA regimen.

Method: We prospectively enrolled adult CHB patients who switched from any NA to TAF at 14 centers in Japan, Korea, Taiwan, and the U.S.

All patients gave written informed consent. Primary outcomes were complete viral suppression (CVS, HBV DNA<20 IU/ml), biochemical response (BR, ALT<35/25 U/L men/women), and complete response (CVS+BR). Safety assessments included changes in estimated glomerular filtration rate (eGFR) and bone T-scores.

Results: We enrolled 270 eligible patients. Mean age was 58.1 ± 10.6, 58.2% were male, 99.6% were Asian, 12.2% had cirrhosis, and 7.8% had chronic kidney disease (CKD). 73.7% switched from entecavir monotherapy, 23% from TDF/adefovir-based therapy (7.8%: combination therapy), 3.3% from another nucleoside analogue, and mean duration of NA treatment prior to TAF was 7.5 ± 4.0 years. Between switch and week 96 follow-up, the proportions of patients with CVS (95.2% to 98.8%), BR (75.2% to 78.7%), and complete response (72.6% to 77.9%) significantly increased (all p < 0.001). As shown in Figure, comparing levels at switch vs. week 96 of follow-up, there was no significant difference in mean eGFR (88.4 ± 16.9 vs. 89.5 ± 16.3, p = 0.13) or the distribution of CKD stage (p = 0.10). In contrast, between switch and 96-week after switch, mean T-scores significantly improved (from – 1.43 ± 1.36 to – 1.17 ± 1.38, p < 0.001), more patients had normal bone density (47% vs. 35%) and fewer patients had osteoporosis/osteopenia (53% vs. 65%) or osteoporosis (14% vs. 20%) (p = 0.019, Figure). In multivariable analysis, significant factors associated with worsening eGFR were age (adjusted odds ratio [aOR] 1.09, p = 0.004) and baseline eGFR, while male sex was associated with lower risk of developing osteopenia/osteoporosis (aOR 0.29, p = 0.020). Twelve patients (4.4%. 15/270) did not complete week-96 follow-up. There were 15 SAEs (5.6%, 15/270) and none were related to TAF.

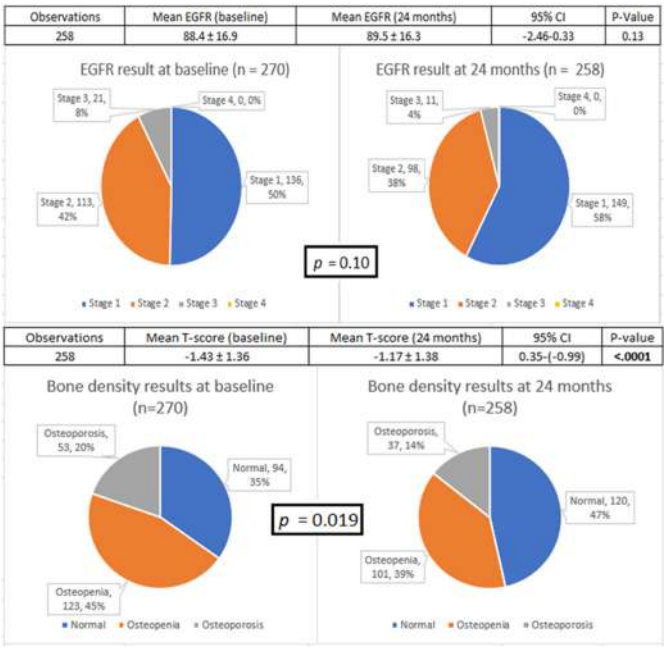

Figure: Week 96 safety results of TAF after other NA treatment

Conclusion: At 96-week following switch to TAF after an average of 7.5 years of treatment with other NA regimen, complete treatment response rated increased while renal function remained stable and bone density significantly improved.

SAT443

Long-term suppression maintained after cessation of AB-729 treatment and comparable on-treatment response observed in HBeAg+ subjects

Background and aims: AB-729 is an *N*-Acetylgalactosamine (GalNAc)-conjugated single trigger RNA interference therapeutic that targets all HBV RNA transcripts, including HBx, resulting in suppression of viral replication and all viral antigens. AB-729 is in Phase 2 clinical development for the treatment of chronic hepatitis B (CHB). Here we report additional on treatment and follow-up data from AB-729–001 including a dedicated HBeAg+ cohort.

Method: In AB-729–001 Part 3, 41 non-cirrhotic, CHB subjects received AB-729 60 mg every 4 weeks (Q4W, Cohort E, N = 7), 60 mg every 8 weeks (Q8W, Cohort F, N = 7), 90 mg Q8W (Cohorts I (N = 6), G (N = 7) and K (N = 7)), or 90 mg every 12 weeks (Q12W, Cohort J, N = 7). Cohort G was HBV DNA+ and initiated tenofovir disoproxil fumarate on Day 1; all other Cohorts were virologically suppressed on stable nucleos (t)ide analogue (NA) therapy. Cohort K was all HBeAg+ at baseline. Eligible subjects could continue AB-729 through Week 48. Subjects are followed 48 weeks or more after AB-729 discontinuation.

Results: 40/41 eligible subjects consented to treatment extension. Complete on-treatment data for Cohorts E and F have been reported; at Weeks 32 and 36 post last dose, respectively, mean HBsAg change in Cohorts E and F was – 1.0 $\log_{10}$ or more and 4/11 subjects with data remained <100 IU/ml. One subject in Cohort E underwent HBsAg seroconversion after AB-729 discontinuation while still on NA. The mean HBsAg declines for the 90 mg Cohorts I, J, K and G were similar (Table). In Cohorts I, J and G, 12/17 subjects with data were <100 IU/ml and 6 were <10 IU/ml at Week 48. At 20 Weeks post last dose, 11/18 subjects with data were <100 IU/ml and 3 were <10 IU/ml. The mean (SE) $\log_{10}$ change in HBeAg was – 0.71 (0.44) at Week 32 in Cohort K. There were no deaths or discontinuations due to AEs. There were 2 unrelated SAEs; all other AEs were Grade 1 or 2.

Baseline and Preliminary Mean (SE) $\log_{10}$ Change in HBsAg

	HBV DNA–		HBV DNA+	HBeAg+ only
Nominal Visit	Cohort I **N = 6**	Cohort J **N = 7**[1]	Cohort G **N = 7**	Cohort K **N = 7**
Baseline IU/ml	3.36 (0.23)	3.37 (0.28)	3.14 (0.14)	3.23 (0.14)
Week 12	–1.37 (0.22)	–1.11 (0.35)	–1.56 (0.32)	–1.63 (0.39)
Week 24	–1.80 (0.23)	–1.56 (0.25)	–1.82 (0.29)	–1.99 (0.35)
Week 36	–2.06 (0.28)	–1.70 (0.39)	–2.08 (0.32)	–2.28 (0.43)
Week 48	–1.91 (0.32)	–1.80 (0.41)	–2.16 (0.34)	_
20 Weeks Post Last Dose[2]	–1.42 (0.26)	–1.63 (0.39)	–1.50 (0.13)	_

[1]N = 6 entered treatment extension in J.
[2]Last dose Cohort J: Week 36, Cohorts I, G, K: Week 40.

Conclusion: AB-729 repeat dosing continues to be generally safe and well tolerated with robust and sustained declines in HBsAg that are comparable across treatment regimens. Neither HBeAg status nor DNA+ at baseline appear to affect response. In 17/31 subjects with data across all cohorts, HBsAg <100 IU/ml was maintained at least 20

weeks post last dose of AB-729. These data support the continued evaluation of AB-729 as the cornerstone of combination CHB treatment.

SAT444

Identification of novel antivirals against hepatitis delta virus infection via high throughput screening

Eirini Tseligka[1], Sophie Clément-Leboube[1], Francesco Negro[2].
[1]*University of Geneva Medical School;* [2]*University Geneva Hospital*
Email: eirini.tseligka@unige.ch

Background and aims: Chronic hepatitis delta (CHD) is the most severe form of chronic viral hepatitis with major clinical challenges. HDV tight dependence on its helper virus, Hepatitis B Virus (HBV) and the host cell machinery for its life cycle limits the development of drugs directly acting on HDV, while its therapeutic management remains unsatisfactory. We aim to identify compounds that block HDV replication by targeting HDV ribozymes (Rz), specific viral RNA sequences that undergo self-cleavage and ensure an efficient viral replication. We performed a high throughput screening (HTS) of FDA approved drug libraries to identify novel antivirals against HDV infection.
Method: We generated stable Huh7 human hepatoma cells expressing a reporter gene (secreted Gaussia luciferase, Gluc) either downstream (2xRz-Gluc) or upstream (Gluc-2xRz) of two HDV antigenomic Rz sequences. The cis-acting HDV Rz is self-cleaved leading to mRNA degradation and no detection of the secreted luciferase, whereas in the case of its inhibition, the detection of Gluc was monitored. Construct with Gluc alone was used as control. Validation of the assay was performed using a morpholino antisense nucleotide (GeneTools) as a positive control. We performed HTS of FDA approved drug libraries and measured the secreted luciferase as a readout of Rz inhibition after the addition of the molecules. Each plate with Z factor>0.4 was considered valid. Dose-response effect and toxicity evaluation of the hits with Z-score >5 was calculated. Analyses and statistic calculations were performed using an excel macro based on Genedata and ActivityBase softwares (IDBS). All data were generated from two independent experiments.
Results: No effect in the luciferase induction was observed in 2xRz-Gluc transfected cells treated with the antisense morpholino, whereas a dose dependent induction of the luciferase expression was detected in Gluc-2xRz transfected cells, implying the efficient inhibition of HDV antigenomic Rz autocatalytic cleavage (EC50 = 27.3 µM). We thus performed HTS on Gluc-2xRz. Gluc cells were included to ensure the specific induction of Gluc due to the inhibition of the HDV antigenomic Rz. The compounds with a Z-score>5 were selected as positive hits with potentially promising inhibitory effect. We identified six compounds, namely APE000288, APE000286, APE000283, APE000285, APE000916 and APE000445 that showed a specific inhibitory effect on HDV antigenomic Rz in the Gluc-2xRz cells. No sign of toxicity was observed.
Conclusion: Six out of 6644 screened compounds showed a specific inhibitory effect on HDV antigenomic Rz. Further studies investigating the antiviral effect in a relevant cell culture infection model and the mechanism of action are currently ongoing. Drug combinational studies and resistance emergence studies will be additionally performed in the future.

SAT445

Generation and functional analsis of spacer modified HBV-specific chimeric antigen receptors that harbor a Fab fragment as binding domain

Zhe Xie[1], Oliver Quitt[1], Lisa Wolff[1], Elfriede Nößner[1], Ulrike Protzer[1,2].
[1]*Institute of virology, Technical University of Munich/Helmholtz Zentrum München, München, Germany;* [2]*German Center for Infection Research (DZIF), partner site Munich, Munich, Germany*
Email: protzer@tum.de

Background and aims: Chimeric antigen receptor (CAR) T-cell therapy is a promising novel therapeutic approach for cancer, but has recently also been explored in the context of chronic viral infection. CARs are synthetic receptors designed to drive antigen-specific activation of T cells upon binding to cognate antigen, however, some of these artificial receptors have been found to elicit different levels of ligand-independent constitutive signaling. Our study aimed at generating novel CARs using antibody Fab fragments that target the hepatitis B virus envelope protein (HBVenv) on the membrane of HBV-infected cells and to study how their specificity can be guaranteed and which role different spacer lengths play.
Method: We constructed novel CARs that contain the HBVenv-specific human B cell-derived antibody fragment (4D06) as binding domain and CD3- as well as CD28 signaling domains (FabCAR). To determine the impact of spacer length on constitutive signaling, we employed several human immunoglobulin G (IgG) spacers with different lengths (IgG1CH2CH3 (225aa), IgG4CH2CH3 (226aa), IgG4CH3 (116aa) or IgG4Hinge (9aa)) and studied the activation of FabCAR-engrafted T cells in the presence and absence of target antigen. T-cell activation was assessed by quantification of pro-inflammatory cytokines and elimination of HBVenv-transgenic hepatoma cells.
Results: T cells from healthy donors were successfully engrafted with 4D06 FabCARs and efficiently eliminated HBVenv-transgenic Huh7S and HepG2 SML cells. Elimination of target cells was accompanied by secretion of interferon gamma, tumor necrosis factor alpha and granzyme B. However, T cells expressing FabCARs with a long spacer showed high levels of antigen-independent cytokine release and eliminated antigen-negative control cells. This constitutive, ligand-independent T-cell activation correlated with the spacer length and limiting spacer length allowed for antigen-specific T-cell activation. Employing the shortest spacer domains (IgG4 Hinge) completely abolished the constitutive T-cell activation and rendered the FabCAR-engrafted T cells HBV specific.
Conclusion: Our findings demonstrate that the spacer region of a CAR construct can significantly influence ligand-independent signaling and indicate that spacer length modification is an interesting strategy to improve efficacy and safety of CAR T cells. T cells stably transduced with 4D06 FabCARs containing a short spacer efficiently eliminated HBVenv-positive cells in an antigen-dependent manner and represent an interesting novel means to treat chronic hepatitis B and HBV-associated hepatocellular carcinoma.

Randomised double-blind study of nitazoxanide for virologically suppressed HBeAg negative chronic Hepatitis B

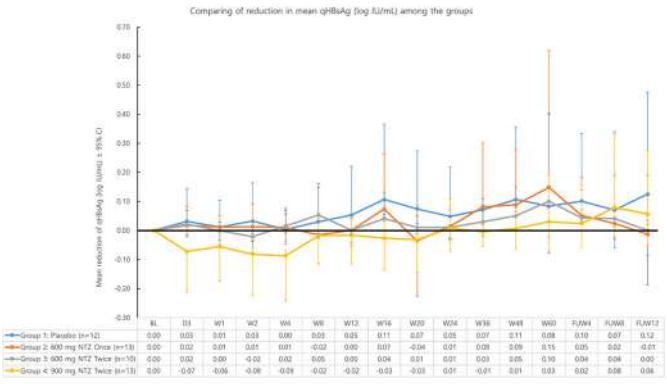
Yong Chuan Tan[1,2], Liang Shen[3], Htet Htet Toe Wai Khine[1], Yuh Ling Amy Tay[1], Celina Adraneda[1,2], Jean-Francois Rossignol[4], Celine Rossignol[4], Seng Gee Lim[1,2]. [1]*Yong Loo Lin School of Medicine, National University of Singapore, Singapore, Department of Medicine, Singapore, Singapore;* [2]*National University Hospital, Singapore, Division of Gastroenterology and Hepatology, Singapore, Singapore;* [3]*Yong Loo Lin School of Medicine, National University of Singapore, Singapore, Biostats Unit, Singapore, Singapore;* [4]*Romark L C, United States*
Email: mdcv341@nus.edu.sg

Background and aims: Nitazoxanide (NTZ) is a potential HBV therapeutic agent. NTZ disrupts Hepatitis B x protein (HBx) and host DNA-binding protein 1 (DDB1) interaction and prevents the formation of HBx-DDB1 protein complex responsible for the degradation of host restriction factor-structural maintenance of chromosomes 5/6 (SMC5/6). Restoration of SMC5/6 level after NTZ treatment suppresses Hepatitis B covalently closed circular DNA expression *in vivo*. (Sekiba, Otsuka et al. 2019) A subsequent pilot study demonstrated good anti-viral efficacy with 33% of patients (3 of

9 patients) achieving HBsAg loss (Rossignol and Brechot 2019). Consequently, this randomized controlled trial was designed to test NTZ efficacy.

Method: We conducted a phase 2, double-blinded, placebo-controlled, dose-finding, randomized control trial for Hepatitis B e antigen (HBeAg) negative Chronic Hepatitis B patients on long-term (>1 year) nucleos (t)ide analogues (NUCs) (Tenofovir disoproxil fumarate, Tenofovir alafenamide, or Entecavir). Participants were randomized (1:1:1:1) to receive either placebo (Group 1), NTZ 600 mg once daily (Group 2), NTZ 600 mg twice daily (Group 3), or NTZ 900 mg twice daily (Group 4), in addition to their NUC therapy. Primary efficacy end point was defined by the mean change in quantitative Hepatitis B surface antigen (qHBsAg) from baseline to week 48. Secondary end points included sustained off-treatment Hepatitis B surface antigen (HBsAg) loss, qHBsAg reduction, HBsAg seroconversion, Hepatitis B DNA suppression, and change in baseline Fibroscan and/or Fibrosis-4 score

Results: In total, 48 patients were enrolled. 12, 13, 10, and 13 patients were randomized to Group 1, 2, 3, and 4 respectively. There were no statistical differences in the key baseline patient characteristics (age, gender, presence of fatty liver, cirrhosis, Fibroscan score, Fibrosis-4 score, previous PEG-IFN exposure) between treatment groups. Overall, 4 patients who received NTZ and 1 patient who received placebo experienced severe adverse events (SAEs). 4 cases of grade 3 SAEs were deemed to be unrelated to NTZ (hepatocellular carcinoma (n = 2); gastroesophageal reflux (n = 1); perianal abscess (n = 1)). Grade 4 SAE for alanine transaminase and aspartate aminotransferase elevation occurred in 1 patient (group 4) before resolving uneventfully with NTZ dose reduction. The primary and secondary efficacy end points were not met in all groups. No statistical difference in qHBsAg reduction or mean qHBsAg was detected between groups at all study time-points. Analysis of individual patient quantitative HBsAg kinetics did not identify any NTZ responder. The study was terminated early because of the lack of efficacy.



Conclusion: NTZ is safe and tolerable in CHB. Regrettably, the addition of NTZ to NUC therapy did not increase anti-viral efficacy.

SAT447

Low-level viremia in patients with chronic hepatitis B receiving entecavir, tenofovir and tenofovir alafenamide

Xiaohao Wang[1], Dachuan Cai[1], Zhang Juan[1]. [1]*The Second Affiliated Hospital, Chongqing Medical University, Infectious Diseases, Chongqing, China*
Email: cqmucdc@cqmu.edu.cn

Background and aims: Low-level viremia (LLV) has been reported to be associated with unfavourable outcomes in patients with chronic hepatitis B (CHB). The aims are to evaluate the effect of therapeutic drugs including entecavir (ETV), tenofovir (TDF) and tenofovir alafenamide (TAF) on LLV in CHB patients.

Method: CHB patients who received either ETV, TDF or TAF as a first-line antiviral agent were recruited from July 2020 to March 2021 at the Second Affiliated Hospital of Chongqing Medical University. The demographic characteristics and clinical data were collected. Binary logistic regression analysis was performed to identify the risk factors on the LLV.

Results: In total, 1043 patients (685, 284 and 74 in the ETV, TDF and TAF group) were recruited in this study. At baseline, the mean HBV-DNA level in ETV, TDF and TAF groups was 5.6 (SD:1.3), 5.6 (SD:1.2), and 5.5 (SD:1.1) $\log_{10}$ IU/ml, respectively. About half of the patients were HBeAg positive (46.1%, 56.7% and 54.1%, respectively). After receiving a median of 100.0 (IQR: 66.0–192.0) weeks of antiviral therapy, the incidence of LLV was 30.2% (207/685), 34.9% (99/284) and 28.4% (21/74) in ETV, TDF and TAF groups respectively (p = 0.31). Univariate analysis found that female, age, antiviral time, cirrhosis, and baseline parameters including serum ALT, AST, HBeAg status, HBV-DNA level, albumin, glomerular filtration rate, and high-density lipoprotein-cholesterol were significantly associated with the LLV (p < 0.05). After adjusting for potential confounding factors in the binary logistic regression analysis, it was found that compared with ETV, TDF and TAF could significantly reduce the risk of LLV in patients with CHB (adjust OR: 0.59; 95% CI:0.40–0.88; p = 0.01, adjust OR: 0.50; 95% CI: 0.26–0.96, p = 0.04, respectively).

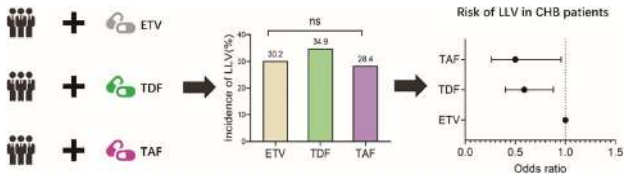


Figure: After receiving a median of 100.0 (IQR: 66.0–192.0) weeks of antiviral therapy, the incidence of LLV was 30.2% (207/685), 34.9% (99/284) and 28.4% (21/74) in ETV, TDF and TAF groups respectively (p = 0.31).

Conclusion: Compared with ETV, TDF and TAF are superior in reducing the risk of LLV in CHB patients.

SAT448

Continued suppression of viral markers observed following discontinuation of nucleos (t)ide analogue therapy in chronic hepatitis B subjects with low hepatitis B surface antigen levels after 48 weeks of treatment with AB-729

Man-Fung Yuen[1], Simone Strasser[2], Wattana Sukeepaisarnjaroen[3], Varun Sharma[4], Deana Antoniello[4], Elina Medvedeva[4], Emily P. Thi[5], Gaston Picchio[4], Timothy Eley[4], Karen Sims[4]. [1]*The University of Hong Kong, Division of Gastroenterology and Hepatology, Hong Kong;* [2]*Royal Prince Alfred Hospital, AW Morrow Gastroenterology and Liver Centre, Australia;* [3]*Khon Kaen University, Department of Medicine, Thailand;* [4]*Arbutus Biopharma, Clinical Development, Warminster, United States;* [5]*Arbutus Biopharma, Discovery, Warminster, United States*
Email: ksims@arbutusbio.com

Background and aims: AB-729 is an *N*-Acetylgalactosamine (GalNAc)-conjugated single trigger RNA interference therapeutic that targets all HBV RNA transcripts, including HBx, resulting in suppression of viral replication and all viral antigens. AB-729 is currently in Phase 2 clinical development in combination with other antiviral agents for the treatment of chronic hepatitis B (CHB). Study AB-729-001 assessed up to 48 weeks of AB-729 in combination with nucleos (t)ide analogue (NA) therapy. Here we report early follow-up data for subjects who met protocol eligibility criteria and elected to stop NA therapy at least 24 weeks after their last dose of AB-729.

Method: Subjects participating in study AB-729-001 who received 60 mg or 90 mg of AB-729 every 4 (Q4W), 8 (Q8W), or 12 (Q12W) weeks for 48 weeks were assessed for eligibility to stop NA therapy at least 24 weeks after their last dose of AB-729. Stopping criteria included ALT <2 × ULN, HBeAg negative, HBV DNA undetectable, and HBsAg <100 IU/ml on two separate measurements. Safety and PD

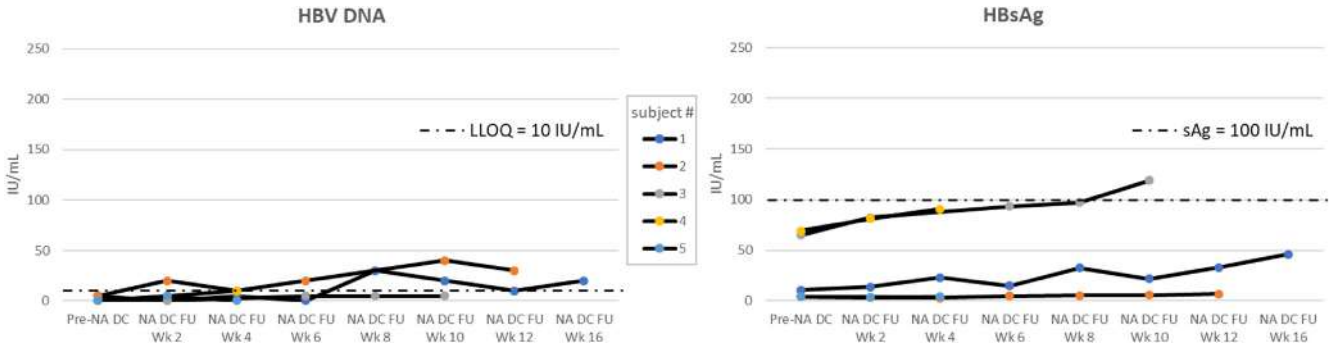

Figure: (abstract: SAT448)

assessments, including HBV DNA, HBsAg, HBV RNA, and HBcrAg were assessed every 2–4 weeks after NA discontinuation.

Results: To date, 27 subjects in the AB-729–001 study have completed at least 24 weeks of follow-up post-last dose of AB-729. Of these, 7 met all eligibility criteria to stop NAs, and 5/7 consented to stop all therapy. NA discontinuation subjects' mean age was 45 years (range 33–59), 3/5 were female, and 4/5 were Asian. One subject was in Cohort E (60 mg Q4W), 3 were in Cohort F (60 mg Q8W) and 1 was in Cohort I (90 mg Q8W). Three were taking entecavir and 2 were taking tenofovir disoproxil fumarate. At study entry, all were HBeAg negative, mean HBsAg was 2886.8 IU/ml (range 1392–6765) and HBcrAg ranged from <3.0 to 4.2 $\log_{10}$ U/ml. At the last visit prior to NA discontinuation (at least 24 weeks-post last AB-729 dose), mean HBsAg was 30.49 IU/ml (range 3.95–69.1) and HBcrAg ranged from <3.0 to 4.5 $\log_{10}$ U/ml. To date, all 5 subjects have completed between 4 and 16 weeks of follow-up off NA therapy, and no subjects have met clinical or viral relapse criteria. No AEs have been reported, no ALT elevations have been observed, and HBV DNA levels have remained either <LLOQ (3 subjects) or have transiently risen to 30 or 40 IU/ml and subsequently decreased in 2 subjects without intervention (Figure). HBsAg levels remain well below pre-study levels for all 5 subjects (Figure).

Conclusion: Discontinuation of NA therapy after AB-729-induced suppression of HBsAg to <100 IU/ml appears to be well-tolerated and leads to continued suppression of HBV DNA and HBsAg without evidence of early clinical or viral relapse. These subjects (and any others from this study who may discontinue NA in the future) will be followed for at least 48 weeks post-NA discontinuation to assess for sustained viral response and evidence of functional cure.

SAT449

Tenofovir alafenamide fumarate increased lipid levels in hepatitis B virus patients

Wenjuan Zhao[1], Yi Liu[2], Feng Ye[1], Zixin Cui[1], Shumei Lin[1], Lei Shi[1], Xi Zhang[1], Jianzhou Li[1], Xiaojing Liu[1], Yunru Chen[1]. [1]*The First Affiliated Hospital of Xi'an Jiaotong University Medical College, Department of infectious disease, Xi'an, China;* [2]*The First Affiliated Hospital of Xi'an Jiaotong University Medical College, traditional Chinese medicine department, Xi'an, China*
Email: chenyunru_2002@126.com

Background and aims: Tenofovir alafenamide fumarate (TAF) is among the main drugs for long-term antiviral therapy. Long term administration of TAF can lead to dyslipidemia in HIV patients Dyslipidemia is associated with arteriosclerosis and hepatocarcinogenesis.Therefore, this study prospectively investigates the effects of TAF on blood lipids after 24 weeks in chronic hepatitis B (CHB) patients.

Method: Forty CHB patients with normal blood lipids were treated with TAF for 24 weeks among them there are 19 female and 21 male patients, 13 patients treated with ETV switching to TAF, 13 patients treated with TDF switching to TAF, 14 patients treated with initial TAF, and 7 patients with fatty liver. The serum level of cholesterol (TC), low density lipoprotein (LDL), high density lipoprotein (HDL-C), and triglyceride (TG) at baseline and 24 weeks treatment were analyzed.

Results: After TAF treatment for 24 weeks, the HDL, LDL and TG levels showed a trend of increasing, and the TC level increased significantly ($p = 0.006$). Typically, the TC level increased significantly in female patients ($p = 0.041$) and in patients with TDF switching ($p = 0.036$). Compared with the non-fatty liver patients, the TG levels increased significantly in the patients with fatty liver ($p = 0.006$). In addition, the dyslipidemia rate increased after TAF treatment, and the LDL abnormal rate (LDL ≥2.5 mmol/L) was up to 20% ($p < 0.005$).

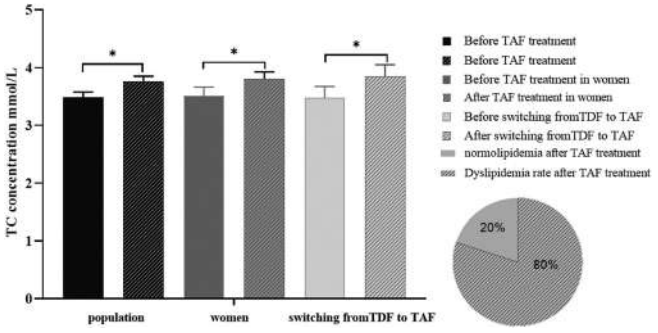

Figure: Changes of TC levels before and after TAF treatment in total patients (n = 40), in female patients (n = 19), in TDF switching to TAF patients (n = 13) and dyslipidemia rate of TAF treatment for 24 weeks. TAF: tenofovir alafenamide fumarate; TDF: tenofovir disoproxil; TC total cholesterol; *P < 0.05. Before TAF treatment; After TAF treatment; Before TAF treatment in female; After TAF treatment in female; Before TAF treatment in TDF switching to TAF; After TAF treatment in TDF switching to TAF.

Conclusion: TAF treatment for 24 weeks impacted lipid metabolism. Our study indicated that to monitor the blood lipids was necessary in CHB patients with TAF treatment. Especially, the changes in blood lipids should be closely observed in female patients, in switching from TDF to TAF patients, and in patients with fatty liver during TAF treatment. In addition, we only collected 24-week data. The serum lipid profiles after 48 weeks and 96 weeks TAF treatment required further investigation. Lastly, the mechanisms associated with dyslipidemia induced by TAF remained to be clarify in further investigation.

M. and A. Migliavacca" Center for Liver Disease, Department of Pathophysiology and Transplantation, Milan, Italy
Email: maria.anolli@unimi.it

Background and aims: Bulevirtide (BLV) has been recently approved for the treatment of chronic hepatitis Delta (CHD) in Europe, yet the rates of the off-therapy sustained responses following long-term BLV based treatment are currently unknown.
Method: A 54-year Caucasian male with HDV related compensated cirrhosis and clinically significant portal hypertension (CSPH) was treated with BLV monotherapy for 3 years and then followed for 48 week off-therapy. Clinical and virological characteristics were collected every 2 months after BLV withdrawal. HDV RNA was quantified by Robogene 2.0 (LOD 6 IU/ml), HBcrAg by LUMIPULSE® G (LOQ 3 Log U/ml), HBV RNA by cobas® 6800 (LOQ 10 cp/ml).
Results: At the end of the 3 years of BLV monotherapy, ALT were within the normal range, HDV RNA <6 IU/ml and liver function was preserved (CPT score A). During 48 weeks of post-BLV follow-up, HDV RNA levels remained undetectable (HDV RNA <6 IU/ml) and liver function tests within the normal range at all timepoints. While no changes were observed for HBV DNA (always <10 IU/ml) and HBV RNA (always <10 cp/ml) levels, HBsAg and HBcrAg levels declined (4 *vs.* 3.4 log IU/ml; 4.5 *vs* 3.4 log IU/ml, respectively). Compared to baseline, liver stiffness measurement (LSM) by Fibroscan© declined (17.9 *vs.* 11.5 kPa) and stigmata of portal hypertension improved: PLT normalized (74 *vs.* $144 \times 10^3/mm^3$) and oesophageal varices disappeared. Likewise, autoimmune features secondary to HDV infection, like IgG and γglobulins, normalized. Biliary acids fell into the normal range immediately after BLV withdrawal. A liver biopsy was performed at the end of the post-treatment follow-up: histological response will be presented at the meeting.
Conclusion: A 3-year course of BLV monotherapy may cure HDV infection even in difficult-to-treat cirrhotic patients.

Combination treatment of a PAPD5/7 inhibitor with an antisense oligonucleotide bepirovirsen with concurrent dosing shows additive HBsAg decreases in the AAV-HBV mouse model

Jared Delahaye[1], Edward Long[1], Chi Lau[1], Jacob Parsons[1], Bo Wen[1], Zhiyi Cui[1], Melanie Paff[1], Shihyun You[1], Martin Leivers[1].
[1]GlaxoSmithKline, Collegeville, PA, United States
Email: martin.r.leivers@gsk.com

Background and aims: Achieving high levels of functional cure of chronic hepatitis B (CHB) will likely require a treatment regimen containing multiple mechanisms of action. Small molecule inhibitors of the noncanonical poly (A) polymerase 5 and 7 (PAPD5/7) have been shown preclinically to reduce hepatitis B surface antigen (HBsAg) in a mouse model of HBV infection. This current work describes investigation of combinations of a PAPD5/7 inhibitor, GSK3965193, (GSK193) with bepirovirsen (BPV, antisense oligonucleotide against HBV, currently completed a Ph2b study (study NCT04449029)) in a mouse model of HBV infection. Sequential and concomitant treatment of the two agents were explored and the results used to inform future clinical combination trial design.
Method: The AAV-HBV mouse model of HBV infection was used to establish a dose response for both GSK193 and bepirovirsen as monotherapies. Then, two potential clinical treatment paradigms were tested where both agents were administered concurrently or GSK193 preceding treatment with bepirovirsen in a sequential fashion. GSK193 was dosed at 0.3–30 mg/kg, PO, BID for 28 days and bepirovirsen was dosed at 20 or 40 mg/kg, subcutaneous on days 0, 3, 7, 11, 14 and 21) HBsAg was the key viral end point measured for these studies.
Results: Monotherapy treatment of the PAPD5/7 inhibitor GSK193 resulted in an up to 1 log reduction in HBsAg levels with BID dosing for 28 days. Monotherapy treatment of the antisense oligonucleotide bepirovirsen resulted in an up to 2 log reduction in HBsAg levels with doses on days 0, 3, 7, 11, 14 and 21. When both agents were administered concurrently over 28 days, additional decreases reaching 3 logs in HBsAg were observed over either mono therapy alone. For the sequential treatment of GSK193 followed by bepirovirsen, rapid rebound in HBsAg occurred after discontinuation of GSK193 resulting in no added benefit in this regimen.

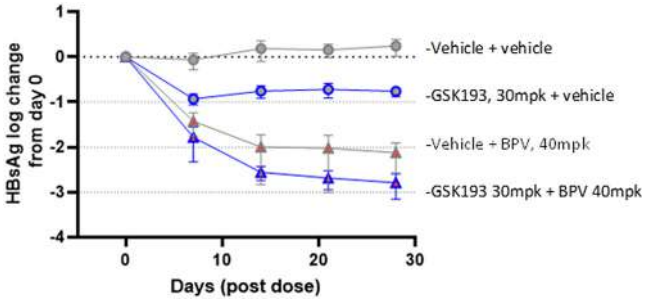

Figure: Reductions in HBsAg with monotherapy or combination dosing of PAPD5/7 inhibitor (GSK193) and ASO (bepirovirsen)

Conclusion: Combinations of a PAPD5/7 inhibitor (GSK193) and antisense oligonucleotide (bepirovirsen) provide additional reductions in HBsAg when dosed concurrently in the AAV-HBV mouse model of HBV. Concurrent dosing of these compounds is also superior in terms of maximal HBsAg suppression to sequential dosing preclinically.

SAT452

Efficacy and safety of bepirovirsen in patients with chronic hepatitis B virus infection not on stable nucleos (t)ide analogue therapy: interim results from the randomised phase 2b B-Clear study

Seng Gee Lim[1], Cristina Pojoga[2,3], Harry Janssen[4], Denis Gusev[5], Robert Plesniak[6], Keiji Tsuji[7], Ewa Janczewska[8], Corneliu Petru Popescu[9], Pietro Andreone[10], Jinlin Hou[11], Manuela Arbune[12], Adrian Gadano[13], Diana Petrova[14], Jun Inoue[15], Teerha Piratvisuth[16], Young-Suk Lim[17], Apinya Leerapun[18], Masanori Atsukawa[19], Ji-Dong Jia[20], Eternity Labio[21], Jennifer Cremer[22], Robert Elston[23], Tamara Lukic[24], Geoff Quinn[23], Stuart Kendrick[23], Punam Bharania[23], Fiona Campbell[23], Melanie Paff[22], Dickens Theodore[22]. *[1]National University Health*

Background and aims: Bepirovirsen (BPV; GSK3228836) is an antisense oligonucleotide shown to induce a reduction in hepatitis B surface antigen (HBsAg), and in some cases transient HBsAg seroclearance, following 4 weeks (wks) treatment with a favourable safety profile in a phase 2a study in patients (pts) with chronic hepatitis B (CHB) infection. B-Clear is a phase 2b trial (NCT04449029) assessing the efficacy and safety of 12 or 24 wks BPV treatment in pts with CHB on-stable nucleos(t)ide analogue (NA) treatment or not on-NA therapy at study start. The study is ongoing; here we present interim results through the end of BPV treatment (EoT) for pts not on NA therapy.
Method: Multicentre, randomised, partial-blind (investigator unblinded), parallel-cohort study in pts with CHB. Pts required HBsAg >100 IU/ml, HBV DNA >2000 IU/ml and alanine aminotransferase <3× upper limit of normal. Pts were randomised (3:3:3:1) to 1 of 4 treatment arms, with treatment administered weekly with (w/) or without (w/o) loading doses (LD) on Days 4 and 11: 1. BPV 300 mg w/LD for 24 wks; 2. BPV 300 mg w/LD for 12 wks then 150 mg for 12 wks; 3. BPV 300 mg w/LD for 12 wks then placebo (PBO) for 12 wks; 4. PBO for 12 wks then BPV 300 mg w/o LD for 12 wks. Pts were stratified by baseline hepatitis B e antigen (HBeAg; positive/negative) and HBsAg level (≤3 or >3 log10 IU/ml). Primary end point: proportion of pts achieving HBsAg <lower limit of quantification (LLOQ) and HBV DNA <LLOQ sustained for 24 wks without rescue medication after planned BPV EoT. Secondary end points reported here: proportion of pts achieving HBsAg <LLOQ and HBV DNA <LLOQ by BPV EoT. Safety was assessed via adverse event (AE) monitoring.
Results: 230 pts (54% male, 57% Asian, 74% HBeAg negative, 19% HBsAg ≤3 log10 IU/ml) were included in the intent-to-treat population (70, 68, 68 and 24 pts, respectively, in arms 1–4); 21 pts (9%) discontinued treatment. At EoT, 29%, 13%, 7% and 0% pts had HBsAg <LLOQ and HBV DNA <LLOQ in arms 1–4, respectively. HBsAg response data are shown in Figure. Overall, serious AEs (SAEs) were reported in 4% pts and treatment-related SAEs in 1% pts. No clinically meaningful differences in AEs across treatment arms.

Conclusion: 24 wks of 300 mg BPV resulted in HBsAg <LLOQ and HBV DNA <LLOQ in 29% of pts at EoT; the durability of this response is being assessed. There were no safety signals to preclude further development.

Evaluation of Interleukin-6 for stepwise diagnosis of minimal hepatic encephalopathy in patients with liver cirrhosis

Simon Johannes Gairing[1,2], Julian Anders[1], Leonard Kaps[1,2], Michael Nagel[1,2,3], Maurice Michel[1,2], Wolfgang Maximilian Kremer[1,2], Max Hilscher[1,2,3], Peter Galle[1,2], Jörn Schattenberg[1,4], Marcus-Alexander Wörns[1,2,3], Christian Labenz[1,2]. *[1]University Medical Center of the Johannes Gutenberg-University, Department of Internal Medicine I, Mainz, Germany; [2]University Medical Center of the Johannes Gutenberg-University, Cirrhosis Center Mainz (CCM), Mainz, Germany; [3]Dortmund Hospital, Department of Gastroenterology, Hematology, Oncology and Endocrinology, Dortmund, Germany; [4]University Medical Center of the Johannes Gutenberg-University, Metabolic Liver Research Program, Mainz, Germany*

Email: sgairing@uni-mainz.de

Background and aims: Minimal hepatic encephalopathy (MHE) is associated with poor quality of life and dismal prognosis. Psychometric testing is time consuming and therefore often neglected in routine clinical practice. Thus, predictive biomarkers are urgently needed to stratify patients at risk for MHE. This study aimed to evaluate the diagnostic accuracy of interleukin-6 (IL-6) serum levels as part of a stepwise diagnostic algorithm to detect MHE in patients with liver cirrhosis.

Method: The development cohort comprised 197 prospectively recruited patients without evidence of HE grade 1–4. A total of 52 patients served as the independent validation cohort. The Psychometric Hepatic Encephalopathy Score (PHES) was used for MHE diagnosis.

Results: In total, 50 (25.4%) patients of the development cohort were diagnosed with MHE. Serum IL-6 levels were more than twice as high in patients with MHE as in patients without MHE (16 vs 7 pg/ml, p <0.001). In logistic regression analysis, elevated IL-6 levels remained independently associated with MHE (OR 1.036, 95%CI 1.009–1.064, p = 0.008) after adjusting for other variables such as MELD, albumin, CRP and history of ascites. Using a cut-off value of IL-6 ≥7 pg/ml would have avoided subsequent time-consuming psychometric testing in 38% of all patients (sensitivity 90%, 95%CI 77%-96%; negative predictive value 93%, 95%CI 84%-98%). These results were confirmed in the validation cohort (sensitivity: 94%, NPV: 93%).

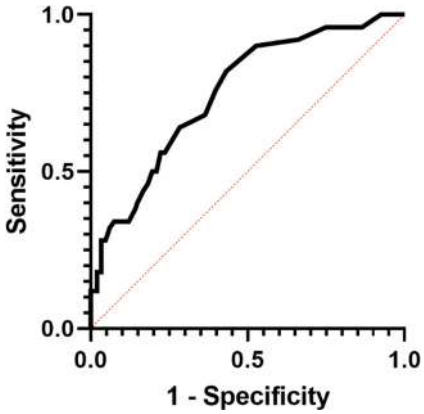

Figure: Discriminative ability of Interleukin-6 to detect minimal hepatic encephalopathy in the development cohort of patients with liver cirrhosis. AUC = 0.751, 95% CI 0.675–0.827, p <0.001.

Conclusion: IL-6 serum levels may serve as biomarker in a stepwise diagnostic algorithm reducing the number of patients requiring elaborate testing with PHES. In particular, IL-6 would be helpful in patients being incapable of performing other tests e.g., due to language barriers.

Evaluation of statins as a new therapy to alleviate chronotropic dysfunction in cirrhotic rats

Qamar Niaz[1,2], Sania Mehreen[3], Mahmoud Ghazi-Khansari[1], Farahnaz Jazaeri[1]. [1]*Department of Pharmacology, School of Medicine, Tehran University of Medical Sciences, Tehran, Iran;* [2]*Department of Pharmacology and Toxicology, Faculty of Bio-Sciences, University of Veterinary and Animal Sciences, Lahore, Pakistan;* [3]*Department of Zoology, Faculty of Fisheries and Wildlife, University of Veterinary and Animal Sciences, Lahore, Pakistan*
Email: fjazaeri@yahoo.com

Background and aims: Liver cirrhosis defines by regenerative nodules and fibrotic septa which causes cirrhotic cardiomyopathy (CCM) with chronotropic hypo-responsiveness. Statins have been reported to decrease inflammation, fibrosis, and portal pressure (PP) in liver cirrhosis through inhibition of Ras homolog family member A (RhoA) and stimulation of endothelial nitric oxide synthase (eNOS). Therefore, we studied the effect of atorvastatin on chronotropic hypo-responsiveness in biliary cirrhotic rats.

Method: Bile duct ligation (BDL) or sham surgery performed on Wistar *(Rattus norvegicus)* male rats and grouped as BDL/Saline, BDL/Ator-7d (days) (Atorvastatin 15 mg/kg/day), and BDL/Ator-14d groups or Sham/Saline, Sham/Ator-7d, and Sham/Ator-14d groups for cirrhosis or control groups respectively. Corrected QT (QTc) interval, chronotropic responses, serum brain natriuretic peptides (BNP), and heart tumour necrosis factor-alpha (TNF-alpha), nuclear factor erythroid 2-related factor 2 (Nrf2), and malondialdehyde (MDA) levels were studied along with liver histopathology, and atrial RhoA and eNOS genes expression.

Results: The chronotropic responses were decreased in BDL/Saline and increased in BDL/Ator-7d group. The QTc interval, BNP, TNF-alpha, and MDA levels were elevated in BDL/Saline and reduced in BDL/Ator-14d group. The Nrf2 level raised non-significantly in BDL/Saline and significantly in BDL/Ator-14d group. The liver inflammation and fibrosis increased in BDL/Saline and were not affected in BDL/Ator-7d and BDL/Ator-14d groups. The RhoA expression down-regulated in BDL/Saline, BDL/Ator-7d, and BDL/Ator-14d groups while the eNOS expression up-regulated non-significantly in BDL/Saline and down-regulated in BDL/Ator-14d group.

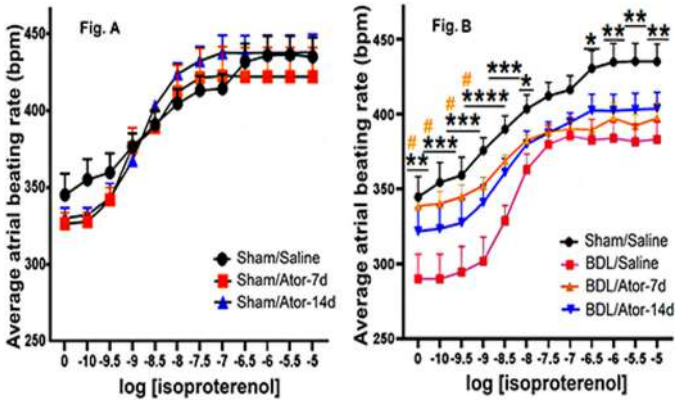

Figure: Average atrial beating rates of sham (control) and BDL (cirrhotic) rats after treatment with saline or atorvastatin (15 mg/kg/day for 7 and 14 days). The atrial beating rates were recorded before, and after stimulation with 10^{-10} to 10^{-5} M cumulative concentrations of isoproterenol. The data represent the mean ± SEM. At least, 6–8 rats were included per experimental group. (4B): [$^{*}P < 0.05$, $^{**}P < 0.01$, $^{***}P < 0.001$ and $^{****}P < 0.0001$ BDL/Saline group compared to Sham/Saline group], and [$^{\#}P < 0.05$ BDL/Ator-7d group compared to BDL/Saline group]

Conclusion: Atorvastatin alleviates the chronotropic hypo-responsiveness, and down-regulates the RhoA and eNOS expressions along with anti-inflammatory, anti-oxidant, and anti-stress effects in CCM.

SAT488

The effect of sarcopenia on survival of patients with cirrhosis: a systematic review and meta-analysis

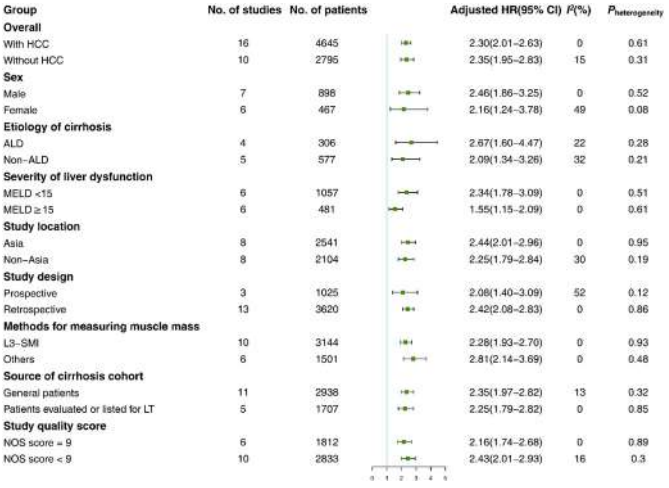
Email: jifanpu1979@163.com

Background and aims: The association between sarcopenia and prognosis in patients with cirrhosis remains to be determined. In this study, we aimed to quantify the association between sarcopenia and the risk of mortality in patients with cirrhosis, by sex, underlying liver disease etiology, and severity of hepatic dysfunction.

Method: PubMed, Web of Science, EMBASE, and major scientific conference sessions were searched without language restriction through 13 January 2021 with additional manual search of bibliographies of relevant articles. Cohort studies of ≥100 patients

with cirrhosis and ≥12 months of follow-up that evaluated the association between sarcopenia, muscle mass and the risk of mortality were included.

Results: 22 studies with 6965 patients with cirrhosis were included. The pooled prevalence of sarcopenia in patients with cirrhosis was 37.5% overall (95%CI 32.4%-42.8%), higher in male patients (41.9%), patients with alcohol associated liver disease (ALD) (49.6%), patients with CTP grade C (46.7%), and when sarcopenia was defined in patients by lumbar 3- skeletal muscle index (L3-SMI) (44.4%). Sarcopenia was associated with the increased risk of mortality in patients with cirrhosis (adjusted-hazard ratio [aHR] 2.30, 95% CI 2.01–2.63), with similar findings in sensitivity analysis of cirrhosis patients without HCC (aHR 2.35, 95% CI 1.95–2.83) and in subgroup analysis by sex, liver disease etiology, and severity of hepatic dysfunction (Figure). The 1-, 3-, and 5-year cumulative probabilities of survival in patients with sarcopenia were 76.6%, 64.3%, and 45.3%, compared to 93.4%, 82.0%, and 74.2%, respectively in patients without sarcopenia (all P < 0.001). The association between quantitative muscle mass index and mortality further supports the poor prognosis for patients with sarcopenia (aHR 0.95, 95% CI 0.93–0.98).



Conclusion: Sarcopenia was highly and independently associated with higher risk of mortality in patients with cirrhosis.

SAT489

Effectiveness of probiotics in the secondary prevention of hepatic encephalopathy among cirrhotic patients

Muhammad Farooq Hanif[1], Abdul Rehman[2], Raja Omar Fiaz[3], Khalid Mahmud Khan[4]. [1]*Pakistan Kidney And Liver Institute And Research Centre, Gastroenterology and Hepatology, Lahore, Pakistan;* [2]*Mayo Hospital, Gastroenterology and Hepatology, Lahore, Pakistan;* [3]*Central Park Medical College, Gastroenterology and Hepatology, Lahore, Pakistan;* [4]*Jinnah Hospital, Lahore, Gastroenterology and Hepatology, Lahore, Pakistan*
Email: farooqdr@hotmail.com

Background and aims: Cirrhosis is one of the leading cause of death around the globe[1]. The prevalence of hepatic encephalopathy (HE) which is one of its complication is 10–14% in general, 16–21% with decompensated cirrhosis and 30–40% are of those with cirrhosis at some time during their clinical course[2]. The risk for first bout of overt hepatic encephalopathy is 5–25% within 5 years after cirrhosis[3]. This study compared the effectiveness of lactulose alone versus combination of lactulose plus probiotics for secondary prevention of hepatic encephalopathy in cirrhotic patients[4–9].

Method: Patients with known chronic liver disease admitted with hepatic encephalopathy, were randomized to group A (Lactulose alone) and group B (Lactulose + Probiotics). Probiotic used was Cap. Ecotec 180 mg, 1 trillion CFU (L.acidophilus, Bifidobacterium, S. thermophilus, L.bulgaricus). After discharge each patient was followed for six months for hepatic encephalopathy recurrence. The absence of hepatic encephalopathy at the end of six months treatment for each patient was considered as effective treatment response. Compliance to the treatment and side effects were also noted during this time period.

Results: 166 patients included in the study. Mean age was 55.84 ± 7.82 and 52.37 ± 6.95 in group A and B respectively. Majority of patients were of child class B (75.90%), whereas 6% were child class C and 18% were child class A. Overall encephalopathy occurred in 51.80% and 36.14% of patients in group A and B respectively ($p = 0.02$). Encephalopathy was more common among relatively older females and patients with advanced child class with baseline ammonia more than 80ug/dl. Abdominal bloating, distaste and diarrhea were the common side effects in both groups with no significant difference in the side-effect profile. Patients were compliant to the treatment in both groups.

		Study Groups A N = 83	B N = 83	p value	Total N = 166
Hepatic Encephalopathy	Yes	43 (51.80%)	30 (36.14%)	0.02	73 (43.97%)
	No	31 (37.34%)	48 (57.83%)		79 (47.59%)
	Lost follow-up	09	05		14 (8.43%)
Male		37 (44.57%)	45 (63.85%)		82 (49.39%)
Female		46 (55.42)	38 (36.14)		84 (50.60%)
Symptoms free Male		19 (51.35%)	30 (66.66%)		47 (52.22%)
Symptom free Female		12 (26.08%)	18 (47.36%)		32 (42.10%)

Conclusion: In our cohort of cirrhotic patients, combination of lactulose and probiotics showed better response compared to lactulose alone in the long term secondary prevention of hepatic encephalopathy.

SAT490

Sarcopenia as a predictor of mortality and complications in cirrhosis patients-A prospective cohort study

Nidhin Devadas[1], K Sandesh[1], K SunilKumar[1]. [1]*Government Medical College, Kozhikode, Medical Gastroenterology, Kozhikode, India*
Email: niddas@gmail.com

Background and aims: Sarcopenia is a promising tool for prognostication of cirrhosis.EWGSOP2 guidelines define sarcopenia based on muscle strength, muscle quantity or quality and physical performance.Many previous studies didn't use a standardized definition of sarcopenia and was based on skeletal muscle measurement by CT or MRI.Ultrasound guided thigh muscle thickness (TMT) measurement is a validated, cost effective and easy method for assessment of muscle quantity.There is paucity of Indian studies analysing prognostic role of sarcopenia in cirrhosis.

To study the predictive role of sarcopenia on mortality and complications in cirrhosis patients.

Method: This was a prospective cohort study with 120 consecutive patients each in sarcopenia and no sarcopenia groups. Sarcopenia was diagnosed based on EWGSOP2 guidelines using ultrasound guided measurement of TMT.They were followed up for 6 months.Kaplan-Meier analysis with LogRank test was used to compare survival and

Cox proportional hazards model was used for multivariate analysis to determine risk factors of mortality.

Results: Cirrhosis patients with sarcopenia[N1 = 120, M:F = 80:40, Median age-58yrs (51–64)] and without sarcopenia[N2 = 120, M:F = 93:27, Median age-54yrs (46.25–60)] were enrolled.Six month cumulative survival was 56.7% and 76.7% in sarcopenia and no sarcopenia groups respectively (p = 0.001).Six month cumulative survival in severe and non-severe sarcopenia was 23.9% and 70% respectively (p = 0.001).Age, sex, nutritional status, sarcopenia status, CTP score, MELD score, Bilirubin, Albumin, INR and Sodium were significantly associated with survival.A multivariate analysis showed sarcopenia (HR = 1.283, 95%CI 1.092–2.130, p = 0.031), female sex (HR = 1.851, 95%CI 1.106–3.097, p = 0.019), CTP class C (HR = 1.447, 95%CI 1.252–1.794, p = 0.002) and MELD score>15 (HR = 1.116, 95%CI 1.056–2.203, p = 0.05) as independent predictors of mortality. Development of complications like ascites, HE, Covid infection and UGI bleed were significantly higher in sarcopenia group, while SBP, AKI, cellulitis, UTI, HCC and ACLF were not statistically significant between two groups.

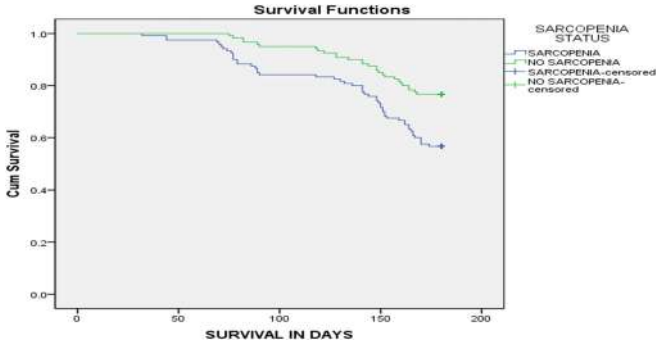


Figure 1. Survival curves in both groups (Log rank p = 0.001)

Conclusion: Sarcopenia is an independent prognostic marker of mortality in cirrhosis and is associated with increased risk of complications like ascites, HE, Covid infection and UGI bleed. Severe sarcopenia has even poorer outcome. It appears that addition of sarcopenia to existing scoring systems of cirrhosis will improve prognostication of patients.

Key Words: Sarcopenia, Cirrhosis, Thigh muscle thickness, Prognostic tool

SAT491

Diagnosis and pathophysiological analysis of sarcopenia using liver MR in chronic liver disease

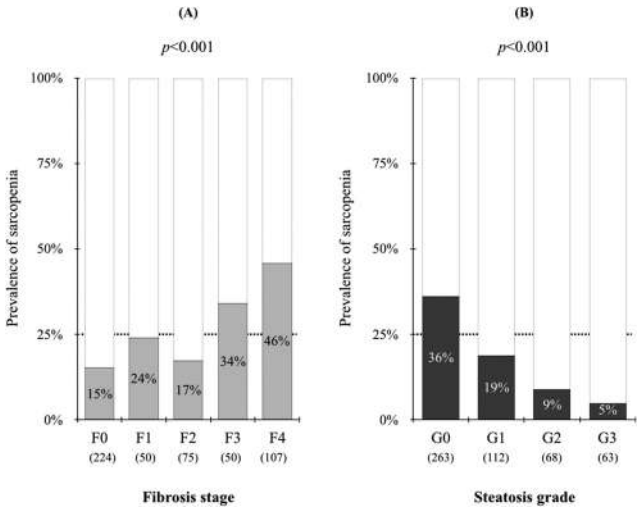
Atsushi Nakamura[1]. [1]*Kawasaki, Japan*
Email: naka2722@gmail.com

Background and aims: There are a few studies of sarcopenia (SP) diagnosed by magnetic resonance imaging (MRI), and paraspinal muscle area (PSMA) measurement at the level of superior mesenteric artery (SMA) has been reported to be useful (*Hepatology 2018*). However, there are racial differences in body size, and there is no standard for Asians in MRI. On the other hand, in liver cirrhosis (LC), adipopenia (AP) is also associated with worse prognosis, and MRI proton density fat fraction (PDFF) has been shown to reflect body fat mass closely. The aim of this study was to develop SP criteria for MRI based on the GLIM criteria, which are global diagnostic criteria for malnutrition, and to clarify the relationship with patient prognosis. In addition, we analyzed the significance of AP assessment.

Method: This is a retrospective study using imaging data from 506 patients with chronic liver disease (CLD) who underwent MR elastography (mean age 62 years, 60% male, LC 119, HCC 47). The etiologies was HBV/HCV, 241; NAFLD, 153; alcohol, 53; and others, 59. SP was diagnosed by determining the cut off value of PSMI (PSM index: PSMA/Height^2) for each gender based on ROC analysis of body mass index (BMI) against the criteria for malnutrition (in Asian population). AP was also diagnosed by setting the cut off value of MRI-PDFF according to the GLIM criteria by ROC analysis.

Results: 1) SP in CLD: BMI and PSMI were correlated in patients without ascites (M/F: r = 0.477/0.534, p < 0.001), and the cut off value of SP in males and females was 12.62 and 9.77 cm^2/m^2, respectively (AUC: 0.91/0.77, p < 0.001). The prevalence of SP in CLD was 25%, and there was no difference by sex; the prevalence of SP was significantly higher in LC and HCC cases (p < 0.05). Furthermore, by MRE fibrosis stage (F0/1/2/3/4), SP increased from F3 and was inversely correlated with steatosis grade (p < 0.01). On the other hand, PDFF was significantly correlated with subcutaneous fat area at the SMA level (M/F: r = 0.558/0.628, p < 0.001) and AP (PDFF<2.2%) was 17%. In multivariate analysis of factors contributing to SP, age (OR 1.05), Alb (0.23), and PDFF (0.91) were extracted (p < 0.05 for each).

2) Prognosis of LC: Child-Pugh classification (A/B/C) was 66/35/18 cases, prevalence of SP was 32/58/82%, AP was 26/33/76%, and SP and AP was 17/42/79%. During the observation period (25 ± 16 m), there were 22 liver-related deaths. The 3-year survival rate by Kaplan-Meier method was 96% in the non-SP group, 55% in the SP group, and 23% in the SP/AP group (log-rank test p < 0.01). In the Cox proportional hazard model, Child-Pugh score (HR 1.34) and SP and AP (5.60) were independent prognostic factors (p < 0.01).



Conclusion: We demonstrated the validity of new SP diagnostic criteria assessed by SMA levels on MRI in Asians. Our results indicate that the combination of SP and AP is a new phenotype of severe SP, and suggest the need to screen for SP in CLD from the pre-cirrhotic stage.

SAT492

Use of a cirrhosis database can positively impact patient care in United Kingdom practice

Jessica Shearer[1], Dianne Backhouse[1], Lynsey Corless[1]. [1]*Hull Royal Infirmary, Department of Gastroenterology, Hepatology and Endoscopy, Kingston upon Hull, United Kingdom*
Email: lynsey.corless@nhs.net

Background and aims: Screening for oesophageal varices and surveillance for hepatocellular carcinoma (HCC) are advised for patients with cirrhosis but adherence to recommendations is poor. The study aimed to provide descriptive analysis of a new cirrhosis

database and evaluate rates of surveillance in a large teaching hospital.
Method: All patients diagnosed with advanced fibrosis/cirrhosis in our centre entered the database sequentially from April 2018. The service covers a population of 600000, with expected prevalence of 600 cirrhotic patients. The database-rather than clinic visits-became the primary means to monitor HCC surveillance/endoscopic screening requests. Subsequent adherence to recommendations was measured in 2021.
Results: 841 patients entered the database over 3 years, with only 200 at inception-less than the predicted cirrhosis prevalence. 36 people died during follow-up and 5 left the area. Of the remaining 800 patients, median age was 60 years; 40% female. 46% of patients had alcohol related disease, 21% non-alcoholic fatty liver disease, 14% viral hepatitis. 63% of the cohort had Childs-Pugh (CP) A or advanced fibrosis, 14% CP-B, 3% CP-C. 21% had no stage recorded. 157 patients (20%) were on primary prophylaxis for variceal bleeding. Of the remaining 643 patients, 237 (37%) were on active endoscopic surveillance and a further 100 (16%) had attended endoscopy in the past 3 years. 43 patients (7%) were overdue, 40 (6%) declined, and 30 (5%) had documented clinical decision not to proceed. 191 patients (24%) had no documentation about screening. 603 (78%) of appropriate patients were up to date with HCC surveillance with a further 105 (14%) awaiting scan, significantly more than our historically reported adherence of 50% (p = <0.0001).
Conclusion: The database improved our knowledge of clinical characteristics of our patient population, and provided a way to readily monitor surveillance intervals. Most had appropriate HCC surveillance, surpassing our previous (or nationally reported) adherence rates. A quarter of patients had no documentation of variceal screening, highlighting an area for improvement. Given the rapid rise in cohort size, it is likely the database also reduces numbers lost to follow-up/surveillance in the event of clinic non-attendance, which may be particularly valuable in the post-Covid era of delayed appointments. This study shows the potential of a registry to improve care and outcomes in people with cirrhosis.

SAT493

Psychomotor speed from minimal hepatic encephalopathy testing is associated with physical frailty in patients with end-stage liver disease

Andres Duarte Rojo[1], Rachel K. Grubbs[1], Randi Wong[2], Pamela M. Bloomer[1], Robert Rahimi[3], Alexandra Steinberg[4], Jennifer Lai[2]. [1]*University of Pittsburgh Medical Center;* [2]*University of California San Francisco;* [3]*Baylor University Medical Center;* [4]*Axcella Therapeutics*
Email: duarterojoa@upmc.edu

Background and aims: The Stroop EncephalApp (StE) is a neuropsychological test assessing psychometric speed and cognitive processing and has been validated to diagnose minimal hepatic encephalopathy (HE). Frailty, as measured by the Liver Frailty Index (LFI), is highly prevalent in end-stage liver disease (ESLD), particularly among patients with HE. While the LFI comprises tests of physical function, it might conceivably also capture the contributions of cognitive impairment to physical frailty in ESLD. This study assessed the relationship between cognitive function (StE) and physical function (LFI) in ESLD.
Method: Patients with ESLD underwent LFI, StE and overt HE testing using modified orientation log (MO-log) and Clinical Hepatic Encephalopathy Staging Scale (CHESS) at 3 centers. Expected StE values were obtained from www.encephalapp.com. Pearson correlation and multivariable linear regression models were used to investigate StE variability. Stroop On, Stroop Off, and their combinations were analyzed separately to characterize StE contribution in terms of cognitive processing (On-Off) versus psychomotor speed (Off).
Results: Of 172 subjects (58 ± 10 years; 59% male; 93% white; 37% alcohol, 25% NASH), 68% had Child-Pugh B/C cirrhosis, and 69% had prior overt HE. On testing, 97% had normal mentation (MO-log ≥23), none had overt HE (CHESS ≥3) and 81% had minimal HE. Cognitive function in terms of StE On+Off increased across frailty categories and showed a fair linear relationship with LFI (Fig.), of similar magnitude to that observed for age (rho = 0.29, p < 0.001) and education (rho = – 0.24, p < 0.002). However, StE and LFI correlation weakened from Off (rho = 0.37, p < 0.001) to On (rho = 0.20, p = 0.008) and On-Off (rho = – 0.05, p = 0.5) modalities, suggesting that psychomotor speed was the main factor driving the association between cognitive and physical function. On multivariable analysis, adjusted for age, education and sex, only StE On+Off (β = 15.38, p < 0.02) and StE Off (β = 8.95, p < 0.001) remained associated with LFI.

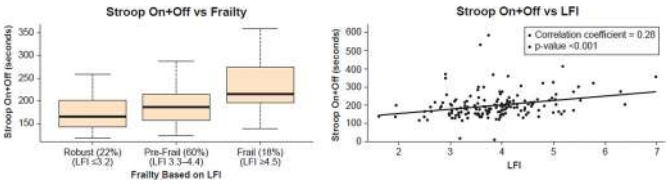


Figure: Box plot of Stroop On+Off value for different categories of frailty; and scatter plot of individual Stroop On+Off and LFI values. Increasing Stroop On+Off time denotes increasing cognitive impairment; increasing LFI denotes increasing frailty.

Conclusion: Using StE and LFI, an association between cognitive and physical function in ESLD was found, likely attributable to psychomotor speed over cognitive processing. Our findings suggest that the comprehensive assessment of minimal HE should include frailty metrics, and vice versa. Also, such brain-muscle relationship further supports investigating interventions targeting both physical and cognitive function in ESLD.

A multistrain probiotic increases serum glutamine/glutamate ratio in patients with cirrhosis. A metabolomic analysis

German Soriano[1,2], Eva Roman[2,3,4], Luca Laghi[5], Juan Camilo Nieto[6], Qiuyu Lan[5], Maria Poca[1,2], Edilmar Alvarado-Tapias[1,2], Berta Cuyas[1], Silvia Vidal[4,6], Candido Juárez[7], Carlos Guarner[1,2,4], Àngels Escorsell[1]. [1]*Hospital de la Santa Creu i Sant Pau, Department of Gastroenterology, Barcelona, Spain;* [2]*Instituto de Salud Carlos III, CIBERehd, Madrid, Spain;* [3]*School of Nursing EUI-Sant Pau, Barcelona, Spain;* [4]*Universitat Autònoma de Barcelona;* [5]*University of Bologna, Italy;* [6]*Research Institute IIB-Sant Pau, Spain;* [7]*Hospital de la Santa Creu i Sant Pau, Department of Immunology, Spain*
Email: gsoriano@santpau.cat

Background and aims: Probiotics can improve gut dysbiosis, intestinal barrier, ammonemia and proinflammatory state, as well as cognitive function and risk of falls in patients with cirrhosis. To explore the potential mechanisms underlying these effects, we aimed to analyze the changes in the blood metabolome of patients with cirrhosis after probiotic treatment.
Method: We performed untargeted metabolomics using ^{1}H-NMR spectroscopy in serum samples from 32 patients with cirrhosis and cognitive dysfunction (Psychometric hepatic encephalopathy score [PHES]<-4) or previous falls. These patients were included in a previous double-blind placebo-controlled trial (Román, Hepatol Commun 2020) and were randomized to receive the multistrain probiotic (brand name Vivomixx in Europe and Visbiome in USA), 450×10^{9} cfu bid for 12 weeks, or placebo. Baseline and end of treatment blood samples were analyzed. A false discovery rate (FDR)

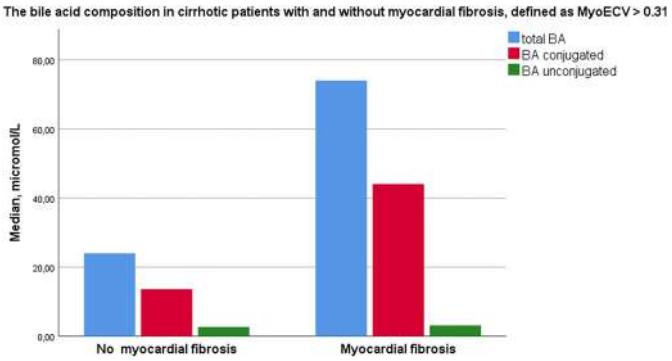
5% correction for multiple testing was applied using the Benjamini-Hochberg method.
Results: Patients treated with the probiotic (n = 17) presented a statistically significant improvement in cognitive function and risk of falls (evaluated by the PHES and gait speed, respectively), proinflammatory state (C-reactive protein and TNF-α) and intestinal barrier (fatty acid binding protein [FABP]-6) at the end of treatment. No changes were observed in the placebo group (n = 15). After analyzing 54 metabolites, the main findings were an increase in blood glutamine (FDR p = 0.007), a decrease in glutamate (FDR p = 0.03) and an increase in the glutamine/glutamate ratio in the probiotic group (FDR p = 0.01), while glutamate increased (FDR p = 0.02) and the glutamine/glutamate ratio decreased (FDR p = 0.03) in the placebo group. There was a correlation between the change in the ratio glutamine/glutamate and the change in the PHES (r = 0.34, p = 0.05), change in gait speed (r = 0.47, p = 0.008), and change in FABP-6 (r = – 0.37, p = 0.04).
Conclusion: Our results suggest an influence of the multistrain probiotic Vivomixx on the glutamine/glutamate metabolism, and therefore in the capacity of ammonia detoxification, that could contribute to explain the beneficial effects observed in patients with cirrhosis.

SAT495

The composition of the bile acid pool is closely associated with fibrosis in the heart and liver of patients with cirrhosis

Signe Wiese[1], Jens Hove[2], Henriette Ytting[1], Svend Hoime Hansen[3], Søren Møller[4], Flemming Bendtsen[1]. *[1]Hvidovre Hospital, Gastro Unit, Medicial Division, Denmark; [2]Hvidovre Hospital, Dept. Cardiology, Denmark; [3]Rigshospitalet, Dept. Clinical Biochemistry; [4]Hvidovre Hospital, Centre of Functional Imaging and Research, Denmark*
Email: signeswiese@gmail.com

Background and aims: The role of bile acids (BA) in relation to liver fibrosis and signs of heart disease in chronic liver disease are areas of increasing interest. We have previously reported a close association between increased total BA (tBA) concentrations and myocardial fibrosis in patients with cirrhosis, and a strong relationship between the extent of fibrosis in the liver and the heart. These fibrotic changes can accurately be determined by MRI with assessment of myocardial and liver extracellular volume (ECV). Our aim was to identify specific groups or individual BA related to fibrosis in the liver and heart of patients with cirrhosis.
Method: We prospectively included 52 cirrhotic patients. All patients underwent contrast-enhanced MRI with T1-mapping and ECV quantification, and assessments of tBA, a panel of 15 specific BA and C4, a biomarker of de novo BA synthesis.
Results: The BA composition of cirrhotic patients with myocardial fibrosis was altered with increased conjugated BA levels (44 umol/l (21;87) vs. 14 umol/l (10;40), p = 0.02), predominantly glycine-conjugated BA (p = 0.01). The following specific BA were markedly increased: glyco-chenodeoxycholic acid (GCDCA) (p = 0.016), glyco-ursodeoxycholic acid (GUDCA) (p = 0.005), glyco-cholic acid (GCA) (p = 0.04) and tauro-ursodeoxycholic acid (TUDCA) (p = 0.026). Similarly, patients with a high liver ECV indicating the most advanced liver fibrosis had increased tBA levels (p <0.001) and the BA pool consisted predominantly of primary BA (p <0.001) and conjugated BA (p <0.001) both glycine- and taurine-conjugated BA (p = 0.001). In these patients the following specific BA were increased: GCDCA (p <0.001), GCA (p <0.001), tauro-chenodeoxycholic acid (TCDCA) (p = 0.001), tauro-cholic acid (TCA) (p = 0.001), GUDCA (p = 0.006) and TUDCA (p = 0.001). Moreover, C4 levels were reduced (p = 0.005). When we assessed the relation to disease severity, we found the highest levels of tBA, primary BA and conjugated BA in Child Pugh C patients (p = 0.002, p = 0.003, p = 0.003, respectively). Conversely, C4 levels decreased with disease severity (p <0.001). MELD also correlated with BA levels (r = 0.62, p <0.001) and C4 levels (r = – 0.69, p <0.001).



Conclusion: The strong associations between myocardial fibrosis and in particular conjugated BA suggest a potential role of BA in the development of structural cardiac abnormalities in cirrhosis. Moreover, the composition of the BA pool is markedly altered in patients with advanced liver fibrosis and is closely related to disease severity.

SAT496

SBP vs. non-SBP bacterial infections at admission have comparable outcomes in a multi-center cohort of inpatients with cirrhosis

Jacqueline O'Leary[1], K. Rajender Reddy[2], Puneeta Tandon[3], Patrick S. Kamath[4], Guadalupe Garcia-Tsao[5], Florence Wong[6], Jennifer C Lai[7], Ram Subramanian[8], Paul J. Thuluvath[9], Benedict Maliakkal[10], Hugo E. Vargas[11], Scott Biggins[12], Leroy Thacker[13], Jasmohan S Bajaj[13]. *[1]Dallas VA Medical Center, Dallas, United States; [2]University of Pennsylvania, Philadelphia, United States; [3]University of Alberta, Edmonton, Canada; [4]Mayo Clinic Rochester, MN, Rochester, United States; [5]Yale University, New Haven, United States; [6]University of Toronto, Toronto, Canada; [7]University of California San Francisco, San Francisco, United States; [8]Emory University, Atlanta, United States; [9]Mercy Medical Center; [10]University of Tennessee, Knoxville, United States; [11]Mayo Clinic, Scottsdale, United States; [12]University of Washington, Seattle, United States; [13]VCU, Richmond, United States*
Email: dr_jackieo@yahoo.com

Background and aims: Infections in cirrhosis lead to high rates of morbidity and mortality. While there are clear guidelines for diagnosis, treatment and prophylaxis for SBP, non-SBP infections are managed per local standards of care. We hypothesized that admission SBP would have a better prognosis compared to non-SBP bacterial infections in hospitalized patients with cirrhosis. Define outcomes in SBP vs. non-SBP infections in a large inpatient multi-center cohort adjusted for clinically relevant factors.
Method: NACSELD (North American Consortium for study of End-stage Liver Disease) included patients with cirrhosis without HIV or transplant admitted non-electively and followed for 30 days post-discharge. Demographics, cirrhosis details, admission reasons, hospital course and outcomes (ACLF, death, transplant) were recorded. We included patients admitted with bacterial infections (SBP vs others) diagnosed within 48 hours per IDSA guidelines. We excluded those with multiple admission infections, fungal or viral infections. Outcomes of SBP vs non-SBP patients were compared for transplant censored in-hospital mortality, transplant-censored 30-day mortality, transplant and 2nd infections after adjustment for admission factors (MELD, Na, HE, Albumin).
Results: 2, 062 total patients were included: 458 had admission infections (103 SBP and 354 non-SBP bacterial infections) and 1605

had no admission infection. No differences were seen between the 2 infected groups with respect to ACLF/organ failures, medications and outcomes (Table 1). The adjusted analysis found no difference between the SBP and Non-SBP groups for transplant censored in-patient mortality, transplant, risk for 2nd infection, ACLF and transplant-censored 30-day mortality (Table 2).

Table: Summary of Study Cohort

	SBP	Non-SBP	No Infection	
	(*n* = 103)	(*n* = 354)	(*n* = 1605)	p value
Age	56.9	56.5	57.5	0.33
Gender (Male)	68%	59%	64%	0.16
MELD	22	19	18	<0.0001
Prior HE	65%	64%	57%	0.01
Hospital course				
ICU Transfer	28%	30%	18%	<0.0001
Brain failure	13%	17%	13%	0.11
Respiratory failure	15%	19%	9%	<0.0001
Circulatory failure	12%	14%	6%	<0.0001
AKI	60%	53%	36%	<0.0001
Renal failure	16%	11%	6%	<0.0001
Clinical Outcomes				
Txp Censored	17%	8%	4%	<0.0001
In-Hospital Mortality				
Txp Censored	19%	13%	8%	<0.0001
30-day Mortality				
Transplant	11%	5%	3%	0.0001
2nd Infection	14%	19%	1%	<0.0001

Table 2: Comparison of Adjusted OR of SBP vs. No-SBP

	OR	p value
Txp Censored In-Hospital Mortality	1.9	0.07
Txp Censored 30-day Mortality	1.3	0.43
Transplant	1.7	0.25
2nd Infection	0.7	0.20
ACLF	0.7	0.35

Conclusion: Patients with bacterial SBP and non-SBP infections were statistically similar with respect to development of 2nd infections, mortality, and transplant requirement after controlling for admission factors. Therefore, all patients with bacterial infections, not just SBP, should be monitored closely to prevent negative outcomes.

SAT497

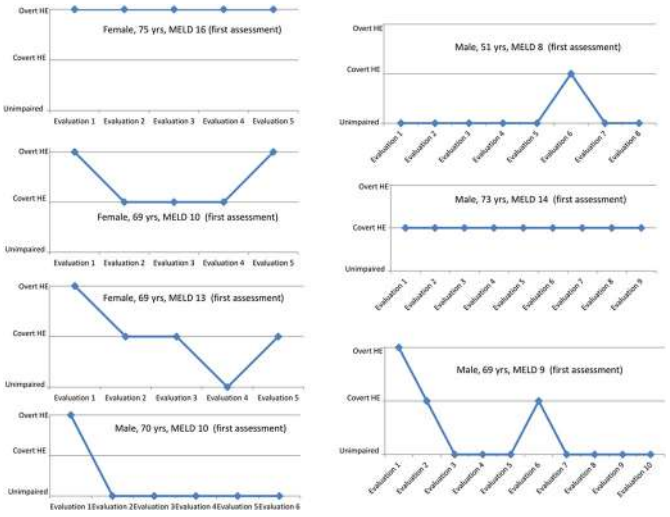
Natural history of Hepatic Encephalopathy (HE) in a tertiary referral centre for hepatology

Chiara Mangini[1], Chiara Formentin[1], Alberto Biscontin[1], Gianluca Giusti[1], Paolo Angeli[1], Lisa Zarantonello[1], Sara Montagnese[1]. [1]*Department of Medicine, Padova, Italy*
Email: sara.montagnese@unipd.it

Background and aims: The occurrence and recurrence of HE mark significant progression in the natural history of cirrhosis. While it is well known that HE is an unfavourable prognostic factor, few data on its evolution over time are available. Our aim was to study the evolution of HE (neuropsychiatric indices, also in relation to HE treatment and severity of liver disease) in patients with varying degree of HE on first assessment.

Method: 87 patients with cirrhosis (age 58 ± 11 years; 72 males) referred to the HE outpatient clinic of the Regional Centre for Liver Diseases at Padova University Hospital between June 2009 and January 2019 were included. They were evaluated from 2 up to 10 times (varying time-intervals), for purposes of liver transplantation selection, differential diagnosis or treatment optimization. The presence/severity of HE was assessed by clinical, neuropsychological (PHES) and neurophysiological (EEG) tools. The severity of liver disease was assessed by the MELD score. Treatment was instituted/modified according to both guidelines and local experience after each evaluation.

Results: On first assessment, 23 patients were classed as unimpaired, 32 as having covert and 32 as having overt HE. Amongst unimpaired patients, on second/third evaluation 56%/6% remained unimpaired, 35%/3% developed covert HE, 9%/0% developed overt HE. Amongst patients with covert HE, on second and third evaluation 25%/10% became unimpaired, 44%/19% remained covert, 31%/13% developed overt HE. Finally, amongst patients with overt HE, 19%/16% became unimpaired, 25%/13% became covert and 56%/25% remained overt. PHES results tended to improve over time in patients with overt HE and the EEG worsened over time (despite remaining within normal limits) in unimpaired patients. These trends were not confirmed after adjustment for HE history, HE treatment and MELD. Finally, in patients with multiple evaluations, HE evolution was manifold and difficult to predict (fig. 1).



Conclusion: While there is obvious HE risk associated with HE on first assessment, our data suggest that evolution over time is extremely variable and largely dependent on HE history/management and MELD. These data also support the concept that HE is an essentially reversible condition.

SAT498

Public knowledge and attitudes toward liver diseases and liver cancer in the brazilian population

Paulo Bittencourt[1], Liana Codes[1], Maria Lucia Ferraz[1]. [1]*Brazilian Liver Institute*
Email: plbbr@uol.com.br

Background and aims: Cirrhosis, particularly viral hepatitis (VH) and alcoholic liver disease (ALD), are the 8th leading cause of death in Brazil. Hepatocellular carcinoma (HCC) was also shown to rank 11th among all cancers in terms of mortality. Despite the burden of liver diseases in Brazil, little is known about public awareness of the Brazilian population regarding screening and diagnosis of the most cirrhosis and HCC in the country. To investigate in a representative sample of the Brazilian population public knowledge, level of awareness and attitudes toward cirrhosis and HCC and their most frequent risk factors according to age, gender, average family income,

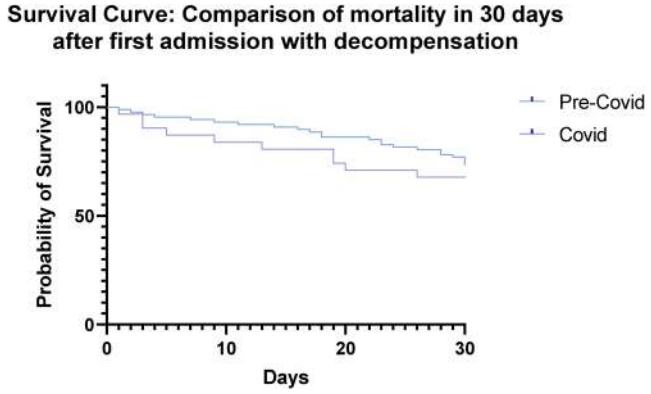
level of education and place of living. **Method:** BetweenSeptember 8th to 15th2021, 1.995 subjects ≥18 years (53% women, mean age 44 years and average family income of 654 USD per month) living in five Brazilian regions were prospectively interviewed using a questionnaire consisting of a set of nine questions regarding knowledge about the main causes of cirrhosis and HCC, clinical burden of non-alcoholic fatty liver disease (NAFLD) and information regarding current attitudes toward hepatitis B vaccination, hepatitis B and C testing, alcohol intake as well as previous assessment of liver health by any laboratory or imaging test.
Results: Most of the Brazilian subjects believe that alcohol abuse (63%-87%), NAFLD (29%-53%) and smoking (31%-47%) are the main causes of cirrhosis and HCC. On the contrary, VH were less often linked to either cirrhosis (23%) or HCC (15%). Unexpectedly, more than 2/3 of the Brazilians agreed that NAFLD is a risk factor for cirrhosis, cancer, diabetes and cardiovascular diseases. 55% of the Brazilians were alcohol drinkers and 32% of them claimed to drink more often than once a week. Nearly half of those drinkers use more than three doses of alcohol per day. Previous evaluation of liver disease was referred at least once by 41% of the subjects. Attitudes toward hepatitis B vaccination and hepatitis B and C testing was carried out by 66%, 48% and 40% of the subjects, despite the fact that 80% of them were aware of the availability free of charge of those tests in the public health system. The main reasons for not being tested for VH were perception that there is no need for testing or absence of symptoms. In general, knowledge and attitudes toward prevention of liver diseases were significantly higher in older people and subjects with higher level of education and income (p <0, 05).
Conclusion: Despite its major association with liver disease, VH was not considered by the majority of the Brazilian population as the main cause of cirrhosis and HCC, leading a large proportion of those subjects to neglect hepatitis B vaccination and VH testing. Despite the large alcohol consumption and knowledge of its adverse impact in liver health, less than half of the Brazilians have been evaluated at least once for liver disease.

SAT499

The negative impact of the pandemic on hospital admissions, morbidity and 30-day mortality for acute cirrhosis decompensation: a tertiary care perspective

Kohilan Gananandan[1], Alexandra Phillips[1], Anmol Chikhlia[2], Hannah Old[2], Niharika Thakur[3], Konstantin Kazankov[4], Raj Mookerjee[1], Sharmaine Jia Ying Sim[5]. *[1]The Liver Failure Group, Institute for Liver and Digestive Health, United Kingdom; [2]Royal Free Hospital, United Kingdom; [3]UCL Medical School, United Kingdom; [4]Aarhus University Hospital, Aarhus, Denmark; [5]University College London, London, United Kingdom*
Email: alexandra.phillips5@nhs.net

Background and aims: The global pandemic has inevitably diverted resources away from management of chronic diseases, including cirrhosis, where up to 40% of patients are readmitted with new cirrhosis decompensation events. Whilst there is increasing knowledge on COVID-19 infection in liver cirrhosis, little is described on the impact of the pandemic on decompensated cirrhosis admissions and outcomes, which was the aim of this study.
Method: A single-centre, retrospective study, evaluated decompensated cirrhosis admissions to a tertiary London hepatology and transplantation centre, from October 2018 to February 2021. Patients were included if they had an admission with cirrhosis decompensation defined as new onset jaundice or ascites, infection, encephalopathy, portal hypertensive bleeding or renal dysfunction. Admissions were excluded if they lasted <24 hours, were elective or occurred post liver-transplant.
Results: There were 351 admissions in the pre-COVID period (October 2018 to February 2020) and 240 admissions during the COVID period (March 2020 to February 2021), with an average of 20.4 admissions per month throughout. Patients transferred in from secondary centres had consistently higher severity scores during the COVID period (UKELD 58 versus 54; p = 0.007, MELD Na 22 versus 18; p = 0.006, AD score 55.0 versus 51.0; p = 0.055). The proportion of ITU admissions pre versus during-COVID stayed constant (22.9% versus 19.2%), but there was a trend towards increased ICU admissions with acute-on-chronic liver failure (ACLF) (73.9% versus 63.8% pre-pandemic). Of those admitted to the intensive care without ACLF, there was a significant increase in EF-CLIF acute decompensation (AD) scores during the COVID period (58 versus 48, p = 0.009). In addition, there was a trend towards increased hospital re-admission rates during the COVID period (29.5% versus 21.5%, p = 0.067). When censored at 30 days, time to death post discharge was significantly reduced during the COVID period (p < 0.05) with a median time to death of 35 days compared to 62 days pre-COVID.



Conclusion: This study provides a unique perspective on the impact that the global pandemic had on the clinical course and characteristics of decompensated cirrhosis admissions. The findings of increased early mortality and re-admissions, and higher AD scores, indicating increased disease morbidity, highlight the need to maintain resourcing on providing high-level hepatology care. Given that COVID-19 will likely be a chronic issue, alternative care pathways such as remote monitoring may need adoption to facilitate continuity of care post-discharge and to reduce readmission rates and morbidity in the future.

SAT500

Comparison of recommended daily energy intakes in people with cirrhosis, based on current guidelines, and their directly measured energy requirements: an individual patient data analysis

Email: marsha.morgan@ucl.ac.uk

Background and aims: Weight-based guidelines for the nutritional management of patients with cirrhosis have been formulated by EASL, ESPEN, AASLD and ISHEN. However, the guidance is discordant both in terms of recommended daily energy intakes, which range from 25 to at least 35 kcal/kg, and whether the reference for calculation should be actual, estimate dry or ideal body weight. This study aimed to compare recommended daily energy intakes with daily energy requirements based on direct measurement of resting energy expenditure (REE).

Method: REE was measured, using indirect calorimetry, in 900 patients with cirrhosis (mean [± 1SD] age 55.7 ± 11.6 yr; 70% men); total daily energy requirements were determined, for individual patients, using 1.3 × REE. Daily energy intakes were calculated based on recommended intakes of 25, 30 and 35 kcal/kg referenced to actual body weight; ideal body weight calculated using the Hamwi, Devine, Robinson and Miller formulae, and, in patients with ascites, the estimated dry weight. The limits of agreement for each permutation of the recommended intakes and weight reference standards were compared with the calculated required intakes.

Results: Daily intakes of 25 kcal/kg would provide less energy than required and hence underfeeding in the majority of patients, irrespective of the weight standard used or the presence/absence of ascites. In contrast, daily intakes of 35 kcal/kg would provide more energy than required and hence overfeeding in the majority of patients. Daily intakes of 30 kcal/kg are closest to requirements but would still provide from 452 kcal less to 749 kcal more than required, based on actual body weight in patients without ascites, and from 833 kcal less to 767 kcal more than required based on estimated dry body weight in patients with ascites (Table).

Reference weight (kg)	Cirrhosis: no ascites (n = 770)					
	Recommended daily energy intake					
	25 kcal/kg		30 kcal/kg		35 kcal/kg	
	Mean	LoA	Mean	LoA	Mean	LoA
Actual	−215	−784: 354	148	−452: 749	484	−202: 1170

IBW: Devine	−342	−1100: 417	−65	−792: 662	236	−508: 980
IBW: Robinson	−331	−1097: 435	−55	−770: 667	247	−476: 970
IBW: Miller	−284	−1068: 500	−1	−735: 734	311	−416: 1037
Reference weight (kg)	Cirrhosis: ascites (n = 130)					
	Recommended daily energy intake					
	25 kcal/kg		30 kcal/kg		35 kcal/kg	
	Mean	LoA	Mean	LoA	Mean	LoA
Actual	−170	−946: 606	206	−624: 1035	581	−322: 1484
Estimated dry	−369	−1126: 389	−33	−833: 767	303	−560: 1165
IBW: Hamwi	−453	−1301: 396	−134	−1011: 744	185	−733: 1103
IBW: Devine	−470	−1308: 367	−155	−1013: 703	161	−728: 1049
IBW: Robinson	−476	1305: 352	−162	−998: 674	152	−698: 1002
IBW: Miller	−446	−1274: 382	−126	−952: 701	195	−635: 1024

IBW: ideal body weight: LoA: limits of agreement

Conclusion: The current weight-based guideline for determining daily energy intakes in patients with cirrhosis may pose a significant risk of under or overfeeding and need to be urgently reviewed.

SAT501

Rifaximin for the prevention and treatment of hepatic encephalopathy: a systematic review and meta-analysis of randomized clinical trials

Harry D Zacharias[1], Jaclyn Yizhen Tan[1], Fady Kamel[1], Nina Kimer[2], Lise Lotte Gluud[2], Marsha Morgan[1]. *[1]UCL Institute for Liver and Digestive Health, Division of Medicine, Royal Free Campus, University College London, London, London, United Kingdom; [2]Gastrounit, Medical Division, Copenhagen University Hospital Hvidovre, Hvidovre, Denmark*
Email: marsha.morgan@ucl.ac.uk

Background and aims: Rifaximin has been used for the treatment of hepatic encephalopathy (HE), in patients with cirrhosis, since the 1990s. However, whilst individual studies have shown benefit in acute/recurrent, chronic, and minimal HE, its main licensed indication remains the prevention of recurrent HE in combination with non-absorbable disaccharides (NAD). This systematic review and meta-analyses of randomised clinical trials (RCTs) for the prevention and treatment of HE, in patients with cirrhosis, compared (i) rifaximin *vs.* placebo/no intervention; (ii) rifaximin *vs*. NAD; and (iii) rifaximin co-administered with NAD *vs.* NAD alone.

Method: Electronic/manual searches of the literature were undertaken; further information was obtained from authors/pharmaceutical companies. Meta-analyses were conducted and results presented as relative risks (RR) and 95% confidence intervals (CI). Sources of heterogeneity and the influence of random and systematic errors were evaluated in subgroup/sensitivity analyses.

Results: A total of 38 RCTs involving 4376 people were included; Individual patient data were available for 7 trials and additional information for a further 17; some trials included more than one comparison. Twelve studies compared rifaximin with placebo/no intervention minimal (n = 5) or chronic HE (n = 3) or for HE prevention (n = 4); meta-analysis showed no effects of rifaximin on mortality or serious adverse events (SAEs) but an overall beneficial effect on HE (RR = 0.58, 95% CI 0.56–0.91; NNTB = 5; participants = 969), confirmed in subgroup analyses in minimal HE but not in

chronic HE or for HE prevention. Rifaximin was compared with NADs in 13 studies acute (n = 4), chronic (n = 4) and minimal HE (n = 2) and for HE prevention (n = 3); there were no effects of rifaximin on mortality, SAEs or HE. The effects of rifaximin plus lactulose against lactulose alone were compared in 16 trials in acute HE (n = 8) and for HE prevention (n = 8); rifaximin plus lactulose had a beneficial effect on mortality (RR 0.69, 0.55–0.86; NNTB = 20; participants = 1836), subgroup analyses confirmed mortality benefit in acute HE (RR 0.65, 0.46–0.92; NNTB = 13; participants = 692) but not in HE prevention. Co-administration of the two drugs also had a beneficial effect on HE (RR 0.58, 0.48 to 0.71; n = 2306), with a NNTB of 5. Subgroup analyses confirmed benefit in both the treatment of acute HE (RR 0.62, 0.45 to 0.87) and in HE prevention (RR 0.54, 0.42 to 0.69) (Figure 1); there was no overall effect on SAEs; the evidence was of low to very low quality.

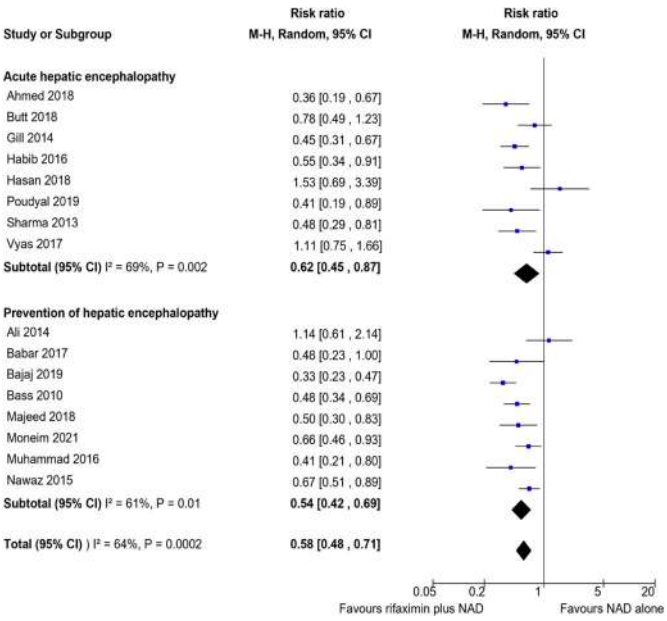

Figure: Random-effects meta-analysis of RCTs comparing the effect of rifaximin plus NAD *vs*. NAD alone

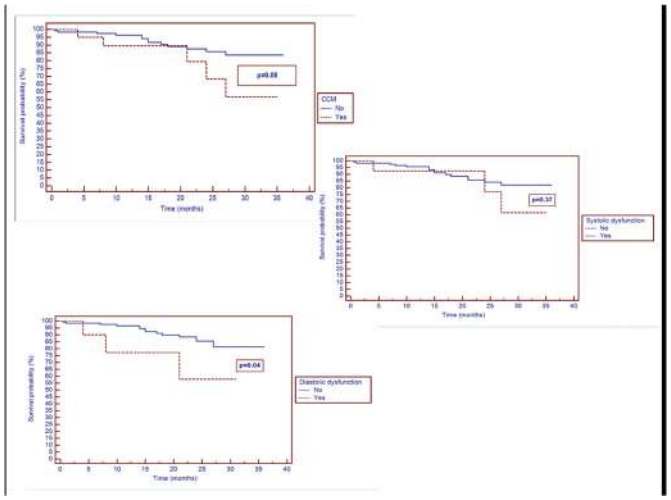
Conclusion: Rifaximin monotherapy does not convey benefit compared to NADs. However, rifaximin combined with lactulose is a safe and effective intervention for people with cirrhosis and acute HE, and for the prevention of recurrent HE. However, further high-quality studies are needed.

SAT502

Infuence of cirrhotic cardiomyopathy defined according to the new multidisciplinary diagnostic criteria on overall mortality among cirrhotic patients

Simona Bota[1], Marcel Razpotnik[1], Philipp Wimmer[2], Michael Hackl[2], Gerald Lesnik[3], Hannes Alber[2], Markus Peck-Radosavljevic[1].
[1]Klinikum Klagenfurt am Wörthersee, Department of Internal Medicine and Gastroenterology (IMuG) and Emergency Medicine (ZAE), Klagenfurt, Austria; [2]Klinikum Klagenfurt am Wörthersee, Department of Internal Medicine and Cardiology (IMuK), Klagenfurt, Austria; [3]Klinikum Klagenfurt am Wörthersee, Institut for diagnostic and interventional Radiology, Klagenfurt, Austria
Email: bota_simona1982@yahoo.com

Background and aims: New criteria of cirrhotic cardiomyopathy (CCM) were published from a multidisciplinary consortium (Izzy et al. Hepatology 2019 Nov 11. doi: 10.1002/hep.31034) and define systolic dysfunction of the left ventricle as ejection fraction (EF) ≤50% and/or global longitudinal strain (GLS) <-18%, while the diastolic dysfunction is diagnosed when three of the following conditions are present: average E/e' >14, peak tricuspid regurgitation velocity >2.8 m/s, septal e'<7 cm/s, left atrial volume index >34 ml/m^2.
Our aim was to assess the influence of CCM defined according the new criteria on overall mortality among cirrhotic patients.
Method: Our prospective study included consecutive patients with liver cirrhosis without structural heart disease, arterial hypertension, HCC outside Milan criteria, portal vein thrombosis, presence of TIPS and with optimal acoustic echocardiography window. The patients were evaluated between 12/2018–11/2021 in our in- and out-patient Department. Conventional and speckle-tracking echocardiography (Vendor GE, EchoPAC PC software) were performed by a single investigator (EACVI TTE certified). The follow-up was performed until the patient was last seen or death.
Results: 412 cirrhotic patients were evaluated during the study period and 133 fulfilled the inclusion criteria and were included in the final analysis. The mean age of patients was 57.1 ± 10.2 years (60.1% males), 70.1% with alcoholic etiology and 48.1% with compensated liver cirrhosis.
CCM (systolic and/or diastolic dysfunction) was present on 15% of patients, only systolic dysfunction on 9.7% and only diastolic dysfunction on 7.5% of the cirrhotic patients.
The median follow-up was 21 (0.5–36) months and 18/133 (13.5%) of cirrhotic patients died during the follow-up.
The presence of diastolic dysfunction was associated with significantly higher mortality (p = 0.04) in our cohort of cirrhotic patients (Figure). The presence of CCM (systolic and/or diastolic dysfunction) tends also to increase mortality but did not achieve statistical significance.



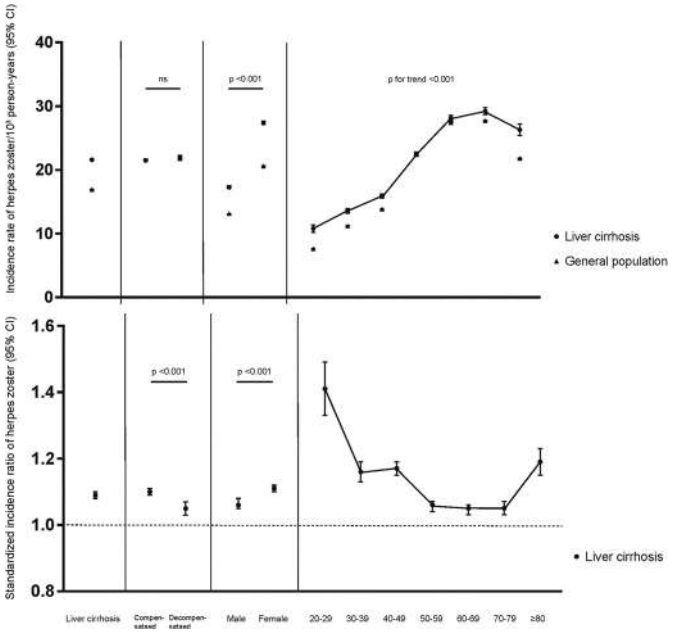
Severity of liver disease, assessed by Child-Pugh and MELD score was not correlated with the presence of CCM: r = – 0.0209, p = 0.73 and r = – 0.010, p = 0.90.
Conclusion: Even if the follow-up was relatively short in our study, the presence of CCM (especially diastolic dysfunction) was associated with higher overall mortality among cirrhotic patients. Our data shows the importance of a cardiac (especially echocardiography with strain) evaluation of cirrhotic patients.

SAT503

Risk of herpes zoster infection in patients with cirrhosis: a nationwide population-based study in Korea

Dongsub Jeon[1], Seon-Ok Kim[2], Ye-Jee Kim[2], Jonggi Choi[1]. *[1]Asan Medical Center, Department of Gastroenterology, Liver Center, Seoul, Korea, Rep. of South; [2]Asan Medical Center, Biostatistics and Clinical Epidemiology, Seoul, Korea, Rep. of South*
Email: j.choi@amc.seoul.kr

Background and aims: Few data are available on the risk of herpes zoster (HZ) infection in patients with liver cirrhosis. We investigated whether patients with liver cirrhosis have an increased risk of HZ infection compared with general population and risk factors associated with HZ infection in patients with cirrhosis.
Method: We performed a nationwide population-based study, using the claim data of the Korean national health insurance database between 2009 and 2019. In total, 505, 750 patients with liver cirrhosis were included, yielding 3, 266, 470 person-years of follow-up. We calculated the incidence rates and standardized incidence ratios (SIRs) of HZ infection in patients with liver cirrhosis to evaluate the risk of HZ infection compared with general population in the same sex and age group. Hazard ratios (HRs) for HZ infection and their 95% confidence intervals (CIs) were estimated using a Cox proportional hazard model for factors associated with increased risk for HZ infection.
Results: In this nationwide population-based study, the overall incidence rate of HZ infection was 21.6/1000 person-years and SIR was 1.09 (95% CI, 1.08–1.10) in patients with liver cirrhosis. Among the patients with liver cirrhosis, the incidence rate and SIR for HZ infection was significantly higher in female patients than male (incidence rate, 27.4 vs. 17.3; SIR, 1.11 vs. 1.06; p <0.001 for both). The incidence rate of HZ increased with age (P trend <0.001), whereas the SIR of HZ infection showed U-shaped graph in the age curve showing non-linear relationship (Figure 1); The lowest SIR of HZ infection was observed in the patients aged 50–59, 60–69, and 70–79, with peaks in both young and elderly patients. In multivariable analysis adjusting sex, age, and Charlson comorbidity index, viral hepatitis (Hepatitis B for adjusted HRs [95% CI], 1.04 [1.01–1.07], Hepatitis C for 1.05 [1.00–1.10]) as reference to alcoholic cirrhosis showed higher risks of HZ infection. Meanwhile, decompensated cirrhosis was not associated with an increased risk for HZ infection. (adjusted HRs [95% CI], 0.98 [0.96–1.00])



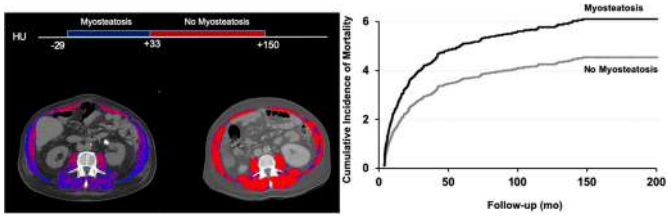
Conclusion: In this population-based study in Korea, we found patients with liver cirrhosis have an increased risk for HZ infection, especially in female, with the peaks of SIR in both young patients under 50 and the elderly over 80. Therefore, zoster vaccination might be considered for patients with liver cirrhosis aged under 50 as well as the elderly.

SAT504

Skeletal muscle pathological fat infiltration (myosteatosis) associates with higher mortality in patients with cirrhosis

Maryam Ebadi[1], Elora Rider[1], Abha DunichandHoedl[2], Maryam Motamedrad[2], Vera C. Mazurak[2], Vickie Baracos[3], Rahima A. Bhanji[1], Aldo J Montano-Loza[1]. [1]*University of Alberta, Division of Gastroenterology and Liver Unit, Edmonton, Canada;* [2]*University of Alberta, Human Nutrition and Metabolism, Edmonton, Canada;* [3]*University of Alberta, Department of Oncology, Cross Cancer Institute, Edmonton, Canada*
Email: montanol@ualberta.ca

Background and aims: Myosteatosis (pathological fat accumulation in muscle) is common in patients with cirrhosis and is defined by lower mean skeletal muscle radiodensity on CT. Cut-off points derived from cancer patients have been used to predict myosteatosis related outcomes in patients with cirrhosis. Given fluid retention in the majority of these patients, the applicability of these cut-offs is questionable. We aimed to determine the optimal cut-offs for myosteatosis, using a large North American cohort of 855 patients with cirrhosis.
Method: CT images were taken as part of the liver transplant evaluation at the 3rd. lumbar vertebra and were used to determine the skeletal muscle index (SMI) and radiodensity expressed by cm^2/m^2 and Hounsfield Unit (HU), respectively. Sarcopenia was defined using established cut-offs in patients with cirrhosis as SMI<50 cm^2/m^2 in males and <39 cm^2/m^2 in females. Muscle radiodensity values below the lowest tertile were considered as myosteatosis. Competing-risk analysis was performed to determine associations between muscle radiodensity and pre-transplant mortality.
Results: Sixty-four percent of the patients were male (64%) with a mean MELD score of 15 ± 8. Muscle radiodensity less than 33 and 28 HU in males and females, respectively were used as cut-off points (Figure 1a). Using these cut-offs, myosteatosis was identified in 34% of the patients. Cirrhosis etiology, MELD score, refractory ascites, variceal bleeding, hepatic encephalopathy, sarcopenia and myosteatosis (sHR 1.56, 95% CI, 1.26–1.92, p < 0.001) were predictors of mortality in the univariate competitive risk analysis. Myosteatosis association with mortality remained significant after adjusting for confounding factors (sHR 1.47, 95% CI, 1.17–1.84, p = 0.001). The cumulative incidence of mortality was higher in patients with myosteatosis (Figure 1b). Sarcopenia was more frequent in patients with myosteatosis compared to their counterparts (50% vs. 32%, p < 0.001). Patients with concurrent presence of myosteatosis and sarcopenia constituted 17% of the patient population and had the highest risk of mortality (sHR 2.22, 95% CI, 1.64–3.00, p < 0.001) when compared to patients without any of these features in an adjusted model.



Conclusion: Myosteatosis is commonly seen in patients with cirrhosis and is associated with higher mortality. Concomitant presence of myosteatosis and sarcopenia is associated with an increased risk of worse outcomes.

SAT505

Application of CT-contrast media is not associated with a higher risk for acute kidney injury in patients with decompensated liver cirrhosis

Tammo Lambert Tergast[1], Marie Griemsmann[1], Benjamin Schulte[1], Denise Menti[1], Neslihan Deveci[1], Julia Kahlhöfer[2], Petra Dörge[2], Anke Kraft[1,3], Heiner Wedemeyer[1,4], Markus Cornberg[1,3,4], Benjamin Maasoumy[1,4]. *[1]Hannover Medical School, Department of Gastroenterology, Hepatology and Endocrinology, Hannover, Germany; [2]Deutsche Leberstiftung, HepNet Study-House, Germany; [3]Centre for Individualised Infection Medicine (CiiM), Hannover, Germany; [4]German Centre for Infection Research (Deutsches Zentrum für Infektionsforschun), partner site Hannover-Braunschweig, Hannover, Germany*
Email: tergast.tammo@mh-hannover.de

Background and aims: Acute kidney injury (AKI) is a severe complication in patients with decompensated liver cirrhosis and is associated with a poor prognosis. Identifying and preventing the application of potential trigger substances for AKI is important in the management of these patients. In this context, only insufficient data regarding the nephrotoxic potential of CT-contrast media (CM-CT) is available. Here we investigate the nephrotoxic potential of CM-CT in patients with decompensated liver cirrhosis.
Method: In an exploratory analysis, patients with decompensated liver cirrhosis and ascites that received a paracentesis between 2012 and 2016 at Hannover Medical School (MHH) were included. Patients with AKI or relevant interventional procedures 7 days prior to baseline were excluded from this study. Propensity score matching (PPSM) was conducted, matching for MELD score, leukocyte count, intake of diuretics, presence of diabetes and age. Results were confirmed using data from a prospective registry that collects clinical data and biosamples from patients with liver cirrhosis and ascites that underwent a paracentesis between 2016 and 2020 (validation cohort) at MHH. Analyzed end points were 28-day incidence of AKI, severe AKI and liver transplant (LTx) free survival. Furthermore, measurement of neutrophil gelatinase-associated lipocalin (NGAL), an early marker for AKI, was conducted in plasma-samples from the prospective cohort.
Results: Overall, 140 patients were eligible for analysis in the retrospective cohort, of whom 61 patients received a CM-CT (43%). After PPSM, 51 patients with CM-CT were matched with 51 patients without CM-CT. Baseline parameters like MELD (CM-CT: 15 vs. No CM-CT: 16, $p = 0.44$), CRP values (CM-CT: 32 mg/dl vs. No CM-CT: 34 mg/dl, $p = 0.80$) and presence of infections at baseline (CM-CT: 35% vs. No CM-CT: 37%, $p = 1.00$) were comparable between both groups. The 28-day AKI incidence did not differ between both groups ($p = 0.56$). Furthermore, LTx-free survival and incidence of severe AKI was comparable ($p = 0.37$ and $p = 1.00$). In the validation cohort, CM-CT was noted in 13 patients (11%), while 105 patients had no CM-CT (89%). Incidence of AKI and severe AKI was comparable between the groups ($p = 0.85$ and $p = 0.54$). Finally, NGAL-levels did not differ significantly between CM-CT an no CM-CT patients (311 ng/ml vs. 266 ng/ml, $p = 0.35$).
Conclusion: CM-CT does not increase the risk for AKI in patients with decompensated liver cirrhosis.

SAT506

Proton pump inhibitors are associated with higher mortality risk and higher risk of decompensation in patients with liver cirrhosis-A retrospective cohort study from the Amsterdam metropolitan area

Koos de Wit[1], Thijs Kuipers[1], Koen van der Ploeg[1], Bert Baak[2], Ulrich Beuers[1], Bart Takkenberg[1]. *[1]Amsterdam UMC, location AMC, Department of Gastroenterology and Hepatology, Amsterdam, Netherlands; [2]OLVG, Department of Gastroenterology and Hepatology, Amsterdam, Netherlands*
Email: k.dewit1@amsterdamumc.nl

Background and aims: The clinical course of patients with liver cirrhosis in the Netherlands is insufficiently studied and adherence to hepatocellular carcinoma (HCC) screening guidelines is unknown. This study was performed to get insight in the clinical course of patients with liver cirrhosis, to determine factors that predict decompensation and transplant-free survival (TFS), and to study adherence to HCC screening guidelines.
Method: A retrospective cohort study of patients with confirmed liver cirrhosis in two large hospitals in Amsterdam, the Netherlands. Patients were identified by ICD-10 code [2014–2020]. Patients were excluded when lost to follow-up within one year after diagnosis (except death) or if there were less than two visits at the outpatient clinic. Clinical parameters, number of decompensation events, development of HCC, hepatic encephalopathy (HE) and medication use were extracted from medical records.
Results: In total 681 patients were included for analyses (67% male, median age 58 years (IQR 50–66)). Main etiologies were alcohol use (40%), chronic hepatitis C (15%) and NAFLD/NASH (10%). Median TFS was 100 months. Decompensated patients at time of diagnosis had a TFS of 86 months compared to 136 months for compensated patients ($p < 0.01$). Mortality risk was increased in multivariate analysis by: age at diagnosis (HR 1.05 (1.03–1.07) per year, $p < 0.01$), smoking (HR 2.30 (1.50–3.55), $p < 0.01$), decompensated initial presentation (HR 1.93 (1.28–2.91), $p = 0.03$) and PPI use (HR 1.93 (1.28–2.91), $p < 0.01$). In multivariate analysis, risk of future decompensation was increased if patients initially presented decompensated (HR 2.67 (1.72–4.16), $p < 0.01$) and used PPIs (HR 1.54 (1.04–2.27), $p = 0.03$). PPIs were used by 81% of the patients and in 54% there was no clear indication. In multivariate analysis the risk of development of overt HE was decreased in patients that used statins (HR 0.55 (0.33–0.92), $p = 0.02$). A total of 127 patients (19%) developed HCC. Patients who were adequately screened (46%) had a longer TFS (48 months) compared to patients who were not (22 months, $p < 0.01$).
Conclusion: In this retrospective cohort study of patients with cirrhosis, PPI use was associated with an increased mortality risk and increased risk of future decompensation, statin use was associated with a reduced risk of HE, and adequate HCC surveillance was associated with markedly better survival.

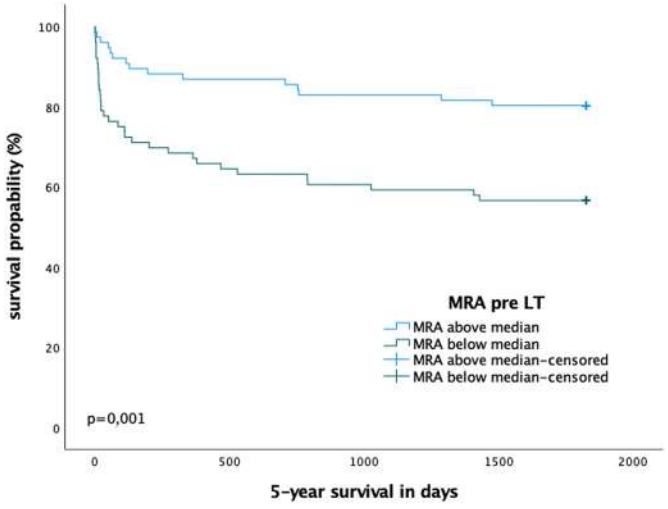
SAT507

Maintenance of sarcopenia and myosteatosis after liver transplantation

Franziska Recklies[1], Isabel Molwitz[2], Maria Stark[3], Thomas Horvatits[1], Johannes Salamon[2], Samuel Huber[1], Lutz Fischer[4], Ansgar Lohse[1], Martina Sterneck[1], Karoline Horvatits[1]. *[1]University Medical Center Hamburg-Eppendorf, Department of Medicine, Hamburg, Germany; [2]University Medical Center Hamburg-Eppendorf, Department of Diagnostic and Interventional Radiology and Nuclear Medicine, Hamburg, Germany; [3]University Medical Center Hamburg-Eppendorf, Institute of Medical Biometry and Epidemiology, Hamburg, Germany; [4]University Medical Center Hamburg-Eppendorf, Department of Hepatobiliary and Transplant Surgery, Hamburg, Germany*
Email: k.horvatits@uke.de

Background and aims: Presence of sarcopenia and myosteatosis in liver transplant (LT) candidates is associated with adverse outcomes before and after LT. Aim of this study was to evaluate the course of sarcopenia and myosteatosis before and after LT, and to study its impact on the overall survival.
Method: In this retrospective observational study all patients receiving LT, between 2011-2015 at a tertiary care center, with a CT scan <8 months pre-LT, were studied. Radiological follow-up (FU) was assessed in patients with additional CT scan >6 months post-LT. Clinical characteristics, body mass index (BMI), skeletal muscle index (SMI), sarcopenia (defined as SMI <39 cm^2/m^2 in females and <50 cm^2/m^2 in males), and muscle radiodensity attenuation (MRA) in Houndsfield Units (HU) were assessed. To analyze the development of MRA, SMI, and BMI after LT a linear regression model was applied. For survival analysis, log-rank test, and Cox proportional hazards regression were used.

Results: 152 patients (male: 72%; alcoholic liver disease: 35%, viral hepatitis: 22%; HCC 32%) were included in the study. 5-year survival was 68%. Sarcopenia pre-LT was present in 93 (62%) patients. Mean MELD did not differ between patients with and without sarcopenia (21 vs. 22; p = 0.4). Mean MRA pre-LT was 37 HU. Reduced MRA pre-LT was associated with higher BMI (p = 0.033), age (p <0.001), male sex (p = 0.019), and a lower SMI (p = 0.041). Patients with hepatorenal syndrome or need of hemodialysis showed a lower MRA than those without (p = 0.018; p = 0.002). At short- term FU (11 months after LT) mean MRA was 35 HU and 35/50 (70%) fulfilled criteria of sarcopenia, whereas at long-term FU (56 months after LT) mean MRA was 34 HU and 35/52 (67%) were classified as sarcopenic. Neither MRA nor SMI improved after LT. Both, MRA and SMI decreased after LT (-2.213 HU [95%-CI – 4.314; – 0.113], p = 0.039; – 2.646 cm^2/m^2 [95%-CI – 4.524; – 0.767], p = 0.007) while BMI stayed stable (–0.644 kg/m^2 [95%-CI – 1.466; 0.177], p = 0.121). MRA and MELD-score predicted short- and long-term survival (30 days: MRA: HR = 0.913 [95%-CI 0.857; 0.973], p = 0.005; MELD-score: HR = 1.061 [95%-CI 1.007; 1.118], p = 0.027; 1 year: MRA: HR = 0.952 [95%-CI 0.909; 0.997], p = 0.037; MELD-score: HR = 1.046 [95%-CI 1.01; 1.083], p = 0.011; 5 years: MRA: HR = 0.956 [95%-CI 0.918; 0.995], p = 0.029; MELD-score: HR = 1.03 [95%-CI 1; 1.06], p = 0.049).



Conclusion: Neither SMI nor MRA as parameters of sarcopenia improved after transplantation. Besides the MELD score, MRA predicted short- and long-term survival after transplant. MRA and muscle quality should thus be defined prior to transplantation to stratify the patient's risk profile and should be validated in future studies.

SAT508

Clinical and prognostic characterization of the patterns of decompensation of liver cirrhosis

Marta Tonon[1], Simone Incicco[1], Valeria Calvino[1], Alessandra Brocca[1], Antonio Accetta[1], Carmine Gabriele Gambino[1], Marco Cola[1], Daniel Salinas[1], Salvatore Piano[1], Paolo Angeli[1]. [1]*University of Padova, Unit of Internal Medicine and Hepatology, Department of Medicine, Padova, Italy*
Email: salvatorepiano@gmail.com

Background and aims: The clinical course of liver cirrhosis is characterized by two phases, compensated and decompensated cirrhosis, the latter characterized by the onset of complications (ascites, variceal bleeding, hepatic encephalopathy) and a worse prognosis. Recently, Acute Decompensation (AD), i.e. the development of complications that require hospitalization, has been characterized. However, complications of cirrhosis do not necessarily require hospitalization and can develop progressively. This type of decompensation has recently been defined as Non Acute Decompensation (NAD). At present time, there is no information regarding the incidence and prognostic impact of NAD. The aim of the study was therefore the evaluation of the incidence of NAD and AD in a group of outpatients with liver cirrhosis and the prognostic impact of these two decompensation patterns.

Method: 749 outpatients with cirrhosis were enrolled and consequently followed up until death, liver transplantation or the end of the study (August 2021). Clinical and biochemical data were collected, as well as the development of complications during follow-up, which were considered as AD if they resulted in hospitalization or NAD if they were managed at outpatient clinic.

Results: 379 patients (50.6%) did not develop any decompensation, 163 patients (21.8%) had NAD as first decompensation and 207 (27.6%) had AD. During follow-up, 216 patients (28.8%) died and 145 (19.4%) were transplanted. Survival at 10 years was significantly higher in patients who did not develop decompensations (79.6%) than in patients who developed NAD or AD (33.7% and 21.3%, respectively; p < 0.001, Fig. A). Eighty-three patients with NAD (50.9%) subsequently developed AD. There was no significant difference in 10-year survival between patients who developed AD after NAD and those who only had AD, while both of these groups showed shorter survival than patients who had only NAD. In multivariate analysis, age (HR 1.05, p < 0.001), MELD (HR 1.10, p < 0.001), varices at inclusion (HR 1.48, p = 0.03), albumin (HR 0.94, p < 0.001), MAP (HR 0.98, p = 0.006), effective etiological treatment (HR 0.38, p < 0.001) and NAD (HR 2.65, p < 0.001) or AD (HR 3.51, p < 0.001) were independent predictors of mortality.

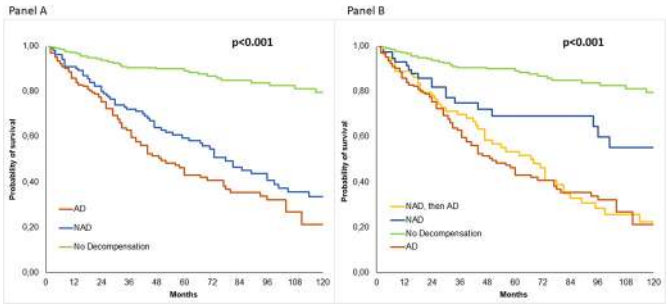


Figure: 120-month survival in patients according to the pattern of decompensation

Conclusion: In more than 20% of patients with cirrhosis the first decompensation is a NAD, which often precedes AD and is associated with a decreased survival. Patients who develop NAD must be monitored closely to prevent any development of AD.

SAT509

Safety, pharmacokinetics and pharmacodynamics of TNP-2092 capsule in chinese liver cirrhosis patients with hyperammonemia: a randomized, double-blind, placebo-controlled, dose-escalation phase Ib/IIa study

Jia Xu[1], Jingrui Liu[1], Jing Chen[1], Zhenkun Ma[1], Yanhua Ding[1], Junqi Niu[1]. [1]*China*
Email: 747740607@qq.com

Background and aims: TNP-2092, a locally acting drug candidate, exhibits broad-spectrum antibacterial activity by inhibiting three essential drug targets RNA polymerase, DNA gyrase and topoisomerase IV. TNP-2092 has a lower propensity for the development of resistance than rifaximin.

Method: Thirty-six liver cirrhosis patients with fasting venous blood ammonia higher than normal were enrolled and received multiple ascending doses of TNP-2092 (100 mg 300 mg and 600 mg, BID for 14 days) or placebo under fed conditions. Patients with Child-Pugh

grade C cirrhosis and grade 2 or above hepatic encephalopathy were excluded.

Results: TNP-2092 was safe and well tolerated in all treatment groups. The most commonly observed treatment emergent adverse events (TEAEs) were neutropenia (29.2%), leucopenia (16.7%) and lipase elevation (12.5%). The most of the TEAEs were mild and lack of dose relationships.

The AUC and C_{max} for TNP-2092 exhibited a dose-proportional increase. The systemic exposure of TNP-2092 increased 2- to 4-fold compared to that in healthy volunteers.

The blood ammonia level decreased in a dose-dependent fashion during and after the treatment (Table 1). TNP-2092 (600 mg BID) reduced the blood ammonia level by 24.03 ug/dL, compared to 15.43 ug/dL produced rifaximin (400 mg, TID) after 14 days of treatment as reported in literature.

Table 1. The change of blood ammonia before and after treatment

Dose（mg）		100 mg（N=8）	300 mg（N=8）	600 mg（N=8）	placebo（N=12）
During the treatment (D2-D15) , the proportion of blood ammonia measurements returned to normal*1	Ammonia level returned to normal	13%	22%	32%	7.40%
	P vs. placebo	0.22	0.01	0.0004	-
During the treatment (D2-D15), the proportion of blood ammonia level decreased*2	Ammonia level decreased	47%	50%	69.40%	52.80%
	P vs. placebo	0.4656	0.7173	0.0339	-
After the treatment (D15), the reduction of blood ammonia level from pretreatment *3	Change of blood ammonia level (μg/dL)	9.71	-3.62	-24.03	0.85
	P vs. placebo	0.7128	0.1393	0.0353	-

*1 Including blood ammonia measurements conducted on D2,3,4,5,7,9,11,13 and 15.

*2 The proportion of measurements that decreased from the mean blood ammonia before treatment.

*3 Fasting blood ammonia on D15 compared to the mean blood ammonia level before treatment.

Figure: 120-month survival in patients according to the pattern of decompensation

Conclusion: TNP-2092 was safe and well tolerated with a linear pharmacokinetic and pharmacodynamic profile in liver cirrhosis patients with hyperammonemia. TNP-2092 showed potential to have a stronger effect on the blood ammonia level than rifaximin.

SAT510

Serological assessment of the collagen type III deposition predicts outcome in decompensated liver cirrhosis

Mette Juul Nielsen[1], Robert Schierwagen[2,3], Christian Jansen[2], Frank Uschner[2,3], Sabine Klein[2,3], Maximilian J Brol[2,3], Michael Praktiknjo[2], Chang Johannes[2], Morten Karsdal[1], Diana Leeming[1], Jonel Trebicka[2,3,4,5]. *[1]Nordic Bioscience A/S, Denmark; [2]University Hospital of Bonn, Department of Internal Medicine I, Bonn, Germany; [3]University of Frankfurt, Department of Internal Medicine I, Frankfurt, Germany; [4]European Foundation for Study of Chronic Liver Failure, Barcelona, Spain; [5]University Clinic Odense, Department of Hepatology, Odense, Denmark*
Email: mju@nordicbio.com

Background and aims: Fibrosis is the result of excessive collagen and extracellular matrix (ECM) accumulation, consequent to an imbalance in collagen formation and degradation. The balance between fibrogenesis and fibrolysis may be of importance for patient management and prognosis. Over time, the collagen fibrils become enzymatically cross-linked resulting in increased stiffness of the tissue. Here we investigated a novel fibrosis resolution biomarker, C-terminal cross-linked type III collagen degradation (CTX-III) in combination with the collagen formation biomarker PRO-C3, and their association with decompensation and predictors of mortality in patients with trans jugular intrahepatic portosystemic shunt (TIPS).

Method: In 83 patients with decompensated liver cirrhosis, plasma samples were taken from the hepatic vein at the time of TIPS insertion. Fibrogenesis was assessed using PRO-C3 and fibrolysis by the cross-linked collagen fragment CTX-III. The association between individual biomarkers and presence of ascites, Child-Pugh category, and MELD score was investigated. Patients with high fibrogenesis and low fibrolysis and vice versa were identified by CART analysis. The net type III collagen remodeling was defined as the ratio between fibrogenesis and fibrolysis, i.e., the PRO-C3:CTX-III ratio. Kaplan-Meier and Cox regression analyses were used to investigate the association of the balance between fibrogenesis and fibrolysis with 5-year transplant-free survival.

Results: At TIPS insertion, PRO-C3 was significantly elevated in patients with MELD score >11 (p = 0.014) and Child-Pugh Class C (p = 0.017). Interestingly, the degree of the type III collagen remodeling was not associated with disease severity, including MELD score, presence of ascites, and Child-Pugh class. When stratifying individual biomarkers according to their median, none of the biomarkers was associated with survival. Nevertheless, patients with excessive type III collagen deposition, defined by high fibrogenesis (PRO-C3) and low fibrolysis (CTX-III), at TIPS insertion had significantly shorter survival time compared to those with less type III collagen deposition (p = 0.020).

Conclusion: High level of fibrosis resolution is associated with less severe decompensation and better survival in liver cirrhotic patients with TIPS. The balance of collagen formation and collagen degradation provide additional information compared to each biomarker and is essential for the prediction of outcome in cirrhotic patients.

SAT511

Liver frailty index predicts poor outcomes in patients hospitalized for acute decompensation of cirrhosis

Simone Incicco[1], Roberta Gagliardi[1], Marta Tonon[1], Valeria Calvino[1], Nicola Zeni[1], Alessandra Brocca[1], Carmine Gabriele Gambino[1], Paolo Angeli[1], Salvatore Piano[1]. *[1]Unit of Internal Medicine and Hepatology, Department of Medicine, University of Padova, Padova, Italy*
Email: salvatorepiano@gmail.com

Background and aims: Physical frailty is highly prevalent in patients with end stage liver disease and has been associated with poor outcomes. Liver Frailty Index (LFI) is a standardized tool to assess frailty in patients with cirrhosis on liver transplant waiting list. However, there is a paucity of data on the prognostic value of LFI in patients hospitalized for acute decompensation (AD) of cirrhosis. We

evaluated LFI in patients hospitalized for AD and the association of LFI with complications occurred during hospitalization and 90-day survival.

Method: We enrolled 117 consecutive patients admitted for AD of cirrhosis from 2019 to 2021. LFI was performed at the time of hospital admission. Occurrence of complications (hepatic encephalopathy [HE], sepsis, organ failures, ACLF) during hospitalization was recorded. Patients were followed up until death, liver transplant or 90 days.

Results: **M**ean age and MELD-Na were 64 ± 10 and 20 ± 7, respectively. The majority of patients were male (71%) and had and alcohol-related cirrhosis (56%). Median LFI was 6.1 (IQR 5.0–6.5). LFI showed a weak, but significant, correlation with age ($r = 0.202$; $p = 0.029$), MELD-Na ($r = 0.292$; $p = 0.001$) and parameters of systemic inflammation such as C-Reactive Protein ($r = 0.235$; $p = 0.014$) and white blood cell (WBC) count ($r = 0.207$; $p = 0.025$).

LFI was significantly higher in patients developing hepatic encephalopathy, sepsis, renal failure, circulatory failure, respiratory failure and ACLF than in those who did not (Figure 1). Patients transferred to the ICU had significantly higher LFI than those who did not (Figure 1).

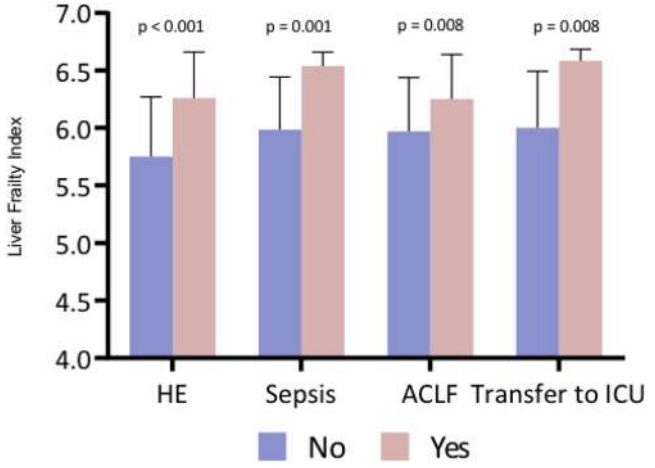

Figure: Liver Frailty Index in patients developing or not complications during hospital stay.

LFI was significantly higher in patients who died than in those who survived during hospitalization (median = 6.5 [IQR = 6.0–6.7] vs 6.0 [IQR 4.8–6.5]; p = 0.006) and at 90 days (6.45, IQR 6–6.64 vs 5.87, IQR 4.81–6.37; p = 0.001). In multivariate analysis LFI was an independent risk factor of 90-day mortality (HR = 1.88, 95% CI 1.07–3.32; p = 0.028), as well as MELD-Na (HR = 1.11, 95% CI 1.04–1.18; p = 0.01) and WBC (HR = 1.08, 95% CI 1.00–1.17, p = 0.046).

Conclusion: In patients with cirrhosis hospitalized for AD**,** LFI identifies patients at higher risk of worse outcomes and can be used for the assessment of frailty in these patients.

SAT512

Urinary proteomics identifies oxidative stress and inflammation pathways as key factors differentiating acute-kidney injury-hepatorenal syndrome from acute tubular necrosis in patients with cirrhosis

Pere Ginès[1,2,3,4], Laura Napoleone[1,2,3], Mikel Azkargorta[2,5], Jordi Gratacós-Gines[1,2,3], Cristina Solé[1,2,3], Adria Juanola[1,2,3], Ann Ma[1,2,3], Marta Carol[1,2,3,4], Martina Perez[1,2,3,4], Ana Belén Rubio[1,2,3], Marta Cervera[1,2,3,4], Anna Soria[1,2,3], Octavi Bassegoda[1,2,3], Manuel Morales-Ruiz[2,3,4,6], Núria Fabrellas[1,2,3,4], Isabel Graupera[1,2,3,4], Juanjo Lozano[2], Elisa Pose[1,2,3], Felix Elortza[2,5], Elsa Solà[1,2,3]. *[1]Hospital Clinic, Liver Unit, Barcelona, Spain; [2]Centro de Investigación Biomédica en Red de Enfermedades Hepáticas y Digestivas (CIBEReHD), Madrid, Spain; [3]Institut d'Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS), Barcelona, Spain; [4]School of Medicine and Health Sciences. Email: pgines@clinic.cat

Background and aims: Acute kidney injury-hepatorenal syndrome (AKI-HRS) and acute tubular necrosis (AKI-ATN) are two common causes of AKI in cirrhosis with differential treatment. Frequently, the distinction between AKI-HRS and AKI-ATN is difficult, in part because there are no objective biomarkers for differential diagnosis. This difficulty is also related to the limited knowledge that exists about the pathogenic mechanisms of these two conditions. The aim of this study was to evaluate the differences between AKI-HRS and AKI-ATN by using proteomics in urine, a technique that allows the identification of large amounts of protein in biological fluids.

Method: Prospective study including 61 patients with a diagnosis of cirrhosis (38 patients with AKI-HRS, 23 patients with AKI-ATN) admitted to the hospital for complications of the disease.

Proteins in urine were analyzed by a nano-flow liquid chromatography technique coupled to tandem mass spectrometry (nLC MS/MS: in Orbitrap XL-ETD system, Thermo).

Differencial proteomics (Label Free Quantification) was performed using Progenesis IQ software. Bioinformatics analysis was performed using GenOntology and metabolic pathway analysis was performed using MetaboAnalyst 5.0.

Results: A total of 491 proteins were analyzed. Proteins that were significantly increased in AKI-HRS compared to AKI-ATN corresponded to metabolic pathways related to oxidative stress and inflammation. In particular, some of the most altered pathways corresponded to glycogen metabolism, sucrose metabolism, nitrogen metabolism, glutathione metabolism, riboflavin metabolism, taurine metabolism, arachidonic acid metabolism, tryptophan metabolism and pentose phosphate pathway.

A number of proteins were specifically and differentially up-regulated in both conditions.

Conclusion: These results suggest that oxidative stress and inflammatory pathways play important roles in the pathogenesis of AKI-HRS. This study opens new avenues in the differential diagnosis between AKI-HRS and AKI-ATN in cirrhosis, as well as for new therapies targeting specific proteins or metabolic pathways.

SAT513

Kidney transplant alone recipients with advanced liver disease have similar outcomes to those without advanced liver disease-a single center study of 150 patients

Rohit Nathani[1], Stephanie Rutledge[2], Carolina Villarroel[3], Ron Shapiro[4], Gene Im[5]. *[1]Icahn School of Medicine at Mount Sinai Morningside-West, Department of Medicine, New York, United States; [2]Icahn School of Medicine at Mount Sinai, Division of Gastroenterology, Department of Medicine, New York, United States; [3]Icahn School of Medicine at Mount Sinai Beth Israel, Department of Medicine, New York, United States; [4]Icahn School of Medicine at Mount Sinai, Recanati/Miller Transplantation Institute, Department of Surgery, New York, United States; [5]Icahn School of Medicine at Mount Sinai, Recanati/Miller Transplantation Institute, Division of Liver Diseases, Department of Medicine, New York, United States*
Email: rohit.nathani@mountsinai.org

Background and aims: The prevalence of concomitant liver disease (LD) in patients with end-stage renal disease is reported to be 7–40%. The safety of kidney transplant alone (KTA) in those with advanced LD (F3–4) is controversial, with KDIGO guidelines recommending KTA consideration in compensated cirrhosis based on few small studies. The aim of this study was to compare outcomes in KTA patients with advanced LD to KTA patients with non-advanced LD.

Method: Retrospective analysis of all KTA patients at our center from 1/2012–12/2020 was performed. KTA patients with concomitant LD were identified by chart review. Advanced LD and cirrhosis status were determined by clinical criteria and if available, liver biopsy. Matched cohort analysis was performed using matching based on age, time on hemodialysis (HD), sex, and ethnicity. Primary outcome was mortality and secondary outcomes included serious infection (requiring intravenous antibiotics), allograft rejection, allograft failure, and liver decompensation.

Results: Over 8 years 1741 KTAs were performed, with 150 (8.6%) recipients having concomitant LD. KTA with LD cohort was mostly male (81%) and African American (50%) with a median age of 65 years (59–69), median time on HD of 37.5 (8–76.5) months, hepatitis C virus infection as the most common etiology of LD (72%) and a mean follow-up of 1807 (SD ± 960) days. Transjugular liver biopsies were available for 62 (41%) patients with mean hepatic venous pressure gradient of 6.2 (SD ± 3.2) mmHg prior to KTA. We identified 29 (19%) patients with advanced LD at the time of KTA and 27/29 (93%) had compensated cirrhosis, mean MELD 21.8 (SD ± 3.8). The 1-, 3- and 5-year survival rates were 95.5%, 89.8% and 79.5% respectively. KTA patients without advanced LD (n = 46) were selected as a matched cohort. Kaplan-Meier survival analysis showed similar outcomes between KTA with LD subgroups (p = 0.09). On matched cohort analysis, 6 (21%) cases died compared to 9 (20%) controls (p = .9). Mean time to death was 1645 (SD ± 939) days in cases compared to 689 (± 514) days in controls (p = .06). Secondary outcomes were similar between the 2 groups: serious infection 21% vs 28% (p = .51); allograft rejection 14% vs 13%, (p = .55); allograft failure 14% vs 4.3% (p = .2). Liver decompensation occurred in 4 (14%) cases after KTA vs 0 in control group (p = .6), mostly due to ascites (3/4), but also esophageal varices and hepatocellular carcinoma (causing death).

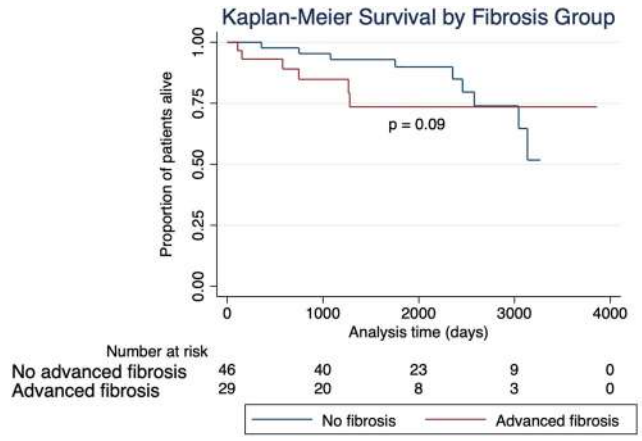

Figure: Similar outcomes in KTA patients with and without advanced LD

Conclusion: This is one of the largest single-center studies comparing outcomes in KTA patients with and without advanced LD. Although limited by small numbers, KTA patients with LD had excellent outcomes, with similar patient, graft, infection and liver decompensation outcomes between advanced LD and those without. This supports the practice of KTA in patients with concomitant LD, even with advanced fibrosis.

SAT514

Clinical features of exacerbation of portal vein thrombosis after discontinuation of anticoagulants

Takayuki Kondo[1], Kisako Fujiwara[1], Sae Yumita[1], Takamasa Ishino[1], Keita Ogawa[1], Miyuki Nakagawa[1], Hidemi Unozawa[1], Terunao Iwanaga[1], Takafumi Sakuma[1], Naoto Fujita[1], Keisuke Koroki[1], Hiroaki Kanzaki[1], Kazufumi Kobayashi[1], Soichiro Kiyono[1], Masato Nakamura[1], Naoya Kanogawa[1], Tomoko Saito[1], Sadahisa Ogasawara[1], Shingo Nakamoto[1], Tetsuhiro Chiba[1], Jun Kato[1], Naoya Kato[1]. *[1]Graduate School of Medicine, Chiba University, Department of Gastroenterology, Chiba, Japan*
Email: takakondonaika@yahoo.co.jp

Background and aims: Portal vein thrombosis (PVT) is not a rare complication in cirrhosis. Currently, optimal management of PVT has been reported in the clinical guidelines. However, recommendations for the discontinuation of anticoagulants are not strictly defined. The present study aimed to clarify the clinical features of exacerbation of PVT after discontinuation of anticoagulants.

Method: This retrospective study included data from our institutional database between 2009 and 2020. This study enrolled 75 consecutive patients diagnosed with PVT by Doppler ultrasound (US) and contrast-enhanced computed tomography (CECT) who received anticoagulants and were followed up with at least one more CECT after diagnosis of PVT. Of the 75 patients, 50 patients discontinued anticoagulants at the physician's discretion. The PVT volume was measured using CECT images that included the whole spleno-porto-mesenteric axis. The outline of the PVT was traced manually in each slice and obtained at 5-mm intervals, and its volume was calculated by integrating all images. The sum of the diameter of portosystemic shunts diagnosed by Doppler US and CECT were calculated. The therapeutic assessment of the PVT was defined as complete response (0%), partial response (1–50%), slight response (51–75%), no response (76–100%), progression (≥101%).

Results: The PVT volume decreased significantly after anticoagulant therapy (pre-treatment 10.4 ± 10.8 cm^3 vs. post-treatment 5.3 ± 7.5 cm^3; p <0.01). Fifty-six patients (74.7%) achieved at least slight response (complete response 38.7%, partial response 26.7%, slight response 9.3%). Fifty patients discontinued anticoagulants, and 31 patients (62.0%) had the exacerbation of PVT after discontinuation of anticoagulants. The cumulative exacerbation rate of PVT was 24.0% at 3 months, 44.6% at 6 months, and 56.4% at 12 months. Multivariate

analysis showed that the sum of the diameter of portosystemic shunts (p = 0.02) and unknown cause of PVT (p = 0.02) were the significant predictive factors for the exacerbation of PVT after discontinuation of anticoagulants. A predictive model for the exacerbation of PVT after discontinuation of anticoagulants obtained by classification and regression tree analysis indicated the following subpopulations with distinct exacerbation rate: high risk (with unknown cause of PVT, exacerbation rate: 85%); intermediate risk (the sum of portosystemic shunts ≥12 mm and without unknown cause of PVT, exacerbation rate: 75%); and low risk (the sum of portosystemic shunts <12 mm and without unknown cause of PVT, exacerbation rate: 19%).
Conclusion: Patients with unknown cause of PVT or the development of portosystemic shunts should be monitored carefully after discontinuation of anticoagulants because of the high rate of exacerbation of PVT.

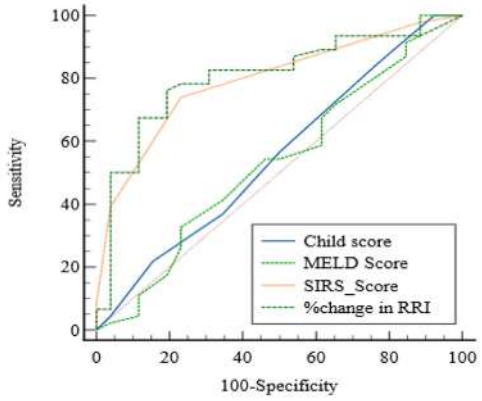
SAT515

Systemic inflammatory response syndrome and renal resistive index as early predictors of treatment response to terlipressin in hepatorenal syndrome-acute kidney injury

Vijay Narayanan[1], Avisek Chakravorty[2], Shivabrata Dhal Mohapatra[2], Rushil Solanki[2], Devika Madhu[2], Ravindra Pal[2], Krishnadas Devadas[3]. *[1]Government Medical College, Trivandrum, Medical Gastroenterology, Trivandrum, India; [2]Government Medical College, Trivandrum, Medical Gastroenterology; [3]Government Medical College, Trivandrum, Medical Gastroenterology, Trivandrum, India*
Email: vijaynh@gmail.com

Background and aims: A combination of terlipressin and albumin is the first-line pharmacologic treatment for Hepatorenal Syndrome-Acute Kidney Injury (HRS-AKI). The early identification of patients with a low likelihood of response to treatment is crucial, as they can be fast-tracked for liver transplantation. We assessed the response rates to terlipressin-albumin therapy in patients with decompensated cirrhosis and determined early predictors of treatment response. The mortality between treatment responders and non-responders was compared and predictors of six-month mortality were also assessed.
Method: This was a prospective observational study conducted in the Department of Medical Gastroenterology, Government Medical College, Trivandrum. Patients diagnosed to have HRS-AKI (based on the International Club of Ascites criteria) and treated with terlipressin-albumin were included. Univariate and multivariate logistic regression analysis was used to determine parameters that were predictive of HRS reversal. Best cut-offs of prediction were obtained from ROC curves.
Results: 84 patients with HRS-AKI were included. There was complete response to therapy in 54.8%, partial response in 14.3%, and no response in 31%. The factors associated with complete response to treatment were the presence of systemic inflammatory response syndrome (SIRS) at baseline (p <0.001), a rise in mean arterial pressure (MAP) ≥5 mmHg by day 3 of treatment (p <0.001), baseline serum creatinine ≤2.5 mg/dL (p <0.001), and a reduction in the renal resistive index (Delta-RRI) ≥5% by day 3 of treatment (p <0.001). On multivariate analysis, the independent predictors of complete response to treatment were the presence of SIRS at baseline (p = 0.016, OR = 6.19 (CI: 1.40–27)) and Delta-RRI ≥5% by day 3 (p = 0.001, OR = 24.2 (CI: 3.4–168.6)). The AUROC for predicting complete response to treatment was higher for SIRS Score (0.797) and Delta-RRI (0.803) than CHILD score (0.554) and MELD score (0.503) respectively. Non-responders had significantly higher mortality at 1 month (27% vs 9.5%, p = 0.04) and 6 months (74% vs 45%, p = 0.025). The factors significantly associated with six-month mortality were the presence of hepatic encephalopathy (p = 0.05), stage of AKI (p = 0.036), MELD score (p = 0.014) and non-resolution of SIRS by day 3 of terlipressin treatment (p = 0.029). On multivariate analysis, MELD >23 was found to be an independent predictor of six mortality (p = 0.019, OR = 4.4 (CI: 1.3–15.4)).

Figure: Comparison of AUROC curves to predict treatment response in HRS-AKI



Variable	AUC	SE [a]	95% CI [b]
CHILD score	0.554	0.0713	0.432 to 0.671
MELD Score	0.536	0.0731	0.415 to 0.655
SIRS Score	0.797	0.0617	0.686 to 0.883
% Change in RRI	0.803	0.0550	0.692 to 0.887

Conclusion: SIRS and Delta-RRI are simple parameters to predict treatment response in HRS-AKI. Non-responders have higher mortality and should be identified early to expedite liver transplantation.
In HRS-AKI, the renal resistive index is a measure of the intrarenal vasoconstriction, and SIRS reflects the exaggerated systemic inflammation, both of which are reversed by terlipressin, leading to an enhanced treatment response.

SAT516

A prospective study of global myocardial function in decompensated cirrhosis using advanced echocardiographic techniques and its clinical significance

Jeyamani Ramachandran[1], Purendra Kumar Pati[2], Teresa Hecker[3], Fadak Mohammadi[3], Libby John[3], Vidyaleha Chandran[2], Matthew Chapman[2], Yasmina Tashkent[3], Rosemary McCormick[3], Kylie Bragg[3], Majo Joseph[3], James Gunton[3], Asif Chinnaratha[2], Kate Muller[3], Alan Wigg[3]. *[1]Flinders Medical Centre, Flinders University, Australia; [2]Lyell McEwin Hospital, Elizabeth Vale, Australia; [3]Flinders Medical Centre, Bedford Park, Australia*
Email: jeyamani.ramachandran@sa.gov.au

Background and aims: Cirrhotic cardiomyopathy (CCM) is cardiac dysfunction due to cirrhosis without a primary cardiac cause. This study investigated CCM using global longitudinal strain (GLS) and global work index (GWI), sensitive measures of myocardial performance and their clinical significance over a 12-month follow-up. Assessed clinical events included acute kidney injury/hepatorenal syndrome (AKI/HRS), refractory ascites, cardiac failure, and death.
Method: Consenting consecutive cirrhotic patients with ascites and those undergoing liver transplant (LT) assessment were studied prospectively after excluding those with prior cardiac diagnosis. Transthoracic echocardiography (TTE) and dobutamine stress echocardiogram (DSE) were performed. GLS by speckle tracking echocardiography (STE) and GWI by combining STE and brachial artery blood pressure were calculated. CCM was defined according to 2019 criteria.
Results: Since January 2021, 65 cirrhotic patients were studied; Median (interquartile range, IQR) age 56 (13) years; 60% male; 72% related to alcohol misuse; 11 patients on beta-blockers; 28 in Child's

class C, 30 in class B and 7 in class A; Median (IQR) MELD-Na 16 (12). CCM was diagnosed in 16 patients (25%) and was subclinical; systolic dysfunction (SD) in 9 patients, none with left ventricular ejection fraction (LVEF) <50%; Advanced diastolic dysfunction (DD) in 7 patients. If grade 2 DD seen in a further 16 patients were included, the prevalence of CCM reached 49%. A lower MELD-Na was associated with SD (mean MELD-Na 12 Vs 18 in patients with and without SD respectively, p = 0.015) with no significant association between DD and MELD Na. During the median follow-up of 181 days, 16 patients developed AKI/HRS and 33 patients experienced, refractory ascites, recurrent hydrothorax and or sepsis including peritonitis. No association was seen between SD, DD and CCM and these events. However, age (adjusted odds ratio = 1.018, 95%CI 1.037–1.185, *p* = 0.002) and AKI/HRS (adjusted odds ratio = 5.153, 95%CI 1.108–23.959, *p* = 0.037) emerged as independent predictors of CCM when grade 2 DD was included. Four patients died and three underwent successful LT. LVEF, GLS and GWI at baseline and on DSE were compared in 53 patients:

	At rest mean (standard deviation)	Peak values on DSE mean (standard deviation)	*p value* (Mann-Whitney's test)
LVEF	69 (7)	78 (7)	<0.001
GLS (%)	−21 (2)	−20 (3)	0.044
GWI (mmHg %)	1917 (370)	1554 (396)	<0.001

GLS and GWI were reduced or unchanged in 30 (57%) and 46 (87%) patients, on DSE. There was no association between this lack of augmentation and clinical events.

Conclusion: A quarter of patients with advanced cirrhosis had CCM as per the new criteria. Low GLS with preserved LVEF and lack of augmentation of GLS and GWI on DSE suggest that advanced cirrhosis is a negative inotropic state. Ongoing follow-up and repeat studies after LT could explore clinical impact and reversibility of CCM.

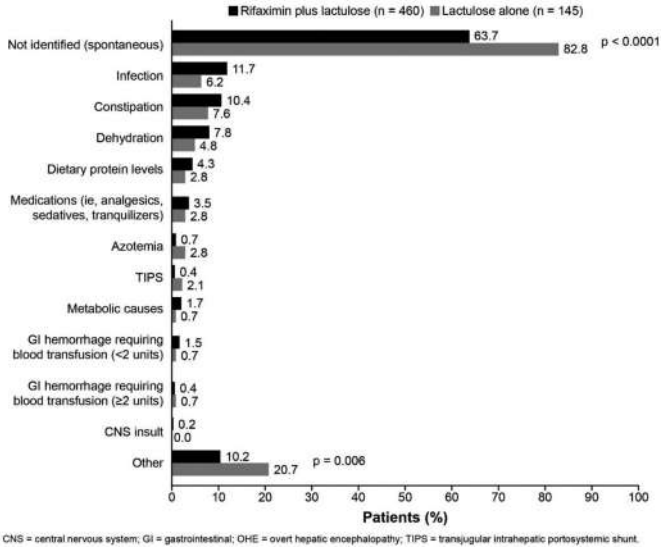
SAT517

Identification of overt hepatic encephalopathy precipitating factors: a pooled analysis of 3 clinical trials of rifaximin plus lactulose

Arun Jesudian[1], Arun Sanyal[2], Robert Brown[1], Zeev Heimanson[3], Robert Israel[3], Jasmohan S Bajaj[2,4]. *[1]Weill Cornell Medicine, New York, United States; [2]Virginia Commonwealth University, Richmond, United States; [3]Salix Pharmaceuticals, Bridgewater, United States; [4]McGuire VA Medical Center, Richmond, United States*
Email: abj9004@med.cornell.edu

Background and aims: Hepatic encephalopathy (HE) is a cirrhosis-related complication and its occurrence has been linked with several precipitating factors (eg, infection). Guidelines recommend rifaximin as add-on therapy to lactulose for reduction in risk of overt HE (OHE) recurrence. The aim was to summarize precipitating factors associated with breakthrough OHE events, during 3 clinical trials, in patients who received rifaximin plus lactulose or lactulose alone.
Method: Data were pooled from 3 trials: a 6-month, randomized, double-blind, placebo-controlled trial; a 24-month, open-label maintenance trial; and a 6-month, randomized, open-label trial. Adults with cirrhosis who had a history of OHE and were currently in OHE remission (Conn score <2) and received rifaximin 550 mg twice daily plus lactulose or lactulose alone were included. For each OHE episode, investigators were asked to record any contributing factors or precipitating events if they could be identified. p values were determined using the Fisher's exact test.
Results: 460 patients treated with rifaximin plus lactulose and 145 patients treated with lactulose alone were included. In the rifaximin plus lactulose group, 60.4% were male, the mean (SD) age was 57.1 (9.3); 38.9% were aged less than 55 y. In the lactulose alone group, 68.3% were male, the mean (SD) age was 56.6 (9.3); 37.2% were aged less than 55 y. The most commonly identified precipitating factors were infection, constipation, and dehydration, each observed in a similar percentage of patients in each group (p >0.05; Figure). Precipitating actors were not identified (ie, spontaneous) in a majority of patients in the rifaximin plus lactulose and lactulose alone groups (63.7% vs 82.8%; p <0.0001). Results were generally similar when subgrouped by male/female or by age (less than 55 y; at least 55 y).

Figure. Precipitating Factors of Breakthrough OHE Events



CNS = central nervous system; GI = gastrointestinal; OHE = overt hepatic encephalopathy; TIPS = transjugular intrahepatic portosystemic shunt.

Conclusion: Guidelines recommend identification and correction of precipitating factors to improve outcomes. In this analysis, the most commonly identified precipitating factors for OHE events in patients with a history of OHE were infection, constipation, and dehydration. A precipitating factor was not identified in a majority of cases; therefore, empiric therapy should be promptly initiated in the clinic, while factors are being identified. Prevention or early identification of OHE precipitating factors is an important part of cirrhosis disease management strategy to reduce the risk of OHE recurrence and related hospitalizations.

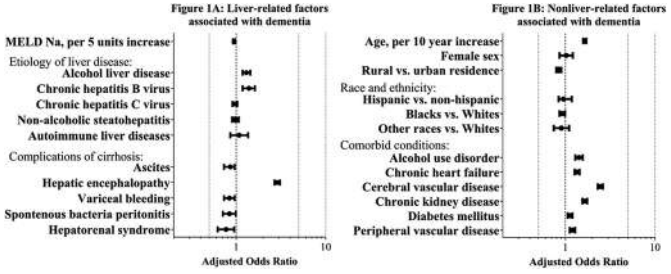
SAT518

Dementia frequently co-exists with hepatic encephalopathy but not other cirrhosis complications in US veterans with cirrhosis

Adeyinka Adejumo[1], Shari Rogal[1,2], Patrick Spoutz[3], Linda Chia[4], Jasmohan S Bajaj[5]. *[1]University of Pittsburgh, Medicine, Pittsburgh, United States; [2]VA Pittsburgh Healthcare System, Center for Health Equity Research and Promotion, Pittsburgh, United States; [3]Veterans Integrated Service Network 20, Pharmacy Benefits Management, Vancouver, United States; [4]Veterans Integrated Service Network 8, Pharmacy Benefits Management, Bay Pines, United States; [5]Virginia Commonwealth University and Richmond VAMC, Division of Gastroenterology, Hepatology, and Nutrition, Department of Medicine, Richmond, United States*
Email: adeyinka_adejumo@yahoo.com

Background and aims: Dementia and hepatic encephalopathy (HE) can manifest similarly in patients with cirrhosis, though the treatments differ. The purpose of this study was to evaluate the prevalence of and risk factors for dementia among Veterans with cirrhosis.
Method: US Veterans with cirrhosis who received VA care between 2019 and 2021 were identified using ICD-10-CM codes. Factors associated with having a diagnosis of dementia were evaluated using multivariate logistic regression models, adjusting for demographic,

comorbid illnesses, cirrhosis etiology, and cirrhosis complications (all defined by ICD-10-CM codes).
Results: The cohort included 71, 552 veterans with cirrhosis, who were mostly men (96.2%) with a with median age of 65.7 years (IQR 61–70). Ten percent (n = 7, 295) of the overall cohort had a diagnosis code of dementia overall, which increased to 12.4% among patients ≥65 years. Dementia was significantly associated with age (adjusted odds ratio and 95% confidence interval, AOR per 10-years: 1.64 [1.58–1.71]), white race (1.09[1.01, 1.16]), urban residence (1.19[1.11, 1.27]), alcohol-related cirrhosis (1.30[1.18–1.44]), hepatitis B (1.39[1.18–1.62]), alcohol use disorder (1.42[1.29–1.6]), cerebral vascular disease, peripheral vascular disease, diabetes, chronic kidney disease, and chronic heart failure, and negatively associated with MELD-Na (0.95 [0.92–0.95]/5 points) in multivariate logistic regression (Figures 1A and 1B). Dementia was significantly positively associated with HE (2.87[2.68–3.08]), but negatively associated with other cirrhosis complications in these models.



Conclusion: Diagnostic codes for dementia were found in 10% of Veterans with cirrhosis and most strongly associated with HE, but not other complications of cirrhosis. Furthermore, alcohol use disorder along with cardiovascular risk factors were associated with dementia, but not NASH itself. Further research is needed to determine strategies to differentiate between HE and dementia and manage this population with specific needs to prevent burden on families, patients and VHA system.

SAT519

Bacterial infections as a predisposing factor for the development of portal vein thrombosis in cirrhotic patients: a prospective study

Leonardo De Marco[1], Filippo Cattazzo[1], Michele Bevilacqua[1], Anna Mantovani[1], Andrea Dalbeni[1], David Sacerdoti[1]. [1]*Azienda Ospedaliera Universitaria Integrata Verona, Medicina interna C/Liver Unit, Verona, Italy*
Email: leonardo.demarco93@gmail.com

Background and aims: Non-malignant portal vein thrombosis (PVT) is one of the complications of liver cirrhosis. The predisposing factors for PVT in cirrhotic patients are not entirely clear. The aim of this study was to identify possible clinical risk factors related to the development of PVT in patients with liver cirrhosis.
Method: We prospectively collected data of 229 consecutive cirrhotic patients followed in our Liver Unit in Verona, enrolled from 2017 to 2020 with an median follow-up of 3.3 years. PVT was determined by ultrasound, computer tomography and/or magnetic resonance imaging. Malignant PVT was considered an exclusion criteria.
Results: Of the 229 patients with liver cirrhosis 26 (11%) developed non-malignant PVT. 17 (65%) were male, with a mean age of 67.3 ± 12.3 y. In patients with non-neoplastic PVT compared to the remaining population, we observed that the prevalence of bacterial infections (sepsis, pneumonia, urinary tract infections, cholangitis, gastroenteritis, bacteriaemia, spontaneous bacterial peritonitis) that required hospitalization was significantly higher (50% vs 27.2%; p = 0.017). In the multivariate logistic regression analysis, when adjusted for age, sex, type 2 diabetes mellitus and chronic kidney disease, PVT was significantly and independently associated with bacterial infections (OR 2.72 [95% CI 1, 12 to 6.57; p = 0.026]) and hepatocellular carcinoma (HCC) (OR 2.87 [95% CI 1.11 to 7.41; p = 0.029].
Conclusion: Our study showed that bacterial infections requiring hospitalization in patients with liver cirrhosis could be a predisposing factor for the development of PVT. Further studies will be needed to confirm this evidence.

SAT520

Impact of the COVID-19 pandemic on the incidence and type of infections in hospitalized patients with cirrhosis

Berta Cuyas[1], Anna Huerta[1], Maria Poca[1,2], Edilmar Alvarado-Tapias[1,2], Anna Brujats[1], Eva Roman[1,2,3], Carlos Guarner[1,2], Àngels Escorsell[1,2], German Soriano[1,2]. [1]*Hospital de la Santa Creu i Sant Pau, UAB, Gastroenterology, Barcelona, Spain;* [2]*Centro de Investigación Biomédica en Red de Enfermedades Hepáticas y Digestivas (CIBEREHD), Spain;* [3]*School of Nursing EUI-Sant Pau, Spain*
Email: gsoriano@santpau.cat

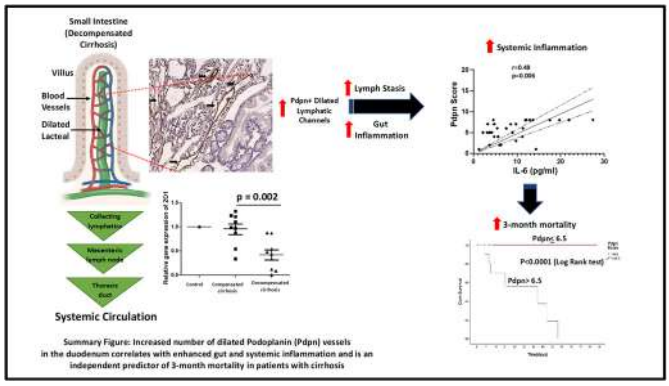
Background and aims: Infections are a major cause of morbidity and mortality in patients with cirrhosis, especially those caused by multiresistant bacteria. Restrictive measures implemented due to the COVID-19 pandemic have changed hospital protocols: social distancing, hand washing, personal protective equipments. This situation may have changed the incidence and types of infections in patients with cirrhosis during the pandemic. We aimed to compare the infections in patients with cirrhosis hospitalized before the COVID-19 pandemic versus those hospitalized during the pandemic.
Method: We retrospectively analysed the infections in patients with cirrhosis hospitalized in the Gastroenterology department at a high complexity hospital, during the pre-pandemic period (3/2019–2/2020) and during the pandemic (3/2020–2/2021). Baseline characteristics, type of infections, type of bacteria, multiresistance and mortality were evaluated.
Results: A total of 421 episodes of hospitalization were analysed: 252 pre-pandemic and 169 during the pandemic (mean number of hospitalizations/month 21.0 ± 5.2 vs 14.1 ± 3.8, p = 0.001). Patients' baseline MELD was lower in the pre-pandemic group (9 ± 3.7 vs 12 ± 5, p < 0.001). A total of 223 infections were detected in 42% of hospitalizations (40.9% vs 43.8%, p = 0.55), and the percentage of nosocomial infections was 43.4% vs 42.6% (p = 0.89). Spontaneous bacterial peritonitis and respiratory infections were less frequent during the pandemic (24.8% of total infections in the pre-pandemic period vs 13.8% during the pandemic, and 22.5% vs 17%, respectively) and urinary tract infections were more frequent (22.5% vs 33%) (pNS). Culture positivity rate was similar (55% vs 60.6%, p = 0.40), and gram-negative bacteria were the most frequent bacteria isolated in both groups. We found a non-significant trend to a lower rate of multiresistant bacteria in the pandemic group (25.4% vs 19.3%, p = 0.41). ACLF incidence was 18.4% vs 12.9% (p = 0.27), and 30-day mortality was 14% vs 11.7% (p = 0.62).
Conclusion: There were less hospitalizations of patients with cirrhosis in the Gastroenterology department during the COVID-19 pandemic but they had worse baseline liver function. The incidence of infections and the rate of nosocomial infections were similar despite the restrictive measures. A non-significant trend to a lower rate of multiresistant bacteria and spontaneous bacterial peritonitis, and higher percentage of urinary infections were observed during the pandemic.

SAT521

Increased expression of podoplanin, a marker of dilated lymphatic vessels in duodenal biopsies is an independent predictor of three-month mortality in patients with cirrhosis

Savneet Kaur[1], Pinky Juneja[1], S Muralikrishna Shasthry[2], Guresh Kumar[2], Dinesh Mani Tripathi[1], Vijayraghavan Rajan[2], Archana Rastogi[2], Shiv Kumar Sarin[3]. [1]*Institute of Liver and Biliary Sciences, Molecular and Cellular Medicine, New Delhi, India;* [2]*Institute of Liver and Biliary Sciences, New Delhi, India;* [3]*Institute of Liver and Biliary Sciences, Department of Hepatology, New Delhi, India*
Email: shivsarin@gmail.com

Background and aims: The intestinal lymphatic capillaries (lacteals) and the mesenteric collecting vessels regulate gut immunity and fluid homeostasis. In cirrhosis, a dysfunction of the gut lymphatic vessels has been reported. We studied markers of lymphatic vessels in duodenal biopsies and investigated the performance of a highly expressed marker of lymphatic endothelial cells, podoplanin (pdpn), as a predictor of clinical outcomes in cirrhosis.
Method: A prospective, observational, single-centre cohort study was performed in consenting patients with cirrhosis of varying aetiology (n = 31) and matched healthy controls (n = 10). All subjects underwent an upper gastrointestinal tract endoscopy, during which duodenal biopsies were obtained. Gene expression of lymphatic channel markers, such as vascular endothelial growth factor3 (vegfr3), pdpn and lymphatic vessel endothelial hyaluronan receptor 1 (lyve1) were studied in biopsies. Pdpn protein scores were calculated by the number and intensity of pdpn stained lymphatic channels/high power field. Gut inflammation was scored by counting the number of CD3-positive intraepithelial lymphocytes (IELs) in the biopsies and serum levels of TNF-alpha and IL-6 were studied by ELISA.
Results: Gene expression of lymphatic channel markers, vegfr3 and pdpn were enhanced in duodenal biopsies of cirrhosis patients compared to controls. Mean pdpn scores in patients with decompensated cirrhosis (6.91 ± 1.26) were significantly higher than compensated cirrhosis (3.25 ± 1.60, P < 0.0001). Control biopsies showed a weak and minimal pdpn positivity. Pdpn scores were significantly correlated with serum albumin (r = – 0.62, p < 0.0001), bilirubin (r = 0.69, p < 0001) and creatinine (r = 0.48, P = 0.005). In Cox regression analysis, pdpn score emerged as a significant and independent 3-month mortality predictor (HR: 5.61; 1.08–29.109; p = 0.04). Area under the curve for pdpn was 84.2 (70.6–97.8) and the cut-off value of pdpn score for predicting significant mortality was above 6.5 with a sensitivity of 100% and specificity of 75%. Although the number of IELs and TNF-alpha levels were not significantly different in patients with compensated and decompensated cirrhosis; IELs, serum TNF-alpha and IL-6 levels positively correlated with pdpn scores (p < 0.05 each). Pdpn score was also inversely associated with expression of gut permeability marker, zona occludin-1 (r = –0.46, p = 0.05).



Conclusion: An increased number of dilated lymphatic vessels characterized by high pdpn expression, in the duodenal biopsies are a characteristic feature of patients with decompensated cirrhosis and serve as an independent predictor of 3-month mortality. An increased gut permeability and inflammation in cirrhotic patients with dilated duodenal lymphatic channels might be contributing to enhanced systemic inflammatory responses and mortality.

SAT522

Blood metabolomics unveils mitochondrial dysfunction as a potential key feature in the pathogenesis of hepatorenal syndrome

Ann T Ma[1,2,3], Adria Juanola[1,2], Martina Perez-Guasch[1,2,3,4], Marta Carol[1,2,3,4], Jordi Gratacós-Gines[1,2,3], Laura Napoleone[1,2,3], Ana Belén Rubio[2,3], Emma Avitabile[1,2,3], Anna Soria[1,2,3], Marta Cervera[2,3], Octavi Bassegoda[1,2,3], Carlota Riba[2,3], Núria Fabrellas[2,3,4], Isabel Graupera[2,3], Juanjo Lozano[3], Elisa Pose[1,2,3], Manuel Morales-Ruiz[2,3,4,5], Elsa Solà[1,2,3], Pere Ginès[1,2,3,4]. [1]*Liver Unit, Hospital Clínic de Barcelona, Barcelona, Spain;* [2]*Institut d'Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS), Barcelona, Spain;* [3]*Centro de Investigavción Biomédica en Red de Enfermedades Hepática y Digestivas, Madrid, Spain;* [4]*Facultat de Medicina-Universitat de Barcelona, Barcelona, Spain;* [5]*Servei de Bioquímica i Genètica Molecular, Hospital Clínic de Barcelona, Barcelona, Spain*
Email: pgines@clinic.cat

Background and aims: Important hemodynamic changes occur in hepatorenal syndrome (HRS), including splanchnic vasodilation, decreased cardiac output, and resulting decreased renal perfusion. However, the exact metabolic pathways involved in HRS are unknown. Recently, studies using blood metabolomics have found distinct metabolic alterations in cirrhosis, but no specific studies on HRS have been reported. The aim of this study was to use blood metabolomics to unveil metabolic pathways involved in HRS, as well as identify potential biomarkers for diagnosis of HRS and prediction of treatment response.
Method: Untargeted metabolomics by liquid chromatography coupled to high-resolution mass spectrometry was performed in serum samples of patients with cirrhosis in different disease phases: severe HRS, meeting the definition of type 1 HRS (n = 28), acute tubular necrosis (ATN, n = 16) and acute decompensation of cirrhosis without acute kidney injury (AKI) (AD, n = 16). Of the patients with HRS, blood samples were collected prior to treatment with terlipressin and albumin, and 7–14 days post-treatment (available for 22/28; 17 treatment responders).
Results: Patients were predominantly male (90%), with a median age of 61. Principal component analysis revealed clear differences between AD and the other states (Figure). HRS was characterized by a significant upregulation of pentose and glucuronate interconversions pathways and by an accumulation of fatty acylcarnitines, both of which then decreased towards levels in AD after response to treatment. These findings are consistent with previous data in ACLF, and suggest the presence of mitochondrial dysfunction in HRS. Next, a regression analysis revealed that the combination of 3 metabolites could accurately differentiate HRS from ATN (AUROC of 0.94 (0.88–1.00)). Finally, we found that the combination of 2 metabolites predicted treatment response in HRS (AUROC 0.96 [0.89–1.00]).

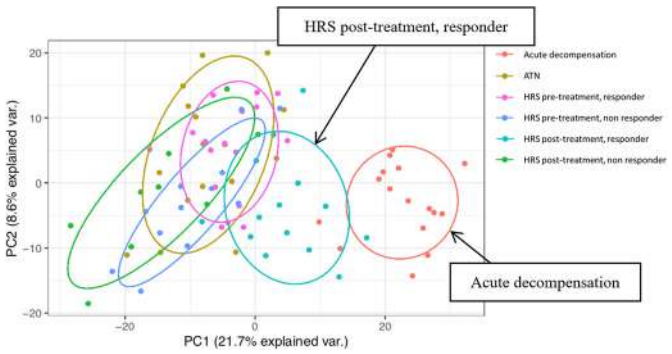


Figure: Principal component analysis of all disease states

Conclusion: The results of this first untargeted blood metabolomics study that specifically investigated the changes in metabolic pathways involved in HRS suggests the presence of mitochondrial dysfunction, which improves following treatment response with terlipressin and albumin. Furthermore, findings may help to uncover novel biomarkers that could be useful in differentiating HRS from ATN, as well as in predicting treatment response.

SAT523

Hyperammonaemia is an independent biomarker of liver-related complications and mortality in clinically stable outpatients with cirrhosis

Tom H Tranah[1], María Pilar Ballester[2], Juan Antonio Carbonell-Asins[3], Annarein Kerbert[4], Gonçalo Alexandrino[5], Maria Capilla[2], Andra Caracostea[1], Desamparados Escudero-García[2], Karen Louise Thomsen[6], Miguel Serra[2], Debbie L. Shawcross[1], Rajiv Jalan[4]. *[1]Institute of Liver Studies, Dept of Inflammation Biology, School of Immunology and Microbial Sciences, Faculty of Life Sciences and Medicine, King's College London, London, United Kingdom; [2]Hospital Clínico Universitario de Valencia, Digestive Disease Department, Valencia, Spain; [3]INCLIVA Biomedical Research Institute, Valencia, Spain; [4]Institute for Liver and Disease Health, University College London, Royal Free Campus, Liver Failure Group, London, United Kingdom; [5]Hospital Prof. Doutor Fernando Fonseca, Amadora, Gastroenterology and Hepatology Department, Portugal; [6]Aarhus University Hospital, Department of Hepatology and Gastroenterology, Denmark*
Email: mapibafe@gmail.com

Background and aims: Ammonia is important in the pathogenesis of hepatic encephalopathy (HE). Ammonia has also been implicated in the pathogenesis of liver-related complications such as liver cell death, sarcopenia, immune dysfunction and portal hypertension. We therefore, hypothesized that hyperammonaemia is a risk factor for the development of not only HE but also other liver-related complications and consequent mortality in clinically-stable outpatients with cirrhosis. We aimed to determine the role of ammonia in the risk of liver-related complications and/or mortality and derive a threshold value of ammonia that defines the risk. We also developed a prognostic model defining outcomes.
Method: A prospective observational cohort study of clinically stable cirrhotic outpatients followed-up in three tertiary hospitals was performed. Main outcomes were occurrence of liver-related complications and mortality. As normal ammonia varied across centres, it was normalized according to the upper limit of normality (A_ULN). Multivariable frailty competing risk modelling was performed with either liver-related complications or mortality as events of interest with liver transplantation as a competing risk. AUROC was calculated to compare prediction performance between A-ULN and severity scores at 1-year. Cut-off for A_ULN was calculated using maximally selected rank statistics. Fast unified random forests for survival with 500 trees using log-rank as splitting criteria was used to predict complications and mortality.
Results: 754 patients were included (66% males; mean 56 years) with median follow-up of 223 days (range: 2–2453). A total of 260 (35%) patients developed liver-related complications, infection being the most prevalent (16%). A_ULN was an independent predictor of both complications (HR = 2.27; 95CI = 1.97–2.61; $p < 0.001$) and mortality (HR = 1.59; 95CI = 1.33–1.89; $p < 0.001$). AUROC of A_ULN was 77.9% for 1-year complications; higher than traditional severity scores. Statistical differences in survival were found between high and low levels of A_ULN both for complications and mortality ($p < 0.001$) using 1.4 as cut-off from the training set. A_ULN remained the most important variable for the prediction of complications (Figure 1).

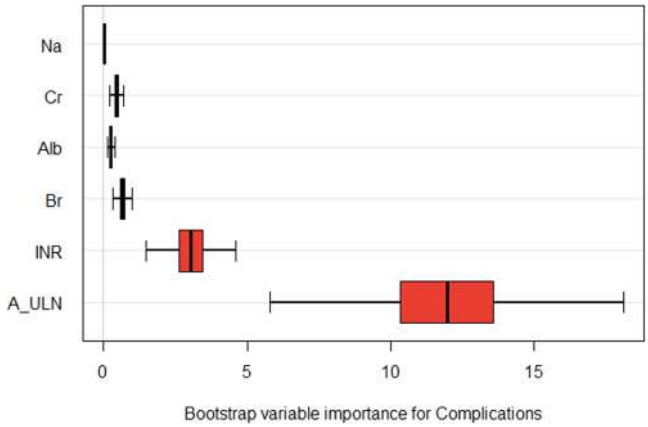

Figure 1: Abbreviations: sodium (NA), creatinine (Cr), albumin (Alb), bilirubin (Br), INR (International Normalized Ratio), ammonia upper limit of normal (A_ULN).

Conclusion: Ammonia is an independent predictor of liver-related complications and mortality in clinically stable outpatients with cirrhosis and performs better than traditional severity scores in predicting complications.

SAT524

Prospective evaluation of the EASL clinical guidelines algorithm of management of acute kidney injury in cirrhosis

Ann T Ma[1,2,3], Cristina Solé[1,2,3], Laia Escude[1], Adria Juanola[1,2,3], Laura Napoleone[1,2,3], Emma Avitabile[1,2,3], Martina Perez[1,2,3,4], Marta Carol[1,2,3,4], Ana Belén Rubio[1,2,3], Marta Cervera[2,3], Octavi Bassegoda[1,2,2,3], Jordi Gratacós-Gines[1,2,3], Anna Soria[1,2,3], Núria Fabrellas[2,3,4], Isabel Graupera[1,2,3], Elisa Pose[1,2,3], Manuel Morales-Ruiz[2,3,4,5], Esteban Poch[2,4,6], Elsa Solà[1,2,3], Pere Ginès[1,2,3,4]. *[1]Liver Unit, Hospital Clínic de Barcelona, Barcelona, Spain; [2]Institut d'Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS), Barcelona, Spain; [3]Centro de Investigavción Biomédica en Red de Enfermedades Hepática y Digestivas (CIBEREHD), Madrid, Spain; [4]Facultat de Medicina-Universitat de Barcelona, Barcelona, Spain; [5]Biochemistry and Molecular Genetics Department, Hospital Clínic de Barcelona, Barcelona, Spain; [6]Nephrology and Kidney Transplantation Department, Hospital Clínic de Barcelona, Barcelona, Spain*
Email: pgines@clinic.cat

Background and aims: The EASL guidelines propose an algorithm for managing acute kidney injury (AKI) in cirrhosis. The effectiveness in clinical practice of this algorithm, based on expert opinion, has not been assessed. This study aimed to characterize the clinical outcomes of patients with AKI managed according to this algorithm.
Method: Single center prospective cohort study including consecutive patients admitted for acute decompensation of cirrhosis and AKI from 2019 to 2021. The management of patients followed the recommended EASL AKI algorithm, which includes categorization of patients according to AKI stage (1A or >1A) and albumin administration in the first 48 h for those with a stage>1A. Three crucial groups of patients were identified: 1/AKI 1A responders; 2/AKI>1A responders after albumin therapy; and 3/AKI>1A non-

responders after albumin therapy meeting AKI-HRS criteria. Response rates, defined as resolution of AKI in group 1, resolution or improvement to stage 1A in group 2, and resolution or improvement to a lower AKI stage in group 3, were calculated for each group. Three-month overall survival was also analyzed.

Results: A total of 203 AKI episodes in 138 patients were evaluated (median age 62, 76% male, 67% alcohol-related liver disease, Child-Pugh C 52%). Most patients with AKI-1A had resolution or persistent AKI-1A by day 3 (43% and 26% respectively), while only 31% progressed (Figure). Out of the 173 episodes with AKI>1A, 61 (35%) had resolution or improvement with albumin by day 3. Remarkably, most patients with persistent AKI>1A after albumin administration who met HRS-AKI criteria responded to vasoconstrictors (terlipressin) and albumin (73%). Three-month survival rate of patients in the 3 crucial groups were: 88%, 82%, and 50%, respectively. Non-responders to vasoconstrictor therapy had significantly lower 3-month survival compared to responders (17% vs 65% respectively).

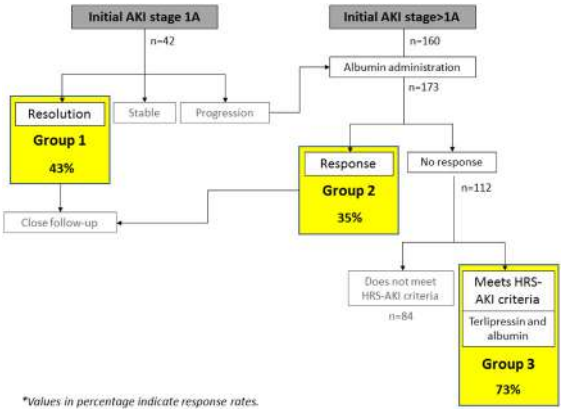

Figure: Flowchart of patients according to the EASL AKI management algorithm*

Conclusion: This study provides real-world data on application of the EASL AKI management algorithm, demonstrating high response rates in the three crucial groups of the algorithm. Specifically, the EASL-AKI algorithm rapidly and accurately identifies patients with AKI-HRS with high response rate to vasoconstrictors and albumin therapy. These findings support the use of this algorithm in clinical practice.

SAT525

MELD 3.0 accurately predicts short term survival of patients with end-stage liver disease

Anna Vidovszky[1], W. Ray Kim[1], Allison Kwong[1], Ajitha Mannalithara[1].
[1]*Stanford University, Division of Digestive Health, Redwood City, United States*
Email: wrkim@stanford.edu

Background and aims: MELD 3.0 is the latest version of the Model for End-stage Liver Disease (MELD) which includes sex and albumin as new variables and updates all of its coefficients. We evaluated calibration of survival prediction of MELD 3.0.

Method: MELD 3.0 was developed based on data from liver transplant waitlist registrants in the US from Jan, 2016 and Dec, 2018. The entire cohort was randomly divided into model training and testing data sets. From the final Cox model for MELD 3.0 derived in the training set, we calculated survival function in mortality prediction. The model was then applied in the testing set to compare the predicted versus observed survival for the score quintiles.

Results: Out of the entire cohort (n = 29, 410), a random 30% (n = 8, 823) was set aside as the testing set. As reported previously, MELD 3.0 is calculated by the following formula: MELD 3.0 = 1.33 (if female) + 4.56 * $\log_e$ (bilirubin) + 0.82 * (137-Na)-0.24 * (137-Na) * $\log_e$ (bilirubin) + 9.09 * $\log_e$ (INR) + 11.14 * $\log_e$ (creatinine) + 1.85 * (3.5-albumin)-1.83 * (3.5-albumin) * $\log_e$ (creatinine) + 6 (online calculator available at medcalculators.stanford.edu/meld). Survival function for up to 90 days is shown below. The predicted and observed survival up to 30 days of the quintiles based on MELD 3.0 matched closely with no statistically significant difference between the two (GND test, p = 0.11), whereas the comparison based on MELD-Na was significantly different (p = 0.01). Calibration was less robust for 90-day predictions with both scores, with majority of the discrepancy being survival between 30 and 90 days for the highest risk patients (p < 0.01 for both MELD 3.0 and MELD-Na).

t (days)	15	30	45	60	75	90
So (t)	0.991	0.981	0.971	0.963	0.955	0.946

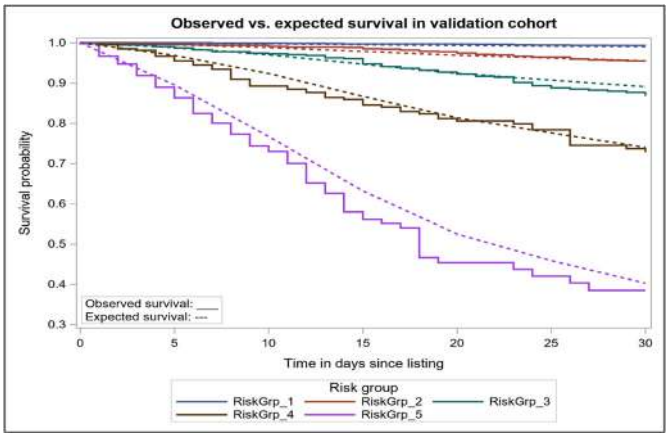

Figure: Survival function for MELD 3.0

Conclusion: While MELD 3.0 is being considered to replace MELD-Na for organ allocation priorities in the US, it provides better calibration of short-term survival than MELD-Na as well, which would be useful for patient management plan and counseling.

SAT526

CyberLiver Animal Recognition Test (CL-ART): a novel remote monitoring tool to assess minimal hepatic encephalopathy

Kohilan Gananandan[1], María Pilar Ballester[2], Ahmed El Shabrawi[1,3], Konstantin Kazankov[4], Rajiv Jalan[1], Ravan Boddu[5], Ravi Kumar[5], Maruthi Raja[5], Anu Balaji[5], Karen Louise Thomsen[4], Raj Mookerjee[1].
[1]*The Liver Failure Group, UCL Institute for Liver and Digestive Health, United Kingdom;* [2]*Hospital Clínic Universitari, Digestive Disease Department, València, Spain;* [3]*Endemic Hepatology and Gastroenterology, Egypt;* [4]*Aarhus University Hospital, Department of Hepatology and Gastroenterology, Aarhus, Denmark;* [5]*CyberLiver Limited, United Kingdom*
Email: mapibafe@gmail.com

Background and aims: The CyberLiver Animal Recognition Test (CL-ART) is a novel smartphone application (app) that was developed as part of a program for remote monitoring of cirrhosis, and specifically, to diagnose non-overt hepatic encephalopathy and to guide need for intervention. The aim of this study was to compare CL-ART with established tests for minimal hepatic encephalopathy (MHE), as well as to assess its diagnostic performance, and establish an optimal cut-off for MHE.

Method: A prospective study of cirrhosis patients and healthy controls, applying clinical assessment and three different cognitive tests at a tertiary hepatology centre. The CL-ART test involved a timed recognition and appropriate naming of animals using a smartphone app; with time to perform test and failed attempts logged. EncephalApp Stroop Test and Psychometric Hepatic Encephalopathy Score (PHES) (used as the reference to diagnose MHE) were chosen as test comparisons. Pearson rank correlation and

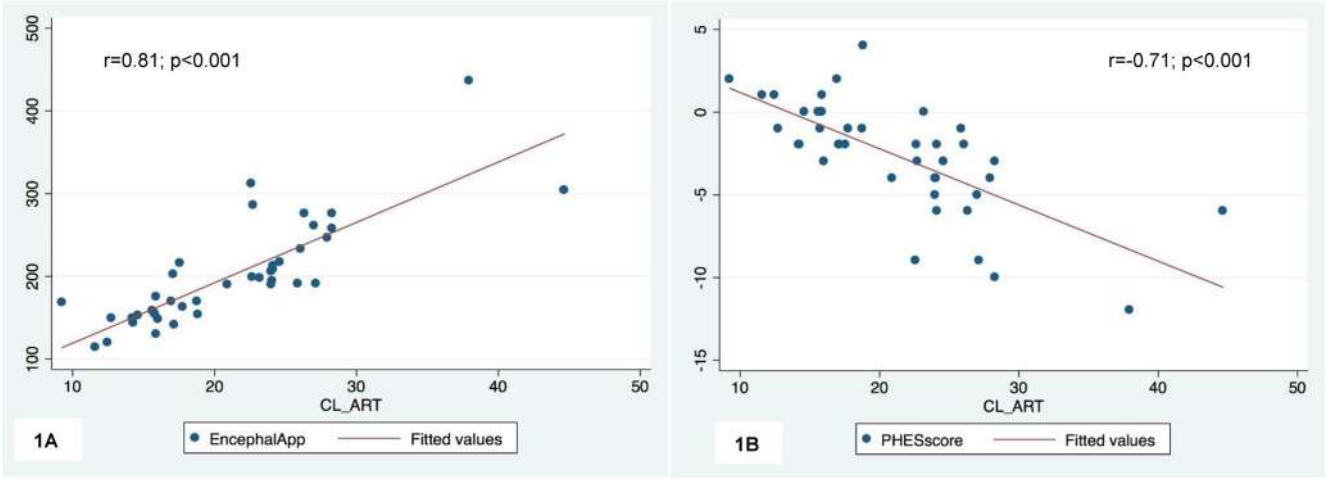

Figure: (abstract: SAT526): Graphs showing correlation between CL-ART with EncephalApp (1A) and PHES (1B)

area under the receiver operator curves (AUROC) were calculated. Youden Index was used to determine a cut-off to diagnose MHE.
Results: 30 cirrhosis patients, deemed at risk of decompensation (67% male; median 56 years, Child-Pugh Score 8[IQR 7–9], MELDNa 15 ± 5.4), and 11 controls with no evidence of liver disease (55% male; median 58 years), were included. Compared to controls, cirrhosis patients performed significantly worse in CL-ART (23 ± 7 vs. 15 ± 4 s; p < 0.001), EncephalApp (204 [IQR 173–259] vs 154 [IQR 149–169]; p < 0.001) and PHES (-3 [IQR – 5 to – 2] vs 0 [IQR 0–2]; p < 0.001). CL-ART showed a good correlation with both EncephalApp (r = 0.81; p < 0.001; Figure 1A) and PHES tests (r = – 0.71; p < 0.001; Figure 1B). According to PHES, a total of 9 patients (30%) had MHE. Mean CL-ART was significantly worse in patients with MHE (29 ± 7 vs 21 ± 5 s; p < 0.001). AUROC to diagnose MHE was 0.85 (95% CI = 0.70–0.99) and 0.83 (95% CI = 0.65–1.00) for CL-ART and EncephalApp, respectively. A cut-off of >23 seconds in CL-ART showed a sensitivity of 89% and specificity of 62%, to diagnose MHE.
Conclusion: CL-ART is a novel smartphone app, with good patient usability, that is comparable to other established tests and has a good diagnostic performance in MHE. In addition, its rapid testing (usually <30 s) and smartphone application, make for a potential tool for remote monitoring of cirrhosis.

SAT527

Acute kidney injury during hospitalization in patients with liver cirrhosis is associated with increased mortality and chronic kidney disease on follow-up

Anna Cederborg[1,2], Björn Lindkvist[1,2], Evangelos Kalaitzakis[3], Einar S. Björnsson[4,5], Hanns-Ulrich Marschall[1,2]. [1]*Institute of Medicine, Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden;* [2]*Department of Medicine, Sahlgrenska University Hospital, Gothenburg, Sweden;* [3]*University of Crete, Department of Gastroenterology, University Hospital of Heraklion, Heraklion, Greece;* [4]*Department of Internal Medicine, Landspitali University Hospital, Reykjavik, Iceland;* [5]*Faculty of Medicine, University of Iceland, Reykjavik, Iceland*
Email: anna.cederborg@vgregion.se

Background and aims: Acute kidney failure (AKI) in patients with advanced liver cirrhosis is associated with a poor prognosis. The aim of the study was to evaluate the impact of AKI, AKI progression, infections and acute on chronic liver failure (ACLF) grade 1 and 2 on the development of chronic kidney disease (CKD) and survival.
Method: A total of 313 patients admitted for complications of cirrhosis during a 6-year period were retrospectively evaluated. ACLF grade 1 and 2 was defined according to the European Foundation for the Study of Chronic Liver Failure Consortium (CLIF-C) ACLF score, AKI according to International Club of Ascites criteria (ICA-AKI), infections as positive cultures or radiological findings, and CKD according to an estimated glomerular filtration rate (eGFR) <60 ml/min/1.73 m^2.
Results: AKI was present at admission in 27% of patients of whom 72% progressed in AKI stage during hospitalization, with a 3-month survival of 39% versus 78% (p < 0.001) in the patients without AKI. ACLF grade 1 or 2 was present in 24% of patients with a 3-month survival of 31% versus 78% among patients without ACLF (p < 0.001). Infections developed in 30% of patients during admission. Patients with prior decompensation (45%) had a lower 3-month survival if infected (50%) than compensated patients with infection (73%) and decompensated patients without infection (69%) (p < 0.001). Progression of AKI during admission was associated with a hazard ratio for mortality of 2.3 (1.6–3.2), even when adjusting for the presence of ACLF grad 1 or 2 and presence of infection, with a 3-month survival of 32%. Most patients with AKI who survived the first hospitalization presented with CKD at the following admission (82%) with a median follow-up of 2.2 (range 0.3–55.8) months.
Conclusion: Chronic kidney disease was common in patients with liver cirrhosis who survived AKI during the first hospitalization. Even though the presence of infection and ACLF grade 1 or 2 during admission were associated with a worse prognosis, the progression of AKI additionally increased the risk of mortality in patients with liver cirrhosis.

Ascites bacterial DNA and IL-6 are promising tools in the diagnosis of spontaneous bacterial peritonitis

Arno Hagenunger[1], Niklas F Aehling[1], Adam Herber[1], Rhea Veelken[1], Sandra Krohn[1], Katharina Zeller[1], Kathrin Jaeger[2], Daniel Seehofer[3], Sebastian Rademacher[3], Robert Sucher[3], Cornelius Engelmann[1,4], Thomas Berg[1]. [1]*Leipzig University Medical Center, Division of Hepatology Department of Medicine II, Leipzig, Germany;* [2]*Leipzig University Medical Center, IZKF FACS Core Unit, Leipzig, Germany;* [3]*Department of Visceral, Vascular, Thoracic and Transplant Surgery, Leipzig, Germany;* [4]*Campus Virchow-Klinikum, Charité-Universitaetsmedizin Berlin, Department of Hepatology and Gastroenterology, Berlin, Germany*
Email: niklas.aehling@medizin.uni-leipzig.de

Background and aims: Spontaneous bacterial peritonitis (SBP) is a common complication in patients with decompensated cirrhosis or acute on chronic liver failure. Diagnosis is based on an ascitic neutrophil count (PMN) of ≥250/µl. Its sensitivity is limited. We investigated, whether determination of bacterial DNA (bactDNA) or

cytokine levels in ascites could help optimize the diagnostic approach.
Method: Ascites and serum of 98 patients with cirrhosis (42 with SBP and 56 without) as well as serum of 21 control patients without liver disease were collected and analyzed. The majority of patients were male (SBP: n = 29 (69%), Non-SBP: n = 41 (73.2%); controls n = 12 (57.1%)). The main cause of cirrhosis was alcoholic liver disease (SBP: n = 30 (71.4%), Non-SBP: n = 42 (75%)) The mean MELD of patients with SBP was 19.5 (6–40) and 18 (8–38) in patients without SBP. BactDNA was detected using a quantitative 16S rRNA PCR (Molzym, Bremen, Germany). Every detection of bactDNA was seen as positive without any threshold. In addition, the concentrations of IL-1beta, TNF-α, IL-6, IL-8 and IL-10 were determined in serum and ascitic fluid using a LEGENDplex™ (BioLegend, Koblenz, Germany) multi-analyte flow assay. Bacterial DNA and cytokine levels were correlated with clinical outcomes.
Results: BactDNA could be detected in ascites of 24/42 (57.1%) of SBP patients as compared to 5/56 (8.9%) in the non-SBP group (p < 0.001). Ascitic fluid culture was positive in 17/42 patients in the SBP group, of which all were positive for bactDNA, and 0/56 patients in the non-SBP group (p < 0.001). Serum bactDNA was positive in four patients only, all belonged to the SBP group (p = 0.031). The 30-day survival of patients with positive bactDNA in the non-SBP group was 60% as compared to 90.2% in the bactDNA negative ones (p = 0.042).
Figure 1 shows different ascites cytokine concentrations between groups. Serum IL-6 levels were significantly higher in the SBP vs non-SBP group and controls (SBP: 733.4 pg/ml (83.4–17550.8) vs 306.1pg/ml (59.8–3500.8); p = 0.036; vs. 35.97pg/ml (0.98–186.7); p = 0.005), respectively. Ascites IL-6 levels showed a similar correlation (SBP:35293.2pg/ml (1876.6–507929.7) vs non-SBP 9865.3pg/ml (1319.0–427434.4); p <0.001). Receiving operator curve analysis revealed an area under the curve of 0.810 (95%CI 0.714–0.905) for the diagnosis of SBP. BactDNA and ascitic IL-6 showed a positive correlation with r = 0.509 (p < 0.001)

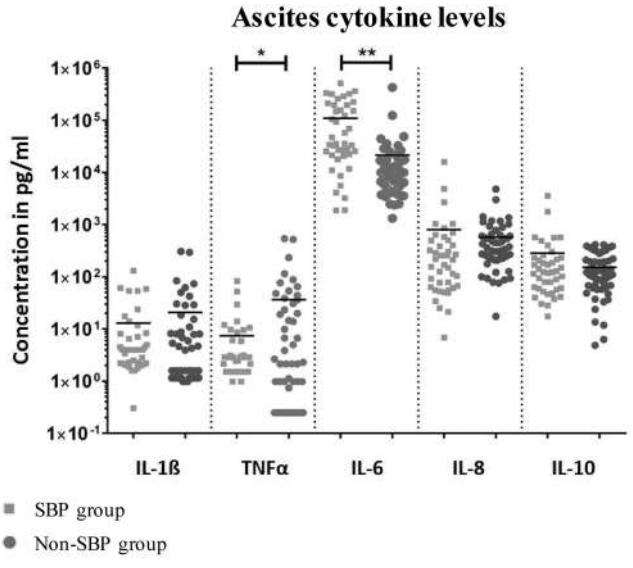

Figure 1: Scatterplots for cytokine concentrations in ascites of patients with cirrhosis with or without SBP. * p < 0.05; ** p < 0.001

Conclusion: Ascitic BactDNA and IL-6 might be a promising tool in the diagnosis of SBP, perhaps being more sensitive than PMNs. Further analysis in a larger cohort is necessary to prove this.

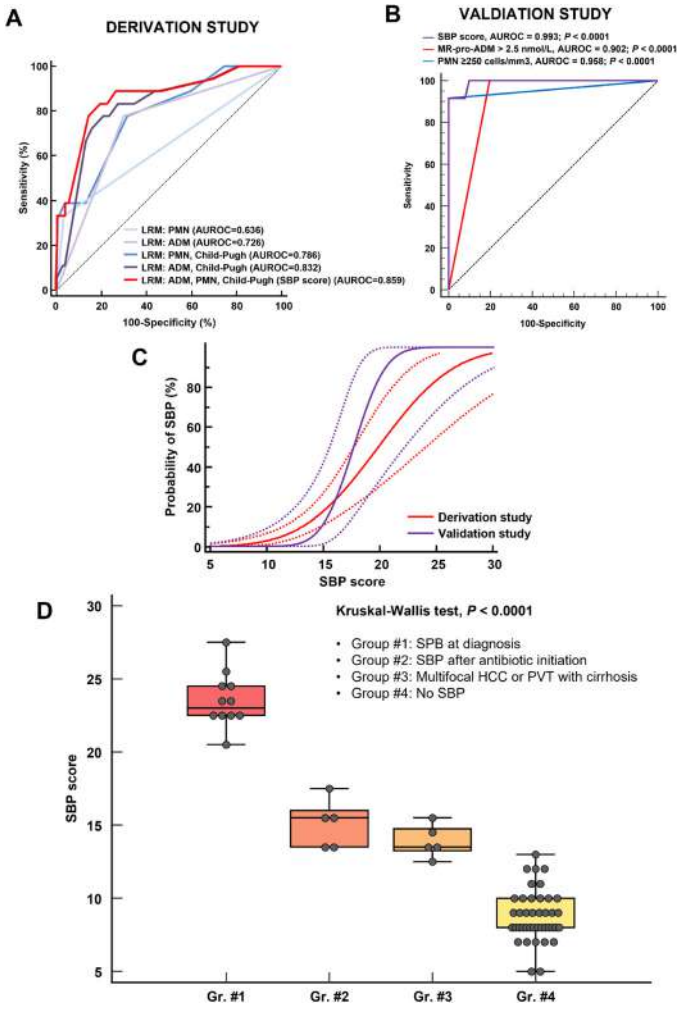
Ascitic fluid mid-regional-pro-adrenomedullin (MR-pro-ADM): a novel rapid-assay sepsis biomarker to diagnose spontaneous bacterial peritonitis in cirrhotic patients

Abderrahim Oussalah[1], Anne-Sophie Lagneaux[2], Tom Alix[1], Pierre Filhine-Tresarrieu[1], Jonas Callet[1], Janina Ferrand[2], Jean Jung[1], Julien Broseus[3], Sylvain Salignac[3], Amandine Luc[4], Cédric Baumann[4], Philipp Schuetz[5], Alain Lozniewski[2], Katell Peoch[6], Hervé Puy[7], Jean-Louis Guéant[1], Jean-Pierre Bronowicki[8]. *[1]Department of Molecular Medicine, Division of Biochemistry, Molecular Biology and Nutrition, University Hospital of Nancy, F-54000 Nancy, France; [2]Department of Bacteriology, University Hospital of Nancy, F-54000 Nancy, France; [3]Laboratory of Hematology, University Hospital of Nancy, F-54000 Nancy, France; [4]Methodology, Data Management and Statistics Unit, University Hospital of Nancy, F-54000 Nancy, France; [5]Medical University Clinic, Departments of Internal and Emergency Medicine and Department of Endocrinology, Diabetology and Clinical Nutrition, Kantonsspital Aarau, Switzerland; [6]Laboratory of Biochemistry, Beaujon Hospital, University of Paris, Clichy, France; [7]Centre de Recherche sur l'Inflammation, Université de Paris, INSERM, CNRS, 75018Paris, France, Laboratory of excellence GR-EX, Paris, France; [8]Department of Gastroenterology and Hepatology University Hospital of Nancy, F-54000 Nancy, France*
Email: abderrahim.oussalah@univ-lorraine.fr

Background and aims: Spontaneous bacterial peritonitis (SBP) is a frequent and severe complication of cirrhosis. We determined the diagnostic accuracy of two rapid-assay sepsis-related biomarkers in the ascitic fluid (mid-regional pro-adrenomedullin [MR-pro-ADM] and procalcitonin) to diagnose SBP among patients with cirrhosis.
Method: We performed a two-stage cross-sectional biomarker study. In the derivation study, we assessed the diagnostic accuracy of MR-pro-ADM and procalcitonin in ascitic fluids. The study end point was a diagnosis of SBP with a positive ascitic fluid bacterial culture. We derived the "SBP score" based on the more discriminant criteria from the logistic regression model. In the validation study, we assessed the diagnostic accuracy of the "SBP score" for diagnosing SBP. All SBP and bacteriological diagnoses were adjudicated by a senior gastroenterologist and a senior microbiologist. The "Nancy Biochemical Database" is registered under CNIL #1763197v0.
Results: The derivation study included 236 cases. MR-pro-ADM was significantly higher in ascitic fluids of patients with SBP when compared with those of patients without SBP (3.14 nmol/L [IQR, 2.39–6.74] vs. 1.91 nmol/L [IQR, 1.33–2.80]; p = 0.0002). In Bayesian ANOVA, MR-pro-ADM was highly discriminant for SBP diagnosis with a high likelihood ratio (Bayes factor [BF_M], 2505), while procalcitonin showed poor discrimination with a low likelihood ratio (BF_M, 0.45). In ROC analysis, ascitic MR-pro-ADM had an optimal cut-off of ≥2.50 nmol/L to diagnose SBP (AUROC, 0.746; 95% CI, 0.685–0.801; p <0.0001) (**A**). Multivariable logistic regression analysis identified three independent predictors of SBP that were integrated in the "SBP score": MR-pro-ADM ≥2.5 nmol/L (odds ratio [OR], 7.25; 95% CI, 2.04–25.79; p = 0.002), absolute polymorphonuclear leukocyte (PMN) count ≥250 cells/mm3 (OR, 14.38; 95% CI, 3.17–65.21; p = 0.0005), and Child-Pugh score (OR, 1.61; 1.15–2.26; p = 0.006). The "SBP score" had improved discrimination when compared to the logistic regression model which only included the absolute PMN count ≥250 cells/mm3 and the Child-Pugh score. In the validation study (n = 63), the "SBP score" had an AUROC of 0.993 (95% CI, 0.929–1.000; p <0.0001) for diagnosing SBP (**B, C**). The SBP score was significantly higher among patients with SBP (23; IQR, 22.5–24.5) when compared to those with SBP after antibiotic initiation (15.5; IQR, 13.5–16.0), multifocal hepatocellular carcinoma and/or portal vein thrombosis (13.5; IQR, 13.25–14.75), or those without SBP (8 [IQR, 8–10]) (p <0.0001) (**D**).



Conclusion: We derived and validated the "SBP score" based on a rapid-assay sepsis-related biomarker (MR-pro-ADM) that significantly improved the diagnostic accuracy of SBP in cirrhotic patients. The usefulness of the "SBP score" deserves formal validation in large prospective studies.

SAT530

Non-invasive prediction of risk of liver-related events in non-alcoholic fatty liver disease patients

Monica Pons[1], Jesús Rivera[1], Grace Lai-Hung Wong[2], Terry Cheuk-Fung Yip[2], Adele Delamarre[3], Tracy Davyduke[4], M Mang[4], Salvador Augustin[1], Juan Manuel Pericàs[1,5], Victor de Lédinghen[3], Vincent Wai-Sun Wong[2], Juan G Abraldes[4], Joan Genesca[1,5]. *[1]Hospital Universitari Vall d'Hebron, Vall d'Hebron Institut de Recerca (VHIR), Vall d'Hebron Barcelona Hospital Campus, Universitat Autònoma de Barcelona, Liver Unit. Email: monica_xina@hotmail.com

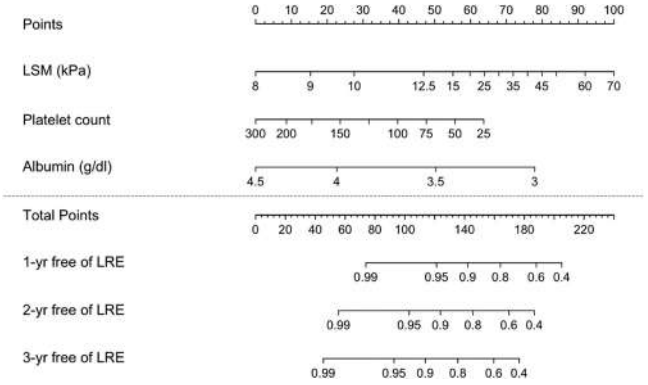
Background and aims: Simple non-invasive tools for predicting liver-related events (LRE) in non-alcoholic fatty liver disease (NAFLD) are needed for prognostic stratification and clinical trial patient selection. We aimed at developing a risk prediction model based on non-invasive tests (NITs), including liver stiffness measurement (LSM), to determine the risk of developing LRE in NAFLD patients at point-of-care. In addition, we studied LRE incidence in compensated advanced chronic liver disease (cACLD) LSM thresholds.

Method: This is a multicenter retrospective cohort study with NAFLD patients from 4 centers in Canada (n = 72), Hong Kong (n = 1537), France (n = 681) and Spain (n = 348). Patients included had available NITs (LSM by transient elastography and serological tests), had no prior decompensation and a minimum follow-up of 12 months. Patients with concomitant etiologies were excluded. LRE were defined as hepatocellular carcinoma, clinical decompensation, liver transplantation or liver-related death. Risk of LRE was modeled with a Cox regression model using well stablished predictors and selected by backwards elimination method combined with bootstrapping. The relationship between hazard ratio and NITs was assessed using a cubic spline function. A nomogram was derived from the model.

Results: 2638 patients were included (53% male, mean age 58.4 years (SD 12.4), mean BMI 30.0 kg/m2 (SD 5.7), and 60.8% with diabetes mellitus). Among them, 1820 (69%) had LSM <10 kPa, 479 (18%) LSM between 10–15 kPa and 339 (13%) LSM >15 kPa. Forty-five (1.7%) patients developed LRE during a median follow-up of 27 months (IQR 22–35 months). The incidence rate of LRE in patients with LSM <10 kPa was 0.04/100 patient-years, in LSM 10–15 kPa was 0.3/100 patient-years, in LSM 15–25 kPa was 2.1/100 patient-years and in LSM ≥25 kPa was 8.0/100 patient-years. Predictors evaluated in multivariate analysis were diabetes, BMI, platelet count, albumin and LSM. Only platelet count, albumin and LSM were retained in the final model. The performance for predicting LRE based on the area under the receiver operating curve (discrimination) was 0.92, also the calibration of the model was excellent. A nomogram was constructed to assess the individual risk of presenting events at 1, 2 and 3 years of follow-up (figure). The model is currently being validated in 3 external cohorts.



Conclusion: NAFLD patients with LSM <10 kPa (no-cACLD) have a very low incidence of LRE and could be followed in primary care, and the risk increases significantly in patients with LSM >15 kPa. This simple easy-to-use prediction tool for LRE could be very useful for prognostic stratification and selecting NAFLD patients for clinical studies.

SAT531

In-hospital falls and impaired nutritional status are independently associated with in-hospital mortality in patients with liver cirrhosis

Nada Abedin[1], Moritz Hein[1], Christoph Welsch[1], Jörg Bojunga[1], Stefan Zeuzem[1], Georg Dultz[1]. [1]*Department of Internal Medicine I, University Hospital Frankfurt, Goethe University, Frankfurt am Main, Germany*
Email: nada.abedin@kgu.de

Background and aims: Chronic liver disease is associated with severe complications leading to recurrent hospitalization and a high mortality in general. Complications associated with liver cirrhosis are one of the most frequent causes of death in hospitalized patients. This study aimed at detecting risk factors that can be addressed to increase patient safety and outcome.
Method: Hospitalized patients with liver cirrhosis between 2017 and 2019 in the department for gastroenterology at the University Hospital Frankfurt were included in a retrospective analysis. Clinical data, laboratory work and follow-up data from patients' electronic files were gathered and assessed. Statistical analysis was performed using SPSS.
Results: In a total of 1985 hospitalizations our study revealed an in-hospital mortality of 9.6%. Median age was 61 years and 70.5% were male patients. Overall, patients who died during their stay had a significantly longer period of hospitalization (19.1 days vs. 7.7 days, p <0.0001). 1016 cases were from patients with alcoholic liver disease, 15.2% were associated with Hepatitis C, 14.8% were patients with NASH. While there were significant clinical predictors (p <0.0001) for in-hospital mortality in the univariate analysis, such as lower blood pressure, an ongoing infection and different lab values (higher CRP, hyponatremia, leukocytosis, elevation in creatinine), in the uni- and multivariate analysis two factors were independently associated with in-hospital mortality. These include a nutritional risk score >1 (p = 0.006, OR 2.029, 95%CI) and a falling incident during hospitalization (p = 0.002, OR 3.495, 95%CI). As a general marker for severity of liver disease, the MELD Score was also independently associated with higher in-hospital mortality (p <0.001, OR 4.404, 95%CI).
Conclusion: Patients with liver cirrhosis are at high risk for developing severe complications that can be fatal. Our study reveals two independently associated factors with in-hospital mortality in patients with liver cirrhosis, i.e. nutritional risk and in-hospital falls that can and must be addressed and screened for on admission to alleviate patients' risk and allow for a better outcome.

SAT532

PD-1/PD-L1 pathway is related to infection development and early mortality in patients with cirrhosis

Adria Juanola[1,2,3], Elisa Pose[1,2,3], Delia Blaya[2], Cristina Solé[1], Gabriel Mezzano[1], Natalia Jimenez-Esquivel[1], Joaquin Andrés Castillo[1], Jordi Ribera[2,3,4], Irene Portoles[2,3,4], Martina Perez[1,2], Ann Ma[2,3], Laura Napoleone[1,2,3], Ana Belén Rubio[2,3], Marta Cervera[2,3], Marta Carol[2,3], Octavi Bassegoda[1,2,3], Jordi Gratacós-Gines[1,2,3], Anna Soria[1], Núria Fabrellas[2,3,5], Manuel Morales-Ruiz[2,3,4], Mar Coll[2,3], Isabel Graupera[1,2,3], Gonzalo Crespo[1,2,3], Elsa Solà[1,2,3,6], Pere Ginès[1,2,3,5]. Enfermedades Hepáticas y Digestivas (CIBEREHD), Madrid, Spain;* [4]*Biochemistry and Molecular Genetics Department, Hospital Clinic de Barcelona, Spain;* [5]*Faculty of Medicine and Health Sciences, University of Barcelona., Barcelona, Spain;* [6]*Institute for Immunity, Transplantation and Infection, Stanford University, Stanford, CA, USA*
Email: juanola@clinic.cat

Background and aims: Infections, often recurrent, are a very characteristic complication of advanced liver cirrhosis and represent a very common cause of hospitalization, acute kidney injury, ACLF and death. The high risk of infections in cirrhosis is associated, among others, with alterations of the intestinal microbiome as well as defective function in some immune cells. Recent studies in experimental animals suggest the existence of an activation of the PD1-PDL1 pathway (Programmed cell death 1) that would produce an immuneparalysis and predispose to infections. It is unknown whether this pathway participates in the pathogenesis of infections in human cirrhosis. The aim of the present study was to evaluate the activity of the PD-L1 pathway in patients with cirrhosis and its relationship with the development of infections and mortality.
Method: Prospective study of 310 patients with cirrhosis in different disease stages (13% outpatients, 87% hospitalized). PD-1/PD-L1 pathway activity was estimated by measuring serum levels of PD1 and PDL1 (ELISA), which assess the soluble isoform of PD1 (sPD1) and PDL1 (sPDL1) expressed in lymphocytes and monocytes. Main outcomes of the study were infections and ACLF development and death during a 3-month follow-up period.
Results: During follow-up, 99 patients (32%) developed at least one new episode of infection. Baseline serum levels of sPD1 and sPDL1 were higher in patients who developed a new infection compared to those patients who did not develop new infection [sPD1: 2.7 (2.3–3.3) vs 2.5 (2.1–3.0) pg/ml, p = 0.038; sPDL1: 160 (115–221) vs 129 (95–172) pg/ml, p = 0.002]. On multivariate analysis, sPDL1 together with liver function assessed by MELD Sodium, were the only two independent predictive factors of development of new infections during 3-month follow-up. One-hundred forty-eight patients had an active infection at inclusion. Patients with infection at baseline had higher levels of sPDL1 compared to those in patients who did not have infection [164 (115–224) vs 124 (94–161) pg/ml, respectively, p < 0.001]. During hospitalization, 30 patients (20%) with infection at baseline died. sPDL1, MELD Sodium and leukocyte count were independently associated with in-hospital mortality among this population. Finally, 16 patients without ACLF at inclusion, developed it during follow-up. sPDL1 was higher among those who developed ACLF [182 (106/242) vs 121 (93–166) pg/ml, p = 0.001], irrespective of the presence of infection. Furthermore, sPDL1 was the only independent predictor factor of ACLF at 3 months.
Conclusion: In patients with cirrhosis, serum levels of PDL1 correlate with the development of infections, ACLF and short-term mortality. These results suggest the existence of an activation of the PD1-PDL1 pathway in human cirrhosis that could be an important pathogenic factor for the development of infections and early mortality.

SAT533

Short term intravenous albumin effects in decompensated cirrhosis: about single hospitalization event

Han Seul ki[1], Moon Young Kim[1]. [1]*Yonsei University Wonju College of Medicine, Department of Internal Medicine, Division of Gastroenterology and Hepatology, Wonju-si, Korea, Rep. of South*
Email: drkimmy@yonsei.ac.kr

Background and aims: For intravenous administration of albumin, it is known that long-term administration has a positive effect on the survival rate of cirrhosis. We aimed to investigate the effects of short-term albumin administration on days of hospitalization and change of MELD score, creatinine level, complication during the hospitalization and short-term prognosis.
Method: We investigated patients who were admitted to a single-center hospital, due to acute decompensated events from January 2018 to December 2020. Causes of hospitalization include gastrointestinal bleeding, jaundice, hepatic encephalopathy, newly developed ascites requiring paracentesis and IV antibiotics administration, infection, hepatorenal syndrome, Acute on chronic liver failure. We excluded data about mortality during hospitalization due to aggressive management beyond the standard management.
After investigating the total albumin dose administered to patients during hospitalization, patients who received 40 g or more per week and those who did not were compared and analyzed. The patients

receiving 40 g of albumin or more was defined as the high dose albumin group.
Results: In entire cohort, administration of high dose albumin shortened the hospital stay (10.01 vs 12.76 days, p = 0.015). In subgroup analysis, it showed a better effect in CTP class C (10.18 vs 15.35 days, p = 0.003), and there is a tendency to reduce complications in all hospitalized patients (9 vs 17 cases, p = 0.21). After excluding bleeding cases which is expected to have lesser effect of albumin, the shortening of hospitalization period was also remarkably found in high dose albumin administration (9.91 vs 14.25 days, p = 0.008) and total complications event during hospitalization also tended to decrease (7 vs 10 cases, p = 0.4).
There was no difference between the two groups in the 3 months survival rate (10vs 10 case p = 0.88). And the decrease of creatinine level was not different between two groups (0.53 vs 0.51 p = 0.86), and that was same in decrease of MELD score (4.35 vs 3.53 p = 0.37). But in subgroup in CTP class C, the decrease of creatinine level was more prominent in high dose albumin group (0.60 vs 0.48 p = 0.4)
Conclusion: In the group of patients hospitalized for acute decompensation events, excluding mortality due to disease, albumin administration of 40 g or more per week was reducing the length of hospitalization of patients. In subgroup analysis, in the non-bleeding cases, and the higher CTP patients, the more effective it is. And it is expected that there will also be a creatinine reduction effect, and there seems to be a tendency to reduce the incidence of complications. It is recommended to consider active albumin administration when patients were hospitalized cause of acute decompensation.

SAT534

Myosteatosis is associated with sarcopenis, frailty and fat body composition abnormalities in liver corrhosis

Eleni Geladari[1], Theodoros Alexopoulos[1], Meropi Kontogianni[2], Ilianna Mani[1], Larisa Vasilieva[1], Alexandros-Pantelis Tsigas[2], Roxani Tenta[2], Evangelia Stroumpouli[3], Alexandra Alexopoulou[1].
[1]Medical School, National and Kapodistrian University of Athens, 2nd Department of Internal Medicine and Research Laboratory, Athens, Greece; [2]School of Health Sciences and Education, Harokopio University, Department of Nutrition and Dietetics, Athens, Greece; [3]Hippokration General Hospital, Department of Radiology, Athens, Greece
Email: alexopou@ath.forthnet.gr

Background and aims: Myosteatosis is defined as increased fat infiltration in skeletal muscle and implies impaired muscle quality. Although it has been included in the recent sarcopenia criteria as suggested by the European Working Group on Sarcopenia in Older People (EWGSOP-2), further research is required exploring myosteatosis' associations with clinical characteristics of patients with liver cirrhosis (LC). The aim was to investigate the prevalence of myosteatosis and potential associations with other body composition parameters and clinical characteristics in patients with LC.
Method: Computed tomography (SliceOmaticV4.3 software, Tomovision, Montreal, PQ) was used to assess muscle mass [skeletal muscle index (SMI, cm^2/m^2)] at the third lumbar vertebrae (L3). The same software was utilized to calculate visceral adipose tissue index (VATI, cm^2/m^2), subcutaneous adipose tissue index (SATI, cm^2/m^2) and VATI/SATI (VSR) ratio. Myosteatosis was defined as muscle radiodensity <33 Hounsfield Units (HU) at L3. Sarcopenia was diagnosed according to EWGSOP-2 criteria, muscle performance was evaluated with the short physical performance battery (SPPB) and frailty using the liver frailty index (LFI).
Results: 167 consecutive patients [67.6% male, MELD 12 (IQR 7–17), 65.3% with decompensated cirrhosis, 43.1%, 23.4% and 33.5% with alcoholic, viral and other causes of liver disease respectively] were included. Myosteatosis was identified in 59.3%, sarcopenia in 43.1% and frailty in 29.3% of the population.
Patients with myosteatosis vs those without, were more often female (42.4% vs 17.6%, p = 0.001), older than 60 years of age (58.6% vs 39.7%, p = 0.012), sarcopenic (61.6% vs 16.2%, p < 0.001), frail (40.4% vs 13.2%, p < 0.001) and had more often decompensated cirrhosis (71.7% vs 55.9%, p = 0.026). Moreover, patients with myosteatosis displayed higher VATI [55.4 (36.6–75.7) vs 32.8 (20.7–56.6), p < 0.001], SATI [63.3 (37.0–95.1) vs 46.8 (28.7–66.8), p = 0.005], VSR [0.99 (0.54–1.4) vs 0.69 (0.43–1.18), p = 0.024] and decreased SPPB [10 (5.5–11) vs 11 (10–12), p < 0.001]. Liver disease etiology and body mass index did not differ between the groups.
Conclusion: High myosteatosis prevalence was demonstrated in this sample of patients with cirrhosis. Myosteatosis was associated with older age, presence of sarcopenia, frailty, decreased performance status, high visceral, and subcutaneous adiposity and more severe liver disease.

SAT535

Correction and prevention of hyponatremia in patients with cirrhosis and ascites-post hoc analysis of the ANSWER study database

Background and aims: Hyponatremia is a frequent and ominous complication in patients with decompensated cirrhosis. Human albumin (HA) administration improves hyponatremia in patients with cirrhosis hospitalized because of acute decompensation, but no data are available on the effects of long-term HA administration.
We aimed at determining whether long-term HA administration could help in treating and preventing hyponatremia in outpatients with decompensated cirrhosis and ascites.
Method: We performed a post-hoc analysis on the intention-to-treat population (431 patients) enrolled in the ANSWER trial, grouping patients according to their baseline serum sodium levels. Resolution rates of hyponatremia in hyponatremic patients and incidence rates (IRs) and IR ratios (IRRs) of at least moderate hyponatremia (<130 mmol/l) during a follow-up of 18 months were calculated.

Results: 149 (35%) patients presented hyponatremia (<135 mmol/l) at baseline (74 vs 75 in the standard medical treatment [SMT] and in the SMT+HA arms, respectively). 116 of them (78%) had mild hyponatremia (≥130 and <135 mmol/l), while 33 (22%) had at least moderate hyponatremia (<130 mmol/l). Patients with hyponatremia had higher Child-Pugh and MELD scores as compared to normonatremic patients. At baseline, hyponatremic patients randomized to receive long-term HA did not differ from those randomized to SMT. Normalization of hyponatremia (≥135 mmol/l) was reached more frequently and faster in SMT+HA than SMT group: 45% vs 28% (p = 0.042) after 1 month, and 71% vs 44% (p = 0.006) after 3 months. Long-term HA was also effective in preventing episodes of hyponatremia, as the incidence rate of at least moderate hyponatremia was significantly lower in the SMT+HA than in SMT arm, both in hyponatremic and non-hyponatremic patients (incidence rate ratios: 0.245 [CI 0.167–0.359, p < 0.001] and 0.539 [CI 0.338–0.859, p = 0.008], respectively.
Conclusion: Long-term HA administration appears an effective intervention in managing hyponatremia in outpatients with decompensated cirrhosis and ascites.

SAT536

Low incidence of adverse liver events in a real-world cohort of patients diagnosed with liver disease via a community diagnostic pathway

Alexander Smith[1,2], Florina Borca[2], Julie Parkes[1], Janisha Patel[2], Hang Phan[1], Callum Robins[2], Ryan Buchanan[1]. [1]*University of Southampton, Faculty of Medicine, Southampton, United Kingdom;* [2]*University Hospital Southampton NHS Foundation Trust, Southampton, United Kingdom*
Email: asmith49@nhs.net

Background and aims: Community liver diagnostic pathways use non-invasive liver fibrosis tests to identify patients with compensated alcohol-related liver disease (ArLD) and non-alcohol related fatty liver disease (NAFLD). However, the longitudinal association between test scores and adverse liver events is uncertain.
Method: The Southampton Liver Pathway (SLP) involves fibrosis assessment with an enhanced liver fibrosis (ELF) score in primary care and transient elastography (TE). We retrospectively examined the occurrence of adverse liver events in patients with ArLD or NAFLD identified in the SLP. Patients with an ELF test taken between 1st January 2017 and 31st August 2019, TE conducted within 6 months of the ELF test and a negative non-invasive liver screen (e.g. chronic viral hepatitis, autoimmune profile, serum ferritin and transferrin saturation) were included in the analysis. Data were collected at baseline from hospital records including age, sex, BMI, history of alcohol excess, and known type 2 diabetes mellitus (T2DM).
Adverse liver events were defined *a priori* as development of ascites, spontaneous bacterial peritonitis, overt hepatic encephalopathy, variceal bleeding, and hepatocellular carcinoma. We performed a search of hospital electronic records for adverse liver events occurring from the date of ELF test up to 30th April 2021. Kaplan-Meier (KM) curves and hazard ratios (HR) with 95% confidence interval (CI) were produced from univariable cox regression for risk of adverse liver events, stratified by recognised cut-offs for advanced fibrosis for ELF score (>10.5 or ≤10.5) and TE (>15 or ≤15kPa).
Results: A total of 324 patients were identified with 57% NAFLD, 37% ArLD, 6% unclassified. Median follow-up was 29 months (IQR 23–40). 213 patients (66%) were male and median age was 61 years (IQR 50–69). Median BMI was 30 kg/m2 (IQR 27–35) and 113 patients had T2DM (35%). Median ELF score was 10.5 (IQR 9.8–10.9) and median TE 7.2kPa (IQR 5.5–11.4). 152 (47%) patients had ELF>10.5 and 54 (17%) had TE >15kPa.
Only 5 (1.5%) patients experienced an adverse liver event. KM curves are shown in Figure 1. The HR for prediction of adverse liver events according to ELF score was 4.10 (95% CI 0.46–36.68, p = 0.208) and for TE result 2.84 (95% CI 0.47–17.01), p 0.254).

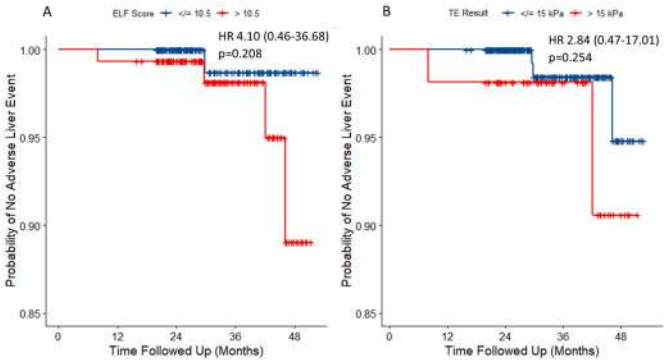

Figure 1: Kaplan-Meier survival curves from univariable Cox regressions for adverse liver events stratified by (A) ELF score and (B) TE result.

Conclusion: Patients from primary care populations with compensated liver disease diagnosed using non-invasive tests have a good medium-term prognosis. High ELF and TE results were not significantly associated with adverse liver events but this was affected by the low incidence of events in the follow-up period.

SAT537

The use of decompensated cirrhosis admission care bundles improves the standard of inpatient care but utilisation is poor across the UK

The Trainee Collaborative for Research and Audit in Hepatology UK[1]. [1]
Email: oliver.tavabie@doctors.net.uk

Background and aims: The standard of inpatient care for patients with cirrhosis in the United Kingdom (UK) is variable. Previous reports have demonstrated that less than 50% of inpatients admitted with alcohol-related liver disease (ARLD) receive good care. UK hepatology and gastroenterology societies have developed standards to improve care of patients with decompensated cirrhosis in the first 24 hours of admission. These have been integrated into a number of care bundles. We aimed to audit the uptake of these bundles and assess the impact on patient outcomes across the UK.
Method: Trainees from across UK hospitals were invited to participate in this audit through the ToRcH-UK network. Patients admitted to hospital between 1/11/2019–30/11/2019 with decompensated cirrhosis were identified by coding used for the NHS Cirrhosis Quality Dashboard. Admission clinical, demographic and laboratory data were collected with outcome and trust-specific data. Sites were grouped by NHS region, specialist/non-specialist hepatology centre designation and outcome groups. Univariable and multivariable analyses (MVA) were performed.
Results: 1224 admissions (1168 patients) from 104 hospitals (36 specialist hepatology centres) were included. Median age was 58 (IQR 48–68) and 61.6% were male. 62.3% of admissions were out of hours, 74.8% were for patients with ARLD, 85.1% had an established diagnosis of chronic liver disease with 67.2% having previously decompensated. Median model for end-stage liver disease (MELD) score was 17 (IQR 12–21) and admission inpatient mortality was 15.6%. Admission care bundles were used in 11.4% of admissions and there was significant regional variation in use (see Figure). Care bundle use was higher in patients with; ARLD (p < 0.0001), jaundice (p = 0.005) and those with higher MELD scores (19 (IQR 14–23) v 16 (IQR 12–21), p = 0.001), and reduced in patients with gastrointestinal bleeding (p = 0.005). The use of a care bundle was associated with increases in the following; appropriate blood tests requests (p < 0.0001), septic screens (p = 0.0001), diagnostic paracentesis (p = 0.005), appropriate alcohol care (p = 0.0006) and acute kidney injury management (p = 0.0007). Mortality was higher in patients where a care bundle was used (p = 0.01). However, when adjusted for MELD score, age and critical care admission, care bundle use was not associated with mortality (adjusted odds ratio 0.97–2.65, p = 0.06).

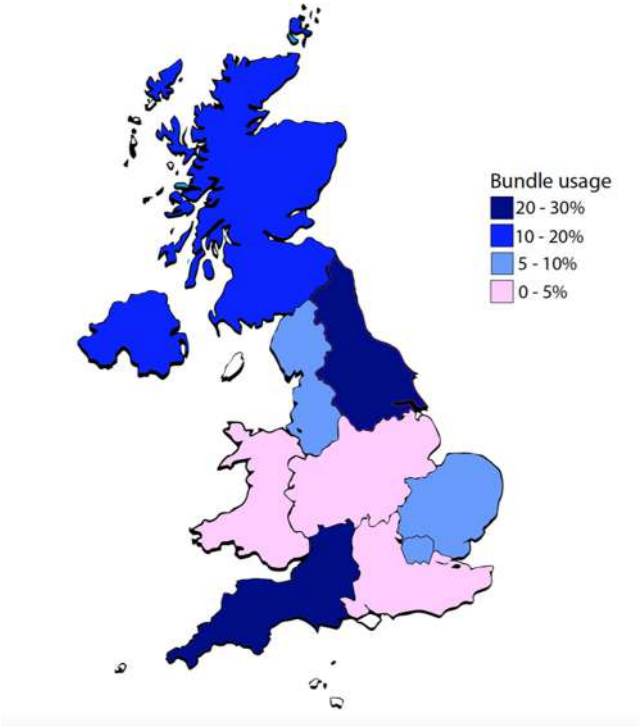

Figure: Heatmap demonstrating regional variation in admission care bundle use across the UK

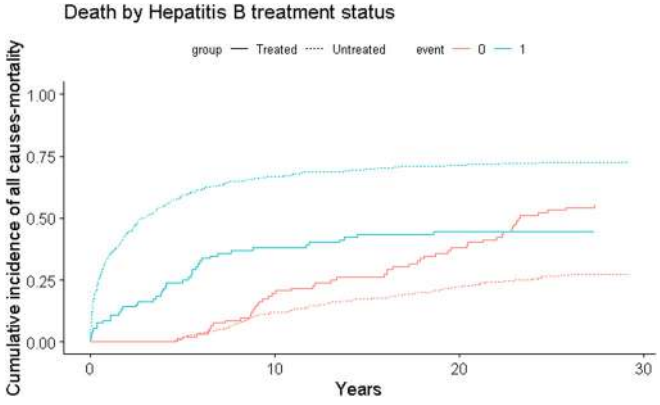
Conclusion: The use of admission care bundles improves the standard of care of patients with decompensated cirrhosis within the first 24 hours of admission. However, uptake is poor and variable across the UK. Work is required to understand the barriers to use to improve inpatient care for patients with decompensated cirrhosis.

SAT538

Effect of hepatitis B virus treatment on all causes and liver-related death among patients living with HBV with cirrhosis in British Columbia in a population-based cohort study

Makuza Jean Damascene[1,2,3], Dahn Jeong[2,4], Mawuena Binka[2], Prince Adu[2,4], Georgine Cua[2], Hector Velasquez[2,4], Amanda Yu[2], Stanley Wong[2], Maria Alvarez[2], Sofia Bartlett[2], Alnoor Ramji[5], Hin HIn Ko[5], Eric Yoshida[5], Mel Krajden[2], Naveed Janjua[2,4,6]. *[1]The University of British Columbia, School of Population and Public Health, Vancouver, Canada; [2]BC Centre for Disease Control, Clinical Prevention Services, Vancouver, Canada; [3]Rwanda Biomedical Center (RBC), IHDPC, Kigali, Rwanda; [4]The University of British Columbia, School of Population and Public Health, Vancouver, Canada; [5]The University of British Columbia, Division of Gastroenterology, Vancouver, Canada; [6]St. Paul's Hospital, Centre for Health Evaluation and Outcome Sciences, Vancouver, Canada*
Email: makorofr@gmail.com

Background and aims: The hepatitis B virus (HBV) is a significant burden of liver disease in Canada. We evaluated the effect of HBV treatment on all-cause mortality and liver-related mortality among individuals with HBV and cirrhosis in British Columbia (BC), Canada.
Method: This analysis used the BC Hepatitis Testers Cohort, which includes all individuals diagnosed with HBV since 1990 in BC, integrated with data on medical visits, hospitalizations, prescription drugs, and mortality. The study population included individuals who tested positive for HBV and were diagnosed with cirrhosis, followed from their HBV first testing date until death or December 31, 2020. We computed all-cause and liver-related mortality rates by HBV treatment status. We used inverse probability of treatment weighting (IPTW) to balance the baseline characteristics with the standardized mean difference (SMD) cut-off of 0.2 for treated and untreated individuals. We performed multivariable cox proportional hazard modeling to assess the effect of HBV treatment and coinfection with Hepatitis C virus (HCV) on all-cause and liver-related mortality in the overall sample and in the IPTW dataset.
Results: The analysis included 654 HBV-positive individuals with cirrhosis; 100 (15.3%) received HBV treatment. The mean follow-up for treated individuals was 10.29 (SD: 7.61) years and 5.84 (SD: 6.71) years for untreated individuals. A higher proportion of those treated compared to untreated were males [67 (67%) vs 370 (66.8%)], born between 1945 and 1above [66 (75.9%) vs 330 (65.9%)], those of East and South Asian ethnicity [40 (40.0%) vs 108 (19.5%)], and those with liver cancer [20 (20.0%) vs 68 (12.3%)]. The highest all-cause (124.28; 95%CI: 112.70, 137.04 vs 44.71; 95%CI: 33.49, 59.69per 1, 000 person-years [PYs]); and liver-related mortality (75.74; 95%CI: 66.83, 85.85 vs 29.16; 95%CI: 20.39, 41.70 per 1, 000 PYs) rates were higher among individuals who were not treated for HBV compared to those who were treated the liver-related. The multivariable models revealed that HBV-positive cirrhotic individuals who were not treated had a greater risk of dying from all causes (adjusted hazard ratio [aHR] 1.75; 95% CI: 1.25, 2.45) and liver-related mortality (adjusted sub-distribution HR [asHR] 1.78; 95%CI: 1.19, 2.67) compared to treated individuals. Compared to individuals without co-infection HBV/HCV, those co-infected HBV/HCV, not treated for HBV infection had a higher hazard for both all causes and liver-related mortality (aHR 2.60; 95% CI 1.63, 4.14, and 2.93; 95% CI 1.68, 5.14 respectively). Other risk factors for all-cause and liver-related mortality included male sex and HCV infection.



Conclusion: HBV treatment was associated with a significant reduction in all-cause and liver-related mortality among individuals with cirrhosis.

SAT539

Secondary infections in hospitalizes patients with cirrhosis: epidemiology, clinical chracteristics and prognostic relevance

Gustavo Pereira[1], Caroline Baldin[1], Juliana Piedade[1], Nathalia Galhardi[1], Barbara Rodrigues[1], Raquel Godoy[1], Camila Marques de Alcanatara Barreto[1], Flavia Fernandes[1].
[1]Bonsucesso General Hospital, Gastroenterology and Hepatology Unit, Rio de Janeiro, Brazil
Email: ghspereira@gmail.com

Background and aims: Bacterial infections are frequent in cirrhotic patients and may induce a state of immune paralysis and, consequently, greater susceptibility to secondary infections. There is a paucity of data respect the frequency and clinical characteristics of secondary infections in this population. Our aim was to describe incidence and predictive factors of secondary infections and their correlation with prognosis.
Method: retrospective analysis of patients diagnosed with bacterial infections at admission, originally included in a prospective

observational cohort, followed for 3 months or until death or transplantation.
Results: 225 patients were included (59 ± 12 years, 57% female, HCV ± alcohol etiology in 74%, Child C in 48%, MELD-sodium 21 ± 7, ascites and hepatic encephalopathy in 70 and 38%). Fifty percent of infections were classified as community-based. Skin, SBP and urinary tract i were the most common at admission (25, 23 and 20%). SIRS, qSOFA ≥ 2, and ACLF were observed in 45, 19, and 32 patients. Secondary infection developed in 93 patients (41%) after a median of 11 (7–19) days. The most common secondary infections were respiratory, undetermined site and SBP (27, 23 and 17%). In only 18% of patients the secondary infection developed in same site as the first. The probability of developing secondary infection at the end of the first and second weeks was 12 and 33%. At admission, ACLF (OR 2.84, 95%CI 1.42–5.69, p = 0.003), non-community infections (OR 7.82, 95%CI 1.69–36.12, p = 0.008), as well as Child C and age, were predictors of secondary infections. Patients with secondary infections had higher in-hospital mortality (59 vs. 13%, p < 0.001) as well as at 3 months (64 vs. 26%%, p < 0.001). Development of secondary infection (OR 2.25, 95%CI 1.35–3.73, p = 0.002) and MELD-sodium (OR 1.1, 95%CI 1, 06–1.14, P < 0.001) were independent predictors of 3-month mortality.
Conclusion: secondary infections are frequent in cirrhotic patients, occurring early and usually in sites other than the index infection. Diagnosis of non-community infections as well as worse liver function at admission were predictors of secondary infections. Development of secondary infections is associated with higher mortality irrespectively of the severity of liver disease.

SAT540

Circulating cell-free DNA levels increment with worsening cirrhosis severity and associate with platelet exhaustion and mortality

Marilena Stamouli[1], Jelle Adelmeijer[2], Dana Huskens[3], Savannah Rivera[4], Kevin O'Reilly[5], Elena Palma[1], Neil Youngson[1], William Bernal[4], Shilpa Chokshi[1], Mark Roest[3], Ton Lisman[2], Vishal Patel[1,4,6]. Email: m.stamouli@researchinliver.org.uk

Background and aims: Chronic liver disease (CLD) is accompanied by changes in pro- and anti-haemostatic pathways, resulting in a fragile restored haemostatic balance. Thrombocytopenia is a common complication in decompensated cirrhosis (DC) and acute-on-chronic liver disease (ACLF), and granule storage pool deficiency has been shown to impair platelet function and favour bleeding. Circulating cell-free DNA (cfDNA) has been proposed to drive organ failure and interact with critical coagulation pathways and platelet function. The aim of this work was to characterise cfDNA in the evolution of CLD, coagulation dysfunction and associated organ failure.
Method: Plasma and serum haemostatic profiles were studied extensively in the full spectrum of CLD of increasing severity: stable cirrhosis (SC, n = 40), DC (n = 63), ACLF (n = 50), and were compared to healthy individuals (n = 40). Plasma-extracted cfDNA was also characterised by way of its host components (genomic (g) and mitochondrial (mt)). cfDNA content, coagulation and platelet activation markers were compared between groups and correlated with clinical characteristics.
Results: Plasma levels of total cfDNA and its mitochondrial and genomic components were significantly elevated in CLD patients when compared to healthy controls (p < 0.001). There was no significant difference across the cohorts in plasma coagulation markers, but serum platelet activation markers decreased significantly as liver disease progressed (p < 0.001) (Figure 1a). Interestingly, both mt- and gDNA correlated with serum platelet activation markers, CXCL4 (mtDNA $r_{(s)}$ = 0.34, 95% CI 0.19–0.47, gDNA $r_{(s)}$ = –0.45, 95% CI 0.57–0.32), CXCL7 (mtDNA $r_{(s)}$ = 0.32, 95% CI 0.17–0.46, gDNA $r_{(s)}$ = –0.58, 95% CI 0.68–0.46) and thrombospondin (mtDNA $r_{(s)}$ = 0.27, 95% CI 0.11–0.41, gDNA $r_{(s)}$ = –0.49, 95% CI 0.60–0.36) (Figure 1b). Host gDNA and platelet granule proteins were significantly associated with patient mortality (30- and 90-day), cirrhosis scores (Child-Pugh, MELD, CLIF-C) and routine haemostasis laboratory tests (platelets, INR, fibrinogen).

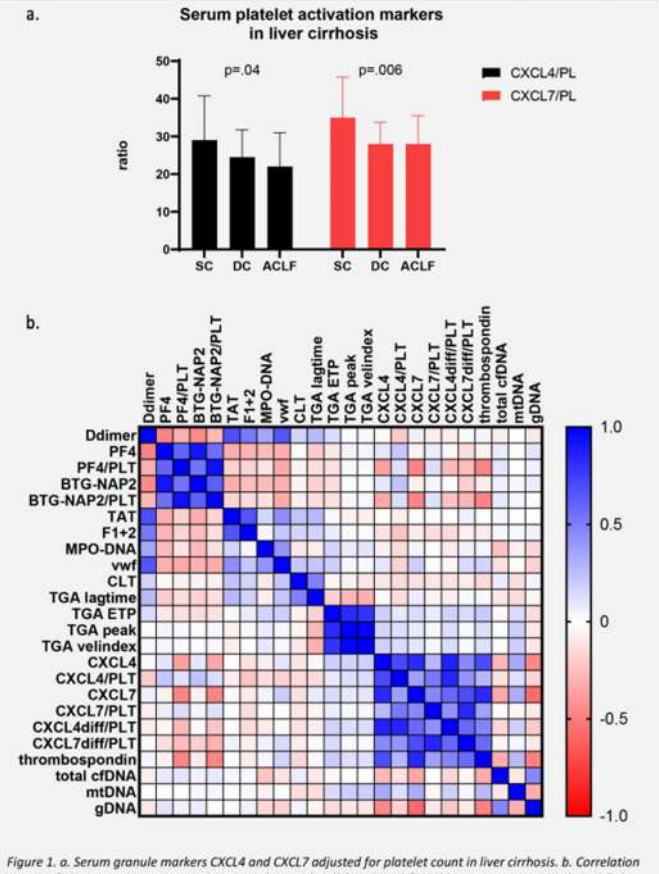

Figure 1. a. Serum granule markers CXCL4 and CXCL7 adjusted for platelet count in liver cirrhosis. b. Correlation matrix of plasma and serum coagulation markers with cell-free DNA (cfDNA) host components in chronic liver disease compared to heathy individuals. SC=stable cirrhosis, DC=decompensated cirrhosis, ACLF=acute-on-chronic liver failure, PLT=platelet, CXCLdiff=serum-plasma CXCL, mtDNA=mitochondrial cfDNA, gDNA=genomic cfDNA

Conclusion: cfDNA from mitochondrial and genomic sources share similar pathophysiological properties. cfDNA levels are elevated in patients with advanced CLD, but do not appear to be associated with coagulation activation or inhibition of fibrinolysis. Rather, serum platelet granule content is significantly reduced as cirrhosis progresses and is linked to both mtDNA and gDNA, suggesting that cfDNA may be involved in platelet activation. Our data suggest a mechanism of platelet exhaustion or 'acquired storage pool disease', differentiating patients with and without hepatic decompensation. We conclude that circulating cfDNA is not just a prognostic marker, but may also contribute to changes in platelet content and function.

Liver tumours: Clinical aspects except therapy

Email: poxue@channing.harvard.edu

Background and aims: Intake of sugar-sweetened beverage (SSB), a postulated risk factor for obesity, diabetes, and cardiovascular disease, may drive insulin resistance and inflammation which are strongly implicated in liver carcinogenesis. However, evidence on the association between SSB intake and liver cancer is scarce. We hypothesized that higher SSB intake would be associated with a greater risk of liver cancer.

Method: We included 97, 601 women aged 50–79 years from the Women's Health Initiative Observational Study and Dietary Modification Trial comparison arm. SSB intake was defined as the sum of soft drinks and fruit drinks (1 serving = one 12 fl. oz can or 355 ml), which was assessed by a validated food frequency questionnaire administered at baseline between 1993 and 1998. Incident liver cancers were reported by self-administered questionnaires and further confirmed by medical record review. Cox proportional hazards regression models were used to estimate multivariable hazard ratios (HRs) and 95% confidence intervals (CIs) with adjustment for age, race and ethnicity, education, alcohol intake, smoking status, body mass index, non-steroidal anti-inflammatory drug use, physical activity, total caloric intake, and history of diabetes.

Results: After a median of 19.5 years follow-up, 206 women had confirmed liver cancer. Approximately 6.8% of women consumed ≥ 1serving/day of SSB at baseline. Higher SSB intake was associated with a 99% greater risk of liver cancer ($HR_{\geq 1/day\ vs\ never\ to\ <3/month}$ = 1.99, 95%CI = 1.25–3.18, P linear trend = 0.004) as compared to intake of <3 servings/month. Non-statistically significant positive associations with liver cancer were observed for fruit drinks ($HR_{\geq 1/day\ vs\ never\ to\ <3/month}$ = 1.83, 95%CI = 0.80–4.17) and soft drinks ($HR_{\geq 1/day\ vs\ never\ to\ <3/month}$ = 1.79, 95%CI = 1.05–3.07). Results were similar after further adjustment for coffee/tea intake, or history of liver diseases, or when liver cancer cases diagnosed within the first 2 years of follow-up or those with history of diabetes were excluded. Substitution analyses indicated replacing SSB with water and/or coffee or tea could significantly lower liver cancer risk.

Conclusion: Our findings suggest SSB as a potential modifiable risk factor for liver cancer in postmenopausal women. Studies in men and diverse populations are needed to examine these associations more comprehensively. If our findings confirmed, reducing SSB consumption might serve as a public health strategy to reduce liver cancer burden.

Email: ediagosempere@gmail.com

Background and aims: Vaccines against SARS-Cov2 have been authorized with an efficacy of 95%. However registration studies have not included cancer patients at risk of lower immunogenicity. The aim of this study is to evaluate the immune response and safety after vaccination in patients with liver cancer.

Method: Case-control study, patients with primary liver cancer who received any of the COVID-19 vaccines were included. The immune response was evaluated by detecting tests against Spike protein by electrochemiluminescence. Study titers were defined as undetectable (<0.4 U/ml), suboptimal (0.4–250), and adequate (>250 U/ml). 1Cancer-free individuals were selected as controls and matched for age and sex. A second control cohort of cirrhotic patients is ongoing. The results of the interim analysis corresponding to 4 weeks after the second dose are presented.

Results: 244 liver cancer patients and 340 controls were prospectively included. Liver cancer patients had a significant lower serologic response (≤250 U/ml) 4 weeks after the second dose than the control group (18.9% vs 7, 1%; p < 0.001) (Table 1).

	RESPONSE: ADEQUATE IG > 250 U/ml	RESPONSE: SUBOPTIMAL IG 0, 4–250 U/ml	IG UNDETECTABLE IG < 0, 40 U/ml
HCC PATIENTS	73, 4%	15, 6%	3, 3%
HEALTHY CONTROLS	92, 9%	6, 7%	0, 4%

In patients with liver cancer, age >60 years, recurrence at the time of vaccination, treatment with sorafenib, nivolumab, cabozantinib, Child-Pugh B, and BCLC C/D stage were significantly associated with an inadequate immune response.

The adequate response after vaccination with Pfizer-BioNTech was significantly lower than with Moderna (74% vs 92%, p < 0.001). 36% of patients presented adverse effect 28 days after the second dose.

Conclusion: Liver cancer patients develop a significantly lower immune response to SARS-CoV-after two doses in comparison with general population. Factors influencing poorer response include age,

active systemic therapy, tumor stage, and severity of liver disease. The findings confirm the need for a reassessment of vaccination mechanisms in this population.

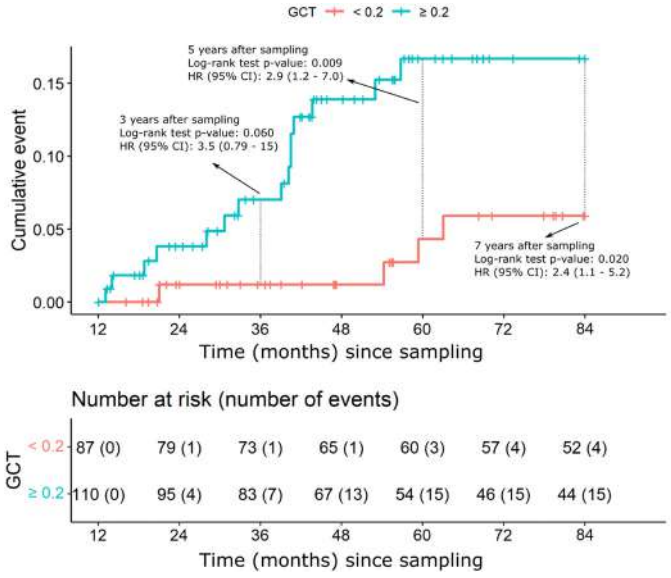
Email: xavier.verhelst@uzgent.be

Background and aims: Cirrhosis is the main risk factor for the development of hepatocellular carcinoma (HCC). Six-monthly screening with ultrasound is advocated for the surveillance of cirrhotic patients. We recently showed that a glycomics-based test (GlycoCirrhoTest [GCT]) can provide additional information regarding the risk of HCC development in cirrhotic patients.
The aim of this study is to provide an independent clinical validation of the GCT for the assessment of the risk of HCC development in cirrhosis.
Method: Validation study on serum samples of patients with established compensated cirrhosis (CHILD Pugh AandB) in a tertiary liver center. Serum N-glycan profiling was performed and GCT was calculated at baseline using DNA sequencer assisted fluorophore assisted capillary electrophoresis. During the follow-up period, patients were screened for the presence of HCC every 6 months with ultrasound and alpha foeto protein (AFP) measurements.
Results: A total of 198 cirrhotic patients were followed during a median follow-up time of 7 years. Twenty-nine patients developed HCC and one died during follow-up. At baseline, the mean GCT value was significantly higher in patients who developed HCC within 3 and 5 years compared to patients who did not develop HCC (Welch's t-test, p value 3 years: 0.034, 5 years: 0.022). Hazard ratio for HCC development at 5 years based on GCT was 2.9 (95% CI, 1.2–7.0). Applying the same cut-off as from the proof-of-concept study (0.2), the negative predictive value of GCT for HCC development was 98.9%. Figure 1 illustrates the discriminative power of this biomarker in patients with cirrhosis. GCT is based on changes in serum protein glycosylation related to cirrhosis nodularity and malignant transformation.



Conclusion: This independent validation study confirms that GCT is a glycomics-based test that provides additional information for risk assessment of HCC development in cirrhosis. This information could be used to develop personalised HCC screening programs in cirrhotic patients according to the value of GCT. Moreover, refocusing of the screening resources to the reduced number of cirrhosis patients who truly are at elevated risk for developing HCC may result in earlier detection of more HCC cases, for instance by making contrast-enhanced MRI screening cost-effective.

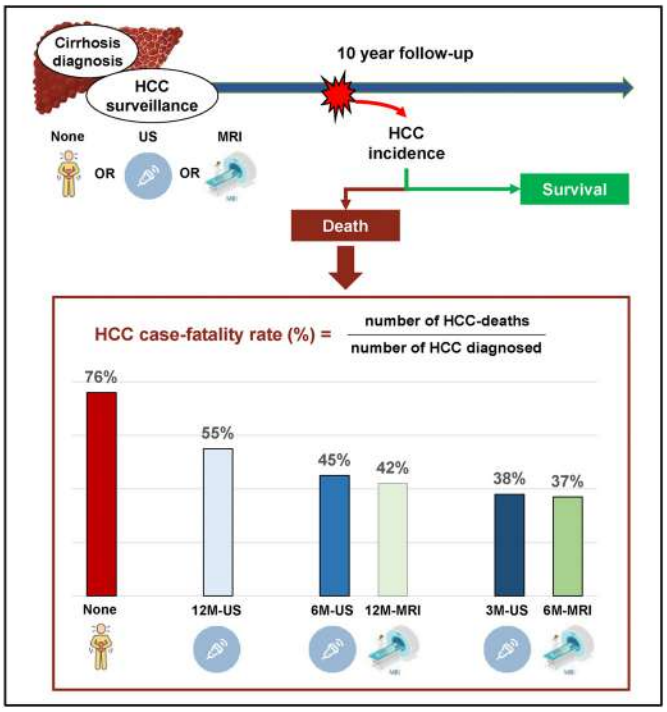
Email: massih.ningarhari@chu-lille.fr

Background and aims: To validate screening programs of solid tumors, expert guidelines now recommend obtaining data supporting reduction of case-fatality rate and cancer-specific mortality. The present study evaluates the benefit of hepatocellular carcinoma (HCC) screening on those outcomes using a modelling approach.
Method: We designed a Markov model to assess 10-year outcomes of HCC surveillance in terms of case-fatality rate (CFR), disease-specific mortality and overall mortality per 100, 000 screened patients with compensated cirrhosis. The model simulates the occurrence of HCC, diagnosis through surveillance or symptoms according to tumor growth, treatment, and follow-up. The model evaluates screening in different scenarios varying annual HCC incidence (0.2%, 0.4% or 1.5%), surveillance interval (none, annual (12M), semestrial (6M) or trimestrial (3M)) and imaging modality (US, ultrasound, or MRI, magnetic resonance imaging).
Results: 6M-US screening in comparison to no surveillance reduced 10-year HCC-CFR from 76 to 45%. According to the size of the main tumor, CFRs decreased from 42 to 36% for main nodule size between 1–3 cm, 68 to 61% for main nodule size between 3–5 cm, and 83% to 82% for main nodule size larger than 5 cm. When annual incidences varied from 0.2%, 0.4% to 1.5%, the model predicts reductions of 289, 580 to 2, 110 HCC-related deaths, and of 209, 419 to 1, 521 total deaths, per 100, 000 screened patients, respectively. In terms of surveillance modalities, 6M-MRI and 3M-US, in comparison to the

recommended 6M-US, yielded reductions of CFRs and cancer-related mortality (−18% and −16%), that were as expected not affected by the variation of incidence. Conversely, effects on overall mortality varied according to annual HCC incidence. In comparison to 6M-US, for incidences varying from 0.2%, 0.4% to 1.5%, 6M-MRI reduced overall mortality from 0.3%, 0.5% to 1.7%, and 3M-US from 0.2%, 0.5% to 1.5%, respectively. Even with extended surveillance interval, 12M-MRI compared to 6M-US leads to a 6% reduction of cancer-related mortality.



Conclusion: Shortening US surveillance or using MRI would reduce HCC case-fatality rate and HCC-related mortality. Conversely, the effect on overall mortality appeared modest. The evaluation of case-fatality rates, absolute numbers of cancer-related and overall deaths, provides additional insights on HCC surveillance.

T cell receptor sequencing reveals HCC diversity according to BCLC stages within liver tissue and peripjeral blood

Yuwei Zhang[1], Junxiao Wang[2], Xiubin Li[3], Hui Xie[2], Yijin Wang[1].
[1]Southern University of Science and Technology, School of Medicine, Shenzhen, China; [2]The Fifth Medical Center of Chinese PLA General Hospital, Department of Invasive Technology, Beijing, China; [3]The Third Medical Centre of Chinese PLA General Hospital, Department of Urology, Beijing, China
Email: yijinwang927015@163.com

Background and aims: T lymphocytes play important roles in human adaptive immune responses and antigen peptides recognition via specific T cell receptors (TCRs). Here we determined the TCR repertoires of tumor, adjacent tissue and PBMC in hepatocellular carcinoma (HCC) patients at different stages, aiming to give a new insight into disease pathogenesis and guiding immune therapy.

Method: We prospectively enrolled 30 patients who were initially diagnosed of HCC at BCLC-A (n = 10), BCLC-B (n = 10), BCLC-C (n = 10), from January 2017 to March 2019 at the 5th Medical Center, Chinese PLA General Hospital. Multi-Immunofluorescence by Tyrosine signal amplification assay was performed in each tumor biopsy to characterize suppressor T lymphocytes with Anti-CD3, Anti-PD1, Anti-CTLA4, and Anti-LAG3 antibodies. Tissue and PBMC samples were then analyzed by high-throughput deep sequencing of TCR using the ImmuHub TCR profiling system. Ethical approval was obtained from the Institutional Ethics Committee.

Results: The number of CD3+ cells was increased in BCLC_B and BCLC_C stages compared to BCLC_A stages, with the BCLC_B stage being the highest. The ratio of PD1+/CD3+ was significantly higher in BCLC_C than that in BCLC_A and BCLC_B. The number of LAG-3+ cells, as well as the ratio of LAG-3+/CD3+ were gradually increased from BCLC_A to BCLC_C stages (Fig 1).

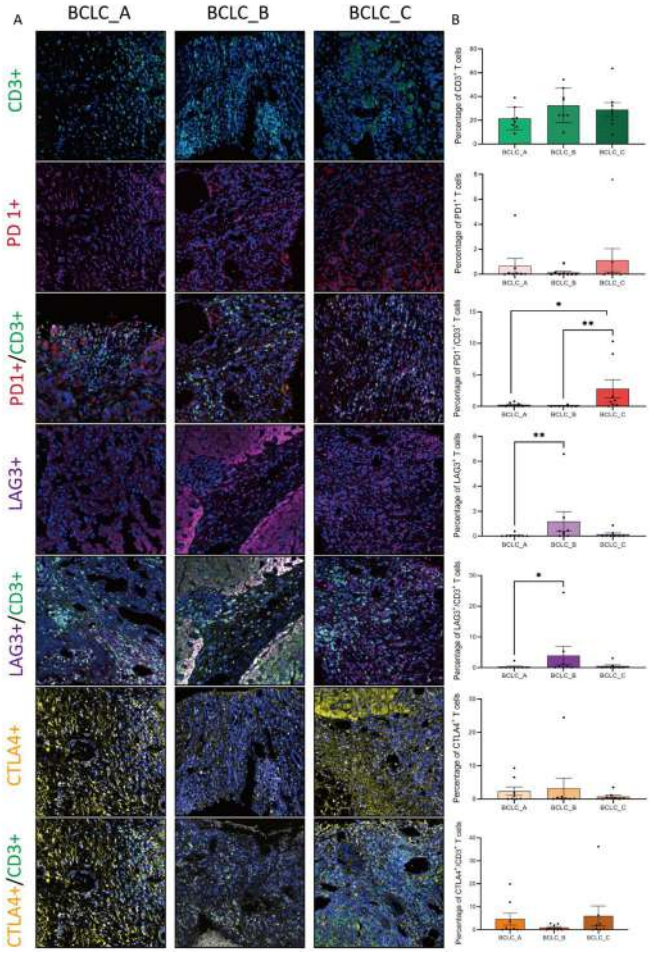

Figure 1:

TCR were successfully sequenced in 78 samples from 28 patients. TRBV5-1, TRBV20-1, TRBJ2-1 and TRBJ2-7 were frequently used in all samples, but seemed no difference between HCC stages. TCR repertoires in tumor tissues are completely different to those in the PBMC, only 4.3% overlaps between tumors and adjacent tissues, and1.5% overlaps between tumors and PBMCs. Furthermore, a significant expansion of TCR clonality in PBMC, but not in tissues, were observed in BCLC_C patients, compared to BCLC_A and BCLC_B patients (Fig 2A–F). The results were further confirmed by analysis of D75 values (Fig 2G–I) and Shannon index (Fig 2J–L). There was no significant difference in CDR3 length between different stages, neither in PBMC, nor in tissues. Hydrophobic amino acids in both positions 6 and 7 amino acids were less used in BCLC_C than BCLC_A and BCLC_B, either in tumor, adjacent tissues or PBMC (Fig 3).

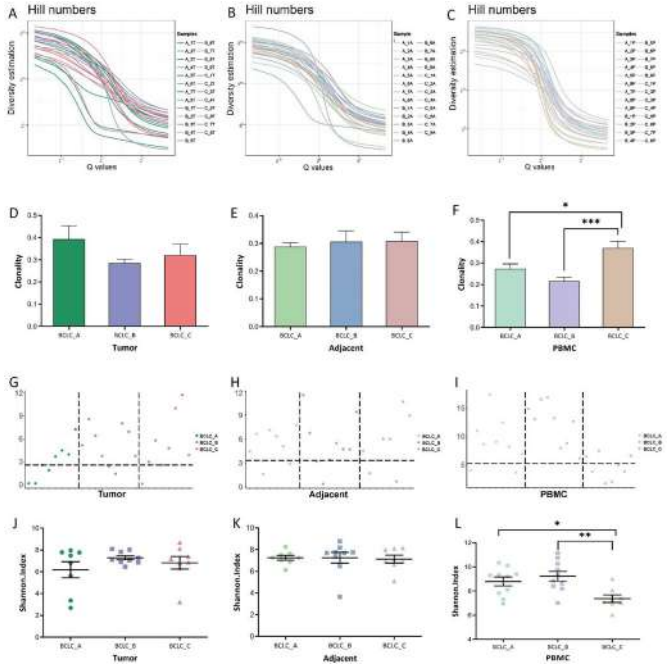

Figure 2:

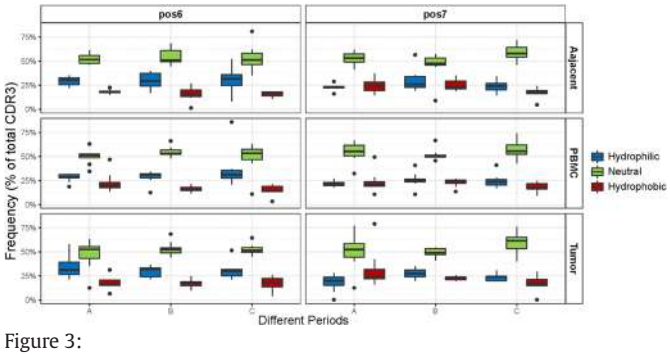

Figure 3:

Conclusion: Despite the number of tumor infiltrating T cells was increased in the BCLC_C stage, most of which were inhibitory T cells, indicating unavailing anti-tumor effect. Through a deep, comprehensive and multidimensional analysis of TCR repertoires, our study found a significant increase in TCR clonality of PBMC in BCLC_C stage, but not in tumors and adjacent. In addition, we found that the use of hydrophobic amino acids at positions 6 and 7 of CDR3 decreased at BCLC_C stage. In conclusion, our findings provide new evidence for future clinical monitoring and immunotherapy of HCC patients.

SAT559

NanoView EV Chip-based profiling in liver cancer differentiation-HCC from intrahepatic CCA-small EVs vs large EVs

Bingduo Wang[1], Tudor Mocan[2], Sabine K. Urban[1], Adelina Horhat[2], Dominik Zölzer[1], Zeno Sparchez[2], Alex Shephard[3], Ben Owen[3], Arnulf Willms[4], Ingo G. Schmidt-Wolf[5], Maria Angeles Gonzalez-Carmona[1], Christian Strassburg[1], Veronika Lukacs-Kornek[6], Miroslaw Kornek[1]. *[1]University Hospital Bonn, Department of Internal Medicine I, Bonn, Germany; [2]Iuliu Haţieganu University of Medicine and Pharmacy, Octavian Fodor Institute for Gastroenterology and Hepatology, Cluj-Napoca, Romania; [3]NanoView Biosciences, European Office: Malvern Hills Science Park, Malvern, United Kingdom; [4]German Armed Forces Central Hospital, Department of General, Visceral and Thoracic Surgery, Koblenz, Germany; [5]University Hospital Bonn, Center for Integrated Oncology (CIO), Bonn, Germany; [6]University Hospital Bonn, Institute of Experimental Immunology, Bonn, Germany*
Email: wang_bingduo@outlook.com

Background and aims: In spite of recent developments it is still very challenging to differentiate hepatocellular carcinoma (HCC) from intrahepatic cholangiocarcinoma (iCCA). Clinical available methods as CT, MRI and contrast-enhanced ultrasonography demand highest operator skills to achieve a robust differentiation between HCC and iCCA. Here, we utilized NanoView's ExoView® Reader to capture small EVs (sEVs) for further analysis and compared them to large EVs (lEVs) and assessed their clinical performances to differentiate HCC from iCCA. lEVs and sEVs differ in size and biogenesis.

Method: CD44v6$^+$, CD133$^+$ and double positive cells were confirmed on human CCA and HCC cell lines. sEVs and lEVs from patients' sera were isolated by SEC columns or 10.000 g centrifugation. To quantify lEVs FACS was applied with AnnexinV (AnnV) serving as lEV marker. sEVs were captures with CD9, CD63 and CD81 on ExoView® Tetraspanin Chips according to manufacture's instruction and analyzed for CD44v6 and CD133. Surface analysis of sEVs was performed with ExoView® R100 (NanoView Biosciences, Boston, USA) using their ExoView® Tetraspanin Kit. Data analysis was performed using ExoView® Analyzer 3.0.

Results: 1) CD133 and CD44v6 were differentially expressed in CCA and HCC cell lines, indicating their potential for differential diagnosis. 2) AnnV$^+$CD44v6$^+$ lEVs were 2.7-fold increased ($p \leq 0.001$) in iCCA patients (AUROC 0.83, 93.3% sensitivity, 71.0% specificity). AnnV$^+$CD44v6$^+$CD133$^+$ lEVs and AnnV$^+$CD133$^+$ lEVs were not conclusive. 3) Individual sEV subpopulations as characterized by tetraspanins (CD9, CD63 and CD81) plus CD44v6 or CD133 were slightly non-significantly elevated without diagnostic relevancy in iCCA as CD63$^+$CD44v6$^+$ sEVs (1.36-fold) and CD9$^+$CD44v6$^+$CD133$^+$ (1.43-fold), or reduced as CD9$^+$CD44v6$^+$ sEVs (0.63-fold). Except and contrary to our lEV data, CD63$^+$CD133$^+$ sEVs and CD9$^+$CD133$^+$ sEVs and CD81$^+$CD133$^+$ sEVs were increased by 6.5-fold ($p = 0.007$) and 3.6-fold ($p = 0.028$) and 9.7-fold ($p = 0.505$). Actually, best clinical performance was observed with CD63$^+$CD133$^+$ with calculated AUROC of 0.89 ($p = 0.009$) and 87.5% sensitivity and 100% specificity. As expected, no meaningful correlations ($r > 0.5$) were observed with AFP and CA19-9.

Conclusion: Our aim was to differentiate a confirmed liver cancer according to its cancer entity, i.e., if HCC or iCCA and to compare clinical performances of lEVs vs. sEVs. Interestingly, sEVs and lEVs performed contrary. AnnV$^+$133$^+$ lEVs performed weaker compared to CD63$^+$CD133$^+$ EVs. Additionally, CD81$^+$CD133$^+$ sEVs were inferior to CD63$^+$CD133$^+$ EVs, indicating that sEVs can be further divided into clinical relevant subpopulations by CD9, CD63 and CD81 sEVs plus a biomarker of interest, here CD133, to separate HCC from iCCA *via* an sEV-based liquid biopsy.

Myosteatosis and excessive visceral adipose tissue as prognostic factors in patients with hepatocellular carcinoma treated with sorafenib

Min Kyu Kang[1], Yu Rim Lee[2], Jae Young Jang[1], Jung Eun Song[3], Young Oh Kweon[2], Won Young Tak[2], SE Young Jang[2], Changhyeong Lee[3], Byung Seok Kim[3], Jae-Seok Hwang[4], Woo Jin Chung[4], Byoung Kuk Jang[4], Jeong Ill Suh[5], Jung Gil Park[1], Soo Young Park[2]. *[1]College of Medicine, Yeungnam University, Internal Medicine, Daegu, Korea, Rep. of South; [2]School of Medicine, Kyungpook National University, Internal Medicine, Daegu; [3]School of Medicine, Daegu Catholic University, Internal Medicine, Korea, Rep. of South; [4]School of Medicine, Keimyung University, Internal Medicine, Korea, Rep. of South; [5]College of Medicine, Dongguk University, Korea, Rep. of South*
Email: kmggood111@naver.com

Background and aims: Recently, low skeletal muscle mass is significant predictor of mortality in patients with hepatocellular carcinoma (HCC). However, the role of myosteatosis and visceral adiposity in patients with HCC is not well understood. This study aimed to evaluate the association between body composition and mortality in patients with HCC treated with sorafenib.
Method: From 2008 to 2019, this multicenter, retrospective study included patients with advanced HCC who treated with sorafenib. Body composition parameters were measured using the cross-sectional CT images at the level of L3 vertebra. Visceral adipose tissue index (VATI) and skeletal muscle index (SMI) are defined as the body composition area (cm^2) by height squared (m^2). Myosteatosis is defined as mean muscle attenuations values using Hounsfield units (HU).
Results: Of the total 245 patients, 168 (68.6%) died. The non-survival group had higher VATI levels (32.6 vs. 45.7 cm^2/m^2, p = 0.005) and lower HU levels (53.3 vs. 51.0 HU; p = 0.023) than the survival group. By multivariate Cox regression analysis, age (hazard ratio (HR), 0.98, 95% confidence interval (CI), 0.97–1.00; p = 0.018), history of previous treatment (HR, 0.55; 95% CI, 0.40–0.76; p < 0.001), albumin (HR, 0.59; 95% CI, 0.42–0.80; p < 0.001), presence of visceral adiposity (HR, 2.25; 95% CI, 1.49–3.42; p = 0.001), and myosteatosis (HR, 2.21; 95% CI, 1.53–3.19; p < 0.001) were independently associated with mortality in patients with HCC treated with sorafenib.

Table: Factors associated with mortality by multivariate Cox analysis in HCC patients treated with sorafenib.

	Univariate	Multivariate analysis	
Variable	*P* value*	*P* value*	Hazard ratio (95% CI)
Age, years	0.148	0.018	0.982 (0.967–0.997)
Male, yes/no	0.955		
BMI, kg/m^2	0.588		
Diabetes, yes/no	0.654		
Hypertension, yes/no	0.905		
Largest tumor diameter, mm	<0.001		
Vessel invasion, yes/no	<0.001		
Extrahepatic metastasis, yes/no	0.698		
Previous treatment history, yes/no	<0.001	<0.001	0.552 (0.400–0.761)
AST, IU/L	<0.001	0.004	1.003 (1.001–1.005)
ALT, IU/L	0.453		
Total bilirubin, mg/dL	0.001		
Albumin, g/dL	0.003	<0.001	0.583 (0.424–0.801)
Total bilirubin, mg/dL	0.831		
Platelet count, 10^9/L	0.224		
PT-INR	0.866		
AFP, ng/ml	<0.001	<0.001	1.002 (1.001–1.005)
Creatinine, mg/dL	0.804		
Sarcopenia, yes/no	0.245		
VATI, high/low	0.006	<0.001	2.253 (1.485–3.416)
SATI, high/low	0.146		
Myosteatosis, yes/no	0.008	<0.001	2.210 (1.533–3.185)

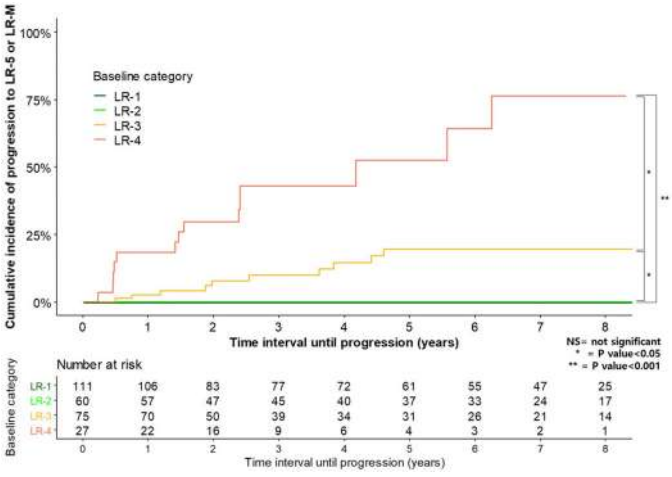
Conclusion: Visceral adiposity and myosteatosis may be associated with mortality in patients with HCC treated with sorafenib.

SAT561

Long term imaging outcomes of liver imaging reporting and data system categories in a prospective hepatocellular carcinoma surveillance cohort

Sang Hyun Choi[1], Byoung Je Kim[1], So Yeon Kim[1], So Jung Lee[1], Jae Ho Byun[1]. *[1]Asan Medical Center, Radiology, Seoul, Korea, Rep. of South*
Email: edwardchoi83@gmail.com

Background and aims: An understanding of the natural history of Liver Imaging Reporting and Data System (LI-RADS) is important. We assessed the imaging outcomes of LI-RADS v2018 categories in prospective hepatocellular carcinoma (HCC) surveillance cohort and determined imaging features significantly predictive of progression to a malignant LI-RADS category.
Method: The imaging outcomes of 183 patients (273 observations) prospectively enrolled between November 2011 and August 2012 were analyzed according to LI-RADS v2018. Cumulative incidences for progression to a malignant category (LR-5 or LR-M) and LR-4 or higher were calculated for each baseline category and compared using log-rank tests. Imaging features significantly predictive of progression to a malignant category were evaluated using Cox proportional hazards modeling.
Results: The 273 observations were initially categorized into 111 LR-1, 60 LR-2, 25 LR-3, and 27 LR-4. For LR-4 observations, the 1-year, 3-year, and 5-year cumulative incidences of progression to a malignant category were 18.5% (95% confidence interval [CI], 6.6–35.2%), 43.0% (95% CI, 23.1–61.5%), and 52.5% (95% CI, 25.9–73.5%), which were significantly higher than those of LR-1, LR-2, and LR-3 ($p \leq 0.009$) (Figure). For LR-3, the 1-year, 3-year, and 5-year cumulative incidences of progression to LR-4 or higher were 4.1% (95% CI, 1.1–10.4%), 13.9% (95% CI, 6.7–23.6%), and 23.1% (95% CI, 12.7–35.4%), which were significantly higher than those of LR-1 and LR-2 ($p < 0.001$). In multivariable analysis, size ≥1.0 cm (hazard ratio [HR] = 2.51, 95% CI, 1.08–5.84) and arterial-phase hyperenhancement (HR = 2.91, 95% CI, 1.28–6.62) were significantly independently associated with progression to a malignant category.



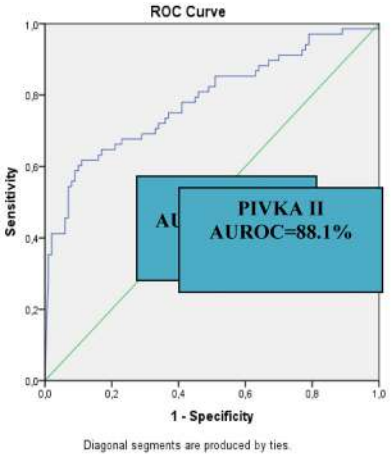
Conclusion: Long-term imaging outcomes differed significantly according to LI-RADS category. Size ≥1.0 cm and arterial-phase hyperenhancement were imaging features significantly predictive of progression to a malignant category.

SAT562

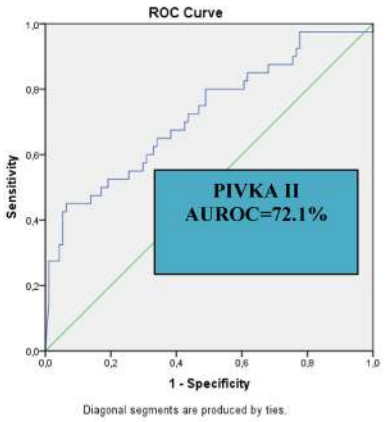
Diagnostic accuracy of protein-induced by vitamin K absence (PIVKA-II) for hepatocellular carcinoma (HCC) among caucasian cirrhotic patients with or without diagnostic serum a-fetoprotein (AFP) levels

Antonia Syriha[1,2], Dionysia Mandilara[2], Spyridon Pantzios[2], Ioanna Stathopoulou[2], Georgia Barla[2], Petros Galanis[1,2], Ioannis Elefsiniotis[1,2]. [1], [2]*General and Oncology Hospital of Kifisia "Agioi Anargyroi," National and Kapodistrian University of Athens, Greece, Academic Department of Internal Medicine-Hepatogastroenterology Unit, Greece*
Email: ielefs@nurs.uoa.gr

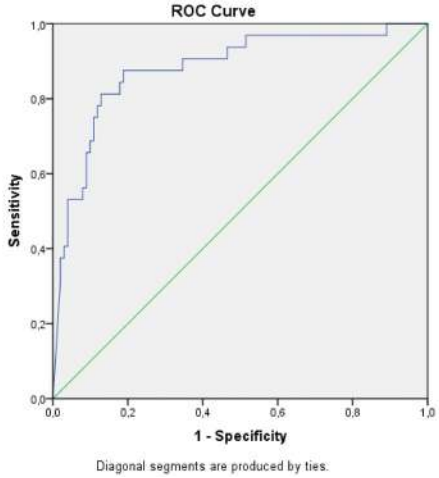
Background and aims: To evaluate the accuracy of serum biomarkers (AFP, PIVKA-II) for HCC diagnosis among patients with liver cirrhosis. **Method:** 168 consecutive patients with liver cirrhosis (128 males, 91 with CTP score A, 89 with varices, 30 with portal vein thrombosis and 53 with diabetes) with (n = 68, HCC group) or without (n = 100, control group) concomitant histologically confirmed HCC were evaluated for serum levels of the two biomarkers, during a programmed outpatient visit. The mean age of the patients was 65 (± 10.8) years and they more often presented with alcoholic or non-alcoholic fatty liver disease (69/168, 41.1%), with the second and third causes of cirrhosis being chronic hepatitis C (44/168, 26.2%) or B (28/168, 16.7%) respectively. Patients with HCC were categorized to stage



Accuracy of PIVKA-II for the diagnosis of HCC
in BCLC-C HCC patients
AUROC=0.881 (0.808-0.953)
Proposed Cut-off : 655 mAU/ml



Accuracy of PIVKA-II for the diagnosis of HCC
excluding HCC patients with AFP >400 ng/ml
AUROC=0.721 (0.622-0.82)
Proposed Cut-off : 1089,53 mAU/ml



Figures: (abstract: SAT562)

0/A (n = 11), stage B (n = 16), stage C (n = 32) and stage D (n = 9), according to BCLC staging system.
Results: Mean/median levels of AFP (10835/155 vs 129/4.3, p < 0.001) and PIVKA-II (11095/2660 vs 864/46, p < 0.001) were significantly higher in HCC group compared to control group. The AUROC curve and the best proposed cut-off value for HCC diagnosis were 82.9% (95%CI 76.3–89.4%)/13.4 ng/ml and 78.4% (95%CI 71.1–85.8%)/654.49 mAU/ml for AFP and PIVKA-II, respectively. The diagnostic accuracy of PIVKA-II among BCLC-C stage HCC patients was the best observed (AUROC = 88.1%, best proposed cut-off value = 655 mAU/ml). Excluding HCC patients with AFP levels above 400 ng/ml, the diagnostic accuracy of PIVKA-II in HCC continued to be significant (best proposed cut-off value 1089.53 mAU/ml) but the AUROC curve (72.1%) for HCC diagnosis was further reduced. It is worth mentioning that extremely high values of PIVKA-II (like those that are noticed in advanced HCC) were observed in 3 cirrhotic patients without HCC following treatment with acenocoumarol (the 2 of them) or having very low levels of vitamin K because of prolonged cholestasis due to sclerosing cholangitis (the third one). In these cases the diagnostic accuracy of the biomarker may be significantly affected.
Conclusion: Both biomarkers showed moderate accuracy for detecting HCC in patients with liver cirrhosis, when they were used separately. The diagnostic accuracy of PIVKA-II in patients with relatively low AFP levels (<400 ng/ml) remained at the same level.

SAT563

An easy to use score to predict survival in patients with hepatocellular carcinoma before the first transarterial chemoembolization session: AFP-DIAM score

Estelle Rebillard[2], Benjamin Buchard[2], Nicolas De Abreu[3], Mathieu Boulin[4], Anne Minello Franza[5], Benoît Magnin[3], Maud Reymond[2], Leon Muti[2], Bruno Pereira[6], Armand Abergel[2]. *[1]Centre hospitalier Universitaire Estaing de Clermont-Ferrand, Department of Hepatology and Gastroenterology, Clermont-Ferrand, France; [2]CHU Estaing, Medecine Digestive et Hepato-Bilaire, Clermont-Ferrand, France; [3]CHU Estaing, Radiologie, Clermont-Ferrand, France; [4]CHU Dijon, Pharmacie, Dijon, France; [5]CHU Dijon, Hepato-gastroenterologie, Dijon, France; [6]CHU Gabriel-Montpied, Direction de la Recherche Clinique et Innovation, Clermont-Ferrand, France*
Email: erebillard@chu-clermontferrand.fr

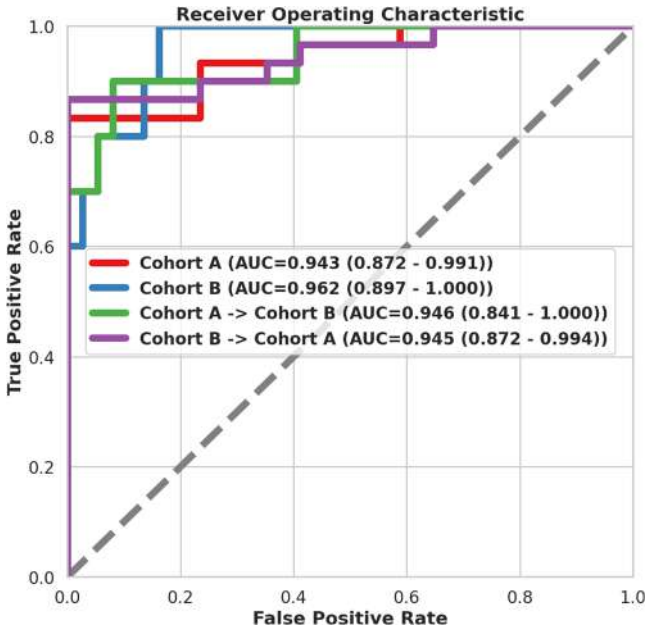
Background and aims: Transarterial chemoembolization (TACE) is widely used for the treatment of the hepatocellular carcinoma (HCC). TACE is recommended as a palliative treatment for patients with preserved hepatocellular function (either CHILD A or B7 without ascites), with a multinodular HCC without vascular invasion or associated metastasis, with a general preserved state. This profile corresponds to the B stage of the Barcelona Clinic Liver Cancer (BCLC) reference classification. This stage is very heterogeneous with a very different tumor profiles for a single therapeutic option available: TACE. Our aims were to develop a pre-therapeutic easy to use score, to assess the prognosis value of existing scores and to evaluate the prognosis value of the radiological response after two TACE sessions.
Method: 191 adult cirrhotic patients treated for HCC with TACE in our hospital from 2007 to 2017 were retrospectively included. We investigated the impact of liver function, patient characteristics and tumor burden on overall survival and developed a prognosis score using a regressing model to identify different prognostic groups in patients. Due to the low number of women, the score was only studied in male patients.
Results: Patients had a median age of 66 years and 126 patients were Child A. Two factors were associated with overall survival in the multivariate analysis: AFP > 500 ng/ml and the sum of the diameter of the nodules>130 mm (AFP-DIAM score). The score distinguishes two groups with significant difference survival time (median OS 28.3 months for a score = 0 versus 17.7 months for a score > 0). The score developed in this work was validated on an external cohort of 89 patients from Dijon University. Its discrimination capacity (c-index 0.58) is better than the existing scores (c-index STATE 0.55; c-index NIACE 0.54).
After two TACE, the radiological response with a threshold of –65% evaluated by mRECIST, identifies two groups with overall survival significantly different (30.1 versus 25.9 months; Se = 52%, Sp = 70%).
Conclusion: The AFP-DIAM score is a reliable and easy to use score which allows to distinguish two groups with different prognosis before first TACE session. An AFP-DIAM score > 0 identifies patients with dismal prognosis for which the question of a first-line treatment with an immunotherapy-tyrosine kinase inhibitor combination can be raised. Its use could provide further support to BCLC system to guide the therapeutic strategy of patients with HCC.

SAT564

Measurement of protease activity using novel plasma biosensors can accurately detect hepatocellular carcinoma

Tram Tran[1,2], Ben Holmes[1], Chris Gulka[1], Anatoly Myaskovsky[1], Andrea Shepard[1], Mackenzie Rowe[1], Sophie Cazanave[1], Fayçal Touti[1], Alejandro Balbin[1], Wendy Winckler[1]. *[1]Glympse Bio; [2]UCLA Division of Digestive DIseases*
Email: tttmd@yahoo.com

Background and aims: Hepatocellular carcinoma (HCC) is the 5th leading cancer globally. Suboptimal adherence to routine surveillance and late diagnosis limit treatment options, thus new diagnostic options are needed for at-risk patients. Dysregulated protease activity may occur in HCC in biological pathways including tumor invasion of extracellular matrix, matrix remodeling, inflammation and fibrinolysis. Glympse's novel liquid biopsy (LBx) technology using fluorogenic biosensors and machine learning can sensitively measure protease activity in plasma samples.
Aims: Assess protease activity changes in plasma of diagnosed HCC patients compared to healthy controls.
Method: We screened >600 peptide substrates to identify a panel of 21 biosensors that interrogate multiple biological pathways implicated in HCC pathogenesis (LBx-HCC). Retrospective plasma samples were obtained from two independent cohorts of patients (pts) diagnosed with HCC (cohorts A and B). Protease biosensor cleavage was assayed from plasma by fluorimetry, and the relative signal was used for classification by regularized logistic regression using 100 cross-validation (80% train, 20% validation splits). Independent classifier models were developed for each cohort and cross-tested without retraining in the second cohort to assess robustness.
Results: In cohort A, 30 pts diagnosed with HCC (M 77%, age 55.8 ± 9.9, BMI 22.3 ± 2.3, Asian 96% and 80% HBV/HCV etiology) were compared to 17 healthy controls (M 59%, age 35.8 ± 12.6, BMI 28.2 ± 4.5, Caucasian 59%/African 24%/Asian 17%).
In cohort B, 10 pts diagnosed with HCC (M 50%, age 59.0 ± 15.4, BMI 23.6 ± 4.7, Caucasian 90% and no underlying viral disease) were compared to 37 healthy controls (M 65%, age 59.2 ± 9.4, BMI 25.8 ± 2.9, Caucasian 100%).
We performed LBx-HCC in all 94 subjects from both cohorts of pts and controls. Protease biosensors were highly effective at differentiating between pts with HCC and healthy controls in both cohorts (cohort A AUC = 0.94 [CI 0.87-1] and cohort B AUC = 0.96 [CI 0.89-1]) (Figure). Importantly, the AUC remains above 0.94 even when naively applying a pre-trained classifier in one cohort to the other despite the differences in the disease etiology of each cohort. The most significant biosensors in HCC were cleaved by DPP4, Cathepsin C, MMP2 and KLK1.



Conclusion: In this study of two independently tested, diverse cohorts of patients with known HCC vs. healthy controls, Glympse's plasma liquid biopsy platform using protease biosensors was highly effective at detecting HCC, with AUCs above 0.94. In the future, this technology could be used in surveillance strategies for earlier, easier, and more accurate diagnosis of HCC.

SAT565

On treatment alpha-fetoprotein reductions predict immunotherapy efficiency in patients with hepatocellular carcinoma

Bernhard Scheiner[1,2], Katharina Pomej[1,2], Lorenz Balcar[1,2], Tobias Meischl[1,2], Christian Müller[1,2], Michael Trauner[1], Matthias Pinter[1,2]. *[1]Medical University of Vienna, Division of Gastroenterology and Hepatology, Department of Internal Medicine III, Vienna, Austria; [2]Medical University of Vienna, Liver Cancer (HCC) Study Group Vienna, Division of Gastroenterology and Hepatology, Department of Internal Medicine III, Vienna, Austria*
Email: bernhard.scheiner@meduniwien.ac.at

Background and aims: Immunotherapy with atezolizumab plus bevacizumab represents the new standard of care in systemic front-line treatment of hepatocellular carcinoma (HCC). Biomarkers to predict treatment success are an unmet need. An alpha-fetoprotein (AFP) decrease on treatment might identify patients with a favourable response to immunotherapy.
Method: Patients with HCC treated with PD- (L)1-based immunotherapy between June 2016 and October 2021 at the Medical University of Vienna were included. We investigated the impact of AFP response on radiological response (mRECIST 1.1) as well as time-to-progression (TTP), progression-free survival (PFS) and overall survival (OS). AFP response was defined as AFP decrease by ≥25% from baseline at week 6 or AFP within normal range at week 6 after immunotherapy initiation.
Results: Of 83 patients, follow-up AFP values at a median of 6.0 (IQR: 6.0–6.3) weeks after treatment initiation were available in 70 patients and only these patients were included in the final analysis. At baseline, AFP was abnormal in 49 (70%) patients (median: 144 (IQR: 6–1574) ng/ml). In total, 45 (64%) patients achieved an AFP response and this was associated with a significantly better radiological response (which was evaluable in 68 patients): complete/partial response (CR/PR): 38.1% vs. 9.1%, stable disease (SD): 42.9 vs. 27.3%, progressive disease (PD): 19% vs. 63.6% (p = 0.001), objective response rate (ORR): 38.1% vs. 9.1% (p = 0.014). AFP response (OR: 10.5 (IQR: 1.6–67.7), p = 0.014) remained an independent predictive parameter for ORR even after multivariable adjustment for baseline AFP ≥100 ng/ml, C-reactive protein (CRP) ≥1 mg/dL, Child-Pugh stage, ECOG PS >1, presence of macrovascular invasion or extrahepatic metastasis by binary logistic regression analysis. Patients achieving an AFP response also had an improved outcome: time-to-progression (TTP): 11.0 (95%CI: 9.8–12.2) vs. 2.5 (95%CI: 2.0–3.0) months (p = 0.007); progression-free survival (PFS): 10.4 (95%CI: 5.2–15.5) vs. 2.3 (95%CI: 1.9–2.7) months (p = 0.009); overall survival (OS): 21.8 (95% CI: 7.4–36.2) vs. 8.5 (95%CI: 0–23.9) months (p = 0.259).

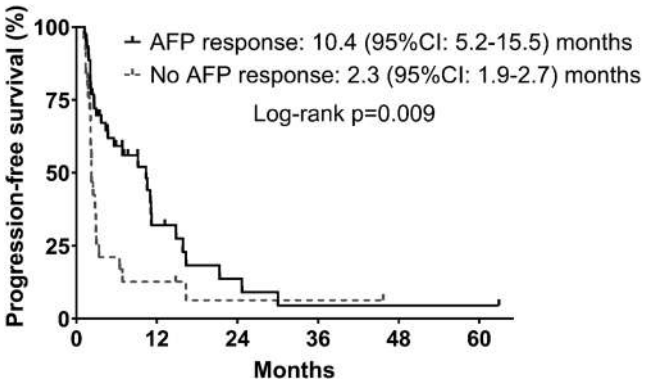


Figure: Comparison of progression-free survival between patients with versus without AFP response (as defined by an AFP decrease ≥25% or normal AFP values at week 6)

Conclusion: AFP decrease by ≥25% or normal AFP at week 6 after immunotherapy initiation identifies patients with favourable radiological response and survival.

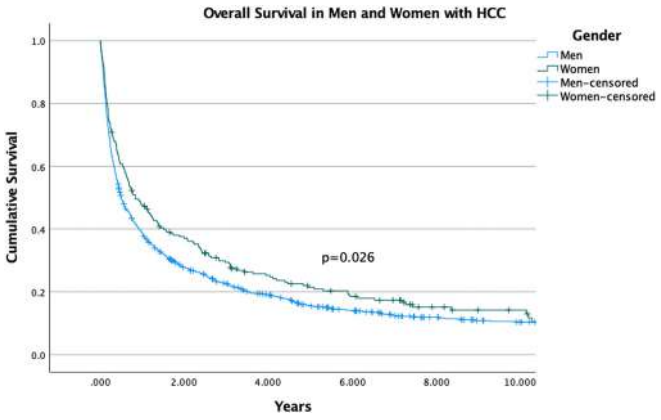
SAT566

Gender differences in hepatocellular carcinoma : is it all due to adherence to surveillance? A study of 1, 716 patients over 3 decades

Wei-Lun Liou[1], Terence Tan[1], Kaina Chen[1], Boon Bee George Goh[1], Pik Eu Jason Chang[1], Chee-Kiat Tan[1]. *[1]Singapore General Hospital, Department of Gastroenterology and Hepatology, Singapore*
Email: liouweilun@gmail.com

Background and aims: Hepatocellular carcinoma (HCC) is one of the commonest causes of cancer-related death worldwide. There is well-established gender disparity in the incidence of HCC, with men 4 times more common than women. Whether gender is an independent factor for HCC survival is debatable. We study the influence of gender on clinical characteristics of HCC and on survival.
Method: We have an ongoing HCC database since 1988 enrolling patients with HCC seen in our department. Clinical data were prospectively captured. We studied and compared demography, HCC characteristics and survival between men and women. Survival analysis was censored on 31 October 2015 with input from our National Registry of Deaths.
Results: There were 1, 716 HCC patients as of August 2021. 343 (20.0%) were women. Women were significantly older at HCC diagnosis (median 69 vs 62 years, p < 0.001). Women had a significantly higher incidence of non-viral liver disease (33.8% vs 24%, p < 0.001). In terms of specific aetiology, autoimmune liver disease was more common (2% vs 0.2%), and alcohol was less common (0.9% vs 5.8%) in women (both p < 0.001). More women were diagnosed via regular HCC surveillance (37.9% vs 29.6%, p = 0.003). Hence, women had less-advanced HCC at diagnosis as seen by higher frequency of single lesion (60.8% vs 52.7%, p < 0.001), smaller median tumour diameter (30 mm vs 39.5 mm, p = 0.038), lower frequency of portal vein tumour thrombus (19.4% vs 33.4%, p < 0.001) and less distant metastases (7.7% vs 11%, p = 0.043). Similarly,

significantly more women were in BCLC stages 0/A (39.7% vs 28.4%, p < 0.001). The overall median survival was significant better in women (10.1 vs 6.1 months, p = 0.003). When stratified by surveillance status, there was no significant gender difference in survival.



Conclusion: In this large cohort of Asian patients, women diagnosed with HCC were significantly more adherent to HCC surveillance and hence presented with less advanced HCC and had better overall survival than men. The gender difference in survival is likely due to women having better adherence with HCC surveillance.

SAT567

Non-alcoholic fatty liver disease and increased risk of incident primary liver tumours: a meta-analysis of observational cohort studies

Andrea Dalbeni[1], Alessandro Mantovani[2], Simone Conci[2], Tommaso Valigi[2], Alfredo Guglielmi[2], David Sacerdoti[2]. *[1]University of Verona, Medicine, Verona, Italy; [2]University of Verona, Verona, Italy*
Email: andrea.dalbeni@aovr.veneto.it

Background and aims: We performed a meta-analysis of cohort studies to quantify the magnitude of the association between non-alcoholic fatty liver disease (NAFLD) and risk of incident primary liver tumors, including hepatocellular carcinoma (HCC), cholangiocarcinoma (CC) and hepato-cholangiocarcinoma (HCC-CC).
Method: We systematically searched PubMed, Scopus and Web of Science databases from the inception date to 30 June 2021, using predefined keywords, to identify observational cohort studies conducted in individuals in whom NAFLD was diagnosed by imaging techniques, International Classification of Diseases codes or biopsy. Meta-analysis was performed using random-effects modelling.
Results: We included 9 cohort studies for a total of 9, 134, 982 middle-aged individuals (10.6% with NAFLD) and 7, 026 incident cases of primary liver tumors, over a median follow-up of 10 years. NAFLD was significantly associated with a nearly 2-fold increased risk of developing primary liver tumors (random-effects hazard ratio [HR] 2.07, 95% confidence interval [CI] 1.62–2.65; $I^2 = 97.2\%$). After stratifying the eligible cohort studies by country, we observed that among non-Asian individuals the presence of NAFLD was associated with an approximately 3-fold increased risk of developing primary liver tumors (random-effects HR 2.88, 95% CI 1.78–4.66; $I^2 = 97.2\%$), whereas such association was less strength amongst Asian individuals (random-effects HR 1.55, 95% CI 1.33–1.80; I2 = 79.6%). Regarding different types of primary liver tumors, NAFLD was associated with a 3.2-fold increased risk of developing HCC (random-effects HR 3.21, 95% CI 1.93–5.33; $I^2 = 96.7\%$), as well as with a 46% increased risk of developing CC or HCC-CC (random-effects HR 1.46, 95% CI 1.27–1.69; $I^2 = 80.7\%$). Sensitivity analyses did not substantially alter these findings. Funnel plot did not reveal any significant publication bias.
Conclusion: This meta-analysis confirms that NAFLD is associated with an increased risk of developing primary liver tumors (especially HCC) over a median follow-up of 10 years. Further research is required to elucidate the complex link between NAFLD and different types of primary liver tumors.

SAT568

Characterization of gut microbiota and exploration of potential predictive model for hepatocellular carcinoma microvascular invasion

Ningning Zhang[1], Zeyu Wang[1], Jiayu Lv[2], Yang Liu[1], Tian Liu[1], Shuwen Zhang[1], Wang Li[1], Lan Gong[3,4], Xiaodong Zhang[5], Emad El-Omar[3,4], Wei Lu[1]. *[1]Department of Hepatobiliary Oncology, Liver Cancer Center, Tianjin Medical University Cancer Institute and Hospital, National Clinical Research Center for Cancer, Key Laboratory of Cancer Prevention and Therapy, Tianjin Medical University, Tianjin, China; [2]Department of Hepatology, Tianjin Third Central Hospital, Tianjin, China; [3]Department of Medicine, University of New South Wales, Sydney, Australia; [4]Microbiome Research Centre, St George and Sutherland Clinical School, University of New South Wales, Sydney, Australia; [5]Department of Gastrointestinal Cancer Biology, Liver Cancer Center, Tianjin Medical University Cancer Institute and Hospital, National Clinical Research Center for Cancer, Key Laboratory of Cancer Prevention and Therapy, Tianjin Medical University, Tianjin, China*
Email: mail4luwei@163.com

Background and aims: The correlation between gut microbiota and microvascular invasion (MVI) in hepatocellular carcinoma (HCC) patients remains unclarified. Prediction of MVI through gut microbiota analysis of HCC patients would be of accurate, non-invasive and very convenient assessment. The aim of the present study was to investigate the characteristics of gut microbiota in HCC-MVI patients and establish a microbial prediction model of HCC-MVI based on microbiome study.
Method: Fecal samples were collected from 59 HCC patients (24 of the total with MVI disease) and 16 healthy controls, and further analyzed by 16S rRNA amplicon sequencing. Bioinformatics methods were used to analyze the obtained sequence data. The diagnostic performance of microbiome characteristics in predicting MVI was assessed by receiver operating characteristic (ROC) curves. The correlation between gut microbiota and tumor microenvironment (TME) in HCC-MVI group were further analyzed with Immunohistochemistry and immunofluorescence assay.
Results: A significant differentiation trend of microbiota composition and structure was observed between the HCC-MVI group and those without vascular invasion (HCC-NVI). Compared with HCC-NVI group and healthy controls, *Klebsiella*, *Proteobacteria*, *Prevotellaceae* and *Enterobacteriaceae* were significantly enriched, whereas *Firmicutes*, *Ruminococcus* and *Monoglobaceae* were significantly decreased in HCC-MVI fecal samples. *Klebsiella* was considered to be the key microbiome signature for HCC-MVI patients. The area under the curve of the established HCC-MVI microbial prediction model was 94.81% (95% confidence interval: 87.63%–100%). The percentage of M2 type tumor-associated macrophage (TAMs) was increased in HCC-MVI group compared with HCC-NVI group (p < 0.001). M2-type TAMs in TME was negatively correlated with Shannon and Simpson index of HCC-MVI gut microbiota (all p < 0.01). In addition, predicted KEGG pathways showed that the functional differences in metabolic pathways of microbiome varied with groups.

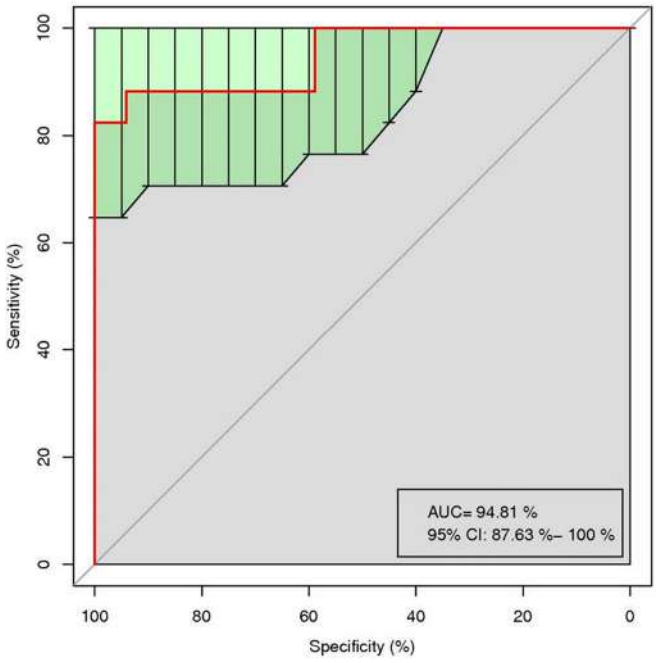


Figure: ROC curves built with twenty significant microbiotas for HCC-MVI predicting.

Conclusion: The results indicated that differences existed in the fecal microbiome of HCC-MVI patients and healthy controls, the prediction model of HCC-MVI established with certain gut bacteria signature may have potential to predict HCC-MVI and the characteristics of fecal microbiome in HCC patients may associate with TME, though future larger-sample studies are required to validate this supposition.

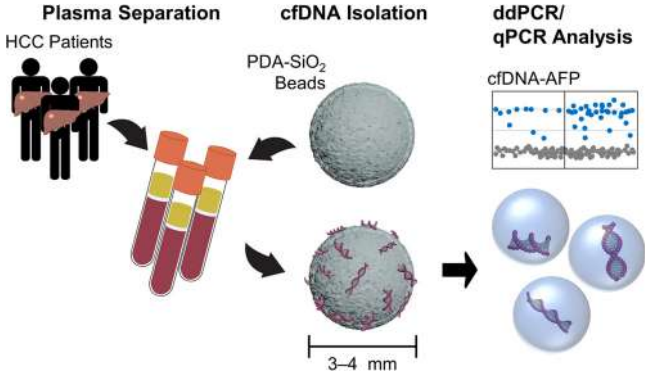
Machine learning algorithm based on dual screening for hepatocellular carcinoma using circulating cell-free DNA and cfDHCC scoring system

Taehee Lee[1,2], Piper A. Rawding[3], Jiyoon Bu[3,4], Sung Hee Hyun[5], Woo Sun Rou[6], Kim Seok Hyun[7,8], Byung Seok Lee[7,8], Luke J. Kubiatowicz[3], DaWon Kim[3,4], Seungpyo Hong[3,4,9], Hyuk Soo Eun[7,8]. *[1]Graduate School, Eulji University, Department of Senior Healthcare, Uijeongbu-si, Korea, Rep. of South; [2]Research Institute for Future Medical Science, Chungnam National University Sejong Hospital (CNUSH), Sejong, Korea, Rep. of South; [3]University of Wisconsin-Madison, Pharmaceutical Sciences Division, School of Pharmacy, Madison, United States; [4]University of Wisconsin-Madison, Wisconsin Center for NanoBioSystems (WisCNano), Madison, United States; [5]Department of Senior Healthcare, Graduate School, Eulji University, Uijeongbu-si, Korea, Rep. of South; [6]Chungnam National University Sejong Hospital (CNUSH), Department of Internal Medicine, Sejong, Korea, Rep. of South; [7]Chungnam National University School of Medicine, Department of Internal Medicine, Daejeon, Korea, Rep. of South; [8]Chungnam National University Hospital, Department of Internal Medicine, Daejeon, Korea, Rep. of South; [9]Yonsei Frontier Lab and Department of Pharmacy, Yonsei University, Seoul, Korea, Rep. of South*
Email: hyuksoo@cnu.ac.kr

Background and aims: Hepatocellular carcinoma is diagnosed clinically by computed tomography or magnetic resonance imaging with or without level of serum AFP. However, there is a problem of high cost and radiation hazard to perform the above tests every time for diagnosis. While the current gold standard for diagnosing HCC is tumor biopsies, it only provides a limited snapshot of tumors and vary in sensitivity due to difficulties in identifying lesions. Therefore, we designed a non-invasive, low cost liquid biopsy platform based on the analysis of circulating cell-free DNA (cfDNA) for the early diagnosis and evaluation of prognosis for HCC.

Method: Our platform was consisting of the polydopamine-silica hybrids alginate beads, in order to enhance the cfDNA adsorption. Overall, 249 individuals were enrolled in this study, including 152 patients with HCC, 43 patients with liver cirrhosis (LC), 24 patients with alcoholic liver disease (LA), and 30 healthy individuals (HD). We integrated the expression profiles of plasma cfDNA and cfDNA-AFP to establish a cfDNA score (cfD_{HCC}) specific to HCC patients using a series of machine learning techniques, including the *k*-means cluster analysis, elbow method, and principal component analysis.

Results: Plasma cfDNA levels were the highest among patients with HCC (median: 0.25 ng/μL), followed by LC (0.18 ng/μL), LA (0.11 ng/μL), and HD (0.06 ng/μL), p value <0.001. The AUROC of plasma cfDNA levels was 0.713 ($p = 0.001$), 0.592 ($p = 0.066$), and 0.805 ($p < 0.001$) for detecting HCC from LC, LA, and HD groups, respectively. The AUROC of cfDNA-AFP to differentiate HCC from LC, LA, and HD were 0.861 ($p < 0.001$), 0.744 ($p < 0.001$), and 0.971 ($p < 0.001$), respectively. In TACE-treated HCC patients, in the evaluation of overall survival using the cfD_{HCC} score, the group with the high cfD_{HCC} score showed a trend of poorer prognosis than the group with the low cfD_{HCC} score (47.7 ± 5.6 vs. 65.7 ± 4.4 months, $p = 0.077$). Moreover, the group with the high cfD_{HCC} score showed a poorer prognosis than the group with the low cfD_{HCC} score, when the cfD_{HCC} score was used in the evaluation of recurrence-free survival for recurrence with tumor multifocality (23.2 ± 5.5 vs. 54.0 ± 4.6 months, $p = 0.001$)) or marginal recurrence (27.4 ± 6.3 vs. 41.1 ± 6.3 months, $p = 0.061$) in TACE-treated HCC patients.



Conclusion: Our novel platform showed high diagnostic and prognostic capabilities. Our results presented herein indicate that cfDNA using polydopamine-silica hybrids alginate beads could be a promising tools for HCC diagnosis and evaluation of prognosis. It could be potentially utilized in the clinic as a reliable system for identifying HCC in early stages, guiding therapeutic decisions, and improving overall survival of HCC patients.

SAT570

Sarcopenia impairs survival and treatment efficacy in patients with hepatocellular carcinoma undergoing immunotherapy

Bernhard Scheiner[1,2], Katharina Lampichler[3], Katharina Pomej[1,2], Lucian Beer[3], Lorenz Balcar[1,2], Tobias Meischl[1,2], Christian Müller[1,2], Michael Trauner[1], Martina Scharitzer[3], Dietmar Tamandl[3], Matthias Pinter[1,2]. *[1]Medical University of Vienna, Division of Gastroenterology and Hepatology, Department of Internal Medicine III, Vienna, Austria; [2]Medical University of Vienna, Liver Cancer (HCC) Study Group Vienna, Division of Gastroenterology and Hepatology, Department of Internal Medicine III, Vienna, Austria; [3]Medical University of Vienna, Department of Biomedical Imaging and Image-Guided Therapy, Vienna, Austria*
Email: bernhard.scheiner@meduniwien.ac.at

Background and aims: Sarcopenia is a common problem in patients with cirrhosis and hepatocellular carcinoma (HCC) and frequently

impairs the clinical course of these patients. The impact of baseline sarcopenia on survival and treatment efficacy in HCC patients undergoing immunotherapy has yet to be evaluated.

Method: Patients with HCC treated with PD- (L)1-based immunotherapy between June 2016 and October 2021 at the Medical University of Vienna were included. Sarcopenia was defined by transversal psoas muscle thickness (TPMT) at <12 mm/m in men and <8 mm/m in women at the level of the third lumbar vertebrae using cross-sectional imaging (CT/MRI) at baseline. We investigated the impact of sarcopenia on radiological response (mRECIST 1.1) as well as time-to-progression (TTP), progression-free survival (PFS) and overall survival (OS).

Results: TPMT was evaluated at a median of 20 (IQR 0–38) days prior to first immunotherapy infusion and sarcopenia was present in 37/83 (45%) patients. Sarcopenia at baseline was much more prevalent in men (53%) compared to women (19%, p = 0.006) and the presence of sarcopenia was associated with a worse radiological response (which was evaluable in 68 patients): complete/partial response (CR/PR): 11.5% vs. 35.7%, stable disease (SD): 30.8% vs. 40.5, progressive disease (PD): 57.7% vs. 23.8% (p = 0.011).

Patients with sarcopenia also had a significantly worse outcome (evaluable in 81 patients due to early loss-of-follow-up in 2 patients): time-to-progression (TTP): 2.5 (95%CI: 1.9–3.1) vs. 10.4 (95%CI: 8.7–12.1) months (p = 0.010); progression-free survival (PFS): 2.3 (95%CI: 1.8–2.7) vs. 9.2 (95%CI: 2.5–15.9) months (p = 0.002); overall survival (OS): 5.3 (95%CI: 2.5–8.0) vs. 22.6 (95%CI: 8.6–36.6) months (p = 0.012). Even after multivariable adjustment for baseline Child-Pugh stage, ECOG PS >1, presence of macrovascular invasion or extrahepatic metastasis and baseline AFP levels (IU/ml), sarcopenia (aHR: 2.24, 95%CI: 1.17–4.31, p = 0.016) remained an independent predictor of survival.

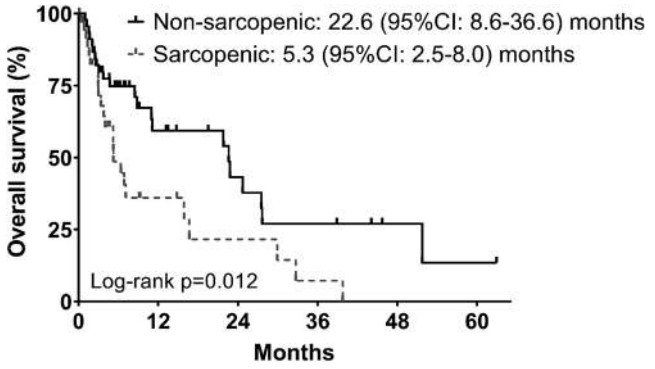


Figure: Comparison of overall survival (OS) between sarcopenic and non-sarcopenic patients prior to initiation of immunotherapy

Conclusion: The presence of sarcopenia as determined by TPMT measurement at the level of the third lumbar vertebrae prior to treatment initiation significantly impairs survival and treatment efficacy in HCC patients undergoing immunotherapy.

SAT571

Comparable efficacy between on-going vs. initiation of antiviral therapy at the time of curative treatment for hepatitis B virus-related hepatocellular carcinoma

Mi Na Kim[1], Beom Kyung Kim[2], Su Jong Yu[3], Seung Up Kim[2]. *[1]CHA Bundang Medical Center, CHA University School of Medicine, Department of Internal Medicine, Seongnam, Korea, Rep. of South; [2]Yonsei University College of Medicine, Department of Internal Medicine, Seoul, Korea, Rep. of South; [3]Seoul National University College of Medicine, Department of Internal Medicine, Seoul, Korea, Rep. of South*
Email: ksukorea@yuhs.ac

Background and aims: Antiviral therapy (AVT) should be applied for patients with newly-diagnosed hepatocellular carcinoma (HCC), if HBV DNA is detectable. We compared the long-term prognosis between patients with on-going AVT and those who initiated AVT at the time of curative treatments for HBV-related HCC.

Method: Between 2013 and 2018, patients with HBV-related HCC who received curative treatments were considered eligible. Primary outcomes were HCC recurrence and overall mortality.

Results: In the study population (n = 545), the cumulative probabilities of HCC recurrence at 1, 3, and 5 years was statistically similar between patients in on-going AVT group (oAVT group, 9.9%, 29.4%, and 39.5%, respectively) and those in the initiation AVT group (iAVT group, 13.1%, 27.8%, and 40.2%, respectively) (p = 0.670 by log-rank test). The cumulative probabilities of overall mortality was also comparable between the 2 groups (4.2%, 10.8%, and 10.8%, respectively, in oAVT group vs. 1.5%, 7.1%, and 10.8%, respectively, in iAVT group) (p = 0.381 by log-rank test). The risk of the early (<2 years) and late (≥2 years) recurrence was statistically similar between the 2 groups (all p > 0.05 by log-rank tests). Propensity score matching and inverse probability of treatment weighting analysis also yielded a similar risk of HCC recurrence and overall mortality between the 2 groups (all p > 0.05 by log-rank tests).

Conclusion: The long-term prognosis of patients who received curative treatments for newly diagnosed HBV-related HCC was comparable regardless of the timing of AVT initiation.

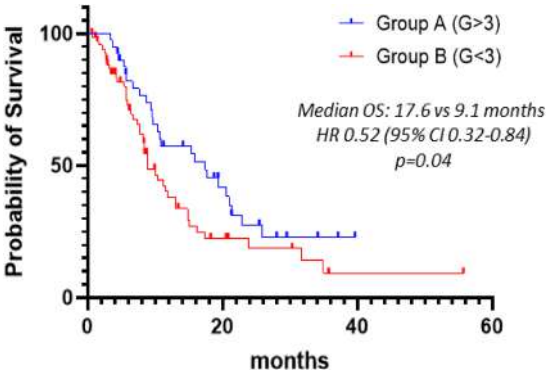
Email: antonella.cammarota@humanitas.it

Background and aims: Immune checkpoint inhibitors (ICIs), as monotherapy or in combinations, have broadened the treatment landscape of unresectable hepatocellular carcinoma (HCC), either in first-line or in further lines. The prognostic role of multikinase inhibitors-induced adverse events has been proven in HCC patients (pts) and the development of immune-related adverse events (irAEs) has been associated with improved outcomes in other cancer types, such as melanoma and non-small cell lung cancer. Despite initial evidence of correlation, whether or not irAEs can predict outcomes in unresectable HCC still needs to be confirmed. In this retrospective analysis we aimed to assess the association between grade (G) = 3 irAEs and the efficacy outcomes, namely overall response rate (ORR), overall survival (OS), progression-free survival (PFS) among pts with unresectable HCC treated with ICIs.
Method: ORRs were calculated as the sum of complete and partial responses per RECIST 1.1 and compared using chi-squared test. OS and PFS were estimated using the Kaplan-Meier method and survival curves were compared using log-rank test. Statistical significance was set at p = 0.05 and all reported p values are two-sided.
Results: From August 2015 to March 2021, 110 pts with unresectable HCC received ICIs within clinical trials available at our Institution. A total of 58 pts (52.7%) received ICIs as first-line systemic treatment and 36 pts (32.7%) received single-agent ICI. Overall, 38 pts (group A) developed G ≥3 toxicities whereas 72 pts (group B) experienced no or G <3 toxicities. The most common G ≥3 AEs were hepatic (28.9%), dermatological (13.2%) and gastrointestinal (7.9%) toxicities. ORR was 18.4% in group A and 11.1% in group B (p = 0.96). Median PFS was 6.9 and 3.9 months (HR 0.66, 95% CI 0.43–0.99, p = 0.04) and median OS was 17.6 and 9.1 months (HR 0.52, 95% CI 0.32–0.84, p = 0.04) in group A and B, respectively (Figure 1).



Conclusion: Despite the small sample size and the retrospective nature, our analysis suggests that the development of G ≥3 irAEs might correlate with survival outcomes in unresectable HCC. Prospective analyses are needed to confirm these results, hopefully providing further insights on possible predictive biomarkers.

SAT573

Multistage epigenome-wide association study identifies highly accurate epigenomic signatures in association with hepatocellular carcinoma: The HCC epigenome score

Email: abderrahim.oussalah@univ-lorraine.fr

Background and aims: Hepatocellular carcinoma (HCC) represents the most common primary malignant tumor of the liver. Epigenomic alterations are a common hallmark of human cancer. We recently developed the smoothing method for calculating and visualizing data from epigenome-wide association studies (EWASs) and demonstrated its utility for identifying highly accurate epigenomic signatures in DNA methylation analyses (patent pending, EP21306458). The primary aim was to look for significant epigenomic signatures associated with HCC through a multistage EWAS approach.
Method: We conducted four-step epigenome association studies of HCC in 357 cases and 239 controls originating from four independent cohorts. In stage #1 (derivation study), we analyzed the epigenome-wide DNA methylome profiles generated from 21 HCC and 100 non-HCC liver tissue samples using the Infinium Human Methylation 450 K BeadChip. We derived an epigenomic score based on the top significant CpG signatures, the "HCC Epigenome Score." We assessed the diagnostic accuracy of the "HCC Epigenome Score" in two replication cohorts using HCC and non-HCC tissue samples (stage #2: 26 vs. 83; stage #3: 306 vs. 50, respectively). In stage #4, we performed in silico epigenome association study using epigenome-wide DNA methylome profiles generated from 10 plasma samples of patients with (n = 4) or without HCC (n = 6).
Results: The epigenome-wide association study highlighted 105 CpG probes in 13 top loci (CpG islands) associated with the HCC phenotype (*RUNX3*, *KCNA3*, *DNM3*, *FOXL2*/*FOXL2NB*, *SHISA3*, *H3C7*, *BVES*, *EYA4*, *CELF2*, *MIR129-2*, *PRKCB*, *SEPT9*, and *LPAR2*) (Figure**, panel A**) (patent pending, EP21306459). In hierarchical clustering analysis, the 105 CpG probes were highly discriminant between HCC and non-HCC samples (Figure**, panel B**). In ROC analysis, the HCC Epigenome Score had an AUROC of 0.960 (95% CI, 0.788–100; p < 0.0001) for detecting HCC samples. In replication studies on tissue samples (stages #2 and #3), all the 13 loci were significantly associated with the HCC phenotype. Random effect meta-analysis confirmed the significance of the 13 top loci. In ROC analysis that used individual-level data, the HCC Epigenome score had an AUROC of 0.955 (95% CI, 0.935–0.969; p < 0.0001) for detecting HCC. According to the underlying chronic liver disease, the HCC Epigenome score had AUROCs of 0.992 (95% CI, 0.968–0.998; p < 0.0001); 0.982 (95% CI, 0.935–0.995; p < 0.0001); 0.950 (95% CI, 0.671–1.000; P < 0.0001); 0.908 (95% CI, 0.845–0.952; p < 0.0001), and 0.952 (95% CI, 0.902–1.000; p < 0.0001) for HCV, HBV, NASH, alcohol, and other etiologies, respectively. Using plasma circulating cell-free DNA (stage #4), the HCC epigenome score discriminated between HCC and non-HCC patients.
Conclusion: Using four independent cohorts, we derived and validated the HCC epigenome score that showed high diagnostic accuracy for diagnosing HCC.

Interleukin-6 as a new marker for advanced sarcopenic HCC patients with different cirrhotic aetiology

Andrea Dalbeni[1], Filippo Cattazzo[1], Antonio Vella[1], Giovanna Zanoni[1], Michele Bevilacqua[1], Jasmin Kassem[1], Anna Mantovani[1], Simone Conci[1], Tommaso Campagnaro[1], Alfredo Guglielmi[1], Michele Milella[1], David Sacerdoti[1]. [1]*University of Verona, Medicine, Verona, Italy*
Email: andrea.dalbeni@aovr.veneto.it

Background and aims: Hepatocellular carcinoma (HCC) is a major cause of liver cancer-related death worldwide. It usually occurs in cirrhosis with different aetiopathogenesis. Serum IL-6 is a proinflammatory cytokine that increases considerably in pathological settings such as trauma, inflammation and neoplasia. Based on preclinical data in HCC, IL-6 signalling leads to tumour progression or local recurrence. Aim of our study is to clarify if the levels of IL-6 are associated with HCC progression and its different aetiopathogenesis in cirrhotic patients.
Method: 111 consecutive HCC cirrhotic patients (with different stages and aetiopathogenesis) were enrolled and compared with 36 cirrhotic patients without HCC. Patients were divided according to Child Pugh (CP) class and severity of HCC disease (BCLC). The major anthropometric and biochemical parameters, particularly serum IL-6, were collected. The degree of sarcopenia was also considerd using TC dedicated software.
Results: IL-6 levels were different between advanced and not advanced HCC ($p = 0.01$), while no difference in IL-6 levels was documented in CP-C with and without HCC; however, IL-6 levels were higher in advanced HCC (OR 4.58 CI: 1.19–17.55; $p < 0.001$). IL-6 levels were different also between different ethiologies of cirrhosis; in particular, no differences in viral and metabolic cirrhosis, low levels ($p < 0.001$) in alcoholic and higher in autoimmune HCC or in combination of different aetiologies. IL-6 correlated also with sarcopenia severity ($p < 0.001$) especially in advanced HCC patients ($p < 0.001$). In no HCC CP-C patients, IL 6 was not correlated with sarcopenia. In linear regression IL-6 was correlated with AFP ($p < 0$, 001, $r = 0.57$). In multivariate analysis IL-6 was linked with aetiopathogenesis, cancer progression, sarcopenia, CP and lymphocytes count.
Conclusion: These data suggest that IL-6 is higher in inflammatory states (like cirrhosis with CP-C) but it has a closer relation with advanced HCC and could be a marker for the disease itself. IL-6 seems to be also a predictor of sarcopenia especially in advanced HCC patients. Also, cirrhosis aetiopathogenesis has shown different IL-6 levels, documenting a different inflammatory setting. IL-6 could be a new marker to classify advanced HCC and a possible future drug target considering the different cirrhotic aetiopathogenesis.

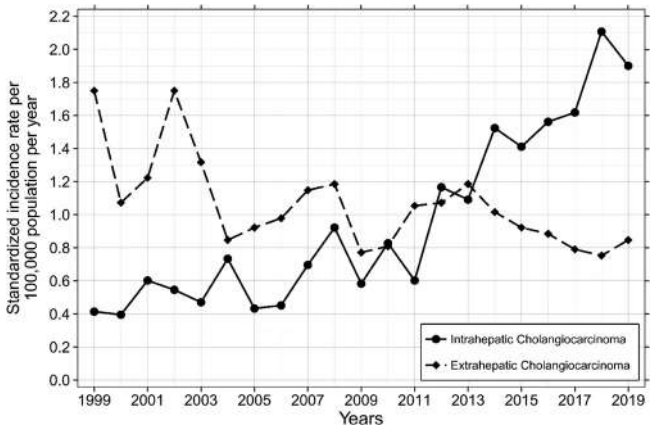
Time-trends in cholangiocarcinoma incidence-a danish nationwide cohort study

Morten Daniel Jensen[1], Joe West[2,3], Frank Viborg Mortensen[4], Peter Jepsen[1]. [1]*Aarhus University Hospital, Department of Hepatology and Gastroenterology, Aarhus N, Denmark;* [2]*University of Nottingham, Lifespan and Population Health, School of Medicine, NG5 1Pb, United Kingdom;* [3]*Nottingham University Hospitals NHS Trust and the University of Nottingham, NIHR Nottingham Biomedical Research Centre (BRC), Nottingham, United Kingdom;* [4]*Aarhus University Hospital, Department of Surgical Gastroenterology, Aarhus N, Denmark*
Email: moje@clin.au.dk

Background and aims: Cholangiocarcinoma (CCA) is a usually fatal primary liver cancer originating from the biliary epithelium. Extensive surgery is the only curative treatment, and adjuvant chemo- and/or radiotherapy is standard. Up-to-date data on incidence are crucial for our understanding of the disease and for designing trials of interventions. Therefore, we set out to examine incidence of CCA in a nationwide Danish cohort.
Method: We included all Danish patients, N = 2600, with an ICD-10 diagnosis code of CCA (intrahepatic [iCCA]: C221; extrahepatic [eCCA]: C240) in the Danish Cancer Registry, between 1999-2019. We computed the standardized annual incidence rates of CCA in the Danish population using publicly available data on population demographics and standardized to the Danish population in 1999. We estimated the annual change in CCA incidence using a Poisson regression model.
Results: The standardized incidence rate (SIR) for iCCA increased from 0.41 (95% confidence interval [CI] 0.26–0.63) in 1999 to 1.90 (95% CI 1.55–2.31) in 2019 (Incidence rate ratio [IRR]: 4.59 [95% CI 2.89–7.28]), while the SIR for eCCA decreased from 1.75 (95% CI 1.41–2.14) in 1999 to 0.85 (95% CI 0.62–1.13) in 2019 (IRR: 0.48 [95% CI 0.34–0.69]). The overall SIR of total CCA (iCCA and eCCA) was 1.89 (95% CI 1.78–2.01) for men and 2.13 (95% CI 2.02–2.26) for women, and the trend of increasing IR for iCCA and decreasing IR for eCCA was observed in both sexes. The SIR of total CCA increased from 2.16 (95% CI 1.79–2.60) in 1999 to 2.79 (95% CI 2.35–3.27) in 2019, yielding an IRR of 1.29 (95% CI 1.01–1.64) and an annual increase of 2.51% (95% CI 1.81–3.22).



Conclusion: The incidence of CCA has increased since 1999, driven by a 4-fold increase in incidence of intrahepatic CCA while incidence of extrahepatic CCA has decreased by half. The reasons for this pattern are unclear but are likely due to changing environmental exposures over time.

SAT576

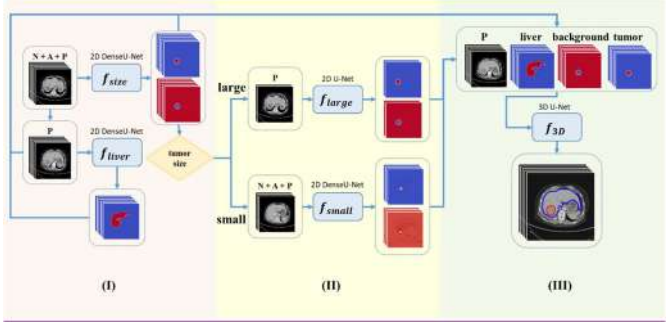
A novel hierarchical fusion strategy of deep learning networks to detect hepatocellular carcinoma from dynamic computed tomography images

I-Cheng Lee[1], Yung-Ping Tsai[2], Rheun-Chuan Lee[1], Shinn-Ying Ho[2], Yi-Hsiang Huang[1]. [1]*Taipei Veterans General Hospital, Taiwan;* [2]*National Yang Ming Chiao Tung University, Institute of Bioinformatics and Systems Biology, Hsinchu, Taiwan*
Email: iclee@vghtpe.gov.tw

Background and aims: Automatic segmentation of hepatocellular carcinoma (HCC) on computed tomography (CT) scans is in urgent need to assist diagnosis and radiomics analysis. Most existing methods including deep learning for HCC segmentation used single-phase CT images or from small datasets. This study aimed develop a deep learning based network to detect HCC using a large dataset of dynamic CT images.
Method: Dynamic CT images of 595 patients with HCC before resection or radiofrequency ablation from Taipei Veterans General Hospital, Taiwan were used. Tumors in triple phase CT images, including non-contrast, arterial and portal venous phases, were labeled by radiologists. Patients were randomly divided into training, validation and test sets in a ratio of 5:2:3, respectively. The proposed

hierarchical fusion strategy of deep learning networks (HFS-Net) consists of three stages based on U-Net and DenseU-Net. The first stage segments tumors in a slice and estimates the tumor size. The second stage uses customized networks for segmenting small and large tumors adaptively. The third stage integrates the outcomes of the first two stages and uses a 3D U-Net to segment 3D liver tumors. Global dice, sensitivity, precision and F1 score were used to measure the performance of HFS-Net model.

Results: The 2D DenseU-Net using triple phase images was more effective for segmenting small tumors, whereas the 2D U-Net using portal venous phase images was more effective for segmenting large tumors. The HFS-Net performed better, compared with the single-strategy deep learning model in segmenting small and large tumors. In the test set, the HFS-Net model achieved good performance in identifying HCC on dynamic CT images, with global dice of 82.8%. The overall sensitivity, precision and F1 score were 84.3%, 75.7% and 0.796 per slice, respectively, and 92.2%, 93.2% and 0.927 per patient, respectively. The sensitivity in tumors <2 cm, 2–5 cm and >5 cm were 57%, 79.2% and 89.5% per slice, respectively, and 72.7%, 93.8% and 100% per patient, respectively.



Conclusion: The HFS-Net model achieved good performance in the detection and segmentation of HCC from dynamic CT images. Automatic 3D tumor segmentation from dynamic CT scans using HFS-Net can support radiologic diagnosis and facilitate automatic radiomics analysis.

SAT577

Changing global epidemiology of liver cancer from 1990 to 2019: NASH is the fastest growing cause of liver cancer

Daniel Huang[1,2], Amit Singal[3], Yuko Kono[1], Hashem El-Serag[4], Rohit Loomba[1]. *[1]University of California San Diego, La Jolla, United States; [2]Yong Loo Lin School of Medicine, Singapore, Singapore; [3]UT Southwestern Medical Center, Dallas, United States; [4]Baylor College of Medicine, Houston, United States*
Email: roloomba@ucsd.edu

Background and aims: The major etiologies for liver cancer are hepatitis B virus (HBV), hepatitis C virus (HCV), alcohol, and non-alcoholic steatohepatitis (NASH). Over the last three decades, there have been changes in the etiology and burden of liver cancer due to increasing alcohol consumption, rising obesity rates and advances in prevention and treatment of HBV and HCV. We assessed the temporal trends in the incidence, mortality rates, disability-adjusted life-years (DALYs) secondary to liver cancer, and the contributions of various liver disease etiologies.

Method: We estimated the annual frequencies and age-standardized rates (ASRs) of liver cancer incidence, death and DALYs, from 1990 to 2019 by country, region and etiology using data obtained from the 2019 Global Burden of Disease study.

Results: In 2019 globally, there were 534, 000 incident cases, 485, 000 deaths, and 12.5 million DALYs due to liver cancer. Between 1990 and 2019, there was a 43% increase in the frequency of incident cases of liver cancer and a 33% increase in liver cancer deaths. However, the incidence ASR fell from 7.0 per 100, 000 in 1990 to 6.9 per 100, 000 in 2019, and the death ASR fell from 6.8 per 100, 000 to 6.3 per 100, 000. In 2019, the highest frequency of deaths occurred in the Western Pacific (52%), followed by South-East Asia (15%), Europe (13%), the Americas (10%), the Eastern Mediterranean region (6%) and Africa (4%). The annual percentage change of the death ASRs by country between 1990 and 2019 is shown in Figure 1. The greatest rise in death ASRs occurred in the Americas (annual percentage change [APC]: 1.15%), followed by Europe (APC: 0.71%) and South-East Asia (APC 0.64%). DALYs increased by 175% in the Americas, 131% in the

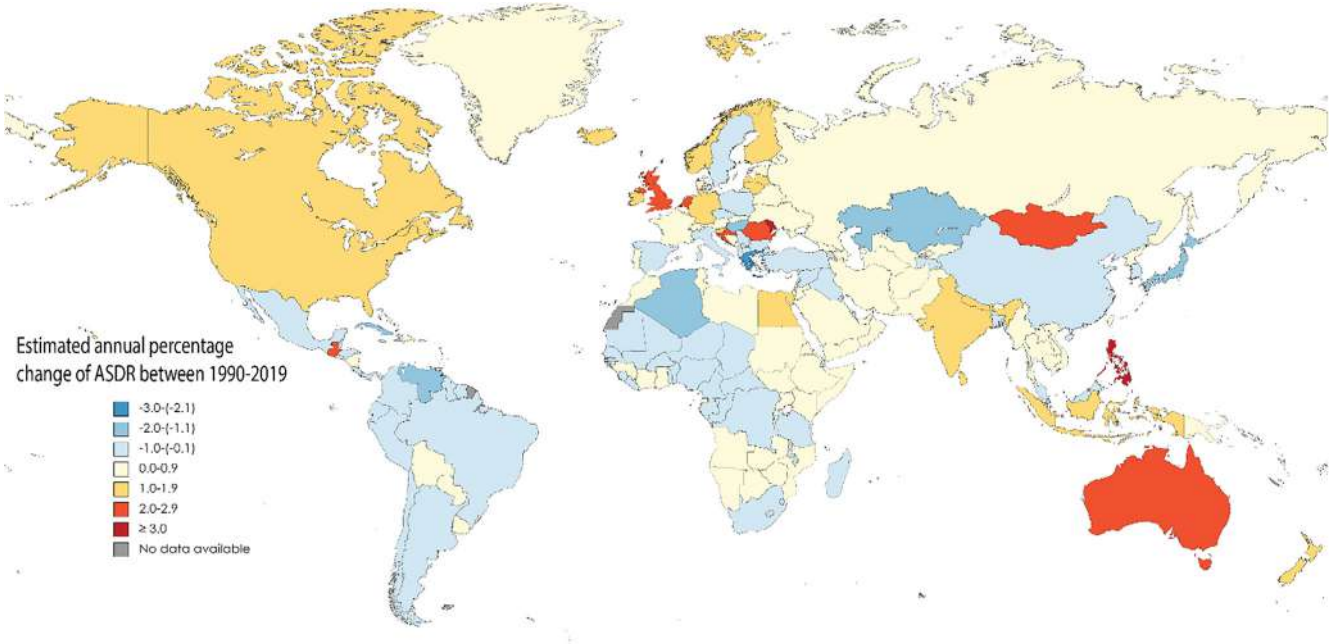


Figure: (abstract: SAT577): Annual percentage change of the age standardized death rate by country, between 1990 and 2019.

Eastern Mediterranean region and 114% in South-East Asia. HBV was the top cause of global liver cancer deaths (40%) in 2019, followed by HCV (29%) and alcohol (19%). NASH (APC: 0.35%) and alcohol (APC: 0.31%) had the fastest growing death ASRs between 1990 and 2019, while HCV grew at a slower rate (APC: 0.16%) and HBV declined (APC – 0.30%).
Conclusion: While the age-adjusted incidence and mortality rates have declined, the frequency of new cases, deaths and DALYs due to liver cancer has increased substantially between 1990 and 2019. The greatest rise in age adjusted liver cancer deaths occurred in the Americas and Europe and were driven by NASH and alcohol. Urgent measures are required to tackle the growing threat of NASH and alcohol-associated liver cancer.

SAT578

Liver resection for single large hepatocellular carcinoma: a prognostic factors study

Giuliana Amaddeo[1], Vincent Nguyen-Khac[1], Rami Rhaiem[2], Vincent Leroy[1], Helene Regnault[1], Raffaele Brustia[1], Alexis Laurent[1], Françoise Roudot-Thoraval[1], Daniele Sommacale[1]. *[1]Henri-Mondor University Hospital, Créteil, France; [2]Hospital Robert Debré, Reims, France*
Email: giuliana.amaddeo@aphp.fr

Background and aims: Liver resection is the only curative therapeutic option for large hepatocellular carcinoma (>5 cm), but survival is less good than in smaller tumors mostly because of the high recurrence rate. There is currently no proper tool for relapse risk stratification. We investigated for prognostic factors before and after hepatectomy for a single large HCC.
Method: We retrospectively identified 119 patients who underwent liver resection for a single large HCC in 2 tertiary care French centers, and collected pre and post-operative clinical, biological and radiological features. The primary outcome was overall survival at 5 years. Secondary outcomes were recurrence-free survival at 5 years, and prognostic factors for recurrence.
Results: 84% of the patients were male, and the mean age was 66 years old (58–74). 39 (33%) had Child-Pugh A cirrhosis, and mean Model for End-Stage Liver disease score was 6 (6–6). Etiology of liver disease was predominantly alcohol-related (48%), followed by non-alcoholic steatohepatitis (22%), hepatitis B (18%) and C ((10%). Mean tumor size was 70 mm (55–110). Median overall survival was 72.5 months (IC 95% : 56.2–88.7), and five-year overall survival was 55.1 ± 5.5%. The median recurrence-free survival was 26.6 months (IC95% : 16.0–37.1), and five-year recurrence-free survival was 37.8 ± 5%. In multivariate analysis, pre-operative prognostic factors of recurrence were baseline AFp > 7 ng/ml ($p < 0.001$), portal invasion on imagery ($p = 0.003$) and cirrhosis ($p = 0.020$). With these factors, we obtained a simple recurrence-risk scoring system that classified 3 groups with different disease-free survival medians ($p < 0.001$) : no risk factor (65 months), 1 risk factor (36 months), ≥2 risk factors (8.9 months). After liver resection, the presence of satellite nodules was the only significant predictive factor on a multivariate analysis. Adding this value to our pre-operative score, we obtained a pre- and post-operative score that was able to differentiate 4 groups with significantly different disease-free survival medians.
Conclusion: Liver resection is the only curative option for large HCC and we confirmed that survival can be satisfying in experienced centers. Recurrence is the main issue of surgery, and we proposed a simple pre-operative score that could help identifying patients with the most worrying prognosis, possible candidates for combining therapy.

SAT579

Characterization and clinical correlation of the immune contexture in intrahepatic cholangiocarcinoma using multiplex immunohistochemistry

Simon Peter[1], Valery Volk[2], Charlotte Hoffmann[1], Melanie Bathon[1], Benjamin Goeppert[3], Thomas Longerich[3], Thomas Albrecht[3], Tanja Reineke-Plaaß[4], Friedrich Feuerhake[2], Arndt Vogel[1], Anna Saborowski[1]. *[1]Medizinische Hoschule Hannover, Gastroenterologie, Hepatologie und Endokrinologie, Hannover, Germany; [2]Medizinische Hoschule Hannover, Institut für Pathologie, Schwerpunkt Neuropathologie, Hannover, Germany; [3]Universitätsklinikum Heidelberg, Pathologisches Institut, Heidelberg, Germany; [4]Medizinische Hoschule Hannover, Institut für Pathologie, Germany*
Email: saborowski.anna@mh-hannover.de

Background and aims: Immune checkpoint blockade inhibitors that specifically modify the programmed cell death protein 1/-ligand 1 (PD-1/PD-L1) signaling pathway have been approved for the treatment of various solid cancers, frequently in conjunction with PD-L1 based companion diagnostics. In light of the positive results from the recent TOPAZ-1 trial, a better understanding of the biological behaviour and immune contexture of biliary tumours is prerequisite for a more precise estimation of prognosis and response to immunomodulatory cancer therapies. Using multiplex immunohistochemistry, we set out to spatially resolve and clinically correlate the immune infiltrates, and to delineate the impact of biopsy "site" on established PD-L1 based scoring systems in intrahepatic cholangiocarcinomas (iCCA).
Method: FFPE tissues from 141 resected and clinically annotated iCCAs were stained using a multiplex immunohistochemistry platform (Phenoptics system, Akoya Bioscience) for the following markers: CD4, CD8, CD20, CD68, PD-L1 and pancytoceratin mix AE1/3.
Results: Morphological heterogeneity of resected human iCCA correlated with marked differences in terms of both immune infiltration and PD-L1 expression. Densities of immune infiltrates and PD-L1 positive cells were highest in stroma-rich tumors, but were not influenced by large vs small duct morphology. In addition, we observed a marked intratumoral heterogeneity for immune cell distribution and PD-L1 expression, with highest densities in the tumor margin. Comparative analysis with traditional semiquantitative evaluation methods for determination of PD-L1 signal revealed a profound variability, dependent on which score and tumor area was considered.
Further analyses indicated a favorable prognostic value of tertiary lymphoid structures (TLS). TLS were not only associated with a higher density of diffusely distributed B cells in the tumor but also with a statistically significant enrichment of T cells in spatial proximity to PD-L1 positive macrophages. Of note, PD-L1 expression was not confined to tumor cells and macrophages, but was also evident on a subset of T cells. Similar to PD-L1 positive macrophages, PD-L1 positive T cells were more likely to have not only another but also overall more T cells in a biologically relevant radius around them than their PD-L1 negative counterparts.
Conclusion: Despite a marked inter- as well as intratumoral heterogeneity of immune infiltrates in iCCA, our analysis points towards the existence of recurrent patterns. We delineate the prognostic value of TLS, and suggest a functionally relevant interaction of T cells with PD-L1 positive macrophages and tumor cells. In addition, we posit that annotated PD-L1 based scoring systems will be required in order to serve as an adequate translationally relevant marker, especially in the context of immunotherapy clinical trials.

Deep view on HCC gene signatures and their comparison with other cancers

Yuquan Qian[1], Timo Itzel[1,2], Matthias Ebert[1,3], Andreas Teufel[1,2,3].
[1]*Medical Faculty Mannheim, University of Heidelberg, Department of Medicine II, Mannheim, Germany;* [2]*Medical Faculty Mannheim, University of Heidelberg, Division of Hepatology, Division of Bioinformatics, Department of Medicine II, Mannheim, Germany;* [3]*Medical Faculty Mannheim, University of Heidelberg, Clinical Cooperation Unit Healthy Metabolism, Center for Preventive Medicine and Digital Health Baden-Württemberg, Mannheim, Germany*
Email: andreas.teufel@medma.uni-heidelberg.de

Background and aims: Throughout the past two decades, numerous HCC-dependent gene expression signatures have been published, but none of them made it into clinical practice. Setting up a comparative transcriptomics profiling approach, we therefore explored the specificity of these signatures to HCC as this may be a critical with respect to clinical usage.
Method: From the existing publications, we collected HCC gene signatures and evaluate them in independent genome wide gene expression profiles of patients suffering from HCC. Evaluations were performed using four different (commercial and non-commercial) gene expression profiles, particularly a modified version of the ProfileChaser, Oncomine Premium, GENEVA, and SigCom LINCS for assigning similar pre-analyzed profiles to our signatures of interests. These results were screened for different canter entities. We furthermore evaluated common core genes, overlapping pathways, and generation approaches among these HCC gene signatures.
Results: Although the specificity of the investigated HCC signatures varied significantly, none of the signatures exhibited strict specificity to HCC. Many signatures expressed similar profiles in other tumors, especially to renal, breast, and colorectal cancers and particularly those signatures designed to distinguish between good and poor survival of patients. Specificity of HCC gene signatures proved difficult, we furthermore found that no common core genes, few overlapping pathways, and a significant heterogeneity in signature generation approaches among HCC gene signatures may account for this phenomenon.

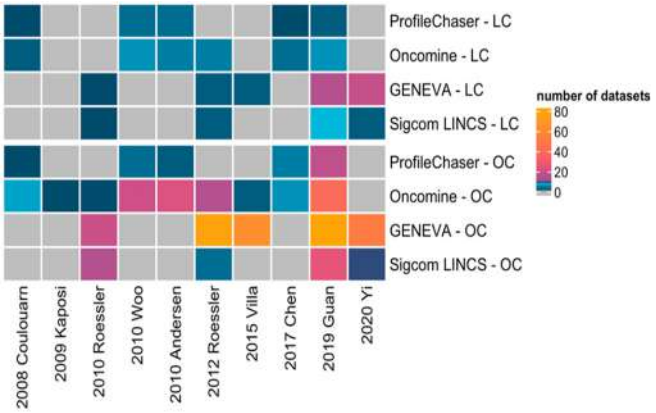

Figure: Gene signature query results of four bio-tools. LC: Liver Cancer, OC: Other Cancers. The color represents the number of datasets matched in each tool; grey means no datasets matched.

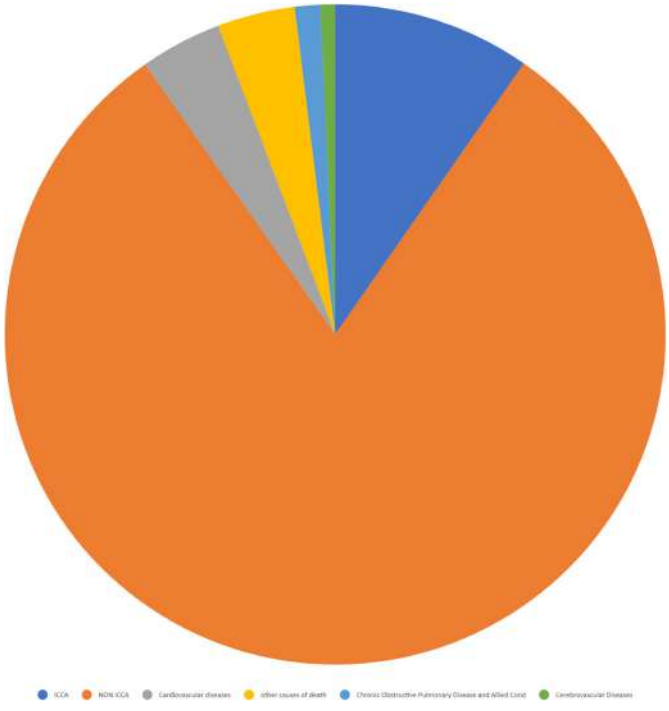
Conclusion: Our study shows the poor specificity of current HCC gene signatures, and demonstrates that the clinical use and independent validation of HCC genetic signatures remains challenging. Overall, our data suggest the necessity of standards in tissue preparation and store, as well as signature generation, statistical methods and independent validation.

SAT581

Causes of death after Intrahepatic cholangiocarcinoma diagnosis: a population-based study

Anas Elgenidy[1], Ahmed Abdelwahab[2], Prasun Jalal[2]. [1]*Faculty of medicine, Cairo University, Cairo, Egypt, Cairo, Egypt;* [2]*Baylor College of Medicine, Department of Medicine, Gastroenterology and Hepatology Division, Houston, United States*
Email: Ahmed.Abdelwahab@bcm.edu

Background and aims: Intrahepatic cholangiocarcinoma (ICCA) has shown a substantial increase in mortality globally. On the contrary, perihilar cholangiocarcinoma (pCCA) and distal cholangiocarcinoma (dCCA) have been decreasing; however, studies on causes of death in ICCA patients remain limited. We aim to focus on and evaluate the causes of death after ICCA diagnosis.
Method: In this retrospective cohort, we studied 276, 712 ICCA patients diagnosed between 2004 and 2016 in the United States. The standardized mortality ratio (SMRs) with 95% confidence intervals (CIs) for each cause of death using the SEER*Stat software version 8.3.9.2.
Results: Out of the 276, 712 patients diagnosed with ICCA, 203, 914 (73.7%) were between 50 and 79 years (The mean age at diagnosis was 63.51 years); 220, 648 (79.7%) were white, and 144, 942 (52.4%) were females. 35, 814 patients (12.9%) died during the follow-up period with a mean age of 70.83 years. The highest number of deaths (34, 444; 96.2%) occurred within the first year following the diagnosis. During all latency periods, 3, 339 (9.3%) deaths were from ICCA, and 27, 790 (77.6%) were from other cancers. The most common cancer causes were lung and bronchus cancer (9862; 27.5%) followed by pancreatic cancer (3475; 9.7%), and 4, 685 (13.1%) from non-cancer causes. Cardiovascular diseases were the leading non-cancer causes (SMR 1.95; 95% CI (1.85–2.06)), followed by Chronic Obstructive Pulmonary Disease and related Conditions (SMR 2.52; 95% CI (2.29–2.78)).



Conclusion: Following ICCA diagnosis, the most common cause of death was lung and bronchus cancer followed by pancreatic cancer and ICCA, and cardiovascular disease represents a substantial percentage of non-cancer deaths (4.97%). Our findings provide

critical insights into how ICCA survivors should be followed-up and monitored regarding future health risks.

SAT582

Genes modulating liver fat accumulation and lipogenesis predict development of hepatocellular carcinoma among direct antiviral agents treated cirrhotics C with and without viral clearance

Ginevra Mocchetti[1], Antonio Acquaviva[1,2], Giulia Francesca Manfredi[1,2], Michela Emma Burlone[2], Francesca Baorda[1,2], Davide Di Benedetto[1,2], Ramana Mallela Venkata[1], Rosalba Minisini[1], Cristina Rigamonti[1,2], Mario Pirisi[1,2]. *[1]Università del Piemonte Orientale, Department of Translational Medicine, Novara, Italy; [2]AOU Maggiore della Carità, Division of Internal Medicine, Novara, Italy*
Email: michela.burlone@uniupo.it

Background and aims: Genetic risk score (GRS) is a polygenic scoring system that estimates the predisposition to accumulate liver fat combining PNPLA3 (rs738409), TM6SF2 (rs58542926), MBOAT7 (rs641738) and GCKR (rs1260326) polymorphisms. GRS score was related to the probability to de novo hepatocellular carcinoma (HCC) development in HCV cirrhotic patients, treated with direct antiviral agents (DAA). In this setting, it is suggested that HSD17B13: TA variant (rs72613567) exhibits a protective role on fibrosis development and hepatocarcinogenesis. Our aim was to evaluate if HSD17B13 variant together with achievement of viral clearance (SVR) affected the efficacy of GRS in HCC prediction.

Method: 328 HCC-free cirrhotic patients were included. Diagnosis of cirrhosis was based on transient hepatic elastography (liver stiffness ≥12.5 kPa) or on clinical diagnosis of liver cirrhosis. Genomic DNA was extracted from whole blood. PNPLA3 and HSD17B13 genotypes were determined using restriction fragment length polymorphism technique. TaqMan® SNP (Life Technologies) genotyping test was used to identify TM6SF2, MBOAT7 and GCKR genotypes. GRS score was calculated as previously described by Degasperi et al, Hepatology 2020.

Results: At the end of the follow-up (median, 7.5 months), n = 21 patients were diagnosed with de novo HCC (Group A). Among them, 4 patients were relapsers and 1 was a drop-out, while in HCC-free patients' group (Group B, n = 307), 8 relapsers (p = 0.001) were observed. The SVR (intention-to-treat) was of 76% in Group A vs. 97% in Group B. In Group A, patients were mainly male, with more advanced liver disease. None of the genes included in the GRS was individually associated with de novo HCC. In a Cox proportional hazards model, a GRS value ≥0.457 (75th percentile) predicted the onset of HCC regardless of gender, diabetes, albumin, INR and FIB4 (HR 2.89, C.I. 1.19–7.07, p 0.02). The goodness of the model was improved by adding SVR achievement and presence of HSD17B13 variant; in particular, male gender (HR 6.75, C.I. 1.62–28.2, p 0.009), GRS ≥0.457 (HR 4.24, C.I. 1.59–11.33, p 0.004), carriage of the splice variant HSD17B13: TA (HR 0.24, C.I. 0.07–0.75, p 0.015) and failure to achieve SVR (HR 7.7, C.I. 2.38–25, p 0.001), were independent predictors of de novo HCC.

Conclusion: The study results confirmed that genes modulating lipogenesis and liver fat are important risk factors for the development of HCC in HCV cirrhotic patients treated with DAA.

SAT583

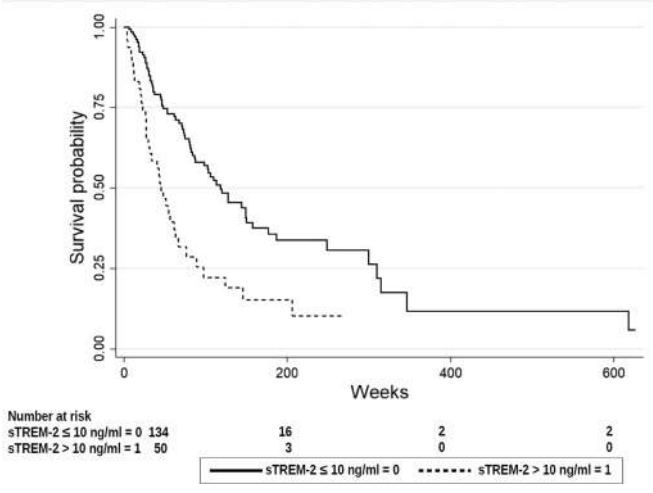
Potential role of soluble triggering receptor expressed on myeloid cells 2 in risk stratification of patients with hepatocellular carcinoma

Francesca Baorda[1,2], Federico Ceruti[1,2], Antonio Acquaviva[1,2], Giulia Francesca Manfredi[1,2], Davide Di Benedetto[1,2], Michela Emma Burlone[2], Rosalba Minisini[1], Mattia Bellan[1,2], Cristina Rigamonti[1,2], Mario Pirisi[1,2]. *[1]Università del Piemonte Orientale, Department of Translational Medicine, Novara, Italy; [2]AOU Maggiore della Carità, Division of Internal Medicine, Novara, Italy*
Email: michela.burlone@uniupo.it

Background and aims: Triggering receptor expressed on myeloid cells 2 (TREM-2) is a transmembrane receptor of the immunoglobulin superfamily that has been recently studied in many diseases including liver cancer. Nevertheless, its role is still unclear and there are no studies that have evaluated its soluble form (sTREM-2) as a biomarker. Thus, we aimed to explore the prognostic value of serum sTREM-2 in hepatocellular carcinoma (HCC).

Method: An observational cross-sectional study was performed on 184 HCC patients of any etiology, in stage A, B or C of the BCLC classification, enrolled between 2005–2021. Diagnosis of HCC was established according to the AASLD and the EASL guideline criteria. All patients underwent genotyping of TREM-2 polymorphism (rs6918289) trough polymerase chain reaction DNA amplification (PCR DNA) and serum sTREM-2 levels were quantified by using an enzyme-linked immunosorbent assay (ELISA).

Results: The median of sTREM-2 was 7.4 ng/ml [5.7–10.4 ng/ml]. sTREM-2 levels had a week correlation with age (p = 0.024) and stronger with AST (p = 0.001). From the univariate analysis, an association with the BCLC stage emerged: more advanced stages corresponded to higher values of sTREM-2 (p = 0.001). The allele frequency of rs6918289 polymorphism was 92% (339/368) for the ancestral allele (G) and 8% (29/368) for the variant allele (T). The distribution by genotype did not differ from what was expected according to the Hardy-Weinberg equilibrium (p = 0.246). At the end of a maximum period of observation (11.9 years), the overall mortality was 58.15% (107/184), with a median survival time of 86 weeks [31–287]. Survival analysis showed that the increase in sTREM-2 levels over the 75th percentile threshold (cutoff = 10 ng/ml) was significantly associated with a reduction in overall survival (log rank test with p < 0.0001, Figure). The Cox proportional hazards model built having as predictors sTREM-2, sex, age, presence/absence of cirrhosis/HCV infection and BCLC stage, confirmed that serum concentration of sTREM-2 >10 ng/ml is an independent predictor of mortality (HR 1.88, CI 1.22–2.88, p = 0.004).



Conclusion: The present study demonstrated the potential negative prognostic role of sTREM-2 on overall HCC survival. However, future prospective studies are necessary to elucidate whether the systematic assessment of sTREM-2 concentrations could be useful to predict the survival in HCC patients.

SAT584

Bone mineral density is a predictor of mortality in female patients with cholangiocarcinoma undergoing palliative treatment

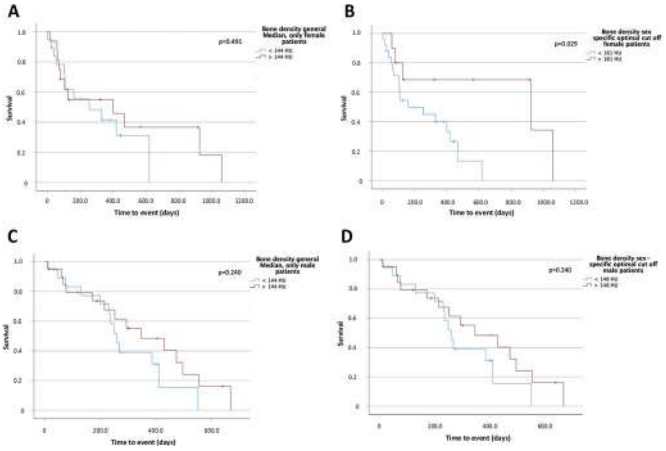
Background and aims: Cholangiocellular adenocarcinoma (CCA) is a rare and aggressive malignancy originating from the bile ducts. Its general prognosis is poor as therapeutic options are limited. Often, patients present at advanced stages of disease and palliative chemotherapy remains the only treatment option. So far prognostic markers to assess the outcome of chemotherapeutic treatment in CCA are limited. We evaluated bone mineral density (BMD), a marker for the body composition as prognostic tool in patients with advanced CCA.
Method: 75 patients with advanced CCA that were treated at the department of Gastroenterology, Hepatology and Infectious Diseases or department of General, Visceral and Pediatric Surgery of the University Hospital Düsseldorf were included into this analysis. 64 patients received chemotherapy, 11 best supportive care. Bone mineral density was analyzed at the first lumbal vertebra, using CT scans in venous phase and the local PACS (IntelliSpace PACS, Philips, Amsterdam, The Netherlands).
Results: We identified an optimal cut off of 167 HU for BMD, with patients above that value having a significantly improved overall survival (474 (95%CI: 297–651) days vs. 254 (95%CI: 211–297) days; log rank X^2 (1) = 6.090; p = 0.014; Figure 3C). The prognostic value for BMD was confirmed using univariate (HR 2.313 (95%CI: 1.170–4.575); p = 0.016) and multivariate (HR 4.143 (95%CI: 1.197–14.343); p = 0.025) Cox regression analysis. Subgroup analysis revealed, that the prognostic value of BMD was only present in women and not in men, suggesting sex specific differences.



Conclusion: Our data suggest, that BMD might represent a valuable and easy accessible independent prognostic marker in patients with advanced CCA for overall survival. Interestingly, subgroup analysis showed sex specificity of this marker only relevant in women.

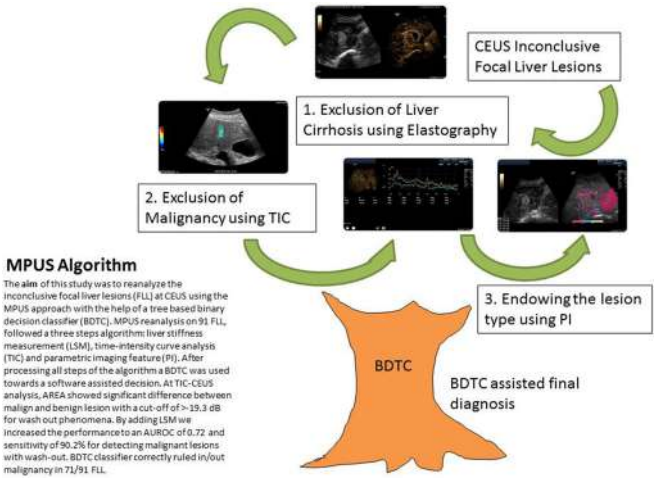
Multiparametric ultrasound approach using a tree based decision classifier for the inconclusive focal liver lesions evaluated by contrast enhanced ultrasound

Tudor-Voicu Moga[1,2], Ciprian David[3], Alina Popescu[1], Raluca Lupusoru[1], Darius Heredea[1], Ana-Maria Ghiuchici[1], Camelia Foncea[1], Adrian Burdan[1], Roxana Sirli[1], Mirela Danila[1], Ioan Sporea[1]. [1]*Victor Babes University of Medicine and Pharmacy, Division of Gastroenterology and Hepatology, Department of Internal Medicine II, Center for Advanced Research in Gastroenterology and Hepatology, Timisoara, Romania;* [2]*Victor Babes University of Medicine and Pharmacy, Division of Gastroenterology and Hepatology, Department of Internal Medicine II, Center for Advanced Research in Gastroenterology and Hepatology, Timisoara, Romania;* [3]*Faculty, "Politehnica" University of Timișoara, Electronics and Telecommunications, Timisoara, Romania*
Email: moga.tudor@gmail.com

Background and aims: Multi-parametric ultrasound (MPUS) is a concept by which the examiner is encouraged to use the latest features of the ultrasound machine. The aim of this study was to reanalyze the inconclusive focal liver lesions (FLL) at CEUS using the MPUS approach with the help of a tree based decision classifier.
Method: We retrospectively analyzed FLL's that were inconclusive at CEUS examination in our Department over a period of two years (2017–2018). All the reexamined lesions had a second line imaging method performed: (CE-CT), (CE-MRI) or biopsy considered as the reference method. CEUS Inconclusive FLLs had been previously evaluated by ultrasound (US) experts with more than 10 years of experience in CEUS, using a single US machine. MPUS reanalysis followed a three steps algorithm: liver stiffness measurement (LSM), time-intensity curve analysis (TIC) and parametric imaging feature (PI). After processing all steps of the algorithm a binary decision tree classifier (BDTC) was used towards a software assisted decision.
Results: From the 91 inconclusive FLLs evaluated, 34 were HCC, 13 metastasis, 7 haemangioma, 7 regenerative nodules, 5 focal fatty alteration, 3 fatty free areas, 4 cholangiocarcinoma's, 2 abscesses, 5 adenomas and 11 were other benign lesions. AREA was the only TIC-CEUS parameter that showed significant difference between malign and benign lesion with a cut-off of >–19.3 dB for wash out phenomena, (AUROC = 0.58, Se = 74.0%, Sp = 45.7%). By adding the value of elastography we increased the performance to an AUROC of 0.72 and sensitivity of 90.2% for detecting malignant lesions with wash-out. MPUS correctly classified 66/91 lesions with an accuracy of 72.3%. Using the binary decision tree classifier (BDTC) algorithm we correctly classified 71/91 lesions according to their malignant or benignant status, with an accuracy of 78.0%, Sensitivity = 62%, Specificity = 45% and Precision = 80%.



Conclusion: By reevaluating the inconclusive FLLs at CEUS using MPUS, we managed to determine that 78% of the lesions were malignant and in 28% of them we establish the lesion type.

SAT586

Adherence to hepatocellular carcinoma screening in patients with hepatitis C cirrhosis treated with direct-acting antivirals against hepatitis C

Elisaul Suarez Zambrano[1], Silvia Acosta-López[1], Dácil Díaz Bethencourt[1], Maria Soledad Garrido[1], Ruth Suarez Darias[1], Francisco Andrés Pérez Hernández[1]. [1]*Our Lady of Candelaria University Hospital, Santa Cruz de Tenerife, Spain*
Email: suarezelisaul@gmail.com

Background and aims: Hepatocellular carcinoma (HCC) screening is indicated for patients with hepatitis C cirrhosis (HCV-C) via biannual ultrasound scan. The risk of HCC and its mortality rate persist after sustained virologic response (SVR), so screening must be maintained. This study aims to analyse HCC screening adherence in patients with HCV-C after SVR and risk factors involved in low adherence. As a secondary aim, we analyse the incidence of HCC and BCLC stage at diagnosis.

Method: A descriptive, trans-sectional, and observational study in which we included patients that have been diagnosed VHC and treated with direct antiviral agents (DAA) between September 2014 and July 2019 with a minimum follow-up period of one year. Demographic and clinical variables were recorded at first specialised consultation. The level of adherence to screening was categorised as 'adequate' if it was conducted within a range of six months. A comparative analysis was carried out, employing nonparametric statistic tests in order to compare the two groups of study (either adequate or inadequate screening processes). Also, a binary logistic regression analysis was carried out in order to determine variables associated to an inadequate screening. For all the analysis, statistical significance was set $p < 0.05$.

Results: 385 patients (114 female) were included. Average age was 57.4 (10.3 SD). The average follow-up was 35.8 months (25 SD). 41.5% had an adequate screening (36.5% for men and 53.5% for women). Screening was adequate only in 20.6% (27/131) for intravenous drug users (IVDU) and 26.4% (24/91) for patients with mental health disorders. The binary multicovariate logistic regression analysis showed IVDU history (OR 3.29) and mental health disorders (OR 2.23) as the only independent risk factors for an inadequate HCC screening process. HCC diagnosis was recorded in 45 patients (11.6%), 57.7% with an adequate screening process. The most frequent BCLC stages were stage A (early) in 53.3% of patients, and stage B (intermediate) in 17.8% of them. The average diagnosis of HCC period since the beginning of the screening was 28.6 months. 32.7% of patients abandon the follow-up before the close out, including the 55.6% of those with an inadequate screening. 11.4% of patients (44) deceased during the follow-up period; 40.9% of them (18) were diagnosed with HCC.

Conclusion: There is a low level of adherence to the HCC screening process in patients with hepatitis C cirrhosis after DAA treatment. IVDU medical history and mental health disorders are independent factors for an inadequate screening process. Nevertheless, the screening enables the HCC diagnosis in early stages for most patients in this group. HCC is common and is a mayor cause for mortality in this population.

SAT587

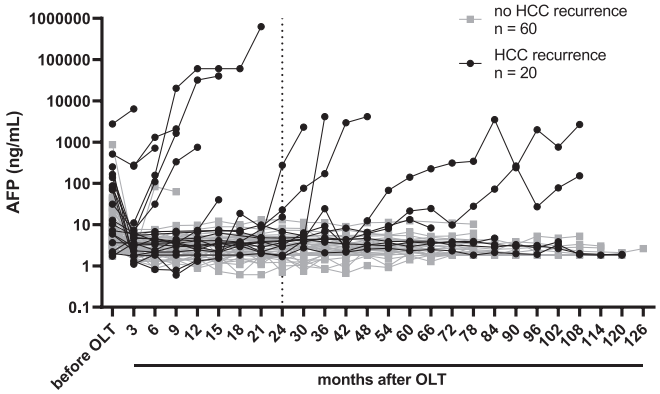
Closely monitored alpha-fetoprotein allows early detection of hepatocellular carcinoma recurrence after orthotopic liver transplantation

Magdalena Hahn[1], Adam Herber[1], Rami Al-Sayegh[1], Janett Fischer[1], Anne Olbrich[1], Sebastian Rademacher[2], Daniel Seehofer[2], Sebastian Ebel[3], Timm Denecke[3], Thomas Berg[1], Florian van Bömmel[1]. [1]*Leipzig University Medical Center, Division of Hepatology, Department of Medicine II, Leipzig, Germany;* [2]*Leipzig University Medical Center, Department of Visceral, Transplant, Thoracic and Vascular Surgery, Leipzig, Germany;* [3]*Leipzig University Medical Center, Department of Diagnostic and Interventional Radiology, Leipzig, Germany*
Email: florian.vanboemmel@medizin.uni-leipzig.de

Background and aims: After orthotopic liver transplantation (OLT) for patients with hepatocellular carcinoma (HCC), HCC recurrence (HCCR) is frequent and has a poor prognosis. An alpha-fetoprotein (AFP) value >1, 000 ng/ml before OLT is used to identify patients at high risk for HCCR. However, the use of AFP for the detection of HCCR is not established. We have assessed longitudinal AFP levels in patients who underwent OLT for HCC.

Method: In this retrospective monocentric study all patients who underwent OLT due to HCC between 2010 and 2020 in one University Hospital were included. Inclusion criteria were diagnosis of HCC by radiologic or histologic criteria before OLT, availability of serum AFP values measured before OLT, 3 monthly within 24 months after OLT and 6 monthly thereafter, and written informed consent. AFP was measured by COBAS assay (Roche, Switzerland, upper limit of normal (ULN) = 7 ng/ml). AFP levels were correlated to data from patient records.

Results: A total of 80 patients were included and followed for a mean time of 58 ± 40 (range 1–132) months (end of observation = EOBS) after OLT. HCC recurred in 20 patients (25%) after a mean of 33 ± 30 months. In the group without HCCR median serum AFP levels dropped from 5.7 (range 1.7–871) before to 2.7 (1.2–7.7) ng/ml at month 3 after OLT ($p < 0.001$), and remained similar until EOBS (4.1 (1.5–62.8), $p = 0.915$). In contrast, in the HCCR group median AFP level decreased from 76.7 (1.7–2, 762) at before OLT to 6.1 (1.1–6, 393) ng/ml ($p = 0.010$) at month 3 after OLT, but increased to 751.3 (1.38–628, 400) ng/ml at EOBS ($p = 0.002$) (Figure). In 15 patients (75%) with elevated AFP at HCCR, including two with AFP below ULN until OLT, after OLT AFP increased above ULN by a mean of 3.3 ± 3 (0–9) months before radiologic confirmation of HCCR. Patients with HCCR within the first 12 months after OLT (n = 7) had significantly higher median AFP levels at OLT, months 3, 6 and 12 after OLT as compared to patients with HCCR after 12 months or no HCCR (OLT: 165.2 (31.3–2, 762) ng/ml vs. 5.9 (1.7–871), $p < 0.001$; 3 months: 11 (4.9–6, 393) vs. 2.7 (1.1–7.7), $p < 0.001$; 6 months: 134 (4.6–1, 307) vs. 2.31 (0.82–83), $p < 0.001$; 12 months: 16, 398.7 (7.3–60, 500) vs. 2.8 (0.9–9.7), $p < 0.001$).



Conclusion: Serum AFP levels measured on a longitudinal basis are useful for early detection of AFP positive HCCR after OLT. The optimal frequency of AFP measurement needs to be defined.

SAT588

Predictors of survival of patients with hepatocellular carcinoma in best supportive care

Claudia Campani[1], Laura Bucci[2], Valentina Adotti[1], Martina Rosi[1], Umberto Arena[1], Stefano Gitto[1], Franco Trevisani[2], Fabio Marra[1], Ita.Li.Ca. Study Group[2]. *[1]University of Florence, Firenze, Italy; [2]Alma Mater Studiorum-Università di Bologna, Bologna, Italy*
Email: fabio.marra@unifi.it

Background and aims: The prognosis of patients with hepatocellular carcinoma (HCC) is very variable. Patients unfit to receive any type of treatment are managed with best supportive care (BSC), and their median overall survival (OS) is around 3–6 months, although longer values may be observed in clinical practice. Aim of this study was to identify prognostic factors associated with longer survival in patients with HCC treated with BSC.
Method: We retrospectively evaluated the clinical characteristics of 916 patients, recorded in the Ita.Li.Ca. database, who had an indication for BSC. We analyzed both patient and tumor characteristics to identify predictors of better OS.
Results: Median age was 71y and 75% of patients were male. Etiology included chronic viral infection (48.7%), alcohol use disorder (20.7%) and non-alcoholic steatohepatitis (4.1%). Approximately 50% of patients had a performance status 0–1 and were in Child-Pugh B class. Median MELD was 13. 60% of patients had a multifocal HCC with a median number of 2 lesions and a median size of 35 mm. 369 patients had vascular invasion. Median alpha-fetoprotein was 63.2 ng/ml. The median OS was 9 months (CI 7.7;10.2). No differences in terms of OS were observed considering the etiology of liver disease. Among comorbidities, heart disease was associated with lower OS ($p = 0.015$). Abdominal pain ($p < 0.001$), vomiting ($p = 0.014$), fatigue ($p < 0.001$), edema ($p < 0.001$), jaundice ($p = 0.01$), higher PS ($p = 0.01$), and a worse liver function ($p < 0.001$) were associated with shorter OS. Patients with multifocal HCC had a better OS (12 mo; CI 10–13.9) compared to those with monofocal HCC (8 months; CI 6.5–9.5) ($p < 0.001$). Lack of vascular invasion was also associated with a better OS (14 months, CI 12.2–15.7, $p < 0.001$). No significant differences were observed comparing patients with or without metastasis ($p = 0.310$). Patients who had an active treatment before BSC had significantly longer OS than those for whom BSC was the only treatment (561 patients, $p < 0.001$). Survival in BCLC-A patients was longer than in other stages. No differences in OS were found comparing BCLC-B and -C groups. Patients in BSC with a median OS longer than 6 months had more lesions ($p = 0.005$), higher levels of albumin ($p = 0.003$), lower bilirubin ($p < 0$, 001) and alpha-fetoprotein (0, 001), and a lower median MELD ($p < 0.001$). A weak association was found between survival shorter than 6 months and the presence of cirrhosis ($p = 0.012$), alcohol consumption ($p = 0.046$), heart disease ($p = 0.007$), obesity ($p = 0.025$), hypercholesterolemia ($p = 0.002$), hypertriglyceridemia ($p = 0.0036$) symptoms ($p = 0.02$), vascular invasion ($p < 0.001$), and non-multifocal HCC ($p < 0.001$). Similar results were found comparing patients with a mOS longer or shorter than 12 months.
Conclusion: In a large series of patients with HCC in BSC we identified several clinical and tumor characteristics associated with the length of survival.

SAT589

Serum exosomal miRNA-720 as a diagnostic marker for hepatocellular carcinoma

Ji Min Kim[1], Hye Seon Kim[1], Jin Seoub Kim[1], Ji Won Han[1], Soon Kyu Lee[1], Heechul Nam[1], Pil Soo Sung[1], Si Hyun Bae[1], Jong Young Choi[1], Seung Kew Yoon[1], Jeong Won Jang[1]. *[1]The Catholic University of Korea, Seoul St. Mary's Hospital, Seoul, Korea, Rep. of South*
Email: garden@catholic.ac.kr

Background and aims: Hepatocellular carcinoma (HCC) remains with a poor prognosis, largely due to late detection. Highly accurate biomarkers are urgently needed to detect early-stage HCC. Exosomal microRNAs (miRs) recently emerged as a biomarker for various cancers. Our study aims to explore the diagnostic performance of serum exosomal miR-720 for HCC.
Method: Exosomal miRNA was measured by quantitative real-time PCR. A correlation analysis was done between exosomal miR-720 and tumor or clinico-demographic data of patients with HCC. The receiver operating characteristic (ROC) curve was applied to assess the diagnostic capacity of serum exosomal miR-720 for HCC, in comparison with AFP (α-fetoprotein) and prothrombin-induced by vitamin K absence or antagonist-II (PIVKA-II).
Results: miR-720 was chosen as a potential HCC marker through miR microarray, due to significantly differential expression between tumor and non-tumor samples. Serum exosomal miR-720 was significantly upregulated in patients with HCC ($n = 114$) and other liver disease (control, $n = 30$), with the higher area under the ROC curve (AUC = 0.931) than the other markers. Particularly, serum exosomal miR-720 showed superior performance in diagnosing small HCC (<5 cm; AUC = 0.930) to AFP (AUC = 0.802) or PIVKA-II (AUC = 0.718). Exosomal miR-720 levels marginally correlated with tumor size and number. The proportion of high-level miR-720 increased with intrahepatic tumor stage progression. Unlike AFP or PIVKA-II showing significant correlation with aminotransferase levels, exosomal miR-720 exhibited no correlation with aminotransferase levels.
Conclusion: Serum miR-720 is an excellent biomarker for diagnosis of HCC, with better performance than AFP or PIVKA-II. Its diagnostic utility is maintained even for small HCC and not affected by aminotransferase levels.
Key words: Hepatocellular carcinoma; Exosome; MicroRNA; Biomarkers; Diagnosis.

SAT590

Prospective evaluation of combining three biomarkers and image tools for early detection of hepatocellular carcinoma: an interim analysis

Hyung Joon Yim[1], Tae Hyung Kim[1], Soon Ho Um[2], Yeon Seok Seo[2], Young Kul Jung[1], Ji Hoon Kim[3], Young-Sun Lee[3], Sun Young Yim[2], Won Hyeok Choe[4], Jae Young Jang[5], Byoung Kuk Jang[6], Dae Won Jun[7], Eileen Yoon[8,9], Yoon Jun Kim[10], Hyung Joon Kim[11], Chang Wook Kim[12], Si Hyun Bae[12], Jeong Won Jang[12], Han Ah Lee[2,9], Do Young Kim[13]. *[1]Korea University Ansan Hospital, Internal Medicine, Ansan, Korea, Rep. of South; [2]Korea University Anam Hospital, Internal Medicine, Korea, Rep. of South; [3]Korea University Guro Hospital, Internal Medicine, Korea, Rep. of South; [4]Konkuk University School of Medicine, Internal Medicine, Korea, Rep. of South; [5]Soonchunhyang University College of Medicine, Internal Medicine, Korea, Rep. of South; [6]Keimyung University School of Medicine, Internal Medicine, Korea, Rep. of South; [7]Hanyang University College of Medicine, Internal Medicine, Korea, Rep. of South; [8]Hanyang University College of Medicine, Internal Medicine; [9]Inje University College of Medicine, Internal Medicine; [10]Seoul National University College of Medicine, Internal Medicine; [11]Chung-Ang University College of Medicine, Internal Medicine; [12]The Catholic University of Korea, Internal Medicine; [13]Yonsei University College of Medicine, Internal Medicine*
Email: gudwns21@korea.ac.kr

Background and aims: Early detection of hepatocellular carcinoma (HCC) is critically important for the improvement of prognosis.

Although combining AFP and ultrasonography (US) are the standard modalities for surveillance of HCC, combining other tumor biomarkers such as PIVKA-II or AFP L3 with AFP is currently suggested to improve the detection rates of HCC. However, prospective evaluation of combinations of such biomarkers has been rarely performed. The present study aimed to confirm the utility of combination of biomarkers and imaging modalities for early detection of HCC inpatients with liver cirrhosis.

Method: Patients with histologically or clinically confirmed liver cirrhosis were enrolled at 14 tertiary hospitals in Korea. Patients with elevated AFP (>20 ng/ml), hepatic nodule ≥1 cm by US or liver CT, or Child-Pugh score ≥11 points were excluded. HCC surveillance using AFP, AFP L3, PIVKA-II, and US were performed every 6 months. In addition, liver CT was scanned every 12 months.

Results: A total of 2810 patients/year were followed-up prospectively. Among them, HCC developed in 56 patients. Under this intensive surveillance program, most of HCCs detected were at early stage (50/56 were BCLC stage 0 or A, 48/56 were TNM stage 1, 54/56 were modified UICC stage1 or 2) and the mean size of HCCs was 1.8 cm (1.3–2.6). The sensitivity of the biomarkers was 42.9% for AFP, 48.2% for AFP L3, 39.3% for PIVKA-II, 59.0% for combination of the three markers when the sensitivity was set to be ≥90%; Three-combination was the highest and the AFP L3 was the next. We assessed the area under the receiver operating curves (AUROC) for one, two, and three combination of the biomarkers such as AFP (0.598), AFP+AFP L3 (0.646), AFP+PIVKA-II (0.664), and AFP+AFPL3+PIVKA-II (0.688), and found that the three combination was the best. In addition, when incorporated the three biomarkers into GALAD (Gender, Age, L3, AFP, and DCP [= PIVKA-II]) score, the AUROC was 0.778, which is the better. The AUROC improved by adding US (0.820) or liver CT (0.864) on combination of three biomarkers.

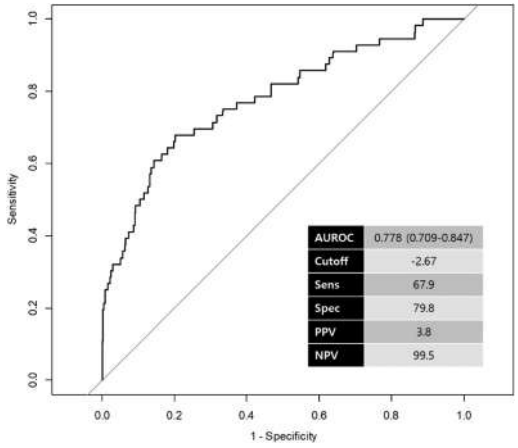


Figure: AUROC of GALAD score in which three biomarkers incorporated.

Conclusion: For early detection of HCCs, a combination of three biomarkers (AFP, AFP L3, PIVKA-II) or GALAD score was shown to be useful in this prospective evaluation. Adding imaging modalities improved the performance further.

SAT591

A natural experiment investigating the impact of waiting time on post-transplant survival for patients with hepatocellular carcinoma: randomization by blood group

Berend Beumer[1], Wojciech Polak[1], Robert De Man[2], Herold J. Metselaar[2], Jan Ijzermans[1]. *[1]Easmus MC Transplant Institute, Department of Surgery, Division of HPB and Transplant Surgery, Rotterdam, Netherlands; [2]Erasmus MC Transplant Institute, Department of Gastroenterology and Hepatology, Rotterdam*
Email: b.beumer@erasmusmc.nl

Background and aims: When listing for liver transplantation we can transplant as soon as possible or introduce a test of time to better select patients as the tumor's biological behavior is observed. Knowing the degree of harm caused by time itself is essential to advise patients and decide on the maximum duration of the test-of-time. Therefore, we investigated the causal effect of waiting time on post-transplant survival for patients with HCC.

Method: We analyzed the UNOS-OPTN dataset and exploited the natural experiment created by blood groups. Relations between variables were described in a causal graph. Inverse probability weighting was used to address selection bias. Confounding biases were avoided using instrumental variable analysis, with an additive hazards model in the second stage. The causal effect was evaluated as a contrast between a scenario in which all patients waited 2 months and one in which all patients waited 12 months. Upper bounds of the test-of-time were evaluated for probable scenarios by means of simulation.

Results: The F-statistic of the first stage was 86.3. The effect of waiting 12 months versus 2 months corresponded with a significant drop in overall survival of 5.07% 95%CI [0.277; 9.69] and 8.33% 95% CI [0.47; 15.60] at 5- and 10-years post-transplant, respectively. The median survival significantly dropped by 3.41 years from 16.21 years 95%CI [15.98; 16.60] for those waiting 2 months to 12.80 years 95%CI [10.72; 15.90] for those waiting 12 months. No significant effect modification by tumor size or number was found.

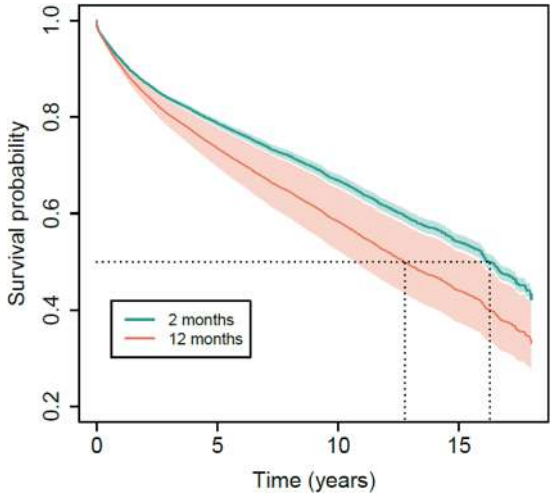

Figure 1: The survival probabilities if all listed HCC patients wait either 2 or 12 months.

Conclusion: From a patient's perspective the choice between ablate-and-wait versus immediate transplantation is in favor of immediate transplantation. From a policy perspective, the extra waiting time can be used to increase the utility of scarce donor livers, although the duration of the test-of-time is bound to be likely less than 8 months.

SAT592

Baveno VII criteria identify varices needing treatment in patients with hepatocellular carcinoma of different BCLC stages undergoing curative hepatectomy

Grace Lai-Hung Wong[1], Terry Cheuk-Fung Yip[1], Angus Wong[1], Brian Chan[1], Matthew Fong[1], Vincent Wai-Sun Wong[1], Stephen L. Chan[2], Kelvin Ng[3]. *[1]The Chinese University of Hong Kong, Medical Data Analytic Centre (MDAC) and Department of Medicine and Therapeutics, Hong Kong; [2]The Chinese University of Hong Kong, State Key Laboratory of Translational Oncology, Department of Clinical Oncology, Hong Kong; [3]The Chinese University of Hong Kong, Department of Surgery, Hong Kong*
Email: wonglaihung@cuhk.edu.hk

Background and aims: The latest Baveno VII consensus, which was published in late 2021 discussed the use of non-invasive tools for the diagnosis of compensated advanced chronic liver disease (cACLD)

and clinically significant portal hypertension (CSPH). We aimed to investigate the predictive value of Baveno VII consensus, as well as other LSM and platelet cutoffs, to predict the presence of varices needing treatment (VNT) in patients with HCC of different stages Barcelona Clinic Liver Cancer staging system (BCLC) undergoing curative hepatectomy.

Method: This was a prospective cohort of patients with confirmed diagnosis of HCC. Patients underwent transient elastography examination before HCC treatment. Patients were prospectively followed for VNT, defined as all grade II to III varices (≥5 mm), and small varices found in patients with Child-Pugh C cirrhosis, and any varices presenting red-wale signs, fibrin clot or active bleeding.

Results: 712 patients (83.3% male, median age 62 years old) were recruited from March 2013 to April 2019. Most patients (76%) suffered from chronic hepatitis B infection, 405 (57%) and 595 (84%) patients had platelet count ≥150 × 109/L and ≥110 × 109/L respectively. Majority of the patients (n = 389, 55%) had HCC of BCLC stage A, whereas 69 (10%) patients had stage 0, 131 (18%) patients had stage B and 121 (17%) patients had stage C tumour. The median follow-up duration of patients was 45.8 months. The median liver stiffness measurement (LSM) was 10.5 kPa (Range: 7.0–20.6 kPa); 461 (65%) patients had LSM ≤ 15 kPa, 516 (72.5%) patients had LSM ≤ 20 kPa and 554 (77.8%) patients had LSM ≤ 20 kPa. Patients of BCLC stage 0 and stage A HCC had lower LSM (9.6 kPa and 9.5 kPa respectively), compared to those of BCLC stage B and C HCC (13.2 kPa and 20.6 kPa respectively). VNT occurred in 57 (8.0%) patients, which occurred a bit more commonly in BCLC stage C (12 patients, 10.0%) than earlier stages of HCC (stage 0, 8.7%; stage A, 7.5%; stage B, 7.6%; Table 2). In patients who fulfilled Baveno VII criteria, i.e. LSM ≤ 20 kPa together with a platelet count above 150 × 109/L, only fourteen (2.0%) patients had VNT. In all BCLC stages of HCC, the proportion of patients with VNT was below 5% (1.5% in stage 0, 1.3% in stage A, 3.1% in stage B, and 3.3% in stage C), which support the validity and applicability of Baveno VII criteria in all BCLC stages of HCC.

	All patients N = 712	BCLC stage 0 N = 69	BCLC stage A N = 389	BCLC stage B N = 131	BCLC stage C N = 121

LSM ≤ 25 kPa & PLT ≥ 150x10⁹/L	15 (2.1%)	1 (1.5%)	6 (1.5%)	4 (3.1%)	4 (3.3%)
LSM ≤ 25 kPa & PLT ≥ 110x10⁹/L	23 (3.2%)	3 (4.3%)	11 (2.8%)	4 (3.1%)	5 (4.1%)
Survival (months)	45.8 (21.5-82.5)	66.5 (49-101)	58.9 (32.9-95.4)	26.0 (10.5-54.2)	14.5 (4.9-39.6)

Figure: Varices in different BCLC stages.

Conclusion: This was the first long-term follow-up study of HCC patients undergoing curative hepatectomy supporting the validity and applicability of the new Baveno VII criteria for selecting patients to undergoing screening endoscopy for VNT. The validity was consistent across different BCLC stages of HCC.

SAT593

Factors associated with HCC stage at presentation and survival in an ethnically diverse UK population

Jessica Spiers[1], Wenhao Li[1], Aloysious Aravinthan[2], Katharine Caddick[3], Yaqza Hussain[4], Ayman Bannaga[4], Saad Muhammad[4], Muhammad Nauman Tahir[4], Abhishek Sheth[2], Ankur Srivastava[3], Mohsan Subhani[2], Esther Unitt[4], Nwe Ni Than[4], William Alazawi[1]. *[1]Blizard Institute, Queen Mary University of London, Barts Liver Centre, London, United Kingdom; [2]Nottingham University Hospitals NHS Trust, Queen's Medical Centre, United Kingdom; [3]North Bristol NHS Trust, Southmead Hospital, Bristol, United Kingdom; [4]University Hospital Coventry and Warwickshire, Coventry, United Kingdom*

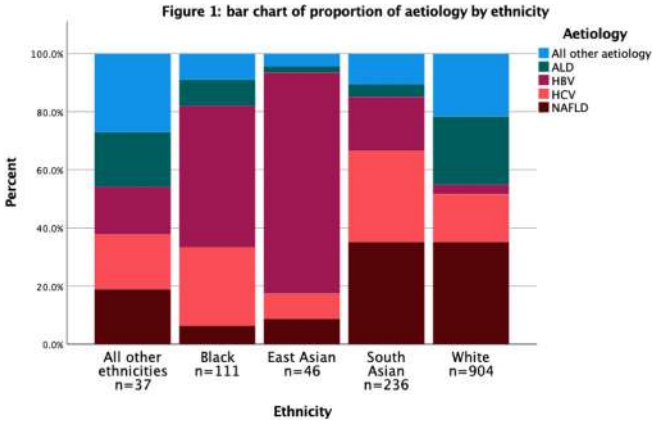
Email: jessica.spiers3@nhs.net

Background and aims: Risk factors for hepatocellular carcinoma (HCC) include cirrhosis and diabetes, but patient- and disease-related factors in prognosis have not been widely explored. Evidence highlights ethnic disparity in HCC stage at presentation and survival in the USA; White patients present earlier and survive longer, but there is little evidence evaluating any disparity in the UK.

We sought to evaluate the factors associated with HCC stage at presentation and survival in a UK population.

Method: We retrospectively analysed data from referrals to HCC multidisciplinary teams in 4 regional centres: East London and Essex, Nottingham, Coventry, and Bristol, between 2007 and 2021, where data available. We included all patients with confirmed diagnosis of HCC. Early stage at presentation was defined as Barcelona Clinic Liver Centre (BCLC) Stages 0 and A, late stage was defined as BCLC Stages C and D. Analyses were conducted using Cox regression models for survival and logistic regression models for stage at presentation, all adjusted for age, sex, aetiology of liver disease, HCC surveillance and centre.

Results: We included 1357 patients with a median follow-up of 12 months. 31% of patients had Non-Alcoholic Fatty Liver Disease (NAFLD), 33% had Viral hepatitis, and 18% had Alcoholic Liver Disease (ALD) (Figure 1).



The overall 2-year survival rate was 40%. White ethnicity was independently associated with reduced mortality (Hazard ratio [HR] 0.835, p = 0.043), but not early-stage presentation (Odds ratio [OR] 1.324, p = 0.089).

21% of patients had non-cirrhotic HCC. Patients with NAFLD were more likely to develop non-cirrhotic HCC compared with patients with Viral hepatitis and ALD (24% vs. 10%, p < 0.001 Chi-square).

While HCC surveillance was associated with overall lower risk of mortality (HR 0.699, p < 0.001), it was not associated with mortality in the 433 patients with NAFLD (HR 0.806, p = 0.183). However, it was an independent predictor of early-stage presentation in this cohort (OR 2.313, p = 0.002).

In patients with diabetes, metformin use was independently associated with early-stage presentation (OR 1.932, p = 0.008) and survival (HR 0.674, p = 0.008). Diabetes diagnosis was not associated with risk of death (HR 0.912, p = 0.304).

Conclusion: In this multi-centre study, White patients were less likely to die following a diagnosis of HCC compared to other ethnicities.

Diabetes status was not an independent predictor of survival but, among patients with diabetes, those on metformin were almost twice as likely to present with early-stage disease, and were less likely to die, consistent with existing evidence for a protective role of metformin in HCC.

HCC surveillance was a predictor of overall survival but not in patients with NAFLD who are at greater risk of developing non-cirrhotic HCC and for whom the current outpatient surveillance programme may require modification.

SAT594

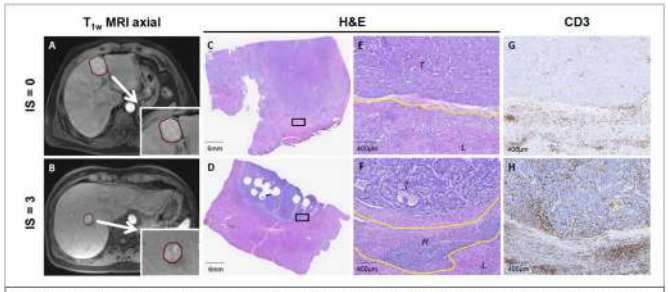
Use of machine learning to predict the histopathological ImmunoScore in hepatocellular carcinoma on multiparametric MRI

Junlin Yang[1], Annabella Shewarega[1], Jessica Santana[1], Vasily Pekurovsky[1], Xuchen Zhang[2], MingDe Lin[1], David Madoff[1], Lawrence Staib[1], Julius Chapiro[1], James Duncan[1]. [1]*Yale University, Radiology and Biomedical Engineering, New Haven, United States;* [2]*Yale University, Pathology, New Haven, United States*
Email: julius.chapiro@yale.edu

Background and aims: Immunotherapy is the new first-line treatment for advanced-stage hepatocellular carcinoma (HCC) and combinations with locoregional therapies are currently under investigation for intermediate disease stages. However, tumor response to immunotherapy is highly variable and depends on immunological features of the tumor microenvironment at baseline. Histopathologic biomarkers such as the ImmunoScore are potent predictors of response to immunotherapy, however, they are not readily available given the need for tissue sampling. Accordingly, there is an unmet need for non-invasive surrogate markers for the immunological state of HCC prior to allocation of therapy. The purpose of this study is to establish ground proof for the ability of machine learning to extract radiomic features from multi-parametric MRI to predict ImmunoScores in HCC.

Method: This study included 17 individual HCC lesions with whole-tumor gross and histopathology obtained via hepatectomy or orthotopic liver transplantation within 30 days of preoperative abdominal contrast-enhanced MRI. The ImmunoScore, an index indicating the density of $CD3^+$, $CD4^+$, and $CD8^+$ tumor-infiltrating T-lymphocytes both in the tumor center and tumor margin, was assessed by a board-certified pathologist. ImmunoScores of 0–2 signified immunologically "cold" tumors while scores of 3–4 signified immunologically "hot" tumors. Arterial and delayed venous phases of the contrast-enhanced T1-weighted MRI were used to segment both tumors and the whole liver volume. The segmentation masks were used to train an autoencoder with binary cross-entropy and mean squared error (MSE) loss. The latent codes consist of 128 features of each phase and 2 clinical non-imaging features, hepatitis C virus and cirrhosis, resulting in 258 features in total. The latent codes were used for prediction in the following steps. Next, a univariate feature selection was used to select 12 features. Then, linear regression and a random forest model were used to predict ImmunoScores.

Results: Leave-one-out cross-validation was used to evaluate the model performance. The linear regression model showed good performance in predicting the ImmunoScore, with a F1 score 58.42, an AUC of 86.67, and an accuracy of 70.59. The random forest model showed a greater degree of predictiveness with a F1 score 88.24, an AUC of 85.83, and an accuracy of 88.24.



Abstract figure: In the vertical direction, two cases of single-nodular HCC with low (IS=0) and high (IS=3) immunoscores, respectively, are juxtaposed. *A, B.* Arterial phase T1-weighted (T_{1w}) axial MRI scans are used to manually delineate the hepatic lesion (red) and the whole liver (white). *C, D, E, F.* digital scans of Hematoxylin-eosin (H&E) and, *G, H,* human CD3 tumor-infiltrating lymphocytes receptor staining reveal peri- and intratumoral immune cell infiltration. The boxes in *C* and *D* indicate areas of magnification for *E, G* and *F, H,* respectively. The yellow lines in *E* and *F* outline the tumor border and the peritumoral rim. L = liver, R = peritumoral rim, T = tumor.

Conclusion: Machine learning-based extraction of radiomic features from multi-phasic MRI may serve as a non-invasive surrogate for ImmunoScore prediction of HCC, potentially facilitating immuno-phenotyping of tumors prior to allocation to immunotherapy. These results demonstrate a proof of principle and require external validation and prospective evaluation in larger clinical cohorts with tumor response as the next study end point.

SAT595

Value of 18-F fluorodeoxyglucose/choline positron emission tomography imaging for predicting hepatocellular carcinoma recurrence after liver transplantation

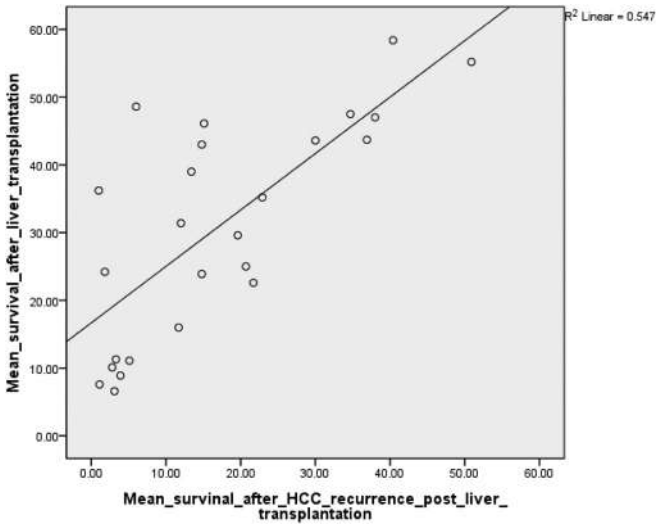
Alina Pascale[1], Florent Besson[2], Nicolas Golse[1], Catherine Guettier[3], Maite Lewin[4], Jean-Charles Duclos-Vallée[1], Rodolphe Sobesky[1], Eleonora De Martin[1], Edoardo Poli[1], Ilias Kounis[1], Lea Duhaut[1], Yasmina Ben Merabet[1], Bruno Roche[1], Tereza Antonini[1], Faouzi Saliba[1], Philippe Ichai[1], Marc Boudon[1], Sophie Sacleux[1], Marie-Amelie Ordan[1], Marc Antoine Allard[1], Gabriella Pittau[1], Oriana Ciacio[1], Antonio Sa Cunha[1], Daniel Azoulay[1], René Adam[1], Eric Vibert[1], Daniel Cherqui[1], Audrey Coilly[1], Olivier Rosmorduc[1], Didier Samuel[1]. [1]*Paul Brousse Hospital, Hepato-Biliary Center, Villejuif, France;* [2]*Bicetre Hospital, Nuclear Medicine-Molecular Imaging, France;* [3]*Bicetre Hospital, Pathology;* [4]*Paul Brousse Hospital, Radiology*
Email: alina_pascale@yahoo.com

Background and aims: The major issue of liver transplantation (LT) for hepatocellular carcinoma (HCC) is predicting patients at low risk for tumor recurrence. Different criteria, such as Milan criteria, alpha-fetoprotein (AFP) score, are used to select candidates before LT. Despite increasing use of positron emission tomography (PET) imaging in HCC, its value in predicting recurrence after LT is not clear and it is not considered among selection criteria for LT. We studied here the correlation between HCC recurrence after LT and positivity of PET imaging before LT.

Method: We retrospectively analyzed 198 patients consecutively transplanted for HCC in Hepato-Biliary Center, Paul Brousse Hospital, France, between January 2015 and December 2019. We collected demographic data, characteristics of cirrhosis, HCC and PET imaging before LT and post LT data, including histological data. 71 patients had available data before LT on 18F-fluorodeoxyglucose (18F-FDG) and choline PET positivity and SUV analyses. Patients were followed at least two years after LT to detect recurrence. Statistical analyses were performed in SPSS, using Spearman's correlations.

Results: The median age of patients was 61.7 years (range: 34–74) and 166 were males (83.8%). The main etiologies of cirrhosis were: alcohol (40.4%), viral hepatitis (37.8%) and metabolic (13.3%). 76 patients (38.4%) had diabetes. The AFP score at listing was 0 in 62.6% of patients, 1 in 20.7% and 2 in 14.1%. The majority (90.4%) had a bridging treatment before LT. Median waiting time for LT was 5.8 months (range: 0.1–54). 35 (17.7%) patients experienced HCC recurrence after LT. The median time to recurrence was 16.1 months (range: 1–47). HCC recurrence was metastatic at diagnosis in 32 patients (91.4%) and 26 patients had only extrahepatic location. The

median follow-up after LT was 30.6 months. The mean survival post HCC recurrence after LT was 17 months (range: 1–50.9). Among the 71 patients with available 18F-FDG PET imaging data, 53 (74.6%) were negative and 18 (25.3%) were positive. Among the 47 patients with available choline-PET imaging data, 25 (53.1%) were negative and 22 (46.8%) were positive. In univariate and multivariate analysis, HCC recurrence after LT is correlated with 18F-FDG PET positivity before LT ($p = 0.03$, $r = 0.262$), but not with choline PET positivity ($p = 0.98$) and histological findings on liver explant: active HCC nodules ($p = 0.002$), microvascular invasion ($p < 0.001$) and macrovascular invasion ($p < 0.001$).



Conclusion: In our cohort, HCC recurrence after LT is a serious adverse event, as it occurs early, is often already metastatic at diagnosis and impacts drastically the survival after LT. HCC recurrence risk after LT could be predicted by the 18F-FDG PET positivity before LT. Further validation is needed but this could be a signal of a potential role of PET imaging for better selecting HCC candidates for LT.

SAT596

Germline genetic risk factors for the development of hepatocellular carcinoma among patients with cirrhosis: a genome-wide association study of U.S. veterans

David Kaplan[1,2], Marijana Vujkovic[1,2], Daniel Dochterman[3], Kirk Wangensteen[1], Poornima Devineni[4], Tae-Hwi Linus Schwantes-An[5], Anoop Sendamarai[4], Purushtotham Karnam[4], Emily Sileo[4], Tori Anglin[3], Trina Norden-Krichmar[6], Philip Tsao[7], Timothy Morgan[8], Saiju Pyarajan[4], Julie Lynch[3,9], Benjamin Voight[1], Kyong-Mi Chang[1,2].

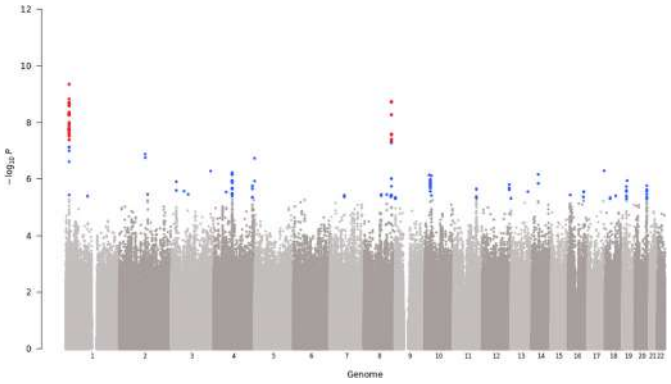
Email: dakaplan@pennmedicine.upenn.edu

Background and aims: Hepatocellular carcinoma (HCC) remains a highly mortal cancer with an approximate 20% 5-year survival rate. The primary risk factor for the development of HCC is the presence of cirrhosis, most commonly caused by chronic hepatitis B (HBV) infection, chronic hepatitis C (HCV) infection, alcohol-related liver disease (ALD) and increasingly non-alcoholic fatty liver disease/non-alcoholic steatohepatitis (NAFLD/NASH). Multiple somatic driver gene candidates in HCC including but not limited to TERT, CTNNB1, TP53, myc, ARID1A, ARID2, AXIN1 have been identified. However, few studies have evaluated germline genetic risk factors for HCC development and none have isolated genes specifically associated with HCC evolving from cirrhosis. The purpose of present study was to identify genetic risk factors for HCC in patients with cirrhosis associated with metabolic and non-metabolic causes of chronic liver disease.

Method: A clinical phenotype consistent with HCC and/or cirrhosis was generated for MVP participants based upon ICD9/10 codes, exclusion of metastatic cancers using VA clinical cancer registry data, FIB-4 scores, and identification of disease etiology using a validated algorithm. Cirrhosis controls were required to have ≥3 years follow-up without identification of HCC. Ancestry-specific and multi-ancestry genome-wide association analyses (customized Affymetrix Axiom Array with total 723, 305 SNPs) were performed comparing HCC cases and cirrhosis controls, with the covariates of age, age squared, sex, etiology and first 10 principal components of genetically defined ancestry.

Results: From ~650, 000 MVP participants, 3, 445 HCC cases and 9, 626 cirrhosis controls were identified with both metabolic and non-metabolic causes of chronic liver disease. Median time from cirrhosis to HCC diagnosis in cases was 1.9 years [IQR 0.0–5.5], and median cancer-free follow-up of controls was 5.8 years [IQR 4.4–8.1]. Multi-ancestry analysis identified 2 novel trans-ancestry loci associated with carcinogenesis that met genome wide significance (5×10^{-8}, EPHA2/ARHGEF19, LINC00824 marking a cancer risk locus on 8q24.21 with multiple candidate genes including MYC) as well as one additional African-specific locus and one Hispanic-specific locus.



Conclusion: Our effort using population-based MVP biobank has identified novel germline genetic risk loci for HCC evolving out of cirrhosis. Efforts are ongoing to expand our sample size and identify external cohorts for further replication. Future work would include validation of these genetic markers as biomarkers for selection for intensified HCC surveillance.

SAT597

A comparative analysis of Elecsys GALAD and Elecsys GAAD score to detect early-stage hepatocellular carcinoma in an international cohort

Henry LY Chan[1], Arndt Vogel[2], Thomas Berg[3], Enrico de Toni[4], Masatoshi Kudo[5], Jörg Trojan[6], Katharina Malinowsky[7], Peter Findeisen[8], Hanns-Georg Klein[9], Johannes Kolja Hegel[10], Wenzel Schöning[11], Konstantin Kroeniger[12], Kairat Madin[12], Ashish Sharma[13], Teerha Piratvisuth[14]. Email: teerha.p@psu.ac.th

Background and aims: The combination of gender (sex) and age plus serum biomarkers alpha-fetoprotein (AFP), Lens culinaris agglutinin-reactive fraction of AFP (AFP-L3) and protein-induced by vitamin K absence-II (PIVKA-II) forms the GALAD algorithm, a promising aid in the detection of early-stage hepatocellular carcinoma (HCC). Here, we present results from the first study comparing the clinical performance of the Elecsys® GALAD and Elecsys GAAD (gender [sex], age, AFP and PIVKA-II) algorithms for differentiating early-stage HCC and benign chronic liver disease (CLD).

Method: Adult patients were prospectively enrolled at 9 hospitals in Germany, Thailand, Hong Kong and Japan. Eligible HCC cases had first-time HCC diagnosis confirmed by ultrasound or liver biopsy. Eligible CLD controls had imaging-confirmed absence of HCC (within 12 months), and presence of cirrhosis or non-cirrhotic: chronic hepatitis B/C virus (HBV/HCV), alcoholic liver disease (ALD) or non-alcoholic steatohepatitis (NASH). Serum levels of PIVKA-II, AFP and AFP-L3 were measured using Elecsys assays on the cobas e 601 analyzer. The established cut-offs for HCC detection were 20 ng/ml for AFP, 2.47 for Elecsys GALAD, and 2.57 for Elecsys GAAD scores (range 0–10 for both).

Results: A total of 465 patients (246 with HCC and 219 CLD controls) were included. Among the HCC/CLD cohorts, mean age was 63.5/52.5 years, 81.7%/59.8% were male and 71.1%/28.9% had cirrhosis. Among HCC patients, 43.5% had early-stage HCC (Barcelona Clinic Liver Cancer [BCLC] 0 and A). Of 219 CLD controls, one was excluded from final analysis due to incomplete biomarker data. Elecsys GAAD and GALAD algorithms showed similar performance for discriminating between HCC and CLD (Table): sensitivity for identification of early-stage (72.9% vs 73.8%) and all-stage (85% vs 85.8%) HCC was comparable, and specificity was >90% for both scores. AUCs were similar across cirrhotic (87.6% vs 87.5% for early-stage, 92.9% vs 92.8% for all-stage HCC) and non-cirrhotic (91.2% vs 91.1%; 93.6% both) etiologies. The performance of Elecsys GAAD and GALAD algorithms were superior to AFP alone (Table).

	Early-stage HCC			All-stage HCC		
Assay/algorithm (cut-off)	AUC	Sensitivity	Specificity	AUC	Sensitivity	Specificity
AFP (20 ng/ml)	82.4 (77.4–87.5)	36.4 (27.4–46.3)	98.2 (95.4–99.5)	87.1 (83.9–90.3)	50.4 (44–56.8)	98.2 (95.4–99.5)
GAAD (2.57)	91.3 (88–94.6)	72.9 (63.4–81.0)	92.2 (87.9–95.4)	94.8 (92.9–96.7)	85.0 (79.9–89.2)	92.2 (87.9–95.4)
GALAD (2.47)	91.3 (87.9–94.6)	73.8 (64.4–81.9)	90.8 (86.2–94.3)	94.7 (92.8–96.7)	85.8 (80.8–89.9)	90.8 (86.2–94.3)

All results shown as % (95% CI)

Conclusion: The Elecsys GALAD and GAAD algorithms showed similar performance in differentiating HCC and CLD controls, irrespective of etiology and disease stages. This suggests that the Elecsys AFP-L3 assay had a negligible impact as part of Elecsys GALAD algorithm in the tested cohort.

SAT598

Mixed reality for ultrasound-guided biopsies and ablations of liver tumors: proof of concept using HoloLens as head-mounted display during liver interventions

Fabiola Lugano[1], Irina Bergamin[1], Pamela Meyer-Herbon[1], Lukas Hechelhammer[2], David Semela[1]. [1]*Kantonsspital St. Gallen, Division of Gastroenterology and Hepatology, St. Gallen, Switzerland;* [2]*Kantonsspital St. Gallen, Institute of Radiology and Interventional Radiology, St. Gallen, Switzerland*
Email: david.semela@kssg.ch

Background and aims: Improving visualization is an important component of facilitating a safe procedure during hepatological interventions. In this context, we have explored whether mixed-reality is feasible and safe in patients undergoing liver biopsy, biopsy of focal liver lesions and interventions such as ultrasound-guided ablation of liver tumors (HCC, liver metastasis) and drainage of liver abscesses. Here we report for the first time the use of SonoEyes® (in combination with a HoloLens® device as head-mounted display projecting the ultrasound screen.

Method: SonoEyes®, a CE certified app (class IIa medical device) projects the image from the conventional ultrasound screen onto a mixed-reality headset (HoloLens 2, Microsoft®) using a head-mounted display projecting the image from the ultrasound screen in front of the user of the device while the surrounding environment can still be seen and remains unaltered (mixed reality, figure). The system can be connected to any ultrasound device via HDMI. The image can be moved and placed to the comfort of the user (i.e. zooming, position, recording) via voice commands or by using hand gestures even during the procedure while sterile.

Results: This novel imaging technique was used in the clinical setting of biopsies (liver, focal liver lesions) as well as hepatic interventions such as US-guided microwave ablations of liver tumors (figure) and

drainage of liver abscesses (3 hepatologists/1 interventional radiologist, 12/2021 through 03/2022, single center, 400+ biopsies, 50+ ablations annually). To increase visibility of liver lesions (hepatocellular and cholangiocellular carcinoma, metastases) contrast-enhanced ultrasound imaging was used if needed. Use of this mixed reality technology in hepatological interventions was immediate and self-explanatory. Addition of a head-mounted display for the procedures allowed reduced movements of the operating physicians and led to increased focus on the intervention since the examiner stays in situ while having the patient, operating fiedl and the needle in one visual field.
Conclusion: Use of this mixed reality technology in hepatological interventions such as biopsies of focal liver lesions, tumor ablations and liver abscess drainages proved to be useful. This proof of concept showed for the first time that using mixed-reality technology in ultrasound-guided liver interventions is feasible and associated with advantages such less movement during biopsy/ultrasound-guided intervention allowing a better focus on the intervention sight, lower risk of contamination of the sterile field. In addition, live recording by this device was useful for physicians in training in order to review their interventions later.

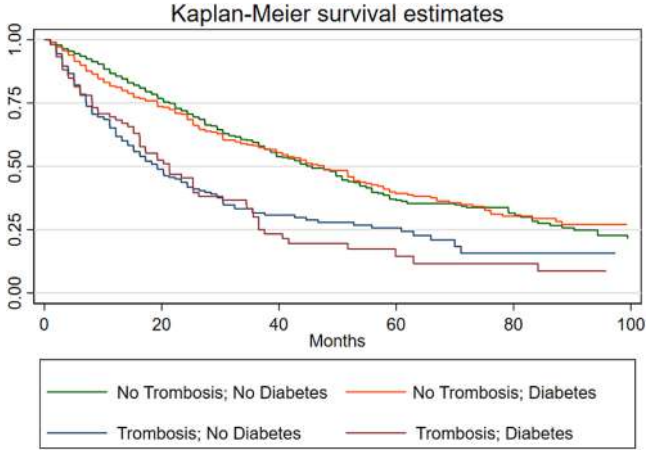
Email: deborangrisani@hotmail.it

Background and aims: Type 2 diabetes combined with portal vein tumor thrombosis worsens prognosis in patients with hepatocellular carcinoma.
Method: we analyzed data of 2243 patients from an online region-wide database (Progetto Epatocarcinoma Campania) collected at 18 community and academic centers located in the Campania region, South of Italy. The database covered the period from January 2013 to April 2021. Kaplan-Meier curves were used to investigate survival in different groups.
Results: There were 398 thrombotic events, 81% of the thrombosis were neoplastic. In 32% of cases the thrombus involved the main trunk, while it involved the right 1st order branch and left 1st order branch in 27% and 11% of cases, respectively. Patients with thrombosis had a risk of death doubled compared to patients without thrombosis. There was no difference in OS in patients with PVTT at the main trunk, or in the left or right portal vein. One hundred and twenty patients with PVTT had type 2 diabetes as comorbidity; in 9% of cases the hepatic disease had a metabolic cause. Patients with diabetes and PVTT had the highest risk of death [HR = 1.02 (0.88–1.18); p = 0.756], although the presence of diabetes was not related to overall survival (Figure).



Conclusion: type 2 diabetes is a risk factor for hepatocellular carcinoma and increases risk of death in patients who develop portal vein tumor thrombosis.

SAT600

British Association for the Study of Liver disease electronic survey on hepatocellular carcinoma UK surveillance practice

Robert Scott[1], Christopher Clarke[2], Stephen Ryder[1], Shahid Khan[3], James Franklin[4], Aloysious Aravinthan[1]. *[1]NIHR Nottingham Biomedical Research Centre, Hepatology, Nottingham, United Kingdom; [2]Nottingham University Hospitals NHS Trust, Radiology, Nottingham, United Kingdom; [3]Imperial College London, St Mary's Hepatology, London, United Kingdom; [4]Bournemouth University and Royal Bournemouth Hospital, Medical Imaging and Visualisation, Bournemouth, United Kingdom*
Email: mszada@nottingham.ac.uk

Background and aims: EASL, AASLD, APSAL recommend eligible patients undergo 6-monthly ultrasound (US) ± alpha feto-protein (AFP) for HCC surveillance. Provision of this service is variable. There are no guidelines for secondary HCC surveillance. We aimed to survey UK HCC surveillance practice.
Method: An electronic questionnaire was distributed to all NHS hospitals via BASL with responses captured July 2021-January 2022 (single response per centre).
Results: 39 centres responded (15 hepatobiliary (HPB), 6 transplant, and 24 non-HPB centres) from across the UK (Figure 1, summarised in Table 1). NICE eligibility criteria were universally applied, but considerable variability exists otherwise (e.g. surveillance of Child-Pugh C, NASH, autoimmune disease). An estimated 80% undergoing surveillance have cirrhosis. 85% of centres do 6 monthly US and AFP. Compliance was estimated (25% unsure) at 80% but not routinely audited.

Figure: Responding BASL centres

No. of patients under HCC surveillance	1250 (300–3000)	500 (100–1250)	
Median no. of patients/ consultant	156 (27–750)	145 (43–500)	
Median no. of patients/SN	140 (60–1500)	233 (54–1250)	
HCC surveillance programme?	95%		
Administrative support?	10%		
Written protocol for HCC surveillance?	36%		
Is HCC surveillance explained to the patient?	No 8%	Verbal 46%	Written and verbal 46%
Regular audit of HCC detection?	13%		
US reported using a template?	20%		
Agreed pathway for poor views?	Yes 28%	No 72%	
Offer CT or MRI for primary surveillance?	Yes 59%	No 41%	
Secondary HCC surveillance database?	41%		
Written protocol for secondary surveillance?	33%		

General sonographers and/or radiologists perform most surveillance and do not use structured reporting, felt desirable by most respondents. Poor views on US are approached heterogeneously with patients variably offered ongoing US, CT or different MRI protocols. Secondary surveillance is variable, typically using regular CT or MRI with contrast every 3–6 months for 2–5 years before 90% return to US surveillance.

Conclusion: Most responding UK NHS hospitals follow 6-monthly surveillance guidance for primary HCC surveillance. However, data recording of HCC screening practice is variable with limited data collection regarding compliance, yield and quality. HCC US screening is mostly performed by non-specialists without standardised reporting with inconsistent approaches to poor views. The quality of HCC screening may be improved by consistent resourcing, standardised pathways, data collection and quality assurance.
