
Conclusion: CHD coinfected patients had significantly greater comorbidities, HRU and costs than CHB monoinfected patients within an age- and gender-matched cohort of Spanish patients from a hospital database study over 19 years of duration. These findings further confirm the need for early linkage to care to alleviate future disease progression.

THU411

Clinical features predictive of cirrhosis in a large cohort of patients with chronic hepatitis delta infection- Insights from the D-LIVR trial

Email: ohadet34@yahoo.com

Background and aims: Chronic hepatitis delta (CHD) infection is the most rapidly progressive form of chronic viral hepatitis. Data regarding predictors of cirrhosis in chronic HDV is fairly limited especially in those of younger age. The aim of the current analysis was to assess the predictive value of demographic and laboratory variables as well as non-invasive test scores of liver fibrosis for diagnosis of biopsy proven cirrhosis in a large cohort of patients CHD.

Method: We prospectively evaluated 407 patients with compensated liver disease who enrolled in the on-going Phase 3 HDV D-LIVR trial (NCT03719313). At baseline, demographic data and anthropometric measurements were collected. Liver stiffness measurement (LSM) and/or Fibrotest were performed, and blood tests were obtained for complete blood count, biochemical panel, and HBV and HDV serologic and viral markers. All patients underwent liver biopsy within 45 days from non-invasive testing. Descriptive statistics were used to summarize demographic and clinical baseline patient characteristics, and chi-square test was used for univariate and multivariate analysis. A series of logistic regression models was fit to the data including cirrhosis status as the outcome, and LSM results, AST, ALT, platelets, albumin, bilirubin, Fibrotest score, HBsAg, and BMI as potential covariates.

Results: Of the 407 patients enrolled to the study, median age of 42.7 (SE 0.55), 69.4% male, with 108 (26.5%) patients showing biopsy confirmed cirrhosis. Of those, 48 (44.4%) were ≤45 years of age. In patients ≥ 45 years of age (146), 60 (41%) were cirrhotic at baseline. In univariate analysis, the following variables were statistically significantly associated with cirrhosis: older age ($p < 0.001$), BMI ($p = 0.02$), AST ($p < 0.001$), but not ALT, platelet count ($p < 0.001$), albumin ($p = 0.002$), INR ($p = 0.006$), HBsAg levels ($p = 0.03$) by both LSM and Fibrotest ($p < 0.001$ for both). In multivariate logistic regression, the model that best fit the data included age, platelets, and Fibrotest result as covariates ($p = 0.04$, 0.007 and 0.008, for age, platelets and Fibrotest, respectively). Odds ratio was 1.032 (CI 1.001–1.064) for age, 0.98 (CI 0.98–0.99) for platelet count and 7.168 (CI 1.647–31.191) for Fibrotest. In the subgroup of patients ≤ 45 years of age, the model that best fit the data included LSM results, platelets, and INR ($p = 0.04$ for all). Odds ratio was 1.079 (CI 1.002–1.162) for LSM, 0.99 (CI 0.98–1.0) for platelet count and 66.9 (CI 1.176->999.999) for INR.
Conclusion: In a large cohort of patients with CHD, alarmingly high rates of cirrhosis were seen among younger patients with compensated liver disease. A high index of suspicion for cirrhosis should be maintained in this population especially as it ages, and in those showing subtle changes in markers of synthetic liver function and portal hypertension.

THU412
Establishment of a new diagnostic model for significant liver tissue damage in patients with chronic hepatitis B virus infection in the immune tolerance phase

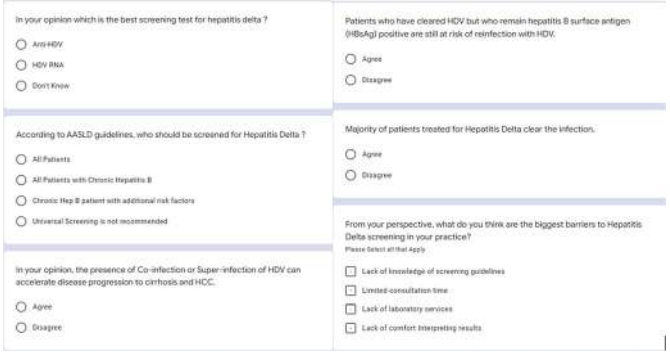
Airong Hu[1], Suwen Jiang[1], Xiaojun Shi[2], Dedong Zhu[3], Zheyun He[2], Chenqian Zhu[4], Lukan Zhang[4]. *[1]HwaMei Hospital, University of Chinese Academy of Sciences, Ningbo Institute of Liver Diseases, Ningbo, China; [2]HwaMei Hospital, University of Chinese Academy of Sciences, Liver Disease Department, Ningbo, China; [3]HwaMei Hospital, University of Chinese Academy of Sciences, Liver Oncology Department, Ningbo, China; [4]Medical School of Ningbo University, Graduate School, Ningbo, China*
Email: huairong@ucas.edu.cn

Background and aims: To establish a new diagnostic model for judging significant liver tissue damage in patients with chronic hepatitis B virus (HBV) infection in the immune tolerance (IT) phase.
Method: The clinicopathological data of 275 patients in the IT phase who underwent liver biopsy from January 2015 to November 2020 were included. According to the liver pathological changes, patients were divided into <G2 group and ≥G2 group, <S2 group and ≥S2 group, non-significant liver pathological damage group (GS0 group, <G2 + <S2) and significant liver pathological damage group (GS1 group, ≥G2 and/or ≥S2). The liver pathological changes and clinical features, the diagnostic models and their evaluation values for significant liver pathological damage were analyzed.
Results: Among 275 patients, 43 cases (15.64%) with liver histologic activity ≥G2, 30 cases (10.91%) with liver fibrosis ≥S2, and 55 cases (20.00%) met the liver pathological damage (GS1, ≥G2 and/or ≥S2). The correlated independent risk factors affecting significant liver pathological damage were age, levels of hepatitis B e antigen, γ-glutamyltransferase, platelet, alkaline phosphatase and alanine aminotransferase ($p < 0.05$). The established diagnostic models included Y_G (≥G2), Y_S (≥S2), and $Y_{G/S}$ (GS1). The diagnostic values of $Y_{G/S}$ were the highest for ≥G2 and GS1, the diagnostic values of Y_G and Y_S were the highest for ≥S2. The threshold of $Y_{G/S}$ was 0.18, the sensitivity, specificity and negative predictive value were 78.18%, 73.64% and 93.10%, respectively. When $Y_{G/S}$ <0.05, the sensitivity, negative predictive value and negative likelihood ratio were 98.18%, 97.96% and 0.08, respectively. When $Y_{G/S}$ ≥0.25, the specificity and positive likelihood ratio were 90.45% and 5.14, respectively. When $Y_{G/S}$ ≥ 0.30, the specificity and positive likelihood ratio were 95.91% and 9.33, respectively.
Conclusion: Approximately 20% of patients with chronic HBV infection in IT phase have significant liver pathological damage. The diagnostic model of $Y_{G/S}$ (<0.05 or ≥0.30) has certain evaluation value for significant liver pathological damage and can avoid liver biopsy to a certain extent.

THU413
Provider factors shaping hepatitis delta screening

Dewan Giri[1], Rohit Nathani[2], Randy Leibowitz[2], Carolina Villarroel[3], Sidra Salman[2], Gres Karim[3], Bo Hyung Yoon[4], Amreen Dinani[5], Ilan Weisberg[6]. *[1]Icahn School of Medicine at Mount Sinai Beth Israel, Department of Medicine, New York, United States; [2]Mount Sinai Morningside/West, Medicine; [3]Mount Sinai Beth Israel, New York, United States; [4]Mount Sinai Beth Israel/Morningside/West; [5]Icahn School of Medicine at Mount Sinai; [6]New York Presbyterian Brooklyn Methodist Hospital, United States*
Email: dewan.giri@mountsinai.org

Background and aims: Hepatitis Delta is a defective RNA Virus that requires Hepatitis B Virus to propagate. Infection results in the most severe form of viral hepatitis and is associated with a high risk of cirrhosis and hepatocellular carcinoma. The global burden remains undefined despite its discovery almost 40 years ago. Increased public health measures saw a decrease in the incidence of HDV in the 1990s leading to under-testing and a complacent view of the HDV public health problem. Despite the resurgence of interest seen in the last few years, it continues to remain unrecognized, especially in the primary care setting. The objective of our study is to assess physician knowledge, attitudes, and behaviors toward hepatitis delta screening.
Method: An anonymous 6-question internet-based survey assessing knowledge, attitudes, and behavior around HDV was sent to internal medicine residents, primary care providers (PCP), gastroenterologists, and Gastroenterology Fellows at tertiary care hospital systems, New York, USA from 2/1/2022 through 03/20/2022.
Results: Approximately 200 surveys were sent, and a total of 121 (60%) responses were completed. There were 75 responses from PCP and 46 responses from Specialty Care Providers. Gastroenterologists and fellows were more likely to order HDV antibody than HDV RNA as a screening test than PCP (66% and 61% vs 18% and 22%). A substantial portion of PCPs (50%) and residents (33%) were unsure about appropriate screening tests for HDV. Less than one-third of PCPs (26%), residents (24%), and fellows (28%) identified chronic hepatitis B (CHB) in combination with additional risk factors (CHB +RF) as a criterion for HDV screening. Gastroenterologists were evenly divided between all CHB and CHB +RF patients (48% vs 44%) for screening. Majority (97%) of the participants acknowledged that HDV infection contributed to disease progression, 78% agreed that patients who have cleared HDV are at risk for re-infection and 63% agreed with the statement that the majority of the patients with HDV cleared the infection with treatment. Lack of knowledge of screening guidelines and lack of comfort interpreting results were the two most commonly cited barriers to HDV screening.



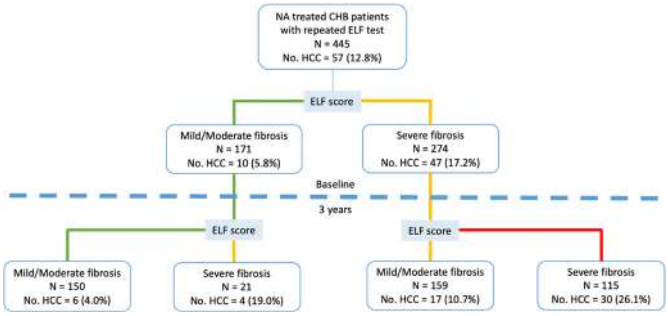
Conclusion: There are significant gaps in knowledge among providers regarding HDV. Our quest to eliminate HDV should start with disease awareness, develop familiarity with guidelines and testing.

THU414

Changes of enhanced liver fibrosis score predict hepatocellular carcinoma in chronic hepatitis B patients receiving antiviral treatment

Yan Liang[1], Terry Cheuk-Fung Yip[1], Che To Lai[1], Shuk Man Lam[1], Yee-Kit Tse[1], Vicki Wing-Ki Hui[1], Henry LY Chan[2], Vincent Wai-Sun Wong[1], Grace Wong[1]. *[1]Department of Medicine and Therapeutics, the Chinese University of Hong Kong, Hong Kong; [2]Union Hospital, Hong Kong*
Email: wonglaihung@gmail.com

Background and aims: Enhanced liver fibrosis (ELF) score is a widely used non-invasive assessment for liver fibrosis. We aimed to derive and evaluate an algorithm based on ELF score changes at three years apart to predict hepatocellular carcinoma (HCC).
Method: Antiviral treated chronic hepatitis B (CHB) patients who had two stored serum samples at about three years apart were included. ELF score was assessed by retrieving the two stored serum samples. Baseline was defined as the date of the first ELF results. The primary end point was the cumulative incidence of HCC.
Results: There were 445 CHB patients (mean age: 51.6 ± 10.3 years; male: 73.9%) included, among whom 57 (12.8%) patients developed HCC during the mean follow-up of 158 months. At baseline, 171 (38.4%) and 274 (61.6%) patients had mild/moderate and severe fibrosis respectively by ELF score (cutoff: 9.8). About three years later, 35.7%, 59.6% and 4.7% of patients had ELF score improved, stable and deteriorated, respectively. 150 patients with continuous low ELF score had lowest risk of HCC (4.0%). 21 patients with deteriorated ELF score had HCC risk increased from 5.8% to 19.0%. 159 patients with ELF score improved had HCC incidence reduced from 17.2% to 10.7%. 115 patients with continuous high ELF score had highest HCC risk (26.1%). (Figure) The cumulative incidence of HCC was significantly different between these four groups (p <0.001).



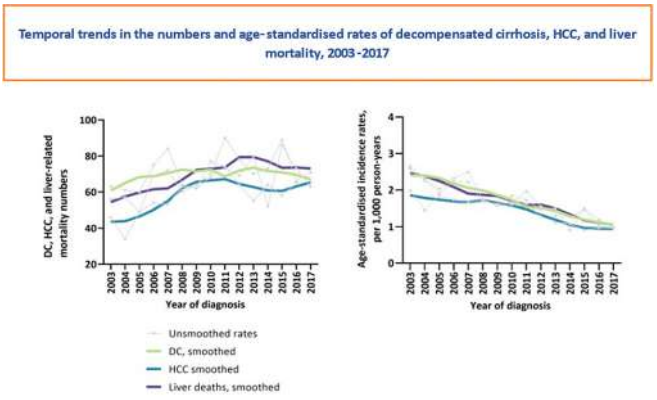
Conclusion: The algorithm based on ELF score changes at three years apart is a good predictor of HCC in CHB patients receiving antiviral treatment.

THU415

Trends in decompensated cirrhosis and hepatocellular carcinoma diagnosis among people with a hepatitis B notification in New South Wales: a population-based data linkage study

Syed Hassan Bin Usman Shah[1], Maryam Alavi[2], Behzad Hajarizadeh[1], Gail Matthews[2], Marianne Martinello[1], Mark Danta[3], Janaki Amin[4], Matthew Law[5], Jacob George[6], Gregory Dore[1]. *[1]The Kirby Institute, UNSW Sydney, Viral Hepatitis Clinical Research Program, Sydney, Australia, [2]The Kirby Institute, UNSW Sydney, Viral Hepatitis Clinical Research Program, Sydney, Australia; [3]St Vincent's Hospital Sydney, Darlinghurst, Australia; [4]Macquarie University, Department of Health Systems and Populations, Macquarie Park, Australia; [5]Kirby Institute, Kensington, Australia; [6]Westmead Hospital, Westmead, Australia*
Email: hbinusman@kirby.unsw.edu.au

Background and aims: Population-level trends and factors associated with hepatitis B virus (HBV)-related decompensated cirrhosis (DC), hepatocellular carcinoma (HCC), and liver mortality are crucial to evaluate therapeutic intervention impacts.
Method: Trends in HBV-DC and -HCC diagnoses and liver-related mortality in New South Wales, Australia, were determined through linkage of HBV notifications (1993–2017) to hospital admissions (2001–2018), mortality (1993–2018), and cancer registry (1994–2014) databases. Late HBV notification was defined as notification at or within two years of DC and HCC diagnosis. Cox proportional hazards regression and multivariable logistic regression analyses were performed to evaluate factors associated.
Results: Among 59, 911 people with HBV notification, 1, 196 (2.0%) DC and 1, 001 (1.7%) HCC diagnoses, and 1, 158 (1.9%) liver-related deaths were documented. Since early 2000s, DC and HCC diagnoses numbers increased; however, age-standardised incidence decreased from 2.58 and 1.99 in 2003 to 0.96 and 0.95 per 1, 000 person-years (PYs) in 2017. Similarly, age-standardised liver mortality decreased from 2.64 in 2003 to 0.97 per 1, 000 PYs in 2017. Among people with DC and HCC diagnoses, late HBV notification declined from 41% and 40% during 2001–2009 to 28% and 26% in 2010–2018, respectively. Predictors of DC diagnosis included older age (birth <1944, adjusted hazard ratio [aHR] 8.15, 95% CI 6.26, 10.61), alcohol-use disorder (aHR 7.19, 95% CI 5.83, 8.86) and HCV co-infection (aHR 2.17, 95% CI 1.74, 2.70). Predictors of HCC diagnosis included older age (birth<1944, aHR 11.61, 95% CI 8.63, 15.61) and male gender (aHR 3.65, 95% CI 2.90, 4.59).



Conclusion: In an era of improved antiviral therapies, HBV liver morbidity and mortality risk has declined. HCV co-infection and alcohol-use disorder are key modifiable risk factors to HBV disease burden.

THU416

Point of care screening tests for hepatitis B and commitment of a dedicated nurse lead to succesful linkage to care of ethnic minorities

Axelle Vanderlinden[1,2], Erwin Ho[2,3], Liesbeth Govaerts[2], Bo De Fooz[2], Pierre Van Damme[4], Peter Michielsen[2,3], Thomas Vanwolleghem[2,3].
[1]University of Antwerp, Viral Hepatitis Research Group, Laboratory of Experimental Medicine and Pediatrics, Antwerpen, Belgium; [2]Antwerp University Hospital, Department of Gastroenterology and Hepatology, Edegem, Belgium; [3]University of Antwerp, Viral Hepatitis Research Group, Laboratory of Experimental Medicine and Pediatrics, Antwerpen, Belgium; [4]University of Antwerp, Vaxinfectio, Antwerpen, Belgium
Email: axelle.vanderlinden@uza.be

Background and aims: In low endemic countries, screening for hepatitis B surface antigen (HBsAg) in migrants is cost-effective to reduce the disease burden of hepatitis B virus (HBV) infections, but linkage to care (LTC) remains a challenge. We previously found outreach screenings for HBV using point of care tests (POCT) to result in a 2.5 times higher LTC compared to venepunctures in an Asian migrant population. In the current study we compared LTC between different ethnic groups screened for HBsAg with POCT in an outreach setting. A secondary objective, was to compare the estimated HBsAg seroprevalence for ethnic minorities to the established prevalence in the general population in order to guide future screening initiatives.
Method: Opportunistic outreach screenings using finger prick Vikia HBsAg tests were performed at municipal integration classes between 11/2017 and 03/2021. If tested positive, an appointment was given immediately at the outpatient hepatology clinic for follow-up and confirmation of HBsAg positivity in blood. A dedicated nurse contacted identified patients via phone, social media or home visits to motivate them for further linkage to care. The latter was defined as having received medical care from a hepatologist, a blood test and an abdominal ultrasound.
Results: A total of 521 persons with different ethnicities (Asia, Middle-East and Africa) were serologically screened using POCT tests. The seroprevalence for HBsAg was 3.45% (18/521) and was significantly higher compared to that of the general population (i.e. 0.66% in 2003 ($p < 0.0001$)). All HBsAg-positive patients were linked to care and assessed by a hepatologist. LTC for all ethnicities combined ($p < 0.0001$), for Sub-Saharan African patients ($p = 0.023$) and Middle-Eastern patients ($p < 0.0001$) was significantly higher compared to the previously observed rate of 34.38% (11/32 patients) using venepunctures as a screening method, but without the commitment of dedicated nurse. Among the HBV infected patients, 22.22% (4/18), 83.33% (15/18) and 22.22% (4/18) met criteria for treatment indication, intrafamilial transmission risk and HCC surveillance respectively. Despite COVID-19 pandemic, linkage to care remains high using POCT and through the commitment of a dedicated nurse. However, the time frame between screening and the first hospital visit is significantly higher ($p = 0.0049$) during the COVID-19 pandemic than in the pre-pandemic period.
Conclusion: HBsAg seroprevalence in ethnic minorities is higher than the general population and warrants targeted screening. Most of the identified patients meet the indication for treatment, counseling to prevent intrafamilial transmission or HCC surveillance. In addition, the use of POCT and commitment of a dedicated nurse can overcome previously identified barriers for linkage to care.

THU417

Prediction of comprehensive prognosis through computed tomography analysis using deep learning algorithm in patients with chronic hepatitis B

Jeongin Yoo[1], Heejin Cho[2], Dong Ho Lee[1,3], Eun Ju Cho[2]. *[1]Department of Radiology, Seoul National University Hospital, Seoul, Korea, Rep. of South; [2]Department of Internal Medicine and Liver Research Institute, Seoul National University College of Medicine, Seoul, Korea, Rep. of South; [3]Institute of Radiation Medicine, Seoul National University Medical Research Center, Seoul, Korea, Rep. of South*
Email: creatioex@gmail.com

Background and aims: Computed tomography (CT)-based metrics, such as spleen, liver volume or body fat area, has been reported to be associated with liver-related or metabolic outcomes; however, the prognostic value of artificial intelligence-based CT metric analysis has not been much studied yet. We aimed to evaluate the comprehensive prognosis through CT analysis using deep learning algorithm in patients with chronic hepatitis B (CHB).
Method: Consecutive patients without hepatic decompensation events who underwent contrast-enhanced abdomen CT for hepatocellular carcinoma (HCC) surveillance between January 2005 and June 2016 were included. CT images were processed in an automated analysis software program using convolutional neural network (DeepCatch and MEDIP, MedicalIP, Seoul, Korea). We assessed the cumulative incidence (CI) of the occurrence of HCC, hepatic decompensation, and diabetes mellitus (DM), and identified the significant predictors of each outcome. The optimal cutoff values related to each outcome was obtained using the minimal p value approach method.
Results: A total of 3041 patients were included and retrospectively reviewed. During the median follow-up period of 10.3 years, HCC occurred in 141 patients, and a larger spleen volume was significantly correlated with HCC development ($p < 0.001$). 103 patients experienced hepatic decompensation, and spleen volume was also significantly associated with decompensation ($p < 0.001$). DM developed in 127 patients, and only the abdominal visceral fat area (VFA) showed a significant association with DM development ($p = 0.002$). The optimal cutoff spleen volume was estimated to be 197 ml for HCC development and 259 ml for the occurrence of decompensation. In addition, the optimal cutoff of abdominal VFA for DM development was predicted to be 7604 mm^2. The estimated 5-year, 10-year, and 15-year CI of HCC occurrence with spleen volume >197 ml were 4.2%, 7.5%, and 9.5%, respectively, and were approximately two times higher than in those of 1.7%, 2.8%, and 4.3% with spleen volume ≤197 ml ($p < 0.001$). For hepatic decompensation, the estimated 5-

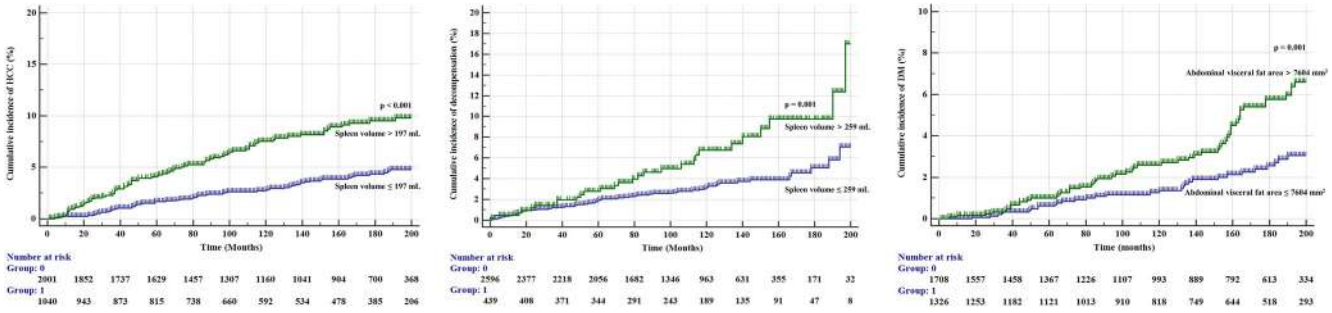


Figure: (abstract: THU417)

year, 10-year, and 15-year CI were 2.8%, 6.7%, and 9.7%, respectively, with greater than 259 ml in spleen volume, compared with 1.9%, 3.2%, and 5.0% with less than 259 ml of spleen volume ($p = 0.001$). In DM development, the estimated 5-year, 10-year, and 15-year CI were 1.0%, 2.6%, and 5.8% with more than 7604 mm^2 in abdominal VFA, significantly different from 0.6%, 1.4%, and 2.5% respectively below 7604 mm^2 of abdominal VFA ($p = 0.001$).

Conclusion: A larger spleen volume was significantly associated with HCC occurrence and hepatic decompensation, and a higher abdominal VFA was strongly correlated with DM development in patients with CHB. Automatically measured spleen volume and abdominal VFA might be used as relevant prognostic biomarkers in CHB patients.

THU418

Analysis on the normal threshold of alanine aminotransferase level based on liver pathology in patients with chronic hepatitis B

Airong Hu[1], Suwen Jiang[1], Xiaojun Shi[1], Dedong Zhu[2], Zheyun He[3], Lukan Zhang[4], Chenqian Zhu[4]. *[1]HwaMei Hospital, University of Chinese Academy of Sciences, Ningbo Institute of Liver Diseases, Ningbo, China; [2]HwaMei Hospital, University of Chinese Academy of Sciences, Liver Oncology Department, Ningbo, China; [3]HwaMei Hospital, University of Chinese Academy of Sciences, Liver Disease Department, Ningbo, China; [4]Medical School of Ningbo University, Graduate School, Ningbo, China*
Email: huairong@ucas.edu.cn

Background and aims: To comparatively analyze the liver pathology and clinical characteristics in chronic hepatitis B virus (HBV) infected patients with normal alanine aminotransferase (ALT) of different upper limits of normal (ULN), and to explore the normal threshold of ALT for initiating treatment.
Method: The clinical data of 667 chronic HBV infected patients who underwent liver biopsy from January 2014 to December 2020 were included in this study. The inclusion criteria were ALT <ULN and HBV DNA positive (>30 IU/ml). According to the ULNs of ALT, the enrolled patients were divided into ALT I group (male for <30 IU/L, female for <19 IU/L), ALT II group (30 IU/L ≤male <35 IU/L, 19 IU/L ≤female <25 IU/L) and ALT III group (35 IU/L ≤male <40 IU/L, 25 IU/L ≤female <40 IU/L). The clinicopathological characteristics and their correlation, and the ALT cut-off value for significant liver pathological damage were analyzed.
Results: The constituent ratios of GS II ($G \geq 2$ and/or $S \geq 2$) in the three groups were 26.05% (99/380), 32.03% (41/128) and 46.54% (74/159), respectively. And there were significant differences in the mean Ridit values of G and S and the constituent ratios of G II (≥G2), S II (≥S2) and GS II among the three groups ($p < 0.001$). There were significant differences in the constituent ratios of gender and HBsAg staining positivity, and the levels of ALT, aspartate aminotransferase (AST), APRI, LIF-5 among the three groups ($p < 0.01$). The positively correlated factor that affect the liver tissue damage was γ-glutamyltransferase level, and the negatively correlated factors were PLT, albumin/globulin and HBV DNA levels. The ALT thresholds for G I (<G2) and G II, S I (<S2) and S II, GS I (<G2 + <S2) and GS II in total patients were 21.5 IU/L, 22.5 IU/L, and 25.6 IU/L, respectively. And those of male patients were 25.6 IU/L, 23.5 IU/L and 25.6 IU/L, respectively. Those of female patients were 17.5 IU/L, 22.5 IU/L and 25.5 IU/L, respectively.
Conclusion: There are statistically significant differences in the significant liver pathological damage in chronic HBV infected patients with normal ALT of different ULN. The normal threshold (diagnostic cut-off value) of ALT for judging significant liver pathological damage is recommended to be adjusted to 25 IU/L.

THU419

Prevalence rates and eligibility for antiviral treatment against hepatitis B in Casamance, Senegal

Victor Arendt[1], Mame Aisse Thioubou[2], Kalilou Diallo[2], Henri Goedertz[3], Daouda Diouf[4], Benjamin Sambou[4], Chabi Bindia[4], Ousseynou Cisse[5], Salimata Camara[4], Noel Manga[2], Esther CalvoLassoDelaVeiga[1], Boubacar Diouf[4]. *[1]Centre Hospitalier de Luxembourg, Infectious Diseases, Luxembourg, Luxembourg; [2]Hôpital de la Paix, Gastroenterology, Ziguinchor, Senegal; [3]SANACCESS, Psychology, Luxembourg, Luxembourg; [4]Enda Santé, Epidemiology, Ziguinchor, Senegal; [5]Centre de Sante Silence, Medicine, Ziguinchor, Senegal*
Email: vic_arendt@yahoo.fr

Background and aims: HBV infection is a major public health problem in Casamance, southern Senegal. A cohort of HBV carriers has been set up within the framework of the CARES program. The objective of this study was to assess the prevalence of HBV in the region and the antiviral treatment needs of patients in this cohort based on current recommendations.
Method: Descriptive multicenter cohort study of patients followed in four health facilities in the region (Bignona and Ziguinchor health centers, Regional and La Paix hospitals), carried out as part of the CARES program from January 01, 2019 to December 31, 2021. Screening for HBsAg was performed with kits from Rapid Signal TM HBsAg Serum/Plasma Dipstrip (Orgenics ltd Israel). Treatment eligibility was assessed based on age, family history of severe HBV-related disease, degree of fibrosis, Hbe antigen, viral load and transaminase levels according to WHO, EASL and the TREAT-B score.
Results: HBV prevalence rates were: 8, 8% in blood donors, 9, 7% in bus drivers, 7, 7% in fishermen; 8, 5% in health care workers, 6% in women living with HIV (WLHIV), 5, 5% in pregnant women, 0% (0/88) in children born to WLHIV. We included 1449 HBsAg positive patients. The mean age was 35.6 years with a sex ratio (M/F) of 1, 37. The predominant circumstances of screening were: blood donation (368 cases), symptoms or medical consultation (306 cases), antenatal screening (167 cases), routine or occupational health visit (148 cases) and a screening campaign (151 cases). To assess the need for treatment we analyzed the available results of the following tests: viral load (969/1449); transaminases and GGT (1153/1449); HBe antigen assay (846/1449), Fibroscan (830/1449), AST-platelet ratio index (609/1449), Fib-4 score (608/1449), history of cirrhosis or hepatocellular carcinoma in first degree relatives (8/463). The complete panel of parameters was available in only 315 patients.
The proportion of eligible patients according to the different recommendations was 6, 3% (WHO 2015), 8, 9% (WHO simplified), 7, 6% (EASL 2017), 8% (TREAT-B).
Conclusion: The prevalence of HBV in Casamance remains high. The proportion of HBV patients eligible for antiviral treatment ranges from 6, 3 to 8, 9% with only small differences according to the different consensus recommendations (WHO 2015, EASL 2017, TREAT-B).

THU420

Comorbidities, and not viral load, are predictors of cirrhosis in AgHBe-negative chronic infection

Sara Archer[1], Luís Maia[1], Catarina Afonso[2,3], Jose Manuel Ferreira[1], Teresa Moreira[1], Marta Rocha[1], Tiago Pereira Guedes[1], Isabel Pedroto[1]. *[1]Centro Hospitalar Universitário do Porto, Portugal; [2]Instituto de Ciências Biomédicas Abel Salazar, Portugal; [3]Instituto de Ciências Biomédicas Abel Salazar, Porto, Portugal*
Email: u13418@chporto.min-saude.pt

Background and aims: There is an ongoing debate about the heterogeneity of the definition of HBeAg-negative chronic HBV infection (formerly inactive carriers, IC), which patients to treat, and how comorbidities can influence its natural course. The aim of our study is to assess risk factors, including higher viral load (VL) and increased ALT, for cirrhosis.

Method: This is a retrospective cohort of chronic HBV hepatitis patients with at least 2 consultations between 2010–2020 in a western center mediterranean terciary centre. Demographic and clinical data were retrieved. Individuals with less than 1 year of follow-up, HCV or HIV co-infection and with insufficient data were excluded. Statistical analysis was performed using SPSS. As per EASL guidelines, upper limit of normal (ULN) of 40U/L for ALT was considered.

Results: 635 patients were included, of which 340 as IC. From these, 53.5% were men with mean current age 56.16 ± 13.4 years, mean follow-up of 10.14 ± 8 years, during which 4.1% developed cirrhosis. Liver-related mortality was 0.9%. 14.5% patients had excessive alcohol consumption; 12.4% diabetes, 15.9% arterial hypertension and 18.2% dyslipidemia.

Risk factors for cirrhosis: diabetes (OR 4.8, p = 0.002), arterial hypertension (OR 7.3, p = 0.000), dyslipidemia (OR 4.46, p = 0.004), alcohol (OR 4.91, p = 0.002), ALT > ULN or VL > 2000 IU/ml (OR 5.32, p = 0.005). On multivariate analysis including age and follow-up time, none was an independent predictor.

When analysed separately, alcohol (OR 18.31, p = 0.031) predicted cirrhosis in patients with both ALT < ULN and VL < 2000 IU/ml, while in the others diabetes (OR 4.4, p = 0.028) and arterial hypertension (OR 5.4, p = 0.012) were the main predictors. This may be justified as alcohol abuse has less influence in ALT values.

The cut-off of 2000 IU/ml for VL did not predict development of cirrhosis in any group of patients.

Conclusion: In our cohort, comorbidities, and not VL, are predictors of cirrhosis in IC. Treating HBV in these patients may not be as relevant as controlling comorbidities. Our results support EASL current guidelines.

THU421

A systematic literature review and meta-analysis of primary sources reporting health state preference values in chronic hepatitis B, C, and D

Ankita Kaushik[1], Sarah Hofmann[2], Mariajoão Janeiro[2], Geoffrey Dusheiko[3,4], Andrew Lloyd[5], Filipa Aragão[2,6]. *[1]Gilead Sciences, Inc., Foster City, California, United States; [2]Maple Health Group, New York, United States; [3]University College London, Medical School, London, United Kingdom; [4]King's College Hospital, London, United Kingdom; [5]Acaster Lloyd Consulting Ltd, London, United Kingdom; [6]Universidade NOVA de Lisboa, NOVA National School of Public Health, Public Health Research Centre, Lisbon, Portugal*

Email: ankita.kaushik@gilead.com

Background and aims: Chronic viral hepatitis is associated with severe patient impairment and reduction in health-related quality of life (HRQoL). This is also reflected in low patient health state preference values (utilities) for severe health states. Utilities for health states are essential variables for cost effectiveness analyses for treatments. This study aimed to derive utilities for health states in chronic hepatitis B (cHBV), C (cHCV) and D (cHDV) through a systematic literature review (SLR) and meta-analyses (MA).

Method: Electronic literature databases (EMBASE and MEDLINE) were searched for primary articles that reported health state utilities for cHBV, cHCV or cHDV. Health states evaluated include Metavir fibrosis stages F0 to F4, decompensated cirrhosis (DC), hepatocellular carcinoma (HCC), post-liver transplant (LT), post-LT in year (Y1), and post-LT in year 2 and beyond (Y2+). MAs were performed with utilities based on EQ-5D-3L and based on a combination of instruments, also including EQ-5D-5L, HUI3, HUI2, SF-6D, SF-36, and standard gamble (SG), time trade-off (TTO) or visual analogue scale (VAS) techniques.

Results: The SLR identified 22 studies that derived utilities for cHBV and/or cHCV but none for cHDV. There was considerable heterogeneity in the methods adopted for utility elicitation and in the health states evaluated. Non-cirrhotic (NC; F0 to F3) and compensated cirrhosis (CC; F4) were the most evaluated health states. Mean utilities were higher in cHBV patients than in cHCV patients (except for advanced liver disease) and higher when determined based on the EQ-5D-3L than when derived from a combination of all instruments. Utility estimates decreased with disease progression, with the development of cirrhosis having the largest impact while LT seems to allow for some recovery.

Health state	cHCV			cHBV		
	Mean utility	95 % CI	n	Mean utility	95 % CI	n
EQ-5D-3L						
NC (F0-F3)	0.85	0.80-0.90	4	0.90	0.86-0.93	3
CC (F4)	0.72	0.65-0.79	2			
DC	0.70	0.61-0.79	3			
HCC	0.69	0.59-0.78	2			
PLT						
PLT (Y1)						
PLT (Y2)						
Combined instruments						
NC (F0-F3)	0.79	0.75-0.82	13	0.85	0.78-0.91	7
CC (F4)	0.66	0.61-0.71	11	0.76	0.65-0.87	3
DC	0.63	0.58-0.69	8	0.46	0.20-0.73	3
HCC	0.70	0.63-0.77	3	0.52	0.22-0.82	3
PLT	0.74	0.70-0.79	3			
PLT (Y1)				0.57	0.51-0.62	2
PLT (Y2)				0.67	0.62-0.72	2

Figure: Results of the MAs by utility instrument and health state

Conclusion: There is a large body of available literature reporting on utilities of patients living with cHCV, less in cHBV, but a paucity of studies in cHDV. The results show a large heterogeneity in reported health state utilities, likely due to the variation in the methods used and health states considered. The most comprehensive set of health state utility estimates were derived using EQ-5D for cHCV and from a combination of instruments for cHBV. This is the first meta-analysis of utilities in chronic viral hepatitis which could be used in future economic evaluations.

Immune-mediated and cholestatic disease: Clinical aspects

Hepatitis B transmission in early life in very remote Aboriginal communities in northern Australia

Richard Sullivan[1,2,3], Jane Davies[1,2], Paula Binks[1], Melita McKinnon[1], Roslyn Dhurrkay[1], Kelly Hosking[1,4], Sarah Bukulatjpi[5], Stephen Locarnini[6], Margaret Littlejohn[6], Steven YC Tong[1,7], Joshua Saul Davis[1,8]. *[1]Menzies School of Health Research, Charles Darwin University, Darwin, Australia; [2]Department of Infectious Diseases, Royal Darwin Hospital, Darwin, Australia; [3]Department of Infectious Diseases, Immunology and Sexual Health, St George and Sutherland Clinical School UNSW, Kogarah, Australia; [4]Population and Primary Health Care, Top End Health Service Northern Territory, Darwin, Australia; [5]Miwatj Health Aboriginal Corporation, Northern Territory, Australia; [6]Victorian Infectious Diseases Reference Laboratory, Peter Doherty Institute for Infection and Immunity, Royal Melbourne Hospital and University of Melbourne, Melbourne, Australia; [7]Victorian Infectious Disease Service, The Royal Melbourne Hospital and Doherty Department University of Melbourne at the Peter Doherty Institute for Infection and Immunity, Melbourne, Australia; [8]John Hunter Hospital, New Lambton Heights, Australia*

Email: richie.sullivan@menzies.edu.au

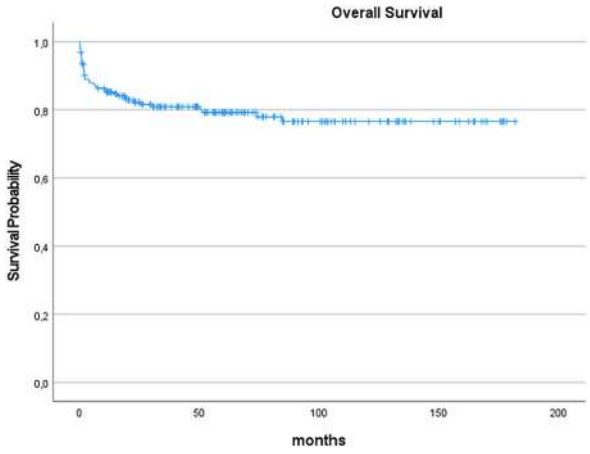
Background and aims: Chronic hepatitis B is a public health concern in Aboriginal communities of northern Australia with prevalence almost four times the non-Aboriginal population in the Northern Territory. Infection is suspected to occur in early life, however, the mode of transmission and vaccine effectiveness is not known in this population. WHO has set a target for hepatitis B elimination by 2030; elimination in this disproportionately affected population will require understanding of transmission and vaccine effectiveness.

Method: We conducted the study at four very remote communities. We approached mothers who were Hepatitis B surface antigen (HBsAg) positive and gave birth between 1988 and 2013. We obtained hepatitis B serology, immunisation and birth details. If both mother and child had hepatitis B viral DNA detected, we performed viral whole genome sequencing.
Results: We included 20 mothers and 38 of their children. The median age of the children was 8.8 years (IQR 5.7–13.0). Of 33 children with results available, 8 (24.2%, 95%CI 11.1–42.3) were anti-hepatitis B core (anti-HBc) positive, 3 (9.1%, 95%CI 1.9–24.3) of whom were also HBsAg positive. Hepatitis B immunoglobulin (HBIg) had been given at birth in 29 (76.3%, 95%CI 59.8 – 88.6) children and 26 children (68.4%, 95%CI 51.3–82.5) were fully vaccinated. Of the 3 children who were HBsAg positive, all had received HBIg at birth and two were fully vaccinated. Of the 5 who were anti-HBc positive and HBsAg negative, 4 had received HBIg at birth and one was fully vaccinated. Whole genome sequencing revealed one episode of mother to child transmission.
Conclusion: Although uncommon, there is ongoing transmission of hepatitis B in Aboriginal communities of northern Australia despite vaccination, and is likely occurring by both vertical and horizontal routes. Prevention will require ongoing investment to overcome the many barriers experienced by this population in accessing care.

THU423
the changing scenario of HBV chronic related disease in the transplant setting

Sara Battistella[1], Martina Gambato[1], Umberto Cillo[1], Alberto Zanetto[1], Alessandro Vitale[1], Enrico Gringeri[1], Marco Senzolo[1], Patrizia Burra[1], Francesco Paolo Russo[1]. [1]*University of Padova, Department of Surgery, Oncology and Gastroenterology, Italy*
Email: sarabattistella93@gmail.com

Background and aims: Hepatitis B virus (HBV) related chronic liver disease is one of the most common indication for liver transplantation (LT), for both decompensated cirrhosis and hepatocellular carcinoma (HCC). Introduction of nucleos (t)ide analogues (NA) significantly modified the natural history of the disease in the pre- and post- transplant setting, preventing decompensation of liver disease, disease recurrence and increasing post-LT patient and graft survival. This study aimed to assess the evolution of admission and management of patients affected by HBV-related liver disease in the WL for LT relatively to the introduction and spreading of high barrier NA and to evaluate overall long-term graft and patient survival after LT.
Method: All adults with HBV listed for LT at Padua University Hospital between 01.2006 to 12.2020 were retrospectively evaluated. Patients were divided in two groups according to their indication to inclusion in the WL (decompensated cirrhosis group: patients listed with MELD >15 with or without HCC; HCC group: patients with MELD <15 and presence of HCC). Patients were further divided according to the time of inclusion in the WL (2006–2013 and 2014–2020). For each patient we evaluated the antiviral treatment and HBV DNA at the time of inclusion in WL and the type of prophylaxis after LT. Patient survival were calculated using Kaplan Meier curves and comparison between different groups were performed using Log-Rank test.
Results: From 01.2006 to 12.2020 a total of 1502 patients included in the WL for LT, among them 186 patients were HBV infected. One fourth of patients had HBV DNA detectable at the time of inclusion in the WL and 86% were on antiviral treatment. Almost 60% of patients were wait-listed for decompensated disease, 30% of them had HCC as well. Eventually 31 patients were excluded from the waiting list: 17 for HCC progression, 3 for not liver related causes and 11 for stability of the disease, principally after the introduction of high barrier NA treatment. A total of 29 patients died in the waiting list, mainly during the first period of the study, and 126 patients underwent LT with a median waiting time of 6 months. The overall survival after LT was 90% at 1 year and 80% at 5 years. No significative difference in survival were observed between HBV patients transplanted for decompensated cirrhosis and those for HCC. Almost all HBV patients were treated with a combination therapy of HBIG and NA after LT and we recorded only 2 cases of transitory HBV reactivation, with no consequences on liver function.



Conclusion: HBV still remains one of the most common indication to LT, both for end stage liver disease and hepatocellular carcinoma. Thanks to high barrier NAs the mortality in the waiting list is decreased during the last years.

THU431
Outcomes of pregnancy in patients with autoimmune hepatitis in the Netherlands

Susan Fischer[1], Elsemieke de Vries[1], Ynto de Boer[2], Adriaan Van der Meer[3], Robert De Man[3], Johan Kuyvenhoven[4], Michael Klemt-Kropp[5], Tom Gevers[6], E.T.T.L. Email: s.e.fischer@lumc.nl

Background and aims: Data regarding the outcomes of pregnancy in patients with autoimmune hepatitis (AIH) are limited. This study focuses on the effects of pregnancy in AIH patients and neonatal outcomes.
Method: A retrospective multicenter cohort study was performed at the Leiden University Medical Centre (LUMC) in collaboration with nine participating hospitals from the Dutch Autoimmune Hepatitis Study Group in the Netherlands. Data concerning maternal and neonatal outcomes during and after pregnancy were collected from medical records in AIH patients with pregnancy. Risk factors were identified using logistic regression analysis to examine the association of defined risk variables with adverse maternal and neonatal outcomes.
Results: 93 pregnancies in 47 women resulted in 66 deliveries (71%) with a live birth rate of 98.5%. Preterm birth was mentioned in 20% and 19% of the children were born dysmature. 34% of the neonates were admitted to the hospital after birth. Flares of disease activity occurred in

4.5% during pregnancy, and in 26% of the postpartum episodes. The absence of biochemical remission at conception was identified as risk factor for the occurrence of postpartum flares (Odds ratio (OR) 6.8, 95% Confidence Interval (CI) 1.6–7.65). Flares in the year before conception were identified as a risk factor for the occurrence of gestational flares (OR 21.6, CI 1.7–282.0) and were associated with the occurrence of postpartum flares (p = 0.01). Maternal hypertensive disorders during pregnancy occurred in 15%. Women who were partially in remission were at higher risk for loss of biochemical remission after delivery (OR 10.0, CI 1.5–67.0) and to develop hypertensive disorders during pregnancy (OR 10.3, CI 1.5–68.6). No risk factors were found for the occurrence of adverse neonatal outcomes. Cirrhosis was found a risk factor for miscarriages (OR 3.4, CI 1.1–10.8). No other correlations between the presence of cirrhosis and adverse outcomes for both mother and child were observed.

Conclusion: Pregnancy in women with AIH ended in childbirth in 71%. There was a high incidence of spontaneous abortion, prematurity, dysmaturity compared to the general population. The rate of postpartum flares of AIH was similar to previous literature. Absence of biochemical remission at conception and a flare in the year prior to conception increases the risk of maternal complications during and after pregnancy. Lastly, cirrhosis was found a risk factor for miscarriages.

THU432

Cholangiopathy after severe COVID-19: what do we know so far?

Valéria Ferreira de Almeida e Borges[1], Helma Pinchemel Cotrim[2], Marcelo Simão Ferreira[3], José Humberto Caetano Marins[1], Haroldo Luis Oliva Gomes Rocha[1], Leonardo Augusto Dias Nascimento[1], Mayra Machado Fleury Guedes[1], Julia Esteves Guerra[1]. [1]*Universidade Federal de Uberlândia, Uberlândia, Brazil;* [2]*Universidade Federal da Bahia, Medicine School, Brazil;* [3]*Universidade Federal de Uberlândia, Medicine School, Brazil*
Email: valeriafaborges@gmail.com

Background and aims: From 2001 to 2018, before the Covid-19 pandemic, at least 16 studies described a type of secondary sclerosing cholangitis (SSC) in critically ill patients. During the pandemic, similar cases of cholangiopathy were observed in patients with severe Covid-19. The hypotheses suggested to explain this disease will be a liver ischemia related to micro thrombosis associated with SARS-CoV-2 or direct biliary epithelial infection. To describe the clinical characteristics of cholangiopathy in patients who survived the ICU period with severe Covid-19.

Method: Adult patients diagnosed with Covid-19, who presented severe cholestasis were included. All of them had prolonged stay in the ICU, needed for mechanical ventilation, high doses of vasopressors, ketamine use, and prone positioning. Criteria for SSC were elevated levels of alkaline phosphatase (ALP) and bilirubin; no previous history of liver disease; magnetic resonance cholangiopancreatography (MRCP) or endoscopic retrograde cholangiopancreatography (ERCP), and or liver biopsy, which showed the biliary tract alterations. The diagnosis of Covid-19 was with a positive PCR test in all cases.

Results: A total of 24 patients were include. Mean age was 57 ± 10 years and 66% were male. All developed cholestasis, after a mean of 20 days. The peak mean level of ALP was 1541 U/L, gamma-glutamyl transferase 2366U/L, aspartate aminotransferase 248, alanine aminotransferase was 276 U/L, and total bilirubin 10 mg/dL. MRCP were performed in 75% of cases, ERCP in 37% and cholangioscopy in one. The most relevant finding was rarefaction of the intrahepatic bile ducts in all, and bacterial cholangitis in two cases. Biliary casts were removed in seven of nine cases who underwent ERCP. All patients presented elevated levels of ALP, GGT and bilirubin after discharge, regardless of the ursodiol used. During the mean follow-up of 205 days, 6 patients progressed to cirrhosis and 7 (29%) to death. At follow-up, the most recent bilirubin dosage was on average 19 mg/dL in the group that died and 3.7 mg/dL in the group that survived *(p < 0.001)*.

Conclusion: In this simple of 24 cases, patients with Covid-19 presented a severe cholestatic disease and with rapid progression to cirrhosis or obit. The role of SARS-CoV-2 seems relevant, however other factors associated should be considered: mechanical ventilation for a long time; high doses of vasopressors and possible severe hemodynamic instability; prolonged stay in the intensive care unit and the ketamine used.

THU433

Enhanced liver fibrosis score correlates with transient elastography in patients with treated autoimmune hepatitis

Anna Stoelinga[1], Elsemieke de Vries[1], Maarten Tushuizen[1], Albert Stättermayer[2], Xavier Verhelst[3], Bart Van Hoek[1]. [1]*Leiden University Medical Center (LUMC), Gastroenterology and Hepatology, Leiden, Netherlands;* [2]*Medical University of Vienna, Wien, Austria;* [3]*Ghent University Hospital, Gent, Belgium*
Email: b.van_hoek@lumc.nl

Background and aims: Cirrhosis is an important prognostic factor for long-term survival of patients with autoimmune hepatitis (AIH). Little is known about progression of fibrosis during adequate therapy. The Enhanced Liver Fibrosis score (ELF-score) has not been validated in patients with AIH. The aim of this study is to evaluate the diagnostic accuracy of the ELF test for fibrosis compared to transient elastography (TE).

Method: Patients with AIH or AIH-variant syndrome, treated for a minimum of 6 months at baseline (BL) were eligible for inclusion. Serum samples of all patients were taken and TE was done simultaneously at BL and after one year. Patients were divided into two groups: complete biochemical remission (CR) (group 1) and incomplete remission (group 2) at BL. ELF-scores and its components were calculated from the collected serum. We investigated if there is a correlation between the ELF score and liver elastography for severe fibrosis. Cut-off for cirrhosis (=F4 fibrosis) at TE was >16 kPa. A cut-off for the ELF score was determined for cirrhosis in a receiver operator characteristics (ROC) curve analysis.

Results: A total of 66 patients in three academic hospitals in the Netherlands, Belgium and Austria were included. 68.2% were female, mean age at inclusion was 51.20 years (±17.24), median treatment duration at inclusion was 6.50 years (IQR: 2.00–11.00). During follow-up, two patients died (3%), two patients were lost-to-follow-up (3%). Group 1 consisted of 35 patients (53.0%), of whom 16 (45.7%) had moderate-severe fibrosis. Group 2 consisted of 31 patients (47.0%). 24 patients (77.4%) had none-mild fibrosis. ELF-score (9.46 vs 9.27, p = 0.58) and liver stiffness (8.70 vs 7.10 kPa, p = 0.078) at BL did not differ significantly between the groups. Liver stiffness did not change after one year irrespective of remission status.

There was a positive correlation between ELF-score and liver stiffness (rho = 0.48, p < 0.001). For F4 fibrosis, the area under the curve was calculated as 0.83. The cut-off value was determined at 9.68. sensitivity, specificity, positive and negative predictive value were 86.4%, 71.7%, 40.4% and 95.9%, respectively.

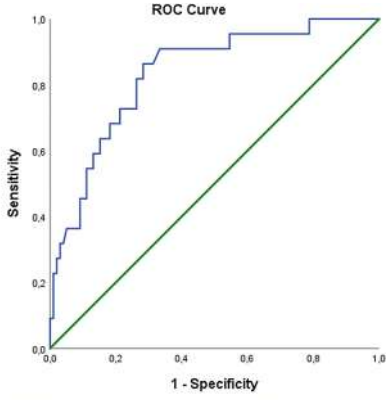

Figure 2: ROC analysis: ELF score. Diagnostic value of ELF score.

Conclusion: ELF-score shows good diagnostic accuracy in patients with AIH under immunosuppressive treatment irrespective of remission status. A cut-off at 9.68 can rule out severe fibrosis in patients with AIH. Change in remission status did not significantly change fibrosis with ELF-score or TE results.

THU434

Rationale for evaluation of PLN-74809 treatment in participants with primary sclerosing cholangitis in Phase 2a study INTEGRIS-PSC

Eric Lefebvre[1], Greg Cosgrove[1], Simon Wong[1], Erica Park[2], Fiona Cilli[1], Theresa Thuener[1], Marzena Jurek[1], Scott Turner[1], Martin Decaris[1], Johanna Schaub[1]. *[1]Pliant Therapeutics, Inc., South San Francisco, United States; [2]Pliant Therapeutics, Inc. (at time of study), South San Francisco, United States*
Email: elefebvre@pliantrx.com

Background and aims: Transforming growth factor beta (TGF-beta) signalling is a key driver of liver fibrosis. In primary sclerosing cholangitis (PSC), integrins over-expressed on injured cholangiocytes (alpha-v/beta-6) and myofibroblasts (alpha-v/beta-1) regulate TGF-beta activity. PLN-74809 is an oral, once-daily, dual-selective inhibitor of integrins alpha-v/beta-6 and alpha-v/beta-1 in development for the treatment of PSC and idiopathic pulmonary fibrosis. It has shown favourable tolerability in over 280 healthy participants, reduced TGF-beta signalling and achieved high target engagement in human lungs. Pre-clinical evaluation of antifibrotic activity resulting from dual integrin inhibition was performed to support clinical evaluation.
Method: PLN-74809 was administered orally for 6 weeks in BALBc.Mdr2-/- mice with established fibrosis. A tool alpha-v/beta-6 and alpha-v/beta-1 inhibitor compound, PLN-75068, was tested therapeutically in a diet-induced mouse model of biliary fibrosis using 3,5-diethoxycarbonyl-1, 4-dihydrocollidine (DDC). Hepatic collagen was quantified by hydroxyproline (OHP) and collagen proportionate area (CPA) and TGF-beta signalling by phosphorylated SMAD3 (pSMAD3) levels. An *ex vivo* study evaluated the effects of 2-day treatment with PLN-74809 on the expression of profibrotic genes, COL1A1 and COL1A2, in precision-cut liver slices (PCLivS) from tissue explants of participants with biliary fibrosis (n = 2 PSC; n = 2 primary biliary cholangitis [PBC]). A review of available blinded safety data from the enrolling Phase 2a study in participants with PSC was performed (NCT04480840).
Results: PLN-74809 dose-dependently reduced OHP (up to ~30%, $p < 0.05$), CPA (up to ~50%, $p < 0.05$) and pSMAD3 (up to ~40%, $p < 0.001$) in the BALBc.Mdr2-/- mouse model, as well as COL1A1 and COL1A2 gene expression (up to ~30%, $p = 0.0789$) in PCLivS from tissue explants of participants with PSC and PBC. PLN-75068 reduced OHP (up to ~20%, $p < 0.05$) in DDC-injured mice in a dose-dependent manner. PLN-74809 was well tolerated in participants with PSC. Most adverse events (AEs) were mild; none were severe. The most common AE was mild headache. One participant experienced serious AEs at least 20 days after the last dose of study drug, deemed not related by the investigator. One participant prematurely discontinued due to COVID-19. PLN-74809 pharmacokinetics in participants with PSC were consistent with those of healthy participants.
Conclusion: Pharmacological inhibition of integrins alpha-v/beta-6 and alpha-v/beta-1 demonstrated antifibrotic activity in two models of biliary fibrosis and in PCLivS from participants with PSC or PBC. Available safety findings from participants with PSC enrolled in the ongoing Phase 2a INTEGRIS-PSC study, continue to support the favourable tolerability profile of PLN-74809.

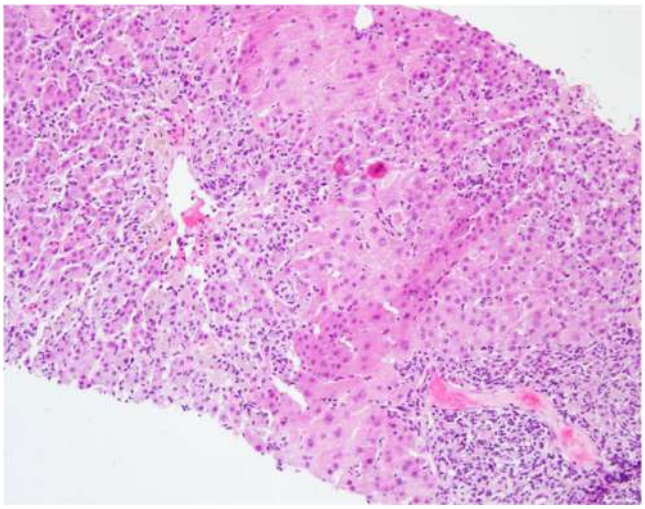
Email: greta.codoni@usi.ch

Background and aims: Autoimmune phenomena and clinically apparent autoimmune diseases, including autoimmune-like hepatitis, have increasingly been reported after SARS-CoV-2 infection, and after vaccination against it. It has been suggested that post-COVID19 vaccine hepatitis may be a novel clinical entity, urgently requiring investigation of well characterized cases. Our international case collection aims at investigating in a standardized way, clinical, serological and pathological features of a large number of patients with acute hepatitis after COVID-19 vaccination.
Method: Patients with acute hepatitis within 2 months from last vaccine dose and available liver biopsy, but without a history of autoimmune hepatitis, are included. Clinical data at diagnosis and outcome after a follow-up of 6 months are collected. Histology and autoimmune serology are centrally reviewed/tested.
Results: 42 patients included so far; 27 (65%) females; median age 59 years (range 16–78). Vaccine type: 16 BNT162b2; 9 ChAdOx1 nCov-19; 6 mRNA-1273; 5 Gam-COVID-Vac; 1 BBIBP-CorV; 2 ChAdOx1 nCov-19 + BNT162b2; 2 Gam-COVID-Vac + ChAdOx1 nCov-19; 1 Gam-COVID-Vac + mRNA-1273. Locally tested serology was positive for anti-nuclear antibody (ANA) in 31 cases; anti-smooth muscle antibody (ASMA) in 14, anti-mitochondrial antibody (AMA) in 3; 12 were ANA and ASMA-positive; none was anti-soluble liver antigen or anti-liver kidney microsomal antibody positive; 11 were seronegative. Mean IgG was 16.8 g/l (range: 6.6–34.4). Median time from vaccination to hepatitis diagnosis: 24.6 days (IQR 10.7–38). 12 had pre-existing extrahepatic autoimmune conditions.
Central histological review of the first 7 cases showed isolated central perivenulitis (n = 2) or mixed portal and lobular hepatitis with interface injury and confluent necrosis (n = 5; Figure). Aggregates of plasma cells and eosinophils (>5 cells/hpf) were observed in 4 and 3 cases, respectively.



35/42 patients were treated with immunosuppressive drugs; 33 steroids, 1 azathioprine, 1 azathioprine + steroids; all but one being still on treatment. Mean follow-up is 5 months; one patient died of extrahepatic cause 7 months after the diagnosis of hepatitis. All treated patients responded satisfactorily.
Conclusion: acute hepatitis arising after COVID-19 appears to be a heterogeneous condition: long-term follow-up will help understanding if in some cases the vaccine triggers autoimmune hepatitis or if it is a novel drug-induced nosological entity.

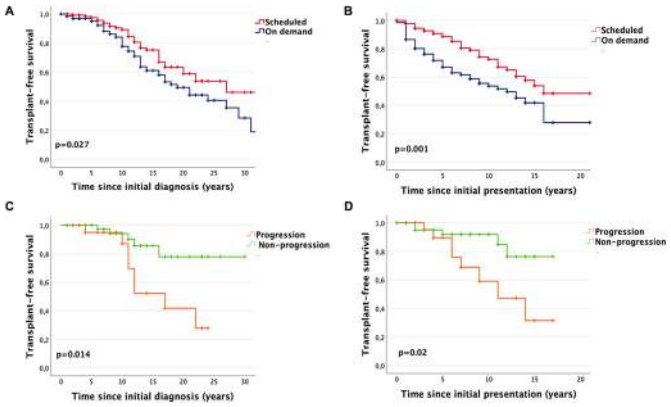
Email: michael.sigal@charite.de

Background and aims: Primary sclerosing cholangitis (PSC) is associated with biliary obstructions that can require endoscopic retrograde cholangiopancreatography (ERCP). While beneficial short-term effects of ERCP are well documented, follow-up interventional strategies are less defined and their long-term impact is debated. Here, we evaluated the outcome of a scheduled program that has been implemented at our tertiary liver center for over more than 20 years.
Method: Within our program, ERCPs were performed at regular and pre-defined intervals to follow-up or treat previously detected biliary stenosis and/or to remove concrements. In this retrospective cohort study, we evaluated the outcomes of this scheduled programmed ERCP approach in comparison to patients, who received endoscopic interventions only on clinical demand. The primary end point was transplantation-free survival. The secondary end points were occurrence of hepatic decompensation, recurrent cholangitis episodes, development of hepatobiliary malignancies and endoscopy-related adverse events.
Results: We included 268 consecutive patients with diagnosed PSC, 135 receiving scheduled ERCP and 133 receiving on demand ERCP. The rates of transplant-free survival since initial diagnosis (median 27 vs. 19 years; p = 0.027) and initial presentation (median 16 vs. 12 years; p = 0.001) were significantly higher in patients receiving scheduled vs. on demand ERCP. Subgroup analysis revealed that progression in cholangiographic findings between the 1st and 2nd ERCP (progression cohort) was associated with a poorer outcome compared to patients without progression (non-progression cohort) (median transplant-free survival:17 years vs. undefined; p = 0.021).



Conclusion: Our data indicate that implementation of a scheduled ERCP program with interventions performed in predefined intervals improves transplant-free survival in patients with PSC. Furthermore, we reveal that a progression in cholangiographic findings after the first ERCP procedure enables a prediction of the future disease activity and outcome.

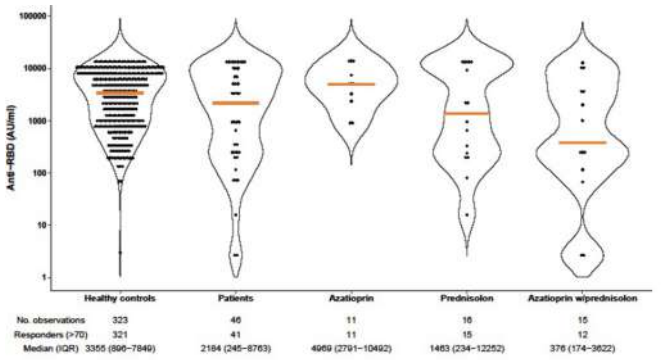
Immune response and safety in standard and third dose SARS-CoV-2 vaccination in patients with autoimmune hepatitis on immunosupressive therapy, a prospective cohort study

Kristin Jorgensen[1,2], Adity Chopra[3], Joseph Sexton[4], Anne T Tveter[4], Johannes R. Hov[2,5,6,7], Ingrid Jyssum[4,7], Lise Sofie H. Nissen-Meyer[3], John T Vaage[3,7], Silje W Syversen[4], Guro L Goll[4], Fridtjof Lund-Johansen[3,8], Jørgen Jahnsen[1,7]. *[1]Akershus University Hospital, Dept. of Gastroenterology, Norway; [2]Oslo University Hospital, Norwegian PSC Research Centre; [3]Oslo University Hospital, Department of Immunology, Norway; [4]Diakonhjemmet Hospital, Division of Rheumatology and Research, Norway; [5]Oslo University Hospital, Research Institute of Internal Medicine, Norway; [6]Oslo University Hospital, Section of Gastroenterology, Department of Transplantation Medicine; [7]University of Oslo, Institute of Clinical Medicine, Norway; [8]University of Oslo, ImmunoLingo Convergence Center*
Email: kristin.kaasen.jorgensen@outlook.com

Background and aims: vaccines against SARS-COV-2 are proven efficacious and safe in the general population. Data on vaccine response in patients with autoimmune hepatitis (AIH) are currently lacking. The aim of this study was to evaluate immunogenicity and safety following standard and three dose SARS-CoV-2 vaccination in patients with AIH on immunosuppressive therapy.
Method: this prospective, observational study included adult AIH patients and healthy controls, both groups receiving standard two dose SARS-CoV-2 vaccination. The patients were voluntarily allotted a third vaccine dose according to the national vaccine strategy. Antibodies to the receptor-binding domain (RBD) of SARS-CoV-2 spike proteins were analyzed in serum samples collected prior to, and after vaccination, and serologic response was defined as >70 AU/ml.
Results: a total of 46 patients (median age 56 years [IQR 47–63], 32 [70%] women), and 1114 healthy controls (median age 43 years [IQR 32–55], 854 [77%] women) were included in the study. All patients had compensated liver disease (Child Pugh A), the median disease duration was 6.2 years (IQR 4.2–9) and 80% received BNT 162b2 as standard two-dose vaccine. After standard vaccination, 89% of patients compared to 99% of healthy controls were serologic responders, p = 0.005. Anti-RBD levels were significantly lower in patients (median 2184 AU/ml [IQR 245–8763]) than controls (3355 AU/ml [IQR 896 – 7849]), p = 0.005. Prednisolone and

azathioprine combination therapy demonstrated the lowest response rate (80%), compared to azathioprine (94%) and prednisolone (100%) monotherapy (figure). The patients received the third vaccine dose median 112 days (IQR 88–133) after the second dose. The serologic response rate increased from 81% at time of receiving the third dose, to 91%, measured 3–5 weeks post third vaccination. Likewise, the overall anti-RBD levels increased from median 264 AU/ml [IQR 115–6485]) to 6383 AU/ml [IQR 1480–9412]). After standard vaccination, adverse events (AE) were reported in 30 (71%) of patients and in 191 (78%) of 244 healthy controls with a comparable safety profile. Following the third dose, 74% of patients reported AEs, without new safety issues emerging. No serious AEs were reported.



Anti-SARS-CoV-2 IgG antibodies following standard two dose SARS-CoV-2 vaccination according to medication group, compared to healthy controls. Violin plot showing the probability density of the data at different values, smoothed by a kernel density estimator. Each data point is a participant, and the solid orange line show the group median.

Conclusion: response rates as well as anti-RBD levels were lower in AIH patients than healthy controls following standard vaccination, with an attenuated serologic response in particular in patients on combination therapy with azathioprine and prednisolone. Third dose vaccination was safe without new safety issues emerging and resulted in an overall increased serologic response.

THU438

Analyses of obeticholic acid treatment retention in UK patients based on medicine delivery data

Carl Gibbons[1], Subash Srinavasan[1], Jaysal Bodhani[2], Jing Li[3], Li Chen[3], Palak Trivedi[4]. *[1]Intercept Pharmaceuticals, United Kingdom; [2]Intercept Pharmaceuticals, Level 6, United Kingdom; [3]Intercept Pharmaceuticals Inc, New York, United States; [4]University of Birmingham, NIHR Birmingham Biomedical Research Centre, Birmingham, United Kingdom*
Email: carl.gibbons@interceptpharma.com

Background and aims: Between 30–40% of patients with primary biliary cholangitis (PBC) inadequately respond to Ursodeoxycholic acid (UDCA) and are candidates for second-line therapy. Obeticholic acid (OCA) is the only licensed second-line treatment in the UK, however, compliance, treatment adherence and rates of drug discontinuation have not been quantified at scale.
Method: 6, 857 orders for OCA were examined, which were delivered to 744 patients with PBC between 1 May 2017 and 1 Sept 2021. We constructed longitudinal datasets allowing study of patient dose order histories. Dropped-out status was assigned to patients against which there had been no new orders for ≥6 months after the date covered by their most recent medicine delivery. Kaplan-Meier estimates were then generated based on the cohort of 744 patients. Additionally, to examine potential relationships between drop-out and dose order history, patients were classified into one of 4 categories: 1) 5 mg doses ordered only; 2) up-titrated to and remained on 10 mg doses; 3) up-titrated to 10 mg but later returned to 5 mg doses; and 4) mixed 5 mg and 10 mg dosing patterns. Separate Kaplan-Meier curves were generated for each of these categories and analysed using Cox regression.
Results: 744 patient order histories yielded 1138 person-years of ordering data and 204 drop-out events, with an estimated 87%, 78% and 69% of patients who continued to receive OCA deliveries at 6, 12 and 24 months respectively after their first Homecare order. Only 51% of patients had order histories indicating successful titration to 10 mg OCA daily, with 43% never increasing beyond 5 mg. The remaining 6% had orders suggesting either mixed dosing, or 10 mg dosing for a period before returning to 5 mg doses. We observed marked separation between some dose order groups in terms of drop-out, with the 5 mg only group most likely to drop out (69%, 56%, and 49% remaining on treatment at 6, 12 and 24 months respectively). By contrast, those who received 10 mg dosing (at any point) remained on OCA at a rate of 99%, 93%, and 82% at 6, 12 and 24 months respectively. The difference in retention was statistically significant (hazard ratio of 10 mg vs 5 mg only dosing: 0.22, 95% CI 0.17, 0.30, $p < 0.001$). See Figure. Moreover, these differences in retention rate remained statistically significant on restricted analysis of those receiving OCA for ≥6 months.

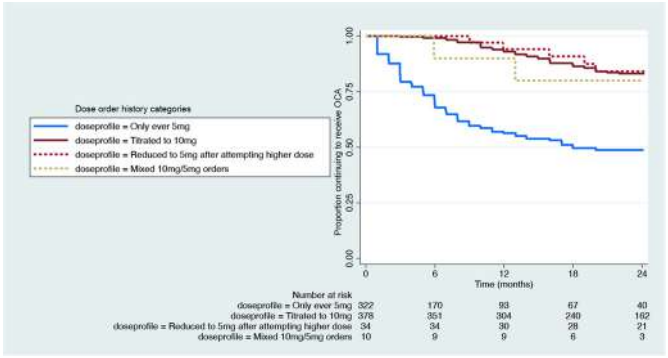


Figure: Proportion of patients continuing to receive OCA orders by time since first Homecare order, separated by dose order history categories

Conclusion: Our findings suggest an association between dose order history category and retention on treatment, prompting further study into optimal systems of management and support for patients on OCA. Conclusions about drop-out should be made with caution, as the analyses only consider product orders, disconnected from clinical characteristics.

THU439

Real-world prevalence of pruritus with obeticholic acid: a systematic literature review and meta-analysis

Patrick Horne[1], Christina Hanson[2], Tracy Mayne[3], Leighland Feinman[3]. *[1]University of Florida, Gainesville, United States; [2]South Denver Gastroenterology, Englewood, United States; [3]Intercept Pharmaceuticals Inc, New York, United States*
Email: patrick.horne@medicine.ufl.edu

Background and aims: Obeticholic acid (OCA) is the only approved 2nd line therapy for patients with primary biliary cholangitis (PBC) with an inadequate response or intolerant to ursodeoxycholic acid (UDCA). High rates of pruritus observed in OCA trials have not been observed in real-world studies. We performed a systematic review and meta-analysis to estimate real-world prevalence of pruritus and associated OCA discontinuation compared to the POISE phase 3 clinical trial.
Method: Systematic review and meta-analysis. We searched Embase and MEDLINE for English-language publications and conference abstracts from real-world settings in patients with PBC treated with OCA monotherapy or combined with UDCA. A fixed- or random-effects pooled estimate was performed based on heterogeneity. POISE. We analyzed data from 209 patients with 1 year follow-up on OCA in the double-blind and open-label phase of POISE. Patients were

censored if they exceeded the approved 10 mg dose. Pruritus was assessed via visual-analogue scale, 5-D pruritus scale, Itch domain of the PBC-40 scale, and standard adverse event assessment. We compared prevalence of pruritus and discontinuations due to pruritus in POISE to the real-world meta-analysis estimates via a chi-square goodness of fit test.

Results: Eleven studies were included in the meta-analysis (total patients = 1192). The random-effects pooled estimate of pruritus prevalence was 29% (95% CI, 24%–33%; Figure 1A); the fixed-effects pooled estimate of treatment discontinuation due to pruritus was 9% (95% CI, 8%–11%; Figure 1B). Real-world pruritus prevalence was significantly lower than in POISE (29% vs 62% in POISE; $\chi^2 = 108.69$; $p < 0.001$); real-world treatment discontinuation was significantly higher than in POISE (9% vs. 4%; $\chi^2 = 5.62$; $p < 0.02$).

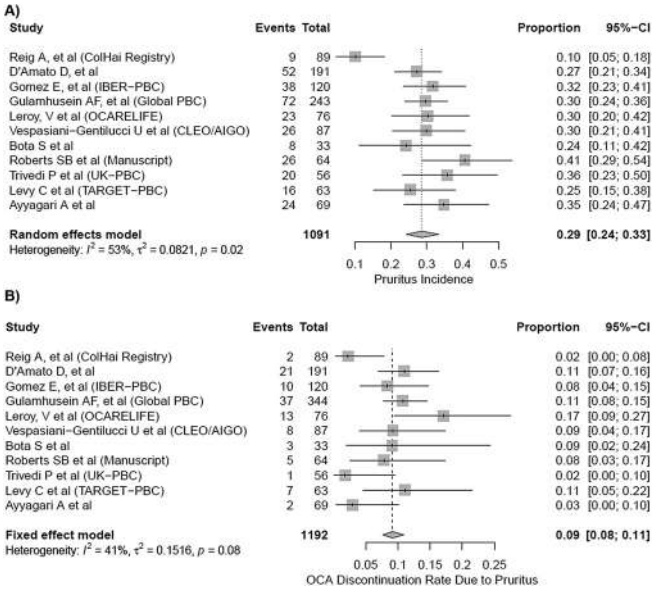

Figure: Forest Plot of Pooled Real-world Prevalence of (A) Pruritus and (B) Treatment Discontinuation due to Pruritus

Conclusion: The prevalence of pruritus in real-world data was significantly lower than observed in POISE. Data collection in POISE, with extensive repeated questions on itch, may have primed subjects to report greater pruritus. The real-world discontinuation estimate of 9% was higher than reported in POISE, though still low. Experience with other drugs indicates discontinuation can be higher in real-world settings, in the absence of mechanisms and motivation in clinical trials to maintain patients on therapy. Our observation of significantly lower pruritus prevalence in the real-world vs clinical trial setting may help providers calibrate treatment expectations when considering OCA treatment.

THU440

Cognitive symptoms in non-cirrhotic primary biliary cholangitis

Naw April Phaw[1], Aaron Wetten[2,3], David Jones[4,5], Jessica Dyson[3], Amardeep Khanna[6]. *[1]Newcastle University, Translational and Clinical Research Institute, Newcastle upon Tyne, United Kingdom; [2]Newcastle University, Translational and Clinical Research Institute; [3]Freeman Hospital, The Newcastle upon Tyne Hospitals NHS Foundation Trust, Hepatology, Newcastle upon Tyne, United Kingdom; [4]Newcastle University, Liver Immunology, Newcastle upon Tyne, United Kingdom; [5]The Newcastle upon Tyne Hospitals NHS Foundation Trust, Hepatology, Newcastle upon Tyne, United Kingdom; [6]Nottingham University Hospitals NHS TRUST, Hepatology Department, Nottingham, United Kingdom*
Email: mail2april@gmail.com

Background and aims: There is emerging evidence of cognitive symptoms, such as memory loss and poor concentration even in early stage Primary Biliary Cholangitis (PBC), with functional imaging studies demonstrating abnormalities of the central nervous system. The aim of this study was to objectively assess performance in cognitive tasks, using CANTAB Neuropsychological Battery in PBC patients and the differences between those with and without cognitive symptoms.

Method: Non-cirrhotic PBC patients were recruited from a single tertiary hospital; those with significant additional medical conditions were excluded. Participants completed PBC-40 questionnaires and CANTAB tasks (PAL, OTS, MTT, SWM, ERT, RTI, RVP) assessing working memory, executive function, emotional cognition, attention and psychomotor speed. Analysis was performed against a normal population, with a z score of <-1.5 standard deviations considered a significant deficit

Results: 38 PBC patients were recruited. Nearly a third of PBC patients demonstrated significant cognitive deficits in memory tasks (PAL) with more errors and fewer correct first attempt responses along with reduced correct hits and slower response times in the emotional cognition domain (ERT). PBC patients underperformed in 2 out of 3 executive function tasks (OTS;p = 0.00, SWM;p = 0.00, MTT;p = 0.42), with fewer correct responses in the attention domain (RVP) and slower responses to stimuli however they outperformed the normative population in psychomotor speed domain (RTI). There was, however, no significant difference in CANTAB performance between cognitively symptomatic (n = 16) and asymptomatic (n = 22) PBC patients when stratified by the PBC-40 cognitive domain. (Table)

Table : CANTAB test scores of different groups in the study

Test		Normative population (NP)	Total PBC (TP) (n=38)	CS PBC (n=16) mean± SD	CAS PBC (n=22) mean± SD	P value
PAL	PALFAMs (+)	13.32±4.0	9.9±5.9	9.1±4	10.4±5.8	NP vs TP (p=0.00)** CS vs CAS (p= 0.26)*
	PALTEA (-)	13.89±12.2	25.2±14.2	26.1±13.5	24.5±14.9	NP vs TP (p=0.00)** CS vs CAS (p= 0.72)*
OTS (+)		10.82±2.7	8.8±3.6	9.8±2.4	8.1±4.2	NP vs TP (p=0.00)** CS vs CAS (p= 0.29)*
SWM	SWMBE (-)	9.9±9.2	17.6±8.9	17.8±6.5	17.5±10.4	NP vs TP (p=0.00)** CS vs CAS (p= 0.93)*
	SWMS (-)	7.00±2.8	9±2.5	9.3±1.7	8.8±2.9	NP vs TP (p=0.00)** CS vs CAS (p= 0.98)*
ERT	ERTMOORT (-)	1267±195.3	1579.89±347.5	1674.2±385.1	1511.2±308.4	NP vs TP (p=0.00)** CS vs CAS (p= 0.28)*
	ERTTH (+)	56.8±6.8	50.5±7.6	53.5±7.95	49±7.2	NP vs TP (p=0.00)** CS vs CAS (p= 0.24)*
RVP (+)		0.9±0.1	0.8±0.1	0.8±0.1	0.8±0.1	NP vs TP (p=0.00)** CS vs CAS (p=0.19)*

NP = normative population; TP = total PBC population; CS = cognitively symptomatic; CAS= cognitively asymptomatic; PAL= Paired Associate Learning; PALFAM= PAL first attempt memory scores; PALTEA=PAL total errors; OTS= One-touch stockings of Cambridge; SWM= spatial working memory; SWMBE = SWM between errors; SWME = SWM strategy, ERT= Emotions recognition Task; ERTMOORT = ERT overall median reaction time, ERTTH =ERT total hits; RVP = rapid visual processing.
(+) = higher scores indicate better performance | (-) = lower scores indicate better performance
** = the mean between the group differed significantly; * = the mean between the group did not differ significantly

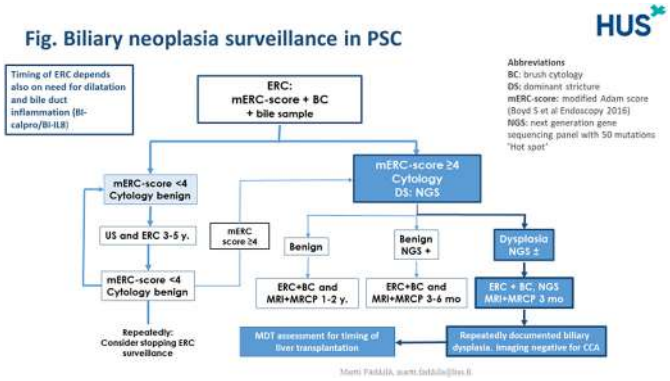
Conclusion: Objective cognitive dysfunction was frequent in PBC patients, with pronounced deficits observed in memory and emotional domains. No significant differences in CANTAB performance was observed between cognitive symptomatic and non-symptomatic patients suggesting behavioral adaption/variation may influence the symptoms exhibited in PBC patients. The patterns of abnormality integrated with functional imaging may shed light on the anatomical abnormality.

THU441

Screening and surveillance of biliary neoplasia based on brush cytology in primary sclerosing cholangitis (PSC): prevalence and outcomes

Martti Färkkilä[1], Sonja Boyd[2], Kalle Jokelainen[1], Andrea Tenca[1], Lauri Puustinen[1], Hannu Kautiainen[3], Johanna Arola[4], Helena Isoniemi[5]. *[1]Helsinki University Hospital, Clinic of Gastroenterology, Helsinki, Finland; [2]Helsinki University Hospital, Clinic of Gastroenterology, Helsinki, Finland; [3]University of Eastern Finland, Institute of Public Health and Clinical Nutrition, Kuopio, Finland; [4]Helsinki University Hospital, Pathology, Helsinki, Finland; [5]Helsinki University Hospital, Transplantation and Liver Surgery, Helsinki, Finland*
Email: martti.farkkila@hus.fi

Background and aims: PSC is characterised with chronic inflammation of biliary epithelium leading to strictures in bile ducts and secondarily to cirrhosis. Chronic inflammation is associated with the increased risk for biliary dysplasia (BD) and cholangiocarcinoma (CCA), with lifetime risk 10%. CCA is the most common cause of death among PSC patients and up to half of CCAs are detected at the time of dg or within one year after. The current guidelines for surveillance for CCA in PSC are contradictory and the evidence for efficacy of surveillance is scarce. AGA guidelines recommend US, CT or MRI, with or without Ca19-9 for surveillance of CCA, none of which are suitable for early detection of biliary neoplasia.
We aimed to evaluate the role ERC with brush cytology (BC) in screening and surveillance of BD and to assess its prevalence and its impact on patient outcome.
Method: In total 989 patients were retrieved from Helsinki University PSC registry referred for ERC: documentation of dg, MRCP/liver histology suggestive for PSC or surveillance of PSC progression and/or BD. We excluded 98 patients: age <18 years (n = 69) or >65 y (n = 19), CCA detected at time of diagnosis or within one year (n = 7), serious concomitant disease or malignancy, liver transplantation (LTx) before f/u, n = 3. BC was systematically collected from intra-and extrahepatic bile ducts, regardless of the presence of dominant strictures for detection of BD. Cytological evaluation from cytospin and cell-block slides was performed, using three-tiered criteria as benign, suspicious, or malignant (CCA). Suspicious cytology: any of the following: biphasic cell population, lack of polarity, nuclear moulding, nuclear membrane irregularities, high nuclear-cytoplasm ratio, hyper/hypochromacy and lack of cohesion. The screening and surveillance strategy is presented in fig.
Results: Prevalence of BD and risk for CCA: Suspicion of dysplasia was detected ≥1 times in 91 patients (10%) during median f/u of 10 years, CCA in 25. If dysplasia was documented ≥3 times, the patient was referred for evaluation for LTx.
LiverTx: 22 patients were transplanted for suspicion of malignancy, 58 for other indications. Out of the 58 patients with suspicion of dysplasia (≤2 times), but not transplanted, 11 (19%) developed CCA. 800 patients without dysplasia, only 7 (0.9%) were diagnosed with CCA. In patients transplanted for dysplasia, 91% were found to have dysplasia in explant, in 3 CCA was detected at LTx. The sensitivity of BC with suspicion of malignancy at least once to detect histologically confirmed biliary neoplasia (transplantation/surgery) was 65% (52–76%) and specificity 94% (93–96%) with OR 30. If patient had BC with suspicion of malignancy ≥3 times the sensitivity to detect histologically confirmed CCA was 100% (48% to 100%) and specificity 98% (97–99%).



Conclusion: ERC with brush cytology is an accurate method to screen and detect biliary neoplasia in PSC.

THU442

Impact of pruritus in primary sclerosing cholangitis (PSC): a multinational survey

Kris Kowdley[1,2], Ricky Safer[3], Rachel Gomel[3], Joanne Hatchett[3], Martine Walmsley[4], Julio Burman[5], Sindee Weinbaum[5], Kerrie Goldsmith[6], MeeJ Kim[7], Will Garner[7], Andrew McKibben[7], Elaine Chien[7]. *[1]Liver Institute Northwest, Seattle, WA, United States; [2]Elson. S. Floyd College of Medicine, Washington State University, Spokane, WA, United States; [3]PSC Partners Seeking a Cure, Greenwood Village, CO, United States; [4]PSC Support, Oxford, United Kingdom; [5]Hetz: The Israeli Association for the Health of the Liver, Ramat Gan, Israel; [6]PSC Support Australia Inc, Melbourne, Australia; [7]Mirum Pharmaceuticals Inc, Foster City, CA, United States*
Email: mkim@mirumpharma.com

Background and aims: Intense pruritus (itch) can be a debilitating complication of cholestatic liver diseases, including primary sclerosing cholangitis (PSC), and in some cases can be an indication for liver transplantation. Currently there are no clinically effective or approved pharmacological therapies to treat cholestatic itch associated with PSC. The aim of this survey was to provide information about the presentation and severity of cholestatic itch in PSC and its broader burden from the patient perspective.
Method: A multinational survey of patients with self-reported PSC was conducted. The 39-question web-based survey was focused on the impact of itch in patients with PSC, how itch severity affected quality of life (QoL), and therapeutic interventions used to address itch. Severity of itch was quantified using a numerical rating scale (0 for no itch, 10 for worst itch you can possibly imagine). The survey was distributed to participants via Hetz, PSC Australia, PSC Partners, and PSC Support. Responses were collected from June 2020 to Feb 2021.
Results: Of the 482 patients who responded, 91% had experienced itch due to PSC and 34% (164/482) were currently experiencing itch, with the median worst itch reported as a 6/10; 45% (74/164) reported the itch episode was at least 1 month in duration. Itch severity was associated with a higher degree of reported sleep disturbance and worsening fatigue, with 63% of respondents indicating that evening and night-time were the worst times of the day for itching. 50% (197/392) reported that itch led to disruption of day-to-day responsibilities and lasted >30 days in 32% (62/197). 22% (88/392) reported missing school or work. Itch was also associated with mood changes, including but not limited to anxiety, irritability, and feelings of hopelessness in more than half of patients (58%; 228/392). The most-commonly used medicines to treat itch were antihistamines (46%), UDCA (39%), Cholestyramine (39%), topical creams/ointments (28%), and Rifampicin (19%). Half of the respondents (235/482) reported using ≥2 medications but 75% (177/235) described only partial or no relief with these interventions (Table).

Table. Anti-Pruritic Medications Utilized By Respondents (N = 482)

	N (%) Taking Medication	N (%) with Full Resolution	N (%) with Partial Resolution	N (%) with No Impact
Antihistamines	224 (46%)	5 (2%)	117 (52%)	85 (38%)
UDCA	188 (39%)	19 (10%)	48 (26%)	86 (46%)
Cholestyramine	188 (39%)	18 (10%)	110 (59%)	50 (27%)
Topical creams/ ointments	134 (28%)	6 (4%)	77 (57%)	44 (33%)
Rifampicin	91 (19%)	22 (24%)	43 (47%)	22 (24%)
Taking 2+ Medications*	235 (49%)	51 (22%)	149 (63%)	28 (12%)

*Outcome is the best response outcome across all medications taken, sorted by "Full Resolution", then "Partial Resolution", then "No Impact". Percentages do not add to 100% due to missing outcomes.

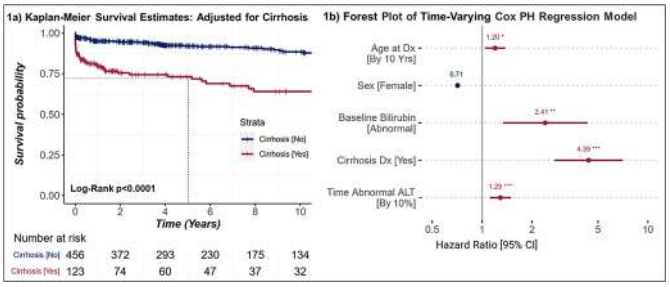
Conclusion: Itch related to PSC has a major adverse impact on QoL (eg, sleep, mood, fatigue), interferes with daily activities in a substantial proportion of patients but remains inadequately treated in most patients. These data highlight a major unmet need for the development of safe and effective therapies for treatment of cholestatic itch in patients with PSC.

THU443

A dynamic approach to modelling baseline disease status and ALT elevation over follow-up on clinical-event free survival in autoimmune hepatitis: a canadian multicentre cohort

Christina Plagiannakos[1,2], Gideon Hirschfield[1,2], Ellina Lytvyak[3], Surain Roberts[4], Marwa Ismail[1,2], Kattleya Tirona[1], Andrew L. Mason[3], Harry Janssen[1,5], Aliya Gulamhusein[1,2], Aldo J Montano-Loza[3], Bettina Hansen[1,2]. *[1]University Health Network, Toronto Centre for Liver Disease, Toronto Western and General Hospital, Toronto, Canada; [2]University of Toronto, Institute of Health Policy, Management and Evaluation, Toronto, Canada; [3]University of Alberta, Department of Medicine-Division of Gastroenterology and Liver, Edmonton, Canada; [4]Unity Health Toronto, St. Michael's Hospital, Toronto, Canada; [5]University of Toronto-St. George Campus, Department of Medicine, Toronto, Canada*
Email: christina.plagiannakos@uhn.ca

Background and aims: Current and future treatments for autoimmune hepatitis (AIH) target ALT as a biomarker of efficacy. In patients with AIH, we sought to model ALT response dynamically over long-term follow-up, to understand clinical associations with clinical-event free survival (CEFS).
Method: Patients diagnosed with AIH (simplified score ≥6) who initiated treatment were included from the Canadian Network for Autoimmune Liver Disease. AASLD sex-specific upper limits of normal (ULN) defined ALT normalization and site-specific ULN were used for other biochemical markers. CEFS included the absence of a decompensation event, liver transplant, or death. Kaplan-Meier estimates and Cox proportional hazards dynamic time-varying models adjusted for age at diagnosis, sex, cirrhosis at diagnosis, baseline total bilirubin, and stratified by site were used; alpha = 0.05.
Results: 579 patients with AIH initiated treatment between November 1987 and June 2020, with a median follow-up time of 6.54 years [IQR 2.70–11.6] and an average of 9 visits [4.0–21]. Median age at diagnosis was 48 years [31.0–59.4], 75.5% of patients were female (n = 437) and 71.2% reported white ethnicity (n = 412). Median baseline ALT was 15.7xULN [5.84–34.2], AST 10.5xULN [3.36–23.8], IgG 1.48xULN [1.12–1.93], total bilirubin 1.8xULN [0.68–6.25] and INR 1.17 [1.05–1.34].
Among the 21.2% (n = 123) of patients with cirrhosis at diagnosis, 40 had an event during follow-up, and of the 456 (78.7%) without cirrhosis, 48 had an event. At 5-years of follow-up, the CEFS estimate was 73% (CI 0.66–0.82) for patients with, and 92% (CI 0.90–0.95) for those without, cirrhosis (Figure 1a. The survival probability at 5 years for patients with elevated and normal bilirubin values were 83% (CI 0.78–0.87) and 94% (CI 0.91–0.98), respectively. In univariate analysis AST (HR 1.58, CI 1.02–2.45), and IgG (HR 3.05, CI 1.1–8.4) were significantly related to long-term outcomes in patients without cirrhosis. In the multivariable model, cirrhosis at diagnosis (HR 4.39, CI 2.73–7.07), baseline bilirubin (HR 2.41, CI 1.34–4.33), and older age (HR 1.20, CI 1.04–1.38, unit = 10 years) were all independently associated with poorer outcomes.
The predicted cumulative impact of time spent with elevated ALT during follow-up was significant (HR 1.29, CI 1.11–1.50, unit = 10% of time, Figure 1b. Patients that spent a greater amount of follow-up time with elevated ALT values had an increased risk of experiencing an event, and this was most marked in patients with cirrhosis.



Conclusion: Patients with AIH are at increased risk of a clinical event as the time spent with abnormal ALT values increases, especially those with cirrhosis at baseline. Persistent improvement in ALT values is a logical treatment goal in AIH.

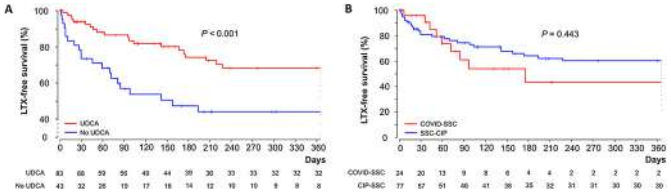
THU444

Secondary sclerosing cholangitis following COVID-19 disease: a multicenter retrospective study

Peter Hunyady[1], Lea Streller[2], Darius Ruether[3], Sara Reinartz Groba[4], Dominik Bettinger[5], Daniel Fitting[6], Karim Hamesch[7], Jens Marquardt[8], Victoria Mücke[1], Fabian Finkelmeier[1], Asieb Sekandarzad[5], Tobias Wengenmayer[5], Ayoub Bounidane[1], Felicitas Weiss[7], Kai-Henrick Peiffer[1], Bernhard Schlevogt[4], Stefan Zeuzem[1], Oliver Waidmann[1], Marcus Hollenbach[9], Martha M Kirstein[8], Johannes Kluwe[3], Fabian Kütting[2], Marcus Mücke[1]. *[1]University Hospital Frankfurt; [2]University Hospital Cologne; [3]University Hospital Hamburg Eppendorf; [4]University Hospital Münster; [5]University Hospital Freiburg; [6]University Hospital Würzburg; [7]University Hospital Aachen; [8]University Hospital Schleswig-Holstein Campus Lübeck; [9]University Hospital Leipzig*
Email: marcus.m.muecke@gmail.com

Background and aims: Secondary sclerosing cholangitis (SSC) is a rare disease with poor prognosis. Cases of SSC have been reported following coronavirus disease 2019 (COVID-19), COVID-SSC. Aim of this study was to compare COVID-SSC to SSC in critically ill patients (SSC-CIP) and to assess factors influencing transplant-free survival.
Method: In this retrospective, multicenter study involving 127 patients with SSC from 9 tertiary care centers in Germany, COVID-SSC was compared to SSC-CIP and logistic regression analyses were performed investigating factors impacting transplant-free survival.
Results: Twenty-four patients had COVID-SSC, 77 patients SSC-CIP and 26 patients had other forms of SSC. COVID-SSC developed after a median of 91 days following COVID-19 diagnosis. All patients had received extensive intensive care treatment (median days of mechanical ventilation 48). Patients with COVID-SSC and SSC-CIP were comparable in most of the clinical parameters and transplant-free survival was not different from other forms of SSC (p = 0.443 in log-rank test). In the overall cohort, the use of ursodeoxycholic acid (UDCA, OR 0.36, 95%-CI 0.16–0.80, P = 0.013; P < 0.001 in log-rank test) and high serum albumin levels (OR 0.40, 95%-CI 0.17–0.96, P = 0.040) were independently associated with an increased transplant-free survival, while the presence of liver cirrhosis (OR 2.52, 95%-CI

1.01–6.25, P = 0.047) was associated with worse outcome. MDRO colonization or infection did not impact patients' survival.



Conclusion: COVID-SSC and CIP-SSC share the same clinical phenotype, course of the disease and risk factors for its development. UDCA may be a promising therapeutic option in SSC, though future prospective trials need to confirm our findings.

THU445

The efficacy of combined treatment of bezafibrate and ursodeoxycholic acid was reduced in patients with primari cholangitis at advanced stage

Kosuke Matsumoto[1], Junko Hirohara[2], Toshiaki Nakano[2], Atsushi Tanaka[1]. [1]*Teikyo University School of Medicine, Department of Medicine, Tokyo, Japan;* [2]*Kansai Medical University, The Third Department of Internal Medicine, Osaka, Japan*
Email: m-kosuke0716@med.teikyo-u.ac.jp

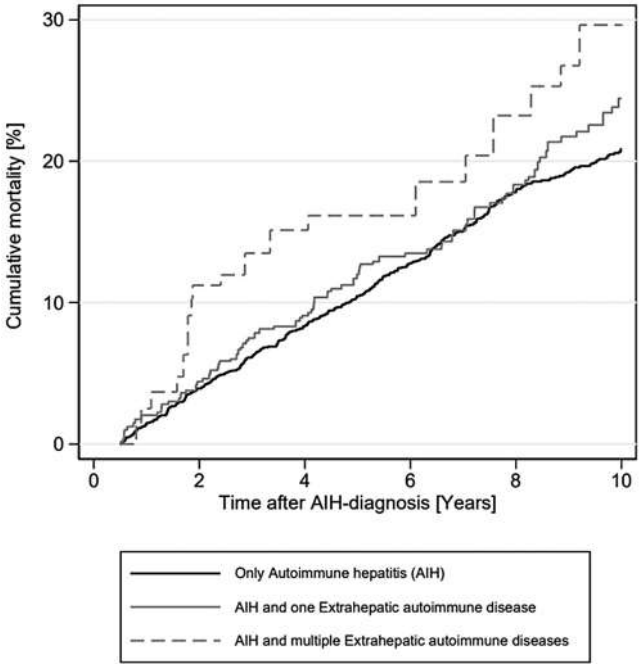
Background and aims: Bezafibrate (BZF) is a dual PPARs/PXR agonist with potent anti-cholestatic efficacy. Previously, we took advantage of a large-scale retrospective cohort of patients with primary biliary cholangitis (PBC) in Japan and demonstrated that a combination of BZF and ursodeoxycholic acid (UDCA) was significantly associated with an improved liver transplantation (LT)-free survival in patients with PBC. Nevertheless, we found patients who deceased or underwent LT in this cohort even with a combination treatment of UDCA and BZF. In the current study, we explored baseline covariates which were significantly associated with poor outcome, death or LT, in patients treated with UDCA and BZF.
Method: The Japanese PBC cohort is established by the nation-wide surveys, initiated in 1980 and updated every 3 years by the Intractable Hepato-Biliary Diseases Study Group (Japan PBC Study Group). To date, 9, 919 patients with PBC have been registered. Baseline covariates included age, sex, presence of symptoms, serum levels of bilirubin, alkaline phosphatase (ALP), and albumin. Primary outcome (liver-related death or LT) was assessed using multivariable adjusted Cox proportional hazard models.
Results: 1, 739 patients were excluded from the analysis due to missing data in terms of outcome and final follow-up date. Among the remaining 8, 180 patients, 889 patients (mean age at diagnosis 54.8yrs, 139 males (15.6%)) were treated with a combination of UDCA and BZF and enrolled in the current study. During 9.9 ± 6.8 yrs of mean observational period, 16 out of 889 (1.8%) reached primary end point (death in 15, LT in 1). By the Cox proportional hazard model, low albumin (<3.5 mg/dL) and high bilirubin (>1.5 mg/dL) at baseline were significantly associated with death or LT; adjusted hazard ratio (aHR) of low albumin was 5.511 (95% confidential interval 1.754–17.315, p = 0.003), and aHR of high bilirubin was 9.986 (95% CI 3.097–32.199, p < 0.001).
Conclusion: In patients with PBC at advanced stage who had low albumin or high bilirubin at baseline, the risk for death or LT was significantly increased compared to those with normal albumin or bilirubin even with a combination treatment of UDCA and BZF.

THU446

Extrahepatic autoimmune diseases in autoimmune hepatitis: effect on mortality

Rasmine Birn-Rydder[1], Morten Daniel Jensen[1], Peter Jepsen[1], Lisbet Groenbaek[1,2]. [1]*Aarhus University Hospital, Department of Hepatology and Gastroenterology, Aarhus, Denmark;* [2]*Regional Hospital Horsens, Department of Medicine, Horsens, Denmark*
Email: rasmine_br@live.dk

Background and aims: Autoimmune hepatitis (AIH) is a chronic inflammatory liver disease associated with an increased prevalence of extrahepatic autoimmune diseases and an increased mortality compared with the general population. The contribution of extrahepatic autoimmune diseases to the increased mortality has not yet been clarified. Our aim was to determine the effect of extrahepatic autoimmune diseases on mortality in patients with AIH.
Method: This nationwide register-based cohort study included all Danish patients diagnosed with AIH between 1995 and 2019. We examined the presence of extrahepatic autoimmune diseases concurrent with AIH in all included patients. We followed the patients until 30 April 2021 and calculated the cumulative mortality using the Kaplan-Meier estimator comparing AIH-patients with and without extrahepatic autoimmune diseases. We estimated the effect of extrahepatic autoimmune diseases on mortality using Cox regression adjusted for age at AIH-diagnosis, calendar year of AIH-diagnosis, sex, cirrhosis, and other comorbidities (cancer, chronic obstructive pulmonary disease, and ischemic heart disease).
Results: Our study included 2479 patients with AIH of whom 23.1% had one or more extrahepatic autoimmune diseases. The adjusted 10-year cumulative mortality was 27.3% (95% confidence interval [CI]: 25.3–29.4) in patients with extrahepatic autoimmune diseases and 21.6% (95% CI: 19.9–23.6) in patients without. The adjusted mortality hazard ratio was 1.28 (95% CI: 1.10–1.49) in AIH patients with vs. without concurrent extrahepatic autoimmune diseases; it was 1.22 (95% CI: 1.03–1.44) for patients with one extrahepatic autoimmune disease, and 1.59 (95% CI: 1.19–2.12) for those with more than one.



Conclusion: Extrahepatic autoimmune diseases increased the mortality in patients with AIH. Moreover, patients with multiple extrahepatic autoimmune diseases had higher mortality than patients with just one extrahepatic autoimmune disease.

THU447

Confidence in treatment is contributing to quality of life in patients with autoimmune liver diseases. The results of ERN-RARE Liver online survey

Ewa Wunsch[1], Linda Krause[2], Tom Gevers[3,4], Christoph Schramm[4,5,6], Maciej K. Janik[4,7], Marcin Krawczyk[4,8,9], Natalie Uhlenbusch[4,10], Bernd Löwe[4,10], Ansgar W. Lohse[4,11], Piotr Milkiewicz[1,4,7].

Email: ewa.wunsch@gmail.com

Background and aims: Patients with autoimmune liver diseases (AILDs) have been reported to have an impaired health-related quality of life (HrQoL) in studies based on small sample sizes. The aim of this project was to investigate HrQoL in a large transnational cohort of patients with AILDs and to identify potentially modifiable factors in the context of impaired HrQoL.
Method: A cross-sectional online survey was conducted in patients with a diagnosis of autoimmune hepatitis (AIH), primary biliary cholangitis (PBC) or primary sclerosing cholangitis (PSC) from 15 European countries. HrQoL was measured with EQ-5D-5L and EQ visual analogue scale (EQ VAS) and analysed in relationship to demographic, psychosocial, disease- and treatment-related factors. A PHQ-2 score larger than two indicated clinically relevant depression. Multivariable linear regression analyses were used to identify potentially modifiable factors associated with HrQoL and confidence in treatment while adjusting for known confounders.
Results: A group of 1,178 European patients (470 with AIH, 368 with PBC and 317 with PSC, 79% female, mean age 48 ± 14 years) participated in the study. HrQoL was markedly impaired in all three liver diseases (mean EQ-5D-5L = 0.75, mean EQ VAS = 68.9), particularly in patients with PBC (mean EQ-5D-5L = 0.73, mean EQ VAS = 66.2). Clinically relevant depression was reported in 17% of the total sample. Depression, gender, age and advanced disease stage were expectedly associated with HrQoL. Confidence in treatment was identified as a modifiable factor strongly contributing to EQ-5D-5L in the entire cohort (reg. coef.: 0.12, 95%CI: 0.07 to 0.18, p < 0.001). PSC or PBC diagnosis, advanced disease stage, treatment in non-transplant center and depression were negatively associated with patients' confidence in their treatment (Figure).

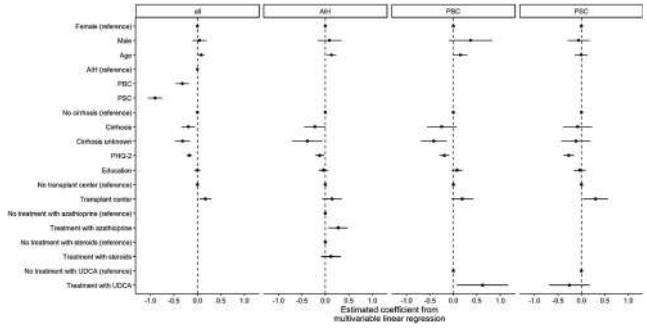

Figure: Factors associated with treatment confidence

Conclusion: Our analysis detects confidence in treatment as a novel central determinant of HrQoL in patients with AILDs. This modifiable and so far undepreciated factor should be further investigated in order to improve care for patients with AILDs.

THU448

A pilot study of PBC symptom management with melatonin and fenofibrate: the PIMBLE study

Beverly Rodrigues[1], Steven Nicolaides[1], Rohit Sawhney[1,2], Amanda Nicoll[1,2], Stephen Bloom[1,2]. *[1]Eastern Health, Gastroenterology; [2]Eastern Health Clinical School, Monash University, Australia*
Email: beverly.rodrigues91@gmail.com

Background and aims: Primary biliary cholangitis (PBC) disease progression is usually well controlled with ursodeoxycholic or obeticolic acid. Bezafibrate has shown benefits in refractory disease but is not available in Australia, and it is unknown if fenofibrate is similarly effective. Despite good biochemical response, the symptoms of pruritus, fatigue and altered sleep often remain. Melatonin may improve fatigue as demonstrated in animal models. We studied the short-term symptomatic and biochemical responses of PBC patients to melatonin and fenofibrate therapy.
Method: A randomised, cross-over 12-week intervention study examining symptoms and biochemistry in response to melatonin and fenofibrate between 20th July 2020–15th November 2021 inclusive.
Results: The interim results of 10 patients are shown in Table 1. Six out of 10 patients completed both trial arms, patient 10 optionally completed the melatonin arm only, and the remaining 3 are soon to complete arm 2 (n = 1 fenofibrate, n = 2 melatonin). Both agents were well tolerated overall; 3 patients had a mild rise in transaminases (<5x upper limit of normal) post commencement of fenofibrate. ALP improvement was seen in 6/8 on fenofibrate and 3/8 on melatonin, with degree of improvement meeting Paris II criteria in all trialled arms. Symptom improvement was seen in 6/8 on fenofibrate and 6/8 on melatonin.

Table 1: Descriptive analyses of clinical and biochemical responses to each trial arm

				Fenofibrate arm				Melatonin arm			
					Improved symptoms Y/N MFIS: SF36: VAS (itch)				Improved symptoms Y/N MFIS: SF36: VAS (itch)		
Patient	Age (years)	Gender	Abnormal ALP (baseline)	Improved ALP (Y/N)	MFIS	SF36	VAS	Improved ALP (Y/N)	MFIS	SF36	VAS
1	54.6	F	N	Y	N/A	Y	N	N	N/A	Y	N
2	68.8	F	N	Y	N/A	N/A	N/A	Y	N/A	N/A	N/A
3	65.8	F	N	Y	Y	N	Y	Y	Y	N	Y
4	57.8	F	N	N	Y	N	Y	N	Y	Y	Y
5	72.7	F	N	N	Y	N	N	N	Y	N	N
6	60.6	F	N	P	P	P	P	Y	N/A	N	N
7	61.3	F	Y	Y	Y	N	N	P	P	P	P
8	55.1	M	N	Y	P	P	P	N	N	N	Y
9	52.9	M	N	Y	Y	N	N	P	P	P	P
10	45.2	F	Y	N/A	N/A	N/A	N/A	N	Y	N	N

Y = (Yes); N = (No); N/A = (not applicable or available); p = (pending)

Conclusion: This pilot study suggests that there is potential benefit in these therapies for PBC and further studies evaluating their efficacy is required.

THU449

Portal hypertension-associated clinical features in patients with primary biliary cholangitis are of distinct prognostic value

Lukas Burghart[1], Emina Halilbasic[1], Philipp Schwabl[1], Benedikt Simbrunner[1], Albert Stättermayer[1], Oleksandr Petrenko[1], Bernhard Scheiner[1], David JM Bauer[1], Matthias Pinter[1], Kaan Boztug[1], Mattias Mandorfer[1], Michael Trauner[1], Thomas Reiberger[1]. *[1]Medical University of Vienna, Austria*
Email: burghartlukas@gmail.com

Background and aims: Primary biliary cholangitis (PBC) may progress to cirrhosis and clinically significant portal hypertension

(CSPH). This study assesses different features of CSPH and their distinct prognostic impact regarding decompensation and LTX-free survival in patients with PBC.

Method: Patients with PBC were identified during a database query of our digital patient reporting system.

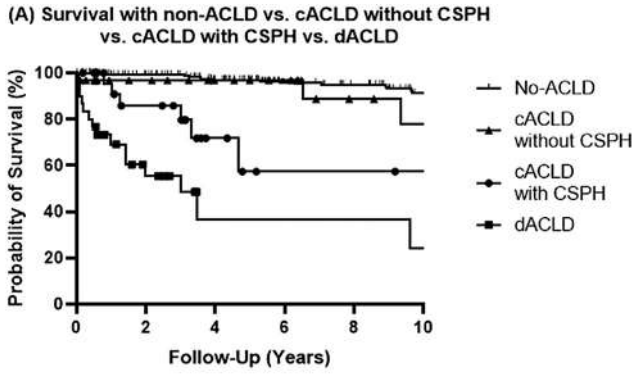
Results: A total of 333 PBC patients (mean age: 54.3 years, 86.8% female, median follow-up: 5.8 years) were retrospectively assessed. Overall, 127 (38.1%) showed features of CSPH: 63 (18.9%) developed varices, 98 (29.4%) splenomegaly, 62 (18.6%) ascites and 20 (15.7%) experienced acute variceal bleeding.

Splenomegaly, portosystemic collaterals and esophageal varices were associated with an increased 5-year (5Y) risk of decompensation (15.0%, 17.8% and 20.9%, respectively).

Patients without advanced chronic liver disease (ACLD) had a similar 5Y-transplant free survival (TFS) (96.6%) compared to patients with compensated ACLD (cACLD) but without CSPH (96.9%). On the contrary, PBC patients with cACLD and CSPH (57.4%) or decompensated ACLD (dACLD) (36.4%) had significantly decreased 5Y survival rates.

During a subanalysis, the combination of LSM <15 kPa and platelets ≥150 G/L indicated a negligible risk for decompensation (5Y 0.0%) and for mortality (5Y 0.0%).

Overall, 44 (13.2%) patients died, with 18 (40.9%) deaths attributed to CSPH-related complications.



Conclusion: In PBC, features of CSPH may occur early and indicate an increased risk for subsequent decompensation and mortality. Hence, regular screening and on-time treatment for CSPH is crucial. Combining LSM and platelets serves as a valuable preliminary assessment, as LSM <15 kPa and platelets ≥150 G/L indicate an excellent long-term outcome.

THU450

The low incidence of HBV reactivation among anti-HBc+ subjects on immunotherapy reduces the impact of suboptimal screening rate

Laia Aceituno[1], Juan Bañares[1], Lourdes Ruiz[1], Ana Callejo-Pérez[2], Eva Muñoz-Couselo[2], Carolina Ortiz-Velez[2], Nely Díaz-Mejía[2], Ana Barreira[1,3], Maria-Josep Carreras[4], Anna Farriols[4], Maria Buti[1,3], Mar Riveiro Barciela[1,3]. *[1]Hospital Vall Hebron, Liver Unit, Barcelona, Spain; [2]Instituto de Oncología Vall d'Hebron (VHIO), Hospital Universitari Vall d'Hebron, Oncology Department, Barcelona; [3]Centro de investigación biomédica en red de enfermedades hepáticas y digestivas, Madrid; [4]Hospital Vall Hebron, Pharmacy Department, Barcelona*
Email: mar.riveiro@gmail.com

Background and aims: Immunotherapy with check-point inhibitors (CPIs) has become the pillar of treatment of many advanced cancers. CPIs can reactivate Hepatitis B (HBV) in patients with chronic infection. However, there is scarce data on their possible impact on subjects with chronic hepatitis C or resolved HBV infection. To date, there is no evidence on awareness of Oncologists about the risk of prescribing CPIs for patients with viral hepatitis.

Method: Retrospective-prospective study of all patients who began Oncological immunotherapy between January 2019 and December 2020 in a University Hospital. Data on viral hepatitis screening prior to the beginning of CPIs were collected retrospectively. In subjects lacking information, serological tests were requested prospectively. HBV reactivation was defined as the increase of 2 log of HBV-DNA compared to baseline (HBsAg+ subjects) or reversed seroconversion to HBsAg+ or detectable HBV-DNA (isolated antiHBc+).

Results: 595 subjects received CPIs: 364 (61.2%) male, mean age 64 years (IQR 57–72). Most prevalent cancers: lung (34.8%), urinary (13.1%), melanoma (12.1%), gastrointestinal (11.6%), gynecological (9.2%). CPIs: anti-PD1 (64.2%), anti-PD-L1 (19.2%), combined therapy with anti-PD1 + anti-CTLA-4 (13.8%), anti-CTLA-4 alone (0.8%), others (2.0%). Time between cancer diagnosis and CPI beginning was 13 months (IQR 3–33). Forty-three (7.2%) patients had underlying liver disease, 15 (2.5%) of them cirrhosis and 16 (2.7%) hepatocellular carcinoma. In 460 (77.3%) subjects anti-HCV was requested prior to the beginning of immunotherapy, HBsAg in 459 (77.1%) and anti-HBc in 332 (55.8%), complete screening (anti-HCV, HBsAg and anti-HBc) in 325 (54.6%). In the remaining cases, serological tests were completed prospectively in those alive, leading to diagnosis of 1 case of HCV, 1 HBsAg+ and 22 antiHBc+. Overall hepatitis prevalence was: anti-HCV 3.6% (19/528), HBsAg 1.3% (7/528), anti-HBc 15.6% (74/473). All anti-HCV positive subjects presented undetectable viral load except two patients with hepatocellular carcinoma. Five out of the 7 HBsAg carriers received antiviral prophylaxis, leading to HBV reactivation in 1case with previously unknown infection without prophylaxis. Only 1 anti-HBc+ subject received antiviral prophylaxis (HIV infection). Among the remaining anti-HBc+ individuals, just one isolated case of HBV reactivation was observed (1.4%).

Conclusion: HBV and HCV screening prior to Oncological immunotherapy is suboptimal, especially regarding anti-HBc+. Though the rate of HBV reactivation among anti-HBc+ subjects is very low, efforts should be done to optimize viral hepatitis screening prior to immunotherapy for selection of candidates to either antiviral prophylaxis or periodical check-up.

THU451

The ABCB4 variant c.711 increases liver injury in PBC but not in PSC: prospective analysis with a median follow-up of 7 years in 331 patients

Beata Kruk[1], Malgorzata Milkiewicz[2], Piotr Milkiewicz[3,4], Marcin Krawczyk[1,5]. [1]*Laboratory of Metabolic Liver Diseases, Department of General, Transplant and Liver Surgery, Medical University of Warsaw, Warsaw, Poland;* [2]*Department of Medical Biology, Pomeranian Medical University in Szczecin, Szczecin, Poland;* [3]*Liver and Internal Medicine Unit, Medical University of Warsaw, Warsaw, Poland;* [4]*Translational Medicine Group, Pomeranian Medical University in Szczecin, Szczecin, Poland;* [5]*Department of Medicine II, Saarland University Medical Center, Saarland University, Homburg, Germany*
Email: marcin.krawczyk@uks.eu

Background and aims: Primary biliary cholangitis (PBC) and primary sclerosing cholangitis (PSC) are two progressive chronic cholestatic liver diseases. The *ABCB4* gene encodes the hepatobiliary phospholipid transporter. Defects in the *ABCB4* gene cause several cholestatic diseases (*Stättermayer et al., J Hepatol. 2020).* Here we aim to investigate role of the *ABCB4* genetic variant in patients with PBC and PSC.
Method: We genotyped the *ABCB4* c.711 polymorphism in a total of 331 patients with PBC and PSC who were prospectively recruited in our center from year 2005. The PBC cohort was composed 196 patients (173 females, median age 59 years, 49% with cirrhosis). The PSC cohort was composed of 135 patients (96 males, median age 35 years, 39% with cirrhosis). Clinical data were collected at least at two time points: The follow-up ranged from 2 to 20 years (median: 7 years) The PBC-40 and Short Form (SF-36) questionnaires were used for assessment health related quality of life.
Results: Allele and genotype distributions of the *ABCB4* variant in patients with PBC and PSC cohort were consistent with Hardy-Weinberg equilibrium ($p > 0.05$). At baseline, the *ABCB4* c.711 variant was associated with an increased cirrhosis risk (OR = 1.84, $p = 0.02$) in the PBC cohort, the risk of cirrhosis was also modulated by patients gender ($p < 0.01$). Carriers of heterozygote genotype showed significantly increased serum AST ($p = 0.02$), GGTP ($p < 0.01$) and ALP ($p < 0.01$). Although we detected significant improvements in laboratory findings (i.e., AST, ALT, ALP and GGTP) during the follow-up, a total of 22 patients developed new cirrhosis and this risk was significantly modulated by the *ABCB4* polymorphism (OR = 5.65, $p = 0.04$). On the other hand, the *ABCB4* genotype did not affect life quality in either of the cohorts, did not modulate liver injury in patients with PSC did not increase the odds of requiring transplantation (all $p > 0.05$).
Conclusion: The *ABCB4* c.711 polymorphism might represent a common risk genetic factors for progressive liver injury in PBC. Carriers of the c.711 *ABCB4* might require more aggressive therapy to lower the progression of liver scarring.

Email: montanol@ualberta.ca

Background and aims: Recurrent PBC (*r*PBC) developed in approximately 30% of patients, and negatively impacts graft and patient survival after LT. Liver function tests and scores to evaluate response to ursodeoxycholic acid (UDCA) have been developed to monitor disease progression and evaluate the addition of second-line treatments before LT. We aimed to evaluate the utility of serum liver function tests and the GLOBE and UK-PBC scores to predict graft and overall survival after LT in patients with *r*PBC.
Method: A total of 231 patients who had a liver biopsy-proven diagnosis of *r*PBC after LT from 18 centers across Europe, North and South America, were evaluated. The mean age at the time of *r*PBC was 58 ± 10 years, and 206 patients (89%) were women. At the time of *r*PBC, 145 patients (63%) were receiving tacrolimus, and 78 (34%) with cyclosporine. The biochemical response was measured with alkaline phosphatase (ALP) and bilirubin, and continuous prognostic (GLOBE and UK-PBC scores) at 1-year after UDCA was started. Graft loss was defined using a death-censored definition of graft failure and therefore, graft loss did not include patients who died with a functioning graft. Cox regression analysis was performed to determine associations between biochemical markers, scores and graft loss and mortality.
Results: A total of 219 patients (95%) received treatment with UDCA after *r*PBC diagnosis. During a median follow-up 9.16 ± 5.47 years, 47 patients (20%) had lost graft and 76 (33%) died. Graft survival after *r*PBC was 92% and 85%, and overall survival was 87% and 76%, at 5-, and 10-years, respectively. Use of tacrolimus or cyclosporine was not associated with graft or overall survival. Serum ALP (HR 1.002, 95% CI 1.001–1.004, $p = 0.01$), and bilirubin (HR 1.009, 95% CI 1.004–1.015, $p = 0.001$) at 1-year after UDCA were associated with graft survival. The GLOBE (HR 2.45, 95% CI 1.45–4.16, $p < 0.001$) and UK-score 5-year formula (2.99, 95% CI 0.48–18.77, $p < 0.001$) at 1-year after UDCA initiation were associated with graft survival. In addition, serum ALP (HR 1.31, 95% CI 1.10–1.55, $p = 0.002$), and bilirubin (HR 1.008, 95% CI 1.004–1.012, $p < 0.001$) at 1-year after UDCA initiation were

associated with overall survival. The GLOBE (HR 2.04, 95% CI 1.38–3.01, p < 0.001) and UK-score 5-year formula (1.94, 95% CI 0.37–10.05, p < 0.001) at 1-year after UDCA were associated with overall survival. Patients with an ALp > 2 × ULN (Figures 1a–b) and bilirubin >1 × ULN (Figures 1c–d) at 1-year of UDCA treatment had worse graft and overall survival. Only two (1%) and 10 patients (4%) started second-line treatment with obeticholic acid and fibrates, respectively.

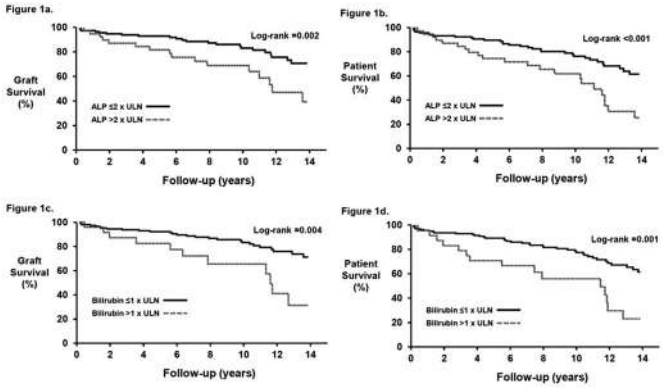

Figure: Graft and patient survival according to ALP and bilirubin at 1-year of UDCA.

Conclusion: Patients with *r*PBC and disease activity as indicated by standard PBC risk scores have impaired outcomes, supporting efforts to treat recurrent disease in similar ways to pre-transplant PBC.

THU453

Associations between novel serum biomarkers chitinase-2-like protein (YKL-40), type IV collagen, and thrombospondin-2 (TSP-2) with fibrosis stage and clinical outcomes in patients with primary sclerosing cholangitis (PSC)

Michael Trauner[1], Andrew Muir[2], Jun Xu[3], Mina Khoshdeli[3], Bryan Downie[3], Andrew Billin[3], Chuhan Chung[3], Robert Myers[3], Zachary Goodman[4], Mitchell Shiffman[5], Harry Janssen[5], Aldo J Montano-Loza[6], Stephen Caldwell[7], Velimir Luketic[8], Michael P. Manns[9], Cynthia Levy[10], Christopher Bowlus[11]. *[1]Medical University of Vienna, Vienna, Austria; [2]Duke Clinical Research Institute, Durham, United States; [3]Gilead Sciences. Email: jun.xu@gilead.com

Background and aims: Primary sclerosing cholangitis (PSC) is a chronic and progressive fibrotic liver disease associated with an increased risk of liver-related complications and mortality. Non-invasive biomarkers of fibrosis are needed for risk stratification and monitoring of PSC patients. YKL-40, TSP-2, and type IV collagens (α-subunit) are biomarkers of liver injury, inflammation, or extracellular matrix turnover during hepatic fibrogenesis. Our study aimed to evaluate associations between these biomarkers with fibrosis stage and PSC-related clinical events in a longitudinal study.

Method: Serum biomarkers YKL-40, TSP-2, and COL4A1 were measured via ELISA at baseline (BL) and Week 96 (W96) in PSC patients enrolled in a 96-week, phase 2 trial of simtuzumab (NCT01672853). Since simtuzumab was ineffective in this trial, data from the treatment and placebo groups were combined. Fibrosis was staged according to the Ishak classification and biomarker values were log-transformed. Odds ratios (OR) for associations between BL biomarker values with progression to cirrhosis (Ishak 5–6) at W96 among non-cirrhotic patients (Ishak 0–4) at BL were calculated using logistic regression models.

Results: At BL, serum COL4A1 and TSP-2 were moderately correlated with other serum markers, including ELF score, AST, ALP, and GGT (Spearman correlations ρ = 0.38–0.74, all p < 0.001). YKL-40 demonstrated weaker but significant correlations to ALP, AST and ELF score (ρ = 0.24–0.54, p < 0.05). TSP-2 and COL4A1 were increased with fibrosis stage in PSC patients (both p < 0.001), but YKL-40 was increased mainly in patients with cirrhosis (Figure). By W96, 44 patients (20%) developed a PSC-related clinical event (hepatic decompensation, cholangiocarcinoma, ascending cholangitis, or jaundice). Compared with patients without events (n = 175), those with events had higher YKL-40 (median 42.5 vs 29.0 ng/ml, p = 0.001), COL4A1 (168.4 vs 121.1 ng/ml, p < 0.001) and TSP-2 (85.0 vs 50.4 pg/ml, p < 0.001) at BL. Among 176 non-cirrhotic patients at BL, 27 progressed to cirrhosis at W96. Compared with patients without progression to cirrhosis (n = 149), those with progression had higher BL levels of YKL-40 (OR = 1.91, p = 0.002), TSP-2 (OR = 4.24, p < 0.001), and COL4A1 (OR = 8.24, p < 0.001). In addition, patients with progression to cirrhosis had greater relative increases from BL to W96 in YKL-40 (median 45.8% vs 11.8%, p < 0.001), COL4A1 (34.9% vs – 3.4%, p = 0.0025) and TSP-2 (24.7% vs 0.1%, p < 0.001).

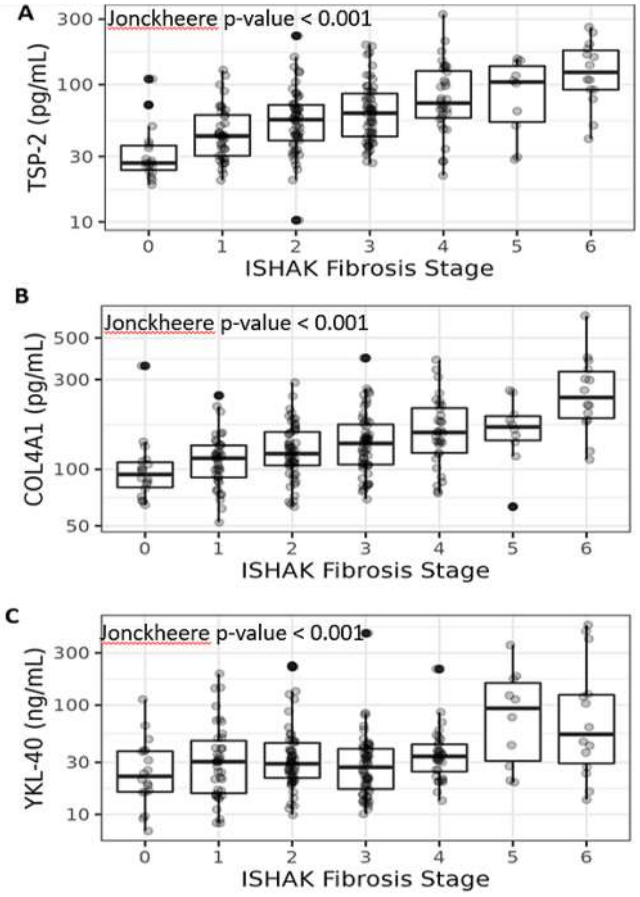

Figure: Associations between serum COL4A1, TSP-2, and YKL-40 and Ishak fibrosis stage

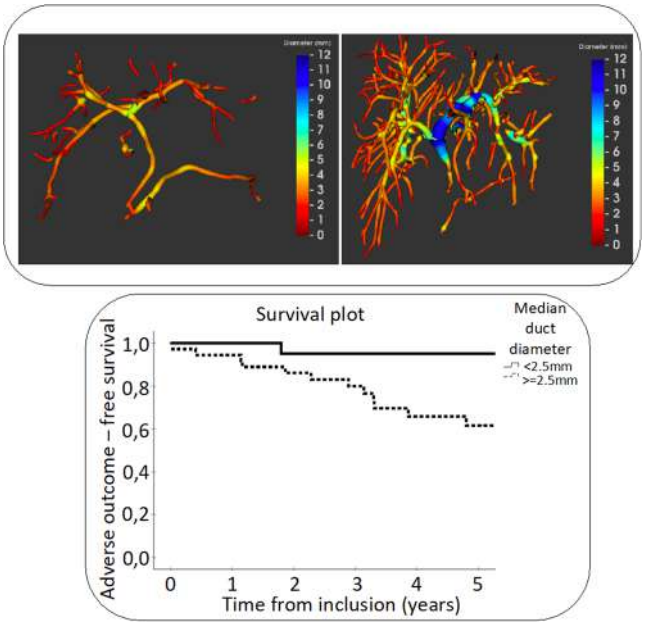
Conclusion: Serum levels of the novel fibrosis markers YKL-40, TSP-2, and COL4A1 are associated with fibrosis stage, progression to cirrhosis, and liver-related clinical events in patients with PSC. The utility of these biomarkers for the staging of fibrosis, risk stratification, and disease monitoring in PSC will be explored in additional studies.

THU454

MRCP+TM-derived biliary metrics are associated with disease severity and clinical outcomes in patients with primary sclerosing cholangitis

Nora Cazzagon[1,2], Sanaa El Mouhadi[3], Quentin Vanderbecq[3], Carlos Ferreira[4], Sara Lemoinne[1], Christophe Corpechot[1], Olivier Chazouillères[1], Lionel Arrivè[3]. [1]*Assistance Publique-Hôpitaux de Paris, Sorbonne University, INSERM, Reference Center for Inflammatory Biliary Diseases and Autoimmune Hepatitis and Saint-Antoine Research Center (CRMR MIVB-H, ERN RARE-LIVER), Saint-Antoine Hospital, Paris, France, Paris, France;* [2]*Department of Surgery, Oncology and Gastroenterology, University of Padova, European Reference Network on Hepatological Diseases (ERN RARE-LIVER), Azienda Ospedale-Università Padova, Padova, Italy, Padova, Italy;* [3]*Assistance Publique-Hôpitaux de Paris, Sorbonne University, Department of Radiology, Saint-Antoine Hospital, Paris, France, Paris, France;* [4]*Perspectum Ltd, Oxford UK, Oxford, United Kingdom*
Email: nora.cazzagon@gmail.com

Background and aims: Patients with primary sclerosing cholangitis (PSC) have a variable, and often progressive disease course which is associated with biliary and parenchymal changes. These changes are typically assessed by magnetic resonance imaging (MRI), including magnetic resonance cholangiopancreatography (MRCP). Our aim was to study the association of novel quantitative MRCP metrics with prognostic scores and patient outcomes.
Method: We performed a retrospective study including 77 large-duct PSC patients with baseline MRCP images, which were post-processed to obtain quantitative measures of bile ducts and biliary volume using MRCP+™ (Perspectum Ltd, Oxford). The participants' ANALI scores, liver stiffness (measured by vibration controlled transient elastography) and biochemical indices were collected at baseline. Adverse outcome-free survival was measured as the absence of decompensated cirrhosis and liver transplantation. The prognostic value of MRCP+™ derived metrics was assessed by univariate analysis and multivariate Cox regression modelling.



Results: During a total 386 patients-years, we recorded 16 cases of decompensated cirrhosis, 2 liver transplantations and 5 liver-related deaths. At baseline, ~50% of the patients were classified as being at risk of developing disease complications based on radiological, elastographic, and biochemical prognostic scores. MRCP+™ metrics, particularly those describing the severity of bile duct dilatations, were correlated with all prognostic factors. Univariate analysis showed that MRCP+ metrics representing duct diameter, dilatations, and the percentage of ducts with strictures and/or dilatations were associated with survival. According to the multivariate Cox regression model, the median duct diameter was independently associated with adverse outcome-free survival over 5 years (HR 10.9, 95% CI 1.3–90.3, p = 0.027) (Figure). Biliary tree volume was significantly higher in patients with advanced disease as defined by the ANALI scores.

Conclusion: MRCP+™ metrics demonstrated a significant correlation with biochemical, elastographic and radiological prognostic scores and were predictive of patients' outcomes highlighting its prognostic utility in PSC.

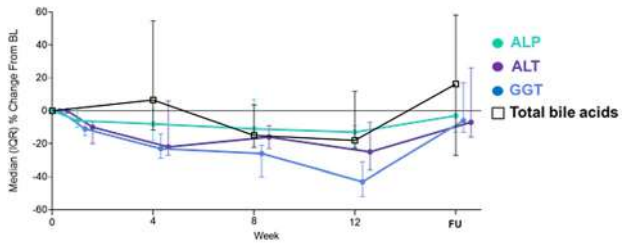
Email: clevy@med.miami.edu

Background and aims: Cilofexor (CILO) is a nonsteroidal FXR agonist being evaluated in the phase 3 PRIMIS trial of non-cirrhotic patients with PSC. The safety and efficacy of CILO in patients with cirrhosis is unknown. This proof-of-concept, open-label study evaluated the safety and efficacy of escalating doses of CILO in patients with PSC and cirrhosis.
Method: Subjects with PSC and compensated cirrhosis were treated with escalating doses of CILO for 12 weeks (30, 60, and 100 mg daily for 4-week intervals). Safety, liver biochemistry, and serum markers of fibrosis, cellular injury, and pharmacodynamic effects of CILO (bile acids [BAs]) were evaluated.
Results: Among 19 subjects screened, 11 were enrolled and 10 (91%) completed the study. The median age was 48 years, 55% were male, 55% had IBD, and 46% were on ursodeoxycholic acid. At baseline (BL), median (IQR) laboratory parameters were: total bilirubin 1.1 mg/dL (0.8, 1.5), albumin 4.0 g/dL (3.9, 4.6), INR 1.0 (0.9, 1.1), platelets 201 × 10^3/μL (113, 218), ALP 510 U/L (269, 592), and GGT 344 U/L (208, 455). BL ELF and liver stiffness by transient elastography were 10.4 (9.5, 12.6) and 18.0 kPa (8.5, 67.6), respectively. At week 12 (W12), liver biochemistry tests improved relative to BL values including serum ALP (median: −13% [IQR: −22, −9]; p = 0.006), GGT (−43% [−52, −31]; p = 0.002), ALT (−25% [−36, −7]; p = 0.012), and AST (−12% [−29, 7]; p = 0.32), and rebounded after 4 weeks of untreated follow-up (Figure). Total bilirubin decreased at W12 relative to BL (−13% [−25, 0], p = 0.13), while albumin and INR remained stable. Among 10 subjects with detectable serum BAs at baseline (26.1 μM/L [19.7, 52.9]), median change in BAs at W12 was −18% (−23, 12; p = 0.73). One patient discontinued treatment prematurely (subject decision). While no treatment-emergent (TE) serious adverse events (AEs) or deaths occurred in the study, Grade 2 or higher TEAEs occurred in 5 subjects (45%). Pruritus was reported by 8 subjects (73%), the majority (7 of 8) being Grade 1 or 2.



ALP, p=0.006; GGT, p=0.002, ALT, p=0.012, total bile acids, p=NS at W12 versus baseline. 4-week dose escalation regimen, 30 mg at BL, 60 mg at W4, and 100 mg at W8.

Conclusion: In this proof-of-concept study of patients with compensated cirrhosis due to PSC, escalating doses of CILO over 12 weeks were well tolerated and improved markers of cholestasis and liver biochemistry.

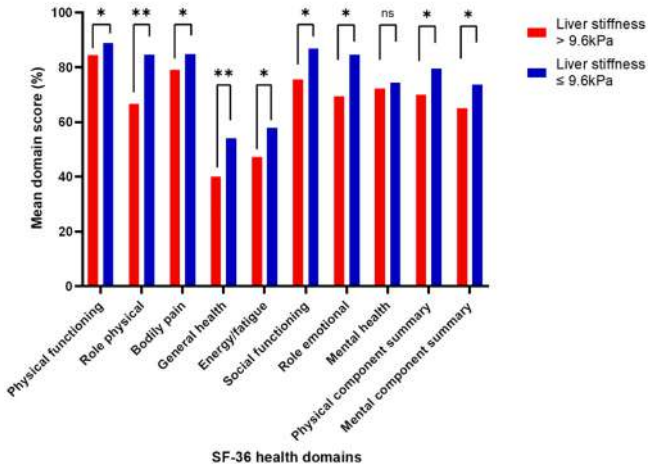
THU456

Association between patient-reported outcome measures and surrogate markers of liver fibrosis in large-duct primary sclerosing cholangitis

Emmanuel Selvaraj[1,2,3], Jane D. Collier[2], Emma Culver[2], J Michael Brady[4,5], Adam Bailey[2,3], Michael Pavlides[1,2,3]. *[1]University of Oxford, Oxford Centre for Clinical Magnetic Resonance Research, Radcliffe Department of Medicine, Oxford, United Kingdom; [2]University of Oxford, Translational Gastroenterology Unit, Nuffield Department of Medicine, Oxford, United Kingdom; [3]NIHR Oxford Biomedical Research Centre, Oxford University Hospitals NHS Foundation Trust, Oxford, United Kingdom; [4]University of Oxford, Department of Oncology, Oxford, United Kingdom; [5]Perspectum Ltd., Oxford, United Kingdom*
Email: emmanuel.selvaraj@cardiov.ox.ac.uk

Background and aims: Liver fibrosis is the main driver of disease progression in primary sclerosing cholangitis (PSC). Patient-reported outcome measures (PROMs) are increasingly used as exploratory end points in clinical trials. The aim of this study was to investigate the impact of liver fibrosis on health-related quality of life (HrQoL) using generic (SF-36) and disease-specific (PSC-PRO) tools.
Method: Patients with large-duct PSC were invited to complete HrQoL questionnaires in an outpatient setting. SF-36 and PSC-PRO domains were scored out of a maximum of 100% and 5, respectively. Mean scores were calculated for each health domain with lower SF-36 and higher PSC-PRO scores representing poorer quality of life. Transient elastography liver stiffness (LS; Echosens, France), enhanced liver fibrosis (ELF; Siemens Healthineers, Germany) and Liver*MultiScan*-derived iron-corrected T1 (cT1; Perspectum, Oxford, UK) were obtained on the same day. Advanced fibrosis was defined as LS >9.6 kPa and ELF >9.8 according to published cut-offs in PSC.
Results: Eighty patients (68% male) with median age 42 years (range: 18–76) and median PSC duration 8 years (range: 1–25) completed both HrQoL questionnaires. Median cT1 was 760ms (range: 640–1053), median LS was 6.9 kPa (range: 3.7–45.5) and median ELF was 9.4 (range: 8.0–13.7). For the SF-36, median cT1 correlated with all health domains. Mental health (rho –0.37, $p < 0.01$), bodily pain (rho –0.31, $p < 0.01$) and physical functioning (rho –0.31, $p < 0.01$) showed the strongest correlations. LS also correlated with all domains of SF-36 with bodily pain (rho –0.28, $p = 0.02$), social functioning (rho –0.27, $p = 0.02$) and physical functioning (rho –0.25, $p = 0.03$) showing the strongest correlations, albeit weaker than median cT1. ELF did not correlate with any of the SF-36 domains. SF-36 scores were lower in patients with advanced fibrosis defined by LS cut-off, particularly for role physical (67% vs 85%, $p < 0.01$) and general health (40% vs 54%, $p < 0.01$) domains (Figure 1). For the PSC-PRO, median cT1 did not correlate with any of the domains. Physical function correlated with LS (rho 0.30, $p < 0.01$) and ELF (rho 0.26, $p = 0.02$) with higher scores in those with advanced fibrosis (LS: 1.5 vs 1.2, $p = 0.01$; ELF: 1.5 vs 1.2, $p = 0.02$). Activities of daily living correlated with LS (rho 0.26, $p = 0.02$) and ELF (rho 0.25, $p = 0.03$) with higher scores in those with advanced fibrosis (LS: 1.5 vs 1.2, $p = 0.01$; ELF: 1.5 vs 1.3, $p = 0.03$).

Figure 1: Mean scores for SF-36 health domains stratified by severity of liver fibrosis



Conclusion: SF-36 and PSC-PRO health domains showed significant correlations with surrogate markers of liver fibrosis. Advanced fibrosis appears to have a greater impact on the physical than mental components of both PROMs. Future antifibrotic drug trials in PSC should consider assessing the impact of drug on physical well-being as one of the secondary end points.

THU457

Association between patient-reported outcome measures and severity of cholangiopathy in large-duct primary sclerosing cholangitis

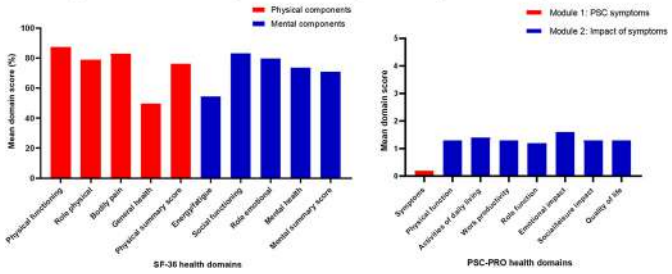
Emmanuel Selvaraj[1,2,3], Ahmed Ba-Ssalamah[4], Sarah Poetter-Lang[4], Jane D. Collier[2], Emma Culver[2], J Michael Brady[5,6], Adam Bailey[2,3], Michael Pavlides[1,2,3]. *[1]University of Oxford, Oxford Centre for Clinical Magnetic Resonance Research, Radcliffe Department of Medicine, Oxford, United Kingdom; [2]University of Oxford, Translational Gastroenterology Unit, Nuffield Department of Medicine, Oxford, United Kingdom; [3]NIHR Oxford Biomedical Research Centre, Oxford University Hospitals NHS Foundation Trust, Oxford, United Kingdom; [4]Medical University of Vienna, Department of Biomedical Imaging and Image-Guided Therapy, Vienna, Austria; [5]University of Oxford, Department of Oncology, Oxford, United Kingdom; [6]Perspectum Ltd., Oxford, United Kingdom*
Email: emmanuel.selvaraj@cardiov.ox.ac.uk

Background and aims: Magnetic resonance cholangiopancreatography (MRCP) is used alongside serum alkaline phosphatase (ALP) to assess the severity of cholangiopathy in primary sclerosing cholangitis (PSC). Patient-reported outcome measures (PROMs) are increasingly used as exploratory end points in clinical trials. The aim of this study was to investigate the impact of ALP and the severity of cholangiopathy on MRCP on health-related quality of life (HrQoL) using generic (SF-36) and disease-specific (PSC-PRO) tools.
Method: Patients with large-duct PSC were invited to complete HrQoL questionnaires in an outpatient setting. SF-36 and PSC-PRO domains were scored out of a maximum of 100% and 5, respectively. Mean scores were calculated for each health domain with lower SF-36 and higher PSC-PRO scores representing poorer quality of life. 3D MRCP and serum ALP were acquired on the same day. Two radiologists reviewed MRCP images for the presence of dominant stricture (DS) and measured the maximum intrahepatic bile duct dilatation (IHBD) for Anali score. Images were analysed using a quantitative biliary tool, *MRCP+* (Perspectum, Oxford, UK) to compute

the intrahepatic sum of relative severity of dilatations (SumRelSevDilat). Patients were classified into high or low risk group for disease progression using ALP cut-off 1.5x upper limit normal (ULN) and the presence of DS.

Results: Eighty patients (68% male) with median age 42 years (range: 18–76) and median PSC duration 8 years (range: 1–25) completed both questionnaires. Median ALP was 150 IU/ml (range: 48–1180). DS was reported in 25 (31%) patients. Maximum IHBD was ≤3 mm in 26 (33%), 4 mm in 19 (23%) and ≥5 mm in 35 (44%) patients. Median *MRCP+*–derived SumRelSevDilat was 7.0m^{-1} (range: 0.0–19.8). The mean score for each health domain is shown in Figure 1 below. DS correlated with SF-36 bodily pain (rho –0.28, p = 0.02). Maximum IHBD correlated with PSC-PRO physical function domain (rho 0.36, p < 0.01). SumRelSevDilat correlated with physical functioning (rho –0.25, p = 0.04) and bodily pain (rho –0.26, p = 0.03) domains of SF-36, and the physical function (rho 0.26, p = 0.03) and activities of daily living (rho 0.29, p = 0.01) domains of PSC-PRO. ALP correlated with bodily pain (rho –0.37, p < 0.01), general health (rho –0.26, p = 0.03), and energy/fatigue (rho –0.29, p = 0.01) domains of SF-36, and the physical function (rho 0.30, p < 0.01) and emotional impact (rho 0.38, p < 0.01) domains of PSC-PRO. Bodily pain score was lower in those with DS compared to those without (74% vs 87%, p = 0.02). Both physical functioning (80% vs 92%, p = 0.04) and bodily pain (78% vs 85%, p = 0.03) scores were lower in patients with ALP greater than 1.5x ULN.

Figure 1: Mean scores for SF-36 (out of maximum 100%) and PSC-PRO (out of maximum 5) health domains



Conclusion: The presence of DS, severity of intrahepatic biliary dilatations, and ALp >1.5x ULN have a significant impact on both physical and mental health of patients with large-duct PSC.

THU458

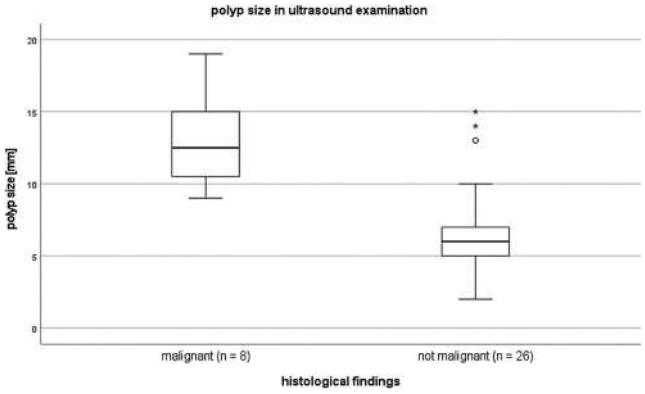
Ultrasound for the diagnosis of gallbladder polyps in PSC: polyps greater than 8 mm indicate malignancy

Johannes Altenmüller[1], Marcial Sebode[2,3], Christina Weiler-Normann[2,4], Christiane Wiegard[2], Ansgar Lohse[2,3,5], Christoph Schramm[2,3,4,5]. *[1]University Medical Center Hamburg-Eppendorf, Hamburg, Germany; [2]University Medical Center Hamburg-Eppendorf, Ist Department of Medicine, Hamburg, Germany; [3]European Reference Network on Hepatological Diseases (ERN RARE-LIVER); [4]University Medical Center Hamburg-Eppendorf, Martin Zeitz Centre for Rare Diseases, Hamburg, Germany; [5]University Medical Center Hamburg-Eppendorf, Hamburg Center for Translational Immunology, Hamburg, Germany*
Email: 6817657@stud.uke.uni-hamburg.de

Background and aims: The risk of gallbladder carcinoma is increased in primary sclerosing cholangitis (PSC). Surveillance imaging every 6–12 months is used for early diagnosis. The aim of the study is to assess the reliability of ultrasound and MRI in detecting gallbladder polyps in people with PSC.

Method: All patients with PSC and a history of cholecystectomy were included for the evaluation and comparison of the two imaging methods, ultrasound and MRI for the detection of gallbladder polyps. Data including gallbladder histology were gathered retrospectively from the electronic medical records. Polyps with high-grade dysplasia were assigned to the malignancy group. We determined a cut-off for detecting malignant polyps in ultrasound using a receiver operating characteristics curve.

Results: From a cohort of 596 people with PSC at the University Medical Center Hamburg-Eppendorf, 139 patients underwent cholecystectomy. 77 patients underwent cholecystectomy for a suspected underlying gallbladder pathology. In 37 of those patients (21 m, 16 f) the detection of a polyp on imaging was the indication for surgery. Additionally, 62 patients had their gallbladder removed in the context of other interventions such as liver transplantation. Looking at all 139 cholecystectomy patients, ultrasound (sensitivity = 100%) was significantly more sensitive than MRI in detecting gallbladder polyps (sensitivity = 35%) (p < 0.001). MRI missed 3 of the 8 polyps with malignant histology. In ultrasound, malignant polyps (n = 8, median size = 13 mm) were found to be significantly larger than non-malignant polyps (n = 26, median size = 6.6 mm) (p < 0.001). Ultrasound was able to reliably detect a malignant polyp (area under the curve = 0.92, p < 0.001). At a cut-off value of 8 mm, sensitivity was 100% and specificity was 81%.



Conclusion: In people with PSC, ultrasound is more sensitive in the detection of gallbladder polyps than MRI. Based on the size of polyps, a reliable distinction can be made between malignant and benign findings: no malignant polyp was smaller than 8 mm. This validates previously published data from the Mayo Clinic. Cholecystectomy needs to be offered if a polyp of 8 mm or more is detected. Therefore, ultrasound and MRI may be complementary methods for hepatobiliary malignancy surveillance in people with PSC. A multicentre validation of the data is ongoing.

THU459

Temporal changes in patient-reported outcome measures stratified by liver fibrosis severity in large-duct primary sclerosing cholangitis

Emmanuel Selvaraj[1,2,3], Jane D. Collier[2], Emma Culver[2], J Michael Brady[4,5], Adam Bailey[2,3], Michael Pavlides[1,2,3]. *[1]University of Oxford, Oxford Centre for Clinical Magnetic Resonance Research, Radcliffe Department of Medicine, Oxford, United Kingdom; [2]University of Oxford, Translational Gastroenterology Unit, Nuffield Department of Medicine, Oxford, United Kingdom; [3]NIHR Oxford Biomedical Research Centre, Oxford University Hospitals NHS Foundation Trust, Oxford, United Kingdom; [4]University of Oxford, Department of Oncology, Oxford, United Kingdom; [5]Perspectum Ltd., Oxford, United Kingdom*
Email: emmanuel.selvaraj@cardiov.ox.ac.uk

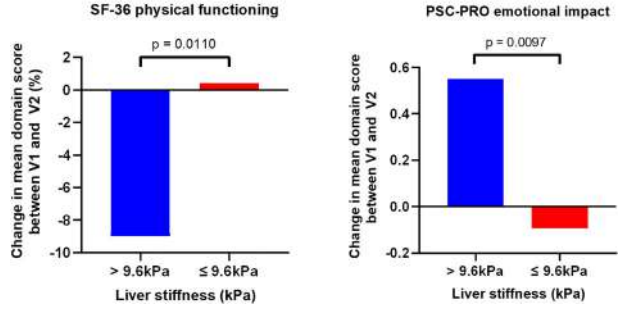
Background and aims: Patient-reported outcome measures (PROMs) are increasingly used as exploratory end points in clinical trials. The aim of this study was to evaluate the temporal relationship between health-related quality of life (HrQoL) and liver fibrosis using generic (SF-36) and disease-specific (PSC-PRO) tools.

Method: Patients with large-duct PSC were invited to complete HrQoL questionnaires in an outpatient setting at baseline (V1) and

follow-up (V2) visits at least 12 months apart. Transient elastography liver stiffness (LS; Echosens, France) measurements were recorded on the same day. SF-36 and PSC-PRO health domains were scored out of a maximum of 100% and 5, respectively. Mean scores were calculated for each domain with lower SF-36 and higher PSC-PRO scores representing poorer quality of life. Advanced fibrosis (F3-6) was defined based on published cutoff of LS >9.6kPa in PSC.

Results: Fifty-five patients (64% male) with median age 45 years (range: 20–77) and median PSC duration 11 years (range: 2–26) attended both study visits. The median time between visits was 417 days (range: 362–582). The mean scores were numerically lower at V2 than V1 in all the SF-36 domains but only three domains showed statistically significant difference: bodily pain (74% vs 83%, $p < 0.01$), energy/fatigue (47% vs 57%, $p < 0.0001$), and mental summary score (66% vs 71%, $p < 0.001$). There were no differences in any of the PSC-PRO domains between the visits. When stratified by baseline LS >9.6 kPa threshold (Figure 1), SF-36 physical functioning mean score dropped in the F3-6 group but increased slightly in the F0-2 group (−9.0 ± 17% vs 0.4 ± 21%, $p = 0.01$). In the PSC-PRO, the emotional impact mean score increased in the F3-6 group but decreased in the F0-2 group (0.6 ± 0.7 vs −0.1 ± 0.5, $p < 0.01$). There were no significant differences in mean scores in the other domains between the visits.

Figure 1: Temporal change in mean domain score stratified by severity of liver fibrosis at baseline



Conclusion: There was worsening of bodily pain, levels of energy and mental health even within a year in patients with large-duct PSC. Patients with advanced fibrosis reported lower physical functioning and higher emotional impact of their disease compared to those without advanced fibrosis. Changes in PROMs are related to liver fibrosis and need to be considered in future antifibrotic drug trials. These findings, however, need to be interpreted in the context of imposed restrictions during the Covid-19 pandemic which may have had a significant psycho-social impact on patients.

THU460

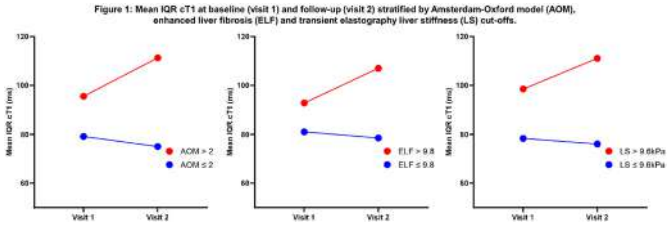
Temporal increase in interquartile range iron-corrected T1 in high-risk patients with large-duct primary sclerosing cholangitis

Emmanuel Selvaraj[1,2,3], Jane D. Collier[2], Emma Culver[2], J Michael Brady[4,5], Adam Bailey[2,3], Michael Pavlides[1,2,3]. [1]*University of Oxford, Oxford Centre for Clinical Magnetic Resonance Research, Radcliffe Department of Medicine, Oxford, United Kingdom;* [2]*University of Oxford, Translational Gastroenterology Unit, Nuffield Department of Medicine, Oxford, United Kingdom;* [3]*NIHR Oxford Biomedical Research Centre, Oxford University Hospitals NHS Foundation Trust, Oxford, United Kingdom;* [4]*University of Oxford, Department of Oncology, Oxford, United Kingdom;* [5]*Perspectum Ltd., Oxford, United Kingdom*
Email: emmanuel.selvaraj@cardiov.ox.ac.uk

Background and aims: Median iron-corrected T1 (cT1) derived from Liver*MultiScan* (Perspectum, Oxford, UK) correlates well with histological liver fibrosis. Interquartile range (IQR) cT1 has been proposed to better reflect the patchy liver fibrosis in primary sclerosing cholangitis (PSC). The aim of this study was to investigate the temporal changes in IQR cT1 in large-duct PSC.

Method: Patients with large-duct PSC attended study visits at baseline (V1) and follow-up (V2). Standardised liver T1 and T2* maps, transient elastography liver stiffness (LS; Echosens, France), enhanced liver fibrosis (ELF; Siemens Healthineers, Germany), and blood tests were performed on the same day at each visit. MRI data were analysed using Liver*MultiScan* to derive liver IQR cT1. The Amsterdam-Oxford model (AOM) score was also calculated. Patients were classified into high-risk or low-risk groups for disease progression using baseline data according to published cut-offs in PSC: AOM >2, ELF >9.8 and LS >9.6 kPa. Mixed ANOVA models were used to examine the within-subject effect (time), between-subject effect (high-risk or low-risk), and interaction between the two on changes in IQR cT1. The magnitude of effects (partial-ETA squared) was defined as: 0.01 (small), 0.06 (medium), and 0.14 (large). Receiver operating characteristic curve (ROC) analyses were conducted to assess the diagnostic performance of V1 and delta V1–V2 measurements to identify the high-risk groups.

Results: Fifty-five patients (64% male) with median age 45 years (range: 20–77) and median PSC duration 11 years (range: 2–26) attended both study visits. The median time between visits was 417 days (range: 362–582). IQR cT1 was higher in the high-risk groups compared to low-risk groups at either time points (AOM: $p < 0.001$; ELF: $p = 0.001$; LS: $p < 0.001$). IQR cT1 increased over time in the high-risk group and not in the low-risk group (AOM: $p = 0.03$; ELF: $p = 0.04$; LS: $p = 0.07$). There was a significant interaction between time and risk grouping on IQR cT1 when stratified by AOM ($F = 15.3$, $p < 0.001$; partial-ETA squared = 0.23), ELF ($F = 9.1$, $p < 0.01$; partial-ETA squared = 0.15) and LS ($F = 7.2$, $p = 0.01$; partial-ETA squared = 0.12). Delta V1–V2 (AUC = 0.78, 95% CI: 0.61–0.95) numerically had a higher diagnostic performance than V1 IQR cT1 (AUC = 0.75, 95% CI 0.61–0.89; $p < 0.001$) to detect the AOM >2 group but was no better when stratified by ELF and LS.



Conclusion: Patients who are at higher risk of death and/or liver transplantation (AOM >2) or with advanced fibrosis (ELF >9.8, LS >9.6 kPa) are likely to have a progressively higher IQR cT1 over time. Single baseline measurements alone outperformed dynamic measurements over two time points in detecting the high-risk group. Further follow-up data points with repeated-measures analysis and correlation with clinical outcomes are needed.

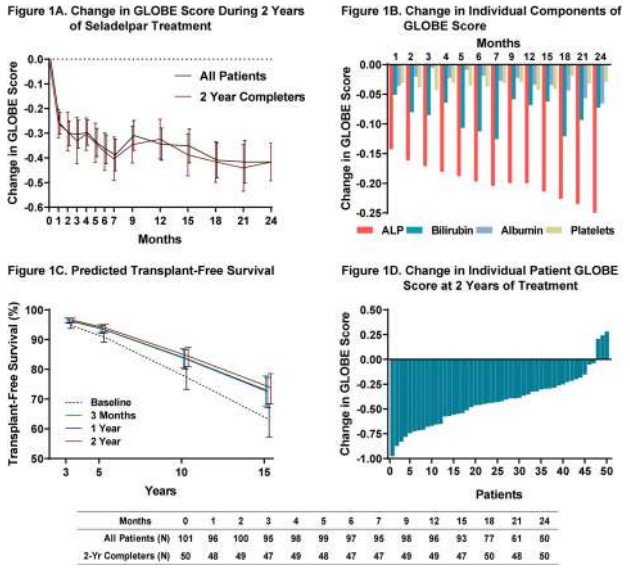
THU461

Seladelpar treatment of patients with primary biliary cholangitis (PBC) for 2 years improves the GLOBE PBC score and predicts improved transplant-free survival

Bettina Hansen[1,2], Elaine Watkins[3], Ke Yang[3], Yun-Jung Choi[3], Charles McWherter[3], Gideon Hirschfield[4]. [1]*Toronto Centre for Liver Disease, Toronto General Hospital, University Health Network, Toronto, Canada;* [2]*Institute of Health Policy, Management and Evaluation (IHPME), University of Toronto, Toronto, Canada;* [3]*CymaBay Therapeutics, Inc, Newark, United States;* [4]*Toronto Centre for Liver Disease, University of Toronto, Toronto, Canada*
Email: bettina.hansen@utoronto.ca

Background and aims: The GLOBE score is a validated risk assessment tool providing an estimate of transplant-free survival for patients with PBC. Seladelpar is a PPAR-delta agonist with anti-cholestatic, anti-inflammatory and anti-pruritic activity in PBC

patients. Our aim was to evaluate change in GLOBE score in patients with PBC treated with seladelpar for 2 years.
Method: Eligible patients with PBC and an inadequate response or intolerance to UDCA (alkaline phosphatase (ALP) ≥1.67xULN) were enrolled into an open-label one-year phase 2 study (EudraCT: 2016-002996-91) receiving daily oral 5 or 10 mg seladelpar. After 1 year, patients were eligible for an open label long-term study (EudraCT: 2017-003910-16). The change in GLOBE score following seladelpar treatment over 2 years and the resulting predictions of transplant-free survival were assessed. The contributions of alkaline phosphatase, total bilirubin, albumin, and platelets to changes in GLOBE score were examined.
Results: 101 patients entered the long-term study with available GLOBE score and were evaluated: 94% female, mean (SD) age 57 (9.0) years, duration of PBC 10 (6.6) years, and UDCA dose of 15 (3.7) mg/kg/day. Mean baseline values were ALP 321 (165) U/L, bilirubin 0.8 (0.3) mg/dL, albumin 4.1 (0.3) mg/dL, platelets 237 (82) × 10^3/μL and GLOBE score 0.390 (0.656). After treatment with seladelpar for 3 months, 1 year and 2 years the mean (SD) change from baseline in GLOBE score was −0.330 (0.321), −0.324 (0.281), and −0.417 (0.269), respectively. The observed early fall of GLOBE score within 3 months was followed by a gradual decline through 2 years (Fig. 1A). The improvements in GLOBE score for all patients and those completing two years were comparable. The greatest changes in GLOBE score were attributable to changes in alkaline phosphatase values followed by those of total bilirubin (Fig. 1B). Seladelpar treatment led to predicted changes in survival (Fig. 1C) at 3 months, 1 year and 2 years with hazard ratios of 0.72, 0.72 and 0.66 compared to baseline, respectively. The improvements in GLOBE score were observed for nearly all patients completing 2 years treatment (47 of 50, Fig. 1D).



Conclusion: Seladelpar treatment over 2 years resulted in a sustained decrease in GLOBE score for patients with PBC that is associated with a predicted improvement in transplant-free survival.

THU462

Validation of a novel method of identifying patients with Primary Sclerosing Cholangitis (PSC) in a canadian population

Harshil Patel[1], Fengjuan Yang[1], Mark G Swain[1], Gideon Hirschfield[2], Gilaad Kaplan[1], Bettina Hansen[2], Abdel-Aziz Shaheen[1]. [1]*University of Calgary, Calgary, Canada;* [2]*University Health Network, Toronto, Canada*
Email: az.shaheen@ucalgary.ca

Background and aims: Studies describing the epidemiology of primary sclerosing cholangitis (PSC) have been limited due to suboptimal case-finding and case-ascertainment. Using administrative databases to identify PSC in the population is not reliable. Guidelines recommend PSC patients should undergo a colonoscopy to rule out inflammatory bowel disease (IBD). Therefore, we aimed to evaluate the role of using an endoscopy database to improve PSC patient identification.
Method: We used the Pentax medical endoscopy endoPRO iQ® database to identify adult (≥18 years) patients who had undergone a colonoscopy in the Calgary Health Zone [(CHZ) population ~1.5 million]. We searched the endoscopy report database for one of the following predefined texts: *primary sclerosing cholangitis, PSC, sclerosing cholangitis*, between 2005 and 2019. The CHZ is a one-payer system providing medical care to all residents in the zone. All endoscopies performed in the CHZ are captured within a secure Pentax medical database. We used the International Classifications of Diseases (ICD) codes to identify patients with PSC in the following administrative databases: inpatient, ambulatory, and physician claims. Finally, for case-ascertainment, we conducted a validation study using medical charts on all PSC patients identified in the endoscopy database and a systematic random sample of patients identified by the administrative databases but not by the endoscopy database (sample size = 207). In our validation study, we identified patients with ulcerative colitis (UC), Crohn's disease (CD), and indeterminate colitis.
Results: During our study period, we identified 535 patients using the endoscopy database and 4, 544 patients in administrative databases with a potential PSC diagnosis. Within the endoscopy database, we identified 406 PSC patients (male sex 59.4%) who had a confirmed PSC diagnosis using radiological modalities and/or a liver biopsy. In this cohort, 1.5% (n = 6) patients were not identified in the administrative databases. IBD was prevalent at 81.5% (n = 331) in our cohort (UC 149 [36.7%], CD 146 [36.0%], and 36 [8.9%] indeterminate colitis). In our validation study (n = 742 charts), 412 patients had a confirmed PSC diagnosis. Using the endoscopy database alone to identify PSC patients had sensitivity 98.5% (406/412), specificity 60.9% (201/330), positive predictive value (PPV) 75.9% (406/535), and negative predictive value (NPV) 97.1% (201/207). Using multiple previously recommended algorithms in the administrative databases to identify PSC patients had a maximum PPV of 62% and sensitivity of 54%.
Conclusion: Using endoscopy databases to identify PSC patients is a reliable, accurate and feasible method compared to using administrative databases. Our proposed method would lead to better case-ascertainment and should improve the quality of future studies evaluating the natural history of PSC.

THU463

The prevalence of primary biliary cholangitis (PBC) is on the rise: a canadian population-based study

Bryce Tkachuk[1], Fengjuan Yang[2], Gideon Hirschfield[3], Mark G Swain[2], Abdel-Aziz Shaheen[2]. [1]*University of Calgary, Medicine, Calgary, Canada;* [2]*University of Calgary, Calgary, Canada;* [3]*University Health Network, Toronto, Canada*
Email: az.shaheen@ucalgary.ca

Background and aims: Canada has one of the highest rates of primary biliary cholangitis (PBC) incidence and prevalence worldwide. Our group reported the natural history of PBC in Calgary (population ~1.5 million) more than a decade ago. Significant awareness and recent advancement of PBC management were reported. Therefore, we aimed to study the impact of these factors on the natural history of PBC in a well-defined Canadian population and evaluate the temporal trends of PBC incidence and prevalence.
Method: We used population-based administrative data (inpatient, ambulatory care, and physician claims) and a previously validated International Classification of Diseases coding algorithm to identify PBC patients in the Calgary Health Zone between 2003 and 2018. We applied the same validated methods that we implemented in our

original study (*Myers et al.,* 2009, study period: 1996–2002). We conducted a validation study on incident cases to confirm the performance of the used algorithm in order to identify definite PBC patients (those who had at least two of the following criteria: positive anti-mitochondrial antibody, cholestatic liver enzymes, and a compatible liver biopsy). The positive predictive value (PPV) was 78.2%, while PPV of the original algorithm was 73.1%. We used a washout period of 2 years (2003–2004) to identify incident PBC cases. We chose March 31st of each year as point prevalence. Temporal trends were evaluated using generalized linear models assuming a Poisson distribution or a negative binomial distribution if over-dispersion is present. Rates were adjusted to the Canadian population census of 2016.

Results: Between 2005 and 2018, the overall age/sex annual incidence of PBC was 39.4 cases per million. Age-adjusted incidence rates were 60.7 per million in women versus 16.7 per million in men (incidence rate ratio [IRR] 3.68; 95% CI 2.98–4.54). The highest adjusted incidence was observed among the age group 60–79 years (74.0 case per million). Age/sex-adjusted point prevalence rates of PBC increased from 295.8 to 500.0 per million between 2005 and 2018, $p < 0.001$. As expected, adjusted point prevalence rates were much higher among women than men (799.8 versus 169.0 per million). We identified 520 incident cases during our study time (female 78.7% [n = 409]). After a median follow-up of 6.8 years (IQR 3.9–10.6), 29 patients underwent transplantation (5.6%) and 81 patients died (15.6%). The annual mortality rate was 8.1% (95% CI 9.8%–14.0%). The estimated 5- and 10-year survival rates were 90.7% (87.5%–93.0%) and 77.4% (72.2%–81.7%), respectively. Survival was not significantly different between men and women, $p = 0.50$.

Conclusion: In this well-defined cohort, we reported a significant increase in the prevalence of PBC in a Canadian population. Prevalence of PBC is higher among the older age group which could reflect better case-identification and management.

THU464

Rituximab is a safe and effective treatment for patients with autoimmune hepatitis: results from the Spanish registry for cholestatic and autoimmune hepatitis

Ana Barreira[1,2], Maria Carlota Londoño[2,3], Carmen Álvarez-Navascués[4], Carlos Ferre Aracil[5], Indhira Perez Medrano[6], Juan Turnes[2,6], Diana Horta[7], Álvaro Díaz-González[8], Fernando Diaz Fontela[9], Magdalena Salcedo[2,9], Mar Riveiro Barciela[2,10]. Email: mar.riveiro@gmail.com

Background and aims: The evidence of second-line therapy for autoimmune hepatitis (AIH) is relatively scarce, especially concerning biological agents such as rituxumab. This study aims to evaluate the efficacy and safety of rituximab in patients with autoimmune hepatitis (AIH).

Method: multicenter retrospective study of all patients with AIH from the ColHai registry who received rituximab from January 2015 to September 2021. Efficacy was assessed by improvement in transaminases and Immunoglobulin (Ig) G or normalization (biochemical response) and later development of flares; safety in terms of adverse reactions, infectious and tumoral complications.

Results: 2763 AIH patients were included in the ColHai registry (Spanish registry for cholestasic and autoimmune disorders). Out of them, 13 patients with type 1-AIH were treated with rituximab in 8 different hospitals. The majority were women (10/13), median age 43 years. At diagnosis 1 presented an acute severe hepatitis and 2 had liver cirrhosis. Time from diagnosis to beginning of rituximab was 20 months and to last follow-up 5 years. The reasons for biological therapy were: 4 difficult-to-manage AIH and 9 due to indication for other concomitant autoimmune disorder (4 multiple sclerosis, 3 vasculitis and 2 rheumatoid arthritis). The majority (11/13) received a 2-dose induction course followed by a new dose every 6 months. After rituximab, at the 1-month follow-up an improvement of IgG levels was observed ($p = 0.018$) and a tendency towards decrease of AST/ALT. At month 6, the reduction in AST/ALT was statistically significant ($p = 0.012$ and $p = 0.008$). Eight out of 13 presented increased transaminases and IgG levels at the start of rituximab, and 5/8 achieved biochemical response after rituximab therapy. Treatment was well tolerated, without infusion reactions, though 3 patients developed non-severe infectious complications. All patients but one were on corticoids at the beginning of rituximab and in 8/12 they could be tapered or discontinued. Moreover, in five of these patients other immunosuppresants could be stopped due to the positive impact of rituximab as shown in the figure. Despite initial improvement, four patients presented flares of AIH during follow-up that were successfully managed with new doses of ritixumab.

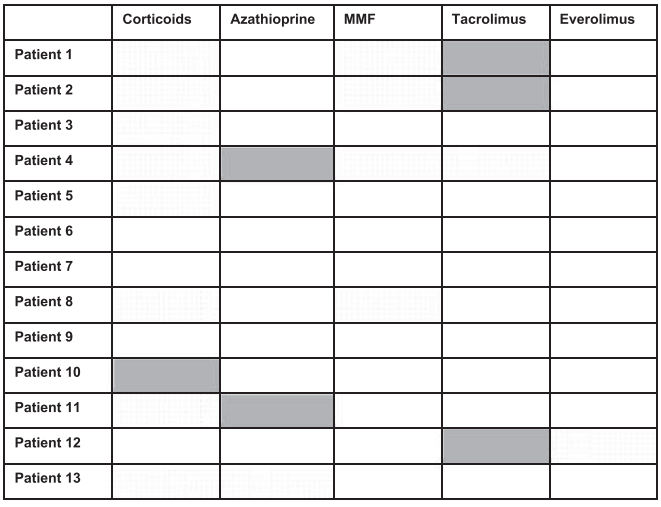

Figure: Individual therapy at the beginning of rituximab (grey squares) and drugs that were reduced or discontinued during follow-up (striped squares).

Conclusion: Rituximab is a safe and effective treatment for AIH, leading to reduction of immunosuppression in a high proportion of patients and improvement of transaminases and IgG levels.

THU465

Autoimmune hepatitis diagnosed after COVID-19 vaccination. Results from the spanish registry for autoimmune and cholestatic hepatitis

Ana Barreira[1,2], Mar Riveiro Barciela[1,2], Agustin Castiella[3], Álvaro Díaz-González[4], Maria Carlota Londoño[2,5], Indhira Perez Medrano[6], Judith Gómez-Camarero[7], Marta Casado[8], Carmen Del Pozo-Calzada[9], María Dolores Antón Conejero[2,10], Magdalena Salcedo[2,11]. *[1]Hospital Universitario Vall de Hebrón, LIver Unit; [2]Instituto de Salud Carlos III., Centro de Investigación Biomédica en Red de Enfemerdades Hepáticas y Digestivas (CIBERehd).; [3]Hospital Universitario de Donostia, Liver Unit; [4]Hospital Universitario Marqués de Valdecilla. Email: magdalena.salcedo@salud.madrid.org

Background and aims: Universal vaccination has become the main strategy against the COVID-19 pandemic. The SARS-CoV-2 spike protein used in the vaccines is believed to be responsible for stimulating the immune system, thus suggesting a possible association between COVID-19 vaccines and the development of autoimmune diseases. To date, different events of probable autoimmune origin have been reported in association with the COVID-19 vaccine, including few cases of autoimmune hepatitis (AIH). The aim of this study was to describe the clinical and epidemiological characteristics of a number of patients with AIH debut or reactivation after COVID-19 vaccination.

Method: Multicenter, retrospective-prospective study, that included subjects who have received one or two doses of any of the approved COVID-19 vaccines and later presented increased transaminases values due to AIH within the 90 days after vaccination.

Results: 23 patients from 9 Spanish academic hospitals were included. 17/23 were female, mean age 51 (±15) years. 19/23 patients were biopsied and four were not, 3 of them had a previous diagnosis of AIH. Seven patients had another prior autoimmune disorder. COVID-19 vaccines: 12/23 Pfizer, 4 Moderna, 5 Astrazeneca and 2 Janssen. In 14/23 patients the AIH episode happened after the second dose and in 9 after the first dose. Median time from the last dose of vaccine to AIH was 21 (11–36) days. Table 1 summarizes the analytical data of patients at the time of hepatitis. Antinuclear antibodies (ANA) ≥1/80 was observed in 18/23 patients. Regarding the severity of hepatitis, it was mild in the majority of patients (20/23), two patients presented with fulminant hepatitis and in one subject it was severe. All but one of the biopsied patients showed histological findings compatible with AIH. The RUCAM to assess causality showed at least possible association (≥4 points) in 11 patients. Simplified AIH Score showed at least probable AIH (≥6 points) in 16/23 patients. All patients received treatment with corticosteroids and in 19 patients immunosuppressive treatment with azathioprine was initiated.

	Median (IQR)
Aspartate aminotransferase (AST), IU/L	915 (622-1448)
Alanine aminotransferase (ALT), IU/L	966 (704-1498)
Alkaline phosphatase (AP), IU/L	135 (131-239)
Gamma-glutamyl transferase (GGT), IU/L	183 (120-266)
Total bilirrubin, mg/dL	2.96 (1.8-10.3)
Direct bilirubin, mg/dL	2.3 (1.3-11)
International Normalized Ratio (INR)	1.09 (0.98-1.28)
Immunoglobulin G (IgG), mg/d	1684 (1252-2240)
Total proteins, mg/dL	7.4 (6.6-7.9)

Figure: Analytical data of the patients at the time of hepatitis

Conclusion: An increase in transaminase values after administration of COVID-19 vaccine should be evaluated given the possibility of diagnosing autoimmune hepatitis.

THU466

A prospective trial of a gluten free diet in primary sclerosing cholangitis with associated colitis

Timur Liwinski[1], Sina Hübener[1], Lara Henze[1], Peter Huebener[1], Melina Heinemann[1], Bettina Jagemann[1], Marcus Tetzlaff[1], Guido Schachschal[1], Thomas Rösch[1], Erika Monguzzi[2], Corinna Bang[3], Andre Franke[3], Ansgar W. Lohse[1], Detlef Schuppan[2], Christoph Schramm[1]. *[1]University Medical Center Hamburg-Eppendorf, Hamburg, Germany; [2]Universitätsmedizin der Johannes Gutenberg-Universität Mainz, Mainz, Germany; [3]University of Kiel, Kiel, Germany*
Email: liwinskt@gmail.com

Background and aims: Primary sclerosing cholangitis (PSC) is a progressive autoimmune disease of the bile ducts associated with inflammatory bowel disease. Several studies indicated that gluten restriction might ameliorate autoimmune liver disease and inflammatory bowel disease (IBD) symptoms. We investigated whether patients with PSC with associated IBD can benefit from a diet free of wheat and gluten (GFD) using a prospective multi-omics approach.

Method: We performed a prospective clinical pilot study administering an eight-week GFD to PSC patients with non-advanced liver disease and associated colitis without overt clinical activity. A clinical dietitian trained patients and controlled adherence to the intervention by validated questionnaires and measuring gluten peptides in urine. The patients were evaluated at several time points, including endoscopy before and after the GFD period. We recorded multiple clinical parameters, dietary information, and biologically relevant parameters, including intestinal mucosal cytokine levels, intestinal bulk RNA-Seq transcriptomics. The enteric fecal and mucosal microbiota were analyzed by sequencing the variable region V1/V2 of the 16S rRNA gene and shotgun metagenomics.

Results: In total, fifteen patients were enrolled and completed the study. A decreased expression of proinflammatory mucosal cytokines and chemokines such as IL6 ($p < 0.001$), IL8 ($p < 0.001$), CCL2 ($p = 0.042$), and TNF-alpha ($p < 0.001$) was observed after GFD. Moreover, the intestinal transcriptome indicated improvement of the gut barrier, with an increase of pathways related to "adherens junction" ($p = 0.0471$), "cell-substrate junction" ($p = 0.0262$), "cell-substrate adherens junction" ($p = 0.0233$), and "focal junction" ($p = 0.0217$). We found mild to moderate changes in luminal microbiota composition after GFD, including a decrease of Romboutsia ilealis (FC = –9.02, FDR < 0.001). As expected from the short intervention period and the low disease activities, no statistically significant response was observed regarding clinical parameters such as the endoscopic score ($p = 0.398$) and patient-reported outcome measures. According to the food frequency questionnaire, the macronutrient composition (other than gluten) did not change during eight weeks of diet.

Conclusion: This is the first study to demonstrate that GFD may improve intestinal inflammation and barrier function in patients with PSC-IBD. This effect was linked to changes in the enteric microbiota composition. This pilot study justifies subsequent studies in patients with more severe disease activity.

THU467

The international autoimmune hepatitis group retrospective registry: quality assessment and analysis of clinical characteristics and liver-related outcome

Charlotte Slooter[1], Floris van den Brand[1], Ana Lleo[2], Francesca Colapietro[2], Marco Lenzi[3], Paolo Muratori[3], Nanda Kerkar[4], George Dalekos[5], Kalliopi Zachou[5], Maria Isabel Lucena[6], Mercedes Robles-Díaz[6], Daniel E. Di Zeo-Sánchez[6], Raul J. Andrade[6], Aldo J Montano-Loza[7], Ellina Lytvyak[7], Guilherme Macedo[8], Gerd Bouma[1], Rodrigo Liberal[8,9], Ynto de Boer[1]. *[1]Amsterdam University Medical Center, Netherlands; [2]Humanitas University, Italy; [3]University of Bologna, Italy; [4]Golisano Children's Hospital, University of Rochester Medical Center, Rochester, United States; [5]University Hospital of Larissa, Greece; [6]Vírgen de Victoria University Hospital, University of Málaga, Spain; [7]University of Alberta Hospital, Edmonton, Canada; [8]Centro Hospitalar Sao Joao, Porto, Portugal; [9]King's College, United Kingdom*
Email: y.deboer1@amsterdamumc.nl

Background and aims: The International Autoimmune hepatitis (AIH) Group retrospective registry (IAIHG-RR) is a web-based platform for large scale aetiological and therapeutic studies in paediatric and adult subjects enrolled with a diagnosis of AIH. This study aimed to ascertain data quality and describe the clinical characteristics and outcomes of this cohort.
Method: This retrospective analysis included all patients with a clinical diagnosis of AIH (n = 2278) from the IAIHG-RR entered between December 2018 and September 2021. This registry contains data on clinical characteristics and liver-related outcomes from 37 centers in 7 countries. Quality assessment included cohort completeness for 31 pre-defined variables, consistency and data was externally validated.
Results: Completeness of individual data was 75.8% (range 3.0–100). Per center, completeness varied between 69.5% and 99.9%. Consistency of inclusion criteria and outlier analysis was nearly 100%. Among patients for whom a simplified AIH score was available, diagnosis was classified as possible in 27, 5%, probable in 25.0% and in 47.5% as definite. At diagnosis, 21.9% showed signs of cirrhosis and median Model for End-Stage Liver Disease (MELD) score was 11 [range 6–40]. Primary biliary cholangitis and primary sclerosing cholangitis were reported in 10.0% and 7.0%, respectively. Other associated diseases were reported in 26.3%. For 1191 patients follow-up and outcome data was available. With a median follow-up period of 12 [range 0–49] years 36.8% demonstrated signs of cirrhosis, 2.2% were diagnosed with hepatocellular carcinoma and 10.6% underwent liver transplantation. 172 patients died during the follow-up period at a median age of 65 (range 15–94). In 49.7%, the cause of death was reported liver-related. Liver transplantation and liver related death were both associated with signs of cirrhosis at baseline (hazard ratio [HR] 1.90; $p < 0.001$), the MELD score at baseline (HR 1.09; $p < 0.001$) and with persistence of elevated aminotransferases at 6 months (HR 2.75; $p < 0.001$).

Conclusion: The IAIHG-RR represents world's largest patient cohort with moderate-to-good quality of baseline and follow-up data with relevant number of liver-related adverse events. This study showed that cirrhosis and MELD score at baseline and persistence of elevated aminotransferases at 6 months are associated with liver transplantation and liver-related death. This registry is a suitable platform, which allows for patient selection for future therapeutic and aetiological studies.

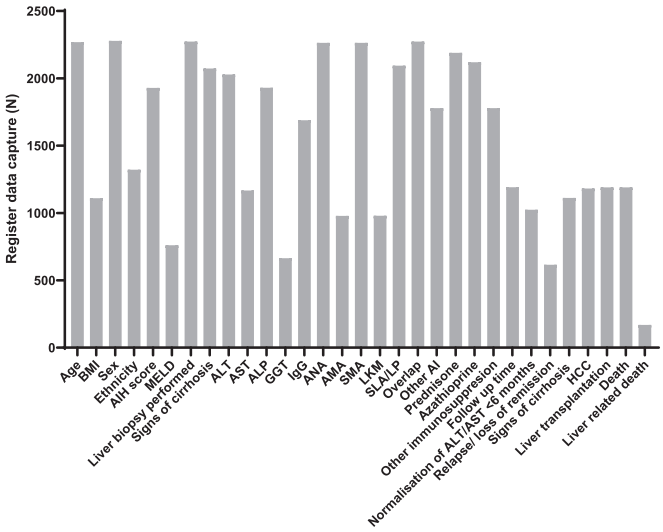

Figure: Data captured in absolute numbers for a pre-defined set of 31 variables in the IAIHG-RR (n = 2278).

Liver inflammation activity in autoimmune hepatitis patients with normal ALT and IgG levels

Chuanwu Zhu[1], Jiacheng Liu[2], Jian Wang[3], Huali Wang[4], Yilin Liu[2], Yiguang Li[5], Li Zhu[1], Weimao Ding[6], Yuanwang Qiu[5], Yongfeng Yang[4], Jie Li[3], Rui Huang[3], Chao Wu[3]. *[1]The Affiliated Infectious Diseases Hospital of Soochow University, Department of Infectious Diseases, Suzhou, China; [2]Nanjing Drum Tower Hospital Clinical College of Traditional Chinese and Western Medicine, Nanjing University of Chinese Medicine, Department of Infectious Diseases, Nanjing, China; [3]Nanjing Drum Tower Hospital, The Affiliated Hospital of Nanjing University Medical School, Department of Infectious Diseases, Nanjing, China; [4]Nanjing Second Hospital, Nanjing University of Chinese Medicine, Department of Hepatology, Nanjing, China; [5]The Fifth People's Hospital of Wuxi, Department of Infectious Diseases, Wuxi, China; [6]Huai'an No. 4 People's Hospital, Department of Hepatology, Huai'an, China*
Email: dr.wu@nju.edu.cn

Background and aims: Serum alanine transaminase (ALT) and IgG levels are considered as surrogate markers for histological activity in autoimmune hepatitis (AIH). We assessed the inflammatory activity in AIH patients with normal ALT and IgG levels.
Method: 257 AIH patients underwent liver biopsy (LB) were retrospectively included from four medical centers. Liver inflammation and fibrosis were estimated by Scheuer scores. The definitions of advanced inflammation and fibrosis were $G \geq 3$ and $S \geq 3$, respectively.
Results: 163 (63.3%) AIH patients had advanced inflammation, while 125 (48.6%) patients had advanced fibrosis. The proportion of advanced inflammation was 62.1% in patients with normal ALT and 55.6% in patients despite normal ALT and IgG. The proportion of advanced inflammation was 44.0% in patients without advanced fibrosis and was 81.8% in those with advanced fibrosis. Of patients with advanced fibrosis, 78.6% (33/42) of patients with normal ALT presented advanced inflammation, which was 75.0% in patients with normal ALT and IgG. Among patients without advanced fibrosis, the proportion of advanced inflammation was as high as 33.3% in those with normal ALT and 31.3% in those despite normal ALT and IgG. Red cell distribution width was independently associated with advanced inflammation (OR: 1.521, 95%CI: 1.193–1.938, $P = 0.001$) in entire patients.

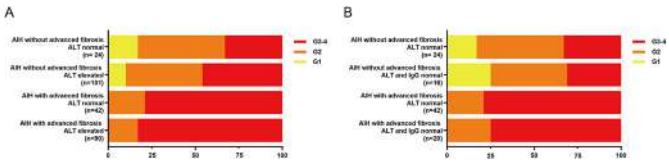

Figure: Histological activity in relation to ALT and IgG levels in AIH patients with or without advanced fibrosis

Conclusion: High proportion of advanced inflammation was found in AIH patients despite normal ALT and IgG levels even for those without advanced fibrosis. Though fibrosis can be ruled out by non-invasive methods in AIH patients with normal ALT and IgG, LB is encouraged to assess inflammatory activity.

THU469

Novel screening test for primary sclerosing cholangitis: the role of serology, liver function tests, histology and radiology

Nina Barner-Rasmussen[1], Nelli Sjöblom[2], Hannu Kautiainen[3], Johanna Arola[2], Martti Färkkilä[1]. [1]*University of Helsinki and Helsinki University Hospital, Departement of Gastroenterology, Helsinki, Finland;* [2]*University of Helsinki and Helsinki University Hospital, Department of Pathology, Helsinki, Finland;* [3]*University of Eastern Finland, Institute of Public Health and Clinical Nutrition, Kuopio, Finland*
Email: nina.barner-rasmussen@hus.fi

Background and aims: Primary sclerosing cholangitis (PSC) is a chronic cholestatic liver disease. There is no specific laboratory test for surveillance or screening in PSC unlike in primary biliary cholangitis. At present, the screening of PSC is mainly based on elevated alkaline phosphatase (ALP) in patients with inflammatory bowel disease (IBD). However, ALP and gamma-glutamyl transferase (GT) may be normal, even in advanced bile duct disease. The diagnosis is made by magnetic resonance cholangiopancreatography (MRCP) or by endoscopic retrograde cholangiography (ERC). The latest guidelines from Europe and America do not recommend liver biopsy, apart from small-duct PSC or a suspicion of an overlap syndrome. We aim to produce a screening system to predict the likelihood of PSC evaluating the role of laboratory tests, liver histology and MRCP.
Method: We retrieved 395 PSC patients from the PSC registry of Helsinki University Hospital who came for their 1st ERC to confirm the diagnosis. 69 patients with suspicion of PSC who underwent ERC, liver biopsy and MRCP excluding PSC, served as controls (non-PSC patients). Liver histology was scored according to the Nakanuma classification from Herovici stained core needle biopsy specimens. MRCP before diagnosis was scored from the existing radiology report as negative for PSC, finding suggestive for PSC, and clear findings for PSC. We included demographics and eleven different laboratory tests in the analysis. Area under the curve (AUC), positive prediction value, likelihood ratio, sensitivity, specificity, and odds ratio (OR) were calculated. Variables with highest OR were selected for multivariate logistic regression, which was used to create the novel scoring system.
Results: IBD, perinuclear anti-neutrophil cytoplasmic antibodies (P-ANCA) and ALP had the best predictive value. A score was assigned to each statistically significant predictor. Presence of IBD and P-ANCA gives 2 points each and ALp >UNL 1 point. The optimal cut-off point for the score was ≥3, with AUC of 0.83 (95%CI 0.78–0.88). If a patient got a score of 3 or higher, the probability of a true PSC diagnosis was >90%. Adding liver histology or MRCP to the score did not add predictive value.

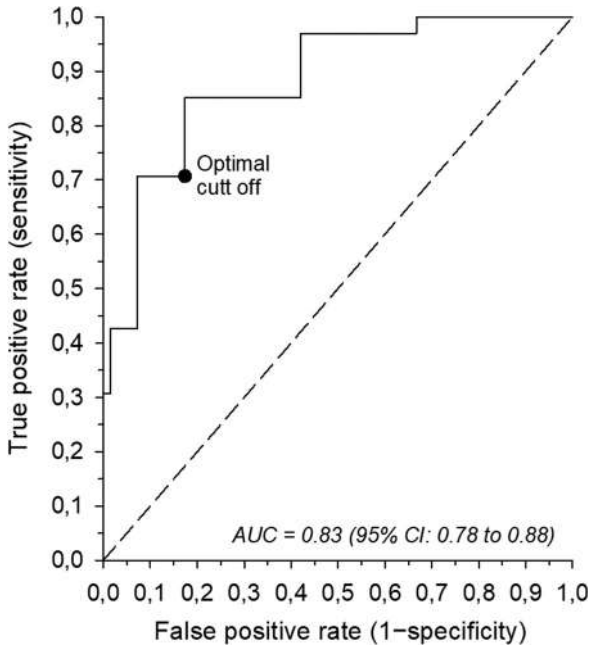

Figure: Prognostic performance of HelPSCreening-score

Conclusion: We have created a novel scoring system to screen the probability of PSC using non-invasive tests. The HelPSCreening-score may help target further investigations in patients with suspicion of PSC.

THU470

More than just an itch: impact of cholestatic pruritus in primary biliary cholangitis (PBC) on health-related quality of life (HRQoL)

Helen Smith[1], James Fettiplace[1], Robyn von Maltzahn[1], Sugato Das[2], Megan McLaughlin[3], David Jones[4]. [1]*GlaxoSmithKline, United Kingdom;* [2]*GlaxoSmithKline, India;* [3]*GlaxoSmithKline, United States;* [4]*Newcastle University, United Kingdom*
Email: helen.t.smith@gsk.com

Background and aims: Pruritus associated with PBC affects sleep and social and emotional wellbeing. Limited data exist on the impact of pruritus on health utility (a single value between 0 [death] and 1 [perfect health]), commonly used in health technology assessments to calculate quality-adjusted life years and compare different conditions. A recent UK study explored EQ-5D utilities in a broad PBC population (Rice et al. *Clin Gastroenterol Hepatol* 2021;19:769–76). Here, using data from the Phase 2b GLIMMER study (post hoc) investigating linerixibat for the treatment of pruritus in PBC (NCT02966834), the impact of itch severity on health utility in PBC is explored and quantified for the first time.
Method: Patients in GLIMMER recorded itch twice daily on a 0–10 numeric rating scale (NRS) and completed the EQ-5D-5L at study entry, baseline (BL) and end of treatment. BL followed a.
4-week single-blind placebo run-in. Patients were classed as having mild (<4), moderate (≥4 to <7) or severe pruritus (≥7 to 10) based on mean Worst Daily Itch NRS score in the 7 days prior to BL.
Results: The GLIMMER population (N = 147) was 94% female with a mean (SD) age at BL of 55.8 (11.04) years. Most patients had moderate pruritus (n = 76), with similar numbers with mild (n = 35) and severe (n = 36) pruritus. At BL, alkaline phosphatase levels were higher with greater itch severity: mean (SD).
177 (115.4) and 249 (190.8) IU/L in patients with mild and severe itch, respectively. Overall, mean (SD) BL utility was 0.69 (0.23), lower than the general PBC population (Figure) and with a clear and notable impact of pruritus severity on health utility. Thus, patients with mild or moderate pruritus at BL had similar utilities (0.75 [0.17] and 0.76 [0.17], respectively), marginally lower than the general UK population

(mean at age 55–64 years: 0.804). Patients with severe pruritus at BL had notably worse utility (0.49 [0.28]), similar to patients with severe Parkinson's disease (0.47 [0.22]; Figure). Over the course of the study health utility declined in the placebo group (−0.01) and increased across all linerixibat arms (0.04–0.05). Although improvements were small (confidence intervals crossed zero), the directional change supports a treatment effect of linerixibat.

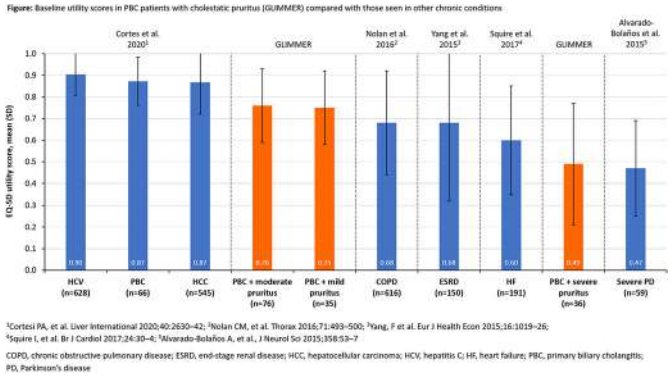

Figure: Baseline utility scores in PBC patients with cholestatic pruritus (GLIMMER) compared with those seen in other chronic conditions

[1]Cortesi PA, et al. Liver International 2020;40:2630–42; [2]Nolan CM, et al. Thorax 2016;71:493–500; [3]Yang, F et al. Eur J Health Econ 2015;16:1019–26; [4]Squire I, et al. Br J Cardiol 2017;24:30–6; [5]Alvarado-Bolaños A, et al., J Neurol Sci 2015;358:53–7

COPD, chronic obstructive pulmonary disease; ESRD, end-stage renal disease; HCC, hepatocellular carcinoma; HCV, hepatitis C; HF, heart failure; PBC, primary biliary cholangitis; PD, Parkinson's disease

Conclusion: Pruritus (particularly severe pruritus) has a significant negative impact on HRQoL and health utility. Presence and severity of itch should be evaluated in PBC and prioritised in treatment plans.

Isolated IgG elevation is not associated with worse outcome in patients with autoimmune hepatitis

Alvaro Diaz Gonzalez[1], Lorena Carballo-Folgoso[2], Carmen Álvarez-Navascués[2], Judith Gómez-Camarero[3], Diana Horta[4], Beatriz Mateos Muñoz[5], María Del Barrio[1], Marina Cobreros[1], Sergio Rodriguez-Tajes[6], Olivas Ignasi[6], Indhira Perez Medrano[7], Inmaculada Castello[8], Alberto Gómez[9], Manuel Rodríguez-Perálvarez[9,10], Javier Crespo[1], Magdalena Salcedo[11], Ana Barreira[12], Mar Riveiro Barciela[12], Maria Carlota Londoño[6]. *[1]Marqués de Valdecilla University Hospital, Digestivo, Santander, Spain; [2]Central University Hospital of Asturias, Oviedo, Spain; [3]Burgos University Hospital, Burgos, Spain; [4]Hospital Universitari MútuaTerrassa, Terrassa, Spain; [5]Hospital Ramón y Cajal, Madrid, Spain; [6]Hospital Clínic de Barcelona, Barcelona, Spain; [7]Complejo Hospitalario Universitario de Pontevedra, Digestivo, Pontevedra, Spain; [8]Consorci Hospital General Universitari de València, València, Spain; [9]Hospital Universitario Reina Sofia, Córdoba, Spain; [10]University of Córdoba, IMIBIC, CIBERehd, Department of Hepatology and Liver Transplantation, Córdoba, Spain; [11]Gregorio Marañón Hospital, Madrid, Spain; [12]Hospital Universitari Vall d'Hebron, Barcelona, Spain*
Email: mlondono@clinic.cat

Background and aims: The goal of treatment in patients with autoimmune hepatitis (AIH) is biochemical remission, (normalization of transaminases and IgG). However, the clinical impact and the management of isolated IgG elevation is unknown. We aimed to describe the outcome of AIH patients with persistently normal transaminases attending to evolutionary changes in IgG levels.
Method: Multicenter retrospective study of patients with AIH diagnosed at 10 referral centres in Spain. Only patients with persistently normal transaminases after induction treatment were included in the study. Patients were divided according to IgG levels during the follow-up as: a) persistently normal (IgGn); b) persistently elevated (IgGe); c) IgG flares (IgGf).
Results: Out of 1253 patients with AIH, 266 (21%) presented persistently normal transaminases during the follow-up. Baseline characteristics are shown in table 1. IgG was persistently elevated in 78 (29%) patients and flared in 28 (11%). The median time to transaminases normalization was 15 months (IQR 7–27). Patients with IgGn were more frequently diagnosed with non-severe acute AIH (NS-AIH; p = 0.001) and those with IgGe had lower prevalence of positive anti-smooth muscle antibody (SMA, p = 0.001). Immunosuppression was intensified in 13 (12%) patients with abnormal IgG, leading to normalization in 7 patients. 95 patients had at least two liver stiffness measurements (LSM) available. After a median follow-up of 4.5 years (IQR 3–8), LSM worsen in 12 (13%) patients, improved in 23 (24%), and remained stable in 60 (63%). IgG levels did not impact the evolution of LSM. 17 patients (6%) developed cirrhosis, without differences between groups. The risk of cirrhosis was higher in patients who normalized transaminases beyond month 15 after induction treatment (OR 3.42; CI95% 1.1–10.8) and in those with LSM higher than 10.5 kPa at the time of transaminases normalization (OR 6.13; CI95% 1.18–31.8).

Age	Total (n = 266). 64 (52–73)	IgGe (n = 78). 63 (52–72)	IgGn (n = 160). 63 (52–73)	IgGf (n = 28). 67.1 (59–75)
AIH at diagnosis				
Acute liver failure	3 (1)	2 (23)	0	1 (4)

ALT (UI/L)	584 (230–1204)	580 (390–1141)	622 (229–1264)	426 (161–1094)
Bilirubin (mg/dL)	2.2 (0.8–8)	2.1 (0.6–8)	2.4 (0.8–8)	1.3 (0.7–8.1)
INR	1.1 (1–1.3)	1.2 (1.03–1.44)	1.1 (1–1.24)	1.18 (1–1.24)
ANA (n, %)	209 (80)	56 (75)	126 (80)	27 (100)
ASMA (n, %)	121 (46)	24 (32)	77 (49)	20 (71)
Anti-SLA (n, %)	5 (2)	1 (1)	2 (1)	1 (3)
IgG (mg/dL)	1954 (1405–2560)	2033 (1462–2520)	1740 (1300–2290)	2800 (2200–3330)
Cirrhosis follow-up (n, %)	17 (6)	4 (5)	10 (6)	3 (11)

Continuous variables are presented as median and IQR.

Conclusion: Isolated IgG elevation in patients with persistently normal transaminase levels, did not impact the outcome of patients with AIH.

THU472

Linerixibat dose-response analysis of C4 concentrations as a quantitative approach to predict gastrointestinal tolerability

Fernando Carreño[1], Rashmi Mehta[2], Andrea Ribeiro[3], Jon Collins[2], Brandon Swift[2]. *[1]GlaxoSmithKline, Upper Providence, PA, United States; [2]GlaxoSmithKline, Research Triangle Park, NC, United States; [3]GlaxoSmithKline, Madrid, Spain*
Email: fernando.o.carreno@gsk.com

Background and aims: Linerixibat is an ileal bile acid transporter (IBAT) inhibitor in Phase 3 development for the treatment of cholestatic pruritus in primary biliary cholangitis (PBC). IBAT inhibition reduces bile acid (BA) reabsorption from the intestine, reducing circulating systemic BA concentrations and pruritus but leading to excess BA in the colon with potential to cause diarrhoea. Linerixibat increases concentrations of 7-alpha-hydroxy-4-cholesten-3-one (C4), a prognostic biomarker for BA-induced diarrhoea. Here we evaluate the relationships between (1) linerixibat and serum C4 concentrations; and (2) effect of C4 on probability of diarrhoea using the gastrointestinal symptoms rating scale (GSRS).
Method: Serum C4 data were included from healthy subjects in three Phase 1 studies (114985, 116511, 205808) and from patients with PBC in two Phase 2 studies (177213, 201000 [GLIMMER]).
C4 concentrations over time were described by a k-PD indirect-response model with a stimulatory effect of linerixibat on C4 production. Weekly GSRS data were collected in GLIMMER, which evaluated the impact of five linerixibat treatment regimens in patients with PBC.
Results: The k-PD model showed a saturable dose-response relationship with C4 concentrations. The two BID linerixibat

regimens led to a 24% increase in C4 compared with the change from baseline for a similar daily QD dose (i.e. 90 mg BID vs 180 mg QD). Increased C4 concentrations trended with increased diarrhoea scores in the GSRS tool. C4 concentrations ≥52 ng/ml were associated with a 62% increased probability of moderate-to-severe diarrhoea scores compared with C4 concentrations <14 ng/ml, as observed in participants in the placebo arm. Simulations showed increases of 9%, 17%, 20%, 19% and 23% in moderate-to-severe diarrhoea scores for the 20 mg, 90 mg and 180 mg QD, and 40 mg and 90 mg BID doses, respectively, after the first week of linerixibat dosing. This was consistent with the rate of on-treatment diarrhoea adverse events by treatment arm in GLIMMER (placebo: 11%; 20 mg QD: 38%; 90 mg QD: 65%; 180 mg QD: 67%; 40 mg BID: 52%; 90 mg BID: 68%).
Conclusion: Linerixibat led to dose-dependent increases in serum C4 concentrations that predicted an increased probability of moderate-to-severe diarrhoea. The increase in diarrhoea scores highlights the trade-off between maximising the pharmacodynamic effect of linerixibat on pruritus and increase in GSRS scores, which guided dose selection for Phase 3.

THU473

Urinary sulfated progesterone metabolites are diagnostic markers for cholestatic pregnancy and markers of treatment response to ursodeoxycholic acid

Luiza Borges Manna[1], Caroline Ovadia[1], Jenna Sajous[1], Anita Lövgren-Sandblom[2], Hanns-Ulrich Marschall[3], Catherine Williamson[1]. *[1]King's College London, Women and Children's Health, London, United Kingdom; [2]Karolinska University Hospital Huddinge, Stockholm, Sweden; [3]University of Gothenburg, Department of Molecular and Clinical Medicine, Gothenburg, Sweden*
Email: blmanna@hotmail.com

Background and aims: Serum concentrations of sulfated metabolites of progesterone are elevated in intrahepatic cholestasis of pregnancy (ICP), and have been proposed as predictive and diagnostic biomarkers. Ursodeoxycholic acid (UDCA) treatment can alter urinary excretion of progesterone sulfates. We aimed to determine whether urinary progesterone sulfate excretion is predictive or diagnostic of ICP, and whether their levels are associated with UDCA treatment response.
Method: Urine was obtained from women with cholestatic and uncomplicated pregnancies throughout pregnancy and postpartum, including matched samples before and 1–2 weeks after commencing UDCA treatment. Urinary progesterone sulfates were measured by ultra performance liquid chromatography-mass spectrometry, and normalised according to creatinine levels (measured by colorimetric assay). Results were compared in Graphpad Prism by multiple t tests with Benjamini-Hochberg correction for multiple testing, Fisher's exact test and logistic regression.
Results: Urinary 5α-pregnan-3α, –20α-diol-3, 20-disulfate (PM2DiS), 5β-pregnan-3α, 20α-diol-3, 20-disulfate (PM3DiS), 5β-pregnan-3α, -20α-diol-3-sulfate (PM3S), 5α-pregnan-3α-S, 20-one (PM4S) and 5α-pregnan-3β, 20β-diol-3-sulfate (PM8S) were higher in women with cholestatic than uncomplicated pregnancies; PM8S differentiated well between the two groups (AUC 0.86, figure 1). UDCA treatment was associated with significantly reduced PM2DiS and PM3DiS (from 19.10 to 12.22, p = 0.032). Symptomatic response (pruritus improvement) with UDCA was predicted by the total disulfated progesterone metabolites (area under curve (AUC) = 0.80), whilst biochemical response (fall in total serum bile acid concentration) was predicted by urinary 5α-pregnan-3β-ol-20-one-sulfate (PM5S) and 5β-pregnan-3β-ol-20-one-sulfate (PM7S) (AUC = 0.81).

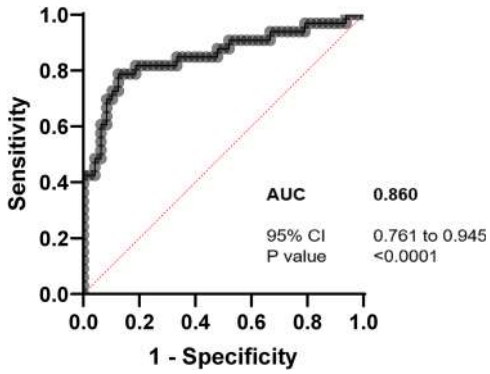

Figure: Receiver operating characteristic curve demonstrating the ability of urinary PM8S to diagnose ICP at disease onset

Conclusion: Urinary progesterone sulfate excretion appears useful diagnostically for ICP, which obviates the need for blood sampling. Similarly, using the individual profile of urinary PMS may be helpful to identify the subgroup of women for whom UDCA treatment is beneficial, and may contribute to the variable clinical response to UDCA treatment that complicates trials of its use in ICP.

COVID-19 vaccine induced autoimmune hepatitis-a first case series from India

Sowmya Iyengar[1], Anand Kulkarni[1], Goutham Reddy Katukuri[2], Mithun Sharma[1], Nageshwar Reddy[2], Nagaraja Rao Padaki[1]. *[1]AIG Hospital, Hepatology, Hyderabad, India; [2]AIG Hospital, Gastroenterology, Hyderabad, India*
Email: sowmyaiyengar.18@gmail.com

Background and aims: Liver injury is common in patients with coronavirus disease-2019 (COVID-19) infection. Recently, few studies have reported the development of autoimmune hepatitis (AIH) following COVID-19 vaccination. However, there is a lack of studies reporting the outcomes of AIH following ChAdOx1 (vector-based) and BBV152 (inactivated virus) from India. Here we aimed to describe the clinical profile of patients who developed AIH following COVID-19 vaccination. The causal association is attributed based on the temporal relationship in patients with no prior liver diseases.
Method: Patients presenting with deranged liver functions following COVID-19 vaccination to hepatology clinic were included. Virus infections were ruled out in all patients either by serology or viral quantification methods. We aimed to assess the demographics, clinical profile, and outcome of patients with vaccine-induced AIH (V-AIH) in the absence of known liver disease.
Results: A total of 31 patients presented with altered liver chemistries following vaccination. Seventeen patients were diagnosed with V-AIH (age-39.8 ± 11.4 years; males-70.4%). None of the patient had history of alcohol overconsumption. Seventy six percent of patients had received ChAdOx1 and 23.53% had received BBV152 vaccine (Table). Seventy six percent of patients following first dose of vaccine and 23.5% following second dose of vaccine were diagnosed as V-AIH. Mean duration for development of symptoms after first dose was 25.7 days. Common symptom at presentation was jaundice in 82.3% of patients. Antinuclear antibody was positive in 71% of patients and 17% patients were negative for all serological markers of autoimmune hepatitis but had elevated IgG levels. Fifty-nine percent of patients required immunosuppression of which 41% percet of patients received oral steroids, 17% patients received intravenous steroids for 3 days followed by oral steroid, 12% patients received azathioprine. One patient succumbed to pneumonia with multiorgan failure by day 30. At 3 months, it was observed that only 17% patients needed prolonged immunosuppression and had deranged liver functions until last follow-up. Mean duration of recovery amongst rest of 76.4% patients was 5.15 ± 3.1 weeks.

Table: Clinical characteristics and outcome of V-AIH

Characteristics	Number of patients (Total-17 patients)
Gender	
Male	12(70.6%)
Female	5(29.4)
AGE(Mean±SD)	39.8±1.4 years
Vaccine type	
COVISHILED	13(76.5%)
COVAXIN	4(23.5%)
Symptom onset	
After first dose	13(76.5%)
After second dose	4(23.5%)
Mean duration for symptom onset	
After first dose	25.7±6.8 days
After second dose	24.2±5.1 days
Mean BMI	24.23±3 kg/m2
Comorbidities	
Hypothyroidism	4(23.5%)
Type 2 diabetes	4(23.5%)
Rheumatoid arthritis	1(5.9%)
CKD	1(5.9%)
Hypertension	1(5.9%)
NAFLD	1(5.9%)

Anti SLA	0
Seronegative(biopsy proven)	3(17.6%)
Liver biopsy	10(58.8%)
Typical features of AIH	10(100%)
Interface hepatitis	
Mild	2(20%)
Moderate	5(50%)
Severe	3(30%)
Fibrosis	Mild in all cases (Metavir score 0-2)
DILI pattern and severity	
Hepatocellular pattern	16(94.1%)
Cholestatic pattern	1(5.9%)
Mild	5(29.4%)
Moderate	8(47.1%)
Severe	4(23.5%)
Treatment	
Conservative	7(41.2%)
Steriods	10(58.8%)
Oral streoids alone	7(41.2%)
IV followed by oral steriods	3(17.6%)
Outcome	
Alive	16(94.1%)
Death	1(5.9%)
Mean duration for recovery	5.1±3.1 weeks

SD-standard deviation, CKD- chronic kidney disease, NAFLD- Non-alcoholic fatty liver disease, ALT- alanine amino transferase, AST- aspartate amino transferase, ALP- alkaline phosphatase, ANA-anti-nuclear antibody, ASMA- anti smooth muscle antibosy, Anti-LKM1- liver-kidney microsomal antibody type 1, AMA-Anti mitochondrial antibody.

Conclusion: COVID-19 vaccine can trigger autoimmune hepatitis. Males are affected more often than females. Treatment with steroids has high success rate and significant proportion of patients have self-limiting disease and may not require long term immunosuppression.

THU475

Lymphoma in IgG4-related disease: should we be concerned?

Arif Hussenbux[1,2], Rory Peters[1,2], Charis Manganis[1], Eve Fryer[3], Helen Bungay[4], Joel David[5], Emma Culver[1]. *[1]John Radcliffe Hospital, Gastroenterology, Oxford, United Kingdom; [2]Authors contributed equally; [3]John Radcliffe Hospital, Histopathology, Oxford, United Kingdom; [4]John Radcliffe Hospital, Radiology, Oxford, United Kingdom; [5]John Radcliffe Hospital, Rheumatology, Oxford, United Kingdom*
Email: arif.hussenbux@hotmail.co.uk

Background and aims: Immunoglobulin G4-Related Disease (IgG4-RD) is a systemic fibroinflammatory disorder, with a predilection for the pancreas and biliary tree. We have reported an association of malignancy in our cohort of IgG4-related pancreato-biliary disease[1]. We sought to assess the frequency and type of malignancy in our prospective cohort of IgG4-RD patients with radiological and histological evaluation through our monthly IgG4-RD multi-disciplinary meeting (MDM).

Method: Patients diagnosed with IgG4-RD and discussed at the MDM between November 2016 and September 2021 were included, with diagnosis based on established HISORt, CDC or Boston histopathological consensus criteria. Retrospective evaluation of presence and timing of malignancy confirmed radiologically and histologically through the MDM. UK national cancer registry data[2] was used to determine the age and gender standardised incidence ratios (SIR) for malignancy and non-hodgkin's lymphoma (NHL) for comparison.

Results: Of 105 IgG4-RD patients (median age 67; IQR 56–76 years, male:female ratio 2.4:1), 21 (20%) developed malignancy (table 1), with an SIR of 12.3 (95%CI 7.6–18.8).

Table 1:

Primary Cancer	Observed Cases
Lymphoma	7
Renal	2
Gastric	1
Biliary	2
Breast	1
Oesophagus	1
Thyroid	1
Pancreas	1
Prostate	2
Colon	2
Ovarian	1

One-third (7/21) had lymphoma. Most (6/7) were NHL B cell lymphomas, SIR 93.6 (95%CI 34.2–203.7). 3 patients with lymphoma had IgG4-related pancreato-biliary disease, 3 had IgG4-related head and neck disease and 1 had IgG4-related renal disease. 3 lymphomas were diagnosed prior, and 4 subsequent, to their IgG4-RD diagnosis. The median time between lymphoma and IgG4-RD diagnosis was 4.4 years; (range −10.5–11.8 years). Of these, 1 had been exposed to an immunomodulator, azathioprine, prior to lymphoma. Lymphoma was successfully treated with R-CHOP chemotherapy in all cases.

Conclusion: We demonstrate an increased incidence of malignancy in our IgG4-RD cohort with a striking incidence of NHL, which otherwise accounts for <4% of annual UK new cancer diagnoses. There are currently no cancer surveillance guidelines in IgG4-RD, and the frequency of lymphoma makes us question the use of off-label azathioprine as relapse prevention in this older male cohort.

THU476

Measurement properties of the PBC-10 in a dutch population

Maria van Hooff[1], Rozanne de Veer[1], Maren Harms[1], Geraldine Da Silva[1], José Willemse[2], Herold Metselaar[1], Elaine Utomo[3], Adriaan Van der Meer[1]. *[1]Erasmus University Medical Center, Department of Gastroenterology and Hepatology, Rotterdam, Netherlands; [2]Dutch Liver Patients Association, Hoogland, Netherlands; [3]Independent Researcher, Berkel en Rodenrijs, Netherlands*
Email: m.vanhooff@erasmusmc.nl

Background and aims: Practice guidelines advice to evaluate the Health Related Quality of life (HRQoL) of all patients with primary biliary cholangitis (PBC). The PBC-40 has proven to be an adequate PBC-specific HRQoL measure. However, as this measure can be time consuming and thus less practical, the UK-PBC group developed the PBC-10 as a shorter version for screening HRQoL in clinical practice. The aim of this study was to assess the measurement properties of the items selected for the PBC-10 in a Dutch PBC population.

Method: Our study group previously translated the PBC-40 into Dutch and validated it in a Dutch population. Existing data of the Dutch PBC-40 questionnaire was used to assess patients responses on the PBC-10 items. Internal consistency of the PBC-10 was assessed by Cronbach's alpha. A value between 0.70 and 0.95 is considered as adequate. Content validity was assessed by determination of floor and ceiling effects (i.e. >15%). Each PBC-10 item was correlated with the total score of the corresponding original PBC-40 domain.

Results: In total, 177 patients with PBC were included. The mean (SD) age was 61.1 (9.9) years and the majority of patients was female (n = 164; 92.7%). Of the total 1770 items, 81 items (4.6%) were missing. The PBC-10 showed a Cronbach's alpha of 0.895. Floor and ceiling effects were observed in 7 and 3 items, respectively. Floor effects ranged from 13.6% to 61.0%. All PBC-10 items were significantly correlated with the corresponding domains of the PBC-40 (Pearson correlations ranged from 0.711 to 0.912, $p < 0.001$ for all) (Table).

					Pearson correlation with PBC-40 domains p < 0.001 for all				
PBC-10 items		n	Floor (%)	Ceiling (%)	Symptoms (7 items)	Itch (3 items)	Fatigue (11 items)	Cognition (6 items)	Social (10 items)
1	Embarrassed because of itching	105	61.0	1.9		0.854			
2	Bloated after small amounts of intake	177	36.8	2.3	0.711				
3	Very dry mouth	176	21.6	11.9	0.730				
4	Fatigue interfered with daily routine	177	13.6	12.4			0.894		
5	Need to force myself to be active	177	14.7	6.2			0.885		
6	Need extra day to recover	176	15.9	23.9			0.850		
7	Difficult to concentrate	175	28.0	1.7				0.912	
8	Guilt regarding impact PBC on activity	175	54.3	8.0					0.772
9	Social life almost stopped	175	44.0	3.4					0.833
10	PBC reduces quality of life	176	17.0	18.2					0.893

Conclusion: In a Dutch population, the PBC-10 showed an adequate internal consistency and reflects the content of corresponding PBC-40 domains. There were, however, substantial floor effects. The PBC-10 may be considered in clinical practice as a screening tool for patients with a profound impact of PBC on their HRQoL. However, the Dutch PBC-10 may be less suitable to identify PBC patients with less severe HRQoL impairment or to detect further improvement of their HRQoL following intervention.

THU477

Gluco-regulatory disturbances in primary biliary cholangitis and non-alcoholic fatty liver disease compared with healthy individuals

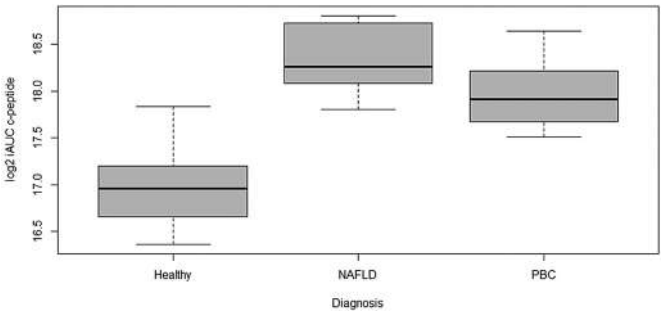
Anne-Sofie Houlberg Jensen[1,2], Henriette Ytting[1,3], Josephine Grandt[1,2], Andreas Møller[1], Mikkel Werge[1], Elias Rashu[1], Liv Hetland[1], Mira Thing[1], Anders Junker[1], Lise Hobolth[1], Christian Mortensen[1], Flemming Bendtsen[1,4], Flemming Tofteng[1], Mogens Vyberg[5,6], Reza Serizawa[5], Lise Lotte Gluud[1], Nicolai J Wewer Albrechtsen[2,7,8]. *[1]Hvidovre Hospital, Gastro Unit, Hvidovre, Denmark; [2]Novo Nordisk Foundation Center for Protein Research, København, Denmark; [3]Rigshospitalet, European Reference Network on Hepatological Diseases (ERN-RARE-LIVER), København, Denmark; [4]The University of Copenhagen, Faculty of Health and Medical Sciences, København, Denmark; [5]Hvidovre Hospital, Department of Pathology, Hvidovre, Denmark; [6]Center for RNA Medicine, Aalborg, Denmark; [7]Rigshospitalet, Department of Clinical Biochemistry, København, Denmark; [8]The University of Copenhagen, Faculty of Health and Medical Sciences, Department of Biomedical Sciences, København, Denmark*

Email: nicolai.albrechtsen@sund.ku.dk

Background and aims: Gluco-regulatory disturbances such as hepatic insulin resistance, hyperinsulinemia and pre-diabetes are observed in individuals with non-alcoholic fatty liver disease (NAFLD). Whether autoimmune liver diseases-herein primary biliary cholangitis (PBC)-also carry gluco-regulatory disturbances is unknown. We therefore investigated glucose and hormonal responses to an oral glucose tolerance test (OGTT) in patients with biopsy-verified non-cirrhotic PBC and NAFLD and healthy controls. The data presented are early results from FALL, a prospective cohort study.

Method: 23 participants have been included hereof 8 healthy controls (mean age 23, mean BMI 23 kg/m^2), 9 patients with PBC (mean age 55, mean BMI 31 kg/m^2) and 6 patients with NAFLD (mean age 38, mean BMI 31 kg/m^2). None of the included patients had diabetes. In the PBC group, 3 had NAFLD. Blood samples were obtained at baseline (fasting) and 15, 30, 45, 60, 90 and 120 minutes during the OGTT. Glucose, c-peptide and insulin concentrations were measured. A validated marker for hepatic insulin resistance (the homeostasis model assessment of insulin resistance (HOMA-IR)) and the incremental area under curve (iAUC) for glucose, c-peptide and insulin responses were calculated. Results are presented as means (95% CI).

Results: Fasting glucose, c-peptide and insulin levels were significantly increased in both PBC (glucose 5.6 mM (4.7–6.7), c-peptide 993 pM (556–1773), insulin 98 pM (33–298)) and NAFLD (glucose 5.7 mM (5.2–6.1), c-peptide 1334 pM (1036–1719), insulin 166 pM (103–267)) compared with healthy (glucose 4.7 mM (3.9–5.6), c-peptide 483 pM (268–869), insulin 43 pM (14–136)). Hepatic insulin resistance (reflected by fasting HOMA-IR) was present in PBC (4.0 (1.2–13.9)) and NAFLD (7.0 (4.1–11.9)) but not in healthy individuals (1.5 (0.4–5.4)). No significant difference in glucose levels was observed between the groups ($p = 0.106$). Beta-cell secretion (c-peptide) was significantly increased in PBC ($p < 0.001$) and NAFLD ($p < 0.001$) suggesting that peripheral insulin resistance was present in patients with PBC and NAFLD. Insulin responses (reflecting both beta-cell secretion and hepatic insulin extraction) were numerically higher in both PBC and NAFLD compared with healthy but only reached statistical significance in NAFLD ($p = 0.002$).



Conclusion: Our data suggest that patients with PBC may have gluco-regulatory disturbances including both hepatic insulin resistance and altered pancreatic endocrine function. Whether these impairments reflect an obesity prone phenotype in PBC and NAFLD patients cannot be concluded from the current data. Metabolic dysfunction of PBC may be underestimated and warrant further investigation.

THU478

Proportion of time and degree to which liver biochemistries are out-of-range predicts time to first occurrence of negative hepatic outcomes in people with primary biliary cholangitis

Timothy Ritter[1], Christina Hanson[2], Christopher C. Fernandes[3], Joanna MacEwan[4], Xin Zhao[4], Craig Parzynski[4], Erik Ness[5], Gail Cawkwell[5], Darren Wheeler[5], Tracy Mayne[5]. *[1]GI Alliance, United States; [2]South Denver Gastroenterology, United States; [3]TCU and UNTHSC School of Medicine, United States; [4]Genesis Research, United States; [5]Intercept Pharmaceuticals Inc, United States*
Email: tim.ritter@gialliance.com

Background and aims: Previous research has demonstrated a significant association between abnormal liver biochemistries at one time point and the risk of death and liver transplant in patients with primary biliary cholangitis (PBC). We hypothesized that both the proportion of time and degree to which liver biochemistries are out-of-range, including normal values associated with adverse liver health, predict time to first occurrence of negative hepatic outcomes.
Method: Patients in the Optum Clinformatics database between July 1, 2016 and December 31, 2020 were included if they were diagnosed with PBC by either ≥1 inpatient discharge claim with a PBC diagnosis or ≥2 outpatient claims with a primary PBC diagnosis on separate days and had >1 of each liver biochemistry available (ALP, TB, AST, ALT, and ALB). Patients with autoimmune hepatitis, HIV, gastric bypass, liver disease, hepatic decompensation, or use of second line (2L) treatment (obeticholic acid or fibrates) prior to PBC diagnosis were excluded. Survival analysis with the proportion of time spent out-of-range as a time-dependent variable and a composite end point of hepatic decompensation, liver transplant, or death was conducted. Biochemistry values were carried forward until the next recorded value. Patients were censored at end of follow-up or initiation of 2L treatment.
Results: 2, 379 patients (85.3% female) were included. At baseline, mean age was 63 years; 11% had cirrhosis; 7% had NASH. During the follow-up period (mean 2.5 yrs), 73.8% received ursodeoxycholic acid and 3.6% (N = 86) were censored at start of 2L treatment. Mean number of measures per biochemistry ranged from 7.2–8.4. On average patients spent 52.5%, 8.5%, 37.5%, and 20.7% of the follow-up period over ULN for ALP, TB, AST, and/or ALT, respectively, and 19.1% under LLN for ALB. For each individual biochemistry the risk of negative hepatic events increased significantly with greater proportion of time out-of-range and greater divergence from desired values (Figure). For example, for a patient with all 5 years follow-up (i.e., 100% time) with ALB ≤0.9xLLN, the risk of an event was 271% higher than that of a patient with ALB >0.9xLLN all 5 years (i.e., 0% time); 104% higher for ALp >1.5x ULN; 124% for ALT >2xULN; 145% higher for AST >1.5xULN; and 157% higher for TB >1x ULN.

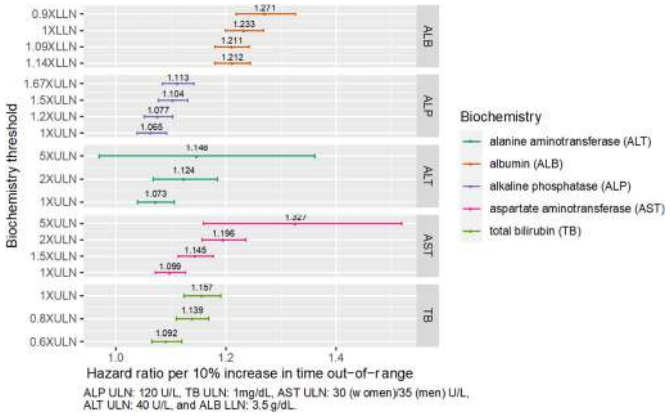


Figure: Hazard ratio of decompensation, transplant, or death for each additional 10% of time out-of-range by biochemistry threshold

Conclusion: Greater proportion of time spent out-of-range and greater divergence from normality on each liver biochemistry was associated with significantly increased risk of hepatic decompensation, liver transplant, or death in patients with PBC. These results suggest that avoiding substantial time with out-of-range liver biochemistries, potentially through greater utilization of effective first line and 2L therapies, may improve hepatic outcomes for patients with PBC.

THU479

Outcomes following immune checkpoint inhibitor re-challenge in patients who developed grade 3 and 4 hepatotoxicity

Amy Hicks[1], Ramu Chimakurthi[1]. *[1]Leeds Teaching Hospitals NHS Trust, Hepatology, Leeds, United Kingdom*
Email: amy.hicks@nhs.net

Background and aims: Immune checkpoint inhibitors (ICI) are used to treat a variety of cancers. Immune-related adverse events (irAEs) are not uncommon, with Grade 3 hepatitis in 1–2% of those treated with single agents and ~15% in those treated with Ipilimumab and Nivolumab combination (ESMO guidelines 2017). European and American society guidelines recommend discontinuation of ICI after development of Grade 3 or 4 hepatitis. Re-challenge with single ICI can be considered in those who developed Grade 3 hepatitis on combination therapy. We reviewed our outcomes following re-challenge in those who developed Grade 3 and 4 hepatitis in our regional oncology centre.
Method: Patients who received ICI from January 2018 to January 2022 were reviewed. Those who developed Grade 3 and 4 hepatotoxicity were identified by accessing their electronic health record. We assessed the following outcomes in these patients: a) those who had re-challenge with ICI b) choice of ICI in re-challenged c) whether they developed further hepatitis d) outcomes in those who were not re-challenged.
Results: 1045 patients received ICIs over a 4-year period (807 single agent and 238 Ipilimumab-Nivolumab combination). 54 patients developed Grade 3 or 4 hepatitis. Of these, 22 (40.7%) were re-challenged and their outcomes are shown in Table 1. All patients were off immunosuppression at the time of re-challenge. Contrary to existing guideline recommendations, 3 patients with Grade 4 hepatitis and 7 patients with Grade 3 hepatitis on single agent were re-challenged with ICIs. 4 out of 11 (36%) developed further hepatitis (Grade ≥ 3) on re-challenge. Of note, all patients with recurrent hepatotoxicity developed this after only 1 cycle of re-treatment. ICI were discontinued permanently in the remaining 32 patients. 15 had complete response to treatment, 8 had disease progression and were switched to an alternative treatment, 6 patients deteriorated and died (1 from irAE and 5 from disease progression), 1 is due for re-challenge soon, and 2 patients changed to an alternative regimen due to the hepatitis.

Table 1: ICI re-challenge outcomes.

Initial hepatitis grade (n = no. patients)	Initial ICI	Re-challenge ICI	Recurrence of hepatitis and cycle number (Cx)
Gr 3 = 19	Ipi and Nivo = 12	Nivo = 12	- 2 pts (17%): - Gr 2 (C2) - Gr 4 (C1)
	Nivo = 3	Nivo = 3	- 1 pt (33%): - Gr 4 (C1)
	Pembro = 4	Pembro = 3 Ipi = 1	None - 1 pt (100%): - Gr 3 (C1)
Gr 4 = 3	Pembro = 2	Pembro = 2	- 2 pts (100%): - Gr 3 (C1) - Gr 3 (C1)
	Ipi and Nivo = 1	Nivo = 1	None (Stopped due to colitis after C2)

Conclusion: Re-challenge with ICI following Grade 4 hepatitis resulted in early irAE recurrence in our group. However, the vast majority (>70%) re-challenged with ICIs after Grade 3 hepatitis on

single agent did not develop hepatitis recurrence. Nearly 50% of patients are in remission and alive to this day despite cessation of ICI following Grade 3 and 4 hepatitis. Our numbers are small but will add to a growing body of evidence in this field.

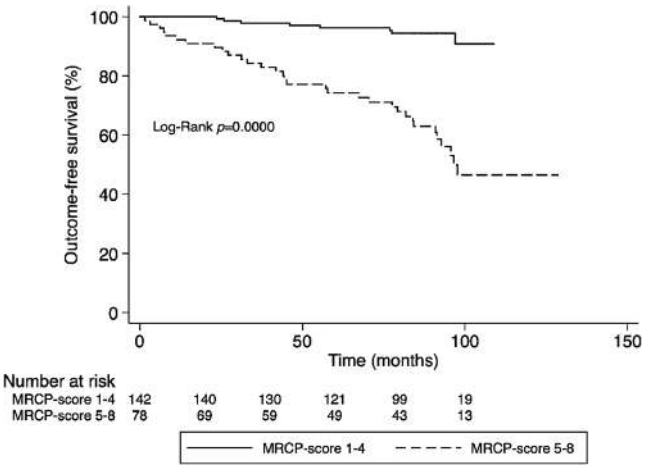
THU480

Development of a novel MRCP-score for patients with primary sclerosing cholangitis, and assessment of agreement and prognostic value

Aristeidis Grigoriadis[1,2], Kristina Ringe[3], Johan Bengtsson[4,5], Erik Fridh Baubeta[6], Cecilia Forsman[7], Nafsika Korsavidou-Hult[8], Fredrik Rorsman[9], Emma Nilsson[10], Nikolaos Kartalis[2,11], Annika Bergquist[1,12]. *[1]Karolinska Institutet, Medicine, Stockholm, Sweden; [2]Karolinska University Hospital, Radiology, Stockholm, Sweden; [3]Hannover Medical School, Diagnostic and Interventional Radiology, Hannover, Germany; [4]Lund University, Department of Clinical Sciences/ Division of Radiology, Lund, Sweden; [5]Skåne University Hospital, Center for Medical Imaging and Physiology, Lund, Sweden; [6]Skåne University Hospital, Diagnostic Radiology, Department of Translational Medicine, Lund, Sweden; [7]Uppsala University Hospital, Medical Imaging Centre, Sweden; [8]Uppsala University, Radiology and Nuclear Medicine, Sweden; [9]Uppsala University Hospital, Gastroenterology and Hepatology, Sweden; [10]Skåne University Hospital, Department of Clinical Sciences, Lund, Sweden; [11]Karolinska Institutet, Department of Clinical Science, Intervention and Technology (CLINTEC), Stockholm, Sweden; [12]Karolinska University Hospital, Hepatology, Stockholm, Sweden*
Email: aristeidis.grigoriadis@ki.se

Background and aims: MRCP is used for diagnosis and follow-up of patients with primary sclerosing cholangitis (PSC). Interest in the prognostic value of MRCP is increasing. Aim of our study is to develop an MRCP-score based on cholangiographic findings previously associated to outcomes and assess its reproducibility and prognostic value in PSC.

Method: The MRCP-score was developed based on the extent and severity of cholangiographic changes of intrahepatic and extrahepatic bile ducts (range 0–8) in coronal 3D-MRCP. In this ethics review-board approved retrospective, multicenter study, three pairs of radiologists (2 pairs of experienced, one pair of experienced and less experienced) from three tertiary centers, applied the score independently on MRCP-examinations of 220 consecutive PSC patients (103, 52, and 65, respectively) from a prospectively collected PSC-cohort, with median follow-up of 7.4 years. Interreader and intrareader agreements were assessed with intraclass correlation coefficient (ICC). After consensus reading, the prognostic value of the score was assessed with Cox-regression and outcome-free survival rates with Kaplan-Meier estimates. Area under the curve (AUC) was calculated and 10-fold cross-validation was performed.



Results: 40 patients developed outcomes (liver transplantation or liver-related death). Interreader agreement between experienced radiologists was good (ICC = 0.82; 95%CI:0.74-0-87, and ICC = 0.81; 95%CI:0.70–0.87, respectively) and better than agreement for the pair of experienced/less experienced radiologist (ICC = 0.48; 95%CI:0.05–0.72). Agreement between radiologists from the three centers was good (ICC = 0.76; 95%CI:0.57–0.89). Intrareader agreement was good to excellent (ICC = 0.85–0.93). AUC for the MRCP-score was 0.83. Patients with MRCP-score 5–8 had 8.4 times higher risk (HR = 8.4; 95%CI:3.9–18.3) for developing outcomes, and significantly worse survival ($p < 0.000$), compared to those with MRCP-score 0–4.

Conclusion: This novel MRCP-score is reproducible and strongly associated to outcomes which indicates its value for the prognosis of PSC-patients in clinical practice.

THU481

Right and left lobe biopsies by mini-laparoscopy reveals clinically significant sampling error in staging and grading in AIH

Johannes Hartl[1], Marcial Sebode[1], Malte Wehmeyer[1], Sören Weidmann[1], Christoph Schramm[1], Ansgar Lohse[1], Till Krech[1], Jörg Schrader[1]. *[1]University Hospital Hamburg-Eppendorf (UKE), First Department of Medicine, Hamburg, Germany*
Email: j.hartl@uke.de

Background and aims: Liver diseases may affect the liver heterogeneously. Thus, not only diagnosis but also grading and staging of inflammatory activity and fibrosis may largely depend on the area of liver biopsy. Hence, the aim of this study was to assess the added benefit of double biopsy of both liver lobes during minilaparoscopy in patients with autoimmune liver disease.

Method: We identified all patients with autoimmune hepatitis (AIH), primary biliary cholangitis (PBC), primary sclerosing cholangitis (PSC) or variant syndromes (AIH/PBC and AIH/PSC), who underwent a double biopsy of both liver lobes via minilaparoscopy between 01/2016–12/2020 in our prospectively maintained database. Differences in fibrosis stage and disease activity between liver lobes were assessed by an experienced hepato-pathologist.

Results: A total of 111 patients with AIH received a biopsy of both liver lobes (AIH: N = 83, AIH/PBC: N = 24, AIH/PSC: N = 4). Differences in inflammatory activity as assessed by Ishaks`s modified activity index (mHAI) were observed in 69 (62%) patients. In 41 (38%) patients the difference was ≥2 points, in 12 patients (11%) ≥3 points. According to current EASL guidelines, starting/intensification of immunosuppression should be discussed in patients with a mHAI of 4–5, as it was reported to be associated with excess mortality, a mHAI ≥ 6 prompts intensified immunosuppression in most cases. Thus, a mHAI 4–6 represents a most relevant range for guiding treatment decisions. 48% of the AIH patients had a mHAI within this range. Importantly, in 21 patients (20%) a mHAI ≥ 4 was only observed in one liver lobe. Also, 17 (15%) patients demonstrated a mHAI ≥ 6 in only in one liver lobe. Based on these observations, the number needed to double-biopsy to identify clinically relevant differences in inflammatory activity was only 5 patients. Differences of fibrosis stage were identified in 31/111 (28%) AIH patients. In 3/18 (17%) cirrhotic patients, histological changes consistent with cirrhosis were only observed in one liver lobe.

A biopsy of both liver lobes was performed in 16 PSC and 13 PBC patients. Differences of fibrosis stage were observed in 1/16 and 3/13 patients, and differences in mHAI in 8/16 and 5/13 patients, respectively. However, no treatment relevant difference was identified.

No major adverse event occurred.

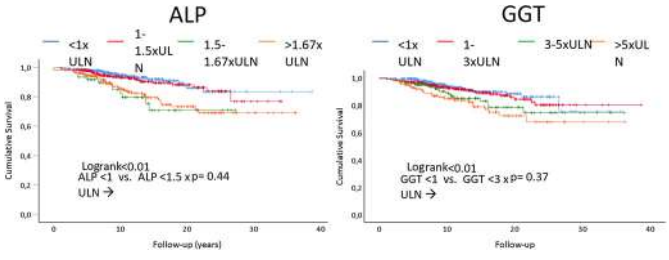
Conclusion: Obtaining a biopsy of the right and left liver lobe is a safe procedure during minilaparoscopy that results in more accurate staging and grading with direct therapeutic consequences in patients with AIH.

THU482

Should we seek complete liver tests normalization in primary biliary cholangitis? Data from ColHai registry

Álvaro Díaz-González[1], Sergio Rodriguez-Tajes[2], Mercedes Vergara Gómez[3], Emilio Fabrega[1], Manuel Romero Gomez[4], Agustin Albillos[5], Judith Gómez- Camarero[6], Diana Horta[7], Adolgo Gallego[8], Montserrat Garcia-Retortillo[9], Raul J. Andrade[10], Moises Diago[11], Rosa M Morillas[12], Manuel Hernández Guerra[13], Carlos Ferre Aracil[14], Margarita Sala[15], Elena Gómez Domínguez[16], Marina Berenguer[17], Maria Carlota Londoño[18], Grupo del Registro Col-Hai Enfermedades Autoinmunes y colestásicas[19]. *[1]Hospital Marqués de Valdecilla; [2]Hospital Clínic Barcelona; [3]Hospital Universitario Parc Taulí; [4]Hospital Universitario Virgen Del Rocío; [5]Hospital Universitario Ramón y Cajal; [6]Hospital Universitario de Burgos; [7]Hospital Mutua de Terrassa; [8]Hospital de la Santa Creu i Sant Pau; [9]Hospital del Mar; [10]Universidad de Málaga; [11]Hopsital Universitario General de Valencia; [12]Hospital Germans Trias i Pujol; [13]Hospital Universitario de Canarias; [14]Hospital Universitario Puerta del Hierro; [15]Hospital Josep Trueta; [16]Hospital Universitario Doce de Octubre; [17]Hospital La Fe; [18]Hospital Clínic Barcelona, Liver Unit, Barcelona, Spain; [19]AEEH, CIBEREHd*
Email: mlondono@clinic.cat

Background and aims: Response criteria to ursodeoxycholic acid (UDCA) treatment in patients with primary biliary cholangitis (PBC) are based on the reduction of alkaline phosphatase (ALP), total bilirubin (TB), and aspartate aminotransferase (AST). However, recent studies suggest that complete normalization of these tests result in better clinical outcomes. More studies are necessary to validate these data and to determine the need for increasing the strictness of UDCA treatment-response criteria. Therefore, we sought to investigate the impact of TB, AST, ALP and gamma-glutamyl transferase (GGT) normalization after 12 months of UDCA treatment on patients' survival.
Method: Retrospective analysis of 1154 patients with PBC patients included in the ColHai registry (Spanish registry for patients with autoimmune and cholestatic liver disease). Liver tests were categorized according to the upper limit of normal (ULN) for each center: 1) AST: <1, 1–1.5, >1.5; 2) ALP: <1, 1–1.5, 1.5–1.67, >1.67; 3) GGT: <1, 1–3, 3–5, >5; 4) TB: <0.6, 0.6–1.2, >1.2.
Results: Most of the patients were female (90%), with a median age of 55 years (range 46–63). 116 (10%) died during a median follow-up period of 10 years (range 6.7–15.7). In the univariate analysis AST < ULN (HR 0.45; 95CI% 0.35–0.65), ALp < ULN (HR 0.51; 95CI% 0.34–0.78), GGT < ULN (HR 0.60; 95CI% 0.38–0.94) and TB <0.6 × ULN (HR 0.35; 95CI% 0.24–0.52) were associated with a significantly lower mortality rate. There were no significant differences in survival between patients with ALp < ULN vs. <1.5 × ULN or those with GGT < ULN vs. <3 × ULN (Figure). In the multivariate analysis, only TB < 0.6 × ULN and ALp < 1.5 × ULN were independently associated with lower mortality (HR 0.42; p < 0.01 and HR 0.57; p = 0.01, respectively).



Conclusion: ALP normalization was not better than the usual cut-off of 1.5 × ULN to predict survival but decreasing TB to better than normal levels (0.6 × ULN) significantly improved patients' survival.

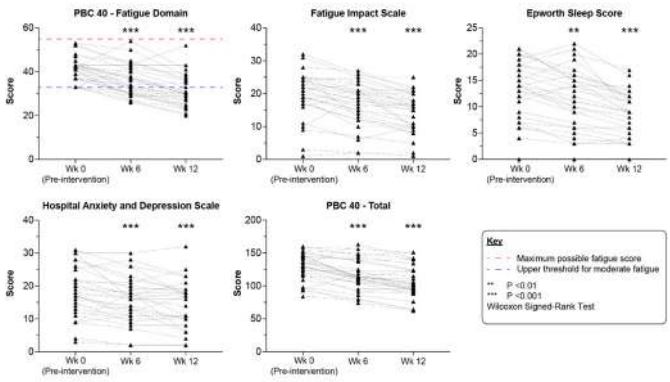
THU483

Home-based exercise in patients with refractory fatigue associated primary biliary cholangitis: final results from the EXerCise Intervention in cholesTatic LivEr Disease (EXCITED) clinical trial

Alice Freer[1], Felicity Williams[1,2], Simon Durman[1], Jennifer Hayden[1], Matthew Armstrong[1], Palak Trivedi[1,3]. *[1]University Hospital Birmingham NHS Foundation Trust, Liver Department, Birmingham, United Kingdom; [2]University of Birmingham, Institute of Inflammation and Ageing, Birmingham; [3]University of Birmingham, NIHR Birmingham Centre for Liver and Gastrointestinal Research, Birmingham, United Kingdom*
Email: freerae218@yahoo.com

Background and aims: Debilitating, refractory fatigue is the most commonly reported symptom of primary biliary cholangitis (PBC), affecting 40–80% of patients (pts). The pathogenesis is unknown, but muscle bioenergetic abnormalities are proposed to contribute. Herein, we present the results of a single-arm, open-label clinic trial, to assess the efficacy and safety of a novel home-based exercise program (HBEP) in pts with PBC and severe fatigue (NCT04265235).
Method: A remotely-monitored, 12-week (wk) HBEP was delivered to patients with PBC and moderate-severe fatigue (PBC40 fatigue score >33; other causes excluded). This consisted of individualised body weight resistance exercises completed at moderate intensity and weekly telephone health calls (first 6 wks only). Adherence was monitored using GeneActiv wrist monitors. The primary efficacy outcome measure was the proportion of individuals attaining at least a >5-point reduction in the PBC40 fatigue domain at wk 12. Key secondary outcomes included assessment of the Fatigue Impact Scale (FIS), other domains of the PBC-40, the Chronic Liver Disease Questionnaire, (CLDQ), the Epworth Sleep Score (ESS), the Hospital Anxiety and Depression Scale (HADS), aerobic exercise capacity (incremental shuttle walk test [ISWT]; Duke Activity Status Index [DASI]; metabolic equivalent of task [MET]), and functional capacity (short physical performance battery [SPPB]) at 6 and 12wks. Full study protocol is available at BMJ Open Gastro (PMID33707216).
Results: In all, 31 pts were recruited. One individual withdrew prior to wk12 due to unforeseen personal issues. The remaining thirty participants (29 women, 1 man) completed the 12-wk HBEP: median age 53yrs, ALP 1.9xULN, bilirubin 17 μmol/L, MELD 7, and baseline PBC40 fatigue score 41. The primary outcome was met by 26 pts (87%); the median reduction in PBC40 fatigue score at wk12 was 11 points (interquartile range −9 to −13 (Fig). Significant reductions were also observed in the FIS, score, ESS, HADS and the composite PBC40 score (Fig), alongside individual symptom, cognition, emotion and social domains, and the CLDQ (data not shown). Significant changes were seen in METs (+0.46, p < 0.001) and SPPB (+1 point, p < 0.001), with 28 pts (93%) achieving the maximum SPPB score at 12 wks (vs. 43% at baseline; p < 0.001). No significant differences in ALP values or MELD score were observed from baseline to 12wks. No significant adverse events were observed during the course of the study.
Conclusion: A 12-wk individualised HBEP, incorporating resistance and aerobic exercise, is safe, feasible, and significantly improves fatigue, quality of life, and exercise/functional capacity in patients with refractory fatigue associated with PBC. These findings warrant validation through a longer duration randomised control trial.

Figure: Efficacy of HBEP on PBC-associated fatigue and quality of life



Dot plots indicating changes from baseline to 6 and 12wks, following introduction of HBEP.

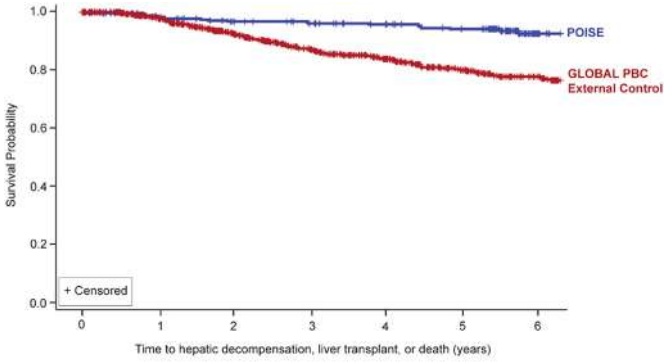
Email: fiorella.murillo@uhn.ca

Background and aims: The POISE randomized double-blind (DB) placebo-controlled trial and open label extension (OLE) demonstrated that obeticholic acid (OCA) reduced biomarkers associated with adverse clinical outcomes in patients with primary biliary cholangitis (PBC). The objective of this analysis was to evaluate event-free survival in OCA-treated patients in POISE (DB + OLE) compared to non-OCA treated external controls.

Method: The treatment arm included patients in the POISE study. External controls were OCA-naive patients from the GLOBAL PBC registry who were diagnosed with PBC, treated or untreated with ursodeoxycholic acid (UDCA), with >1 year of follow-up. Study end point was time to first occurrence of hepatic decompensation, liver transplant (LT) or death. As treatment was not assigned randomly, baseline variables could influence both the chances of a clinical event and of receiving treatment. To ensure a fair and balanced comparison, inverse probability of treatment weighting (IPTW) was used to balance groups. Logistic regression model was used to create weights for the following key baseline confounders: age, sex, calendar year of diagnosis, PBC duration, UDCA use, ALP, bilirubin and AST or ALT. Weights were assigned to each patient. Cox-proportional hazards models were run to establish the hazard ratio (HR) and 95% confidence. A secondary analysis examined the impact of adding cirrhosis to the model.

Results: Over the 6.3 years of follow-up, there were 16 events of hepatic decompensation, liver transplant or death in 209 subjects in the POISE arm (Incidence rate (IR) 18.0 per 1, 000 person-years; 95% CI 10.7–28.6) and 212 events in 1381 patients (IR 35.5 per 1, 000 person-years; 95% CI 31.0–40.5) in the GLOBAL PBC external control group. The IPTW HR = 0.42 (95% CI 0.21, 0.85; p = 0.02), indicating that patients treated with OCA in a trial setting had significantly greater event-free survival than patients in the Global PBC control group. The Kaplan-Meier curve is shown in Figure. When cirrhosis was added to the model, it was a significant predictor (HR = 0.26; 95% CI 0.21–0.43, p < 0.01), and increased the effect size of treatment (HR = 0.35; 95% CI 0.17–0.71, p < 0.01). For patients with cirrhosis, HR = 0.38 (95% CI 0.12, 1.20) versus Global PBC controls; for patients without cirrhosis, HR = 0.34 (95% CI 0.14, 0.82). With widely overlapping confidence intervals, while cirrhosis significantly predicts time to events, it does not significantly affect treatment response.



FIRST EVENT	POISE (n=16)	Global PBC (n=212)
Decompensation	12	126
Liver Transplant*	1	23
Death	3	63

Conclusion: Patients treated with OCA in a trial setting demonstrated a statistically significant and clinically meaningful 58% reduction in relative risk of hepatic decompensation, LT or death compared to non-OCA treated patients in the GLOBAL PBC registry. Reduction in risk was independent of cirrhosis. These results support the continued use of long-term OCA therapy to optimize prognosis of patients with PBC.

THU485

Investigation of linerixibat 40mg BID for cholestatic pruritus of primary biliary cholangitis (PBC); further data from the phase 2b GLIMMER study to support the phase 3 GLISTEN study

James Fettiplace[1], Brandon Swift[2], Shu Zhang[2], Robyn von Maltzahn[1], Megan McLaughlin[2]. *[1]GlaxoSmithKline, United Kingdom; [2]GlaxoSmithKline, United States*
Email: jamesfettiplace@hotmail.com

Background and aims: Reduction of pruritic bile acids in circulation is under investigation for the treatment of cholestatic pruritus in PBC. Due to lack of previously approved therapies, what constitutes a meaningful within-patient change in itch has not been determined. The phase 2b GLIMMER study was a randomized, double-blind, placebo-controlled, dose response study of linerixibat, a minimally

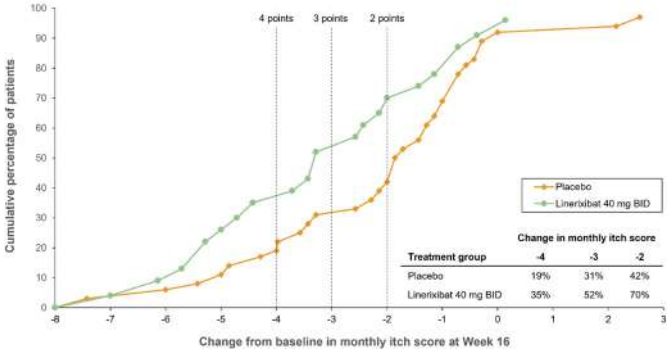
absorbed ileal bile acid transporter inhibitor, in PBC patients with moderate to severe pruritus;12 weeks of treatment followed a 4-week placebo run-in (N = 147). Data from GLIMMER was reanalyzed to look at multiple potential itch responder definitions for the linerixibat 40mg BID group, the phase 3 dose. Consistent with the mechanism of action, changes in total serum bile acids (TSBA) are also reported.

Method: Participants assessed itch daily using a 0–10 numeric rating scale. Proportion of responders were assessed using reductions in monthly itch scores (MIS) at week 16 compared to baseline. An empirical cumulative distribution function (eCDF) graph was generated for the percentage of participants with change from baseline in MIS for the linerixibat 40mg BID (N = 23) and placebo (N = 36) groups. Bile acid samples from GLIMMER were reanalyzed using an enzymatic assay that quantifies TSBA consistent with the Phase 2a study method (the original analysis summed specific bile acids utilizing a liquid chromatography tandem mass spectrometry method). Change from baseline in TSBA were analyzed using a mixed model repeated measures analysis (MMRM).

Results: The eCDF curves showed clear separation of linerixibat 40 mg BID and placebo groups. The percentages of participants with an improvement from baseline in MIS at week 16 were greater in linerixibat group than placebo group for a wide range of responder threshold values. The largest differences between the curves were observed between thresholds of –3 to –2, where the cumulative percentages were more than 20% greater in the linerixibat group than the placebo group.

Linerixibat 40mg BID (n = 22) reduced mean TSBA from a baseline of 18.6 µM (21.8) by –6.94 µM (17.5) [Mean (SD)] on average after 12-weeks of treatment. A MMRM analysis resulted in a significant decrease of 39% (p = 0.0001) from baseline and 37% (p = 0.0030) from placebo (n = 36) over the 12-week double-blind treatment period.

Figure. Cumulative percentage of patients with specified change from baseline in monthly itch score at Week 16



Conclusion: Consistent with inhibition of reuptake of bile acids, 40 mg BID linerixibat resulted in significant reductions in total serum bile acids. The proportion of participants with change from baseline in MIS at week 16 was greater in the linerixibat 40mg BID group than placebo over a range of responder threshold values. Linerixibat 40 mg BID is being studied in the ongoing confirmatory phase 3 GLISTEN study (NCT04950127). Responder thresholds of 2, 3 and 4-point improvements in MIS compared to baseline are key secondary end points of this phase 3 study.

Funding: GSK (study 201000)

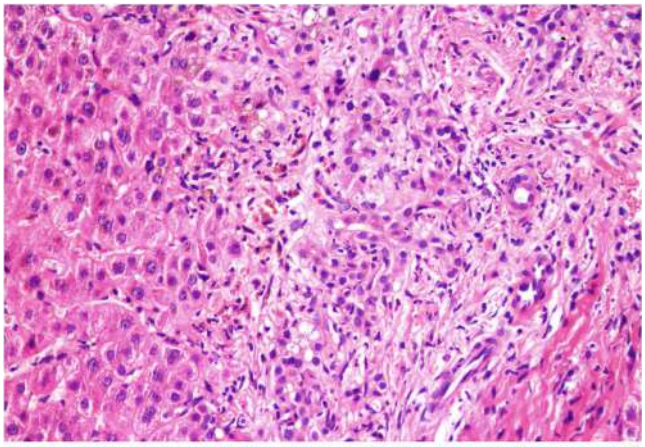
Post-COVID-19 cholangiopathy: does SARS-CoV-2 play a relevant role in histopathological findings?

Valéria Ferreira de Almeida e Borges[1,2], Helma Pinchemel Cotrim[3], Marcelo Costa Silva[4], Liliana Sampaio Costa Mendes[5], Francisco Guilherme Cancela Penna[6,7], Antônio Ricardo Cardia Ferraz de Andrade[3], Frederico Chaves Salomão[8], Juliana Daud[2], Luiz Antônio Rodrigues de Freitas[3,9,10]. *[1]Federal University of Bahia, Postgraduate Program in Medicine and Health, Brazil; [2]Federal University of Uberlândia, Brazil; [3]Federal University of Bahia, Medicine School, Brazil; [4]Hospital e Clínica São Roque, Ipiaú, Brazil; [5]Hospital de Base do Distrito Federal, Brasília-DF, Brazil; [6]Federal University of Minas Gerais, Instituto Alfa de Gastroenterologia, Belo Horizonte, Brazil; [7]IPSEMG Hospital Governador Israel Pinheiro HGIP, Belo Horizonte, Brazil; [8]Centro Diagnóstico de Patologia, Uberlândia, Brazil; [9]FIOCRUZ Fundação Oswaldo Cruz, Pathology, Salvador, Brazil; [10]Imagepat Laboratory of Pathology, Salvador, Brazil*
Email: valeriafaborges@gmail.com

Background and aims: Cholangiopathy (CHP) occurs in critically ill patients (CIP) after prolonged therapy in intensive care unit. Findings akin to those described in CIP were deemed a novel entity in patients with severe Covid-19. This study evaluates liver histopathological findings in patients with post Covid-19 cholangiopathy.

Method: Liver sections from 10 patients with post-Covid-19 CHP were stained with hematoxylin and eosin and sirius red for fibrosis. Immunostaining for cytokeratin-7 was done in 7 cases to evaluate ductular proliferation and biliary metaplasia of hepatocytes. Semiquantitative analysis included portal changes (fibrosis, inflammation, and biliary tree changes), and parenchymal alterations (cholestasis, inflammation, hepatocellular lesions, and fibrosis).

Results: All 10 patients, 5 women and 5 men, mean age: 54 ± 11.29 years, were RT-PCR positive for Sars-CoV-2 infection, with respiratory distress requiring mechanical ventilation, pronation, sedation and vasoactive drugs. Median of liver enzymes closely before the biopsy procedure were serum gamma-glutamyl transferase 925 U/L, alkaline phosphatase 605 U/L, alanine aminotransferase 91 U/L, aspartate aminotransferase 90 U/L and bilirubin 3 mg/dL. Imaging studies revealed irregularities in the intrahepatic bile ducts. Biliary casts were seen in 6 cases. Biopsies were performed 190 ± 16 days after the molecular diagnosis of the infection. The median number of portal tracts was 25 (15–32). Portal and periportal fibrosis were evidenced in all cases, and septal fibrosis in 7. A mild to moderate inflammatory infiltrate (mononuclear and neutrophilic with rare eosinophils) was seen in all without interface activity. Moderate to severe ductular proliferation was found in all, as well as bile duct dystrophy (irregular contours, cytoplasmic vacuolization, loss of nuclear polarization, nuclear pyknosis and cellular drop-out). Bile plugs were found in the ductules in 6 cases. Mild swelling of endothelial cells of arterioles was observed in 5 cases. In one case, a thrombus was found in a small portal vein branch and in another a mild periductal fibrosis was present. Ductopenia was not seen. Mild to severe parenchymal cholestasis was evidenced in 9 cases. One case had multiple small biliary infracts. Hepatocyte biliary metaplasia (CK7+ cells) was found in all seven tested cases. Acinar inflammation, as well as hepatocyte necrosis and apoptosis, were minimal and focal. One case showed multiple small biliary infarcts.



Case 4: an enlarged portal tract with ductular proliferation, dystrophic bile ducts, and mil inflammatory infiltrate. Cholestasis is present at the periportal hepatic parenchyma (hematoxylin-eosin; original magnification ×100).

Conclusion: The present findings are akin to those described in the CHP of CIP. Only Covid-19 patients requiring intensive care develop CHP. This suggests that the virus does not have a direct role in the CHP. It is more likely that, as with CIP, hypoxemia due to arterial hypotension and lung damage associated with vasoconstrictor and other drugs cause damage to the biliary tree.

THU488

Examining the role of thiopurine metabolite testing in the management of patients with autoimmune hepatitis

Andrew Roberts[1], Declan Connoley[1], Ryan Hirsch[1], Gauri Mishra[1], Marcus Robertson[1], Sally Bell[1], Dilip Ratnam[1]. [1]*Monash Health, Department of Gastroenterology and Hepatology, Clayton, Australia*
Email: atr444@gmail.com

Background and aims: Thiopurines (TP) are widely used to maintain steroid-free remission in autoimmune hepatitis (AIH), however there is a lack of data examining the role of metabolite testing in the management of AIH. We evaluated whether metabolite monitoring affected steroid-free remission and TP-attributed adverse event (AE) rates in our AIH patients.
Method: We conducted a retrospective cohort study of adult patients with AIH treated with TPs at a metropolitan health network over a 10-year period (2011–2021). Baseline demographic and clinical data were recorded. Patients were stratified by metabolite testing status. Time of censor was last clinical review. The primary outcome was steroid-free remission status in patients who received metabolite testing compared to those who had not. Secondary outcomes included mean reduction in ALT and IgG levels from diagnosis, rates of AIH flares (defined as an increase in steroid dose or reintroduction of steroids in response to clinical or biochemical change), and TP-related AE rates.
Results: 109 AIH patients treated with TPs were included. Mean follow-up time was 5.7 ± 6.6 years. Mean age was 54.5 ± 19.4 years, 71.6% were female and 74.3% were Caucasian. 43 (39.4%) were anti-smooth muscle antibody, 79 (72.4%) had typical AIH findings on biopsy and 30 (27.5%) were cirrhotic. At time of diagnosis, the median ALT was 666 (IQR 134–1148) U/L. At time of censor, 62 (56.9%) patients remained on TPs with a mean azathioprine dose of 88.5 mg and 6-mercaptopurine dose 32.1 mg in the metabolite tested group vs. 78.8 mg ($p = 0.38$) and 50 mg ($p = 0.08$) in the non-metabolite tested group respectively.
Metabolite testing was performed in 44 (40.4%) patients. No difference in steroid-free remission rate was detected between patients who received TM testing compared to those who did not (59.1% vs. 61.5%, $p = 0.80$). In these patients, achieving a therapeutic 6-thioguanine level (defined as 225–450 pmol/8×10^8 erythrocytes) did not impact steroid-free remission rates (52.4% vs. 66.7%, $p = 0.47$) or low-dose steroid (prednisolone 5mg or less) maintenance rates (90% vs. 100%, $p = 0.57$). An AIH flare was documented in 29.4% of patients over the study period, which did not differ by testing status (40.0% vs 38.1%, $p = 0.86$). No significant differences in mean ALT, IgG or TE were noted between groups from time of diagnosis to time of censor. When stratified by testing status, no differences in TP-related AEs were detected (16% vs. 25%, $p = 0.30$).
Conclusion: TP metabolite testing was not associated with improved steroid-free remission, improvements in AIH disease activity, reduction in AIH flares or reduction in thiopurine-related adverse events. Aiming for therapeutic metabolite levels did not improve steroid-free remission rates. Metabolite testing may provide little utility in the management of AIH patients on TPs and may result in increased patient testing and healthcare resource burden.

THU489

Patient reported symptom burden in primary biliary cholangitis and how to inform trial design

Aaron Wetten[1,2], Claire Johnstone-hume[2], Kathryn Houghton[1], Chris Mitchell[3], David Jones[1,2], Jessica Dyson[1,2]. [1]*Newcastle Freeman Hospital, Liver unit, High Heaton, United Kingdom;* [2]*Newcastle University, Translational and Clinical Research Institute, United Kingdom;* [3]*PBC Foundation, United Kingdom*
Email: aaron.wetten@nhs.net

Background and aims: Primary Biliary Cholangitis (PBC) is a chronic, cholestatic autoimmune liver disease. Symptoms of pruritus, fatigue and 'brain fog' are common, and significantly impact quality of life. Current pruritus treatments are effective for some patients, but no therapies address fatigue or cognitive symptoms. This remains an area of significant unmet need, reflected by the recent increase in clinical trials to identify new agents. This study explored the prevalence of PBC symptoms, patients' priorities for their management, what they consider a meaningful improvement in their symptoms and how we should collect symptom data. These are crucial questions to inform trial design in this area where patient-reported outcomes are key metrics for success.
Method: An electronic survey was sent to members of the PBC Foundation (an international patient support group) in February 2022 with responses collected over 6 weeks. The survey comprised 9 questions regarding: current/past symptom burden; nature/degree of symptom (fatigue, itch and brain fog) management that they would consider a meaningful improvement, and their views on digital symptom assessment.
Results: 599 surveys were completed. Symptom prevalence was high: 64% reporting current/past itch, 93% fatigue and 78% brain fog. '*Any improvement being significant*' was the commonest category for each symptom: brain fog 54%, fatigue 53% and itch 48% (Figure 1). When asked how a treatment should help reduce symptoms, '*a treatment that made all day every day a little better*' was the most frequent response for brain fog (51%) and fatigue (47%), whilst 56% of respondents with itch preferred a treatment that could be taken when '*needed on really bad days*'. 71% preferred symptom collection using an electronic device, 7% did not have a smartphone to use and 3% would decline to participate.

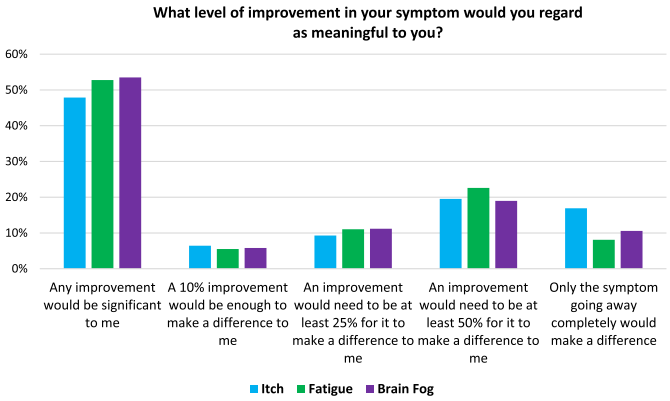


Figure: What level of improvement in symptoms (itch, fatigue and brain fog) are meaningful to patients

Conclusion: The prevalence of fatigue and brain fog were even higher than classically reported, demonstrating the unmet need. The majority of respondents felt that any symptom improvement would be significant, with daily treatment for brain fog and fatigue being preferable. A 'pill in the pocket' approach to treating pruritus is not currently utilised and is an interesting concept. Electronic symptom reporting was preferred by most patients and would standardise data collection and facilitate care delivery. This cross-sectional data helps us understand patient priorities' when designing clinically relevant outcomes from drug trials and how to assess symptom burden and treatment efficacy in clinical practice.

THU490

A randomized control trial evaluating the impact of a web-based mind-body wellness intervention for patients with primary biliary cholangitis

Makayla Watt[1], Ashley Hyde[1], John Spence[1], Gail Wright[2], Shauna Vander Well[2], Emily Johnson[1], Andrew L. Mason[1], Hin HIn Ko[3], Edward Tam[4], Puneeta Tandon[1]. *[1]University of Alberta, Edmonton, Canada; [2]Canadian PBC Society, North York, Canada; [3]The University of British Columbia, Vancouver, Canada; [4]Dr. Edward Tam, Vancouver, Canada*
Email: mewatt@ualberta.ca

Background and aims: People with primary biliary cholangitis (PBC) experience significantly higher rates of mental distress, fatigue and impaired health related quality of life (HrQoL) as compared to the general population. Online mind-body wellness programming has improved mental wellness and decreased fatigue in a variety of chronic disease populations, but limited data is available in PBC. We previously conducted a pilot study of a novel online mind-body wellness intervention in PBC that demonstrated high feasibility and acceptability, as well as promising exploratory efficacy. After refining the intervention using feedback from the pilot study, the current study aimed to assess the efficacy of the online intervention.
Method: This was a sequential mixed-methods randomized control trial (RCT). Adult participants with PBC were randomized to receive either standard of care (SOC) or SOC alongside a 12-week online mind-body intervention involving mindful movement, breathwork, meditation, an acceptance and commitment therapy chronic disease skills program, and tips from PBC physicians. The primary outcome was changes in the Hospital Anxiety and Depression Scale (HADS). Secondary outcomes evaluated fatigue, perceived stress, resilience, HrQoL through the PBC-40, and physical functioning. ANCOVA was used to determine between group differences. A qualitative descriptive approach with semi-structured interviews was used to evaluate study experiences.
Results: Of the 123 patients screened for the study, 87 were randomized to the control (n = 44) and intervention (n = 43) groups (mean age 59.8 ± 10.6 years; 98% female). The between-group HADS total score improved by 20.0% (95% CI 4.7, 35.2, p = 0.011) and the HADS depression score improved by 25.8% (95% CI 4.8, 46.8, p = 0.017). Significant improvements were seen in the PSS (15.2%), and two PBC-40 domains (emotional symptoms by 16.3%, and social symptoms by 11.8%) with a mean satisfaction score of 82/100. While no significant improvements were observed in fatigue, interviews revealed improved ability to cope with fatigue. In the 36/43 participants who completed the intervention, 25 (69%) adhered to the program goal of completing the program at least 3x per week. Enhancing group support was highlighted as a way to improve adherence.
Conclusion: This 12-week intervention improved measures of mental wellness and quality of life. High satisfaction and adherence rates were observed. Future online mind-body online wellness studies could explore strategies to optimize adherence and increase the physical activity intervention, which may in turn result in a greater impact on fatigue.

THU491

Health-related quality of life in patients with primary sclerosing cholangitis: a longitudinal population-based cohort study

Bregje Mol[1], Kim van Munster[1], Johannes Bogaards[2], Rinse Weersma[3], Akin Inderson[4], Joline de Groof[1], Noortje Rossen[1], Willemijn Ponsioen[1], Maud Turkenburg[1], Karel J. van Erpecum[5], Alexander Poen[6], B.W. Marcel Spanier[7], Ulrich Beuers[1], Cyriel Ponsioen[1]. *[1]Amsterdam UMC, Locatie AMC, Gastroenterology and Hepatology, Amsterdam, Netherlands; [2]Amsterdam UMC, Locatie AMC, Epidemiology and Data Science, Amsterdam, Netherlands; [3]University Medical Center Groningen, Gastroenterology and Hepatology, Groningen, Netherlands; [4]Leiden University Medical Center (LUMC), Gastroenterology and Hepatology, Leiden, Netherlands; [5]UMC Utrecht, Gastroenterology and Hepatology, Utrecht, Netherlands; [6]Isala Zwolle, Gastroenterology and Hepatology, Zwolle, Netherlands; [7]Rijnstate, Gastroenterology and Hepatology, Arnhem, Netherlands*
Email: c.y.ponsioen@amsterdamumc.nl

Background and aims: Data regarding health-related quality of life (HRQoL) in primary sclerosing cholangitis (PSC) is sparse and has only been studied cross-sectionally in a disease which runs a fluctuating and unpredictable course. In this study we aim to describe HRQoL longitudinally by using repeated measurements in a population-based cohort.
Method: Every three months from May 2017 up to August 2020 patients received a digital questionnaire at home. These included the Short Form-36, EuroQol-5D-5L, 5-Dimension Itch, patient-based Simple Clinical Colitis Activity Index, and patient-based Harvey-Bradshaw Index. Data were compared with Dutch reference data and a matched IBD disease-control from the population-based POBASIC cohort. Mixed-effects modelling was performed to identify factors associated with HRQoL.
Results: 328 patients completed 2576 questionnaires. A significant reduction compared to the Dutch reference population of both the physical component summary (46.4 versus 48.0, p = 0.018) and mental component summary (47.5 versus 50.5, p = 0.004) scores measured by the SF-36 was found. HRQoL outcomes were significantly negatively associated with a coexisting active IBD which was not the case in case of quiescent IBD. Decreasing HRQoL scores were also negatively associated with increasing age, female sex, diagnosis of AIH overlap, end-stage liver disease, and the presence of itch. The odds of reporting a clinically relevant reduction in EQ-5D score showed seasonal variation, being lowest in summer (OR 0.48 (0.31–0.74), p < 0.001). In patients with a liver transplant, HRQoL outcomes were comparable to the Dutch general population.

	PCS			MCS			
	Estimate	95% CI		Estimate	95% CI		
Intercept	50.6	48.2	53.0	48.9	46.9.	–	50.7
Female	−2.8	−5.0	−0.7				
Age per 10 years (reference 40y)	−0.1	−0.2	−0.0				
End-stage liver disease	−4.3	−7.8	−0.9	3.5	−0.0	–	6.7
AIH Overlap	−3.7	−7.4	0.1				
IBD							
None	(reference)			(reference)			
Ulcerative Colitis	2.3	−0.1	4.8	2.5	−0.0	–	4.8
Crohn's Disease	3.3	0.2	6.4	−0.3	−3.8	–	2.8
IBD activity*	−12.2	−16.7	−7.6	−12.0	−18.9	–	−5.9
*Itch**	−9.2	−12.2	−6.2	−3.1	−6.9	–	0.3

Table *l*inear mixed-effects model SF-36. The intercept indicates the reference value of the *physical component summary (PCS)* and *mental component summary (MCS)* score for all patients without or before LT conditional on the reference value of the other variables included. The estimate of the listed factors indicates the particular effect of each factor.
*Itch and IBD activity are transformed to a 0 to 1 scale. 1 equals most severe complaints.

Conclusion: PSC patients report impaired HRQoL compared to the general population. After liver transplantation, HRQoL scores of PSC patients are at comparable levels as in the general population. HRQoL scores are associated with potentially modifiable factors such as itch and IBD activity, emphasizing the importance of adequate treatment.

Cirrhosis and its complications: ACLF and Critical illness

Email: jbrozat@ukaachen.de

Background and aims: International registries have reported high mortality rates in patients with liver disease and coronavirus disease 2019 (COVID-19). However, the paucity and heterogeneity of data leaves the extent to which comorbidities contribute to excess COVID-19 mortality in cirrhosis as controversial. This study thus aimed to control the influence of comorbidities through propensity score matching, enabling a controlled comparison of symptomatic presentation, disease progression and mortality of patients with COVID-19 and underlying cirrhosis to those without chronic liver disease.
Method: We used the multinational Lean European Open Survey on SARS-CoV-2-infected patients (LEOSS) to identify patients with cirrhosis. We compared symptoms, disease progression and mortality after propensity score matching (PSM) for age, sex, obesity, smoking status, and concomitant diseases. Mortality was further compared with that of patients with another significant precipitator of acute-on-chronic liver failure, spontaneous bacterial peritonitis (SBP).
Results: Among 7096 patients with SARS-CoV-2 infection eligible for analysis, 70 (0.99%) had cirrhosis, and all were hospitalized. Risk factors for severe COVID-19, such as diabetes, renal disease and cardiovascular disease were more frequent in patients with cirrhosis. Case fatality rate in patients with cirrhosis was 31.4% with the highest odds of death in patients older than 65 years (43.6% mortality; odds ratio [OR] 4.02; p = 0.018), Child-Pugh class C (57.1%; OR 4.00; p = 0.026), and failure of two or more organs (81.8%; OR 19.93; p = 0.001). After PSM for demographics and comorbidity, the COVID-19 case fatality of patients with cirrhosis was comparable to that of patients without (28.8% vs. 26.1%, p = 0.644) and similar to 28-day mortality in a comparison group of patients with cirrhosis and SBP (33.3% vs. 31.5%; p = 1.000). In contrast, the number of patients that initially reported no symptoms of COVID-19 was significantly higher in patients with cirrhosis (37.5% vs. 10.5%; p < 0.001), yet more than half progressed into complicated or critical disease phases.
Conclusion: Although patients with cirrhosis and SARS-CoV-2 infection regularly present without any specific symptoms, the mortality in hospitalized SARS-CoV-2-infected patients with cirrhosis is high. Propensity score matching suggests this can be largely attributed to pre-existing comorbid conditions and extrahepatic organ failure.

THU494

Serum metabolites on admission associate with the development of nosocomial infections in inpatients with cirrhosis

Jasmohan S Bajaj[1], Jacqueline O'Leary[2], Puneeta Tandon[3], Guadalupe Garcia-Tsao[4], Patrick S. Kamath[5], Paul J. Thuluvath[6], Ram Subramanian[7], Hugo E. Vargas[8], Sara McGeorge[1], Andrew Fagan[1], Florence Wong[9], Jennifer Lai[10], Leroy Thacker[1], Rajender Reddy[11].

Email: jasmohan.bajaj@vcuhealth.org

Background and aims: The inpatient course of patients with cirrhosis is complicated by a high rate of nosocomial infections (NI). These infections increase the need for intensive care, often lead to acute on chronic liver failure (ACLF), and death and are challenging to predict using clinical biomarkers. Better determination of a group that develops NI on admission could prevent one of the leading causes of ACLF and death in cirrhosis. Aim: Determine predictors of NI using serum metabolomics on admission in large cohort of inpatients with cirrhosis

Method: We enrolled inpatients with cirrhosis admitted non-electively across 7 centres in North America and collected clinical data and infection status on admission. Serum was collected on admission and analysed for LC/MS metabolomics. Hospital course, including NI development, ICU, ACLF and death were analysed. Metabolomic analysis using ANCOVA adjusted for age, sex, admission MELD, WBC, and albumin, rifaximin, infection status was performed. Also, we performed random forest analyses (RFA) for NI development. Finally logistic regression with clinical variables and then additional metabolites to predict NI was performed.
Results: 602 patients (376 men, 231 admission infection) were included. 101 (17%) developed NI 5 ± 2 days after admission. NI patients had more frequent admission infections and longer LOS. NIs resulted in worse inpatient outcomes including ICU transfer, death, and organ failures. *Infection details*: Most common initial infections were SBP followed by UTI and respiratory tract from bacterial causes. On the other hand, NIs were more likely to be fungal (n = 39, p < 0.0001 vs admission infections); rest were bacterial.
Metabolomics: 247 metabolites were significantly different between patients with vs. without a NI using ANCOVA with a AUC of 0.83 (metabolites alone). The top 25 metabolites on RFA are shown in Table 1 and according to mean decrease accuracy (Figure). *Logistic regression*: Higher MELD (OR 1.05, CI 1.02–1.09, p < 0.0001), admission infection (OR 3.54, CI 2.18–5.76, p < 0.0001) and admission WBC (OR 1.05, CI 1.00–1.09, p = 0.04) were significant predictors with AUC of 0.74. Of the metabolites, ↓ 1-linolenoyl-GPC, 1-stearoyl-GPC and and ↑ N-acetyltryptophan and N-acetyl isoputreanine added significantly to the clinical model (AUC 0.77, p = 0.05).

Hospice referral	17 (3%)	14 (14%)	<0.0001
Metabolites			
Metabolites significant on random forest analysis *=significant predictors on logistic regression despite clinical factor adjustment	Lower in NI	Higher in NI	
	1-stearoyl-GPC* 1-linoleoyl-GPC* (N(1)+N(8)-acetylspermidine 1-palmitoyl-GPC Choline 1-linolenoyl-GPC 1-lignoceroyl-GPC Octadecenedioylcarnitine(C18:1-DC)	Pimelate 4-imidazoleacetate Lanthionine 6-oxopiperidine-2-carboxylate N-acetyl tryptophan* Suberate 5-alpha-pregnan-3beta-20 alpha diol sulfate N-acetyl isoputreanine* Estrone-3-sulfate Genistein sulfate	

Conclusion: NIs are seen in almost a fifth of hospitalized patients with cirrhosis and are associated with poor outcomes. Admission metabolites focused on spermidine, tryptophan, and phospholipid metabolism were independently associated with NI prediction with significant contribution over clinical factors.

THU495

Association of impaired neutrophil migration with adverse outcomes in patients with liver cirrhosis

Mona-May Langer[1,2], Stefanie Sichelschmidt[1], Alina Bauschen[1], Sabrina Guckenbiehl[1], Lea Bornemann[3], Matthias Gunzer[3], Christian M. Lange[1,2]. [1]*Essen University Hospital, Department for Gastroenterology and Hepatology, Essen, Germany;* [2]*Hospital of the Ludwig Maximilian University (LMU), Medical Clinic and Polyclinic II, Munich, Germany;* [3]*University Duisburg-Essen, Institute for Experimental Immunology and Imaging, Essen, Germany*
Email: monamay.langer@med.uni-muenchen.de

Background and aims: Neutrophil granulocytes are important cells of the first line defense against bacterial and fungal infections. In the present study, we aimed to determine associations between neutrophil migration capacity and clinical outcome of patients with liver cirrhosis and acute-on-chronic liver failure.
Method: Patients with compensated (n = 11) or acutely decompensated liver cirrhosis (n = 84) or ACLF (n = 29) were recruited from a prospective, monocentric cohort study. Neutrophils were isolated of peripheral blood by magnetic beads. Neutrophil migration was tracked during steady-state-, fMLP-, CXCL1-, or CXCL8-stimulated conditions using time-lapse video microscopy and automated cell tracking. Proportion of migrating cells as well as average migration speed was quantified. Regression analyses were used to determine associations between neutrophil migration and clinical end points.
Results: The percentage of migrating neutrophils was significantly lower in patients with acute decompensation (81.32 ± 1.6%, P = 0.01) or ACLF (76.63 ± 3.4%, P = 0.003) after fMLP-stimulation compared to healthy individuals (89.04 ± 0.8%). Moreover, CXCL8-stimulation was less effective in neutrophils of patients with ACLF (77.56 ± 3.2%) compared to healthy individuals (87.14 ± 2.0%, P = 0.04). Average migration speed of neutrophils was reduced after both fMLP- and CXCL8-stimulation in patients with acute decompensation (fMLP 15.23 ± 3.3 µm/min, P = 0.001; CXCL8 14.42 ± 0.3 µm/min, P = 0.048) or ACLF (fMLP 14.91 ± 0.7 µm/min, P = 0.005; CXCL8 13.82 ± 0.4 µm/min, P = 0.008) compared to healthy individuals (fMLP 17.78 ± 0.5 µm/min, CXCL8 15.78 ± 0.5 µm/min). A low proportion of migrating neutrophils under steady-state or stimulated conditions was associated with the development of ACLF (p < 0.05), sepsis (p < 0.05), or the composite of ACLF, sepsis and death (p < 0.01) within 7 days.
Conclusion: Defective neutrophil migration under *ex vivo* steady-state conditions or after stimulation with fMLP or CXCL8 is associated with adverse outcomes in liver cirrhosis such as the development of sepsis and ACLF. Hence, neutrophil migration analysis might provide as a novel early warning sign for the development of severe complications in liver cirrhosis patients.

THU496

Renal and circulatory effects of terlipressin in patients with hepatorenal syndrome assessed by magnetic resonance imaging

Karen Vagner Danielsen[1], Jens Hove[1], Puria Nabilou[1], Thit Kronborg[1], Signe Wiese[1], Hartwig R. Siebner[1], Søren Møller[1], Flemming Bendtsen[1]. [1]*Hvidovre University Hospital, Denmark*
Email: kvdanielsen@gmail.com

Background and aims: Terlipressin improves renal function in about 40% of the patients with hepatorenal syndrome-acute kidney injury (HRS-AKI), but the pathophysiological mechanisms are unclear and the regional hemodynamic changes following terlipressin in patients with HRS-AKI have not, to our knowledge, been studied
Method: Using cardiac- and phase contrast magnetic resonance-imaging (MRI) we assessed the cardiac function and renal, splanchnic, and peripheral flow changes after first bolus of 2 mg terlipressin in 10 patients with HRS-AKI, six of whom also had acute-on-chronic liver failure. The patients were prospectively followed, and creatinine and mortality registered
Results: Cardiac output decreased by 15% following terlipressin (p < 0.01). Despite a decrease in cardiac output, renal artery blood flow (RBF) increased by 23% (p < 0.01) and RBF percentage of cardiac output increased by 49% (*p* = 0.01). Simultaneously, superior mesenteric artery blood flow and femoral artery blood flow decreased by 27% and 40%, respectively (both with p < 0.01). Mean arterial pressure (MAP) and systemic vascular resistance increased by 13% and 32%, respectively (both with p < 0.01). Baseline RBF correlated with serum-creatinine (p < 0.01), whereas changes in RBF or other cardiocirculatory variables did not correlate to changes in serum-creatinine after terlipressin
Conclusion: Terlipressin increases RBF, while reducing cardiac output and alleviating splanchnic- and peripheral vasodilatation. These effects, together with an increase in MAP, seem to explain the benefits of terlipressin for patients with HRS-AKI. MRI is a feasible, non-

invasive tool for assessing the cardiocirculatory effects of terlipressin; however, additional studies with larger sample sizes are needed to confirm these results.

THU497

SARS-CoV-2 infection in patients with underlying chronic liver disease is associated with significantly greater risks of inpatient hospitalization, intensive care unit admission, and overall mortality

Robert Wong[1], Yi Zhang[2], Mae Thamer[2]. [1]*Stanford University School of Medicine, United States;* [2]*Medical Technology and Practice Patterns Institute, Bethesda, United States*
Email: rwong123@stanford.edu

Background and aims: Patients with chronic liver disease (CLD) are hypothesized to have greater risk of developing liver decompensation following COVID-19. However, it is unclear whether the increased risks of liver decompensation result in higher overall mortality in CLD patients with COVID-19 (CLD+COVID-19). We aim to evaluate whether CLD+COVID-19 patients have higher rates of inpatient hospitalization, intensive care unit (ICU) admission, and overall mortality compared to CLD patients without COVID-19 among one of the largest U.S. cohorts evaluating COVID-19 outcomes.
Method: Using the Common Data Schema from COVID-19 Research Database, a large U.S. database containing over 72 million linked patients with both electronic health records and claims data, we identified patients with CLD (hepatitis C, hepatitis B, alcoholic liver disease, and non-alcoholic fatty liver disease/steatohepatitis) with COVID-19 (CLD+COVID-19) and without COVID-19. Patients were followed for at least 6 months until a censoring event (i.e. death) or end of the study period (August 31, 2021). Outcomes assessed included need for inpatient hospitalization, ICU admission, and overall mortality, and outcomes were compared between groups with chi-square testing. Multivariate regression models evaluated whether COVID-19 was independently associated with greater risk of hospitalization, ICU admission, and overall mortality in CLD patients.
Results: Among 973, 634 adult patients with CLD (55.2% men, 44.8% women, 28.9% age >65y, 40.4% age 45–64y, 30.7% age 18–44, 12.0% with cirrhosis), 3.5% had CLD+COVID-19 and 96.5% had CLD without COVID-19. Compared to CLD without COVID-19, CLD+COVID-19 patients had significantly higher rates of hospitalization (25.7% vs. 9.2%, $p < 0.01$), ICU admission (15.5% vs. 4.9%, $p < 0.01$), and overall mortality (5.6% vs. 3.8%, $p < 0.01$). On adjusted multivariate regression, when compared to CLD patients without COVID-19, patients with CLD+COVID-19 had significantly greater risk of hospitalization (OR 3.27, 95% CI 3.19–3.35, $p < 0.01$), ICU admission (OR 3.36, 95% CI 3.26–3.47), and overall mortality (OR 1.36, 95% CI 1.29–1.42). These findings were likely mediated by increased risks liver decompensation (HR 1.23, 95% CI 1.15–1.32, $p < 0.01$) and acute on chronic liver failure (ACLF) (HR 7.32, 95% CI 6.40–8.38, $p < 0.01$) due to acute SARS-CoV-2 infection observed in CLD+COVID-19 compared to CLD without COVID-19 patients.
Conclusion: Among one of the largest cohorts evaluating COVID-19 outcomes in patients with underlying CLD, we observed that SARS-CoV-2 infection was associated with significantly greater risks of inpatient hospitalization, ICU admission, and overall mortality in patients with CLD. The increased mortality observed in CLD patients with COVID-19 is likely a result of the increased risks of liver decompensation and ACLF due to COVID-19.

THU498

Low FT3 levels are associated with acute decompensation and acute-on-chronic liver failure

Mona-May Langer[1,2], Alina Bauschen[1], Sabrina Guckenbiehl[1], G. Sebastian Hönes[3], Denise Zwanziger[3], Lars Christian Möller[3], Christian M. Lange[1,2]. [1]*University Hospital Essen, Department for Gastroenterology and Hepatology, Essen, Germany;* [2]*Hospital of the Ludwig Maximilian University (LMU), Medical Clinic and Polyclinic II, Munich, Germany;* [3]*University Hospital Essen, Department of Endocrinology, Diabetes and Metabolism and Division of Laboratory Research, Essen, Germany*
Email: monamay.langer@med.uni-muenchen.de

Background and aims: Thyroid hormones (TH) are important for regulation of hepatic lipolysis, gluconeogenesis, and immune-metabolism, and may thereby impact the pathogenesis and severity of liver cirrhosis and acute-on-chronic liver failure (ACLF). Therefore, we determined associations between TH, clinical stages of liver cirrhosis including ACLF and TH targets in immune cells.
Method: From a prospective cohort study, patients with compensated liver cirrhosis ($n = 163$) or acute decompensation ($n = 169$) or ACLF ($n = 36$) were recruited. Thyroid-stimulating hormone (TSH), free T3 (FT3) and free T4 (FT4) levels were determined by immunoassays. Associations between TH and clinical parameters were assessed by regression analyses. T cells of healthy donors and patients were isolated from peripheral blood and characterized for expression of TH target genes by RT-PCR.
Results: TSH concentration in patients with acute decompensation (2.81 ± 0.2 mU/l) was increased compared to patients with compensated liver cirrhosis (2.01 ± 0.1 mU/l, $P = 0.03$) and ACLF (2.18 ± 0.34 mU/l, $P = 0.42$). Contrariwise FT3 levels were significantly lower already in patients with acute decompensation (3.80 ± 0.06 pmol/l) compared to compensated liver cirrhosis (4.79 ± 0.06 pmol/l, $P < 0.0001$), and even lower in those with ACLF (3.24 ± 0.15 pmol/l; compensated vs. ACLF $P < 0.0001$; acute decompensation vs. ACLF $P < 0.01$). Decreased FT3 concentrations were associated with infections in acute decompensated patients (3.45 ± 0.10 pmol/lwith vs. 3.90 ± 0.07 pmol/lwithout infection, $P = 0.0009$), while FT3 concentrations were not different in ACLF with (3.23 ± 0.24 pmol/l) or without infections (3.25 ± 0.16 pmol/l, $P = 0.8$). FT3 concentrations correlated inversely with CLIF-OF-, CLIF-C-AD/ACLF- and MELD-scores ($p < 0.0001$). Furthermore, low FT3 levels ($p < 0.0001$) as well as a low FT3/FT4 ratio ($p < 0.001$) were associated with mortality of liver cirrhosis patients. RT-PCR showed that T cells derived from healthy donors and patients with liver cirrhosis or ACLF did not express TH receptor β, but TH receptor α. Compared to T cells of healthy donors, expression of TH receptor α was significantly decreased in T cells derived from patients with compensated liver cirrhosis ($p = 0.02$) and even more in T cells of patients with acute decompensation ($p = 0.001$) or ACLF ($p = 0.009$).
Conclusion: Acute decompensation complicated with infections as well as ACLF with or without infections is associated with profound alterations in the TH balance resembling low T3 syndrome. Strikingly, low FT3 level and decreased FT3/FT4 ratio are associated with elevated mortality in patients with liver cirrhosis. Reduced TH receptor α expression suggests impaired TH signaling in T cells of patients with liver cirrhosis possibly contributing to reduced survival. Mechanism and functional consequences of these findings will be further explored in the new SFB-CRC/TR 296.

THU499

Post hoc analyses of the ATTIRE trial suggest potential gender differences in response to albumin

Margaret Hook[1], Thais Tittanegro@gmail.com[1], Louise China[1], Alastair O'Brien[1]. [1]*UCL Institute for Liver and Digestive Health Upper 3rd Floor, University College London Division of Medicine, London, United Kingdom*
Email: rmhaajo@ucl.ac.uk

Background and aims: Acute decompensation (AD) and acute-on-chronic Liver failure (ACLF) are characterised by increased systemic inflammation and immunosuppression. There are data supporting gender differences in the inflammatory response in health and differences in outcomes between genders in AD/ACLF. Post-hoc subgroup analyses of the neutral ATTIRE trial (Albumin To Prevent Infection in Chronic Liver Failure) suggested a differential effect of targeted albumin infusions according to gender and so we investigated this in greater detail.
Method: ATTIRE was a randomized, multicenter, open-label trial involving 777 patients including 227 women, hospitalized with decompensated cirrhosis and serum albumin <30 g/L. Patients received standard of care or targeted albumin therapy (aiming for serum albumin >30 g/L) for up to 14 days or discharge. Baseline clinical characteristics and patient outcomes were analysed using appropriate statistical tests in RStudio software.
Results: Baseline characteristics, including MELD (Model for End-Stage Liver Disease) score, age and cirrhosis aetiology were similar between genders apart from an elevated creatinine in men (70 (57–94) vs 60 (48–77) µmol/L, p < 0.001). The volume of albumin infused did not differ between genders but resulting serum albumin values in the targeted albumin group were higher in women throughout the trial treatment period ($p < 0.001$). Women also had higher white cell counts (WCC) throughout the trial independent of treatment group ($p < 0.001$) but not C-reactive protein values. Overall outcomes did not differ between genders, although fewer events of renal dysfunction were seen in women (but not men) in the albumin treatment group compared to standard care (Chi-squared test (X^2 (1) = 6.85, p = 0.009). The incidence of serious adverse events with pulmonary oedema or fluid overload was similar between treatment groups in women, in contrast to men in which these were four times as common in the albumin group.

Table: Outcomes and serious adverse events in ATTIRE according to gender and treatment group

	MALE		FEMALE	
Treatment group (n)	Albumin (257)	Standard care (293)	Albumin (123)	Standard care (104)
Outcome – n (%)				
New infection	55 (21.4)	48 (16.3)	24 (19.5)	23 (22.1)
Renal dysfunction	30 (11.7)	35 (11.9)	10 (8.1)	22 (21.1)
Death during trial	20 (7.8)	23 (7.8)	10 (8.1)	10 (9.6)
Death at 28 days	37 (14.4)	47 (16)	16 (13)	15 (14.4)
Death at 90 days	65 (25.3)	70 (23.9)	27 (22)	23 (22.1)
Death at 180 days	94 (36.6)	87 (29.7)	38 (30.9)	32 (30.8)
Severe adverse advents - n	63	52	24	20
Pulmonary oedema/ Fluid overload	19	4	4	4
GI Bleed	8	9	3	4

Conclusion: Higher WCC levels in women irrespective of treatment group might suggest a difference in the inflammatory response but infection rates and overall outcomes were similar. The improved renal function in albumin-treated women without evidence of increased adverse events may relate to their increased rate of serum albumin increment, however, there was no mortality benefit according to gender. These findings may warrant further investigation.

THU500

Can machines predict liver decompensation? Analysis of 1, 415 patients with liver cirrhosis recruited at three German referral centers

Sophie Elisabeth Müller[1], Cristina Ripoll[2], Alexander Zipprich[2], Tony Bruns[3], Paul Horn[4], Marcin Krawczyk[1], Frank Lammert[1], Matthias Reichert[1]. [1]*Saarland University Medical Center, Saarland University, Department of Medicine II, Homburg, Germany;* [2]*University Hospital Jena, Clinic for Internal Medicine IV, Jena, Germany;* [3]*Aachen University Hospital, Department of Medicine III, Aachen, Germany;* [4]*University of Birmingham, Centre for Liver and Gastrointestinal Research, Institute of Immunology and Immunotherapy, Birmingham, United Kingdom*
Email: mueller.sophie.elisabeth@t-online.de

Background and aims: Since decompensation of cirrhosis significantly increases mortality, early detection of patients at risk of worsening liver function is of paramount importance. Hence, we applied machine learning techniques to identify parameters predicting hepatic decompensation.
Method: Using Python, Keras, and Scikit-Learn, several machine learning techniques including Decision Trees, Random Forests, Neural Networks, and Support Vector Machines (SVM) were applied to the INCA trial database containing both pro- and retrospective data from 1, 415 patients with cirrhosis from three German university hospitals (Homburg, Halle, Jena). In addition to laboratory values and medical history, genetic data (including nucleotide-binding oligomerization domain-containing protein 2 [NOD2] genotypes) were analyzed. The models were trained and tested with an 85:15 split. After performing hierarchical clustering on the numerical variables based on Spearman rank-order correlation using Ward's minimum variance method, we applied Permutation Feature Importance (PFI) to evaluate the impact of features on the prediction of decompensation.
Results: At the index date, 313 patients were permanently compensated, 354 patients had been decompensated before, and 748 patients were currently decompensated. Overall, 825 patients could be followed up (median duration: 12 months, maximum: 55 months), of whom 46.5% decompensated during follow-up. SVM showed the best performance in predicting decompensation, achieving an accuracy of 84.1% for the training and 77.7% for the test data set in retrospective assessment, and 78.4% and 73.8% in prospective analysis. PFI revealed baseline levels of albumin and bilirubin as well as minimum serum sodium concentrations as highest-ranking parameters associated with former decompensation. The maximum level of bilirubin and baseline levels of sodium and albumin were the most accurate variables for prospective data. In addition to the parameters of established scores such as MELD and Child-Pugh, NOD2 genotype and parameters related to infections (e.g. inflammatory markers and intake of antibiotics) were highly ranked.
Conclusion: Among tested machine learning models, SVM seems to have the highest accuracy in predicting liver decompensation. In addition to classical laboratory parameters, genetic factors and infections were critical parameters for individual predictions by SVM.

THU501

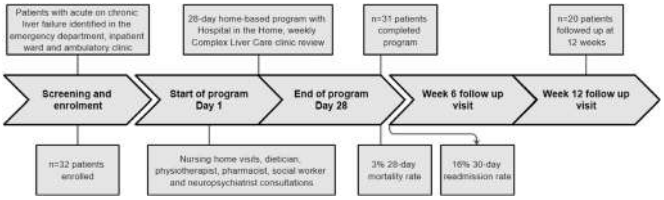
LivR Well: a feasibility study for a home-based, multidisciplinary liver optimization program for the first 28 days after an admission for acute-on-chronic liver failure

Natalie Ngu[1,2], Edward Saxby[1], Patricia Anderson[1], Lisa Stothers[1], Anita Figredo[3], Thomas Worland[1], Stephen Pianko[1,2], William Sievert[1], Benjamin Rogers[2,3], Sally Bell[1,2], Danny Liew[2], Suong Le[1,2]. [1]*Monash Health, Gastroenterology and Hepatology, Melbourne, Australia;* [2]*Monash University Clayton Campus, Faculty of Medicine, Nursing and Health Sciences, Clayton, Australia;* [3]*Monash Health, Hospital in the Home, Australia*
Email: natalielyngu@gmail.com

Background and aims: Acute on chronic liver failure (ACLF) has a 28-day mortality of 33.9% (1) and 30-day re-admission rate of 30% (2).

LivR Well is a multidisciplinary intervention aimed at reducing mortality and readmission through a home-based, liver optimisation program after an ACLF episode. We assessed feasibility, safety, patient acceptability and clinical impact.

Method: A prospective, feasibility study was conducted at an Australian tertiary hospital from March to October 2021. ACLF was defined as an acute hepatic insult with serum bilirubin ≥50 umol/L and International Normalized Ratio ≥1.5, complicated within 4 weeks by ascites and/or encephalopathy. Exclusions included end-of-life care, heart failure management and aged care residents. Participants received weekly medical review and oral nutritional supplementation. Home nursing, dietitian, physiotherapist, pharmacist, social worker, and neuropsychiatrist consultations were provided (Fig 1). The primary outcomes were adverse events/death. Secondary outcomes were attrition, liver disease severity, healthcare utilization, and patient-reported outcomes.



Results: We enrolled 32 patients; 31 patients completed the program. The median age was 53 years (Interquartile range (IQR) 49–60); 75% were male. The median Charlson Co-Morbidity Index score was 4 (IQR 3–5.5). Excess alcohol was the most common etiology (72%). Baseline median Model for End-Stage Liver Disease (MELD) score was 17 (IQR 13–21). Baseline handgrip strength in 11/27 (41%) patients met sex-specific criteria for sarcopenia. Two patients died at 16 and 148 days from enrolment. The 28-day mortality was 3% and the 30-day readmission rate was 16%. LivR Well cost $4, 947 AUD compared to $16, 197 AUD for an inpatient ACLF admission. Median MELD score improved at 28 days (17 vs. 15, p = 0.31). The Chronic Liver Disease Questionnaire showed improvement in 'fatigue' (p = 0.03) and 'worry' (p = 0.05), at 28 days compared to baseline. Qualitative interviews were undertaken in 24 participants with all reporting positive experience pertaining to interactions with clinicians. The importance of health literacy (22/24) and patient autonomy (20/24) were emphasized in >80% of interviews.

Conclusion: LivR Well was safe, feasible, acceptable, and cost-efficient with a reduction in 28-day mortality and 30-day readmission rates. We plan to conduct a randomized controlled trial of LivR Well compared to standard care to evaluate cost-effectiveness and clinical impact on re-admission and mortality.

THU502

Alcohol-associated hepatitis with acute-on-chronic liver failure in a diverse cohort: lung and circulatory organ failures along with MELD 35 are predictive of mortality

Stephanie Rutledge[1], Rohit Nathani[2], Erin Eschbach[3], Lily Chu[4], Parth Trivedi[3], Thomas Schiano[5], Leona Kim-Schluger[5], Sander Florman[5], Scott Friedman[4], Gene Im[5]. *[1]Icahn School of Medicine at Mount Sinai, Division of Gastroenterology, Department of Medicine, New York, United States; [2]Icahn School of Medicine at Mount Sinai Morningside-West, Department of Medicine, New York, United States; [3]Icahn School of Medicine at Mount Sinai, Department of Medicine, New York, United States; [4]Icahn School of Medicine at Mount Sinai, Division of Liver Diseases, Department of Medicine, New York, United States; [5]Icahn School of Medicine at Mount Sinai, Recanati/Miller Transplantation Institute, Division of Liver Diseases, Department of Medicine, New York, United States*
Email: stephaniemrutledge@gmail.com

Background and aims: Severe alcohol-associated hepatitis (sAH) without response to medical therapy is associated with unacceptably high mortality, particularly with concomitant acute-on-chronic liver failure (ACLF). Only a minority of these sAH-ACLF patients are eligible for early liver transplantation (eLT) and the outcomes of declined candidates are unknown. The aim of our study was to determine the outcomes of declined eLT for sAH candidates and to examine variables associated with outcomes in sAH-ACLF.

Method: We analysed a prospectively maintained database of sAH patients (probable or definite per NIAAA guidelines, MELD >20) hospitalized at a LT centre from 1/2012–7/2021. All non-responders to corticosteroids were presented at our transplant selection meeting. Patients declined for eLT for sAH and those accepted who died prior to eLT were identified. The U.S. centralised National Death Index (NDI) was used to determine outcomes of patients lacking follow-up at our centre.

Results: Over 9.5 years, a total of 234 sAH patients were either declined for eLT (n = 207) or accepted and died prior to eLT (n = 27). Median time to eLT decision was 5 days (3–11). The cohort was young and diverse: median age 44 years (35–53), nearly half were women (108/234, 46%) with significant racial minority representation: 55% White, 26% Hispanic, 8% Black, 7% Asian, 3% unknown. Most of the cohort met EASL-CLIF criteria for ACLF (62%); 71% had ACLF grade 2 or 3. Mean MELD score at the time of waitlisting decision was 33 (±8), mean Maddrey's discriminant function was 96 (±79), median CLIF-C Organ Failure score (CLIF-C OFs) was 10 (9–12) and median CLIF-C ACLF score was 49 (43–55). Over a median follow-up of 494 days (17–1291), 145/234 died (62%) Of patients with ACLF-3, 38/45 (84%) died and median time to death was 8 days (3–18) versus 17 days (9–59) in ACLF-2, 78.5 days (22.5–228) in ACLF-1 and 71 days (19.5–210) in patients without ACLF (p = 0.001) (figure).

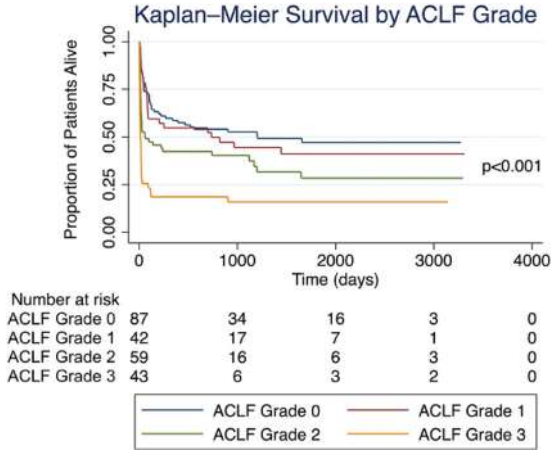

Figure: Kaplan-Meier survival by ACLF grade

Of the components of CLIF-C OFs, lung (HR 3.9, 95% CI 1.4–11.3) and circulatory scores (HR 3.13, 95% CI 1.6–6.2) were most predictive of mortality. Liver (HR 2.5, 95% CI 1.4–4.6), brain (HR 2.4, 95% CI 1.5–3.8), kidney (HR 1.6, 95% CI 1.2–2.2) and coagulation scores (HR 1.4, 95% CI 1.03–1.97) were also significantly associated. MELD >35 was determined as the optimal threshold for predicting mortality (HR 3.1, 95% CI 1.7–5.6). Compared with a "static" bilirubin during admission, a 10% bilirubin decrease had 66% lower mortality risk (p = 0.01) and a 20% increase was associated with 200% higher mortality (p = 0.05).

Conclusion: In a diverse, real-world cohort of patients with sAH declined for eLT, we identified a high prevalence of ACLF with very high short-term mortality. Lung and circulatory components of CLIF-C OFs and MELD >35 at the time of waitlisting decision were most predictive of mortality and may help guide clinical decision-making.

THU503

Bilirubin and its dynamics are independently associated with mortality in patients with acute decompensation of cirrhosis

Konstantin Kazankov[1,2], Peter Holland-Fischer[1,3], Karen Louise Thomsen[1,2], Rajiv Jalan[1], Raj Mookerjee[1]. [1]*University College London (UCL), Institute for Liver and Digestive Health, UCL Medical School, Royal Free Hospital, Liver Failure Group, United Kingdom;* [2]*Aarhus University Hospital, Department of Hepatology and Gastroenterology, Denmark;* [3]*Aalborg University Hospital, Department of Medical Gastroenterology, Denmark*
Email: konskaza@rm.dk

Background and aims: Patients with acute decompensation of cirrhosis (AD) are at high risk of mortality, and current practice is still devoid of accurate parameters indicating poor outcome. In our AD cohort, we assessed the value of bilirubin alone and its dynamic changes to predict mortality.

Method: We included patients with AD cirrhosis from a prospective database in which clinical and biochemical data were registered. Multivariate logistic regression and Kaplan-Meier analysis were used for statistical analysis. Odds ratios (OR) were based on bilirubin increments of 1.45 mg/dL (25 μmol/L).

Results: 519 patients were included, with alcohol (68%) as the predominant etiology. Main precipitants for AD were: harmful drinking (35%), infection (17%) and unknown (24%). 137 patients had alcoholic hepatitis. 354 patients (67%) did not have ACLF on admission or develop ACLF pre-discharge, whereas 24% had ACLF on admission, and 9% developed ACLF during hospitalization. Fifty-nine patients (11%) died within 4 weeks, and 118 (23%) within 12 weeks, with the highest mortality in patients with ACLF on admission or during hospitalization.

In multivariate analysis, admission bilirubin was associated with both 4- (OR 1.09 [CI 1.03–1.15]) and 12-week mortality (OR 1.08 [CI 1.03–1.13]) adjusted for age, sodium, creatinine, INR, white cell count, CRP and presence of alcoholic hepatitis and infection. Bilirubin levels beyond 12 mg/dL, the liver failure threshold according to the CLIF-Consortium ACLF-score, showed increasing 12-week mortality (Figure, log-rank test p < 0.001).

During admission (median 11 [IQR 7–20] days), 328 (63%) patients decreased their bilirubin, whereas it increased or was unchanged in 190 (37%) patients. Lack of reduction in bilirubin was strongly associated with death after 4 (OR 4.12 [CI 2.13–7.99]) and 12 weeks (OR 2.77 [CI 1.65–4.64]) in multivariate analysis. Accordingly, 18% of patients with a *decrease* in bilirubin died after 12 weeks vs. 35% in those with an *increase or no change*.

In patients with AD without ACLF, admission bilirubin lost its association with death at 4 weeks (OR 0.96 [CI 0.75–1.24]) but remained associated with 12-week mortality (OR 1.09 [CI 0.997–1.20]) in multivariate analysis, especially for levels >17.5 mg/dL. In patients without ACLF at admission, bilirubin was independently associated with ACLF development during hospitalization (OR 1.16 [CI 1.07–1.26]).

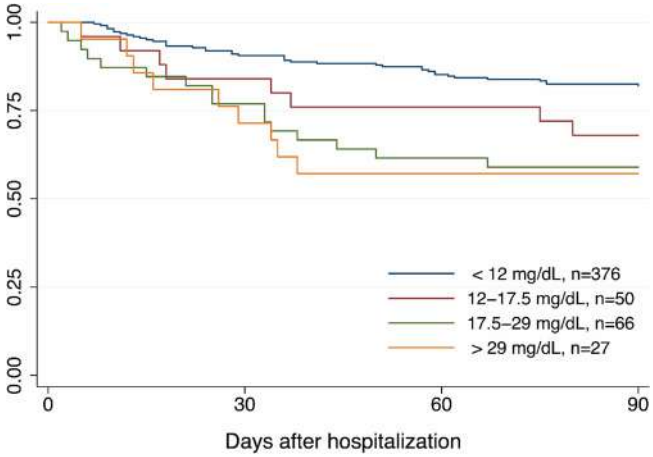

Figure: Kaplan-Meier 12-week survival estimates according to bilirubin at admission.

Conclusion: In AD cirrhosis patients, bilirubin at admission is a strong independent predictor of mortality. A step-wise increase in mortality arises from bilirubin levels >12 mg/dL. Failure to improve bilirubin during admission is an even stronger predictor of death. We propose a more detailed analysis of bilirubin and its dynamics in future studies, to generate new models for prognostication in AD cirrhosis.

THU504

Impact of predisposition and precipitants on the short-term prognosis among inpatients with chronic liver disease

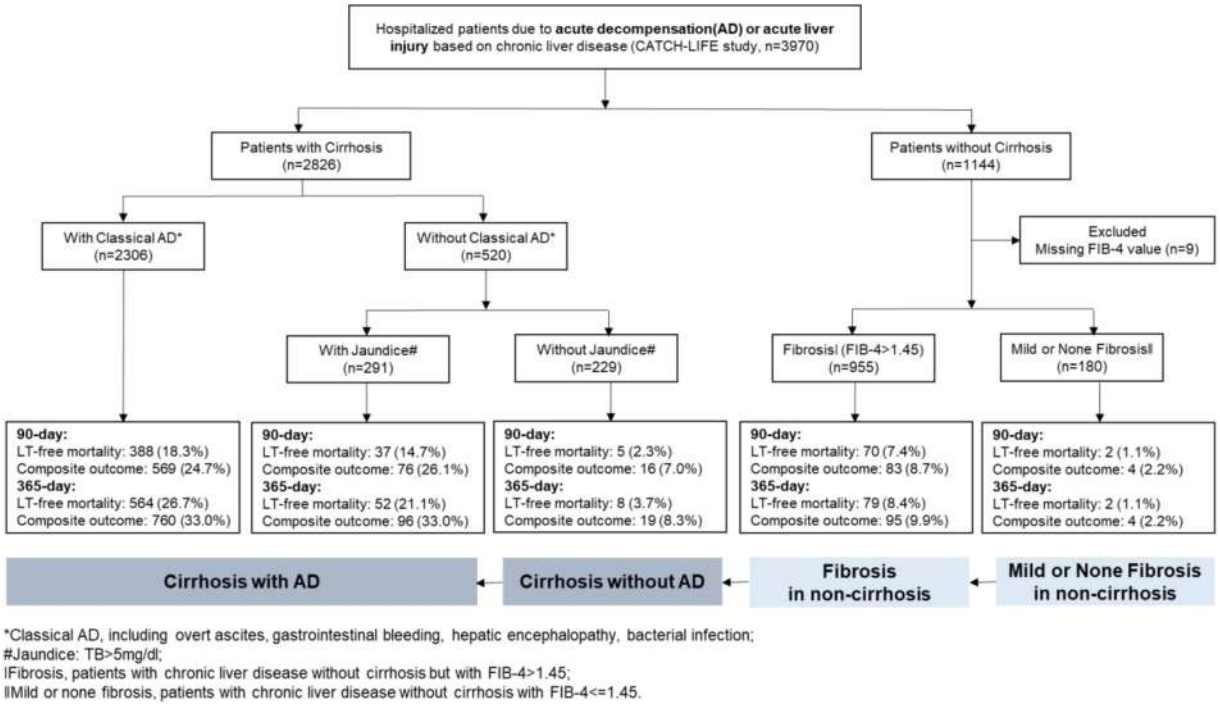
Email: haili_17@126.com

Background and aims: Little is known about the impact of predisposition, especially the severity of liver fibrosis, and the type of precipitants on the short-term prognosis in hospitalized patients with chronic liver disease. We aimed to evaluated the risk of predisposition and precipitants on the short-term prognosis in hospitalized patients with chronic liver disease.

Method: This study was performed in 3970 cirrhosis and other chronic liver disease patients hospitalized for acute decompensation



*Classical AD, including overt ascites, gastrointestinal bleeding, hepatic encephalopathy, bacterial infection;
#Jaundice: TB>5mg/dl;
IFibrosis, patients with chronic liver disease without cirrhosis but with FIB-4>1.45;
IIMild or none fibrosis, patients with chronic liver disease without cirrhosis with FIB-4<=1.45.

Figure: (abstract: THU504)

or acute liver injury from two prospective large multicenter studies in high-endemic HBV areas (NCT02457637 and NCT03641872). The primary end point was a composite outcome comprised of death and liver transplantation. We investigated the natural history of composite outcome within 1 year and assessed the risk of predisposition, precipitants for 90-day or 365-day composite outcome.

Results: In 2826 patients with cirrhosis, 2306 admitted for classical AD (including overt ascites, hepatic encephalopathy, gastrointestinal bleeding and bacterial infection) burden with high 90-day and 365-day composite outcome rate (24.7%, 33.0%), while 291 admitted without classical AD but with jaundice (TB >5 mg/dl) showed comparable high 90-day and 365-day composite outcome rate (26.1%, 33.0%). In 1144 patients without cirrhosis, 955 patients with advanced fibrosis (FIB-4 >1.45) burdened with relatively high 90-day and 365-day composite outcome rate (8.7%, 9.9%) when compared to those with mild or none fibrosis (2.2%, 2.2%). After adjusting age, gender, TB, INR, Creatine and sodium, the severity of liver fibrosis in non-cirrhosis had no impact of 90-day ($p = 0.222$) and 365-day composite outcome ($p = 0.581$). But the occurrence of cirrhosis significantly increased the risk for 90-day ($p < 0.001$, OR = 2.45) and 365-day ($p < 0.001$, OR = 3.09) composite outcome when compared to non-cirrhosis. Moreover, in patients with cirrhosis and AD, previous decompensation independently increased the risk of 365-day adverse outcomes by 1.39-fold ($p = 0.005$) and 365-day composite outcome by 1.85-fold ($p < 0.001$), and the risk of 90-day and 365-day adverse outcomes in patients with extrahepatic precipitants was significantly higher than that in patients with intrahepatic precipitants.

Conclusion: The severity of liver fibrosis did not impact the 90-day and 365-day composite outcome in patients without cirrhosis, but the occurrence of cirrhosis significantly increased the risk for 90-day and 365-day composite outcome. In cirrhosis, jaundice should be also recognized as a kind of AD owing to its contribution to the comparable high 90-day mortality. Moreover, in patients with cirrhosis and AD, long-term surveillance monitoring in patients with previous decompensation and intensive therapy targeting extrahepatic precipitants are suggested which could enhance disease management and decrease the mortality.

THU505

A study evaluating outcomes of a virtual specialist liver cirrhosis clinic

Claudia Moore-Gillon[1], Alex Cole[1], Maria Bashyam[1], Mathew Vithayathil[1], Rooshi Nathwani[1,2], David Koeckerling[2], Sujit Mukherjee[1,2], Benjamin H. Mullish[1,2], Maud Lemoine[1,2], Lucia Possamai[1,2], Heather Lewis[1,2], Nowlan Selvapatt[1,2], Ameet Dhar[1,2]. *[1]Imperial College Healthcare NHS Trust, United Kingdom; [2]Imperial College London, United Kingdom*
Email: c.moore-gillon@nhs.net

Background and aims: Managing patients in a specialist cirrhosis clinic improves survival. The COVID-19 pandemic necessitated the transition to virtual clinics (VC). We aimed to evaluate the clinical impact of VC on survival, admission and decompensation rates in cirrhotic patients managed in a specialist service.

Method: We retrospectively analysed cirrhotic patients who had a specialised VC from March to June 2020. Clinical parameters were collected at baseline and 6 months and compared with a cohort of patients reviewed face to face (F2F) in the same specialist cirrhosis clinics from March to June 2019. Patients with COVID-19 were excluded.

Results: 143 patients attended for VC, 129 for F2F review. Groups were matched for age, sex, aetiology, and Child Pugh grade (CP). There was no difference at 6 months in survival, change in MELD/UKELD, decompensation or need for ambulatory review in all cirrhosis grades combined or CP BandC subgroup alone ($p > 0.05$) (Table 1). Fewer patients were admitted in the VC vs the F2F group ($p = 0.01$) but this was not validated in CP BandC subgroup ($p = 0.28$). Fewer blood tests were ordered for the VC group ($p = 0.0001$). The VC group had longer delays for ultrasound HCC surveillance (<0.0001) without an increase in new HCC cases.

Table: Baseline Patient Demographics and 6 months' outcome (*p < 0.05, **p < 0.01)

	VC (n = 143)	**F2F** (n = 129)
Age-yrs (range)	61 (30–85)	60 (32–84)
Gender-no (%)		
Male	98/143 (69%)	93/129 (72%)
Main Aetiology-no (%)		
Alcoholic Liver Disease	90/143 (63%)	72/129 (56%)
Baseline Disease Severity		
CP A-no (%)	72/143 (50%)	59/129 (46%)
CP BandC-no (%)	71/143 (50%)	70/129 (54%)
MELD	10	11*
UKELD	50	51
Outcomes at 6 months:		
Survival (all)-no (%)	138/143 (97%)	125/129 (97%)
CP BandC	67/71 (94%)	66/70 (94%)
UKELD change (median)	0	0
CP BandC	−1	0
New decomp (all)-no (%)	30/143 (21%)	25/129 (19.4%)
CP BandC	25/71 (35%)	23/70 (44%)
Admissions (all)-no (%)	38/143 (27%)	53/129 (41%) **
CP BandC	29/71 (41%)	35/70 (50%)
Ambulatory Review (all)-no (%)	15/143 (11%)	12/129 (9%)
CP BandC	11/71 (16%)	11/70 (16%)
Blood tests ordered-no (%)	110/143 (77%)	124/129 (96%) **
CP BandC	54/71 (76%)	66/70 (94%) **
Delay in HCC surveillance –months	3.0 ± 2.4	1.7 ± 2.7 **
CP BandC	2.2 ± 2.0	1.2 ± 1.8 **
New HCC cases (all)- no (%)	2/143 (1%)	2/129 (2%)
CP BandC	1/71 (1%)	1/70 (1%)

Conclusion: VC have not resulted in poorer clinical outcomes, even in patients with decompensated cirrhosis. Access to ambulatory care was still required. Fewer blood tests ordered and completed in the VC group did not result in adverse outcomes and this raises the possibility of cost-saving. urther studies need to confirm the long-term clinical impact and cost-effectiveness of specialist VC in management of cirrhotic patients.

THU506

A novel metabolomics-based prognostic model shows superior diagnostic accuracy than MELD in chronic liver failure

Tobias Madl[1,2], Jakob Kerbl-Knapp[1], Florian Rainer[3], Philipp Douschan[3], Vanessa Stadlbauer[3], Alexander Avian[4], Gunther Marsche[5], Joan Claria[6], Rudolf E. Stauber[3]. *[1]Medical University of Graz, Molecular Biology and Biochemistry, Graz, Austria; [2]BioTechMed-Graz, Graz, Austria; [3]Medical University of Graz, Department of Internal Medicine, Graz, Austria; [4]Medical University of Graz, Institute for Medical Informatics, Statistics and Documentation, Graz, Austria; [5]Medical University of Graz, Division of Pharmacology, Graz, Austria; [6]European Foundation for the study of chronic liver failure, Barcelona, Spain*
Email: rudolf.stauber@medunigraz.at

Background and aims: Chronic liver failure is associated with multiple metabolomic alterations that are related to its severity and pronounced in acute decompensation (AD) and more so in acute-on-chronic liver failure (ACLF). We previously showed that high-density lipoprotein cholesterol (HDL-C) levels are reduced in patients with chronic liver failure, showing similar prognostic information as the model for end-stage liver disease (MELD). In the present study we aimed to determine whether a combination of metabolite parameters altered in chronic liver failure can yield superior prognostic accuracy for short- and intermediate-term survival.
Method: We studied a multinational cohort of patients with chronic liver failure of varying severity, including compensated cirrhosis (CC), AD and ACLF. Metabolomics analysis was performed by NMR spectroscopy and revealed several metabolites that were significantly associated with survival in univariate analyses. After checking intercorrelation of prognostic parameters by variance inflation factors (VIF), multivariable competing risk analysis was performed with death as the event and liver transplantation as a competing risk to identify independent predictors of survival. The performance of the new prognostic model was compared to that of MELD using ROC analysis (DeLong test) for 3-month, 1-year and 2-year survival.
Results: We included 423 patients (median age 58 years; 70% male; CC 54%/AD 35%/ACLF 11%; etiology alcohol 55%). Thirty-nine patients received liver transplantation, 160 patients died and 224 were censored. The risk of death (HR, 95%CI) increased with age (1.03, 1.00–1.07), ln (creatinine) (1.88, 1.13–3.13), ln (bilirubin) (1.75, 1.31–2.35), ornithine (0 vs. >0) (1.69, 1.06–2.69) and lower HDL-C (0.98, 0.97–1.00). While the performance of this multivariable model was similar to that of MELD in the prediction of 3-month survival, it was superior to that of MELD for 1-year and 2-year survival (Table).

	90-day survival	1-year survival	2-year survival
	AUROC (95%CI)		
Metabolomics-based model	0.88 (0.82–0.94)	0.90 (0.86–0.95)	0.87 (0.82–0.92)
MELD	0.87 (0.82–0.93)	0.85 (0.80–0.90)	0.81 (0.76–0.87)
p value (DeLong test)	0.934	0.006	0.004

Conclusion: A metabolomics-based prognostic model including age, creatinine, bilirubin, ornithine and HDL-C showed superior accuracy for prediction of 1-year and 2-year survival as compared to MELD. External validation is warranted to confirm our findings.

THU507

Uncovering monocyte transcription, functional and metabolic signatures in recovery and non-recovery ACLF patients

Rita Furtado Feio de Azevedo[1], Hannelie Korf[1], Markus Boesch[1], Silvia Radenkovic[1,2,3], Marie Wallays[1], Lena Smets[1], Lukas Van Melkebeke[1,4], Bart Ghesquière[2,3], David Cassiman[1,4], Philippe Meersseman[5], Hannah Van Malenstein[1,4], Frederik Nevens[1,4], Wim Laleman[1,4], Jef Verbeek[1,4], Schalk van der Merwe[1,4]. *[1]Laboratory Hepatology, KU Leuven, CHROMETA Department, Leuven, Belgium; [2]VIB Center for Cancer Biology, Metabolomics Expertise Center, Center for Cancer Biology, Leuven, Belgium; [3]KU Leuven, Metabolomics Expertise Center, Department of Oncology, Leuven, Belgium; [4]UZ Leuven, Department of Gastroenterology and Hepatology, Leuven, Belgium; [5]UZ Leuven, KU Leuven, Department of Internal Medicine, Leuven, Belgium*
Email: rita.azevedo@kuleuven.be

Background and aims: Cirrhosis is the end-result of a progressive chronic liver disease that may progress to the development of ascites, variceal hemorrhage, encephalopathy and hepatic decompensation. A precipitating event such as an infection can trigger a rapid deterioration of liver function and result in organ failure: acute-on-chronic liver failure (ACLF). It is a devastating clinical entity with a mortality exceeding 70% within a 28-day period in its most severe form. It is not known if these patients have infections due to a failure

of monocytes in dampening the production of pro-inflammatory mediators, or whether they trigger a prolonged anti-inflammatory response making these patients incapable to respond to a secondary infection. Likewise, the functional and metabolic defects in ACLF are incompletely understood, and this information may be the key to restoring immune dysfunction. We aim to study the dynamics of monocyte function during the course of ACLF progression and how this associates with disease outcome.

Method: We performed paired transcriptional, functional and metabolic analysis of CD14+CD16- monocytes at day 0 and 7 from ACLF patients to compare profiles in recovery vs non-recovery. ACLF patients with a CLIF-SOFA score of 2/3 with underlying chronic alcoholic liver disease and no corticoid therapy were included in the study and were followed for 28 days after admission.

Results: Transcriptomic analysis unraveled a distinct pattern between ACLF non-recovery and recovery at baseline together with expression differences between day 0 and 7 in each group. Non-recovery monocytes showed an impaired phagocytic capacity, oxidative response and incapability of inducing CD4+T cell proliferation and low capacity to trigger Tcell activation. Conversely, ACLF patients that recovered showed an improvement in phagocytic and oxidative burst capacity from day 0 to 7, and despite being inefficient in triggering Tcell proliferation they featured an intact ability to induce T cell activation. In addition, monocyte metabolic profile of recovery patients clustered separately from non-recovery ACLF patients at day 0. And, the monocyte metabolic profile clustered separately day 0 from 7 on both groups.

Conclusion: The immune phenotype seen in monocytes from ACLF patients that recover can effectively respond to an infectious challenge. In stark contrast monocytes from non-recovery ACLF patients showed a functional impairment, which renders these patients susceptible to new infections.

THU508

Early initiation of continuous renal replacement therapy improves renal outcomes and survival in patients with acute on chronic liver failure-a prospective cohort study

Rakhi Maiwall[1], Ashini Hidam[2], Sonia Kadyan[1], Mansi Singh[1], Anupam Kumar[2], Rajendra Mathur[3], Harshvardhan Tevethia[1], Hitesh Singh[3], Siva Tez Pv[3], Shiv Kumar Sarin[1]. *[1]ILBS, Hepatology, New Delhi, India; [2]ILBS, Clinical and Molecular Medicine, New Delhi, India; [3]ILBS, Nephrology, New Delhi, India*
Email: shivsarin@gmail.com

Background and aims: Systemic inflammatory response syndrome (SIRS) is a driver of acute kidney injury (AKI) in patients with acute-on-chronic liver failure (ACLF). Early initiation of continuous renal replacement therapy (CRRT) improves outcomes in patients with acute liver failure, however there are no studies in patients with ACLF. We aimed to investigate the impact of initiation strategy of CRRT on AKI outcomes in patients with ACLF. Our primary outcome was to evaluate predictors of renal recovery. Our secondary outcomes included lactate and ammonia clearance, impact of CRRT on systemic inflammation, endothelial function and adverse effects. Early initiation group (EG) was defined as initiation of CRRT within 24 hours of initiation of vasopressors (norepinephrine or terlipressin)

Method: Prospective cohort of ACLF patients admitted to the intensive care unit. In all patients, urine and plasma samples were collected at baseline and 24 hours for analysing the impact of CRRT on markers of inflammation, endothelial function, renal injury and repair. Clinical, hemodynamic and lung parameters (VolumeView system, Edwards Lifesciences) and blood gas parameters were recorded.

Results: Thirty patients with ACLF [early group (EG, n = 15) and late group (LG, n = 15)], aged 43.33 ± 10.1; 87% males, 70% alcoholics with mean MELD 37 ± 5, AARC 10 ± 1.61 and SOFA 14 ± 2.55 score were enrolled. The median time to CRRT after onset of AKI was [44 ± 7.1 vs. 113.6 ± 40] hours and after initiation of vasopressors was [(14.3 ± 7.56) vs. (49.7 ± 17.8)] hours in EG vs. LG respectively ($p < 0.001$). Only 36.7% had renal recovery and shock at day 7 (dialysis responders-DR), majority in the EG [60% vs. 13.3%; $p = 0.008$]. A significant improvement in SIRS, extravascular lung water (EVLW), pulmonary vascular permeability index, arterial lactate and ammonia was noted in dialysis-responders (DR) compared to non-responders ($p < 0.05$). A significant decrease in the renal injury markers and increase in renal repair markers [Figure] was noted in DR compared to non-responders. Responders had lower 15-day mortality [18% vs. 58%; HR 0.21, 0.05–0.96; $P = 0.045$]. Time to CRRT after initiation of vasopressors [OR 0.93, 0.88–0.99] and SOFA score [OR 0.54, 0.32–0.93] were independently associated with dialysis response. Each hour delay in CRRT initiation was associated with 7% decreased chances of renal recovery. The most frequent adverse event was bleeding (40%) followed by hypotension (30%).

Conclusion: Only one in three patients of ACLF achieve renal recovery with CRRT. Response to CRRT is associated with improvement in hemodynamics, systemic inflammation, endothelial and renal function. Each hour delay in CRRT after onset of shock and higher SOFA score are associated with decreased chances of renal recovery and worse outcomes in patients with ACLF.

THU509

Different clinical courses of acutely decompensated cirrhosis in hepatitis B virus high-endemic area: data from Chinese Acute-on-Chronic Liver Failure (CATCH-LIFE) study

Tongyu Wang[1], Yu Shi[2], Hai Li[1]. *[1]Shanghai, China; [2]Hangzhou, China*
Email: haili_17@126.com

Background and aims: Cirrhotic patients with acute decompensation (AD) have different clinical course and pathophysiology base on the PREDICT study in a predominately alcohol-related etiologic population: pre-ACLF (acute-on-chronic liver failure), UDC (unstable decompensated cirrhosis) and SDC (stable decompensated cirrhosis) patients with different pathophysiology and prognosis. However, in hepatitis B virus (HBV) high-endemic area, the characteristics of these three subtypes are not well characterized. The aims of this study were to explore the characteristics and outcomes of different clinical courses within 1 year.

Method: We identified 2597 cirrhotic patients with AD from a prospective multi-center cohort with 66.85% HBV-related etiology and explored the disease dynamics and prognosis within 1 year. Clinical and biological parameters during hospitalization, 3-month re-admission and outcomes during follow-up were collected. Pre-ACLF was defined as patients developed ACLF within hospitalization. Subgroup analysis was conducted based on etiology, prognostic scores were recorded to predict outcomes in ACLF, UDC and SDC patients, respectively.

Results: Totally, 2188 AD without ACLF at baseline were identified. There are 184 (8.41%) pre-ACLF patients with 3-month and 1-year LT-free mortality rates of 60.49% and 70.93%, respectively. 663 UDC (27.38%) patients had at least one readmission within 3 month and had no ACLF development during hospitalization, with 22.05% and

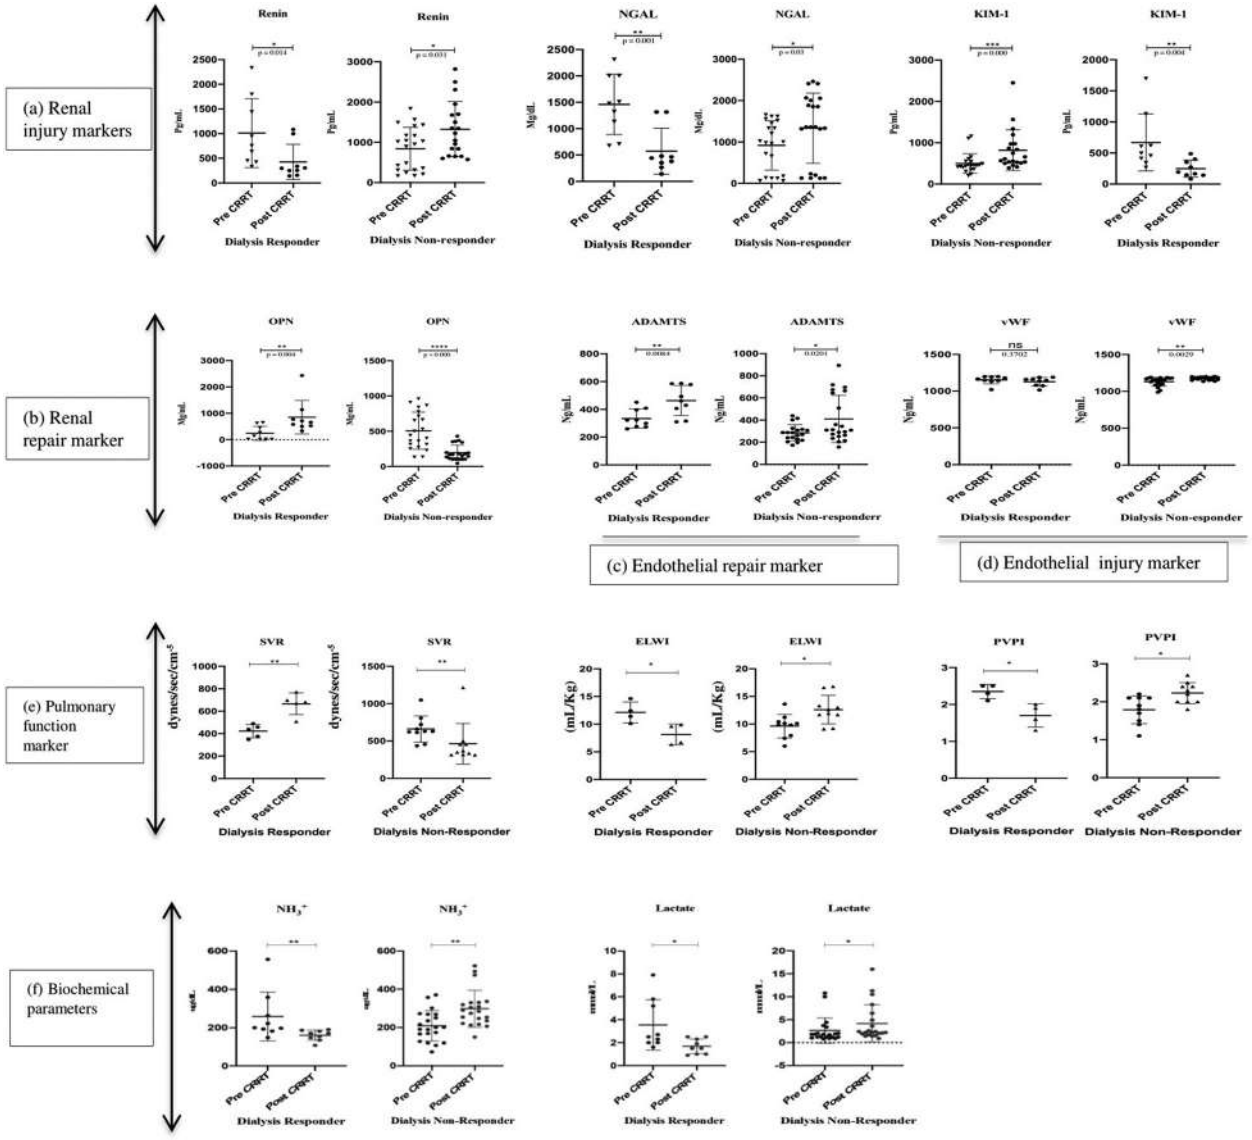


Fig. (a) In urine marker analysis, renal injury markers such as NGAL (neutrophil gelatinase-associated lipocalin), renin and KIM-1 (kidney injury molecule-1) were significantly elevated after post RRT (renal replacement therapy) in dialysis non-responder (D-NR) ACLF patients, while these markers were declined after post therapy in case of dialysis responders (DR). Also, the renal repair marker OPN (osteopontin) was significantly increased after post therapy in DR as compared to D-NR. In vascular functional analysis, vascular protective marker ADAMTS (a disintegrin and metalloproteinase with thrombospondin motifs) was significantly elevated after RRT in DR as compared to D-NR. On the other hand, vascular injury marker vWF (Von Willebrand factor) was significantly increased after therapy in D-NR in comparison to DR. Further, patients with DR showed improvement in (e) pulmonary functions [extravascular lung water (ELWI) (ml/kg), pulmonary vascular permeability index (PVPI) and systemic vascular resistance (SVR) dynes·sec·cm^{-5}], and (f) reduction of arterial lactate and serum ammonia (umol/L).

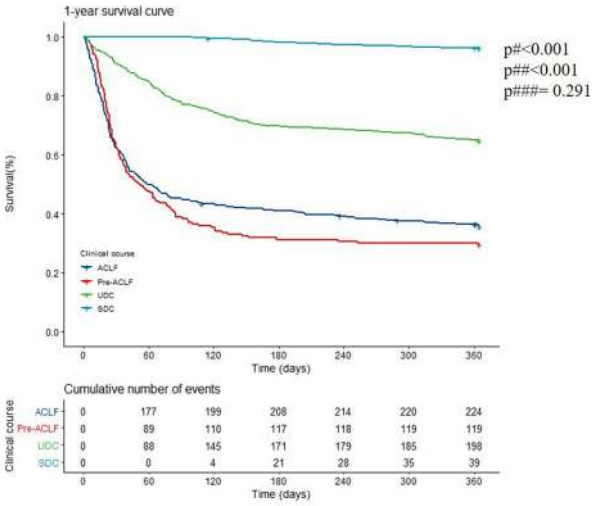
Figure: (abstract: THU508)

35.27% mortality rates. 1232 (49.36%) SDC patients had neither readmission within 3 months nor ACLF development, with 3.42% 1-year mortality. Systemic inflammation parameters including WBC, CRP and PCT increased markedly in pre-ACLF group, while had no significant differences between UDC and SDC group. Portal hypertension related complications including variceal haemorrhage and portal vein thrombosis proportion were significantly higher in UDC group than those in SDC group.

Figure Comparison of 1-year survival between different clinical courses of hospitalized patients with cirrhosis (LT-free mortality).



Annotation:
p# denotes p value for comparisons between UDC and SDC group patients;
p## denotes p value for comparisons between UDC and pre-ACLF group patients;
p### denotes p value for comparisons between ACLF and pre-ACLF group patients;

Conclusion: The recently proposed different courses of hospitalized decompensated cirrhosis with AD are validated in a multi-center large cohort. The systemic inflammation marked ACLF development in cirrhotic AD patients during hospitalization, whereas severe portal hypertension related complications are related to unstable episode of decompensation exclusively, without apparent variation of systemic inflammation. Developing a 90-day readmission prediction model for the rational management of patients with decompensated cirrhosis is necessary.

THU510

Characterization of energy and substrate metabolism in patients with spontaneously breathing and mechanically ventilated patients with liver cirrhosis: an indirect calorimeter based study

Varsha Shasthry[1], Jaya Benjamin[1], Rakhi Maiwall[2], Vandana Saluja[3], Prashant Mohan Agarwal[3], Guresh Kumar[4], Yogendrakumar Joshi[1], Shiv Kumar Sarin[2]. *[1]Institute of liver and biliary sciences, Clinical Nutrition, New Delhi, India; [2]Institute of liver and biliary sciences, Hepatology, New Delhi, India; [3]Institute of liver and biliary sciences, Critical care anesthesia, New Delhi, India; [4]Institute of liver and biliary sciences, Biostatistics, New Delhi, India*
Email: jayabenjaminilbs@gmail.com

Background and aims: Energy and substrate metabolism is anomalous in liver cirrhosis (LC), which may be affected by critical illness. Indirect calorimetry (IC) provides a precise insight into the same.

Aim: To compare the resting energy expenditure (REE- Kcal/day), volumes (ml/min) of oxygen consumed (VO_2) and carbon dioxide released (VCO_2), respiratory quotient (RQ-VCO_2/VO_2), percentage oxidation of carbohydrate (CHO), fat (FO) and protein (PO), between spontaneously breathing LC (sLC), ventilated LC (vLC), ventilated acute on chronic liver failure (vACLF) patients and healthy controls (HC).

Method: In 20 HC and 129 patients with LC [sLC: vLC: vACLF (%)-36:38:26; all males], 24 hour urinary urea nitrogen (UN- g/day) and IC (Quark RMR) was performed after 6 hrs of fasting; within 24 hrs of intubation, following calibration and steady state attainment. Metabolic state [measured REE (IC)/predicted REE (Harris-Benedict equation)*100] was defined as hyper (>110%), hypo (<90%) and normometabolic (90–110%).

Results: The clinical and metabolic characteristics are shown in table 1. Compared to HC, all 129 LC patients had increased REE and a state of accelerated starvation (AS) [low RQ; low CHO; high FO]. Among LC, vACLF had highest REE. Critical illness (sLC vs. vLC) worsens AS (RQ: 0.81vs.0.74) commensurate to incomplete macronutrient oxidation (VCO_2:185 vs.164) with a comparable REE. The prevalence of hypermetabolism was higher in vACLF (38%); hypometabolism was higher in vLC (45%). UN excretion and PO remained comparable.

Table 1: Age and BMI adjusted comparison of clinical and metabolic characteristics

Parameter	1 (HC) (n–20)	2 (sLC) (n–46)	3 (vLC) (n–49)	4 (vACLF) (n–34)	Overall p	Intergroup-p

Data expressed in mean ± SE

Conclusion: Accelerated starvation is the hallmark in LC, that worsens with critically illness. vACLF have highest energy expenditure. Critical illness does not augment energy demands in vLC patients. This characterisation may help to redefine nutritional targets in critically ill LC.

THU511

Extracorporeal membrane oxygenation, a valuable life-saving treatment in liver transplanted patients

Benjamin Buchard[1,2], Sophie-Caroline Sacleux[2,3], Samir Jaber[4], François Stéphan[5], Alain Combes[6], Elise Lemaître[2], Marc Boudon[2,3,7], Audrey Coilly[2,3,7], Faouzi Saliba[2,3,7], Didier Samuel[2,3,7], Armand Abergel[1], Philippe Ichai[2,3]. *[1]Chu Estaing, Medecine digestive et hépatobiliaire, Clermont-Ferrand, France; [2]Chb-Centre Hépato-Biliaire, Liver Intensive Care Unit, Villejuif, France; [3]DHU Hepatinov, Villejuif, France; [4]University Hospital Center Saint Eloi Hospital, Department of Anesthesiology and Intensive Care, Montpellier, France; [5]Hospital Marie Lannelongue, Département de réanimation adulte, Le Plessis-Robinson, France; [6]University Hospitals Pitié Salpêtrière-Charles Foix, Département de réanimation médicale, Paris, France; [7]Université Paris-Saclay, INSERM Unité 1193, Villejuif*
Email: benjamin.buchard@gmail.com

Background and aims: Despite a great improvement in post-liver transplantation (LTx) survival over the last years, multiple organ failure still accounts for 5% of deaths following surgery. ExtraCorporeal Membrane Oxygenation (ECMO) is a salvage therapy providing circulatory and/or ventilatory assistance. Outcomes following ECMO initiation remain uncertain. The procedure itself can lead to bleeding and sepsis, especially in immunocompromised patients. Data on outcome and safety of ECMO after LTx are

scarce. The aim of this retrospective study was to assess both survival and safety under ECMO in post-LTx.
Method: We retrospectively reviewed all LTx patients undergoing veno-venous (VV) or arterio-venous (AV) ECMO between 2010 and 2020 in three LTx centers. We collected data about liver disease before transplantation, indication for ECMO, number of organ failure including Sequential Organ Failure Assessment (SOFA) score, outcomes and complications under ECMO.
Results: Twenty six transplanted patients were referred to an ECMO centre. Five were contraindicated for ECMO as they were considered as too critically ill. ECMO was initiated in 21 out of 26 transplanted patients (80%). 13/21 (62%) had VA ECMO and 8/21 (38%) a VV ECMO. Five patients underwent VA ECMO following cardiac arrest (n = 5). Others developed cardiogenic shock due to: Takotsubo syndrome (n = 2), infectious myocarditis (n = 2), refractory sepsis (n = 1), severe ischemia-reperfusion syndrome (n = 1), right ventricular failure secondary to pulmonary hypertension (n = 1) and unknown biventricular failure (n = 1). The main indication for VV ECMO was septic acute respiratory distress syndrome (ARDS) (n = 7). The other patient developed refractory transfusion-related acute lung injury. Median delay between LTx and ECMO was 10 days. Median duration of VA ECMO and VV ECMO until patient's death or ECMO withdrawal was respectively 2 and 10 days. The survival rates at day 30, in patient treated with VA ECMO and VV ECMO, were 38.5% (5/13) and 37, 5% (3/8) respectively (figure). In total, 11/13 (84.7%) patients died from multiorgan failure and 2 from brain death. One third of patients (7/21) presented bleeding during ECMO, mainly at the insertion site of cannulas (n = 5). Sepsis occurred in 4/21 patients. No liver graft dysfunction was observed in these patients treated with ECMO. The 30-days post-ECMO survival was significantly associated with SOFA score at the initiation (14 in survivors vs. 16 in non-surviving patients, p = 0.03) and 24 hours after initiation of ECMO (12 in survivors vs. 18 in non-surviving patients p = 0.04).

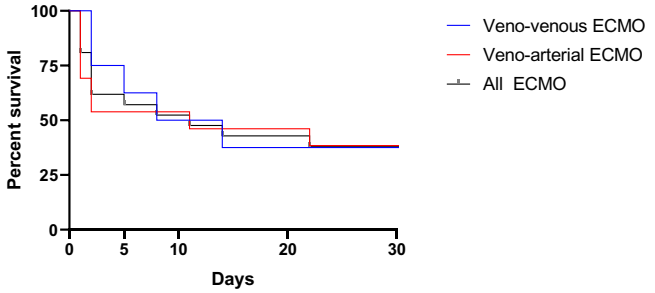

Figure: Survival of transplanted patients during the first 30 days following ECMO initiation

Conclusion: ECMO in liver transplanted patients should be considered as a salvage treatment for refractory respiratory and/or circulatory failure. Our work reveals similar survival under ECMO compared to the general population.

THU512

Prevalence, profile and predictors of invasive fungal infections in acute on chronic liver failure (ACLF): analysis of APASL-ACLF research consortium database

Pratibha Ramchandra Kale[1], Ashok Choudhury[2], Vikas Khillan[1], Niharika Patel[2], Sarin Shiv Kumar[2]. *[1]Institute of Liver and Biliary Sciences, Clinical Microbiology, New Delhi, India; [2]Institute of Liver and Biliary Sciences, Hepatology, New Delhi, India*
Email: drpratibhapgi@gmail.com

Background and aims: Acute-on-chronic liver failure (ACLF) causes immune dysregulation and increased susceptibility to fungal infections. We studied the epidemiology and risk factors associated with invasive fungal infections (IFI) in ACLF. We correlated the timing of occurrence, predictors of development, diagnostic potential of biomarkers, antifungal prophylaxis with the outcome of IFI.
Method: The demographic, clinical and laboratory characteristics of ACLF patients, admitted to ILBS, developing IFI were studied retrospectively based on the APASL ACLF Research Consortium (AARC) data base. The diagnosis of IFI was based on revised definitions of invasive fungal disease from the European organization for research and treatment of cancer/Invasive fungal infections cooperative group and the national institute of allergy and infectious diseases mycoses study group (EORTC/MSG) consensus group. We also measured the biomarkers in bronchoalveolar lavage (BAL) and serum Galactomannan index (GMI).
Results: Amongst 1670 ALCF patients, 320 (19.16%) had recent history of neutropenia, prolonged use of corticosteroids or immunosuppressive therapy, and sufficient clinical evidence consistent with IFD but no mycological evidence were classified as possible IFI. Sixty (3.6%) patients who had host factors, clinical features, and mycological evidence consisting of direct test (cytology, direct microscopy, or culture) and indirect test, positive Galactomannan assay, were classified as probable IFI. Amongst the probable IFI group, the most common site of infection was urinary tract (n = 42/60, 70%) followed by respiratory (n = 12/60, 20%) and blood (n = 6/60, 10%). On univariate analysis, prior antibiotic use, high total leucocuyte count (TLC), acute renal failure, hemodialysis, diabetes mellitus, multiorgan failures, were predictors for development of IFI ($p < 0.05$). On multivariate analysis, TLC >$14.3 \times 10^3/ml^3$, multiorgan failure, hemodialysis and prior antibiotics use predicted the development of IFI ($p < 0.05$). IFI occurrence was associated with significantly high 30 and 90 day mortality ($p < 0.001$). 68.4% patients with IFI in the first 7 days of enrolment died as compared to 47.9% in control group ($p = 0.002$). BAL GMI (cut-off >1) was positive in 38/60 (63.33%) and serum GMI was positive in 11/60, (18.33%). BAL GMI above 3.25 was a better predictor of IFI (sensitivity 72.7%, specificity 51.5%).
Conclusion: Invasive fungal infections cause high mortality in ACLF patients. High TLC at admission, multiorgan failure, hemodialysis, prior antibiotics usage and high BAL GMI predict the development of IFI. High vigilance, early diagnosis and initiation of anti-fungal therapy is essential to prevent mortality due to IFI in ACLF.

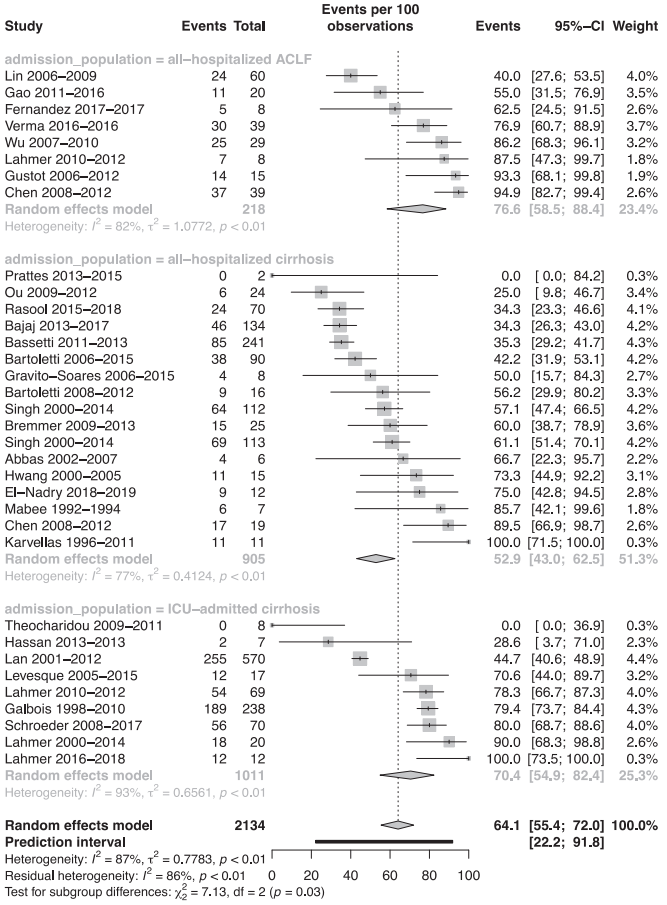
THU513

Outcomes in patients with cirrhosis and fungal infections: a systematic review and meta-analysis with machine learning

Nipun Verma[1], Shreya Singh[2], Akash Roy[3], Arun Valsan[1], Pratibha Garh[1], Pranita Pradhan[4], Meenu Singh[5]. *[1]Postgraduate Institute of Medical Education and Reserach, Hepatology, Chandigarh, India; [2]Postgraduate Institute of Medical Education and Reserach, Microbiology, Chandigarh, India; [3]Sanjay Gandhi Postgraduate Institute of Medical Sciences, Hepatology, Lucknow, India; [4]Postgraduate Institute of Medical Education and Reserach, Pediatrics, Chandigarh, India; [5]Postgraduate Institute of Medical Education and Reserach, Pediatrics, Chandigarh, India*
Email: nipun29j@gmail.com

Background and aims: Fungal infections (FIs) are an emerging threat in patients with cirrhosis. Due to the lack of systematic data, we performed a comprehensive literature search to systematically evaluate the impact of FIs on mortality and contributory factors in cirrhosis patients.
Method: PubMed, Embase, Ovid, and Web of Science were searched since their inception till Oct 30, 2020, for full-text articles describing mortality in cirrhosis patients with FIs. Point and relative-risk estimates of mortality were pooled on random-effects meta-analysis, and their variation (I^2) was explored on subgroups, meta-regression, and machine learning (ML). Quality of studies was evaluated with the New-castle Ottawa scale and estimate's asymmetry with a funnel plot and Eggers regression. (CRD42019142782)

Results: Of 4345, 34 studies (2134 patients) were included (good/fair/poor quality: 12/21/1). The pooled mortality of patients with FIs was 64.1% (95% CI: 55.4–72.0, I^2: 87%, p < 0.01). Patients with proven, probable, and proven + probable FIs had a mortality of 61.4%, 73.6%, and 63.8%, respectively. Patients with acute-on-chronic liver failure (ACLF: 76.6%) and intensive care unit admission (ICU: 70.4%) had a higher mortality than all-hospitalized patients (52.9%), p = 0.03 (Figure 1). Significant variation in mortality estimates was identified on geographic dimensions and site of infection. The highest mortality was noted in pulmonary-FIs (79.4%), followed by peritoneal-FIs (68.3%) and fungemia (55%). On meta-regression, MELD of cases was identified as a predictor of mortality; adjusted estimate: 64.5% (54.5–83.9). The mortality among patients with FIs was 1.7 (1.4–2.1) and 2.9 (1.8–4.9) times higher than bacterial infections and non-infected controls. The relative risk persisted above 1.5 times in ICU-admitted and ACLF patients as well. After adjusting for the proportion of bacterial infection in controls, the relative risk was 2.16 (1.85–2.53). Asymmetry was evident in point-estimate and relative-risk estimates of FIs. Three k-means clusters, 2 DBSCAN clusters, 8 GMM clusters, and 5 outlier studies were detected on ML. On excluding these, the estimate's heterogeneity was abolished (I^2:0%, p = 0.68). Estimates did not vary as per the quality of the study.



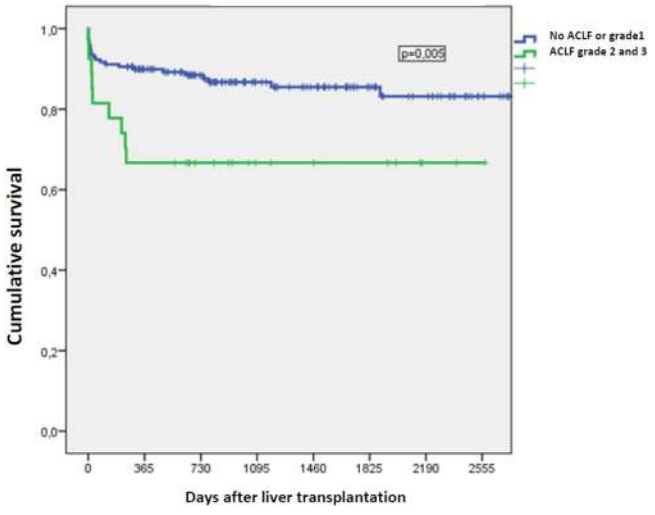
Conclusion: About 2/3rd cirrhosis patients with FIs die with the highest risk of death among ACLF and ICU patients. FIs are more serious than bacterial infections and warrant dedicated efforts in the cirrhosis patients.

THU514

Impact of de presence of acute on chronic liver failure on morbi-mortality after liver transplantation

Carlos Benitez[1], Verónica Cambindo Santana[1], Jorge Arnold[1,2].
[1]*Pontificia Universidad Catolica, Hepatologia, santiago, Chile;* [2]*Pontificia Universidad Católica de Chile, Gastroenterología*
Email: vcambindo@gmail.com

Background and aims: Acute over chronic liver failure (ACLF) implies high short-term mortality. The impact of its presence at the time of liver transplantation (LT) has been less studied.
Objectives: To evaluate the impact of ACLF on post-LT survival.
Method: A retrospective registry of 263 liver recipients between 2013 and 2020 was evaluated; 197 patients met the inclusion criteria and their survival and complications were recorded at one year of follow-up.
Results: The average age was 57.1 ± 10.5, men 55.3%, MELD Na 23.15 ± 9.76. The main etiologies were MAFLD (35.5%), alcohol (12.7%), autoimmune hepatitis (9.6%), PBC (9.1%) and HCV (7.6%). 22.5% of the patients developed ACLF. One year survival of those transplanted without ACLF, ACLF grade 1, grade 2, and grade 3 were 89.8%, 91.7%, 66.7%, and 66.7%, respectively (p = 0.042). Survival of those without ACLF and grade 1 vs grade 2 and 3 were 90% vs 66.7% (p = 0.005) (figure). Transplant patients with grade 2–3 ACLF had more post-LT bacterial infections 59.3% vs 36.5% (p = 0.024), a higher frequency of mechanical ventilation 46.2% vs 19.4% (p = 0.003) and renal replacement therapy (RRT) (42.3% vs 11.6% (p = <0.001). In the multivariate analysis, the variables independently related to survival were the requirement for mechanical ventilation before LT (OR 4.3, p = 0.026, CI (1.19–15.62) and RRT post LT (OR 2.95. p = 0.39, CI (1.05–8.2).



Conclusion: The presence of ACLF grade 2 and 3 at the time of LT is associated with marked reduction of one year patient survival.

Untargeted lipidomics differentiate ACLF precipitated by severe alcoholic hepatitis

Florent Artru[1,2], Stephen Atkinson[1], Ewan Forrest[3], Francesca Trovato[2], Nikhil Vergis[1], Vishal C Patel[2,4,5], Salma Mujib[2], Anna Cavazza[2], Alexandros Pechlivanis[1], Ellen Jerome[2], Marc Zentar[2], Evangelos Triantafyllou[1], Elaine Holmes[1], Mark J W McPhail[1,2], Mark Thursz[1]. *[1]Imperial College London, London, United Kingdom; [2]Institute of Liver Studies, King's College Hospital, London, United Kingdom; [3]UNiversity of Glasgow, Glasgow, United Kingdom; [4]The Roger Williams Institute of Hepatology London, Foundation For Liver Research, London, United Kingdom; [5]Institute of Liver Sciences, King's College London, Department of Inflammation Biology, School of Immunology and Microbial Sciences, FoLSM, London, United Kingdom*
Email: florent.artru@kcl.ac.uk

Background and aims: Severe alcoholic hepatitis (SAH) is a common cause of acute on chronic liver failure (ACLF). Patients with SAH-ACLF present intense systemic inflammation and immune dysfunction. While lipids are involved in inflammatory and immune responses, lipidomics is understudied in the setting of SAH-ACLF. We evaluated whether specific changes in the blood lipidome are observed in ACLF precipitated by SAH.

Method: Untargeted serum lipidomics was performed using reversed phase ultra-performance liquid chromatography coupled to mass spectrometry in patients with SAH participating in the STOPAH trial (n = 154–46 with ACLF labelled SAH-ACLF) and with cirrhosis (n = 74–21 with ACLF labelled Cirrh-ACLF). Serum lipidome changes between patients with and without ACLF in SAH and cirrhosis groups were evaluated by principal component analysis (PCA) and orthogonal partial least squares discriminant analysis (OPLS-DA).

Results: MELD score was higher in patients with SAH without ACLF vs. cirrhotics without ACLF (20.7 vs. 11.3, $p < 0.0001$) but matched between patients with SAH-ACLF vs. Cirrh-ACLF (26.1 vs. 24.7, $p = 0.4$). PCA and OPLS-DA analyses were not able to accurately discriminate between SAH with or without ACLF (OPLS-DA in positive mode $R^2Y = 0.14$ $Q^2 = 0.06$ CV-ANOVA $p = 0.01$ AUROC = 0.71 and negative mode $R^2Y = 0.18$ $Q^2 = 0.04$ $p = 0.22$ AUROC = 0.62). Importantly, PCA and OPLS-DA did accurately discriminate between SAH-ACLF and Cirrh-ACLF (OPLS-DA in positive mode: $R^2Y = 0.78$ $Q^2 = 0.49$ CV-ANOVA <0.0001 AUROC = 0.91; in negative mode: $R^2Y = 0.66$ $Q^2 = 0.4$ $p < 0.0001$ AUROC = 0.88) (Figure 1). The 10 metabolites showing the greatest variable importance projection were included in multivariate analyses adjusting for age, sex and MELD score. Two lipids in positive mode (PE P-38:4, PE P-36:3) and negative mode (PC 41:5, LPC 14:0) disclosed independent associations with SAH-ACLF (Figure 1). Using these lipids, we derived 2 scores relating to positive and negative ionisation modes; both accurately discriminated SAH-ACLF from Cirrh-ACLF with an AUROC of 0.86 (CI95% 0.73–0.93, $p < 0.0001$, sensitivity 76% specificity 88%) and 0.82 (CI95% 0.68–0.90, $p < 0.0001$, sensitivity 71% specificity 84%).

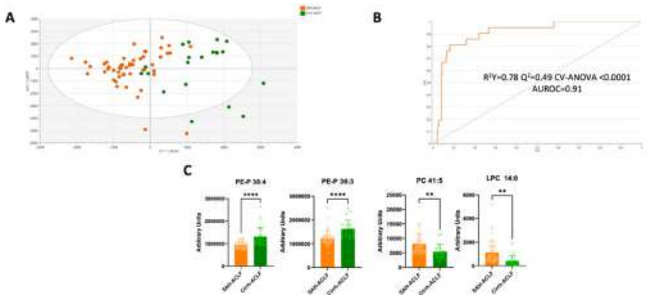

Figure: A. OPLS-DA in positive mode. B. ROC curve of OPLS-DA model in positive mode. C. Univariate analyses of the lipids included in the 2-lipids models in positive (PE-P38:4, PE-P36:3) and negative modes (PC41:5, LPC14:0).

Conclusion: This lipidomic analysis of the STOPAH cohort demonstrates a specific lipidomic signature- mainly composed of species that are known to be involved in immune-modulatory functions and liver repair-in patients with SAH-ACLF. These pathways require further exploration on their diagnostic and mechanistic role in the development of SAH-ACLF compared to other cause of ACLF.

THU517

Metabolomic analysis of organ failure marker compounds in blood samples of patients with decompensated liver cirrhosis after administration of the novel drug VS-01

Frank Uschner[1], Wenyi Gu[1], Olaf Tyc[1], Martin Schulz[1], Philip Ferstl[1], Katharina Katharina Staufer[2], Stoffers Philipp[1], Hans-Peter Erasmus[1], Johannes Masseli[1], Kai-Henrik Peiffer[1], Fabian Finkelmeier[1], Anita Pathil-Warth[1], Jörg Bojunga[1], Stefan Zeuzem[1], Meriam Kabbaj[2], Jonel Trebicka[1,3]. *[1]Department of Internal Medicine I, University Hospital Frankfurt, Frankfurt, Germany; [2]Versantis AG, Zurich, Switzerland; [3]European Foundation for the Study of Chronic Liver Failure, Barcelona, Spain*
Email: jonel.trebicka@kgu.de

Background and aims: Acute-on-chronic liver failure (ACLF) is defined by the presence of organ dysfunctions and failures in decompensated cirrhosis and is associated with high short-term mortality. VS-01 is a novel intraperitoneal (i.p.) pH-gradient liposomal infusion drug that enhances the clearance of ammonia and other potentially harmful metabolites. This study analyzed metabolite clusters already described to be involved in organ failure (OF) of liver, brain and kidney in patients with liver cirrhosis (Moreau et al. 2019) in the phase 1b clinical trial of VS-01 (Eudra no.: 2018-004606-25).

Method: VS-01 was infused in the peritoneal cavity of the patients and removed by paracentesis after two (part A) or three hours (part B). Patients received a single dose of 15, 30 or 45 ml/kg VS-01 (Part A; n = 9) or four consecutive doses of 34–42 ml/kg VS-01 (Part B; n = 3). Metabolomic analysis was performed on plasma samples of patients with ascites and covert hepatic encephalopathy (HE) using an untargeted LC/MS analysis approach. Peak areas were extracted and peak lists containing the mass features and identified compounds were exported to MetaboAnalyst 5.0 for statistical analysis.

Results: In the whole dataset, 24 out of 65 highly upregulated OF metabolites were detected. In part A of the study, we were able to detect 19 OF metabolites in plasma samples, of which 11 showed a decreasing trend in the plasma samples of the patients up to 24 hours after infusion of VS-01. In part B of the study, we could detect 10 OF metabolites in plasma samples of which 7 metabolites showed a decreasing trend during the infusion of VS-01 (Figure 1).

Conclusion: VS-01 is a novel drug, which is able to reduce metabolites that are associated with organ failures e.g. brain, liver and kidney failure. The current metabolic results support the future development of VS-01 in patients with ACLF and organ failure.

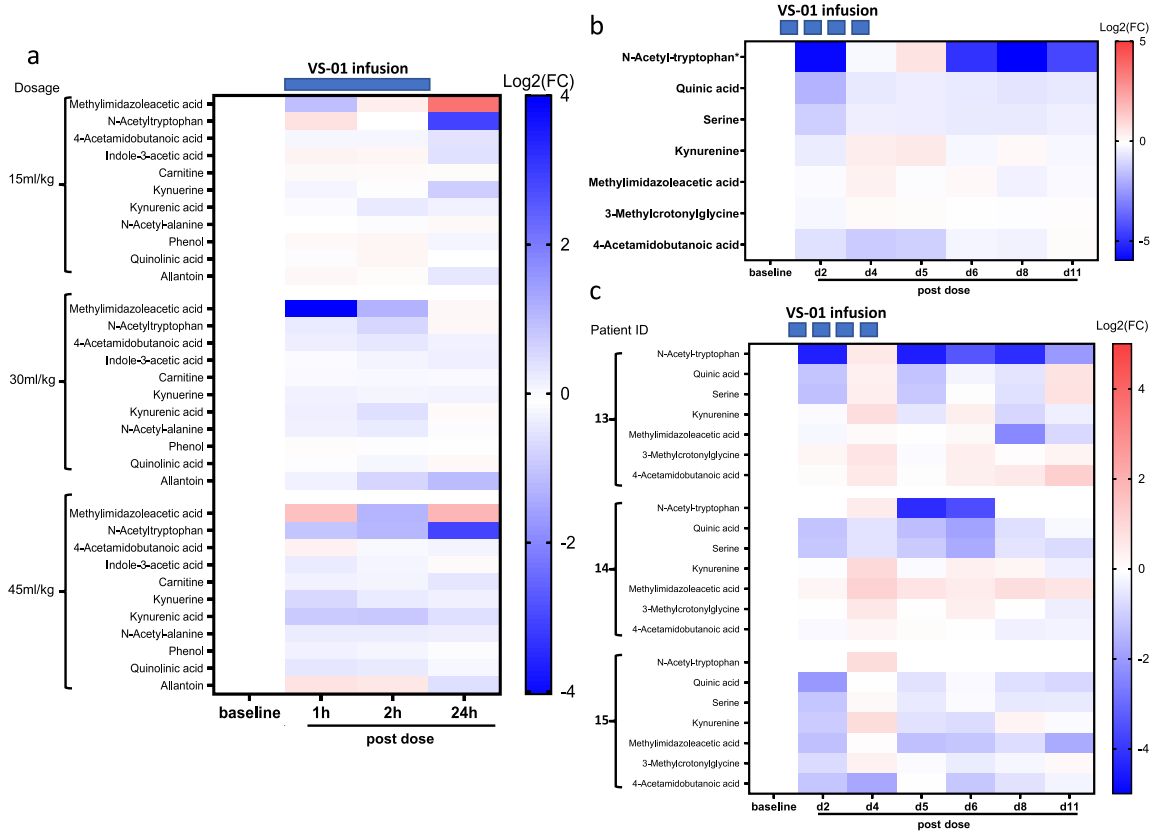

Figure: (abstract: THU517): Heatmap of log2 (fold-change) reduced organ failure markers in plasma samples of study A shown per dosage (a) and study B shown per marker compound (b) and per patient (c) after administration of VS-01 (red = high/Blue = low). *, FDR < 0.05.

THU518

Metabolomic analysis of bacterial infection markers in blood samples of patients with decompensated liver cirrhosis infused with the novel drug VS-01

Frank Uschner[1], Olaf Tyc[1], Wenyi Gu[1], Martin Schulz[1], Philip Ferstl[1], Katharina Staufer[2], Philipp Stoffers[1], Hans-Peter Erasmus[1], Johannes Masseli[1], Kai-Henrik Peiffer[1], Fabian Finkelmeier[1], Anita Pathil-Warth[1], Jörg Bojunga[1], Stefan Zeuzem[1], Meriam Kabbaj[2], Jonel Trebicka[1,3]. *[1]Department of Internal Medicine I, University Hospital Frankfurt, Frankfurt, Germany; [2]Versantis AG, Zurich, Switzerland; [3]European Foundation for the Study of Chronic Liver Failure, Barcelona, Barcelona, Spain*
Email: jonel.trebicka@kgu.de

Background and aims: Bacterial infections are known as one frequent precipitant event for the development of acute decompensation (AD) and its maximal-form acute-on-chronic liver failure (ACLF) (PREDICT study). *VS-01* is a novel intraperitoneal (i.p.) pH-gradient liposomal infusion drug that enhances the clearance of ammonia and other metabolites associated to bacterial infection in patients with ACLF. This study analyzed metabolites described to be associated with bacterial infection in patients with liver cirrhosis (Moreau *et al.* 2019) in the phase 1b clinical trial of *VS-01* (Eudra no.: 2018-004606-25).

Method: The novel drug *VS-01* was infused in the peritoneal cavity and removed by paracentesis after two (part A) or three hours (part B). Patients received either a single dose (15, 30 or 45 ml/kg) *VS-01* (Part A; n = 9) or four consecutive doses of 34–42 ml/kg *VS-01* (Part B; n = 3). Metabolomic analysis was performed on blood samples of cirrhotic patients with ascites and covert hepatic encephalopathy (HE) using untargeted LC/MS analysis. Peak areas were extracted and peak lists containing the mass features and identified compounds were exported to MetaboAnalyst 5.0 for statistical analysis.

Results: Overall, 10 out of 31 metabolites included in the metabolite cluster of infection-related ACLF were identified in plasma samples of the patients. The infusion of *VS-01* resulted in a decrease of several markers for bacterial infection in the blood of the patients (Figure 1). In part A of the study, 6 metabolites related to bacterial infection showed a decreasing trend in plasma up to 24 hours after infusion of *VS-01*. In part B of the study, 7 metabolites related to the infection-related ACLF cluster were detected in plasma samples, from which 4 showed a decreasing trend over time after infusion of *VS-01* (Figure 1).

Conclusion: Single and repeated i.p. administrations of the novel drug *VS-01* was able to reduce the concentration of several metabolites that are associated with the sepsis-related ACLF metabolite cluster. These results support the future investigation of *VS-01* in patients with ACLF and bacterial infection.

THU519

Disturbances in sodium and chloride hemostasis predict outcome in stable and critically-ill patients with cirrhosis-not two sides of the same coin

Georg Semmler[1,2], Bernhard Scheiner[1,2], Rafael Paternostro[1,2], Benedikt Simbrunner[1,2], Lorenz Balcar[1,2], Matthias Pinter[1,2], Michael Trauner[1], Mattias Mandorfer[1,2], Christian Zauner[1], Thomas Reiberger[1,2], Georg-Christian Funk[3,4]. *[1]Medical University of Vienna, Division of Gastroenterology and Hepatology, Department of Internal Medicine III, Wien, Austria; [2]Medical University of Vienna, Vienna Hepatic Hemodynamic Lab, Division of Gastroenterology and Hepatology, Department of Internal Medicine III, Wien, Austria; [3]Klinik Ottakring, Department of Internal and Respiratory Medicine, Vienna, Austria; [4]Karl-Landsteiner-Institute for Lung Research and Pulmonary Oncology, Vienna, Austria*
Email: georg.semmler@meduniwien.ac.at

Background and aims: Serum electrolyte disturbances are common in patients with cirrhosis. Hyponatremia has profound prognostic implications, and thus, has been incorporated in the 2016 update of

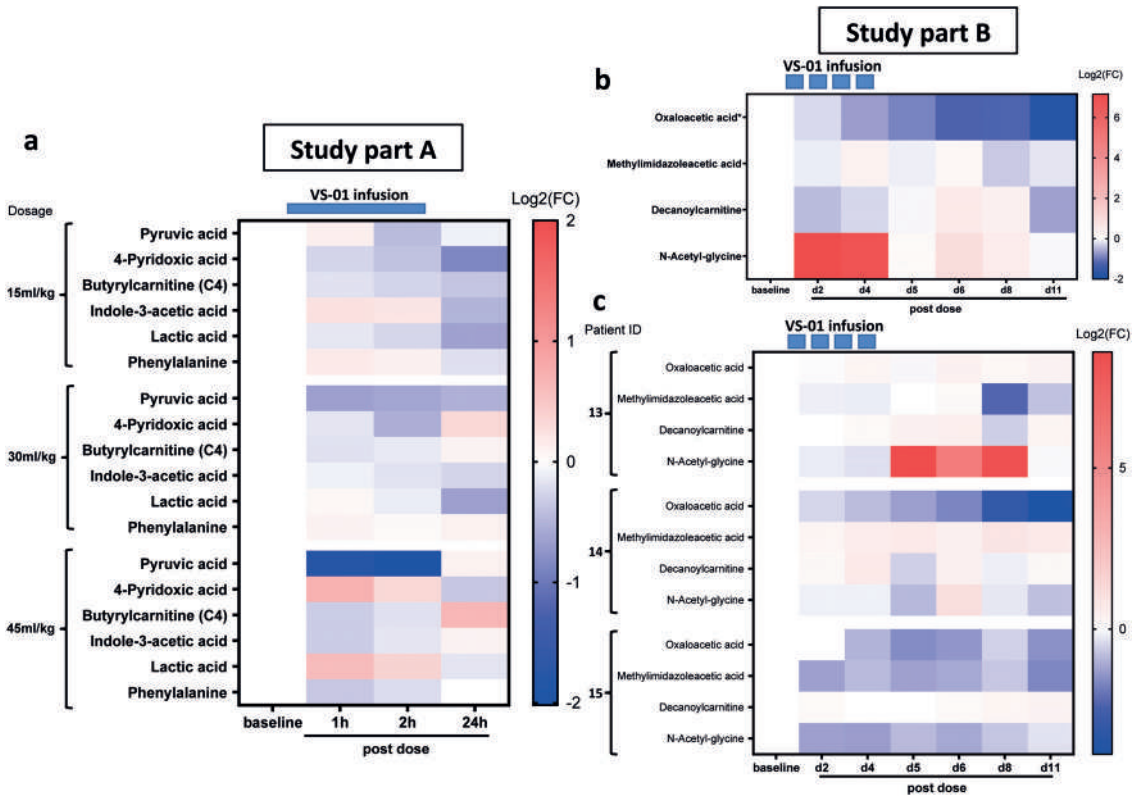

Figure: (abstract: THU518): Heatmap of log2 (fold-change) reduced bacterial infection markers in plasma samples of study A shown per dosage (a) and study B shown per marker compound (b) and per patient (c) after administration of *VS-01* (red = high/Blue = low). *, FDR < 0.05.

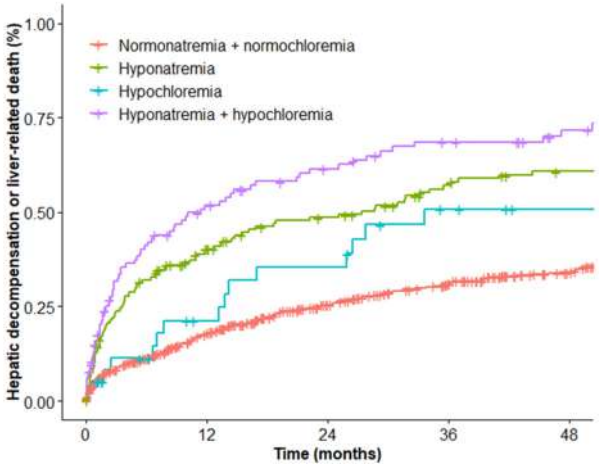
the UNOS MELD. Changes in serum chloride (Cl) are thought to be interrelated, however, are less well studied in the context of cirrhosis. We investigated the prognostic utility of Na- and Cl-changes on hepatic decompensation/liver-related death in patients with stable advanced chronic liver disease (ACLD) as well as on ICU-mortality in critically-ill patients with cirrhosis.

Method: 1256 patients with stable ACLD (defined by hepatic venous pressure gradient (HVPG) ≥6 mmHg) undergoing HVPG measurement at the Vienna Hepatic Hemodynamic Lab between 2003–2020 were included in *cohort I*. 181 critically-ill patients with cirrhosis admitted to our ICU between 1993–2003 were recruited for *cohort II*. Hypo-/hyper-Na (normal: 136–145 mmol/L) and hypo-/hyper-Cl (normal: 98–107 mmol/L) were assessed.

Results: *Cohort I:* 68% male patients with a mean UNOS MELD (i.e., excluding Na) of 12 ± 4 were included (CPS-A/B/C: 53%/35%/12%). Na and Cl levels were significantly interrelated (Spearman's $\rho = 0.54$, $p < 0.001$). Hypo-/hyper-Na was present in 25%/0% and hypo-/hyper-Cl in 15%/8%. Patients with hypo-Na (HR: 2.44 [95%CI:2.05–2.90], $p < 0.001$) and hypo-Cl (HR: 2.19 [95%CI: 1.74–2.77], $p < 0.001$) had an increased risk for hepatic decompensation/liver-related death. When incorporating both variables in a model adjusting for age, HVPG, albumin levels, and MELD score, hypo-Cl (aHR: 1.77 [95%CI:1.37–2.29], $p < 0.001$) but not hypo-Na (aHR:1.10 (95%CI:0.88–1.38), $p = 0.40$) remained independently associated with the outcome of interest. As depicted in the Figure, the presence of hypo-Na, hypo-Cl, none, or both identified patient groups with a distinct prognosis.

Figure: Kaplan-Meier curve comparing the incidence of hepatic decompensation/liver-related death in stable ACLD patients according to the presence of hypo-Na and/or hypo-Cl.



Cohort II: 70% male patients had a mean UNOS MELD of 27 ± 9 at ICU admission (92% with Child-Pugh-stage [CPS] C). Again, Na and Cl levels were strongly correlated (Spearman's $\rho = 0.81$, $p < 0.001$). Hypo-/hyper-Na was present in 47%/7% and hypo-/hyper-Cl in 30%/25%. ICU-mortality was 50% after a median of 6 (IQR:5–7) days. While the effect of Na on ICU mortality was U-shaped in restricted cubic spline analyses, it seemed to be rather linear for chloride with a worse prognosis in patients with hypo-Cl as well as hypo- and hyper-Na. In univariable logistic regression analyses, patients with hypo-Cl (OR: 2.65 [95%CI:1.30–5.53], $p = 0.008$), but not hypo-Na had a significantly worse ICU survival, which was confirmed after adjusting for hypo-Na and MELD (aOR CI: 3.24 [95%CI: 1.31–8.23], $p = 0.012$).

Conclusion: Even though Na and Cl levels are strongly interrelated in patients with stable ACLD/cirrhosis and critical illness, hypo-Cl rather than hypo-Na is associated with a worse outcome.

THU520

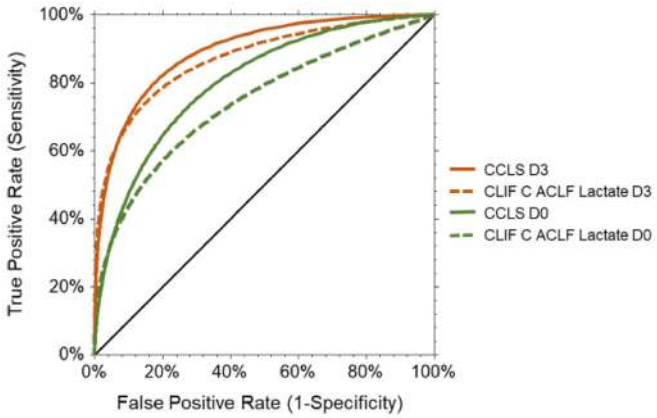
Sarcopenia assessed via computed tomography is associated with short-term outcomes and improves prognostic scores' performance in critically ill patients with acute on chronic liver failure

Thomas Mangana Del Rio[1], Fabio Becce[1], Julien Vionnet[1], Alban Denys[1], Antoine Schneider[1], Alexandre Wetzel[1], Darius Moradpour[1], Jean-Daniel Chiche[1], Florent Artru[1,2]. [1]*Lausanne University Hospital, Lausanne, Switzerland;* [2]*King's College Hospital, Institute of Liver Studies, London, United Kingdom*
Email: florent.artru@kcl.ac.uk

Background and aims: Prognostication of patients with cirrhosis and acute-on-chronic liver failure (ACLF) relies on organ failure scores. Sarcopenia is associated with poor outcomes in patients with cirrhosis but has not been investigated in critically ill patients with ACLF. We aimed to evaluate whether sarcopenia was associated with short-term outcome in this population.

Method: We retrospectively included all patients with cirrhosis and ACLF (as defined by EASL criteria) admitted to the intensive care unit (ICU) of Lausanne University Hospital between January 2010 and December 2019, who had a recent CT (within 15 days from admission to the ICU). L3 skeletal muscle index (L3SMI) was quantified by using a deep learning-based method from a single axial CT image at the level of lumbar vertebra 3. Sarcopenia was defined by previously published sex-specific cut-offs: 50 cm2/m2 in men and 39 cm2/m2 in women.

Results: A total of 194 patients fulfilled the inclusion criteria. Their characteristics at admission were the following: 26% were female, median age was 62 years (IQR, 54–70 years), MELD 21 (13–28), CLIF-C ACLF 79 (74–85), CLIF-C ACLF-lactate 83 (76–92). Sixty percent of patients had ACLF grade 3, 34% grade 2 and 6% grade 1. Median 28-day transplant-free survival (TFS) was 58% (95% CI, 51–65%). Median L3SMI was 43 (37–51), with 59% of patients being sarcopenic. In multivariate Cox-regression analyses at day 0 (D0), the three independent variables associated with 28-day TFS were CLIF-C ACLF-lactate (HR 1.06, 1.04–1.09, $p < 0.0001$), MELD score (HR 1.03, 1.01–1.07, $p = 0.03$) and sarcopenia (HR 2.1, 1.3–3.5, $p = 0.003$). At day 3 (D3), the two independent variables associated with 28-day TFS were CLIF-C ACLF-lactate on day 3 (HR 1.08, 1.07–1.11, $p < 0.0001$) and sarcopenia (HR 1.9, 1.2–3.1, $p = 0.01$). Based on the results of multivariate analyses, we derived two scores (CLIF-C ACLF-lactate-sarcopenia at D0 and D3, CCLS-D0 and CCLS-D3) with the aim of improving prognostic stratification. For the prediction of 28-day TFS, CCLS-D0 had an AUROC of 0.80 and outperformed CLIF-C ACLF-lactate on day 0 (0.74, $p = 0.004$). Similarly, CCLS-D3 had an AUROC of 0.89 and outperformed CLIF-C ACLF-lactate on day 3 (0.86, $p = 0.04$) (Figure 1).



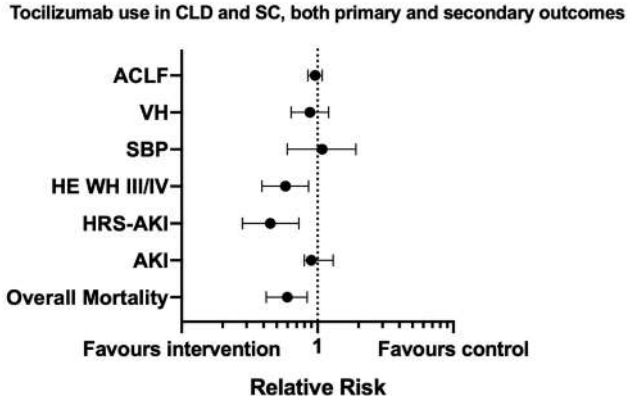
Conclusion: Sarcopenia, as assessed by CT-Scan is independently associated with 28-day TFS in critically ill patients with cirrhosis and ACLF. Adding sarcopenia to CLIF-C-ACLF-lactate score at D0 and D3 improved the performance of the scores. Sarcopenia is an important parameter related to outcomes and should be evaluated in this population.

THU521

Use of Tocilizumab in patients with stable chronic liver disease and severe COVID-19 for prevention of decompensated cirrhosis, a prospective, open-label, randomized controlled trial.

Luis Alejandro Rosales Renteria[1,2], Hiram Jaramillo-Ramírez[3], Francisco Calderón-Mendieta[3], Jesús Camacho-Escobedo[1], José Manuel Avendaño-Reyes[2], Diana Laura López-Rubio[1], Adrián Sández Araiza[1], Gisel Estefania Reyes-Higuera[1], Dulce Renée Soto-González[1], Erikc Jesús Arzola-Renteria[1]. *[1]Mexicali General Hospital, Internal Medicine, Mexicali, Mexico; [2]Faculty Of Medicine UABC, Mexicali, Mexico; [3]Mexicali General Hospital, Mexicali, Mexico*
Email: luis.alejandro.rosales.renteria@uabc.edu.mx

Background and aims: Interleukin-6 (IL-6) is involved both in the pathogenesis of severe COVID-19 (SC) and decompensated Chronic Liver Disease (CLD). Tocilizumab, a monoclonal antibody used to block the IL-6 signal transduction pathway, has been proved to have beneficial effects in the prognosis of patients with SC. However, evidence of its effect on patients with CLD that develop SC is scarce. We aimed to evaluate the efficacy of Tocilizumab on patients with CLD and SC in a tertiary care hospital from Mexico.
Method: A single center, prospective, open-label, randomized controlled trial, which included patients with CLD with either compensated cirrhosis or stable decompensated cirrhosis (according to EASL definition) that developed SC, and were admitted to our hospital in Mexicali, Mexico, from March 1, 2020, to December 31, 2021. General characteristics were obtained. The Primary Outcome was overall mortality according to the absence or presence of Tocilizumab administration (administered in the first 12 hours of arrival according to hospital availability at an 8mg/kg single IV dose), secondary outcomes were mortality according to each stage of CTP, and development of acute decompensation (AD), defined as one or more of the following : Acute Kidney Injury (AKI), Hepatorenal syndrome-AKI (HRS-AKI), Variceal Hemorrhage (VH), West Haven (WH) grade III or IV Hepatic Encephalopathy (HE), Spontaneous Bacterial Peritonitis (SBP) or Acute on Chronic Liver Failure (ACLF). A value of $p < 0.05$ was significant. Exclusion criteria were age younger that 18 years and patients with unstable decompensated cirrhosis at baseline.
Results: A total of 361 patients were included. They were classified according to the Child-Turcotte-Pugh (CTP) classification, and the Model for end-stage Liver Disease-Sodium (MELD-Na). Most patients were classified as CTP B (216 patients, 59.8%). Median MELD-Na in the intervention group was 22 vs 19 in control. 77 patients were randomized to Tocilizumab, and 284 patients were not. With regards to the primary outcome, 32.4% patients in the intervention group died vs 53.8% patients in the control group, this difference was significant with a relative risk (RR) of 0.6, a 95% confidence interval (CI) of (0.4–0.8), $p < 0.001$, and a number needed to treat (NNT) of 4.6 with a NNT 95% CI of (2.9–11.3). Secondary outcomes were significant for mortality reduction in the CTP subgroup for all grades of severity and showed a lower risk of developing HRS- AKI (RR = 0.4, 95% CI [0.2–0.7], NNT 4.3, 95% NNT CI [2.8–9.1], $p < 0.001$) and WH III/IV HE (RR = 0.5, 95% CI [0.3–0.8], NNT 5.2, 95% NNT CI [3.1–14.7], $p = 0.003$).



Conclusion: Tocilizumab reduced mortality in CLD patients with SC, overall, in each stage of CTP classification, and reduced the risk of developing both HRS-AKI and severe HE, but not other events. Whether these results can be reproduced in patients without SC warrants further research.

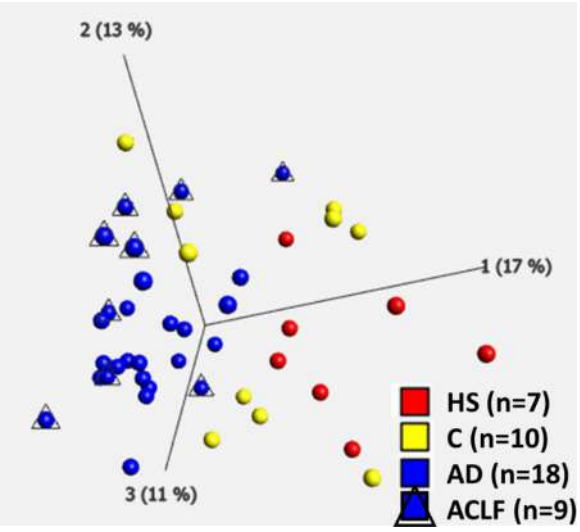
THU522

Comprehensive immunophenotyping reveals profound alterations of T cell subsets in acute decompensation of liver cirrhosis

Yasmina Chouik[1,2], Fabienne Venet[3,4], Morgane Gossez[3,4], Thibault Andrieu[2], Marie-Laure Plissonnier[2], Bordes Isabelle[2], Teresa Antonini[1], Domitille Erard[1], Miroslava Subic-Levrero[1], Francois Villeret[1,2], Wafa Khamri[5], Fabien Zoulim[1,2], Massimo Levrero[1,2], Fanny Lebossé[1,2]. *[1]Hospices Civils of Lyon, Hepatology Unit, Lyon, France; [2]Cancer Research Center of Lyon INSERM U1052, Lyon, France; [3]Hospices Civils of Lyon, Immunology Laboratory, Lyon, France; [4]International Center for Infectiology Research, Lyon, France; [5]Imperial College London, Liver Immunology Laboratory, London, United Kingdom*
Email: fanny.lebosse@inserm.fr

Background and aims: Bacterial infection is a frequent and life threatening event in acute decompensation (AD) of cirrhosis, with a 1-month mortality rate of 20–30%. Septic risk is notably underpinned by cirrhosis-associated immune dysfunction. Recent data suggest the potential involvement of adaptive immune responses in cirrhosis-related immune dysfunction. We conducted a detailed analysis of circulating T cells in patients with AD compared to patients with compensated cirrhosis (C) and healthy subjects (HS) in order to gain insights in circulating adaptive immune cells alterations in cirrhosis.
Method: Thirty seven patients from a monocentric prospective study (EmiC cohort, n = 97 patients) were selected for T cells phenotyping. Clinical and biological samples were collected at hospital admission and up to 6 months after inclusion. PBMC from HS were obtained from the French Blood Bank. Phenotyping of circulating T cells was conducted on frozen PBMC by spectral cytometry (26-color panel). This panel enables the analysis of effector, memory and naïve T cells, regulatory T cells (Treg), T-helper (Th)1, Th2, Th17, Th17+1, Th22 CD4+ T cells, Tc1, Tc2, Tc17, Tc22 CD8+ T cells, gamma delta T cells and NKT cells. Activation, inhibition and death markers were also studied (CD38, HLA-DR, PD1, CD95). Unsupervised analysis was performed using Qlucore™ and Cytobank™. Plasma cytokines were measured by Simple Plex™ immunoassays on a microfluidic ProteinSimple® ELLA analyzer.
Results: Spectral cytometry analysis was performed in 7 HS, 10 C and 27 AD patients including 9 patients with Acute on Chronic Liver Failure. Principal component analysis showed clear distinct T cells features between HS, C and AD patients (Figure 1). T cell phenotyping revealed progressive imbalance between type 1 and type 2 T cell responses with a decrease of the Th1/Th2 and Th1/Treg ratios

throughout cirrhosis progression. T cells of patients with decompensated cirrhosis displayed increased surface expression of both activation and death markers. In addition, circulating Th17 cells significantly decreased in patients with bacterial infection (n = 12) and correlated with C-reactive protein and albumin levels. Increased Th1/Th2 ratio was associated with the occurrence of nosocomial infection (n = 6), while proportion of Th17 could significantly predict 6-month survival in AD patients.



Conclusion: Alterations of circulating T cells subsets are associated with cirrhosis severity and clinical outcomes. These results underlie the role of T cells in cirrhosis-associated immune dysfunction.

THU523

Low hemoglobin level predicts early hospital readmission in patients with cirrhosis and acute decompensation

Enrico Pompili[1], Maurizio Baldassarre[1,2], Giacomo Zaccherini[1], Manuel Tufoni[3], Giulia Iannone[1], Dario Pratelli[1], Clara De Venuto[1], Marco Domenicali[1,4], Paolo Caraceni[1,2,3]. *[1]University of Bologna, Department of Medical and Surgical Sciences, Bologna, Italy; [2]University of Bologna, Center for Applied Biomedical Research, Bologna, Italy; [3]IRCSS Azienda Ospedaliero-Universitaria di Bologna, Division of Medical Semiotics, Bologna, Italy; [4]S. Maria delle Croci Hospital, AUSL della Romagna, Department of Internal Medicine, Ravenna, Italy*
Email: paolo.caraceni@unibo.it

Background and aims: Patients with decompensated cirrhosis are at high risk of emergent hospitalizations leading to a very economic and social burden. This study aimed to determine the incidence of readmission up to 1 year after discharge from an index hospitalization and to identify predictors of liver-related early readmission (within 30 days).
Method: We performed a secondary analysis in a prospectively collected cohort of patients admitted to hospital for acute decompensation (AD) complicated or not by acute-on-chronic-liver-failure (ACLF). After discharge, patients were prospectively followed until death, liver transplantation or up to a maximum of 1 year for recording any emergent hospitalization and related cause. Laboratory and clinical data at admission and discharge of the index hospitalization and the occurrence of nosocomial bacterial infection and ACLF were also collected.
Results: Of the 329 patients included in the analysis, 182 patients were hospitalized during the 1-year follow-up (26% once, 15% twice, 10% three times and 6% four or more times, leading to a total of 369 readmissions). The most frequent causes of readmission were hepatic encephalopathy (36%), ascites (22%) and bacterial infection (21%). Cumulative incidence of all-cause readmission was 19% at 30 days, 36% at 90 days and 56% at 1 year. Fifty-four patients were readmitted for emergent liver-related causes within 30 days after discharge. Early readmission was associated to a higher 1-year mortality (47 vs 32%, p = 0.037). Data collected both at admission (MELD-Na score, diabetes), during hospitalization (development of ACLF, days spent in hospital) and at discharge (hemoglobin (Hb) value, MELD-Na score) were significantly associated with early readmission. Multivariable competing risk regression analysis showed that Hb lower than 8.75 mg/dL (sHR 2.38 [95%CI 1.22–4.64], p = 0.011), MELD-Na > 16 at discharge (sHR 2.25 [95%CI 1.27–3.99], p = 0.005), and diabetes (sHR 1.74 [95%CI 1.02–2.99], p = 0.044) were independent predictors of early readmission. Cumulative incidence of early readmission was 8% (95% CI 4–14) in patients without risk factors, 16% (95% CI 11–22) in those presenting one risk factor and 35% (95% CI 23–47) in those presenting 2 or more risk factors (p < 0.001). For instance, in patients with MELD-Na>16 at discharge, the presence of Hb <8.75 g/dl doubles the risk of early re-hospitalization (42% vs 21%, p = 0.031).
Conclusion: Besides the already documented MELD-Na and diabetes, this study identifies a level of Hb <8.75 g/dl at discharge as a new independent risk factor for liver-related early readmission, thus contributing to identify the subgroup of high-risk patients to be included in programs of transitional care after discharge.

Thrombospondin 1: an emerging key-role in the acute-on-chronic liver failure pathogenesis

Hozeifa Mohamed Hassan[1], Xi Liang[1], Jiaojiao Xin[1,2], Dongyan Shi[1,2], Keke Ren[2], Qi Chen[1], Jiang Li[2], Peng Li[2], Hui Yang[2], Jinjin Luo[2], Jing Jiang[1,2], Jun Li[1,2]. *[1]Taizhou Central Hospital (Taizhou University Hospital), Precision Medicine Center, Taizhou, China; [2]The First Affiliated Hospital, Zhejiang University School of Medicine, State Key Laboratory for Diagnosis and Treatment of Infectious Diseases, National Clinical Research Center for Infectious Diseases, Collaborative Innovation Center for Diagnosis and Treatment of Infectious Diseases, Hangzhou, China*
Email: lijun2009@zju.edu.cn

Background and aims: Acute-on-chronic liver failure (ACLF) is a clinical syndrome that develops in patients with chronic liver diseases following a precipitating event and associated with a high mortality rate due to systemic multiorgan failure. In China, the most common precipitating disorder is hepatic insult due to hepatitis b virus (HBV) reactivation. Although HBV-ACLF disease progress rapidly with limited treatment options, the pathogenesis still unclear and there is a lack of effective biomarkers for early diagnosis and prognosis of HBV-ACLF. Thrombospondin 1 (THBS1) was recognized among the top significantly differentially expressed potential key molecular biomarkers associated with HBV-ACLF disease progression, but the THBS1 key-role participation in ACLF is not clear. This study aimed to evaluate the biomarker probabilities of THBS1 in ACLF pathogenesis.
Method: The biobanked peripheral blood mononuclear cells (PBMCs) from 330 subjects with HBV-related etiologies, including HBV-ACLF, liver cirrhosis (LC), chronic hepatitis B (CHB) and normal controls (NC) from the Chinese Group on the Study of Severe Hepatitis B (COSSH) prospective multicenter cohort were subjected to transcriptome analyses (ACLF = 20; LC = 10; CHB = 10; NC = 15), and the findings were validated in humans and ACLF preclinical rat model. Substantially, a THBS1 knockout mice model was developed to validate the liver protection capabilities following drugs intoxication.
Results: THBS1 was identified as the top significantly differentially expressed genes (DEGs) in PBMCs transcriptome, with most significant upregulation in ACLF, and qPCR (ACLF = 110; LC = 60; CHB = 60; NC = 45) verified the consistency of THBS1 expression with the ACLF disease severity. Moreover, the precision of THBS1 prediction abilities for ACLF short-term mortality were 0.8438 and 0.7778 at 28 and 90 days, respectively (p < 0.05). THBS1 expression patterns were significantly positively correlated with inflammatory-

related cytokine gene (CCL2, IL-6, IL-1α, CXCL2, …etc.), and apoptosis-related genes (Bcl2 and Caspase-9). External validation in ACLF rat serum and liver tissues fortified the functional association between THBS1, immune response and cellular apoptosis. THBS1 knockout improves mice survival, showed significant repressions of major inflammatory cytokines (CCl2, IFNγ, IL-1β, …etc.), enhances expression (p <0.01) of several anti-inflammatory mediators (IL-10, IL-4, IL-13, …etc.) and impedes hepatocellular apoptosis.
Conclusion: THBS1 might be considered as a new key-molecule in severity prediction of ACLF, being a disease development-related biomarker, promoting inflammatory responses and hepatocellular apoptosis, thus facilitating timely intensive clinical interventions by providing clinicians with potential new targets to improve the diagnostic and therapeutic strategies for ACLF management.

Beta-blockers can reduce mortality in patients with acute-on-chronic liver failure-a multi-center study
Anand Kulkarni[1], Madhumita Premkumar[2], Karan Kumar[3], Juned Khan[4], Baqar Gora[1], Sowmya Iyengar[1], Mithun Sharma[1], Nageshwar Reddy[1], Nagaraja Rao Padaki[1]. [1]*Asian Institute of Gastroenterology, Hyderabad, India;* [2]*Post Graduate Institute of Medical Education and Research, Chandigarh, Chandigarh, India;* [3]*Mahatma Gandhi Hospital, Jaipur, Jaipur, India;* [4]*Hopewell Hospital, Lucknow, India*
Email: anandvk90@gmail.com

Background and aims: Beta-blockers (BBs) can reduce the incidence of complications in patients with cirrhosis and prolong survival. The safety and efficacy of BBs in real-world settings in patients with ACLF identified by the Asian Pacific Association for the Study of Liver (APASL) criteria is unknown. Therefore, we aimed to assess the safety and efficacy of BB in patients with APASL defined ACLF.
Method: In this retrospective, multi-center study, patients with ACLF with complete 30 days follow-up were included. The primary objective was to compare day 30, 90, and 1-year mortality among standard of care (SOC) and BB (+SOC) groups. The secondary objectives were: to compare the incidence of infection and variceal bleed on days 30, 90, and one year among both the groups. We also assessed the time to resolution of ACLF (recompensation).
Results: A total of 346 patients were included. Only 26% (n = 89) received BBs, while 74% (n = 257) received only SOC. Age and severity scores (MELD NA-SOC: 28.4 ± 5.21 vs. 27.88 ± 4.9 in BB; p = 0.3) were similar in both groups. Alcohol was the most common cause of ACLF. Heart rate was higher and mean arterial pressure (MAP) lower in the SOC group than in the BB group. The indication for BB was large high-risk varices in 48.3% (43/89), history of acute variceal bleed in 40.4% (36/89), and 11.2% (10/89) were prophylactically started on BB to prevent further decompensation. Fifteen percent in SOC group and 12.35% in BB group were ACLF grade III patients. Though 9% of patients had a history of AVB in the SOC group, BB could not be added either due to sepsis, low MAP, or kidney injury. The incidence of mortality was 21% (54/257) in SOC group compared to only 8% (7/89) in BB group at day 30 (p = 0.005). Similarly, at day 90, mortality was 37.2% (84/226) in SOC group compared to 17% (15/88) in BB group (p = 0.001). Mortality at one year was 48% (88/183) in SOC group compared to 27% (18/66) in BB group (p = 0.003). BB therapy could not reduce the incidence of infections or variceal bleed (Table). Complete resolution of ACLF (recompensation) was noted in 47% (121/257) of patients in SOC group and 73% (65/89) patients in BB group (p < 0.001). The mean time to recompensation was 2.66 ± 1.42 months in the SOC group compared to 2.3 ± 1.15 months in the BB group (p = 0.07). Four percent in SOC group and 1% in BB group underwent liver transplantation. Carvedilol was prescribed in 77.5% and propranolol in 22.5% of patients. Eight patients discontinued BB. On subgroup analysis, BB reduced mortality in ACLF grades I and II but not in grade III. Recompensation was significantly better in those with ACLF I and II but not in grade III. Furthermore, there was a significant reduction in the incidence of infection in the BB group in ACLF grade I.

Outcomes in standard of care of care group and beta-blocker group among the whole cohort.

Outcome	SOC	SOC + Beta blocker	P
Mortality at			
30 days	21% (54/257)	8% (7/89)	0.005
90 days	37.2% (84/226)	17% (15/88)	0.001
one year	48% (88/183)	27% (18/66)	0.003
Infection at			
30 days	20.2%(52/257)	17%(15/89)	0.48
90 days	42% (94/226)	31% (27/88)	0.07
one year	53.55% (98/183)	47% (31/66)	0.35
AVB at			
30 days	4.3% (11/257)	5.6% (5/89)	0.6
90 days	5.75% (13/226)	9% (8/88)	0.28
one year	8.2% (15/183)	13.64% (9/66)	0.19

SOC, standard of care; AVB, acute variceal bleed.

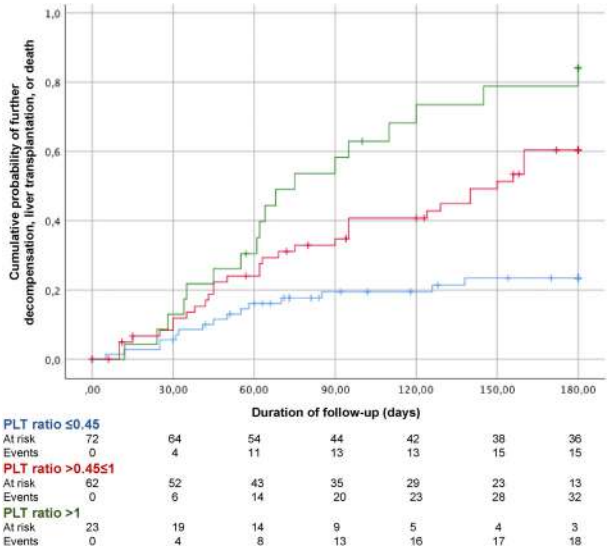
Conclusion: Only 1 in 4 ACLF patients are suitable for beta-blocker therapy. Beta-blocker therapy can reduce mortality and lead to early recompensation, especially in early grades of ACLF.

Cirrhosis and its complications: Experimental and pathophysiology.

THU526
Increased platelet aggregation in decompensated cirrhosis indicates higher risk of further decompensation and liver-related mortality
Alberto Zanetto[1], Elena Campello[2], Cristiana Bulato[2], Sabrina Gavasso[2], Fabio Farinati[1], Patrizia Burra[1], Francesco Paolo Russo[1], Paolo Simioni[2], Marco Senzolo[1]. [1]*Gastroenterology and Multivisceral Transplant Unit, Surgery, Oncology, and Gastroenterology, Padova, Italy;* [2]*Thrombotic and Hemorrhagic Diseases Unit, General Internal Medicine, Medicine, Padova, Italy*
Email: alberto.zanetto@yahoo.it

Background and aims: Studies on platelet aggregation in cirrhosis are controversial because interpretation of platelet function is challenged by thrombocytopenia. In this two-part study, we investigated platelet aggregation in cirrhosis and its correlation with development of liver-related events.
Method: Platelet aggregation was assessed by whole blood aggregometry. To overcome the influence of platelet count, we calculated a "platelet aggregation/platelet count ratio" (PLT ratio) to compare cirrhosis with thrombocytopenia and controls (60 chronic hepatitis and 45 healthy subjects) with normal platelet count (study part #1). Then, we prospectively followed patients with cirrhosis and investigated predictors of hepatic decompensation, transplantation, and death (study part #2).
Results: 203 cirrhosis patients were prospectively recruited (77% decompensated; median MELD 14). PLT ratio was significantly higher in cirrhosis than in chronic hepatitis and healthy subjects (0.44 vs. 0.25 and 0.26, respectively; p < 0.0001). Among patients with

cirrhosis, the ratio increased with disease severity (Child C > B > A) and was particularly elevated in decompensated patients with severe thrombocytopenia. During a 6-month follow-up, among decompensated patients, 65 had further decompensation, transplantation, or died. As shown in the Figure, the relative risk of such events was 4-fold higher in patients with a baseline PLT ratio >1 than in those with a PLT ratio ≤0.45 (RR: 3.8, 95%CI: 2.3–6.2; p < 0.0001). On multivariate analysis, PLT ratio (OR: 22.17, CI95%: 5.88–83.61; p < 0.0001) and MELD score (OR: 1.07, CI95%: 1.01–1.13; p = 0.03) were independently predictive of outcome.



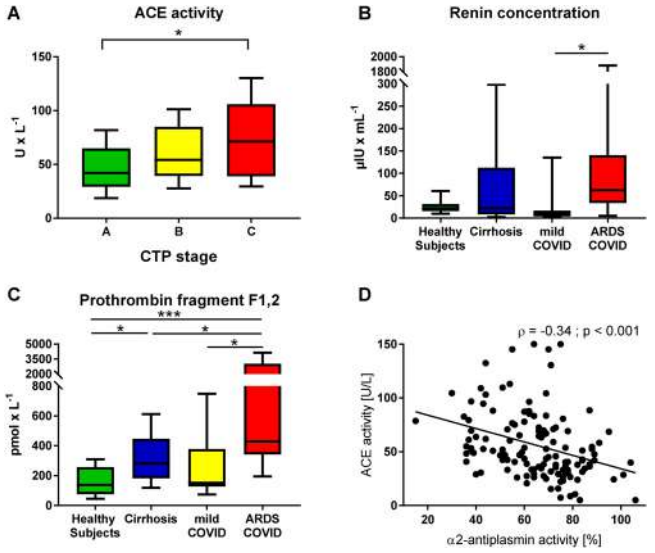
Conclusion: Patients with cirrhosis, particularly when decompensated, have increased platelet aggregation. Among decompensated patients, those with PLT ratio >1 have an 80% probability of progressing towards further decompensation, transplantation, or liver-related death within 6 months.

THU527

Renin/angiotensin system-coagulation-inflammation axis abnormalities: a possible explanation for susceptibility to severe COVID-19 in cirrhosis

Lukas Hartl[1,2], Mathias Jachs[1,2], Benedikt Simbrunner[1,2,3], David JM Bauer[1,2], Georg Semmler[1,2], Daniela Gompelmann[4], Thomas Szekeres[5], Peter Quehenberger[5], Michael Trauner[1], Mattias Mandorfer[1,2], Bernhard Scheiner[1,2], Thomas Reiberger[1,2,3].
[1]Medical University of Vienna, Division of Gastroenterology and Hepatology, Department of Medicine III, Vienna, Austria; [2]Medical University of Vienna, Vienna Hepatic Hemodynamic Lab, Division of Gastroenterology and Hepatology, Department of Medicine III, Vienna, Austria; [3]Medical University of Vienna, Christian Doppler Lab for Portal Hypertension and Liver Fibrosis, Vienna, Austria; [4]Medical University of Vienna, Division of Pulmonology, Department of Internal Medicine II, Vienna, Austria; [5]Medical University of Vienna, Department of Laboratory Medicine, Vienna, Austria
Email: thomas.reiberger@meduniwien.ac.at

Background and aims: Risk for severe coronavirus disease of 2019 (COVID-19) is increased among cirrhotic patients. Plasmin may aggravate COVID-19 by facilitation of cell entry of the virus. We investigated parameters of the renin/angiotensin system (RAS), endothelial dysfunction, coagulation/fibrinolysis and inflammation in both cirrhotic patients and COVID-19 patients.
Method: 127 prospectively characterized cirrhotic patients (CIR), as well as 9 patients with mild COVID-19 (mCOV), 11 patients with COVID-19 ARDS (aCOV) and 10 healthy subjects (HS) were included in the study. In cirrhotic patients, portal hypertension was assessed by hepatic venous pressure gradient (HVPG).
Results: With increasing liver disease severity (Child-Pugh stage A vs. B vs. C) and compared to HS, CIR patients displayed higher RAS activity (renin, angiotensin-converting enzyme [ACE], aldosterone), endothelial dysfunction (von Willebrand-factor [VWF] antigen) and inflammation (C-reactive protein [CRP], interleukin-6 [IL-6]), along with a dysregulated coagulation/fibrinolysis profile (D-dimer, prothrombin fragment F1, 2, plasminogen activity, antiplasmin activity). Renin (i.e. RAS activity), VWF antigen (i.e. endothelial dysfunction), coagulation parameters (D-dimer, prothrombin fragment F1, 2) and parameters of inflammation (CRP, IL-6) were significantly elevated in COVID-19 patients and increased from mCOV to aCOV.
In CIR patients, ACE activity was associated with IL-6 (ρ = 0.26; p = 0.003), independently linked to VWF antigen (aB: 0.10; p = 0.001) and was inversely correlated with prothrombin fragment F1, 2 (aB: −0.03; p = 0.023) and antiplasmin activity (aB: −0.58; p = 0.006).



Conclusion: RAS activity is considerably upregulated in Child-Pugh B/C cirrhosis and linked to endothelial dysfunction, abnormal coagulation profile and systemic inflammation. The cirrhosis-associated abnormalities of ACE (i.e. RAS activation), VWF antigen (i.e. endothelial dysfunction), antiplasmin (i.e. coagulation dysregulation and increased plasmin) and IL-6 (i.e. increased inflammation) may explain the susceptibility for severe COVID-19.

THU528

Improvement of hepatic and extrahepatic functions and anti-inflammatory effects of nitazoxanide in disease models of LPS-induced systemic inflammation and acute-on-chronic liver failure

Vanessa Legry[1], Philippe Delataille[1], Maryse Malysiak[1], Valérie Daix[1], Simon Debaecker[1], Bart Staels[2], Remy Hanf[1], Dean Hum[1]. *[1]GENFIT SA, Loos, France; [2]Univ. Lille, Inserm, CHU Lille and Institut Pasteur de Lille, U1011-EGID, Lille, France*
Email: vanessa.legry@genfit.com

Background and aims: Systemic inflammation (SI) is a hallmark of multiple organ failures in Acute on Chronic Liver failure (ACLF). Therefore, anti-inflammatory compounds may have the potential to alleviate ACLF, especially if they have immediate effects on the inflammatory state. The FDA approved anti-parasitic drug, nitazoxanide (NTZ), is suspected to exert direct anti-inflammatory actions. Our aim was to assess the efficacy of NTZ to rapidly counteract SI and improve hepatic and extra-hepatic functions after LPS challenge in healthy and fibrotic rats.

Method: Direct effects of NTZ on LPS-induced activation of human differentiated THP1 macrophages were assessed in vitro. Single ip LPS injection (1 mg/kg) was applied to healthy rats to induce a transient increase in circulating cytokines at 1–3 hours. A single oral dose of NTZ (100 mg/kg) was administered just before LPS injection and blood samples were collected 3 h later before sacrifice.
To assess NTZ's effects in an ACLF-model, a single ip LPS injection (0.03 mg/kg-adapted dose to limit mortality) was administered to rats with liver fibrosis induced by oral CCl4 administration for 15 weeks followed by 1-week CCl4 washout. Before the LPS challenge, the rats received NTZ (50 mg/kg BID) or vehicle for 3 days. Plasma samples were collected 24 h post-LPS.
Results: In THP1 macrophages, the active NTZ metabolite tizoxanide blunted LPS-induced TNFα secretion (IC50 = 6 µM, Emax = 88%). In healthy rats, NTZ reduced the LPS-induced rise in circulating cytokines (619 vs 1782 pg/ml TNFα, p = 0.01; 17.5 vs 24.8 ng/ml IL6, p = 0.06; 633 vs 834 pg/ml IL1b, p = 0.10; 4740 vs 6760 pg/ml IFNγ, p = 0.09) within 3 hours of treatment. In rats with CCl4-induced fibrosis (F3-F4), NTZ treatment before LPS-induced ACLF reduced ALT (214 vs 919 U/l, p = 0.007), AST (355 vs 2072 U/l, p = 0.005) and total bilirubin (3.7 vs 13.3 µmol/l, p = 0.02), resulting in hepatoprotective effects. Moreover, NTZ treatment also prevented LPS-induced increases in creatinine (48 vs 83 µmol/l, p = 0.009), urea (46 vs 140 mg/dl, p = 0.002) and cystatin C (1471 vs 2869 ng/ml, p = 0.02).
Conclusion: These results suggest that the rapid anti-inflammatory effects of NTZ may participate in beneficial effects on hepatic and extrahepatic functions in a disease model of ACLF.

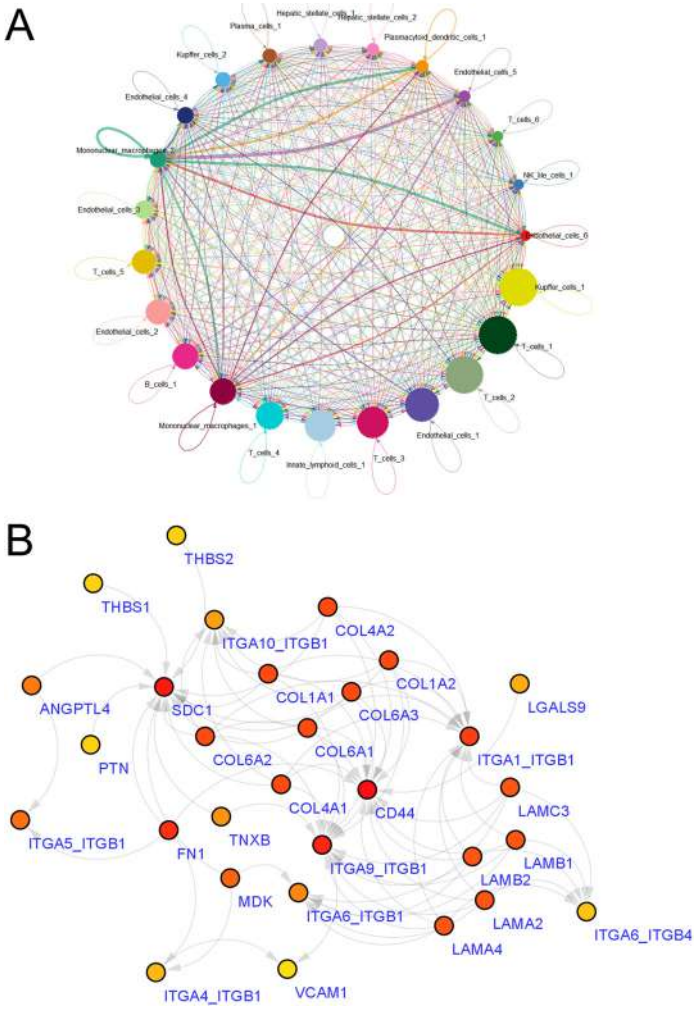
In silico characterization of the interactome of hepatic nonparenchymal cells reveals promising targets for antifibrotic therapy

Oleksandr Petrenko[1,2,3,4], Ksenia Brusilovskaya[1,2,3,4], Benedikt Hofer[1,2,3,4], Philipp Königshofer[1,2,3,4], Benedikt Simbrunner[1,2,3,4], Kaan Boztug[1,2], Michael Trauner[3,4], Philipp Schwabl[1,2,3,4], Thomas Reiberger[1,2,3,4]. *[1]Ludwig Boltzmann Institute for Rare and Undiagnosed Diseases (LBI-RUD), Vienna, Austria; [2]CeMM Research Center for Molecular Medicine of the Austrian Academy of Sciences, Vienna, Austria; [3]Vienna Hepatic Hemodynamic Lab (HEPEX), Division of Gastroenterology and Hepatology, Department of Internal Medicine III, Medical University of Vienna, Vienna, Austria; [4]Christian Doppler Laboratory for Portal Hypertension and Liver Fibrosis, Medical University of Vienna, Vienna, Austria*
Email: thomas.reiberger@meduniwien.ac.at

Background and aims: Advances in tissue dissociation and sequencing methodology allow functional characterization of non-parenchymal liver cells (NPCs) on a single-cell resolution. Based on the cellular expression of ligand-receptor pairs, the predicted molecular crosstalk in distinct cell populations can identify potential therapeutic targets.
Method: We used published single-cell RNA sequencing (scRNA-seq; MacParland-Nature Communications 2018; Ramachandran-Nature 2019) to predict *in silico* the interactome of hepatic non-parenchymal cells (NPCs) from patients with healthy and fibrotic livers. After filtering, integrating, and annotating the scRNA-seq datasets, CellChat algorithms were used to build an interaction network among both healthy and cirrhotic NPCs. Subsequently, Reactome pathway analysis using predicted ligand-receptor pairs revealed key pathways associated with cirrhosis. The PanDrugs platform was used to identify drug-gene associations.
Results: We computed the cellular interactome among NPCs based on both healthy and cirrhotic scRNA-seq datasets (Figure-A). In cirrhosis (vs. healthy), the outgoing interactome of macrophages primarily addressed endothelial and dendritic cells, and hepatic stellate cells (HSCs) had significantly increased interactions, mainly with endothelial and infiltrating immune cells.



Specifically, in cirrhosis, the endothelial cell-selective adhesion molecule (ESAM) and thrombospondin 1 (THBS) pathways were over-represented. Cirrhotic HSCs became a major source of ESAM, especially directed towards endothelial cells. In healthy livers, THBS participated in the cellular crosstalk between macrophages and other immune cells. However, in cirrhosis, HSCs were linked to this THBS-based interaction with immune cells.
Top drug-gene associations were identified based on the elements of the cirrhotic NPC interactome with the highest network centrality score. The latter were represented mainly by extracellular matrix and immunovascular signaling transcripts, such as collagens, laminins, and integrins (Figure-B, red vs. yellow indicating higher network centrality score).
We identified 59 drug candidates (8 approved drugs, 16 in clinical trials, and 35 compounds with experimental evidence) with predicted ESAM and THBS pathways activity.
Conclusion: Prediction of the cellular and cell-matrix interactions based on NPC scRNA-seq data represents a new bioinformatics approach to identify potential therapeutic targets for liver fibrosis, such as ESAM and the THBS. An increased number of high-quality scRNA-seq datasets with clinical annotations will aid in the search for new anti-fibrotic agents.

Long-chain acylcarnitines promote leukocyte mitochondrial dysfunction: role in patients with acutely decompensated cirrhosis

Ingrid Wei Zhang[1,2], Cristina López-Vicario[1,2,3], Mireia Casulleras[1,2], Marta Duran-Güell[1,2], Roger Flores-Costa[1,2], Paula Segalés[3,4], M. Carmen Garcia-Ruiz[3,4,5], José Fernandez-Checa[3,4,5], Joan Clària[1,2,3,6]. Email: ingrid-wei.zhang@charite.de

Background and aims: Acute-on-chronic liver failure (ACLF) is characterized by acute decompensation (AD) of cirrhosis, organ failure (s) and high short-term mortality. The cytokinome of these patients revealed that exaggerated systemic inflammatory response is an important driver of disease progression. Recently, it has been demonstrated that the elevated circulating levels of acylcarnitines predict mortality in patients with AD and ACLF. Therefore, inflammation-associated mitochondrial dysfunction can be regarded as another major contributor to disease progression. Here, we hypothesize that acylcarnitines not only function as biomarkers of mitochondrial dysfunction but also exert biological effects on mitochondria of circulating immune cells. In addition, as organ donors are scarce, we explore whether existing treatments such as human serum albumin (HSA) might modulate the effect of acylcarnitines on mitochondrial function.
Method: Peripheral blood mononuclear leukocytes from healthy subjects were isolated by Ficoll gradient and *in vitro* experiments were performed to assess mitochondrial function under treatment with long- and medium-chain acylcarnitines, in the presence or absence of HSA. We assessed mitochondrial membrane potential (MMP) with the cationic dye JC-1 and mitochondrial respiration using Agilent Seahorse XF technology. This was complemented by electron microscopic evaluation of mitochondrial ultrastructure of immune cells treated with acylcarnitines and expression analysis of genes involved in mitochondrial function and biogenesis.
Results: Palmitoyl- and hexanoylcarnitine were increased in blood of patients with AD cirrhosis. In contrast to hexanoylcarnitine, the long-chain palmitoylcarnitine impaired maximal respiration of leukocyte mitochondria and reduced MMP in peripheral mononuclear leukocytes without affecting cell viability. Palmitoylcarnitine also down-regulated *HMOX-1* gene expression in a concentration-dependent manner, indicating impairment of cell antioxidant responses. The effect of palmitoylcarnitine on *HMOX-1* expression was reversed by etomoxir, an inhibitor of the carnitine palmitoyltransferase 1A located at the outer mitochondrial membrane. Finally, HSA partially reversed the MMP-reducing effect, without being physically localized to mitochondria.
Conclusion: Our results indicate that elevated circulating long-chain acylcarnitines in patients with AD are not only an epiphenomenon but have the potential to actively promote mitochondrial dysfunction in immune cells, thereby contributing to immune dysbalance in these patients.

Reduced plasma extracellular vesicle CD5L content in patients with acute-on-chronic liver failure: interplay with specialized pro-resolving lipid mediators

M. Belén Sánchez-Rodríguez[1], Érica Téllez[2], Mireia Casulleras[1], Francesc Borras[3], Vicente Arroyo[4], Joan Clària[1,4,5], Maria-Rosa Sarrias[2,6]. [1]*Hospital Clínic-IDIBAPS, Biochemistry and Molecular Genetics Service, Spain;* [2]*Innate Immunity Lab, IGTP, Spain;* [3]*IVECAT, IGTP, Spain;* [4]*European Foundation for the Study of Chronic Liver Failure, Spain;* [5]*Universitat de Barcelona, Department of Biomedical Sciences, Spain;* [6]*CIBERehd, Spain*
Email: jclaria@clinic.cat

Background and aims: Acute-on chronic liver failure (ACLF) is a syndrome that develops in patients with acutely decompensated cirrhosis (AD). It is characterized by a systemic hyperinflammatory state, leading to multiple organ failure. Our objective was to analyze macrophage anti-inflammatory protein CD5L in plasma extracellular vesicles (EVs) and assess its as yet unknown relationship with lipid mediators in ACLF.
Method: EVs, isolated by size exclusion chromatography from the plasma of healthy subjects (HS) (n = 9) and patients with compensated cirrhosis (CC) (n = 8), AD (n = 13) and ACLF (n = 14), were defined as positive for CD9, CD5L and CD63 and their size, number, morphology and lipid mediator content were characterized by nanoparticle tracking analysis, electron microscopy and liquid chromatography with tandem mass spectrometry, respectively. Plasma CD5L was quantified by enzyme-linked immunosorbent assay in 10 HS, 20 CC and 149 AD patients (69 with ACLF). Macrophage CD5L expression and the biosynthesis of specialized pro-resolving lipid mediators (SPMs) were characterized in vitro in primary cells.
Results: Circulating EVs were significantly suppressed in cirrhosis, regardless of severity, and showed considerable alterations in CD5L and lipid mediator content as the disease progressed. In AD patients, levels of EV CD5L correlated best with those of the SPM resolvin E1 (RvE1). Analysis of total plasma supported these data and showed that, in ACLF, low CD5L levels were associated with circulatory ($p < 0.001$), brain ($p < 0.008$) and respiratory ($p < 0.05$) failure (Mann-Whitney test). Functional studies in macrophages indicated a positive feedback loop between CD5L and RvE1 biosynthesis.
Conclusion: We have determined a significant alteration of circulating EV contents in ACLF, with a loss of anti-inflammatory and pro-resolving molecules involved in the control of acute inflammation in this condition.

Peptidylglycine alpha-amidating monooxygenase and adrenomedullin measurements suggest cardio-circulatory dysfunction in advanced cirrhosis

Søren Møller[1], Andrei Voiosu[1], Signe Wiese[2], Janun Schulte[3], Paul Kaufmann[3], Andreas Bergmann[3], Emil Bartels[4], Jens Peter Goetze[4]. [1]*Hvidovre Hospital, Center of Functional and Diagnostic Imaging and Research, Department of Clinical Physiology and Nuclear Medicine 260, Hvidovre, Denmark;* [2]*Hvidovre Hospital, Gastro Unit, Hvidovre, Denmark;* [3]*SpingoTec GmbH, Berlin, Germany;* [4]*Rigshospitalet, Department of Clinical Biochemistry, Copenhagen, Denmark*
Email: soeren.moeller@regionh.dk

Background and aims: Peptidylglycine α-amidating monooxygenase (PAM) is a processing enzyme involved in maturation of a plethora of regulatory peptides. One product of PAM activity is adrenomedullin (bio-ADM), which regulates vascular tone and endothelial integrity. In this study, we aimed to examine PAM activity and bio-ADM concentrations in patients with cirrhosis and explore the role of the liver in net release of the two markers.
Method: We enrolled 48 patients with cirrhosis and 16 control subjects. The patients were evenly distributed according to the Child-

Turcotte class (16 patients in class A, 16 patients in class B, and 16 patients in class C). All underwent a complete hemodynamic examination with catheterization of the liver, renal, and femoral veins and corresponding arteries, from where blood was simultaneously collected. PAM activity was determined in heparin plasma with a new assay from PAM Theragnostics GmbH (Hennigsdorf, Germany). Bio-ADM was measured in heparin plasma at a research laboratory at SphingoTec GmbH (Hennigsdorf, Germany).

Results: Patients with Child C cirrhosis displayed increased circulating PAM activity. PAM activity was similar across tissues and there were no significant associations to ascites, esophageal varices, or portal hypertension. We found associations of PAM activity to alanine aminotransferase ($r = 0.30$, $p = 0.04$), bilirubin ($r = 0.47$, $p = 0.001$) and INR ($r = 0.42$, $p = 0.004$). With respect to bio-ADM concentrations, there was a marked difference within the Child classes ($p < 0.0001$) and significant associations of circulating bio-ADM concentrations and prothrombin time and serum albumin, ($p < 0.0001$). We also found a net release of bio-ADM across the liver (hepatic artery: 13.0 (8.7–21.0) vs. hepatic vein: 19.7 (12.7–29.6) pg/ml, $n = 48$, $p < 0.001$). There was a release of bio-ADM across the lower limb (femoral artery: 12.6 (7.6–22.0) vs. femoral vein: 21.8 (13.5–29.2) pg/ml, $n = 48$, $p < 0.001$. Bio-ADM concentrations were increased in patients with ascites ($n = 26$) compared to patients without ($n = 22$).

Conclusion: PAM activity is progressively increased in cirrhosis, but without a net release across the studied organs. In contrast, bio-ADM is released by the liver and relates to the severity of the disease. Given the major expression of PAM in the heart, we propose that increased PAM activity in cirrhosis may reflect a cardio-circulatory dysfunction in advanced cirrhosis.

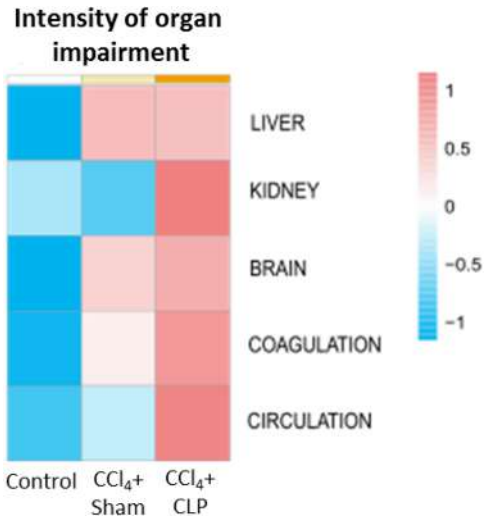
Combination of CCl4-induced decompensated cirrhosis with acute polymicrobial peritonitis as an optimized experimental model mimicking extrahepatic organ failures defined in ACLF

Roger Flores-Costa[1,2], Albert Salvatella[1], Bryan J Contreras[1,2], Marta Duran-Güell[1,2], Mireia Casulleras[1,2], Nico Kraus[3], Sabine Klein[3], Cristina López-Vicario[1,2], Ingrid Wei Zhang[1,2], Pierre-Emmanuel Rautou[4], Javier Fernández[2,5], Jonel Trebicka[2,3], Vicente Arroyo[2], Joan Clària[1,2,6]. *[1]Hospital Clínic-IDIBAPS and CIBERehd, Biochemistry and Molecular Genetics Service, Barcelona, Spain; [2]European Foundation for the study of Chronic Liver Failure (EF-CLIF) and Grifols Chair, Barcelona, Spain; [3]Goethe University Frankfurt, Department of Internal Medicine I, Frankfurt, Germany; [4]Hôpital Beaujon and INSERM, Centre de Recherche sur l'Inflammation, Paris, France; [5]Hospital Clínic-IDIBAPS and CIBERehd, Liver ICU, Liver Unit, Barcelona, Spain; [6]University of Barcelona, Department of Biomedical Sciences, Barcelona, Spain*
Email: jclaria@clinic.cat

Background and aims: Acute-on-chronic liver failure (ACLF), which develops in patients with acutely decompensated cirrhosis, is characterized by multiple extrahepatic organ failures leading to high 28-day mortality. The investigation of ACLF pathophysiology is hampered by the lack of a proper animal model that reproduces the full spectra of extra-hepatic organ failures characteristic of this disease. Since there is an unmet need for an animal model of ACLF, the current investigation explored the value of combining the well-established model of chronic liver cirrhosis induced by carbon tetrachloride (CCl_4) with the acute model of polymicrobial septic peritonitis induced by cecal ligation and puncture (CLP) as novel experimental model of ACLF.

Method: The study was performed in Sprague-Dawley rats induced to cirrhosis ($n = 12$) by CCl_4 (i.p., 1 µL/g, 2 times/week). After developing ascites, rats underwent CLP surgery (CCl_4 + CLP group). The study also included control ($n = 6$) and sham operated CCl_4-treated (CCl_4-sham group) ($n = 6$) rats. Forty-eight hours after CLP or sham surgery, functional tests and collection of blood and tissue samples were performed to assess tissue injury and organ impairments by measuring biochemical and histological parameters (hematoxylin-eosin and sirius red), gene expression of inflammatory genes (qPCR) and serum cytokine levels (Luminex technology).

Results: As compared to CCl_4-sham, CCl_4 + CLP rats exhibited more severe hypoalbuminemia and significantly higher serum levels of AST, GGT and bilirubin accompanied by increased liver expression of inflammatory genes. CCl_4 + CLP rats also showed increased serum creatinine and BUN levels and higher inflammatory gene expression. Of note, 33% of animals of this study group manifested acute tubular necrosis. Compared to CCl_4-sham, CCl_4 + CLP rats showed circulatory (higher plasma renin activity), coagulation (higher INR) and brain (impaired neurological behavior test score) failures. Moreover, CCl_4 + CLP rats exhibited up-regulated expression of lung injury markers and more exuberant systemic inflammation (higher levels of serum cytokines). Importantly, CCl_4 + CLP rats had 25% mortality at 48 hours whilst CCl_4-sham rats showed 100% survival.



Conclusion: The CCl_4 + CLP model in rats reproduces the spectra of extra-hepatic organ impairments present in patients with ACLF and thus appears as an optimized experimental model to explore the pathophysiology of this disease.

THU534

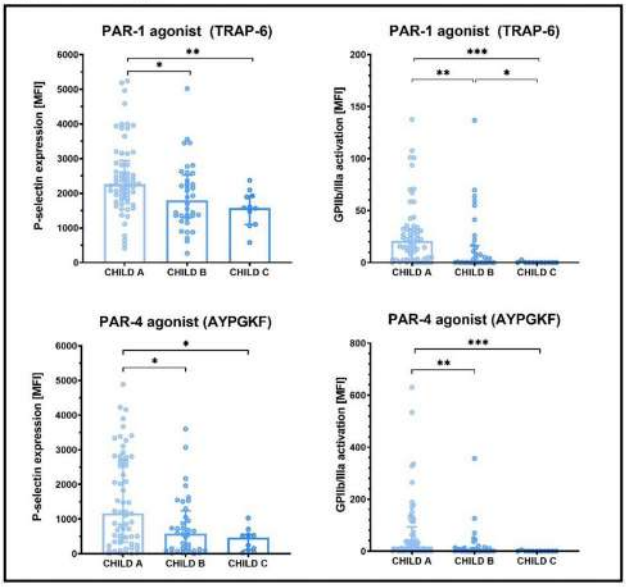
Thrombin-induced platelet activation across distinct stages of portal hyperension and cirrhosis

Ksenia Brusilovskaya[1,2,3], Benedikt Hofer[1,2,3], Beate Eichelberger[4], Simon Panzer[4], Benedikt Simbrunner[1,2,3], Mattias Mandorfer[1,2], Thomas Gremmel[5,6,7], Thomas Reiberger[1,2,3]. *[1]Medical University of Vienna, Division of Gastroenterology and Hepatology, Department of Medicine III, Vienna, Austria; [2]Medical University of Vienna, Vienna Hepatic Hemodynamic Lab (HEPEX), Division of Gastroenterology and Hepatology, Department of Medicine III, Vienna, Austria; [3]Medical University of Vienna, Christian-Doppler laboratory for portal hypertension and liver fibrosis, Vienna, Austria; [4]Medical University of Vienna, Department of blood group serology and transfusion medicine, Vienna, Austria; [5]Medical University of Vienna, Department of Internal Medicine II, Vienna, Austria; [6]Landesklinikum Mistelbach-Gänserndorf, Department of Internal Medicine I, Cardiology and Intensive Care Medicine, Mistelbach, Austria; [7]Karl Landsteiner society, Institute of antithrombotic therapy in cardiovascular disease, St. Poelten, Austria*
Email: thomas.reiberger@meduniwien.ac.at

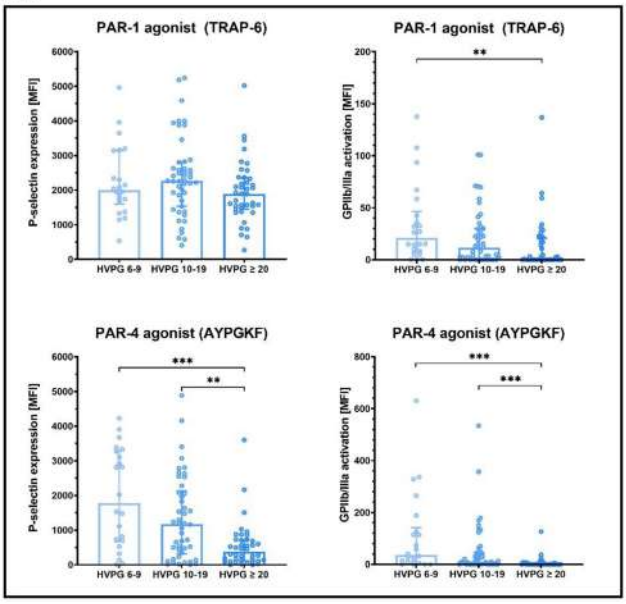
Background and aims: Patients with advanced chronic liver disease (ACLD) often show thrombocytopenia; however, primary hemostasis seems re-balanced by higher levels of von Willebrand factor (VWF). Still, alterations in thrombin-induced platelet activation may put ACLD patients at increased risk for both bleeding and

thromboembolic events. Therefore, we aimed to characterize platelet function in a thoroughly characterized ACLD patient cohort.
Method: 110 ALCD patients with portal hypertension (PH), i.e., a hepatic venous pressure gradient (HVPG) ≥6 mmHg, were prospectively included and stratified by Child-Pugh stage (CPS) and HVPG. Platelet surface P-selectin and activated glycoprotein IIb/IIIa (GPIIb/IIIa) (mean fluorescent intensity, MFI) were assessed with flow cytometry as sensitive parameters of platelet activation in unstimulated and stimulated (agonists of the protease-activated receptors, PAR-1 and PAR-4) conditions.

[A] CHILD stage:



[B] HVPG strata:



Results: The level of "baseline" platelet activation was similar across CPS stages A, B, and C (unstimulated P-selectin expression: 0.0 MFI vs. 0.0 MFI vs. 0.0 MFI, p = ns; unstimulated GPIIb/IIIa expression: 0.0 MFI vs. 0.0 MFI vs. 0.0 MFI, p = ns). PAR-1 mediated platelet activation was significantly impaired in CPS-B and C patients (P-selectin: CPS-A: 2261.0 MFI [1815.0–2942.0] vs. B: 1793.0 MFI [1299.0–2523.0], p = 0.02 vs. C: 1577.0 MFI [1101.0–1926], p < 0.01; GPIIb/IIIa: CPS-A: 20.6 MFI [3.4–32.8] vs. B: 1.8 MFI [0.0–16.2], p < 0.01 vs. C: 0.0 MFI [0.0–0.0], p < 0.001). Similarly, a decreased response to PAR-4 mediated platelet activation was observed with increasing CPS stages (P-selectin: CPS A: 1159.0 MFI [332.8–2721.0] vs. B: 582.3 MFI [101.3–1236.0], p = 0.03 vs. C: 464.0 MFI [107.1–547.1], p = 0.02; GPIIb/IIIa: CPS-A: 18.1 MFI [2.1–93.8] vs. B: 0.0 MFI [0.0–13.7], p < 0.01 vs. C: 0.0 MFI [0.0–0.0], p < 0.001). The severity of PH had no impact on "baseline" activation (all p = ns). PAR-1 mediated platelet surface expression of P-selectin was comparable across the HVPG strata 6–9 vs. 10–19 vs. ≥20 mmHg (p = ns), while activated GPIIb/IIIa was significantly reduced in HVPG ≥20 group (HVPG 6–9: 20.8 MFI [7.5–46.4] vs. HVPG ≥20: 0.5 MFI [0.0–20.8], p < 0.01). PAR-4 mediated platelet activation was also reduced in the HVPG ≥20 mmHg group (P-selectin: HVPG 6–9: 1775.0 MFI [668.6–3287.0] vs. HVPG ≥20 mmHg: 383.9 MFI [112.6–721.6], p < 0.001; GPIIb/IIIa: HVPG 6–9: 36.1 MFI [8.0–141.1] vs. HVPG ≥20: 0.0 MFI [0.0–6.8], p < 0.001).
Conclusion: ACLD patients exhibit decreased thrombin-inducible platelet activation when progressing to Child stages B and C. Moreover, high risk PH (HVPG ≥20 mmHg) is associated with impaired platelet activation upon stimulation. The impact of these alterations on the risk of bleeding or thrombotic events remains to be studied.

THU535
Exploring metabolic space of advanced chronic liver disease regression

Yuly Mendoza[1], Sofia Tsouka[2], Jaime Bosch[1], Annalisa Berzigotti[1], Mojgan Masoodi[3]. [1]*University Hospital Bern, Visceral Surgery and Medicine;* [2]*University hospital Bern, Institute of Clinical chemistry;* [3]*University hospital Bern, Institute of Clinical chemistry, Bern, Switzerland*
Email: mojgan.masoodi@insel.ch

Background and aims: Liver fibrosis is the main determinant of clinical outcomes in advanced chronic liver disease (ACLD) of any etiology. Regression of bridging fibrosis and cirrhosis can take place after effective etiological treatment, but not in all cases, suggesting that factors other than the etiology play a role in the modulation of this important outcome. In patients achieving regression of ACLD, liver function markedly improves, suggesting that several metabolic pathways are influenced by regression of fibrosis. However, the metabolic pathways associated with fibrosis regression in ACLD have not been characterized. We hypothesize that thorough assessment of liver metabolism could provide evidence-based data for better characterization of cirrhosis patients with regression following effective etiological treatment, thus providing a rational basis for personalized interventions.
Method: We performed a case-control pilot study of 60 patients with ACLD of different etiologies, 30 with histological and/or clinical evidence of regression of ACLD (Regressors) and 30 without any improvement (Non-regressors) after a minimum of 24 months of successful etiological therapy. We used the combination of metabolic modelling and metabolic profiling to define metabolic pathways and associated signature that differentiate Regressors from Non-regressors. We have developed a transcriptomics-driven metabolic modelling approach to assess the regression of ACLD. We further investigated the associated metabolic signature using mass spectrometry-based metabolomics.
Results: Although Regressors and Non-regressors showed similar profiles at baseline, our observation is pointing to fatty acid β-oxidation and arachidonic acid metabolism (associated to inflammation and oxidative stress) as key metabolic pathways differentiating Regressors from Non-regressors after therapy, suggesting that lipid metabolism plays a central role in the modulation of the extracellular matrix in ACLD. In addition, Using Least Absolute Shrinkage and Selection Operator (LASSO) analyses, the Regressor phenotype was predicted with 80% accuracy based on the levels of identified lipid markers after etiologic therapy.

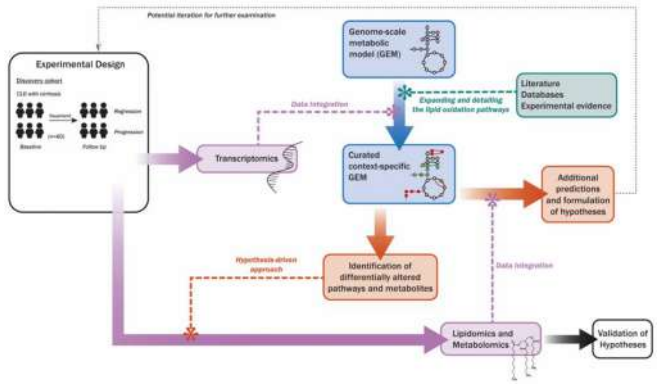


Figure: Workflow for metabolic phenotyping.

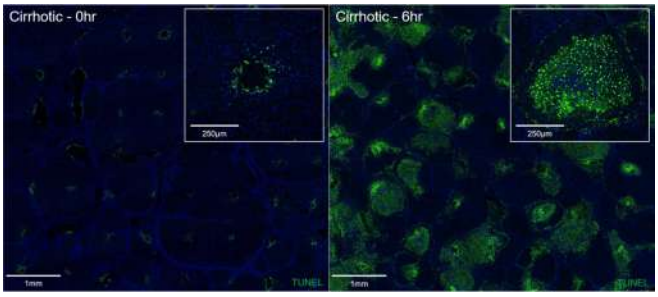
Conclusion: Our preliminary observations suggest several metabolic pathways that were associated with persistence or regression of ACLD after successful etiological therapy. These results allow proposing a metabolic signature of regression of fibrosis in ACLD.

THU536

Exacerbated response to patterned injury in the cirrhotic liver: potential susceptibility to ischemia

Benjamin Leaker[1,2], Mozhdeh Sojoodi[3], Kenneth K. Tanabe[3], R. Rox Anderson[2,4], Joshua Tam[2,4]. *[1]Massachusetts Institute of Technology, Harvard-MIT Health Sciences and Technology, Cambridge, United States; [2]Massachusetts General Hospital, Wellman Center for Photomedicine, Boston, United States; [3]Mass General Cancer Center, Division of Surgical Oncology, Boston, United States; [4]Harvard Medical School, Department of Dermatology, Boston, United States*
Email: leakerb@mit.edu

Background and aims: The response to injury in the cirrhotic liver is an important factor in both the pathogenesis of cirrhosis and the treatment of patients living with end stage liver disease. This study aimed to investigate the differences in the short-term tissue response to a controlled injury between the healthy and cirrhotic liver.
Method: Healthy and cirrhotic rats underwent a laparotomy to expose the liver followed by treatment with a tunable ablative laser to create a pattern of micro-injuries in the left lobe. The roughly 1cm^2 treatment area contains over 100 uniformly spaced micro-injuries, each approximately 300um in diameter and 2 mm deep. Animals were euthanized 0hr, 2hr, 4hr, 6hr, 3d, 7d, and 14d after laser treatment. RNA samples from the 4hr timepoint were used for RNAseq transcriptome analysis. With DESeq2, a difference-in-differences statistical model was used to identify genes that respond differently between the laser-treated cirrhotic and laser-treated non-cirrhotic liver while controlling for the differences between the untreated samples. Over-representation analysis and gene set enrichment analysis were then used to identify biological processes associated with the differential expression results.
Results: In both cirrhotic and non-cirrhotic liver, the laser produced a regular and uniform array of micro-injuries. These injuries completely healed within 7 days in the non-cirrhotic liver. In the cirrhotic liver, TUNEL staining showed expanding zones of cell death between the 4hr and 6hr timepoints, resulting in enlarged and haphazard injuries (see figure). Histology showed cells near blood vessels are spared, particularly near the vascularized fibrous septa encapsulating nodules. Evidence of these injuries could still be found at 14d. Functional analysis of the differential expression data returned enrichment of gene sets related to hypoxia, starvation, and angiogenesis, as well as revealing suppression of a variety of metabolic processes.



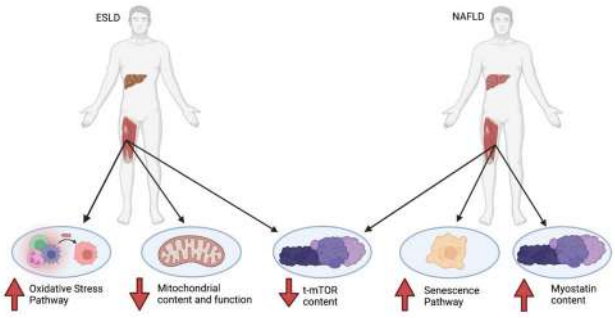
Conclusion: Our histology and transcriptomics data show that the cirrhotic liver has an exacerbated response to injury, possibly due to an increased susceptibility to ischemia which can compound with other injuries to cause far greater damage. This could be a result of the changes in the hepatic microvasculature that occur in cirrhosis, most notably capillarization of sinusoids and the formation of intrahepatic vascular shunts.

THU537

The regulatory protein and gene expression profile of skeletal muscle in chronic liver disease patients

Sophie Allen[1], Jonathan Quinlan[1], Amritpal Dhaliwal[2], Thomas Nicholson[2], Felicity Williams[2], Matthew Armstrong[3], Ahmed Elsharkawy[3], Simon Jones[2], Carolyn Greig[1], Janet Lord[2], Gareth Lavery[4], Leigh Breen[1]. *[1]University of Birmingham, School of Sport, Exercise and Rehabilitation Sciences, Birmingham, United Kingdom; [2]University of Birmingham, Institute of Inflammation and Ageing, Birminghan, United Kingdom; [3]University Hospitals Birmingham, Liver Unit, Birmingham, United Kingdom; [4]Nottingham Trent University, Department of Biosciences, Nottingham, United Kingdom*
Email: s.l.allen@bham.ac.uk

Background and aims: The molecular pathways which may underpin sarcopenia in Chronic Liver Disease (CLD) are largely unclear. The aim of this study was to characterize the intracellular signaling pathways that may underscore sarcopenia in CLD patients of different etiologies and disease stages.
Method: Muscle biopsy and blood samples were obtained from 9 non-cirrhotic non-alcoholic fatty liver disease patients (NAFLD; aged 61.1 ± 9.0), 12 decompensated alcoholic related end-stage liver disease patients (ESLD;55.7 ± 5.7) and 12 healthy, age-matched healthy controls (CON;55.7 ± 8.7). The protein content of skeletal muscle anabolic, catabolic and mitochondrial signaling intermediates was determined via western blot. The muscle transcriptome was analyzed using RNA-sequencing.
Results: Citrate synthase activity (~43%) and the protein content of OXPHOS complex I was significantly lower (~26%) in ESLD vs. CON ($p < 0.01$ for both), whereas OXPHOS complex IV was significantly lower in ESLD vs. CON (71%; $p < 0.01$) and NAFLD (61%; $p = 0.04$). Total-mTOR protein was significantly lower in NAFLD (62%, $p = 0.01$) and ESLD (52%, $p = 0.03$) vs. CON. Myostatin protein content was significantly greater in NAFLD vs. CON (77%; $p < 0.01$) and ESLD (70%; $p < 0.01$). Gene pathway analysis revealed a significant enrichment in pathways related to oxidative stress in ESLD vs. CON. A significant enrichment in genes related to senescence was evident in NAFLD vs. CON.



Conclusion: Collectively these findings highlight some similar but largely distinct signaling pathways that may underscore sarcopenia in CLD patients across different etiologies and disease stages.

Proteomic analysis of dysfunctional liver sinusoidal endothelial cells reveals substantial differences in the most common experimental models of chronic liver disease

Mar Gil[1], Carla Fuster[1], Mikel Azkargorta[2,3], Imma Raurell[1,3], Aurora Barbera[1], Felix Elortza[2,3], Joan Genesca[1,3], Diana Hide[1,3], María Martell[1,3]. *[1]Liver Diseases, Vall d'Hebron Institut de Recerca (VHIR), Liver Unit, Hospital Universitari Vall d'Hebron (HUVH), Vall d'Hebron Barcelona Hospital Campus, Universitat Autònoma de Barcelona (UAB), Barcelona, Spain; [2]Proteomics Platform, CIC bioGUNE, BRTA (Basque Research and Technology Alliance), ProteoRed-ISCIII, Bizkaia Science and Technology Park, Derio, Spain; [3]Centro de Investigación Biomédica en Red de Enfermedades Hepáticas y Digestivas (CIBERehd), Madrid, Spain*
Email: diana.hide@vhir.org

Background and aims: Therapies specifically aimed at liver sinusoidal endothelial cells (LSEC), first inducers of liver damage, could help to slow down the entire pathological process. Although physiological markers of LSEC have been described, there is lack of information regarding dysfunctional LSEC in chronic liver diseases (CLD). Here, we aimed to decipher the molecular profile of dysfunctional LSEC in different pathological situations to improve the effectiveness of potential therapeutic agents.

Method: LSEC from three experimental rat models (bile duct ligation-BDL, inhaled carbon tetrachloride-CCl_4 and high fat glucose/fructose diet-HFGFD) and their controls were isolated and sorted by flow cytometry using cd11b to eliminate macrophages and cd32b to sort dysfunctional ($CD32^-$) LSEC. Full proteomic profile was performed applying label free proteomics by nano-scale liquid chromatography tandem mass spectrometry on an EvoSep ONE (EVOSEP) coupled on-line to a TIMS Tof Pro (Bruker). Obtained data was processed and analyzed with PEAKS software.

Results: The percentage of $CD32^-$ LSEC was different between groups. Of relevance is the comparison between HFGFD (early stage of CLD) with 16.9% $CD32^-$ LSEC and CCl_4 (advanced stage) with only 6.0%, suggesting differences in the capillarization process.

Principal component analysis (PCA) revealed that $CD32^+$ LSEC are more similar between models and to healthy controls than to $CD32^-$ LSEC of their respective model (Fig A). Accordingly, the number of differentially expressed proteins vs. control LSEC is lower in $CD32^+$ than in $CD32^-$ LSEC. Nevertheless, further PCA also clusters $CD32^+$ LSEC in separate groups by models (Fig B) representing protein expression differences between them.

Looking for similarities in the capillarization process, we found 51 common proteins differentially expressed compared to controls in $CD32^-$ LSEC from the 3 models and 354 shared by at least 2 models. Finally, heatmap representation of significantly differentially expressed proteins between models, both for $CD32^+$ and $CD32^-$ LSEC, evidenced specific patterns for each model being CCl_4 and HFGFD more similar to each other than BDL (Fig C).

Conclusion: Substantial differences in dysfunctional LSEC from the three most common models of CLD were found, supporting the idea that in different etiologies/disease stages, LSEC may harbor different protein expression profiles. In deep analysis of deregulated proteins

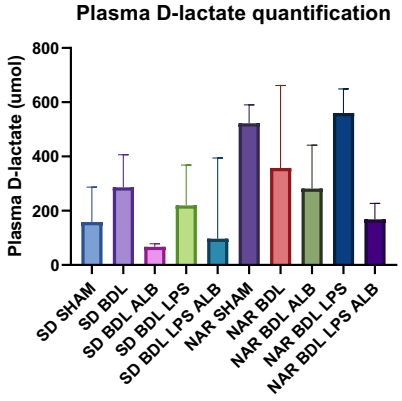
Long-term albumin administration improves survival, reduces TLR4 mediated hepatic inflammation and reduces gut translocation in models of cirrhosis

Alexandra Phillips[1], Qianwen Zhao[2], Abeba Habtesion[1], Fausto Andreola[1], Nathan Davies[1], Lindsey A Edwards[3], Jane Macnaughtan[1], Rajiv Jalan[1]. *[1]University College London, Institute of liver and digestive health, United Kingdom; [2]Sichuan University, Department of Gastroenterology and Hepatology, West China Hospital, Chengdu Shi, China; [3]Institute of Hepatology, King's College Hospital, United Kingdom*
Email: alexandra.phillips5@nhs.net

Background and aims: Long-term albumin administration reduces mortality in patients with decompensated cirrhosis. The underlying mechanisms are unknown. The aims of this study were to investigate how the absence of endogenous albumin and albumin administration impacts liver injury, toll-like receptor 4 (TLR4) signalling and gut translocation.
Method: 10 rodent groups: Naïve, cirrhosis (4-wk; bile-duct ligation (BDL)) and acute-on-chronic liver failure (ACLF) models (induced by lipopolysaccharide (LPS) 0.025 mg/kg intraperitoneal (i.p.) to BDL) ± albumin infusion (1.5 g/kg ip; 2-wk) of analbuminaemic (NAR) and wild-type (SD) rats. Plasma biochemistry and hepatic TUNEL staining. *Hepatic TLR4 expression and pathways (hTLR4)*: qPCR and RT^2 PCR profiler. *Gut permeability*: d-lactate and zonulin in plasma. *Ileal integrity*: western blot of tight junction proteins.
Results: ALT levels showed significant improvement after albumin administration in SD BDL LPS group ($p = 0.01$), and non-significant improvement in SD BDL and NAR BDL LPS. Significant reduction in the liver of TUNEL positive areas in LPS groups with albumin administration ($p < 0.001$). Coma-free survival increased from 62.5% to 80% between NAR and SD animals exposed to LPS respectively, with 100% survival in NAR animals exposed to LPS after albumin administration. *hTLR4*: NAR animals had greater hTLR4 expression, with all treatment groups showing a reduction of hTLR4 expression after albumin administration. hTLR4 gene array confirmed the activation of TLR4 dependent pathways in the cirrhotic NAR animals, which was abrogated by albumin infusion. *Markers of gut permeability*: Plasma D-lactate showed a reduction in all treatment groups with albumin (see figure). Plasma zonulin decreased after albumin in NAR BDL animals with and without LPS administration. *Tight junction*: ZO-1, claudin-4 and occludin in ileum showed a reduction in NAR diseased animals compared to SD groups with albumin administration increasing tight junction protein abundance in all disease groups.



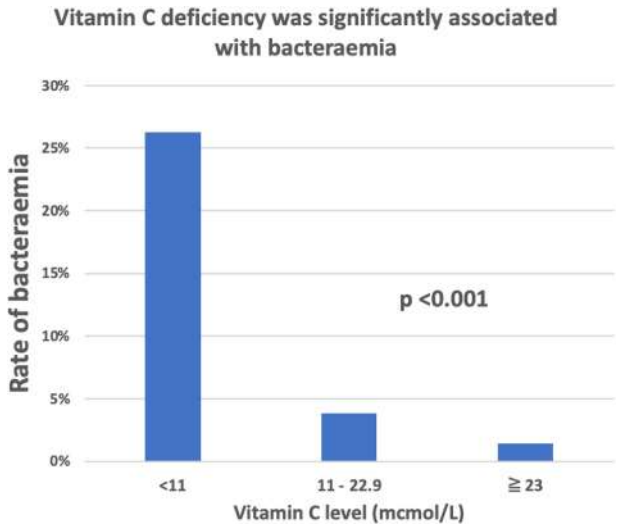
Conclusion: The results of this study show for the first time that that analbuminaemic animals have increased mortality, significantly increased liver injury and increased sensitivity to LPS. Chronic albumin administration partially reversed this, as well as reduces gut translocation resulting in decreased TLR4 pathway activation and improving the integrity of tight junctions. The data provide mechanistic insight into the biological effect on albumin on gut-liver interactions.

THU540

The prevalence and prognostic significance of vitamin C deficiency in patients with cirrhosis: a prospective observational cohort study

Declan Connoley[1], Phil Ha[1], Joseph Nim[1], Elaine Koh[1], Ryan Hirsch[1], Marcus Robertson[1]. *[1]Monash Health, Department of Gastroenterology, Melbourne, Australia*
Email: declan.connoley@gmail.com

Background and aims: Malnutrition is a common comorbidity in cirrhotic patients and confers a poorer prognosis. Vitamin C (VC) is a micronutrient essential for human health. Vitamin C deficiency (VCD) can lead to scurvy and may impair immune and liver functions. Although previously thought to be rare in developed countries, VCD is now well described in patients with pneumonia, COVID19 and upper gastrointestinal bleeding (UGIB). The prevalence and clinical significance of VCD in cirrhosis remains poorly studied.
Method: Patients with cirrhosis admitted to 3 metropolitan tertiary centres in Australia were prospectively included over a 10-month period in 2021. Fasting VC levels were collected on admission and we recorded demographic data and clinical outcomes. The primary outcomes were the prevalence of VCD (defined as VC level <23 mcmol/L) and severe VCD (SVCD), defined as <11 mcmol/L. Secondary outcomes included mortality, intensive care admission, length of stay (LOS) and rate of infection.
Results: 117 patients were included. Mean age was 57.1 ± 13.9 years, 59.0% were male and 23.9% belonged to the lowest socioeconomic decile. The most common aetiologies of cirrhosis were alcohol (62.4%), viral hepatitis (24.0%) and non-alcoholic fatty liver disease (18.8%). Median MELD score was 29 (IQR 22–36) and Child Pugh (CP) grades were 12.8% A, 46.2% B and 41.0% C. Most patients (74.4%) were hospitalised with complications of decompensated cirrhosis, including ascites (59.0%), encephalopathy (31.6%) and variceal bleeding (11.1%).
Median VC level was 34mcmol/L (IQR 16–55) and did not differ with age, gender, or aetiology of cirrhosis. Increasing CP grade correlated with significantly lower median VC levels (CP-A 46.0 mcmol/L vs. CP-B 36.5 mcmol/L and CP-C 20.5 mcmol/L, $p = 0.026$). The prevalence of VCD and SVCD were 39.3% and 17.1% respectively. SVCD was more prevalent in patients with a body mass index <25 (28.3% vs 13.0%, $p = 0.036$).
In-hospital mortality was 12.8% and did not differ by VCD status, however in the subgroup of patients presenting with UGIB, SVCD correlated with significantly higher mortality (50% vs 4.1%, $p = 0.045$). Bacteraemia was more frequent in patients with VCD (13.3% vs. 1.4%, $p = 0.014$) and SVCD (26.3% vs 2.1%, $p < 0.001$), which remained significant at multivariate analysis (OR for every 1mcmol/L increase in VC, 0.91 (95% CI: 0.83–0.99), $p = 0.037$). Overall infection rates were higher in patients with SVCD (40.0% vs. 27.8%) although this was non-significant ($p = 0.279$). Median hospital LOS was 10 (IQR 6–18) days and did not differ by VCD status.



Conclusion: VCD is common in hospitalised cirrhotic patients and prevalence increases with severity of liver disease. VCD increases the risk of infective complications and higher mortality was observed in patients with UGIB and SVCD. Further studies are required to assess the significance of VCD in cirrhosis and the impacts of VC replacement.

THU541

Wnt as activator of regeneration in cirrhosis of human liver: tissue collapse brings the Wnt source in hepatic veins to the site of the progenitor cell niche

IanR Wanless[1], Ashley Stueck[1]. [1]*Dalhousie University, Anatomic Pathology, Halifax, Canada*
Email: ian2460@gmail.com

Background and aims: Recent studies show that Wnt is secreted by hepatic vein endothelial cells (HV-EC). Glutamine synthetase (GS) activation in peri-venular hepatocytes (HC) of normal livers is considered a downstream event initiated by Wnt. Thus, we consider GS activation a surrogate histologic marker for Wnt and call it Wnt-GS. Hepatic regeneration is also activated by the Wnt/beta-catenin pathway. We previously showed that human cirrhotic liver is repopulated by buds of new hepatocytes derived from distal bile ducts. GS expression was a prominent feature in ducts forming buds, which is consistent with a response to local exposure to secreted Wnt. However, in normal livers, Wnt secreted from HV-EC affects a thin rim of perivenular/zone 3 hepatocytes and is then washed toward the cava. In order to reach portal tracts and activate the bud sequence in cirrhosis, we hypothesize that some Wnt is distributed to the distal bile ducts by altered circulation. The aim is to identify the anatomic basis of this pathway in human cirrhosis.
Method: Resected liver samples with chronic disease (n = 38) or normal (2) were serially sectioned and stained with GS, CD34, and CK19. Wnt-GS was semi-quantitated by location.
Results: Perivenular Wnt-GS generally decreased with advancing stage, associated with decreased HV number but also decreased Wnt-GS per HV, likely because of damage to HV-EC and arterialization with washout. Stage 4A and 4B livers usually had occasional nodules with focal increase in Wnt-GS, likely because of retrograde flow. Active budding correlated with Wnt-GS, mostly in septal ducts and associated new hepatocytes, usually in stage 4A and 4B. Wnt-GS in HC at nodular periphery were often seen to connect with intranodular HVs but also appeared to be a response to Wnt-secreting HV remnants that were deeply embedded in adjacent septa (see fig); these HVs appear to be the main conduits allowing HV-derived Wnt to be transported to small duct regions.

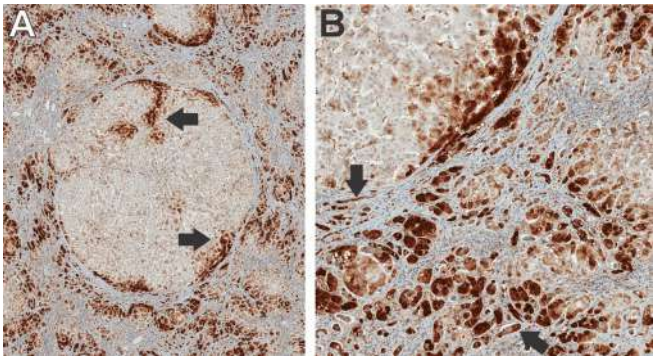


Figure: Cirrhosis (GS stain). A. Nodule showing HVs (arrows) draining into septa with adjacent active GS+ buds. B. High mag. showing Wnt-GS in ducts (arrows) and in new bud HC.

Conclusion: In cirrhotic livers, Wnt appears to migrate in intact HV remnants to distal ductal regions, either by veno-portal approximation in collapsed tissue (PELs) or, where sinusoidal connections are intact, by reversed sinusoidal blood flow aided by focal shunt-related blood flow, as seen in other liver conditions. This explains how Wnt can be delivered from hepatic veins to the progenitor cell niche and activate regeneration.
Wnt-GS is a useful surrogate marker for the location of Wnt, although confirmation with direct techniques is required. The patchy anatomic distribution of Wnt-GS suggests that Wnt concentration is focally suboptimal to support regeneration, justifying therapeutic trial options.

THU542

The portal vein in patients with cirrhosis is not an extensively inflammatory or hypercoagulable vascular bed

Ellen Driever[1], Marta Magaz[2], Jelle Adelmeijer[1], Fanny Turon[2], Anna Baiges[2], Pol Olivas[2], Virginia Hernandez-Gea[2], Annabel Blasi[3], Juan Carlos Garcia Pagan[2], Ton Lisman[1]. [1]*University Medical Center Groningen, Department of Surgery, Groningen, Netherlands;* [2]*Barcelona Hepatic Hemodynamic Laboratory, Liver Unit, Hospital Clínic, Institut de Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS);* [3]*Hospital Clinic, Department of Anesthesiology, Barcelona, Spain*
Email: e.g.driever@umcg.nl

Background and aims: Portal vein thrombosis (PVT) is a common complication in patients with cirrhosis. Although we previously demonstrated that hypercoagulability is a reflection of severity of liver disease rather than a causal factor for PVT, other groups demonstrated elevated levels of markers of inflammation and activation of haemostasis in the portal vein (PV) compared to post-hepatic veins. However, many studies did not take clearance of these markers by the liver into account. We aimed to determine whether the PV in cirrhotic patients has particular proinflammatory or hypercoagulable characteristics by comparing blood sampled in the PV, in the hepatic vein (HV), and in the peripheral circulation.
Method: Plasma samples from 52 cirrhotic patients with clinically significant portal hypertension receiving transjugular intrahepatic portosystemic shunt, were taken from the PV, HV, and jugular vein (JV). Plasma levels of markers of inflammation, endothelial damage and haemostasis were determined and compared between the three vascular beds.
Results: Inflammatory markers LPS and IL-6 were slightly, but significantly higher in the PV than in the HV and JV. The neutrophil extracellular trap markers cfDNA and MPO-DNA were similar between the vascular beds. Endothelial marker VWF and markers of haemostasis were modestly elevated in the PV. Levels of multiple markers are lower in the HV compared to the PV and JV.

Table 1: Levels of markers of inflammation, endothelial damage and haemostasis, measured in plasma sampled from different vascular beds.

	Portal vein	Hepatic vein	Jugular vein
LPS (pg/ml)	162 [96–259]*	125 [68–233] ‡‡	156 [66–251] §§
TNF-α (pg/ml)	12 [6–22.5]	11.7 [5.1–23.9]	11.9 [5.2–21.5]
IL-6 (ng/ml)	16.5 [7–35.1]*	8.5 [5.5–32.5] ‡‡	10.3 [5.4–34.7] §
cfDNA (μg/ml)	1 [0.9–1.2]	1 [0.8–1.2]	1 [0.8–1.2]
MPO-DNA (AU)	0.2 [0.1–0.4]	0.1 [0.1–0.4]	0.2 [0.1–0.4]
VWF (%)	339 [229–449]*	309 [218–456]	301 [216–425] §§
TAT (μg/ml)	47.9 [29.8–47.9]	19.5 [7.2–35.6] ‡	43.8 [12–117] §
PAP (ng/ml)	1091 [556–4845]*	796 [535–1581] ‡	867 [533–2146] §
D-dimers (ng/ml)	3670 [2237–7205]*	2720 [1700–3662] ‡‡‡	3040 [1827–5330]

* Comparison between portal vein and peripheral vein; ‡ comparison between portal vein and hepatic vein; and § comparison between hepatic vein and jugular vein. *: p < 0.05; **: p < 0.001; ***: p < 0.0001.

Conclusion: In contrast to published studies, we found only a slight prothrombotic environment in the PV. In previous studies, comparison of levels of markers in PV with an immediate post-hepatic vascular bed may have erroneously led to the conclusion that the portal circulation is hypercoagulable. Here we demonstrate that many markers are lowest in the HV compared to the PV and the systemic circulation, indicating that the low level of these markers in the HV, at least in part, reflect clearance of those markers in the liver.

THU543

Effect of liver stiffness on hepatocellular carcinoma phenotype in a biometric 3D model

Carlemi Calitz[1], Jaafar Khaled[1], Jenny Rosenquist[2], Maria Kopsida[1], Oliver Degerstedt[3], Hans Lennernas[3], Mårten Fryknäs[4], Ayan Samanta[2], Femke Heindryckx[1]. *[1]Uppsala University, Medical Cell Biology, Uppsala, Sweden; [2]Uppsala University, Department of Chemistry-Ångström Laboratory, Polymer Chemistry, Uppsala, Sweden; [3]Uppsala University, Department of Pharmaceutical Biosciences, Uppsala, Sweden; [4]Uppsala University, Department of Medical Sciences, Cancer Pharmacology and Computational Medicine, Uppsala, Sweden*
Email: c.calitz@amsterdamumc.nl

Background and aims: Hepatocellular carcinoma (HCC) usually occur in patients with an underlying chronic liver disease. The tumor micro-environment (TME) is therefore characterized by an increased deposition of extracellular matrix proteins (ECM). The abundance of ECM results in physical and biomechanical changes in the TME, which could influence tumor behavior. The aim of our study was to determine how liver stiffness affects the HCC phenotype in a novel biomimetic 3D model to study tumor-stroma interactions.
Method: HepG2 and Huh7 cells were grown in a 3D biomimetic hydrogel model with tuneable biomechanical properties for 21 days. Matrix stiffness, epithelial-to-mesenchymal transitions (EMT), metastatic potential, drug sensitivity and overall survival was assessed and compared to current two-dimensional (2D) models, an *in vivo* HCC mouse model and clinical data. Tumour nodules were collected from the culture medium and cells were extracted from the gels for subsequent RT-qPCR analyses.
Results: Cells were embedded in hydrogels mimicking the onset of a fibrotic and cirrhotic TME, as determined by patient-derived data. HepG2 and Huh7 cells grown in a stiffer matrix (resembling a cirrhotic liver) increased proliferation and protein content, compared to those grown in a less stiff matrix (resembling a fibrotic liver). HepG2 cells significantly decreased albumin synthesis in the cirrhotic TME compared to the fibrotic TME, while Huh7 cells increased albumin synthesis. While urea production in HepG2 cells decreased over time, it increased in Huh7 cells in both conditions. Tumor nodules started to form spontaneously outside the 3D gels after 11 days. The HepG2 tumour nodules appeared earlier in the medium outside the cirrhotic gels and were significantly larger in size when compared to those found in the medium outside a fibrotic gel. Cells derived from these tumor nodules showed an increased mRNA expression of aSMA and SNAIL and decrease in E-cadherin when comparing cirrhotic to fibrotic environment, thus suggesting that increased stiffness could induce EMT in HCC cells. HepG2 cells grown in the 3D cirrhotic group were also more resistant to doxorubicin treatment compared with those grown in the 3D fibrotic group or grown in 2D. No differences were seen in drug distribution and penetrations between the two different gel compositions, thus further confirming that stiffness induced changes in the HCC phenotype that could explain a reduced response to chemotherapeutics. This was then confirmed by an increased expression of the drug resistance gene MDR1 in HepG2 cells grown in a cirrhotic gel, compared to those grown in a fibrotic gel.
Conclusion: Increasing the stiffness of the liver markedly increases the formation of metastatic nodules, induces several markers of EMT and reduces response to chemotherapeutics in a biomimetic 3D model of HCC.

THU545

Ascites reduction and anti-inflammatory effects after albumin infusion for the management of cirrhosis: evidence from an animal model

Raquel Horrillo[1], Anna Mestre[1], Estefania Alcaraz[1], Guillermo Fernández Varo[2], Wladimiro Jiménez[2,3], Ricardo Gonzalo[1], Jordi Vidal[1], Vicente Arroyo[4], Joan Clària[2,3,4], Todd Willis[1], Montserrat Costa[1]. *[1]Grifols, Bioscience Research Group, Barcelona, Spain; [2]Hospital Clinic, IDIBAPS and CIBERehd, Barcelona, Spain; [3]University of Barcelona Medical School, Department of Biomedical Sciences, Barcelona, Spain; [4]EF Clif, EASL-CLIF Consortium and Grifols Chair, Barcelona, Spain*
Email: montse.costa@grifols.com

Background and aims: The prevention of mortality by long-term albumin treatment in decompensated cirrhotic patients with ascites is currently under investigation (PRECIOSA phase 3 trial, NCT03451292). Albumin has non-oncotic functions such as binding, antioxidant and immunomodulatory capacities which have been postulated to be related to beneficial effects of albumin administration in cirrhotic patients. However, the specific mechanisms of action associated with albumin in liver cirrhosis are still under research. The present study was aimed at evaluating the effect of therapeutic albumin infusion in cirrhotic rats with ascites. Assessments included were albumin binding capacity, inflammation biomarkers, and a transcriptomic analysis.
Method: Male Wistar rats underwent chronic exposure to carbon tetrachloride to induce cirrhosis. Two weeks after ascites development, rats were randomized to receive intravenously therapeutic human albumin 1.5 g/Kg (Albutein®, Grifols; n = 20) or vehicle (0.9% saline; n = 16) on days 1 and 3. At day 4, ascites volume was assessed and serum and tissue samples were collected for biochemical and inflammatory markers determination (total protein, albumin, IL-2, IL-18, TNF-alpha), albumin binding capacity (using a specific fluorescent marker) and transcriptomic analysis (oxidative stress panel in liver and Toll-Like Receptors (TLR) panel in liver, heart and kidney). Results were expressed as median [IQR].
Results: Therapeutic albumin infusion increased total protein and albumin levels (32 [27–34] g/L), compared to vehicle (22 [18–26] g/L; p < 0.0001), 72 h after the initial administration. Human albumin represented 41% of total albumin. Ascites volume was significantly reduced after albumin infusion (2.0 [2.0–3.0] ml vs vehicle infused rats 13.5 [6.5–25.0] ml; p < 0.01). These changes were accompanied by an increase of albumin binding capacity (treated 49.2 [43.3–55.8] % vs vehicle 35.7 [33.3–43.4] %; p < 0.01) and a decrease of serum proinflammatory cytokines IL-2 (p < 0.01), IL-18 (p < 0.01) and TNF-alpha (p < 0.05) in treated rats compared to vehicle. Furthermore, transcriptomic analysis in albumin-treated rats revealed an increase in albumin gene expression in the liver, and an attenuation of transcriptomic changes associated with TLR signaling pathways previously altered by cirrhosis induction in liver, heart and kidney.

Conclusion: Albumin infusion resulted in increased albumin binding capacity that was accompanied by ascites mobilization and reduced systemic inflammation as observed by a decrease of cytokine levels and attenuation of transcriptomic changes in TLR signaling pathways. These results using an animal model are in agreement with the role of albumin ameliorating liver disease complications.

THU546

Presence of NOD2 mutations is not associated with hepatic or systemic hemodynamic abnormalities of cirrhosis

Robin Greinert[1], Alexander Zipprich[2], Anna Hauptmann[3], Markus Casper[3], Frank Lammert[3], Cristina Ripoll[2]. [1]*Martin-Luther University Halle Wittenberg, Internal Medicine I, Halle, Germany;* [2]*University Hospital Jena, Internal Medicine IV, Jena, Germany;* [3]*Saarland University Medical Center, Internal Medicine II, Homburg, Germany*
Email: robin.greinert@uk-halle.de

Background and aims: Presence of *NOD2* Mutation has been associated to infections in cirrhosis. This association is more evident in compensated patients (pts) (PMID: 30702490). According to the systemic inflammation hypothesis, bacterial translocation is one of the main drivers of complications of end-stage liver disease. The **aim** was to evaluate the association of *NOD2* mutations with hepatic and systemic hemodynamics.
Method: The presence of *NOD2* risk variants (p.N289S, p.R702W, p. G908R, c.3020insC, rs72796367) were evaluated in 825 pts (screening in context of INCA trial: EudraCT 2013-001626-26). From these, 215 pts received a hepatic hemodynamic study and right heart catheterization. This cross-sectional study compared hepatic hemodynamic and systemic hemodynamics according to *NOD2* status. Variables are described with median (IQR) or proportions. Mann Whitney U or Chi-square test were applied.
Results: Two-hundred-fifteen pts were included [median age 59 (IQR 53–66); male 67%; 76% alcohol associated cirrhosis]. Most pts were Child Pugh stage B (A 25%, B 64%, C 11%).Sixty-six pts (31%) carried a *NOD2* risk variant, of which 64 were heterozygous pts. Although there was an increase in the proportion of *NOD2* risk variants among Child Pugh stage C ($p = 0.05$), no differences were observed in MELD score [wild-type: 13 (10–16); *NOD2* variants 13 (10–18)]. No significant differences in hepatic and systemic hemodynamics were observed when comparing patients with and without *NOD2* risk variants (table 1). Analyses were repeated excluding patients who were on prophylactic or therapeutic antibiotics, and again no association between hepatic or systemic hemodynamic parameters and *NOD2* risk variants could be observed.

	NOD2 wild-type	*NOD2* Variants	p value
HR (bpm)	74 (65–83)	78 (65–87)	0.405
MAP (mmHg)	83 (76–89)	83 (75–91)	0.961
CO (l/min)	5.56 (4.67–7.08)	5.97 (4.98–7.64)	0.183
CI (l/min/m2)	2.93 (2.47–3.52)	3.31 (2.59–3.95)	0.075
SVR (dyn·sec·cm^{-5})	1069 (840–1376)	1042 (747–1273)	0.219
SVRI (dyn·sec/cm^5/m^2)	2016 (1641–2490)	1814 (1473–2399)	0.315
PAP (mmHg)	16 (13–20)	17 (14–20)	0.285
PCWP (mmHg)	11 (7–15)	12 (8–15)	0.237
PVR (dyn·sec·cm^{-5})	75 (43–112)	65 (32–112)	0.542
VCI (mmHg)	8 (6–12)	8 (5–11)	0.395
WHVP (mmHg)	29 (23–32)	28 (23–35)	0.483
FHVP (mmHg)	12 (8–15)	12 (7–15)	0.982
HVPG (mmHg)	19 (15–22)	19 (15–23)	0.994

Conclusion: The presence of *NOD2* mutations is not associated with hepatic or systemic hemodynamic abnormalities in patients with cirrhosis, suggesting that other mechanisms leading to bacterial translocation predominate.

THU547

Demonstration of gut-barrier dysfunction and endotoxemia in patients with cirrhosis presenting with acute variceal bleeding: a proof of concept

Rajat Bansal[1], Samagra Agarwal[1], Sanchit Sharma[1,2], Kanav Kaushal[1,2], Srikanth Gopi[1], Deepak Gunjan[1], Anoop Saraya[1]. [1]*All India Institute of Medical Sciences, Gastroenterology and Human Nutrition Unit, New Delhi, India;* [2]*John Radcliffe Hospital, Translational Gastroenterology Unit, Oxford, United Kingdom*
Email: ansaraya@yahoo.com

Background and aims: Limited data exist on the demonstration of gut-barrier dysfunction and factors predisposing to this in patients with chronic liver disease (CLD) presenting with acute variceal bleeding (AVB). We studied the presence of this dysfunction in a prospectively.
recruited cohort of patients with AVB.
Method: Consecutive patients with CLD presenting with AVB were prospectively included, who underwent duodenal biopsy at the time of upper GI endoscopy. Gut-barrier dysfunction was demonstrated by semi-quantitative immunohistochemical (IHC) expression of tight junction proteins like claudin-2, claudin-4, zonulin-1, occludin and junctional adhesion molecule-A (JAM-A) in both villi and crypt of duodenal biopsies. Endotoxemia was estimated indirectly using serum IgM anti-endotoxin assay and systemic inflammation was evaluated using serum interleukin-1 (IL-1) and tumor necrosis factor alpha (TNF-alpha) levels. The expression was compared across different Child-Pugh strata of liver disease and with a control group of cirrhosis without AVB.
Results: Patients with CLD presenting with AVB ($n = 71$) (Child A/B/C: 25/30/16) and controls ($n = 84$) were recruited. Zonulin-1 protein expression was elevated [H score at crypt: AVB: 9 (9-9) vs controls: 2 (1–6), $p < 0.001$; H score at villi: AVB: 6 (6–9) vs controls: 2 (2–6), $p < 0.001$] in patients with AVB. IgM endotoxin levels (AVB: 28.5 ± 9.9 MMU/ml vs controls: 87.4 ± 20.2 MMU/ml; $p < 0.001$) were lower while IL-1 (AVB: 1005 ± 82 pg/ml vs controls: 49 ± 14.4 pg/ml; $p < 0.001$) were elevated in AVB cohort. No difference was seen in the IHC expression of any tight junction barrier proteins, IgM endotoxin, IL-1 and TNF-alpha levels across different strata of liver disease. No association was seen between the studied proteins expression with the aetiology, active alcohol consumption, hypotension at presentation, hepatic venous pressure gradient and presence of active bleeding on endoscopy.

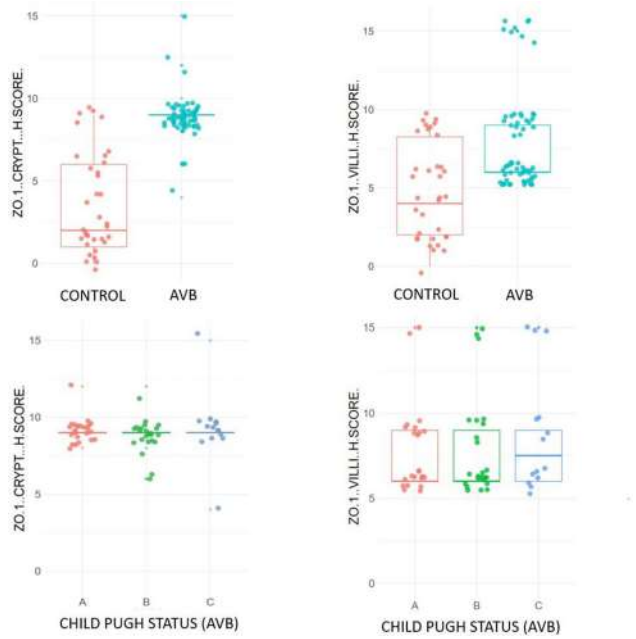

Figure: Scattered boxplots showing Zonulin-1 expression in crypt and villi between controls and AVB and different Child Pugh strata of AVB

Conclusion: While the gut-barrier dysfunction, endotoxemia and systemic inflammation are upregulated in patients with cirrhosis with AVB, the extent of these changes may be independent of aetiology and severity of liver disease, degree of portal hypertension and severity of bleeding episode.

THU548

Worsening of low-grade systemic inflammation heralds decompensation in patients with compensated cirrhosis

Background and aims: Portal hypertension is a major driver of progression and decompensation in cirrhosis. Systemic inflammation has been recognized in decompensated cirrhosis, where it contributes to accelerate the disease course. However, less information is available regarding inflammation in patients with compensated cirrhosis. Our aims were to investigate i) whether systemic inflammation is present in patients with compensated cirrhosis, and if so, ii) whether its worsening associates with the development of complications.

Method: This is a nested cohort study within the PREDESCI trial, a double blind multicentre, RCT to evaluate the efficacy of beta-blockers to prevent decompensation in patients with compensated cirrhosis and clinically significant portal hypertension (HVPG ≥10 mmHg). Biomarkers were measured in blood at baseline and at 1-year follow-up. Development of complications of portal hypertension was registered during the study. A group of 35 healthy controls was included for the specific purposes of this study.

Results: We included 201 patients with compensated cirrhosis, most (56.2%) by chronic hepatitis C, that were followed-up for a median of 37 months (27–47). Decompensation occurred in 17.4% at a median of 24 months (13.6–31.4), being ascites the main cause of decompensation (14.4%). Low-grade systemic inflammation was present at baseline and at 1-year as shown by greater serum levels of IL-6, von Willebrand factor (vWF) and CD163 at both time points in patients compared to controls (Table). Compared to baseline, IL-6 increased ($p < 0.05$) at 1-year in those patients that decompensated on follow-up. Fatty acid binding protein (FABP), used as marker of intestinal barrier function, was greater in patients compared to controls. Values of TNFa, IL1b, IL8 LBP and CD14 were similar in patients and controls at all points. The macrophage activation marker, CD163, correlated ($p < 0.01$) with HVPG at baseline ($r = 0.27$) and at 1-yr ($r = 0.46$).

		Baseline				1-yr			
		Median	IQR	P		Median	IQR	P	P intra
IL-6 (pg/ml)	Controls (n = 30)	1.6	1.01–2.6	<0.05				0.001	
	Cirrhosis (n = 116)	2.3	1.3–3.6		Cirrhosis (n = 97)	2.93	1.29–5.16		0.02
CD163 (ng/ml)	Controls (n = 34)	258.74	210.7–362.4	<0.001				<0.001	
	Cirrhosis (n = 157)	857.72	605.5–1117		Cirrhosis (n = 101)	820.35	524.2–1087.1		0.76
vWF (ng/ml)	Controls (n = 20)	2.95	1.46–5.13	<0.001				0.005	
	Cirrhosis (n = 160)	6	3.61–9.81		Cirrhosis (n = 108)	4.79	2.78–9.18		0.58
FABP (ng/ml)	Controls (n = 30)	0.31	0.19–0.50	<0.001				<0.001	
	Cirrhosis (n = 149)	0.72	0.52–1.04		Cirrhosis (n = 103)	0.73	0.419–1.01		0.95

P: controls vs cirrhosis. P intra: baseline vs 1-yr.

Conclusion: Low-grade systemic inflammation is present in patients with compensated cirrhosis. In this setting, worsening of systemic inflammation herald cirrhosis decompensation.

THU549

Patients with acutely decompensated cirrhosis present a distorted blood lipid landscape that affects the ability of albumin to promote inlammation resolution

Mireia Casulleras[1,2], Roger Flores-Costa[1,2], Marta Duran-Güell[1,2], Ingrid W. Zhang[1,2], Cristina López-Vicario[1,2], Anna Curto[2], Javier Fernandez[2,3], Vicente Arroyo[2], Joan Clària[1,2,4]. *[1]Hospital Clínic-IDIBAPS, Biochemistry and Molecular Genetics Service, Barcelona, Spain; [2]EF-Clif, European Foundation for the Study of Chronic Liver Failure, Barcelona, Spain; [3]Hospital Clínic, Liver ICU, Liver Unit, Barcelona, Spain; [4]University of Barcelona, Department of Biomedical Sciences, Barcelona, Spain*
Email: jclaria@clinic.cat

Background and aims: Lipids, especially lipid mediators derived from polyunsaturated fatty acids (PUFA), play a critical role in the regulation of inflammatory and immune responses. In this investigation, we characterized the blood lipid profile in patients with

acutely decompensated (AD) cirrhosis and explored how changes in this profile might affect the composition of circulating albumin. In addition, we investigated the effects of albumin on the release of PUFA-derived lipid mediators by peripheral leukocytes.

Method: Lipids and lipid mediators were measured by liquid chromatography-tandem.

mass spectrometry in leukocyte incubations, plasma and albumin-enriched and albumin-depleted plasma fractions from 18 patients with AD and 10 healthy subjects. Lipid mediators were also measured in 41 patients with AD included in an albumin therapy trial.

Results: The plasma lipidome associated with AD cirrhosis was characterized by generalized suppression of all lipid classes except FAs. The lipid profile of circulating albumin in AD patients was dominated by reduced content of docosahexaenoic acid (DHA) (omega-3-PUFA) and anti-inflammatory/pro-resolving lipid mediators (i.e. 15-hydroxyeicosatetraenoic (15-HETE) and 17-hydroxydocosahexaenoic (17-HDHA). In addition, albumin from AD patients was depleted in prostaglandins (PGs) (PGE_2, PGD_2 and $PGF_{2\alpha}$), implying dysregulated degradation and higher circulatory content of these pro-inflammatory lipid mediators. Incubation of leukocytes with exogenous albumin reduced PG production while inducing 15-lipoxygenase expression and 15-HETE and 17-HDHA release. Finally, PGE_2 and PGD_2 levels were lower in AD patients receiving albumin therapy whereas 15-HETE was increased after albumin treatment compared to baseline.

Conclusion: Our findings indicate that both blood and albumin lipid landscape is severely disorganized in AD cirrhosis and that exogenous albumin has potential to redirect leukocyte biosynthesis from pro-inflammatory to pro-resolving lipid mediators.

THU550

miRNA associated with systemic inflammation may have prognostic utility in predicting decompensation in patients with chronic liver disease

Oliver Tavabie[1], Vishal C Patel[2,3,4], Siamak Salehi[1], Marilena Stamouli[1], Francesca Trovato[1], Savannah Rivera[1], Salma Mujib[1], Ane Zamalloa[1], Eleanor Corcoran[1], Krishna Menon[1], Andreas Prachalias[1], Michael Heneghan[1], Kosh Agarwal[1], Mark J W McPhail[1], Varuna Aluvihare[1]. *[1]King's College Hospital, United Kingdom; [2]King's College Hospital, Institute of Liver Studies and Transplantation, London, United Kingdom; [3]Foundation For Liver Research, The Roger Williams Institute of Hepatology, London, United Kingdom; [4]Institute of Liver Sciences, King's College London, Department of Inflammation Biology, School of Immunology and Microbial Sciences, FoLSM, London, United Kingdom*

Email: oliver.tavabie@nhs.net

Background and aims: Chronic liver disease (CLD) is associated with significant mortality and encompasses; acute-on-chronic liver failure (ACLF), acute decompensation (AD), chronic decompensation (dCLD) and compensated CLD (cCLD). Transition between these states impacts on patient (Pt) survival. Here we investigate miRNA expression across the spectrum of CLD to evaluate their prognostic utility.

Method: Plasma samples were provided by Pts and healthy controls (HC). Pts sampled included ACLF, AD, cCLD, HC (each groups n = 20) and dCLD (n = 94). ACLF and AD Pts were sampled within 72 hours of admission. 90-day transplant-free survival (TxFS) across Pts with CLD was 68.8%. 6 Pts in the cCLD group decompensated in the year post-sampling. A panel of 21 miRNA developed from our previous studies were analysed. Univariate and multivariate analyses were utilized to identify miRNA associated with decompensated CLD states and 90-day TxFS.

Results: Figure 1 demonstrates significant correlations of miRNA with clinical and laboratory parameters across CLD groups. Notably, miR-24 correlated with markers of systemic inflammation (CRP), liver failure (bilirubin, INR, lactate and ascites) and CLD prognostic models (Child-Pugh $r_{(s)} = 0.25$ (95%CI 0.09–0.40), MELD $r_{(s)} = 0.25$ (95%CI 0.09–0.40)). miRNA expression was compared between ACLF/AD/dCLD cohorts and HC/cCLD cohorts. Downregulation of miR-122, –24 and –30a and upregulation of miR-223, –27a and –29b was associated with decompensated CLD states. MetaCore™ pathway analysis demonstrated an association between these miRNA and systemic inflammation ($z = 188.35$, $p < 0.0001$*). A model including miR-24 and –27a discriminated Pts with ACLF/AD/dCLD from cCLD/HC Pts (AUC 0.77 (95%CI 0.69–0.85)). Sensitivity analyses were performed excluding each group individually. Excluding the HC cohort reduced model performance (AUC 0.69 (95%CI 0.56–0.81)). However, subsequently excluding the 6 cCLD Pts who decompensated the following year improved this (AUC 0.74 (95%CI 0.60–0.88). Only the detection of miR-200b discriminated 90-day TxFS across CLD groups but did not remain significant when adjusted for MELD. Subgroup analysis of Pts with; dCLD, alcohol related CLD (ARLD) and ascites Pts demonstrated different miRNAs associated with 90-day TxFS (miR-24 in dCLD, miR-220b in ARLD and no miRNA in ascites Pts). Only the detection miR-200b in ARLD Pts remained significant when adjusted for MELD (aOR 0.23 (95%CI 0.06–0.82).

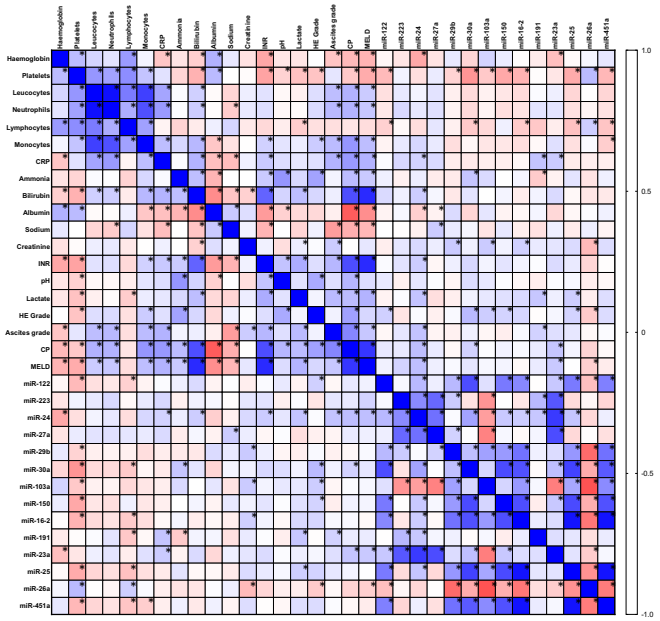

Figure: Correlation matrix of clinical and laboratory parameters with miRNA expression in CLD Pts

Conclusion: miRNA associated with systemic inflammation discriminate Pts with and without decompensated CLD states. Whilst miRNA have limited prognostic value in predicting 90-day TxFS likely reflecting the impact of aetiology, disease phase and decompensation manifestation, they may have prognostic utility in predicting future decompensation.

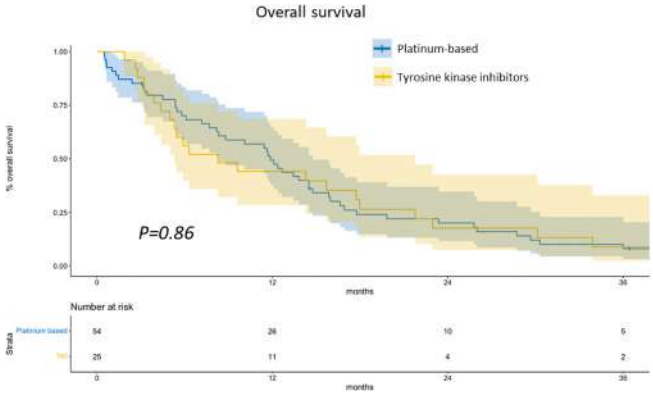
Background and aims: Although there is currently no validated systemic therapy for unresectable hepato-cholangiocarcinoma (cHCC-CCA), tyrosine kinase inhibitors and platinum-based chemotherapy are frequently used in clinical practice. Our study has aim to describe the effectiveness of first-line systemic treatments in patients with cHCC-CCA.

Method: Patients with histological diagnosis of unresectable or metastatic cHCC-CCA confirmed by a centralized review (WHO classification 2019) who received systemic treatment from 2009 to 2020 were included retrospectively in 11 centers. The outcomes of patients with cHCC-CCA were compared with patients with hepatocellular carcinoma (HCC) treated by sorafenib (n = 225) and with intrahepatic cholangiocarcinoma (iCCA, n = 94) treated mainly by platinum using a frailty Cox model. The efficacy of tyrosine kinase inhibitors and platinum-based chemotherapies in patients with cHCC-CCA was assessed using a doubly robust estimator.

Results: A total of 83 patients with cHCC-CCA were included and were predominantly male (72%), 67% of patients had extrahepatic metastases and 31% macrovascular tumor invasion. Compared with iCCA (n = 94) and HCC (n = 225), cHCC-CCA were more often developed on cirrhosis (55%) than iCCA (27%) but less frequently than HCC (88%) (p < 0.001). cHCC-CCA (66%) and HCC (30%) had extrahepatic metastases less frequently than iCCA (81%) (p < 0.001). Unadjusted overall survival was better in CCA (13 months) compared to cHCC-CCA (12 months) and HCC (9 months) (p = 0.017). In multivariate analysis after adjustment by a Cox frailty model, patients with cHCC-CCA had the same survival than HCC and iCCA (HR = 1.5; 95% CI = 0.98, 2.3; p = 0.063). ALBI score (HR = 2.15; CI05%:1.23, 3.76; p = 0.09), ascites (HR = 3.45, CI95%:1.31, 9.03; p = 0.013) and tobacco (HR = 2.29; CI95%:1.08, 4.87; p = 0.032) were independently associated with OS in patients with cHCC-CCA. Among patients with cHCC-CCA, 25 patients treated with tyrosine kinase inhibitors were compared with 54 patients with platinum-based chemotherapies. Patients treated by tyrosine kinase inhibitors had a median overall survival of 7.28 months versus 12.1 months for patients treated with platinum-based chemotherapies (p = 0.86) (Figure). After a robust double adjustment on tumor number and size, vascular invasion, ALBI, MELD and cirrhosis, treatment's regimen had no influence on overall survival (HR = 0.92, 95%CI = 0.27–3.15, P = 0.88) and progression-free survival (HR = 1.24, 95%CI = 0.44–3.49, P = 0.67).



Conclusion: Systemic treatments with tyrosine kinase inhibitors or platinum-based chemotherapies have similar efficacy in first line of patients with unresectable/metastatic cHCC-CCA. The ALBI score predicts overall survival.

Email: fulgeclaud@gmail.com

Background and aims: Systemic inflammation is a hallmark of cancer, and it has a pivotal role in HCC development and progression. The role of systemic inflammation in influencing outcomes of patients treated with immunotherapy for HCC has not been fully elucidated.
Method: We conducted a retrospective study including 362 patients receiving immune-checkpoint inhibitors (ICIs) across 3 continents, evaluating the influence of neutrophiles to lymphocytes ratio (NLR), platelet to lymphocytes ratio (PLR) and prognostic nutritional index (PNI) on overall (OS), progression free survival (PFS) and radiologic responses.
Results: In our 362 patients treated with immunotherapy, median OS and PFS were 9 and 3.5 months respectively. Amongst tested inflammatory biomarkers, patients with NLR ≥5 had shorter OS (7.7 vs 17.6 months, p < 0.0001), PFS (2.1 vs 3.8 months, p = 0.025) and lower ORR (12% vs 22%, p = 0.034), similarly, patients with PLR ≥300 reported shorter OS (6.4 vs 16.5 months, p < 0.0001) and PFS (1.8 vs 3.7 months, p = 0.0006). NLR emerged as independent prognostic factors for OS in univariate and multivariate analysis (HR 1.95, 95%CI 1.45–2.64, p < 0.001; HR 1.73, 95%CI 1.23–2.42, p = 0.002) and PLR remained an independent prognostic factor for both OS and PFS in multivariate analysis (HR 1.60, 95%CI 1.6–2.40, p = 0.020; HR 1.99, 95% CI 1.11–3.49, p = 0.021).

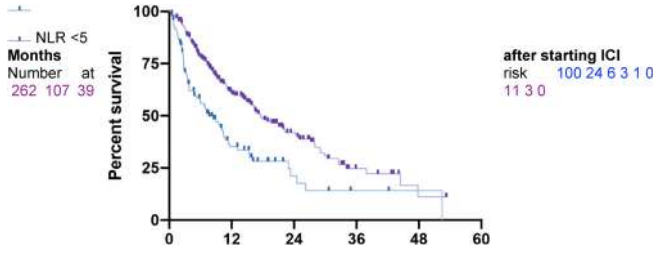

Figure: OS by pre-treatment NLR

Conclusion: Systemic inflammation measured by NLR and PLR is an independent negative prognostic factor in HCC patients undergoing ICI therapy. Further studies are required to understand the biological mechanisms underlying this association and to investigate the predictive significance of circulating inflammatory biomarkers in HCC patients treated with ICIs.

THU568

Combination of crafity score with alpha-fetoprotein response predicts a favorable outcome of atezolizumab plus bevacizumab for unresectable hepatocellular carcinoma

Wei Teng[1], Chen-Chun Lin[1], Po-Ting Lin[1], Yi-Chung Hsieh[1], Ming-Mo Ho[2], Chia-Hsun Hsieh[3], Chun-yen Lin[1], Shi-Ming Lin[1]. *[1]Linkou Chang Gung Memorial Hospital, Gastroenterology and Hepatology, Taoyuan, Taiwan; [2]Linkou Chang Gung Memorial Hospital, Medical Oncology, Taoyuan, Taiwan; [3]Tucheng Hospital, Medical Oncology, New Taipei City, Taiwan*
Email: chunyenlin@gmail.com

Background and aims: Immune checkpoint inhibitors (ICIs) with atezolizumab plus bevacizumab are promising agents for unresectable hepatocellular carcinoma (HCC). Recently, the CRAFITY score composed of baseline alpha-fetoprotein (AFP) and CRP level is associated with survival and radiological response in patients with ICIs treatment. Therefore, we tries to propose an algorithm based on CRAFITY score combining with on-treatment AFP response to guide treatment.
Method: Seventy-two patients who received atezolizumab plus bevacizumab regardless of as a first- or more than a second-line therapy for unresectable HCC in Chang Gung Memorial Hospital, Linkou Medical center were enrolled for analyses. Radiologic evaluation was based on modified Response Evaluation Criteria in Solid Tumors (mRECIST).
Results: Of 72 patients, the objective response rate (ORR) and disease control rate (DCR) were 23.4% and 57.8%, respectively. Twenty-five patients (34.7%) died during median 7.0 months follow-up duration. Multivariate analysis showed that low CRAFITY score (AFp <100 ng/ml or CRp <10 mg/l) and satisfactory AFP response at 6 weeks (≥75% decrease or ≤10% increase from baseline) were independent factors associated with good OS (hazard ratio [HR] = 0.263, p = 0.041 and HR = 0.102, p = 0.004), PFS (HR = 0.681, p = 0.046 and HR = 0.326, p = 0.008) and good responder (odds ratio [OR] = 4.354, p = 0.044 and OR = 6.406, p = 0.017). Patients were further divided into three classes: low CRAFITY score (0–1 points) with satisfactory AFP response at 6 weeks (class I), either high CRAFITY score (2 points) or unsatisfactory AFP response at 6 weeks (class II) and neither low CRAFITY score nor satisfactory AFP response at 6 weeks (class III). ORR was 41.7%, 15.4%, and 0% in class I, II and III patients, respectively (overall p = 0.033). Patients in the class I had the longest overall survival (OS) and progression-free survival (PFS), followed by class II and class III (median OS: not reached vs. 8.6 vs. 4.3 months, log-rank p < 0.001; median PFS: 5.9 vs. 4.7 vs. 2.7 months, log-rank p = 0.014). Combination CRAFITY score and AFP response at 6 weeks with AUROC predicts OS and tumor response to be 0.809 and 0.816, respectively, superior to either CRAFITY score (0.771 and 0.767) or AFP response at 6 weeks (0.725 and 0.729) alone.
Conclusion: The CAR (**C**RAFITY score and **A**FP-**R**esponse) classification which combining CRAFITY score and AFP response at 6 weeks provides a practical guidance for atezolizumab plus bevacizumab therapy in unresectable HCC patients.

THU569

Survival of patients with advanced hepatocellular carcinoma treated with sorafenib in France during 2009–2018: analysis of the French hospital and claim database

Jean-Pierre Bronowicki[1], Julien Dupin[2], Alexandre Pissewoewoe Tanang[2], Anika Gilbert-Marceau[2], Jean-Frédéric Blanc[3], Pierre Nahon[4], Caroline Laurendeau[5], Stéphane Bouée[5], Mélina Gilberg[6]. *[1]CHRU Nancy, Hépato-gastroentérologie, VANDOEUVRE LES NANCY, France; [2]Roche, Boulogne-Billancourt; [3]CHU Bordeaux, Hépato-gastroentérologie, Bordeaux; [4]APHP Hôpital Avicenne, Hépatologie, Bobigny; [5]CEMKA, Bourg La Reine, France; [6]Roche, Boulogne-Billancourt, France*
Email: jp.bronowicki@chu-nancy.fr

Background and aims: Hepatocellular carcinoma (HCC) is often diagnosed at an advanced stage of the disease. Until 2017, sorafenib

was the only systemic therapy indicated in advanced HCC as first-line therapy. This analysis describes the profile, overall survival (OS) and proxy of progression free survival (PFS) in patients with advanced HCC treated with sorafenib in France.
Method: This study was conducted using the French administrative healthcare claims database. All patients treated with sorafenib for HCC (identified by the ICD-10 code for hepatocellular carcinoma) as long-term illnesses or diagnosis-related group during hospitalization were included in the study between 2009 and 2018. The cause of the underlying chronic liver disease (CLD) was identified from ICD-10 codes and ATC codes of specific treatments. OS from sorafenib initiation was measured. PFS was defined on the proxy of the time from sorafenib initiation until treatment discontinuation or death. The Kaplan-Meier method was used to estimate survival rates.
Results: 17, 680 newly treated HCC patients were identified. Their mean age was 66.9 years (SD:10.3) and 87.6% were male. The most frequent causes of underlying CLD were alcohol liver disease (54.8%) and viral hepatitis (24.4%). The median OS from sorafenib initiation was 8.4 months (95% CI = [8.2; 8.7]).
OS differed according to HCC etiologies:
Alcohol + (HCV or HBV) (1, 749 patients, 9.9%), 8.9 months [8.4;9.4]
Alcohol without viral hepatitis (7, 933 patients, 44.9%), 8.8 months [8.4;9.1]
NASH/NAFLD without viral or alcohol hepatitis (403, 2.3%), 9.8 months [8.9;11.8]
Hepatitis B without alcohol hepatitis (655 patients, 3.7%), 5.9 months [5.3;6.9]
Co-infection VHB/VHC without alcohol hepatitis (268 patients, 1.5%), 9.7 months [8.2;11.7]
Hepatitis C without alcohol hepatitis (1, 646 patients, 9.3%), 9.0 months [8.2;9.7]
No identified etiology (5, 026 patients, 28.4%), 7.7 months [7.3;8.1]

The median survival decreased over the years: from 10.0 months in 2009 to 7.3 months in 2018.
The median proxy PFS was 3.5 months [3.3; 3.7]. Probability of sorafenib discontinuation or death before 12 months was 85%.
Conclusion: These results confirmed the high clinical burden of treated HCC regardless of the cause of CLD.
OS in this real-world setting study is lower than in clinical trials and consistent according to all etiologies.
Earlier management adapted as well as the arrival of new treatments such as immunotherapy, will improve the prognosis of patients.

THU570

Textbook outcome after major hepatectomy for perihilar cholangiocarcinoma-definitions and influencing factors

Christian Benzing[1], Lena Haiden[1], Felix Krenzien[1], Alexa Mieg[1], Annika Wolfsberger[2], Cecilia Atik[1], Nora Nevermann[1], Uli Fehrenbach[2], Wenzel Schöning[1], Moritz Schmelzle[1], Johann Pratschke[1]. *[1]Charité University Medicine Berlin, Department of Surgery | Campus Charité Mitte and Campus Virchow Klinikum, Berlin, Germany; [2]Charité University Medicine Berlin, Department of Diagnostic and Interventional Radiology, Berlin, Germany*
Email: christian.benzing@charite.de

Background and aims: The concept of "textbook outcome" (TO) as composite quality measure depicting the ideal surgical outcome has not yet been defined for patients undergoing major hepatectomy (MH) which remains the only curative therapy option for perihilar cholangiocarcinoma (PHC). This study aimed to propose a uniform definition through a systematic literature review as well as to identify patient- or procedure-related factors influencing TO.
Method: In this retrospective study, we analyzed all patients undergoing MH for PHC at our department between January 2005 and August 2019. After conducting a systematic literature search, we defined TO as the absence of 90-day mortality and major complications, no hospital readmission within 90 days after discharge, and no prolonged hospital stay (<75. percentile). A multivariate logistic regression analysis was performed to identify factors influencing TO.
Results: Of 283 patients, TO was achieved in 67 (24%) patients. Multivariate analysis revealed that preoperative biliary drainage was associated with a decreased (OR = 0.405, 95% CI: 0.194–0.845, p = 0.016) and left-sided-resection (OR = 1.899, 95% CI: 1.048–3.440, p = 0.035) with increased odds for TO. Overall survival (OS) and DFS (disease-free survival) did not differ significantly between the outcome groups (OS: p = 0.280, DFS: p = 0.735). However, there was a trend towards better overall survival, especially in the late course with TO. The differences in OS between the TO and no TO groups were statistically significant when analyzing patients with survival of at least 30 months (p = 0.039, Figure 1).

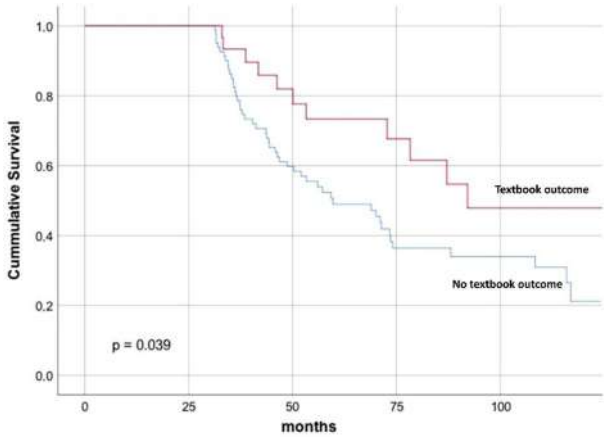

Figure: Long-term survival of patients after major hepatectomy for perihilar cholangiocarcinoma according to textbook outcome groups excluding patients surviving less than 30 months.

Conclusion: Our analysis proposed a uniform definition of TO after MH for PHC. We identified left hepatectomy as an independent factor positively influencing TO. In patients where both right- and left-sided resections are feasible, this underlines the importance of a careful selection of patients who are scheduled for right hepatectomy.

Pinato[1,11], Rohini Sharma[1]. *[1]Imperial College London, United Kingdom; [2]Humanitas University, Italy; [3]Universitätsmedizin der Johannes Gutenberg-Universität Mainz, Mainz, Germany; [4]Bio-Medico Campus University Hospital, Roma, Italy; [5]University of Freiburg, Freiburg University Medical Center, Freiburg im Breisgau, Germany; [6]Hannover Medical School, Hannover, Germany; [7]Medical University of Vienna, Wien, Austria; [8]East Carolina University, Greenville, United States; [9]Humanitas Research Hospital, Cascina Perseghetto, Italy; [10]University of L'Aquila, L'Aquila, Italy; [11]University of Eastern Piedmont, Vercelli, Italy*
Email: mathew.vithayathil@doctors.org.uk

Background and aims: Atezolizumab plus bevacizumab is the new first line-treatment for unresectable hepatocellular carcinoma (HCC). Body mass index (BMI) has demonstrated predictive value for response to immunotherapy in non-HCC cancer types. Our study investigated the effect of BMI on safety and efficacy of real-life use of atezolizumab plus bevacizumab.

Method: Sixty-four consecutive patients from seven centres receiving atezolizumab plus bevacizumab were included in the retrospective study. Overall survival (OS), progression-free survival (PFS), overall response rate (ORR) and disease control rate (DCR) defined by RECIST v1.1 were measured in overweight (BMI ≥ 25) and non-overweight (BMI < 25) patients. Treatment-related adverse events (trAEs) were evaluated for each BMI cohort.
Results: Baseline Child-Pugh class, Eastern Cooperative Oncology Group performance status and Barcelona Clinic Liver Cancer stage was similar between overweight (n = 36) and non-overweight patients (n = 28). Underling non-alcoholic fatty liver disease was more prevalent in overweight patients (27.8 vs. 7.1%; p = 0.04). Overweight patients had a longer OS compared to non-overweight (median OS 11.6 vs. 7.5 months; p = 0.045) (Figure 1). BMI did not influence median PFS (6.9 vs. 3.0 months; p = 0.34), ORR (26.7% vs. 25.0%; p = 0.90) and DCR (63.3% vs. 60.0%; p = 0.81). trAEs were comparable between the two groups (atezolizumab-related 44.4% vs. 53.6%; p = 0.47 and bevacizumab-related 18.8% vs. 12.5%; p = 0.68).

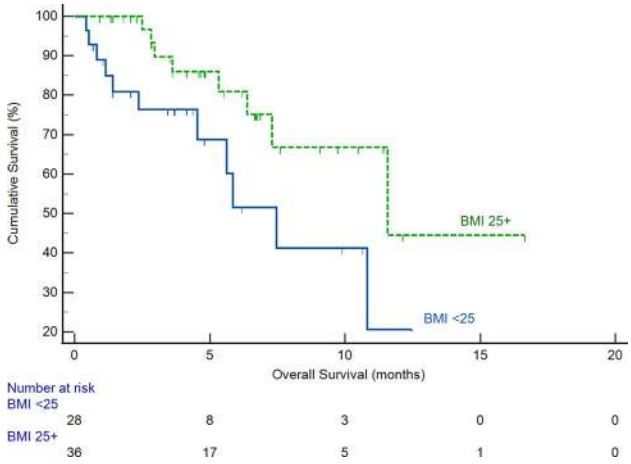

Figure: Kaplan-Meier curve showing increased overall survival (months) for overweight patients compared to non-overweight unresectable hepatocellular carcinoma patients after atezolizumab plus bevacizumab administration.

Conclusion: Higher BMI is associated with increased OS in HCC patients receiving atezolizumab plus bevacizumab for unresectable HCC, without an increase in trAEs. BMI may have a predictive role in immunotherapy treatment response in HCC.

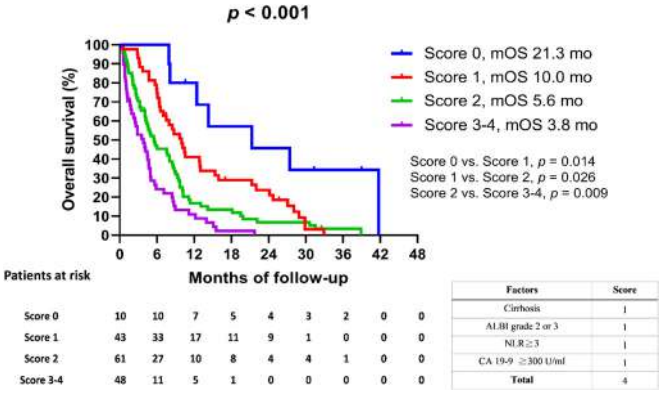
THU572

Outcome predictors of gemcitabine-based or fluoropyrimidine-based chemotherapy for unresectable intrahepatic cholangiocarcinoma

Chen-Ta Chi[1,2], I-Cheng Lee[1], Ming-Huang Chen[3], Pei-Chang Lee[1], Yi-Ping Hung[3], Ming-Chih Hou[1], Yee Chao[3], Yi-Hsiang Huang[1,2].
[1]Taipei Veterans General Hospital, Taipei, Taiwan, Division of Gastroenterology and Hepatology, Department of Medicine; [2]National Yang Ming Chiao Tung University, Taipei, Taiwan, Institute of Clinical Medicine, School of Medicine; [3]Taipei Veterans General Hospital, Taipei, Taiwan, Department of Oncology
Email: yhhuang@vghtpe.gov.tw

Background and aims: Intrahepatic cholangiocarcinoma (ICC) is a highly aggressive malignancy, and the resectability rate for curative surgical resection is low. Gemcitabine-based and fluoropyrimidine-based chemotherapy are the mainstay treatments for Unresectable ICC, even though the survival is still far from satisfaction in real-world experience. This study aimed to assess outcomes and identify the prognostic factors for patients with unresectable ICC patients receiving gemcitabine-based or fluoropyrimidine-based chemotherapy.

Method: From December 2006 to January 2020, consecutive 309 unresectable ICC patients were enrolled. Of them, 162 ICC patients received chemotherapy as first-line treatment were retrospectively reviewed, and 123 patients had evaluable images for tumour response evaluation. Objective response rate (ORR) and overall survival (OS) were assessed and factors associated with ORR and OS were analysed.
Results: Of the 162 ICC patients received chemotherapy as first-line therapy, the mean age was 62 years old. Most patients were within Child-Pugh class A (61.7%) and Albumin-bilirubin (ALBI) grade 2/3 (67.3%). Of them, 106 (65.4%) received gemcitabine-based regimen, while 56 (34.6%) patients received fluoropyrimidine-based regimen. The ORR was 26.0% and disease control rate (DCR) was 48.0% in the whole 123 ICC patients with evaluable images (including 32 partial responses, 27 stable diseases, and 64 progressive disease). HBV infection (OR, 3.223; $p = 0.032$), gemcitabine-based regimen (OR, 4.714; $p = 0.008$) were the independent predictors of ORR. In general, the median OS of the 162 ICC patients was 6.1 months. Presence of cirrhosis, Albumin ≤3.5 g/dl, Child-Pugh B/C, ALBI grade 2/3, NLR ≧ 3, and CA 19-9 ≧ 300 U/ml were independent risk factors associated with OS. A novel ALBI-based scoring system to predict OS was created, the patients could be classified into 4 groups. Kaplan-Meier analysis showed that the new ALBI-based model could significantly discriminate OS between contiguous groups (p < 0.001, Figure). Noteworthily, patients without any risk factors had a promising overall survival of 21.3 months.



Conclusion: Albumin-bilirubin grade is an important factor associated with survival in unresectable ICC patients receiving chemotherapy. The new ALBI-based model can be applied to select patients who can get the best benefit from chemotherapy.
Conflict of interest: The authors declared no conflicts of interest.
Funding: The work was partly supported by the Taipei Veterans General Hospital, Taipei, Taiwan (grant numbers V110A-004).

THU573

Transarterial radioembolisation in non resectable hepatocellular carcinoma in curative strategies: a single centre experience

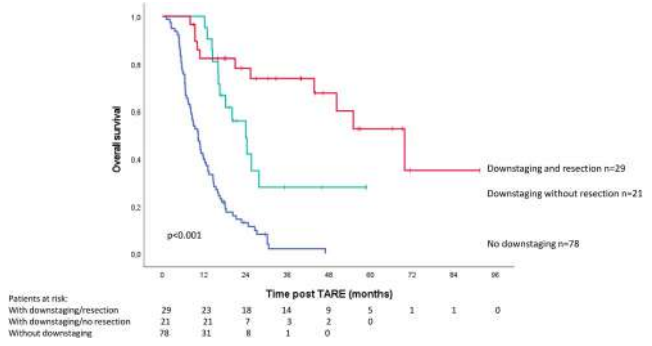
Helene Regnault[1], Clara Perrin[2], Giuliana Amaddeo[1], Sebastien Mulé[1], Hicham Kobeiter[1], Edouard Reizine[1], Emmanuel Itti[1], Christophe Duvoux[1], Alexis Laurent[1], Vincent Leroy[1], Raffaele Brustia[1], Daniele Sommacale[1], Françoise Roudot-Thoraval[1], Lerman Lionel[1], Alain Luciani[1], Julien Calderaro[1], Julia Chalaye[1], Vania Tacher[1], Athena Galletto[3]. *[1]Henri Mondor University Hospital, Hepatology, Créteil, France; [2]Antoine Beclere University Hospital, Hepatology, Clamart, France; [3]Henri Mondor University Hospital, Medical Imaging, Creteil, France*
Email: helene.regnault@aphp.fr

Background and aims: Transarterial radioembolisation (TARE) has the potential to be curative either directly (radiation segmentectomy) or as neoadjuvant strategy before resection or transplantation.

However, its place remains largely debated. The aim of our study was to evaluate the outcome of initially non-operative patients after TARE in a single tertiary centre.

Method: This retrospective, observational study included all consecutive patients treated by TARE in our centre between october 2013 and june 2020. Clinical, biological and imaging data were collected at baseline and every 3 months during follow-up. Tumour response was evaluated at 6 months according to Response Evaluation Criteria in Solid Tumors (RECIST) 1.1 and modified RECIST (mRECIST). The suitability of surgical treatment after downstaging was systematically discussed in a weekly tumour board.

Results: 128 patients (male = 90%, mean age 64 years) were included. The majority (n = 88%) had cirrhosis (CPT A: 84%, CPT B: 16%) mainly due to viral hepatitis (21%), non-alcoholic steatohepatitis (18%) and alcohol (18%). HCC was classified as BCLC A: n = 14 (11%), BCLC B: n = 50 (39%) and BCLC C: n = 64 (50%). The majority of patients had an imaging infiltrative pattern: n = 52 (41%), a median diameter of 50 mm and portal vein invasion (n = 62, 49%) classified as VP1: n = 3, VP 2: n = 22, VP3: n = 28 and VP4: n = 9. Median AFP was 115. TARE was the first-line therapy in 77 patients. TARE could be successfully applied in all patients. At 6 months, the rates of complete and partial responses were 4 and 40% respectively, according to RECIST and 23 and 28% according to mRECIST. A downstaging was obtained in 50 (39%) patients, whom 29 (23%) had access to a curative treatment (transplantation: n = 17 (13%), resection: n = 11 (9%) and ablation: n = 1) in a median time of 4.3 months. Absence of access to surgery was due to general contra-indication (n = 10), progression (n = 5), refusal (n = 4) and presence on waiting list (n = 2). Median overall survival of patients with or without downstaging were 50.1 months [8.6–78.8] and 10.2 months [8.1–12.4] (p < 0, 001) respectively. Progression free survival (PFS) of patients with or without downstaging were 20.8 months [14.8–26.8] and 5.4 months [4.7–6.1] (p < 0, 001) respectively. In patients who achieved downstating, PFS was higher in patients who had surgery (median not achieved). Two variables were independently associated to downstaging: BCLC score (p = 0, 049) and ALBI score (p = 0.042).



Conclusion: These results suggest that TARE could be an effective treatment leading to downstaging of 40% patients with unresectable HCC, and allowed curative treatment in 57% of them. Combination of TARE followed by curative treatment is associated with a 2 year-survival of 70% vs 0% in patients with no downstaging.

Email: a.dalessio@imperial.ac.uk

Background and aims: Atezolizumab plus bevacizumab (A+B) is new standard of care for first-line treatment of unresectable hepatocellular carcinoma (HCC). No evidence exists as to its use in routine clinical practice in patients with impaired liver function.

Method: This retrospective, multi-centre observational study was conducted across 7 tertiary centres and collected 64 HCC patients consecutively treated with A+B. Safety outcomes included treatment-related adverse events (trAEs) graded according to CTCAE v5.0. We also assessed overall survival (OS), progression-free survival (PFS), overall response (ORR) and disease control rates (DCR) defined by RECIST v1.1 in patients treated according to label.

Results: Fifty-four patients had Barcelona Clinic Liver Cancer (BCLC)-C stage HCC (84%), mostly secondary to non-viral aetiology (n = 30; 47%) and Hepatitis C virus (n = 24; 37%). Forty-three patients (67%) suffered from any trAE, of which 11 (17%) were G3 and 1 (2%) G4. Compared to Child-Pugh A (n = 46, 72%), Child-Pugh B patients showed comparable distribution of trAEs, with similar rates of bevacizumab-related bleedings and atezolizumab-related AEs. In the 44 patients (69%) with a pre-treatment esophagogastroduodenoscopy, presence and grade of varices did not correlate with gastrointestinal bleeding events. Median OS of patients treated in first line was 12.7 months (95% CI, 7.6–12.7), while median PFS was 6.97 months (95% CI, 2.8–11.3). ORR and DCR were respectively 29% and 67%, with no difference between patients with Child-Pugh A and B cirrhosis.

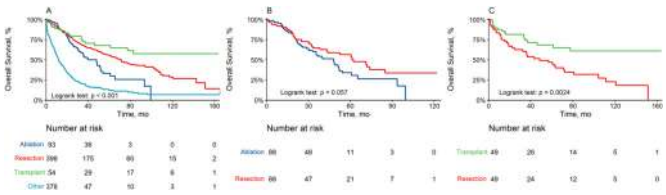
Conclusion: This study confirms reproducible efficacy and safety of A + B in routine practice. Child-Pugh B patients had similar tolerability and radiologic response compared to Child-Pugh A patients, warranting prospective evaluation of atezolizumab plus bevacizumab in this treatment-deprived population.

THU575

Comparative effectiveness of treatment for early-stage intrahepatic cholangiocarcinoma

Yi-Te Lee[1], Amit Singal[2], Marie Lauzon[3], Michael Luu[3], Vatche Agopian[1], Mazen Noureddin[3], Tsuyoshi Todo[3], Irene Kim[3], Kambiz Kosari[3], Nicholas Nissen[3], Gregory Gores[4], Ju Dong Yang[3].
[1]*University of California, Los Angeles, Los Angeles, United States;* [2]*University of Texas Southwestern Medical Center, United States;* [3]*Cedars-Sinai Medical Center, Los Angeles, United States;* [4]*Mayo Clinic Rochester MN, Rochester, United States*
Email: judong.yang@cshs.org

Background and aims: Incidence rates of intrahepatic cholangiocarcinoma (iCCA) continue to increase in western countries. Despite increases in the detection of early-stage iCCA, comparative effectiveness of treatment for early-stage iCCA remains unknown.
Method: We performed a retrospective cohort study using the National Cancer Database (NCDB),.
which represents more than 70 percent of newly diagnosed cancer cases nationwide. Patients diagnosed with single iCCA less than 3 cm in size without lymph node or extrahepatic involvement between 2004 and 2018 were analyzed. Multivariable cox regression was used to compare the efficacy of treatments. Propensity score matched analyses were performed to compare the outcome between resection, liver transplant, and local ablation.
Results: 1093 patients received the following treatments: 464 (42%) resection, 113 (10%) ablation, 62 (6%) transplant, and 454 (42%) other noncurative treatments including best supportive care. Overall median survival was 71.1 months (95% confidence interval [CI]: 60.5–93.7), 48.0 months (95% CI: 33.1–52.1), 11.7 months (95% CI: 10.4–14.3) for resection, ablation, and other treatments, respectively. Median survival was not reached in patients who received liver transplant (95% CI: 77.4-nonestimable). One, three, and five year survival were 89% (95% CI: 86%–92%), 68% (95% CI: 63%–73%), 56% (95% CI: 51%–62%) for resection, 89% (95% CI: 83%–96%), 54% (95% CI: 45%–66%), 33% (95% CI: 23%–47%) for ablation, 89% (95% CI: 81%–98%), 73% (95% CI: 62%–86%), 68% (95% CI: 56%–83%) for liver transplant, 49% (95% CI: 44%–55%), 20% (95% CI: 16%–25%), 13% (95% CI: 10%–17%) for other treatments ($p < 0.001$) (Figure 1A). With surgical resection as a reference group, patients receiving liver transplant had improved overall survival (adjusted hazard ratio [aHR]: 0.61, 95% CI: 0.38–1.00) while those who underwent ablation (aHR: 1.32, 95% CI: 0.96–1.82) or other noncurative treatments (aHR: 3.95, 95% CI: 3.24–4.82) had worse overall survival. Propensity score matched analyses showed a trend toward higher mortality with ablation than resection (aHR: 1.46, 95% CI: 0.91–2.36) (Figure B) and reduced mortality with liver transplant compared to resection (aHR: 0.37, 95% CI: 0.18–0.78) (Figure C).



Conclusion: In early-stage iCCA patients, curative treatments are associated with improved survival. Surgical resection and liver transplantation are associated with improved survival compared to ablation.

THU576

Twenty-year trends in radiofrequency ablation for treatment-naive hepatocellular carcinoma within the Milan criteria

Se Young Jang[1], Soo Young Park[1], Yu Rim Lee[1], Young Oh Kweon[1], Won Young Tak[1], Won Kee Lee[2], Sungmin Kim[3]. [1]*School of Medicine, Kyungpook National University, Kyungpook National University Hospital, Internal Medicine, Daegu, Korea, Rep. of South;* [2]*School of Medicine, Kyungpook National University, Medical Informatics;* [3]*University of Ulsan, Biomedical Engineering, Korea, Rep. of South*
Email: wytak@knu.ac.kr

Background and aims: Radiofrequency ablation (RFA) is widely used to treat hepatocellular carcinoma (HCC) because of its safety, cost effectiveness, and liver function conservation. We examined temporal trends in the long-term results of percutaneous RFA for treatment-naïve HCC within the Milan criteria and analysed factors affecting treatment outcomes.
Method: We retrospectively analysed 1, 099 HCC cases within the Milan criteria treated with percutaneous RFA from January 2000 to December 2019 at a single tertiary hospital. The follow-up period ranged from 0.3 to 247.9 months (median: 53.2 months). Overall survival, recurrence-free survival, and factors affecting survival and progression were analysed. A trend test was performed to analyse the changing trends of subject characteristics and treatment outcome.
Results: The overall and recurrence-free survival rates of patients improved in the later period. Viral hepatitis-related HCC decreased, while alcohol- or non-alcoholic fatty liver disease-related HCC increased from the earlier to the later period (P for trend <0.001). Tumour size and alpha-fetoprotein levels decreased. Older age ($p < 0.001$), Child-Pugh class B ($p < 0.001$), the presence of cirrhosis ($p < 0.001$), non-viral aetiology ($p < 0.001$), and large tumour size ($p = 0.001$) were independent prognostic factors that predicted poor overall survival. Only large tumour size predicted local tumour progression ($p < 0.001$). Tumour location, such as subcapsular, subphrenic, or perivascular, was not a significant factor in survival or local tumour progression.
Conclusion: Twenty-year outcomes of RFA showed excellent results in treating early-stage HCC within the Milan criteria. Both subject characteristics and treatment outcomes of have changed over time. Advances in technology and antiviral therapy have improved treatment outcomes.

THU577

Incidence of hepatocellular carcinoma reduced in chronic hepatitis B patients treated with entecavir plus Biejia-Ruangan: extended follow-up of a multicenter, randomised, double-blinded, placebo-controlled trial

Dong Ji[1], Yan Chen[1], Zheng Dong[1], Xiao-he Xiao[1], Yongping Yang[1].
[1]*Fifth Medical Center of Chinese PLA General Hospital, Senior Department of Hepatology, Beijing, China*
Email: jidg302@126.com

Background and aims: Chronic hepatitis B virus (HBV) infection and liver cirrhosis have been proven to be high-risk factors for hepatocellular carcinoma (HCC), which is the fifth most common tumour worldwide and the second most common cause of cancer-related death in China. Over the past two decades, progress has been made in treating fibrosis with traditional Chinese medicine due to their multi-targeted molecular mechanism. In the present study, we aimed to compare incidence of HCC in chronic hepatitis B (CHB) patients treated with entecavir (ETV) plus Biejia-Ruangan (BJRG) versus entecavir (ETV) plus placebo.
Method: In this study, we extended to followed up the participants of a multicenter, randomised, double-blinded, placebo-controlled trial (NCT01965418) after the end of the original trial. Originally, we had randomised 1000 CHB patients in equal numbers (1:1) to receive either ETV plus BJRG or ETV plus placebo treatment. The eligible patients underwent paired biopsies at treatment baseline and week 72. Afterward, patients entered a long-term prospective

observational open-label study, and were monitored at least every 12 weeks. Surveillance for HCC was performed by ultrasonography and alpha-fetoprotein (AFP) at each visit. HCC was diagnosed by multiphase dynamic contrast-enhanced MRI. Intention-to-treat analysis was performed with the use of Kaplan-Meier curves and log-rank test. The incidence of HCC was estimated with Cox proportional hazards regression models.

Results: Totally 1000 patients who received randomised treatment, 946 (94.6%) patients entered the open-label phase, and 872 (87.2%) completed 84-month follow-up. Overall (during a median follow-up of 89.0 months), 23 (4.6%) in ETV plus BJRG group and 43 (8.6%) patients in ETV plus placebo group developed HCC, cumulative HCC incidence was notably lower for ETV plus BJRG group than ETV plus placebo group (HR 0.52, 95%CI 0.32–0.87, P = 0.001). one (0.2%) patient in the ETV plus BJRG group and 13 (2.6%) patients in the placebo group died. While there was no significant difference in non-HCC events (e.g., colorectal, thyroid or pancreatic cancer, upper gastrointestinal bleeding, ascites, etc.) between the two groups (HR 0.47, 95%CI 0.12–1.89, P = 0.280).

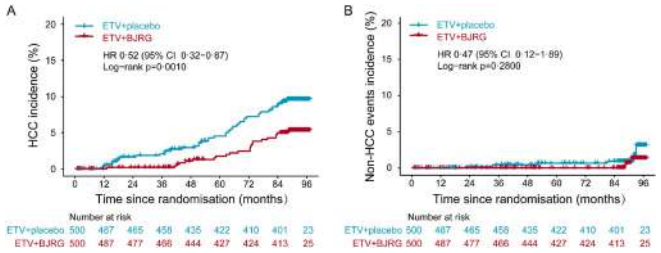


Figure: Cumulative incidence of HCC and Non-HCC events in ETV plus BJRG or ETV plus placebo groups

Conclusion: Comparing to ETV plus placebo treatment, ETV plus BJRG could further markedly reduce the incidence of HCC in chronic hepatitis B patients.

In vitro and in vivo preclinical efficacy of PD-L1-targeted liposomal doxorubicin as a combined therapy for the treatment of hepatocellular carcinoma

Daniela Gabbia[1], Antonella Grigoletto[2], Luana Cannella[1], Ilaria Zanotto[1], Veronica Mazzucco[1], Gianfranco Pasut[2], Sara De Martin[1]. [1]*University of Padova, Dept. of pharmaceutical and pharmacological sciences, Padova, Italy;* [2]*University of Padova, Dept of pharmaceutical and pharmacological sciences, Padova, Italy*
Email: sara.demartin@unipd.it

Background and aims: Hepatocellular carcinoma (HCC), the primary malignancy of the liver and the outcome of chronic liver diseases of different etiologies, remains a global health challenge, due to the lack of effective therapeutic options. The aim of this study is to evaluate a novel liposomal doxorubicin (DXR) formulation targeted with the PD-L1 checkpoint inhibitor atezolizumab, for the selective delivery of DXR to cancer cells, with the double aim of enhancing its activity and decreasing its off-target toxicity.

Method: Two liposomal formulations were evaluated, i.e. atezolizumab-targeted liposomal DXR (Stealth ImmunoLiposomes, SIL_atezolizumab) and untargeted liposomal DXR (Stealth Liposomes, SL). The in vitro cytotoxicity of liposomal doxorubicin was evaluated after 72 h of treatment by means of the ATP assay on the three PD-L1 expressing HCC cell lines Hu7, HepG2 and Hepa1–6 (Figure). In vivo efficacy was evaluated in a syngeneic HCC mouse model, obtained by injecting the murine HCC cells Hepa1–6 in C57BL/6J immunocompetent mice. SIL_atezolizumab and SL were administered e.v. once a week for 4 weeks. Tumor volumes were measured by an electronic caliper and collected and weighed at sacrifice for further analyses.

Results: Atezolizumab targeting increased the *in vitro* cytotoxic effect of liposomal DXR in HepG2 and Hepa1–6 cells, showing significant lower IC50 values with respect to SL ($p < 0.01$ and $p < 0.05$, respectively). Both SL and SIL_atezolizumab decreased tumor growth *in vivo* since tumor volumes measured at sacrifice were significantly lower in treated mice compared to controls ($p < 0.05$). A slight increase of survival was observed in SIL_atezolizumab treated mice.

Conclusion: PD-L1-targeted liposomal doxorubicin is effective in limiting HCC cells growth in vitro and in vivo. This approach could open new avenues for HCC therapy, using two already approved two drugs, joined in a novel combined formulation.

Figure: (abstract: THU578): Anti-proliferative effect of liposomal doxorubicin and IC50 values after 72 h-treatment.

the liver-specific enzyme CYP 450 1A2. Recently, radioembolization (RE) has demonstrated a non-inferior survival outcome compared to systemic therapy for advanced hepatocellular carcinoma (HCC). Therefore, current guidelines recommend RE for patients with advanced HCC and preserved liver function who are unsuitable for transarterial chemoembolization (TACE) or systemic therapy. However, despite the excellent safety profile of RE, post-therapeutic hepatic decompensation remains a serious complication that is difficult to be predicted by standard laboratory liver function parameters or imaging modalities. Our study investigates the potential of LiMAx for predicting post-interventional.

Method: In total, 50 patients with HCC with or without liver cirrhosis and not amenable to conventional locoregional or systemic treatments were included in the study. The study was carried out in a two-step fashion, including a retrospective and a prospective cohort. In both cohorts, LiMAx was carried out one day before RE (baseline). Standard liver function parameters were assessed at baseline, day 28, and day 90 after RE. First, the relationship between baseline LiMAx and pre-and post-interventional liver function parameters was analyzed in the retrospective cohort and subsequently validated in the prospective cohort. Subsequently, the ideal cutoff for LiMAx to predict post-interventional hepatic decompensation has been determined in the prospective part of the study.

Results: We observed a significant correlation between baseline LiMAx and Bilirubin, Albumin, ALBI-Grade, and MELD Score, especially at day 28 in the prospective cohort. Patients presenting with Child-Pugh B Score 28 days after RE had a significantly lower baseline LiMAx than those with a Child-Pugh A Score (223.5 µg/kg/h vs. 309 µg/kg/h, $p = 0.0263$). Using the ROC curve analysis, the potential of LiMAx for predicting hepatic decompensation after RE was determined and compared to MELD Score and ALBI Grade. LiMAx achieved an AUC of 0.8117. Patients with LiMAx values <238 µg/kg/h had a significantly higher risk of suffering hepatic decompensation after RE.

Conclusion: Patients with low LiMAx values (<238 µg/kg/h) despite Child-Pugh A situation at baseline have a significantly increased risk of hepatic decompensation after RE. Therefore, LiMAx can be used as an additional tool to identify patients at high risk of post-interventional hepatic failure.

THU580

The efficacy of molecular targeted therapies after atezolizumab plus bevacizumab in patients with unresectable hepatocellular carcinoma (HCC) in Japan

Kaoru Tsuchiya[1], Yuka Hayakawa[1], Yutaka Yasui[1], Tatsuya Kakegawa[1], Mayu Higuchi[1], Kenta Takaura[1], Shohei Tanaka[1], Chiaki Maeyashiki[1], Shun Kaneko[1], Nobuharu Tamaki[1], Hiroyuki Nakanishi[1], Masayuki Kurosaki[1], Namiki Izumi[1]. *[1]Musashino Red Cross Hospital, Department of Gastroenterology and Hepatology, Japan*
Email: tsuchiyakaoru5@gmail.com

Background and aims: In systemic therapy for unresectable HCC, 6 regimens (sorafenib, regorafenib, lenvatinib, ramucirumab, atezolizumab plus bevacizumab, and cabozantinib) have been approved in Japan. Atezolizumab plus bevacizumab (atez+bev) is recommended as 1st-line, and there is no established regimen after atez+bev. We investigated the efficacy of the other 5 regimens after atez+bev.

Method: A total of 76 patients who received atez+bev at our institution between Oct 2020 and Sep 2021 was enrolled.
Tumor assessments in accordance with RECIST v1.1 were done using dynamic CT or MRI every 6–12 weeks. Clinical course, including the efficacy of molecular targeted therapies after atez+bev was investigated retrospectively.

Results: The median age of the patients was 73 years. The median ALBI score was −2.19, and 58% of the patients were modified ALBI grade 2b. Line of treatment was 1st (n = 41), 2nd (n = 19), 3rd (n = 7), 4th (n = 5), 5th (n = 3), and 6th-line (n = 1). Forty-eight (63%) of the patients were BCLC stage B, and 28 patients were BCLC stage C. Median overall survival (OS) was not reached, and the 6-months survival rate was 83.0%. The median follow-up duration was 6.4 months, and the median time to progression (TTP) was 6.8 months. Overall response rate (ORR) in 1st-line and later-line were 30.5 and 13.5%. Disease control rate (DCR) in 1st-line and later-line were 86.1% and 66.7%. Discontinuation of atez+bev due to disease progression was observed in 33 patients, while discontinuation due to adverse events was reported in 12 patients. In the 12 patients, lenvatinib (n = 4), sorafenib-regorafenib (n = 1), cabozantinib (n = 3), and TACE (n = 3) were performed after atez+bev. Three patients received multiple therapies. Four of 12 (33%) patients received only supportive therapy. In the 33 patients with disease progression, 5 patients (15%) received only supportive therapy, and all 5 patients were pretreatment PS 1 or modified ALBI 2b. Of the 33 patients, 2 were treated with HAIC, and 26 received other molecular targeted therapies after atez+bev. Sorafenib was administrated after atez+bev in 5 patients, and 2 patients showed SD. Regorafenib was started in 4 patients, and 2 patients showed SD. Lenvatinib was started in 12 patients, and ORR and DCR were 22% and 67%. Ramucirumab was administered in 3 patients, and 1 patient showed SD. Cabozantinib was started in 14 patients, and ORR and DCR were 14% and 80%. In total, 33 of 45 (73%) patients who discontinued atez+bev received molecular targeted therapy.

Conclusion: Discontinuation of atez+bev due to adverse events in real-world practice was similar to the clinical trial, and all patients with pretreatment PS 0 and modified ALBI 1 or 2a could receive post-atez+bev therapies after disease progression. The efficacy of molecular targeted agents after atez+bev would be different from the results of the past clinical trials without immunotherapy.

THU581

The LiMAx level before transarterial chemoembolization or radioembolization is a predictor for short-time survival in patients with early stage HCC

Janett Fischer[1], Stella Wellhöner[1], Sebastian Ebel[2], Bettina Maiwald[2,3], Steffen Strocka[2,3], Tim-Ole Petersen[2,3], Albrecht Boehlig[1], Florian Gerhardt[1], Rhea Veelken[1], Timm Denecke[2], Thomas Berg[1], Florian van Bömmel[1]. *[1]Division of Hepatology, Department of Medicine II, University Hospital Leipzig, Leipzig, Germany; [2]Department of Diagnostic and Interventional Radiology, University Hospital Leipzig, Leipzig, Germany; [3]Clinic for Diagnostic and Interventional Radiology, St. Elisabeth and St. Barbara Hospital Halle, Halle (Saale), Germany*
Email: janett.fischer@medizin.uni-leipzig.de

Background and aims: Transarterial chemoembolization (TACE) and transarterial radioembolization (TARE) are standard treatment strategies for patients with hepatocellular carcinoma (HCC). The liver maximum capacity test (LiMAx) is a potential monitoring tool for post-interventional liver failure. The study aimed to investigate the correlation of LiMAx with patients' response to TACE or TARE treatment and the severity of adverse events after therapy as well as short-term and overall survival.

Method: In this study, 69 patients with TACE (n = 57) or TARE (n = 12) treatment were enrolled. Liver function was assessed on the day before as well as at 4 weeks after TACE or TARE using the LiMAx test and the well-established biochemical markers as well as MELD, CHILD Pugh and ALBI scores. Adverse events were each recorded over 4 weeks after the intervention. Survival was followed up until 3 years.

Results: A complete response to TACE/TARE and stable disease were observed in 10.3% and 51.5% of patients, respectively, and progressive disease in 38.2%. Mild adverse events developed in 48.5% of patients whereas 14.7% suffered from severe complications such as ascites and hepatic encephalopathy. LiMAx levels did not show a significant association with the occurrence of adverse events, laboratory parameters, liver function-associated scores and tumor response. However, survival analysis showed significant lower 30-day and 60-day survival rates for patients with LiMAx ≤150 µg/kg/h before

treatment compared to patients with LiMAx >150 μg/kg/h levels (30-day: 86.7% ± 8.8% vs. 100%, p = 0.006; 60-days: 86.7% ± 8.8% vs. 98.1% ± 1.8%, p = 0.048). When the patients were divided into groups according to the BCLC stage (BCLC A: n = 32, BLCL B: n = 29), significant differences in survival rates were detected for early but not for intermediate disease stage. The survival rates of patients with BCLC A stage with LiMAx ≤150 μg/kg/h were significantly lower after 30 days (75.0% ± 15.3% vs. 100%, p = 0.011) and 90 days (62.5% ± 17.7% vs. 95.8% ± 4.1%, p = 0.011) compared to those of patients with higher LiMAx levels. This was even more pronounced after 180 days with 50.0% ± 17.7% vs. 95.8% ± 4.1%, (p = 0.001) survival.
Conclusion: The LiMAx test identifies patients with early stage HCC and reduced short-time survival after transarterial treatment.

THU582
Implementation of a new prognostic scoring system after major hepatectomy in curative intent for perihilar cholangiocarcinoma
Christian Benzing[1], Thea-Charlotte Fritsch[1], Lena Haiden[1], Felix Krenzien[1], Alexa Mieg[1], Annika Wolfsberger[1], Cecilia Atik[1], Nora Nevermann[1], Uli Fehrenbach[2], Wenzel Schöning[1], Moritz Schmelzle[1], Johann Pratschke[1]. [1]*Charité University Medicine Berlin, Department of Surgery | Campus Charité Mitte and Campus Virchow Klinikum, Berlin, Germany;* [2]*Charité University Medicine Berlin, Department of Diagnostic and Interventional Radiology, Berlin, Germany*
Email: christian.benzing@charite.de

Background and aims: Major hepatectomy (MH) is the only curative therapy option for patients with perihilar cholangiocarcinoma (PHC). Despite recent advancements in adjuvant treatments and perioperative management, recurrence rates are still high and overall prognosis is poor. Current staging systems such as the American Joint Committee on Cancer (AJCC)/the Union for International Cancer Control (UICC) or the Bismuth staging system fail to adequately depict the patients' risk profile in terms of tumor recurrence. The present study seeks to establish a reliable scoring system that allows to classify the risk of tumor recurrence for individual patients in order to improve surveillance and adjuvant treatment programs.
Method: In this retrospective study, all patients undergoing MH for PHC at our department between January 2005 and August 2018 were retrospectively reviewed and analyzed. Demographic variables as well as perioperative, histopathological data and information on recurrence and overall survival were collected. After excluding postoperative 90-day mortality (n = 38, 14%), an uni- and multivariate logistic cox regression analysis was performed to identify factors associated with tumor recurrence. Subsequently, a score was assigned to each independent risk factor, which was summed up to a prognostic score ranging from 0 to 3 was created.
Results: We included 232 patients in the analysis. Median age was 64 years (33–86). The majority of patients had Bismuth-Corlette IV tumors (42%, n = 97) and UICC stage IIIb (41%, n = 93). Tumor-free resection margins (R0) were achieved in 160 patients (70%), 131 patients were lymph node negative (N0, 57%). The 1–3- and 5-year disease-free survival (DFS) and overall survival (OS) rates were 77%, 36% and 20% vs. 82%, 45% and 24%, respectively. Multivariate cox regression showed that R1-status (Hazard Ratio, HR = 1.525, (95% Confidence interval, CI: 1.021–2.277), p = 0.039), V1 status (HR = 2.187, 95% CI: 1.378–3.470, p = 0.001), and N+ status (HR = 1.856, 95% CI = 1.272–2.709, p = 0.001) were independently associated with tumor recurrence. When calculating the prognostic score, 82 patients (35%) had a score of 0 points, 72 patients (31%) had a score of 1 point, 32 patients (14%) had a score of 2, and 13 patients (6%) had a score of 3 points. Kaplan Meier analysis showed highly significant correlation of disease-free survival (DFS) and overall survival (OS) with the scoring system (p < 0.001).

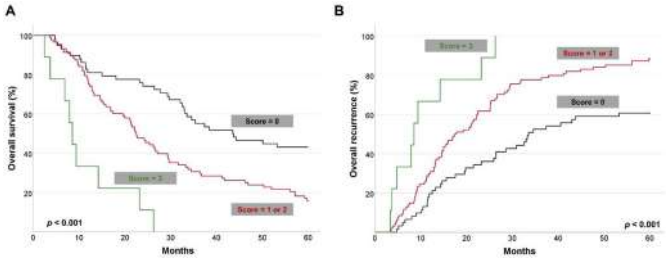

Figure 1: Overall (A) and Disease-free survival (B) after curative resection for perihilar cholangiocarcinoma according to the proposed prognostic score.

Conclusion: We proposed a simple scoring system that showed highly significant correlations with the clinical outcome (DFS and OS). This is of particular clinical significance since it allows a better risk stratification when compared to conventional scoring systems such as UICC and Bismuth stages.

THU583
The effect of discordance between preoperative imaging and postoperative pathology on the prognosis of hepatocellular carcinoma
Woo Sun Rou[1], Byung Seok Lee[2], Hyuk Soo Eun[2], Seok Hyun Kim[2], Hong Jae Jeon[2], In Sun Kwon[3]. [1]*Chungnam National University Sejong Hospital, Gastroenterology and Hepatology, Sejong-si, Korea, Rep. of South;* [2]*Chungnam National University Hospital, Gastroenterology and Hepatology, Daejeon city, Korea, Rep. of South;* [3]*Chungnam National University Hospital, Clinical Trial Center, Statistics Office, Biomedical Research Institute, Daejeon city, Korea, Rep. of South*
Email: gie001@cnuh.co.kr

Background ans aims: In patients who have undergone surgical resection, the discordance between preoperative imaging and postoperative pathological findings may be found. There was a report that the mismatch of the Milan criteria before and after liver transplantation (LT) was reported to be 22.0–27.2% and had an effect on the survival rate. However, there is no studies about impact of this discordance in patients who have undergone surgical resection. In this study, preoperative imaging and postoperative pathologic findings were compared for tumor size, number, vascular or biliary tract invasion, and lymph node (LN) metastasis. In addition, the survival rate according to the discrepancy for each factor is compared, and according to the number of discrepancies, the impact on HCC prognosis is investigated.
Method: Among the 13, 838 patients with HCC extracted randomly from the 2008–2016 national cohort of the Korean Central Cancer Registry, we selected the 2, 781 patients who had undergone surgical resection or LT. And we evaluated the concordance of tumor maximal diameter, tumor number, bile duct invasion, LN metastasis, and vascular invasion including portal vein (PV), hepatic vein (HV), hepatic artery (HA) by comparing preoperative imaging findings with postoperative pathologic findings. In addition, the survival rate was compared by Kaplan-Meier according to the number of discrepancies, and further analyzed by Cox proportional hazards regression analysis.
Results: Vascular invasion including HA, HV and PV invasion had a poorer prognosis than the both negative group when either of the imaging findings or pathological findings were positive ($p = 0.001$ and $p < 0.001$, respectively). In particular, PV invasion, when both findings were positive, was significantly worse prognosis ($p < 0.001$). Bile duct invasion had a poorer prognosis when pathological findings were positive than those that were not ($p = 0.001$), and there was no difference in survival rate when pathologic findings were negative even if bile duct invasion was suspected on imaging findings ($p = 0.911$). When analyzing according to the number of mismatched factors among seven factors, as the number of mismatched factors increased, the prognosis of HCC patients was poor ($p < 0.001$). Multivariate analysis also showed that the number of discrepancies

(for all concordance, *vs*. 1 discrepancy HR 1.529, $p = 0.001$ or *vs*. 2 discrepancy, HR 2.889, $p < 0.001$ or *vs*. 3 discrepancy, HR 3.986, $p < 0.001$, respectively), discrepancy in tumor diameter (HR 0.683, $p = 0.003$), and discrepancy in LN metastasis (HR 2.399, $p = 0.001$) were independent factors for the HCC prognosis.
Conclusion: This study revealed for the first time that the more factors that did not match the preoperative imaging findings and the postoperative pathological findings is associated with the poorer survival rate in patients undergoing surgical resection as independent predictive factor.

THU584

Early Nivolumab addition to Regorafenib in patients with hepatocellular carcinoma progressing under 1st line therapy (GOING trial). Interim analysis and safety profile

Email: mreig1@clinic.cat

Background and aims: Regorafenib (Rego) improves survival in patients with hepatocellular carcinoma (HCC) (RESORCE trial) while Nivolumab (Nivo) is also safe and active in terms of radiologic response (15–20% objective response) in second-line. The GOING trial (NCT04170556) is an investigator-initiated phase I/IIa study assessing the safety of Rego plus Nivo in HCC patients who progress and tolerate sorafenib (Cohort A) or who discontinue atezolizumab plus bevacizumab (Cohort B).
Method: Patients from cohort A receive Rego as monotherapy for the first 2 cycles (starting dose 160 mg/day, 3 weeks on/1 week off and adjusted for adverse events [AEs]) and Nivo is added at day 1 of cycle 3 (the first 10 patients at 3 mg/kg; since they did not present serious-AE (SAE), the final dose is 240 mg every two weeks). Treatment continues until unacceptable AEs, symptomatic tumor progression, patient decision or death. Safety is measured by the rate of AEs, rate of treatment related-AEs (Tr-AE), rate of AEs leading to treatment discontinuation and rate of death. Severity of AEs are evaluated according to CTCAE v.5.0. A futility analysis using the non-binding Lan and DeMets beta-spending functions with a boundary of p = 0.814 is mandated when 32.8% of cohort A has data of tumor assessment at least at week 16 by RECIST 1.1.
Results: Fifty-one patients have been enrolled in cohort A as of May 15, 2021. The first 30 (BCLC-C 73%) were considered in this safety analysis. All patients developed at least one AE, 29 (96.7%) had Tr-AEs of any grade and 10 (33.3%) had grade 3 (no grades 4 or 5 have been reported). Ten (33.3%) patients had a Rego-related AE, 4 (13.3%) Nivo-related, and 4 (13.3%) Tr-AE grade 3 of special interest. Table 1 describes the profile Tr-AE occurring in >10% of patients. Only 4 (13.3%) patients developed Tr-SAE, 3 (10%) Rego-related and 3 (10%) Nivo-related. Four patients discontinued the study due to physician decision, 2 for progression, and 2 for AEs (one related to study treatment). One patient had surgical resection after treatment discontinuation and a complete necrosis was observed at pathology.

Table 1. Profile of Tr-AE occurring in >10% in the first 30 included patients.

Adverse Events	Any Grade		Grade 3	
	Patients, n	Patients, %	Patients, n	Patients, %
Hand-foot-skin reaction	17	56.6	3	10.0
Asthenia	13	43.3	-	-
Diarrhea	11	36.7	1	3.3
Decreased Appetite	9	30.0	-	-
Arterial Hypertension	9	30.0	2	6.7
Hypertransaminasaemia	9	30.0	1	3.3
Hyperbilirubinaemia	6	20.0	1	3.3
Aspartate Aminotransferase Increased	6	20.0	1	3.3
Abdominal Pain	6	20.0	-	-
Dysphonia	5	16.7	-	-
Alanine Aminotransferase Increased	4	13.3	-	-

* None of these Tr-AE was grade 4- 5

Conclusion: The sequential combination of Rego-Nivo has a manageable safety profile. Less than one third of the patients developed grade 3/4 Tr-AE and there was no treatment-related death. Futility analysis allowed to continuing recruitment.

THU585

Impact of endobiliary radiofrequency ablation on survival of patients with advanced extrahepatic cholangiocarcinoma under systemic chemotherapy

Christian Möhring[1], Maria Angeles Gonzalez-Carmona[1], Robert Mahn[1], Taotao Zhou[1], Alexandra Bartels[1], Farsaneh Sadeghlar[1], Maximilian Bolch[1], Annabelle Vogt[1], Dominik Kaczmarek[1], Dominik Heling[1], Leona Dold[1], Jacob Nattermann[1], Vittorio Branchi[2], Hanno Matthaei[2], Steffen Manekeller[2], Jörg Kalff[2], Christian Strassburg[1], Raphael Mohr[1], Tobias Weismüller[1]. *[1]University Hospital of Bonn, Germany, Internal Medicine I, Bonn, Germany; [2]University Hospital of Bonn, Germany, Department of Surgery, Bonn, Germany*
Email: mariangelesgc@gmx.net

Background and aims: Prognosis of patients with advanced extrahepatic cholangiocarcinoma is still poor. The current standard first-line treatment is systemic chemotherapy with gemcitabine and a platinum derivate. Additionally, endobiliary radiofrequency ablation (eRFA) can be applied to treat biliary obstructions. The aim of this study was to evaluate the additional benefit of scheduled regular eRFA in a real-life patient cohort with advanced extrahepatic cholangiocarcinoma under standard systemic chemotherapy.
Method: This is a single center retrospective analysis. All patients with irresectable extrahepatic cholangiocarcinoma treated at University Hospital Bonn between 2010 and 2020 were eligible for inclusion. Patients were stratified according to treatment: standard systemic chemotherapy (n = 26) vs. combination of eRFA with standard chemotherapy (n = 40). Overall survival (OS), progression free survival (PFS), feasibility and toxicity were analyzed using univariate and multivariate approaches.
Results: Combined eRFA and chemotherapy resulted in significantly longer median OS (17.3 vs. 8.6 months, p = 0.004) and PFS (12.9 vs. 5.7 months, p = 0.045) compared to the chemotherapy only group. While groups did not differ regarding age, sex, tumor stage and chemotherapy treatment regimen, mean MELD was even higher (10.1 vs. 6.7, p = 0.015) in the eRFA+CT group. The survival benefit of concomitant eRFA was more evident in the subgroup with locally advanced tumors. Severe hematological toxicities (CTCAE grades 3–5) did not

differ significantly between the groups. However, therapy-related cholangitis occurred more often in the combined treatment group (p = 0.031).
Conclusion: Combination of eRFA and systemic chemotherapy was feasible, well-tolerated and could significantly prolong survival compared to standard chemotherapy alone. Thus, eRFA should be considered during therapeutic decision making in advanced extra-hepatic cholangiocarcinoma.

THU586

Interleukin 10 and Interferon Gamma levels are elevated in patients with hepatocellular carcinoma showing response to treatment with atezolizumab and bevacizumab

Sabine Lieb[2], Aaron Schindler[2], Johannes Niemeyer[2], Rhea Veelken[2], Janett Fischer[2], Rami Al-Sayegh[2], Thomas Berg[2], Florian van Bömmel[2].
[1]Leipzig University Medical Center, Division of Hepatology, Department of Medicine II, Leipzig, Germany; [2]Leipzig University Medical Center, Division of Hepatology, Department of Medicine II, Leipzig, Germany
Email: florian.vanboemmel@medizin.uni-leipzig.de

Background and aims: The combination treatment of the PD-L1 inhibitor atezolizumab plus bevacizumab (atezo/bev) has become standard of care in first line therapy in advanced hepatocellular carcinoma (HCC). However, prediction of treatment response is not well defined. Effector cytokines signalling (e.g. interferon gamma (IFN-g) is supposed to drive clinical response to immune checkpoint blockade. We have analysed circulating cytokine pattern in patients treated with atezo/bev.
Method: Thirty-three patients (31 male, mean age of 65 ± 11 (range 29–80) years) with advanced HCC (7 BCLC B, 26 BCLC C) treated at the University Cancer Center of Leipzig were retrospectively analysed. Twenty-eight patients had liver cirrhosis (23 Child-Pugh A, 5 Child-Pugh B), two underwent liver transplantation, two showed no hepatic disease and one had fatty liver disease. All together 136 cycles (mean 4.12, range 1–16 cycles) atezo/bev were applied to the patients. Tomography imaging was performed after 3 to 4 cycles of atezo/bev and evaluated according to mRECIST criteria. A cytokine panel including interleukin (IL)-1beta, interferon (IFN) alpha2, IFN-g, TNF alpha, IL-6, IL-8, IL-10, IL-12p70, Monocyte chemotactic protein 1 (MCP-1), IL-17A, IL-18, IL-23 and IL-33 was measured at baseline and correlated with treatment outcomes.
Results: The mean overall survival was 7 ± 5.3 (range 0–17) months. At the end of observation, 13 Patient showed stable disease (SD), 2 partial response (PR), 1 patient complete response (CR), 2 progressive disease (PD) and 15 patients died. Patients showing either CR, PR or SD at month 3 of treatment had higher mean baseline levels of IFN-g and IL-10 in comparison to patients with PD (IFN-g: 8.0 ± 5.48 (range 4.18–18.96) vs. 4.6 ± 0.87 (range 4.18–6.79), p < 0.001) and IL-10 (11.19 ± 9.6 (range 4.07–33.64) vs. 5, 74 ± 2, 05 (range 4.07–11.04), p < 0, 001). At month six of treatment, patients with either CR, PR or SD still presented higher mean baseline levels of IFN-g in comparison to patients with PD (8.74 ± 6.01 (range 4.18–18.96) vs. 4.18 ± 0.0, p = 0.026). There was no association of other cytokine levels measured with response to atezo/bev.
Conclusion: Response to atezo/bev in the treatment of HCC may depend on IFN gamma and IL-10 signalling. The value of these cytokines as response predictors needs to be evaluated in a larger cohort.

THU587

Potential faesability of atezolizumab-bevacizumab therapy in patients with hepatocellular carcinoma: a real-world analysis

Benedetta Stefanini[1,2], Laura Bucci[1], Valentina Santi[1], Nicola Reggidori[1], Davide Rampoldi[1], Lorenzo Lani[1], Franco Trevisani[1].
[1]S. Orsola-Malpighi Polyclinic, Division of Medical Semeiotics, Bologna, Italy; [2]Bologna, Semeiotica Medica, Bologna, Italy
Email: benedetta.stefanini@studio.unibo.it

Background and aims: Option treatments for patients with unresectable hepatocellular carcinoma (HCC) not amenable/ responding to locoregional treatments is represented by systemic therapy, and sorafenib and lenvatinib, two tyrosine-kinase inhibitors (TKIs) are currently the standard of care, providing modest but significant benefit on survival. Recently, the IMBrave-150 trial has demostrated that the combination of with atezolizumab plus bevacizumab (Atezo-Beva) is the best first-line systemic therapy for HCC patients, showing a clear superiority compared to sorafenib.
This study aimed at assessing the real-world potential feasibility of the Atezo-Beva therapy in a large cohort of HCC patients treated with TKIs.
Method: We retrospectively analysed 1448 patients diagnosed with unresectable HCC not amenable/not responding to locoregional treatments, treated with TKIs (sorafenib 98%, lenvatinib 2%) and followed-up from January 2010 to December 2020 by 24 Italian centres. The percentage of patients potentially amenable to Atezo-Beva treatment (according to IMBrave-150 trial criteria) and the overall survival (OS) of eligible/non-eligible patients were assessed.
Results: 423 (29.2%) of patients treated with TKIs were found to be qualified for the Atezo-Beva therapy. Their median OS was 17.3 months (95% CI 19.7–14.9) while that of non-eligible patients was 13.1 months (95% CI 14.5–11.6) (p = 0.038), likely due to better baseline clinical characteristics (Table 1). The main exclusion causes were a Child-Pugh class >A (399 cases) and a performance status >1 (187 cases). The proportion of eligible cases considering, as selection criterion, PLT >50000 mmc (instead of >75000 mmc requested by the IMBrave trial) increased by 43 cases (+2.9%), while including Child-Pugh Class B7 it increased by 85 patients (+5.9%).

[1] In Child-Pugh class B 258 (62%) patients showed a score of 7 (B7)
Figure 1. Characteristic of eligible population and not eligible population

Conclusion: Real world data indicate that no more than one-third of HCC patients treated with TKIs are potentially eligible for Atezo-Beva therapy. These patients have a better OS than non-eligible ones, owing to a better baseline clinical profile. Therefore, TKIs will remain the front-line approach for most of the HCC patients qualified for systemic therapy, due to the stringent selection criteria dictated by immunotherapy trials and the use of TKIs currently extended to Child-Pugh B patients. However, further prospective studies in real life may broaden Atezo-Beva indications.

THU588

Progression patterns and therapeutic sequencing following immune checkpoint inhibition for HCC: an observational study

Email: twt18@ic.ac.uk

Background and aims: Different approaches are available after progression of disease (PD) while on treatment with immune checkpoint inhibitors (ICI) for hepatocellular carcinoma (HCC), including continuation of ICI, switching to tyrosine kinase inhibitors (TKIs) and cessation of therapy. Little is known about progression patterns and their relationship with optimal sequencing and survival outcomes post-ICI.

Method: From an international consortium of 13 tertiary-care referral centres, we screened 604 HCC patients treated with ICIs, including only those who experienced PD by data cut-off. We evaluated post-progression survival (PPS) according to treatment strategy at PD and verified its relationship with radiologic patterns of progression: intrahepatic growth (IHG), new intrahepatic lesion (NIH), extrahepatic growth (EHG), new extrahepatic lesion (NEH) and new vascular invasion (nVI).

Results: 364 (60.3%) patients had PD during observation, mostly following PD-1/PD-L1 monotherapy (80%). Median PPS was 5.3 months (95%CI: 4.4–6.9; 271 events). At data cut-off, 165 patients (45%) received no post-progression anticancer therapy. Both IHG (HR 1.64 [95%CI:1.21–2.22]; p = 0.0013) and nVI (HR 2.15 [95%CI:1.38–3.35]; p = 0.0007) at PD were significantly associated with shorter PPS. Continuation of ICI therapy beyond PD occurred in 64 patients (17.6%). Multivariate models adjusted for progression patterns, treatment line, and ALBI grade and ECOG-PS at PD confirmed receipt of ICI beyond PD with (HR 0.17, 95%CI 0.09–0.32; p < 0.0001), or without subsequent TKI (HR 0.39, 95%CI 0.26–0.58; p < 0.0001) as predictors of prolonged PPS compared to no anticancer therapy.

Conclusion: ICI-TKI sequencing is a consolidated option in advanced HCC, with poorer prognosis predicted by nVI and IHG. Despite lack of recommendation, continuation of ICI beyond progression in HCC is adopted in clinical practice: efforts should be made to identify patients who benefit from this approach.

THU590

GALAD score correlates with therapy response for transarterial and systemic therapies in patients with hepatocellular carcinoma

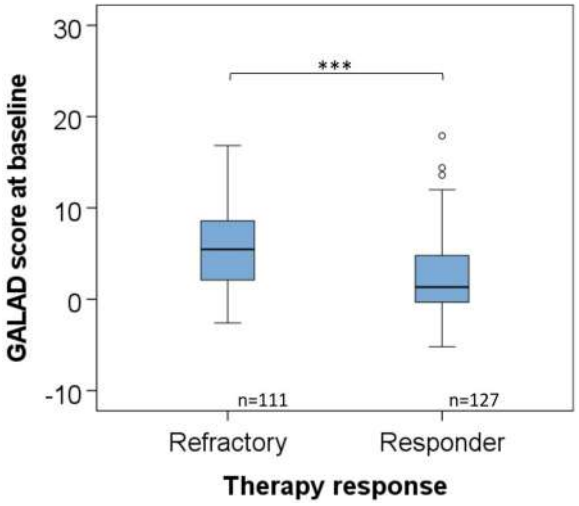
Anne Olbrich[1], Johannes Niemeyer[1], Hendrik Seifert[1], Olga Gros[2], Florian Lordick[3], Dirk Forstmeyer[3], Daniel Seehofer[4], Robert Sucher[4], Sebastian Rademacher[4], Timm Denecke[5], Sebastian Ebel[5], Nicolas Linder[5], Madlen Matz-Soja[1,6], Thomas Berg[1], Florian van Bömmel[1]. *[1]Leipzig University Medical Center, Department of Medicine II, Division of Hepatology, Leipzig, Germany; [2]Helios Clinic Köthen, Department of Anesthesia and Intensive Care, Köthen, Germany; [3]Leipzig University Medical Center, University Cancer Center Leipzig (UCCL), Leipzig, Germany; [4]Leipzig University Medical Center, Department of Visceral, Vascular, Thoracic and Transplant Surgery, Leipzig, Germany; [5]Leipzig University Medical Center, Department of Diagnostic and Interventional Radiology, Leipzig, Germany; [6]University of Leipzig, Rudolf-Schönheimer-Institute for Biochemistry, Leipzig, Germany*
Email: anne.olbrich@medizin.uni-leipzig.de

Background and aims: The GALAD score is a biomarker-based scoring system used for prediction of early hepatocellular carcinoma (HCC) in patients with chronic liver disease. It consists of the two risk factors gender (G) and age (A) and levels of AFP-L3 (L), AFP (A), and DCP (D). So far, a possible association of baseline GALAD score and therapy response was not investigated. For patients with advanced HCC, loco-regional treatment approaches, such as transarterial chemoembolization (TACE) and transarterial radioembolization (TARE) as well as systemic therapies are available, but response to these therapies is highly variable. The study aim is to assess the value of the GALAD model as a response marker to these treatment approaches.

Method: In a retrospective German single-center study, 238 patients with HCC treated with either TARE or TACE or systemic drugs were enrolled. Serum samples at baseline were analyzed to evaluate the prognostic performance of the GALAD score. Treatment efficacy was evaluated by mRECIST criteria based on magnet resonance imaging (MRI) three months (10–14 weeks) after intervention.

Results: In our patient cohort (n = 238) the mean GALAD score at baseline was 3.96 [range, −5.19–17.89]. Baseline GALAD scores were

significantly higher in patients in BCLC stage B or C/D as compared to stages A.
At baseline, mean GALAD scores were significantly higher in the refractoriness group compared to response group (5.66 versus 2.49; $p < 0.001$; Fig.). Regarding the different therapy options, the GALAD score showed a significant discrimination between the refractory and responder in the transarterial therapy group ($p < 0.001$) as well as in the systemic treatment group ($p = 0.01$).



Using ROC analyses the GALAD score for response of transarterial or systemic treatment showed higher AUC (AUC = 0.704; $p < 0.001$) than the individual biomarkers AFP, AFP-L3, and DCP in the overall cohort (AUC = 0.685, 0.629 and 0.645, respectively).
Conclusion: The GALAD model is a potent predictor of tumor response to transarterial and systemic treatment in HCC at baseline.

THU591

Antiviral and antitumor activity of SCG101, an autologous HBV-specific T cell receptor engineered T cell (TCR-T) therapy in HBV-related advanced hepatocellular carcinoma (HCC) patients after receiving ≥2 prior lines of systemic therapies

Shunda Du[1], Yuhong Zhou[2], Xiujuan Qu[3], Wei Wu[4], Ke Zhang[5], Xueshuai Wan[1], Wei Li[2], Dongmei Quan[4], Karin Wisskirchen[6,7], Ulrike Protzer[6,7], Yun Peng Liu[3]. *[1]Peking Union Medical College Hospital, Liver Surgery, Beijing, China; [2]Zhongshan Hospital, Fudan University, Medical Oncology, Shanghai, China; [3]The First Hospital of China Medical University, Medical Oncology, Shenyang, China; [4]The Sixth People's Hospital of Shenyang, Hepatobiliary Surgery, Shenyang, China; [5]SCG Cell Therapy, Shanghai, China; [6]Technical University of Munich, Institute of Virology, Munich, Germany; [7]Helmholtz Munich, Institute of Virology, Munich, Germany*
Email: cmu_trial@163.com

Background and aims: Adoptive cell therapy with TCR-T cells targeting HBV antigens represents an innovative approach for treatment of HBV-related HCC. SCG101 is a first-in-class genetically modified autologous TCR-T with a natural high-avidity TCR directed towards the HLA-A*02-restricted HBsAg peptide S_{20-28}. We here report first results from an ongoing pilot, investigator-initiated trial (IIT) conducted to evaluate the safety as well as the antiviral and antitumor activity of SCG101.
Method: Patients with HBV-related HCC (HBsAg positive, HBeAg negative and HBV DNA $\leq 2 \times 10^3$ IU/ml), who are HLA-A*02 positive and have received at least two lines of systemic therapy including small-molecule tyrosine kinase inhibitors and PD-1 checkpoint inhibitors were eligible. Following leukapheresis, SCG101 TCR-T cells were manufactured using an automated closed system. Prior to intravenous infusion of SCG101, patients receive lymphodepleting chemotherapy (fludarabine 25 mg/m^2/day and cyclophosphamide 500 mg/m^2/day for 3 consecutive days. Ascending dose levels of SCG101 at 1×10^7/kg to 2×10^8/kg TCR-transduced T cells were permitted according to protocol and safety assessment including dose-limiting toxicity (DLT) was adjudicated by a Safety Review Committee.
Results: As of Feb 28th, 2022, three HLA-A*02:01$^+$ patients have been enrolled: subjects ST1301 and ST1401 received 5×10^7/kg TCR-T cells, subject ST1204 received 1×10^8/kg. Transduced T cells were detectable in peripheral blood of all three patients up to last visit. Two patients, ST1301 and ST1204 showed a rapid HBsAg reduction of >1.7 log within 28 days after infusion and sustained with continuous decline thereafter. The HBsAg drop was correlated with a transient ALT/AST flare without significant change of other liver function markers including albumin, bilirubin, etc. Tumor response assessment by mRECIST showed that these two patients had stable disease (SD) with target lesion reduction of 14.5% and 6.2%, respectively, and maintained SD up to last visit (96+ and 55+ days). Patient ST1401 had a transient HBsAg drop of ~0.2 log from day 1–4 post treatment and was diagnosed with progressive disease (PD) at day 28. For all patients, no DLT or drug-related serious adverse events (SAEs) have been observed to date. Drug-related adverse events were typical for a T-cell therapy associated cytokine-release syndrome and transient or reversible after treatment.
Conclusion: Systemic SCG101 TCR-T cell therapy was well tolerated and showed promising early signs of clinical efficacy in advanced HBV-related HCC patients who have exhausted available targeted and immunotherapy options. Early and sustained HBsAg reduction demonstrates encouraging antiviral activity with target engagement of SCG101 and might serve as a potential predictive marker of antitumor efficacy. Preliminary data support further systematic clinical evaluation.

THU592

Current trends and in-hospital mortality of transarterial chemoembolization (TACE) in Germany: a systematic analysis of hospital discharge data between 2010 and 2019.

Sven H Loosen[1], Sarah Krieg[1], Tobias Eßing[1], Andreas Krieg[2], Christoph Roderburg[1], Tom Lüdde[2]. *[1]University Hospital Düsseldorf, Clinic for Gastroenterology, Hepatology and Infectious Diseases, Düsseldorf, Germany; [2]University Hospital Düsseldorf, Department of Surgery (A), Düsseldorf, Germany*
Email: Sven.Loosen@med.uni-duesseldorf.de

Background and aims: Transarterial chemoembolization (TACE) represents a standard of care for intermediate-stage hepatocellular carcinoma (HCC) and is also increasingly performed in patients with cholangiocarcinoma (CCA) or liver metastases. Recently, newer particle-based TACE procedures have been introduced but comprehensive data on clinical trends of TACE as well as its in-hospital mortality in Germany are missing. A systematic evaluation of existing data sets and their careful interpretation can support a rational discussion aiming at further optimizing framework conditions of TACE.
Method: Based on standardized hospital discharge data provided by the German Federal Statistical Office, we systematically evaluate current clinical developments, associated post-interventional complications as well as in-hospital mortality of TACE in Germany between 2010 and 2019.
Results: A total of 49, 595 individual cases undergoing TACE were identified within the observation period. The overall in-hospital mortality was 1.00% and significantly higher in females compared to males (1.12% vs. 0.93%; $p < 0.001$). We identified several post-interventional complications such as liver failure (51.49%), sepsis (33.87%), renal failure (23.9%) and liver abscess (15.87%), which were associated with a significantly increased in-hospital mortality. Moreover, in-hospital mortality significantly differed between the underlying indication for TACE (HCC: 0.83%, liver metastases: 1.22%,

and CCA: 1.40%) as well as between different embolization agents (liquid embolization: 0.80%, loaded microspheres: 0.92%, spherical particles: 1.54% and non-spherical particles: 2.84%), for which we observed large geographic differences in their frequency of use. Finally, in-hospital mortality was significantly increased in centers with a low annual TACE case volume (<15 TACE/year: 2.08% vs. >275 TACE/year: 0.45%).
Conclusion: We identified a variety of factors such as post-interventional complications, the embolization method used as well as the hospitals' annual case volume, which are associated with an increased in-hospital mortality following TACE. These data might help to further reduce mortality of this routinely performed local-ablative procedure in the future.

THU593

Pre-treatment cross-talk between the tumoural and peripheral immune system predicts response to checkpoint inhibition in advanced HCC: a single-cell study

Sarah Cappuyns[1,2,3,4], Gino Philips[2,3], Vincent Vandecaveye[5,6], Chris Verslype[1,7], Eric Van Cutsem[1,7], Diether Lambrechts[2,3], Jeroen Dekervel[1,7]. *[1]Digestive Oncology, Department of Gastroenterology, University Hospitals Leuven, Leuven, Belgium; [2]Laboratory for Translational Genetics, Department of Human Genetics, KU Leuven, Leuven, Belgium; [3]VIB Center for Cancer Biology, Leuven, Belgium; [4]Mount Sinai Liver Cancer Program, Divisions of Liver Diseases, Tisch Cancer Institute, Icahn School of Medicine at Mount Sinai, New York, United States; [5]Radiology Department, University Hospitals Leuven, Leuven, Belgium; [6]Laboratory of Translational MRI, Department of Imaging and Pathology, KU Leuven, Leuven, Belgium; [7]Laboratory of Clinical Digestive Oncology, Department of Oncology, KU Leuven, Leuven, Belgium*
Email: sarah.cappuyns@kuleuven.be

Background and aims: Checkpoint inhibitors have radically changed the treatment of advanced hepatocellular carcinoma (aHCC), albeit that only a subset of patients achieve durable disease control. We aimed to characterize both the tumoural and peripheral immune system of aHCC using single-cell sequencing technology and identify features associated with response and/or resistance to immunotherapy targeting the PD (L)1 axis.
Method: Patients with aHCC were prospectively enrolled prior to initiation of systemic therapy. Clinical response was defined as mRECIST objective response or durable stable disease. Pre-treatment tissue biopsies (n = 31) and both pre- and on-treatment peripheral immune cell samples (n = 58) were subjected to simultaneous single-cell transcriptome, T-cell receptor (TCR) and proteome sequencing, resulting in data from 377 975 single cells.
Results: PD1 and PDL1 were expressed in tumour-infiltrating T-cells versus myeloid cells and tumour cells, respectively. Myeloid cells from tumours responding to immunotherapy expressed significantly higher levels of PDL1 at baseline ($p = 0.014$), driven by pro-inflammatory PDL1-expressing CXCL10+ macrophages involved in T-cell recruitment. In contrast, non-responding tumours were infiltrated by immature 'monocyte-like' CX3CR1+ and CCR2+ macrophages ($p = 0.009$ and $p = 0.01$, respectively). Responding tumours were also characterized by a more clonal baseline TCR repertoire ($p = 0.007$) and a higher degree of TCR sharing ($p = 0.008$) with peripheral blood that decreased significantly on-treatment ($p = 0.026$). In peripheral T-cells, TCRs shared between tumour and blood displayed a higher TCR clonality ($p = 0.003$), while in the tumour they were present in recently activated CD8+ effector T-cells, characterized by high levels of cytotoxic markers.
Conclusion: Response to checkpoint inhibition in aHCC is driven by the pre-treatment presence of clonally expanded, recently activated cytotoxic CD8+ effector T-cells, infiltrating from peripheral blood and supported by a pro-inflammatory tumoural myeloid component.

THU594

The influence of fasting on tumor-targeted drug delivery

Svea Becker[1], Diana Möckel[2], Ilaria Biancacci[2], Jan-Niklas May[2], Qingbi Wang[1], Huan Sun[1], Marek Weiler[2], Twan Lammers[2], Maximilian Hatting[1], Christian Trautwein[1]. *[1]Medical Department III, Universitätsklinikum Aachen, Aachen, Germany; [2]Experimentelle Molekulare Bildgebung, RWTH Aachen, Aachen, Germany*
Email: svbecker@ukaachen.de

Background and aims: Hepatocellular carcinoma is increasing in industrialized countries. Disease progression is accelerated by a number of risk factors, although it can be reduced to some extent by using intermittent fasting. Tumorous cells are stressed by regular food deprivation because they are constantly proliferating. Fasting has also been established in recent clinical research to be a new therapeutic before tumor therapy leading to maintenance and repair processes such as autophagy. As a result, tumor therapy can be more precise and patients can show a higher survival rate.
Here, we aimed to show how fasting induces changes in the tumor microenvironment facilitating tumor-targeted drug delivery.
Method: We used a well-established syngeneic tumor model with the murine liver hepatoma cell line Hep-55.1C. The tumor was implanted subcutaneously and grew over 3.5 weeks. During tumor growth, the mice were either fasted intermittently every 12 h (IF), once overnight after 20 d for 12 h (STF), or fed *ad libitum* (*a.l.*). After 21 d, DSPE-Cy7 labeled liposomes were injected *i.v.* and the biodistribution of the nanoparticles was observed longitudinally up to 72 h *p.i.* via hybrid computed- and fluorescence tomography (CT-FLT).
Results: Our analysis demonstrates that mice in the *a.l.* group have little to no liposome-signal in the tumor but have substantial levels of uptake in reticuloendothelial system organs (RES). The STF group has tumor signals, but the RES-organs still have significant signals. The IF mice had the most signal in the tumor, while the RES-organs had fewer liposome signals detected by the CT-FLT.
In addition, intermittent fasting alters the microenvironment of tumors. Collagen1A1 levels in the IF group were considerably lower. This was accompanied by a considerable rise in the number of vessels that were positive for Lectin. In these tests, there was no difference between STF and *a.l.* mice.
Conclusion: Our findings show that intermittent fasting prior to tumor therapy improves the likelihood of a more precise and direct delivery method. Fasting softens the tissue and increases blood flow, making it easier to deliver (nano-)therapeutics into the tumor through the bloodstream.

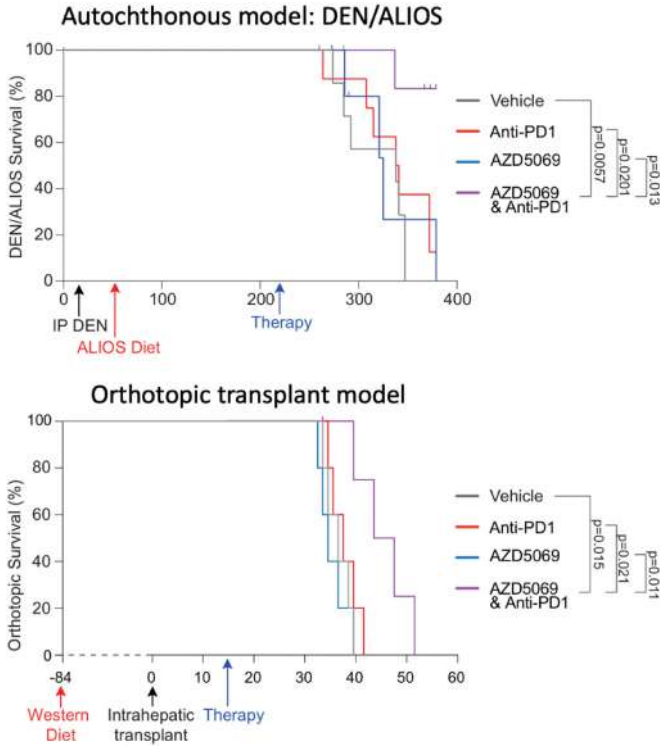
THU595

CXCR2 inhibition sensitises NASH-HCC to immunotherapy

Jack Leslie[1], John B. G. Mackey[2], Thomas Jamieson[2], Helen L. Reeves[1], Josep M. Llovet[3], Carlin Leo[2], Thomas G Bird[2], Owen Sansom[2], Derek A Mann[1]. *[1]Newcastle University Medical School, United Kingdom; [2]Beatson Institute for Cancer Research, Bearsden, United Kingdom; [3]Institut d'Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS), Barcelona, Spain*
Email: jack.leslie@ncl.ac.uk

Background and aims: Non-alcoholic steatohepatitis (NASH) is increasingly a major underlying cause of hepatocellular carcinoma (HCC). Immunotherapy offers great promise for HCC therapy; however, recent published data suggests that NASH is the cause of immune changes that negatively impacts on the efficacy of conventional immune checkpoint inhibition (ICI). Here we aimed to sensitise NASH-HCC to anti-PD1 therapy by targeting neutrophils using a CXCR2 small molecule inhibitor (AstraZeneca-AZD5069).
Method: Neutrophil infiltration was characterised in multiple models of murine HCC and in human patient biopsies. Late-stage intervention with anti-PD1 and/or AZD5069 was performed in two NASH-HCC models (orthotopic and autochthonous). The tumour microenvironment was characterised by a combination of immunohistochemistry, flow cytometry and RNA-seq.

Results: CXCR2$^+$ neutrophils were found to be highly represented in both murine and human NASH-HCC. In models of NASH-HCC lacking response to ICI, the combination of AZD5069 with anti-PD1 effectively suppressed tumour burden and extended survival (Fig 1). The combination therapy increased intratumoral CD103$^+$XCR1$^+$ dendritic cells and CD8+ T cells that are associated with anti-tumoral immunity. The therapeutic effect was lost upon genetic impairment of dendritic cells or antibody mediated depletion of CD8$^+$ T cells. Combination therapy resulted in an unexpected increase in tumour-associated neutrophils (TANs). These TANs were found to be proliferative and by the use of image mass cytometry to be located within immunological hubs in direct contact antigen presenting cells and CD8$^+$ T cells. These immune hubs were enriched for the cytotoxic anti-tumoural protease granzyme B which was found at increased levels in tumours co-treated with CXCR2 antagonist and anti-PD1 compared with monotherapy groups.



TANs in combination-treated tumours displayed a switch from a pro-tumour to anti-tumour progenitor-like neutrophil phenotype, closing resembling a recently characterised acute-inflammatory immature-Ly6G^{Int} neutrophil population isolated from lipopolysaccharide- (LPS)-treated mice. Intravenous infusion of these neutrophils into orthotopic tumour bearing mice, sensitised to anti-PD1 therapy, promoting dendritic cell and CD8$^+$ T cell recruitment and activation.

Conclusion: CXCR2-inhibition induces multi-cellular reprogramming of the tumour immune microenvironment that promotes ICI treatment of HCC in the context of NASH.

THU596

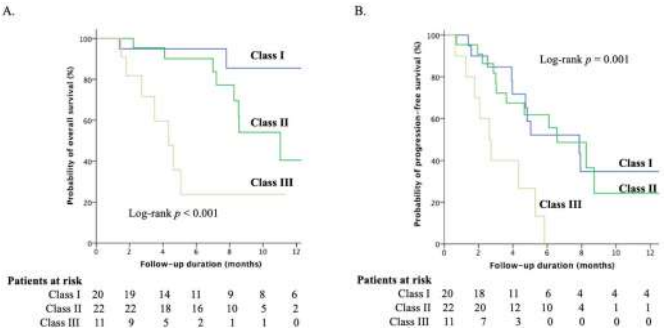
Combination of systemic immune-inflammation index and albumin-bilirubin score predict prognosis of sequential therapy with sorafenib and regorafenib in unresectable hepatocellular carcinoma

Tai-An Cheng[1], Wei Teng[2], Po-Ting Lin[3], Chen-Chun Lin[3], Chun-yen Lin[3], Shi-Ming Lin[3]. [1]*Chang Gung Memorial Hospital, Taiwan;* [2]*Chang Gung University, Taiwan;* [3]*Taipei Chang Gung Memorial Hospital, Taiwan*
Email: lsmpaicyto@gmail.com

Background and aims: Sequential therapy with sorafenib and regorafenib had shown promising results to improve outcomes for unresectable hepatocellular carcinoma (uHCC) patients. Although there have been several reports regarding the efficacy of sequential therapy in real-world, the role of specific inflammation markers for predicting the prognosis are still unclear. This study aimed to investigate prognostic value of systemic inflammatory markers in patients with HCC who received sorafenib-regorafenib sequential therapy.

Method: A total of 122 uHCC patients who received sorafenib-regorafenib sequential therapy from August 2016 to August 2021 were retrospectively enrolled for analysis. Treatment response was evaluated by modified Response Evaluation Criteria in Solid Tumors (mRECIST) criteria. The pre-treatment host factors, tumor status, biochemistry markers and inflammatory index (NLR, PLR, MLR, SII, SIRI, ILIS) were collected. Progression-free survival (PFS) and overall survival (OS) were assessed using the Kaplan-Meier survival curves. The Cox regression model was used to identify independent predictors of PFS and OS.

Results: Among the 122 patients, the median age was 66 years old and 84% were male gender. Regorafenib was used as the second and third lines of therapy in 97 (80%) and 25 (20%) patients respectively. Most patients were Child-Pugh A (96%), ABLI grade II (52%) and BCLC stage C (73%) at baseline. The overall response rate (ORR) and disease control rate (DCR) was 7.4% and 46.7%, respectively. The median OS from the initiation of sorafenib was 39.4 (95%CI: 32.9–45.8) and the median PFS after sorafenib was 3.4 (95%CI: 3.0–3.8) months. Multivariate Cox regression analysis showed that baseline ALBI grade I and systemic inflammatory index (SII) <330 were independent factors associated with good OS (hazard ratio [HR] = 0.655, p = 0.031 and HR = 0.570, p = 0.039) and PFS (HR = 0.725, p = 0.040 and HR = 0.341, p = 0.016). We further stratified our patients into 3 risks group (A: SII ≤330 and ALBI grade I, B: SII >330 or ALBI grade II/III, C: SII >330 and ALBI grade II/III). The combination of SII ≤330 and ALBI grade I showed the best OS (A vs. B vs. C = NR vs. 17.9 vs. 7.5 months, log-rank p = 0.003) and PFS (A vs. B vs. C = NR vs. 3.7 vs. 2.9 months, log-rank p = 0.001) than other two groups.



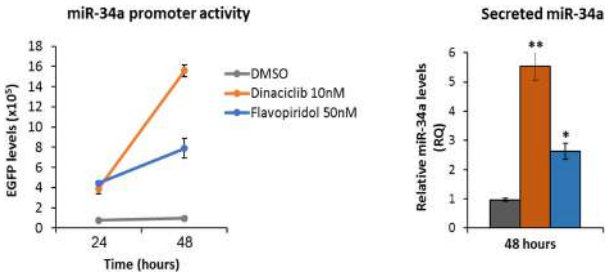
Conclusion: The combination of baseline ALBI grade and SII index can be used as a promising prognostic tool to predict prognosis of uHCC patients receiving sorafenib-regorafenib sequential therapy.

THU597

Induce the endogenous tumor suppressor miR-34a by small molecules to inhibit liver metastasis

Dayana Yaish[1], Tomer Friehmann[1], Alexander Plotnikov[2], Shira Levi[1], Hilla Giladi[1], Amnon Peled[1], Haim Barr[2], Eithan Galun[1]. [1]*Hadassah University Hospital-Ein Kerem, Goldyne Savad Institute of Gene and Cell Therapy, Jerusalem, Israel;* [2]*Weizmann Institute of Science, The Nancy and Stephen Grand Israel National Center for Personalized Medicine, Rehovot, Israel*
Email: dayana.yaish@mail.huji.ac.il

Background and aims: Metastasis originating from different cancers, are commonly spreading to the liver, and as such, are a common cause of death. Recent evidences have indicated the role of microRNAs (miRs) in modulating the metastatic process. There are specific miRs that exhibit tumor-suppressive activity by targeting cancer driver genes. MiR-34a is a well-known tumor suppressor and anti-metastatic miR. We hypothesize that induction of endogenous expression and secretion of miR-34a, could be a new strategy for metastasis therapy.
Method: We performed high throughput screening of synthetic small molecule libraries searching for compounds that induce miR-34a promoter activity and secretion. The compounds were initially tested for their ability to induce EGFP on HepG2 cells carrying a miR-34a-promoter-EGFP reporter. Compounds that induced EGFP levels were tested further for their effect on miR-34a secretion using qRT-PCR analysis performed on RNA extracted from the cell's media.
Results: We identified 6 compounds which induced miR-34a promoter activity. However, only 2 out of these 6 compounds induced miR-34a secretion. Searching databases for predicted activities of these 2 compounds, revealed that both may repress Cyclin Dependent Kinase 5 (CDK5). We therefore, examined the activity of known CDK5 repressors, Dinaciclib and Flavopiridol. Both molecules induced miR-34a promoter activity and secretion.



Conclusion: small molecule induction of miR-34a is a therapeutic approach against liver metastasis.

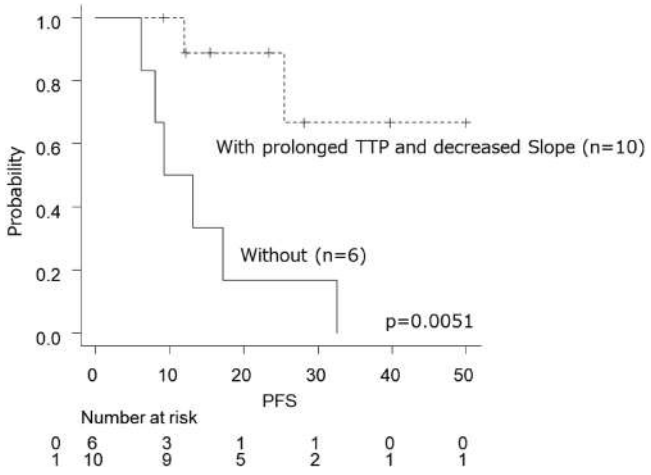
Prediction of treatment response using contrast-enhanced ultrasonography in patients treated with Atezolizumab and Bevacizumab for unresectable hepatocellular carcinoma

Hitomi Takada[1], Shinya Maekawa[1], Nobuyuki Enomoto[1]. [1]*University of Yamanashi, Gastroenterology and Hepatology, Chuo, Japan*
Email: takadahi0107@gmail.com

Background and aims: Atezolizumab plus Bevacizumab therapy (AB) was approved for unresectable hepatocellular carcinoma in 2020. However, the prediction of treatment response that can be easily used in clinical practice is still unknown. In this study, we performed Time-intensity curve (TIC) analyses using the arterial phase of contrast-enhanced ultrasonography (CEUS), and examined its usefulness as a predictive marker of early therapeutic effect after the administration of AB.
Method: Twenty-five patients who received AB for unresectable HCC were included. The initial treatment response after the administration of AB was reported using Response Evaluation Criteria in Solid Tumors (RECIST) after 8–12 weeks. The treatment response was evaluated every 8–12 weeks thereafter. CEUS was performed before administration and early after administration (3–7 days), and TIC analysis was performed using the arterial phase for 2 minutes after injection of the contrast medium. The time to peak (TTP) and the slope of wash-in (Slope) indicators were used for TIC analysis.
Results: The baseline characteristics of 25 patients were 69 (44–81) years old, 20 males, the maximum intrahepatic tumor diameter 64 (21–112) mm, and BCLC stage C 45%. The treatment response was Complete Response 1 case, Partial Response 7 cases, Stable Disease 11 cases, and PD 6 cases.
Patients with prolonged TTP and decreased Slope were 36% using CEUS at 3–7 days, and all cases achieved disease control based on the initial CT after 8–12 weeks. There was a significant difference in the median progression-free survivals (PFSs) between patients with and without prolonged TTP and decreased Slope ($p = 0.0051$). There was a significant difference in the median PFSs between patients with and without decreased α-fetoprotein (AFP) levels ($p = 0.019$). There was also a significant difference in the median PFSs between patients with and without decreased neutrophil-to-lymphocyte ratio (NLR) ($p = 0.038$). PFS stratification was possible by the number of positive numbers among the 3 early markers (TTP prolongation and Slope decrease/AFP decrease/NLR decrease) (0/1 vs. 2/3 8.6 vs. 33 weeks, $p < 0.001$).



Conclusion: Early evaluation using CEUS may be useful in predicting the therapeutic effect in patients treated with Atezolizumab and Bevacizumab for unresectable HCC.

Efficacy and safety of Atezolizumab plus Bevacizumab-based sequential treatment for unresectable hepatocellular carcinoma: a simulation model

Ciro Celsa[1], Giuseppe Cabibbo[1], Salvatore Battaglia[2], Paolo Giuffrida[1], Giacomo Emanuele Maria Rizzo[1], Mauro Grova[1], Marco Giacchetto[1], Gabriele Rancatore[1], Caterina Stornello[1], Maria Vittoria Grassini[1], Giuseppe Badalamenti[3], Marco Enea[1], Antonio Craxi[1], Vito Di Marco[1], Calogero Camma[1]. [1]*Section of Gastroenterology and Hepatology,*

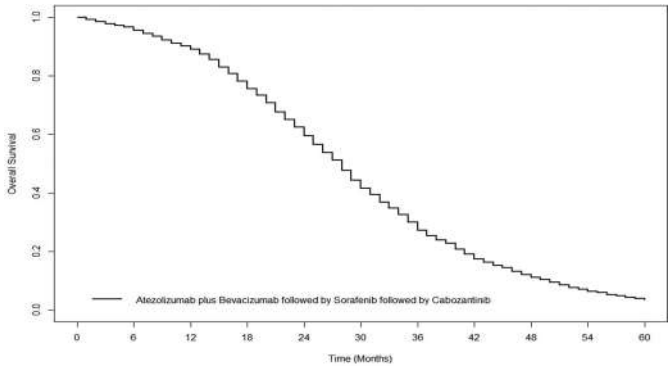
Email: calogero.camma@unipa.it

Background and aims: Systemic therapies for unresectable hepatocellular carcinoma (HCC) have rapidly increased in numbers over recent years and they should be combined in a rationale sequence to offer the best net health benefit. Atezolizumab plus Bevacizumab now represents the standard of care for first-line treatment, but efficacy and safety of subsequent treatment lines still remain unknown. According to hepatological and oncological guidelines, Sorafenib could be an option for second-line treatment after first-line Atezolizumab plus Bevacizumab and Cabozantinib is the only systemic agent tested as third-line treatment. The aim was to estimate the overall survival (OS) of the sequence of Atezolizumab plus Bevacizumab (first-line) followed by Sorafenib (second-line) followed by Cabozantinib (third-line).
Method: A Markov model (Figure 1) was constructed to estimate the OS of the sequence Atezolizumab plus Bevacizumab (first-line) followed by Sorafenib (second-line) followed by Cabozantinib (third-line). The probability of transition between states (first-line treatment, HCC progressions and death) was derived from published randomized controlled trials (RCTs). The proportion of patients who did not receive subsequent lines of therapy due to death was considered when estimating survival. OS was the main outcome. Rates of severe adverse events (SAEs) (defined as ≥grade 3 adverse events) were calculated.



Results: The estimated median OS of the sequential strategy is 28 months (95% Confidence Interval 27–29 months). Rate of SAEs is 67.5%.
Conclusion: This simulation model provides a forecast of the outcomes of the next available sequential systemic treatment of patients with HCC. The sequence including first-line Atezolizumab plus Bevacizumab followed by second-line Sorafenib followed by third-line Cabozantinib leads to a median OS of more than two years, with about two thirds of patients experiencing SAEs. Prospective real-world studies are needed to substantiate the net health benefit of this sequence.

THU600

Risk factors for hepatic encephalopathy in hepatocellular carcinoma after sorafenib or lenvatinib treatment: a real-world study

Bowen Chen[1,2], Linzhi Zhang[2,3], Jiamin Cheng[2], Xu Yang[4], Jin Lei[2,5], Tong Wu[2], Tao Yan[2], Yinyin Li[2], Yinying Lu[1,2]. *[1]Peking University 302 Clinical Medical School, Beijing, China; [2]The 5th Medical Centre of the PLA General Hospital, Beijing, China; [3]Tianjin Medical University Cancer Institute and Hospital, Tianjin, China; [4]Peking Union Medical College Hospital. Chinese Academy of Medical Sciences and Peking Union Medical College, Department of Liver Surgery, State Key Laboratory of Complex Severe and Rare Diseases, Beijing, China; [5]Guizhou Medical University, Guiyang, China*
Email: luyinying1973@163.com

Background and aims: This study aimed to investigate the incidence rate and risk factors for hepatic encephalopathy (HE) among unresectable hepatocellular carcinoma (uHCC) patients with liver cirrhosis who received sorafenib (SOR) or lenvatinib (LEN) treatment.
Method: uHCC patients with cirrhosis who received SOR or LEN treatment from September 2014 to February 2021 were continually recruited in our single-centre retrospective study. Hepatic Encephalopathy Scoring Algorism was used to evaluate occurrence and grade of HE during treatment and logistic regression models were used to further explore risk factors for HE.
Results: 214 patients were enrolled in SOR group, while the other 240 patients were in LEN group, with no statistical difference in baseline characteristics. At time of data cut-off (2021–12), the incidence of HE in SOR group (4.2%, 95%CI: 2%–7%) was significantly lower than that in LEN group (11.3%, 95%CI: 7%–15%) (p = 0.006). Alcohol-related cirrhosis [OR: 5.857 (95%CI: 1.519–22.591)], Child-Pugh Score >7 [OR: 3.023 (95%CI: 1.135–8.053)], blood ammonia ≥38.65 μmol/L [OR: 4.693 (95%CI: 1.782–12.358)], total bile acid ≥29.5 μmol/L [OR: 11.047 (95%CI: 4.414–27.650)], LEN treatment [OR: 6.162 (95%CI: 2.258–16.818)] and duration of treatment ≥5.6 months [OR: 4.350 (95%CI: 1.701–11.126)] were confirmed as risk factors for HE occurrence during tyrosine kinase inhibitors treatment.

Table 1: Occurrence of Hepatic Encephalopathy.

Variables	SOR Group (n = 214, %)	LEN Group (n = 240, %)	P value
Cases of HE	9 (4.2%)	27 (11.3%)	0.006
Grade of HE			
1	0 (0%)	1 (0.4%)	——
2	3 (1.4%)	14 (5.8%)	——
3	5 (2.3%)	4 (1.7%)	——
4	1 (0.5%)	7 (2.9%)	——
Unknown	0 (0%)	1 (0.4%)	——
Therapeutic Effect of HE			
Cure	8 (3.7%)	20 (8.3%)	——
Void	1 (0.5%)	7 (2.9%)	——
Discontinuation of SOR/LEN Treatment	5 (2.3%)	18 (7.5%)	——

——: not applicable
HE: hepatic encephalopathy, SOR: sorafenib, LEN: lenvatinib.

Conclusion: uHCC patients with cirrhosis who receive LEN are more likely to develop HE than SOR, with alcohol-related cirrhosis, Child-Pugh Score, serum ammonia, total bile acid, and duration of treatment to be risk factors for HE.

Acute liver failure and drug induced liver injury

FRI001

Obeticholic acid exacerbates the liver fibrosis of bile duct ligation model by inducing the liver expression of osteopontin

Jie Wang[1], Yuan Zihang[1], Yingying Miao[1], Haoran Zhang[1], Qipeng Wu[1], Xinliang Huang[1], Luyong Zhang[1,2], Q. W. Yu[1], Zhenzhou Jiang[1,3,4]. *[1]China Pharmaceutical University, New Drug Screening Center, Jiangsu Center for Pharmacodynamics Research and Evaluation, Nanjing, China; [2]Guangdong Pharmaceutical University, Center for Drug Research and Development, Guangdong, China; [3]China Pharmaceutical University, Key Laboratory of Drug Quality Control and Pharmacovigilance, Nanjing, China; [4]China Pharmaceutical University, State Key Laboratory of Natural Medicines, Nanjing, China*
Email: jiangcpu@163.com

Background and aims: Liver fibrosis is a dynamic process characterized by the deposition of the accumulated extracellular matrix (ECM). To date, there are still no therapeutic medications approved for fibrosis or cirrhosis. Osteopontin (OPN) is a phosphoglycoprotein of ECM, and has been reported to drive ductular reaction (DR) and the formation of periportal scarring. Obeticholic acid (OCA) is approved for Primary Biliary Cholangitis (PBC), and OCA has been shown to improve the fibrosis in NASH patients evaluated in REGENERATE study. But the applications of OCA are limited due to its side effects. The main objective of this study is to investigate the impact of OCA on liver diseases.
Method: The bile duct ligation model was used to evaluate the effect on fibrosis of OCA assessed by assessment of blood markers of liver injury, pathological section, western blotting, RT-PCR, immunohistochemistry and immunofluorescence stainging. OPN and Thr-OPN were detected by ELISA. The primary mouse cholangiocytes and human intrahepatic bile epithelium cells were chosen to investigate in vitro.
Results: Compared to control, OCA treatment (40 mg/kg) aggravated BDL induced liver injury and liver fibrosis in mice, demonstrated by significantly increase in serum ALT, AST, ALP, TGF-β1, hepatic hydroxyproline, Masson Trichrome, H&E, and Sirius red staining as well as immunohistochemistry staining of α-SMA. The serum and liver content of OPN and its another active form, thrombin-cleaved OPN (Thr-OPN), were obviously increased in OCA-treated BDL mice. Interestingly, there was also a significant increase in the content of Thr-OPN in the liver of OCA-treated sham mice. Next we examined the downstram effects of OPN in liver disease. Immunoblots analysis and immunohistochemistry staining of CK19 revealed that OCA treatment enhanced ductular reaction induced by BDL, and the immunofluorescence staining of CK19 and Ki67 also proved this. Immunoblots analysis of PCNA and immunohistochemistry staining of Ki67 revealed that OCA treatment weakened liver regeneration. RT-PCR analysis of liver nonparenchymal cells revealed that OCA increased the expression of *integrin αvβ3* receptors in BDL mice, which is OPN targeted.
Conclusion: OCA aggravated the degree of liver injury and fibrosis in obstructive cholestasis probably associated an apparent increase of OPN in serum and liver. OPN may be a biomarker of liver toxicity caused by OCA.

FRI002

A report on the Australian Drug Induced Liver Injury Network: AusDILIN

Beverly Rodrigues[1], Stephen Bloom[1,2], Rohit Sawhney[1,2], Geoffrey Haar[1,3], Maria Bishara[1], Ayushi Chauhan[1], Paul Gow[4], Simone Strasser[5], Alan Wigg[6], Karl Vaz[4], Fadak Mohammadi[6], Amanda Nicoll[1,2]. *[1]Eastern Health, Gastroenterology, Australia; [2]Eastern Health Clinical School, Monash University, Australia; [3]Eastern Health, Pharmacy, Australia; [4]Austin Health, Gastroenterology, Australia; [5]Royal Prince Alfred Hospital, Gastroenterology, Australia; [6]Flinders Medical Centre, Gastroenterology, Australia*
Email: beverly.rodrigues91@gmail.com

Background and aims: Drug induced liver injury (DILI) may vary in different regions due to population and prescribing differences. Data on DILI in Australia is limited but is necessary to inform local management. We present prospectively collected data from seventeen Australian liver centres in a new collaboration named AusDILIN.
Method: A prospective multicentre clinical audit was conducted on reported DILI patients between June 2018 to November 2021 inclusive (41 months).
Results: Data on 150 patients was obtained, and showed the commonest causes were: amoxicillin/clavulanic acid (n = 26, 17%), statins (n = 15, 10%) and cephalosporins (n = 12, 8%). Remdesivir was the identified causative agent in 5 (3%) of cases. Sixteen (11%) of patients were icteric on presentation. The median duration to onset and recovery was 3 ± 7.4 weeks, and 8 ± 12.9 weeks, respectively. One hundred and twelve (75%) were managed as inpatients. Forty-seven (31%) received some form of treatment; 11 (7%) were managed with ursodeoxycholic acid and 23 (15%) with corticosteroid monotherapy respectively, although 2 (1%) and 1 (1%) were already on these treatments long-term for chronic conditions. Of the 11 (7%) of patients with unresolving DILI, 4 (3%) were considered for liver transplant. Two (1%) of these were successfully transplanted and 1 (1%) died, with the overall cohort death rate being 4 patients (3%). Fifty patients (33%) were lost to follow up. The DILI persisted beyond 3 and 6 months in 30 (45%) and 10 (7%) of cases, respectively.

 © 2022 All rights reserved.

Table 1: Baseline characteristics of AusDILIN cohort

Median age (years)	56.37 ± 0.44 [18–94]	
Gender (M: F, n, %)	80 (53%): 70 (47%)	
Ethnicity (n, %)	Caucasian/European	114 (76%)
	SE Asian/Arabic	31 (21%)
	African	2 (1%)
	Unknown	3 (2%)
Pattern of liver injury (n, %)	Hepatitic: Cholestatic	54 (36%): 44 (29%)
	Mixed: Unknown	51 (34%): 1 (1%)
Treatment offered (n, %)	CS monotherapy	23 (15%)
	UDCA monotherapy	11 (7%)
	CS plus UDCA combination therapy	5 (3%)
	CS plus IM combination therapy	4 (3%)
	NAC infusion	2 (1%)
Clinical outcomes (n, %)	Self-resolved or resolving	87 (58%)
	Unknown or lost to follow up	50 (33%)
	Persistent or progressed	11 (7%)
	Death (DILI ALF)	4 (3%)
Considered for LTx (n, %)		4 (3%)
	Transplanted	2 (1%)
	Resolved	1 (1%)
	Death	1 (1%)

HTN = hypertension, Chol = cholesterol, DM = diabetes mellitus, CS = corticosteroids, UDCA = Ursodeoxycholic acid, IM = immunomodulator, NAC = N-acetyl cysteine, LTx = liver transplant, ALF = acute liver failure.

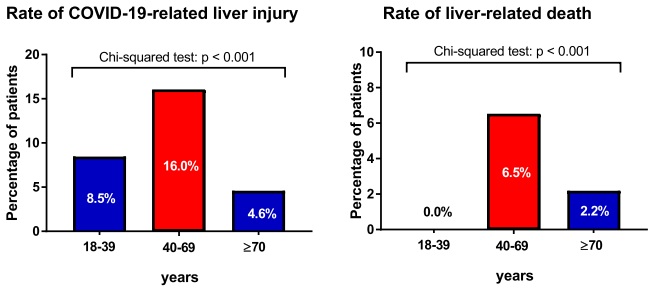
Conclusion: DILI is a significant cause of morbidity and mortality in Australia, with a high proportion suffering persistent liver injury, and with the role of treatment remaining undetermined and requiring further study.

FRI003

Incidence, phenotype and prognostic relevance of COVID-19-related liver injury across different age strata

Bauer[1,2], Bernhard Scheiner[1,2], Ernst Eigenbauer[4], Robert Strassl[5], Monika Breuer[5], Oliver Kimberger[6], Daniel Laxar[6], Michael Trauner[1], Mattias Mandorfer[1,2], Thomas Reiberger[1,2,3]. *[1]Medical University of Vienna, Division of Gastroenterology and Hepatology, Department of Medicine III, Vienna, Austria; [2]Medical University of Vienna, Vienna Hepatic Hemodynamic Lab, Division of Gastroenterology and Hepatology, Department of Medicine III, Vienna, Austria; [3]Medical University of Vienna, Christian Doppler Lab for Portal Hypertension and Liver Fibrosis, Vienna, Austria; [4]Medical University of Vienna, IT-Systems and Communications, Vienna, Austria; [5]Medical University of Vienna, Department of Laboratory Medicine, Division of Clinical Virology, Vienna, Austria; [6]Medical University of Vienna, Department of Anaesthesia, Intensive Care Medicine and Pain Medicine, Vienna, Austria*
Email: thomas.reiberger@meduniwien.ac.at

Background and aims: Severe acute respiratory distress syndrome-coronavirus-2 (SARS-CoV-2) caused the pandemic of coronavirus disease of 2019 (COVID-19). Variable abnormalities in liver chemistries have been reported in COVID-19 patients. We assessed the prevalence rates and trajectories of elevated liver enzymes after SARS-CoV-2 infection, as well as their prognostic values across different age strata in a large cohort of COVID-19 patients.
Method: Patients with a positive SARS-CoV-2 PCR result between 03/2020–07/2021 at the Vienna General Hospital were included in this study. Patients were stratified for age (i.e. 18–39 vs. 40–69 vs. ≥70 years). Multivariate Cox regression analyses were adjusted for pre-existing liver disease, age, sex, albumin, obesity, diabetes mellitus, cardiovascular disease, lung disease and malignancy.
Results: 900 patients (52.4% male) were included with 32.2% aged 18–39 years, 39.7% 40–69 years, and 28.1% ≥70 years age strata, respectively. Frequency of comorbidities, median D-dimer and C-reactive protein increased with age.
After SARS-CoV-2 infection, parameters of hepatocellular (aspartate aminotransferase [AST]/alanine-aminotransferase [ALT]) and cholestatic liver injury (alkaline phosphatase [ALP]/gamma-glutamyl transferase [GGT]) all significantly increased. AST/ALT and ALP/GGT were elevated in 40.3% (n = 262/650) and 45.0% (n = 287/638) of patients, respectively. The rates of COVID-19-associated liver injury and median levels of liver chemistries were highest in patients aged 40–69 (18–39 years: 8.5% vs. 40–69 years: 16.0% vs. ≥70 years: 4.6%; p < 0.001).
Elevated AST after the first SARS-CoV-2 PCR test was associated with the requirement for hospital admission, ICU admission and intubation throughout all age strata and with a higher frequency of death and liver-related death in patients aged 40–69. Elevated AST and total bilirubin (BIL) at the time of first positive SARS-CoV-2 PCR test independently predicted of mortality in the overall cohort (AST: aHR: 1.47; 95%CI: 1.01–2.14; p = 0.043/BIL: aHR: 2.20; 95%CI: 1.22–3.98; p = 0.009) and in patients aged 40–69 years (AST: aHR: 1.78; 95%CI: 1.04–3.06; p = 0.037/BIL: aHR: 2.18; 95%CI: 1.15–4.13; p = 0.017).



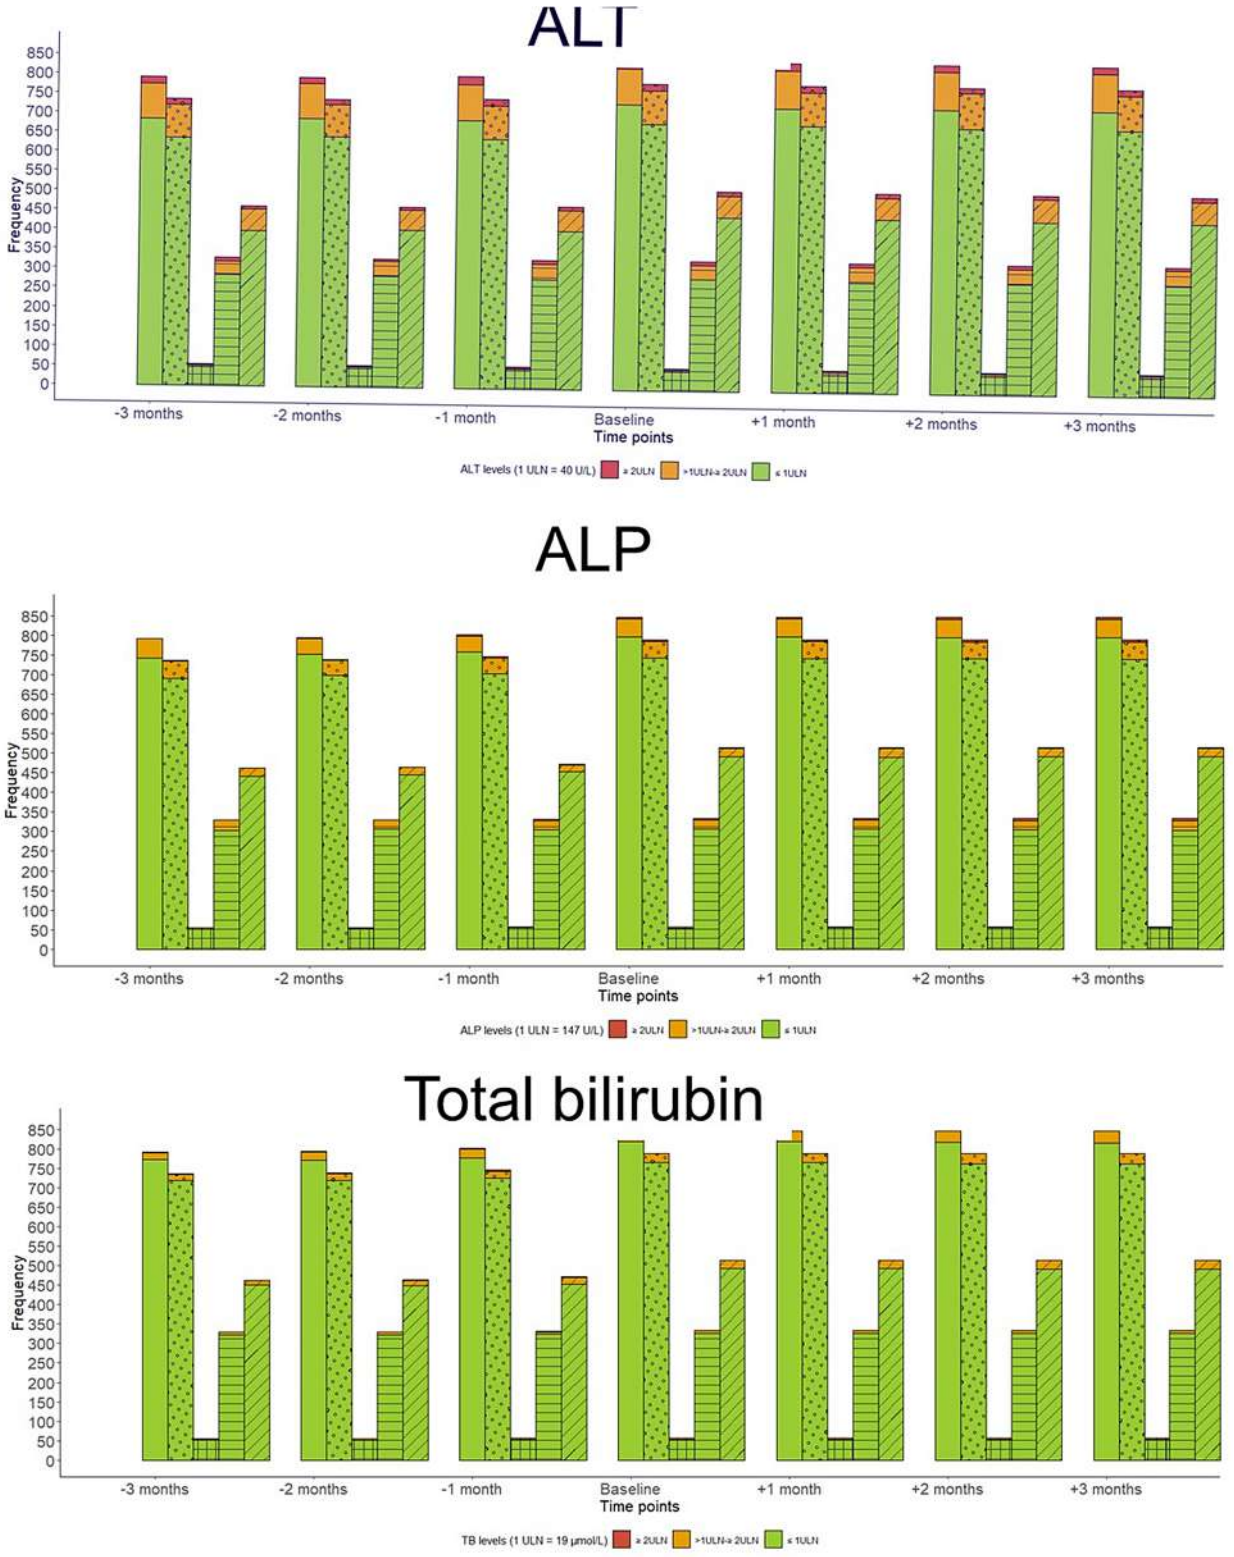
Conclusion: A considerable proportion of COVID-19 patients show abnormal liver chemistries. The subgroup of patients aged 40–69 years was at particularly high risk for COVID-19-related liver injury; elevated ALT was predictive of liver-related mortality. AST and BIL at the time of first positive SARS-CoV-2 PCR were independent predictors of mortality in the overall group, and particularly in patients aged 40–69 years.

FRI004

Two different types of COVID-19 vaccines and serial liver biochemistries

Grace Lai-Hung Wong[1], Vicki Wing-Ki Hui[1], Terry Cheuk-Fung Yip[1], Yee-Kit Tse[1], Vincent Wai-Sun Wong[1]. *[1]The Chinese University of Hong Kong, Medical Data Analytic Centre (MDAC), Hong Kong*
Email: wonglaihung@cuhk.edu.hk

Background and aims: A handful of vaccines against COVID-19 have been approved around the world. These vaccines have excellent safety profiles with few reported side effects. Data concerning the liver safety of COVID-19 vaccines are lacking. We aimed to report the serial liver biochemistries of people before and after receiving COVID-19 vaccines.
Method: This was a territory-wide retrospective observational cohort study in Hong Kong. We identified subjects who had received any of the two COVID-19 vaccines approved in Hong Kong-CoronaVac (the inactivated virus technology platform by Sinovac Biotech (Hong Kong) Limited) and Comirnaty (mRNA technology platform by Fosun Pharma in collaboration with the German drug manufacturer BioNTech, the BNT162b2 mRNA vaccine). Serial liver biochemistries at least 3 months before and after the COVID-19 vaccines were reported, in subjects with or without chronic hepatitis B or C.



Pattern – Group:

Circle – HBV/HCV negative

Crosshatch – HBV/HCV positive

Horizontal stripe – Comirnaty

Diagonal stripe – CoronaVac

Figure: Serial liver biochemistries before and after COVID-19 vaccine.

Results: 851 subjects (513 received CoronaVac and 338 received Comirnaty; 56.2% male, median age 52 years old; 6.8% chronic hepatitis B or C) were included. Majority (87%) subjects had normal ALT (1–2 × ULN: 10.8/%; >2 × ULN: 2.4%), total bilirubin (1–2 × ULN: 3.3%; >2 × ULN: 0%) and ALP (1–2 × ULN: 5.4%; >2 × ULN: 0.5%) before or at the time of receiving COVID-19 vaccines; these parameters remained stable for up to 3 months after the vaccination-ALT (1–2 × ULN: 11.6%; >2 × ULN: 2.1%), total bilirubin (1–2 × ULN: 3.7%; >2 × ULN: 0%) and ALP (1–2 × ULN: 5.4%; >2 × ULN: 0.8%) at or after the time of receiving COVID-19 vaccines. While patients with chronic viral hepatitis had higher ALT and ALP than those without chronic viral hepatitis at most of the times, these parameters remained normal (ALT: median 24 to 26 U/L vs. 20 to 21 U/L; ALP: median 88 to 90 U/L vs. 80 U/L). Similar serial liver biochemistries were observed in subjects who received CoronaVac and Comirnaty vaccine.
Conclusion: Both types of COVID-19 vaccines have very favourable liver safety profile in people with or without chronic viral hepatitis.
Grant support: This work was supported by the Health and Medical Research Fund (HMRF)-Food and Health Bureau Commissioned Research on COVID-19 (Reference no.: COVID1903002) awarded to Grace Wong.

Role of liver biopsy in management of immune checkpoint inhibitors hepatitis: a single-center retrospective study

Kennie Marcin[1], Lucia Parlati[1], Benoit Terris[2], Clemence Hollande[1], Anais Vallet Pichard[1], Helene Fontaine[1], Marion Cororuge[1], Loriane Lair Mehiri[1], Vincent Mallet[1], Philippe Sogni[1], Stanislas Pol[1].
[1]AP-HP.Centre-Université de Paris, Groupe Hospitalier Cochin Port Royal, DMU Cancérologie et spécialités médico-chirurgicales, Service d'Hépatologie, Paris, France, France; [2]AP-HP.Centre-Université de Paris, Groupe Hospitalier Cochin Port Royal, Service de Pathologie, Paris, France
Email: lucia.parlati85@gmail.com

Background and aims: Immune check point inhibitors drug induced-liver injury (ICI-DILI) may be associated with chemotherapy dose reduction and cancer progression. It is unclear whether liver biopsy modifies, or not, the management of ICI-DILI.
The aim of this study was to explore the impact of liver biopsy on the clinical management and the response to corticosteroids according to histological findings.
Method: We conducted a retrospective, single-center study to evaluate the biochemical, histological and clinical data of 28 patients with ICI-DILI who underwent liver biopsy (June 2015 to January 2021) in a teaching hospital in France. The severity of liver injury was graded according to Common Terminology Criteria for Adverse Events version 5.0 guidelines.
Results: Of the 28 patients (median [interquartile range] age 55 [23–80] years, 36% males), 13 patients (46%) had anti PD1 monotherapy, 6 patients (21%) anti PD1/anti CTLA4 combination therapy and 9 patients (32%) other immunotherapy. ICI-DILI occurred later in the other immunotherapy group than in the anti PD1 monotherapy and anti PD1/anti CTLA4 combination therapy groups (18.6 injections [1–60] vs 4 [1–28] and 3 [1–4] respectively, p = 0.047). The type of ICI did not influence the severity of the histological profile of the hepatitis, but patients receiving anti PD1/anti CTLA4 combination therapy had a tendency to more severe hepatitis in comparison to anti PD1 and other immunotherapy (83% of grade 3–4 hepatitis vs 61% and 57% respectively, p = 0.095). We did not observe any severe liver injury in our cohort. Corticosteroids were introduced in 6 (100%) patients of the anti PD1/anti CTLA4 combination therapy group, 7 (54%) patients of the anti PD1 monotherapy group and 4 (44%) patients under other therapy. All patients had a favourable clinical evolution after ICI withdrawal with no significative difference in the ALT normalization interval depending on the introduction of corticosteroids. The response to corticosteroids was similar according to the type of ICI and to the histological findings except for the cholangitic profile which seems to have a poorer response. The interval for ALT normalization was 110 (20–265) days for patients with cholangitic profile without corticosteroids, 120 (18–221) days for patients with cholangitic profile with corticosteroids and 54 (29–79) days for non cholangitic patients (Figure 1).

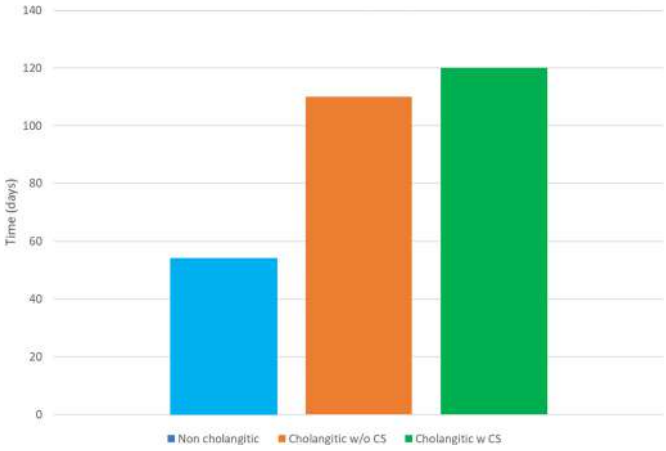

Figure: ALT normalisation interval according to cholangitic histological profile and corticosteroids treatment

Conclusion: In ICI-DILI, liver biopsy must not delay patient care but may be useful in identifying patients with a cholangitic profile who have a poorer response to corticosteroids. Corticosteroids could be reserved to patients who do not improve after ICI withdrawal.

Email: lucy.meunier@chu-montpellier.fr

Background and aims: Immune checkpoint inhibitors (ICI), targeting programmed cell death 1 (PD-1), its ligand (PD-L1) and anti-cytotoxic T lymphocyte-associated protein 4 (CTLA-4) changed the landscape of cancer therapy. Liver toxicity is occurring up to 16% in patients treated with ICI. International guidelines recommend pausing immunotherapy and administering corticotherapy, regardless of the hepatitis phenotype. The aim of our study is to describe the different phenotypes of ICI induced hepatitis and to assess their evolution.
Method: We conduct an observational study in patients with immune-mediated hepatitis due to ICI and submitted to the «ToxImmun» multidisciplinary meeting in Montpellier between December 2018 and October 2021. Data were collected at diagnosis, week 1, 2 and 4, and once a week until hepatitis recovery. Data regarding cancer, hepatitis treatments, and ICI rechallenge were collected. The hepatitis phenotype is defined by the ratio of serum ALT and ALP [R value = (ALT/ULN)/(ALP/ULN)], and categorized as cholestatic ($R \leq 2$), hepatocellular ($R \geq 5$), or mixed ($2 < R < 5$).
Results: Of the 389 patients presented, hepatitis accounted for 14.7% of toxicities due to ICI (n = 57), 52 patients were included. 52.8% were men (n = 28) and the median age was 66 (range 23–87). PD-1 inhibitor was the most prescribed ICI class (n = 48, 92.3%), alone (n = 31, 59.6%), or with CTLA-4 inhibitor (n = 17, 32.7%). Hepatitis

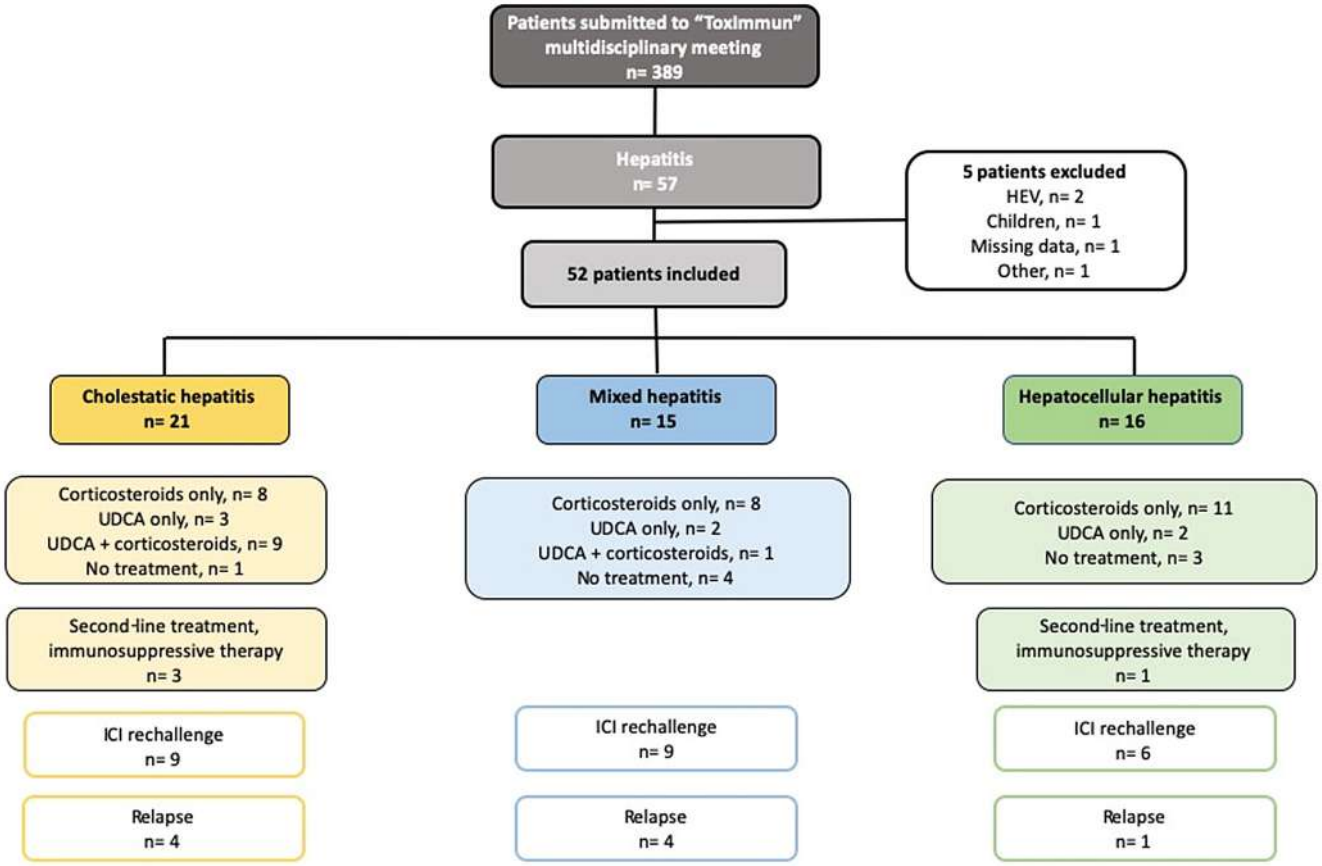

Figure: (abstract: FRI006)

phenotype was cholestatic in 40.4% (n = 21), hepatocellular in 30.8% (n = 16), and mixed in 28.8% (n = 15). Hepatitis were predominantly grade 3, according to the CTCAE system (71.2%, n = 37). No case of severe acute hepatitis has been reported. Liver biopsy was performed in 38.5% (n = 20). Biliary stenosis occurred in 6 patients (28.6%). An extra-hepatic irAE was reported in 46.2% (n = 24). Most patients were treated with corticosteroids (76.9%, n = 40) and ursodeoxycholic acid (UDCA) was in 32.7% (n = 17) patients. ICI was resumed in 46.2% (n = 24), 70.8% received the same ICI (n = 17) and 95.8% received a single ICI (n = 23). The rate of hepatitis recurrence after treatment reintroduction was 37.5% (n = 9). 10 patients died (19.2%), unrelated to ICI.

Conclusion: The frequency of ICI related hepatitis is about 14.7% in our study. This result is consistent with the literature. Future studies should be considered to adapt the treatment to the hepatitis phenotype, particularly in the case of cholestatic pattern, by specifying the place of UDCA.

Background and aims: There are uncertainties on the clinical significance of liver toxicities of immune checkpoint inhibitors (ICI). The aim of our study was to compare liver toxicities under ICI and conventional chemotherapy.

Method: We conducted a retrospective, longitudinal cohort study among cancer patients who received systemic chemotherapy with or without ICI between January 1, 2010, and December 31, 2019, in two teaching hospitals of Assistance Publique-Hôpitaux de Paris (France). We measured the incidence of grade 3–4 liver injury after ICI or

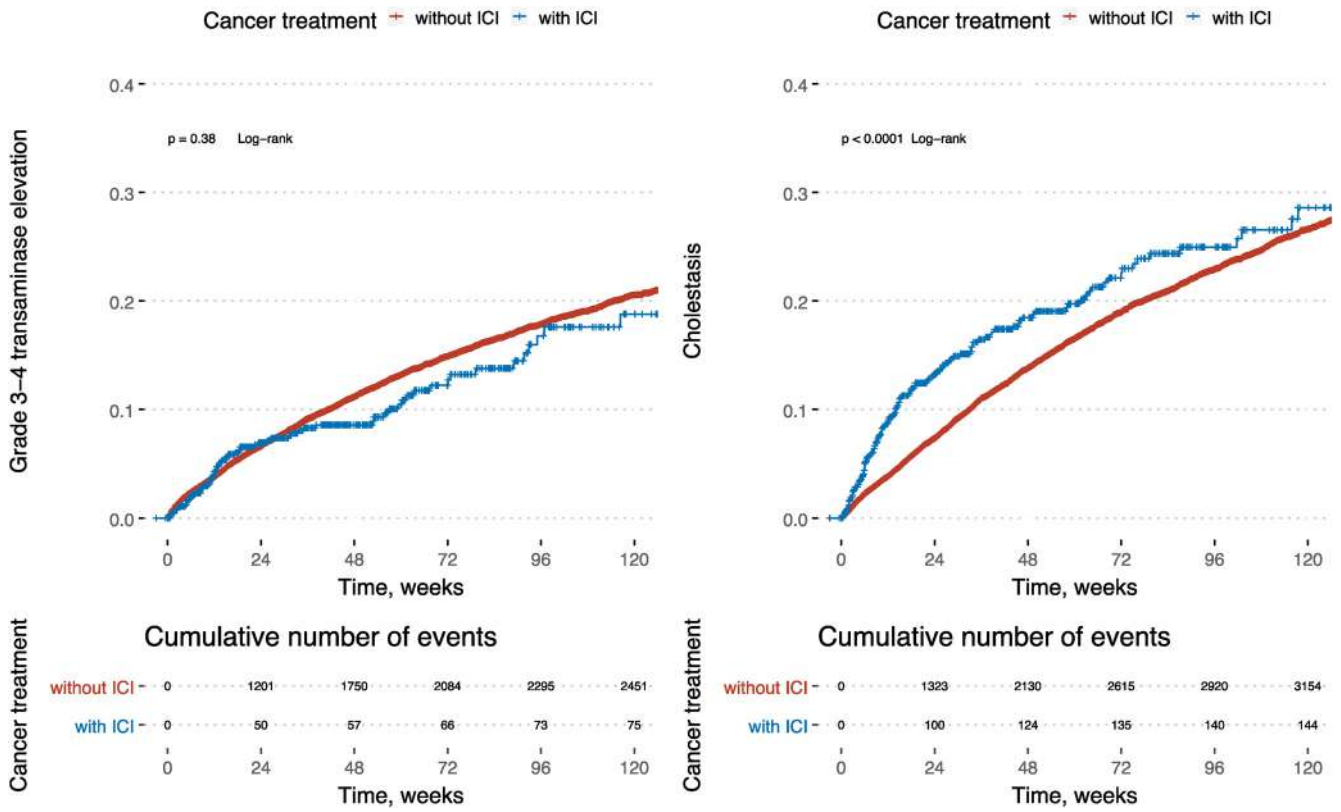

Figure: (abstract: FRI007): Cumulative incidences of liver injury after systemic chemotherapy in a multicenter, retrospective, cohort of cancer patients (N = 22, 206).

conventional chemotherapy, the adjusted hazard ratios [aHR (95% CI)] for hepatocellular injury, cholestasis and jaundice and investigated the management and outcome of patients with ICI drug-induced liver injury (ICI-DILI).
Results: The sample comprised 22, 206 patients (median [interquartile range] age 63 [52–72] years, 54.4% males), including 953 (4.3%) with ICI. The incidence of grade 3–4 liver injury was 209 (21.9%) and 5, 765 (27.1%) for patients treated with and without ICI, respectively (p < 0.001). ICI patients were at risk [aHR 1.46 (1.23–1.75) P < 0.001] for cholestasis without [aHR 0.96 (0.60–1.53) P = 0.860] jaundice. ICI patients were not [aHR 1.12 (0.86–1.45), P = 0.401] at risk for hepatocellular injury. Grade 3–4 liver injury was attributed to ICI-DILI in 26 (2.7%) patients. Grade 4 transaminase and serum bilirubin elevations concerned 6 (0.6%) and 1 (0.1%) ICI-DILI patient, respectively. All patients with ICI DILI had ICI withdrawal, and 11 (42.3%) died thereafter with cancer progression. ICI reintroduction after ICI-DILI was a rare (n = 7; 26.9%) event and was infrequently (n = 1) associated with recurrent liver injury.
Conclusion: Patients treated with ICI were at lower risk of clinically significant liver injury than patients treated with conventional chemotherapy. There may be potential gains from refraining ICI dose reduction in patients with ICI-associated liver injury.

Email: thomas.enke@northwestern.edu

Background and aims: Autoimmune hepatitis (AIH) is a common cause of acute liver failure (ALF). Treatment includes steroids in those with acute liver injury (ALI) and liver transplantation (LT) in those who fail to respond or develop ALF. The aim of this study is to better characterize the clinical and laboratory data of patients presenting with ALI or ALF secondary to AIH and to identify a combination of clinical variables that predict 21-day transplant-free survival (TFS).
Method: The study included hospitalized adults presenting with ALI or ALF enrolled in the Acute Liver Failure Study Group Registry between 1998 and 2019 from 32 centers within the United States. A review panel adjudicated the etiology of all cases and those identified as AIH were reviewed. ALI was defined as international normalized ratio (INR) ≥2.0 without encephalopathy and ALF as any degree of encephalopathy with INR ≥1.5. Laboratory and clinical data were reviewed, and variables significantly associated with 21-day TFS were used to develop a multivariable logistic regression model.
Results: A total of 244 of 3364 cases were identified as AIH and reviewed. 161 patients (66%) were diagnosed with ALF and 83 with ALI (34%). At 21 days, 116 patients (48%) had undergone LT, 69 (28%) had TFS and 59 (24%) had died. Patients presenting with ALI had a higher TFS rate (53%) than patients presenting with ALF (16%). Most presenting with ALI received steroids (73%) and were more likely to have TFS (66%) than those who did not receive steroids

(18%). Administration of steroids in those with ALI, admission values of bilirubin, INR, albumin and platelet count were significantly associated with improved TFS and a diagnosis of ALF in those who received steroids was associated with worse TFS in a multivariable logistic regression analysis. The resulting model predicted TFS with a C-statistic of 0.94.

Table 1: Variables associated with 21-day transplant free survival

	Multivariate model	
Predictor	Adjusted odds ratio	95% CI[a]
Bilirubin	0.04	(0.01, 0.15)
INR[b]	0.30	(0.16, 0.56)
Platelet count	1.06	(1.01, 1.10)
Albumin	3.10	(1.34, 7.16)
Steroid use with ALI[c]	31.19	(3.35, 290.05)
Steroid use with ALF[d]	1.62	(0.57, 4.58)
ALF without steroid use	0.78	(0.11, 5.51)
ALF with steroid use	0.041	(0.01, 0.171)

[a]CI = confidence interval.
[b]INR = international normalized ratio.
[c]ALI = acute liver injury.
[d]ALF = acute liver failure during hospitalization.

Conclusion: Acute severe presentations of AIH are associated with a high mortality. Steroids remain a cornerstone of treatment and nearly half of patients will require LT. Early identification of those needing LT is critical to prevent delays in listing. We developed a model specifically for AIH that may be helpful in predicting 21-day TFS and early identification of patients in need for expedited LT evaluation. Further assessment of model performance and independent model validation are future work.

Single-cell metabolic profiling of primary human hepatocytes shows heterogenous responses to drug metabolism

Eva Sofía Sánchez Quant[1], Maria Richter[1], Celia Martinez Jimenez[1,2], Maria Colome Tatche[3,4,5]. *[1]Helmholtz Zentrum Munich, Helmholtz Pioneer Campus, Munich, Germany; [2]Technical University Munich, Faculty of Medicine, Munich, Germany; [3]Helmholtz Zentrum Munich, Institute of Computational Biology, Munich, Germany; [4]Ludwig Maximilian University of Munich, Biomedical Center (BMC), Physiological Chemistry, Munich, Germany; [5]Technical University Munich, TUM School of Life Sciences Weihenstephan, Munich, Germany*
Email: eva.sanchez@helmholtz-muenchen.de

Background and aims: Drugs are primarily metabolized by hepatocytes in the liver, and primary human hepatocytes (PHHs) are the gold standard model for the assessment of drug efficacy, safety and toxicity in the early phases of drug development. Classic approaches assume that all hepatocytes in culture are homogeneous and share a similar metabolic profile. However, advances in single-cell genomics have shown the relevance of cellular heterogeneity in health and disease conditions.[1,2] Recently, single-cell RNA sequencing has shown that intrahepatic lipid accumulation in Non-alcoholic fatty liver disease (NAFLD) affects the transcriptomic profile of parenchymal and non-parenchymal liver cells.[3,4] The aim of this study is to investigate the metabolic capacity of individual human hepatocytes *in vitro*, and assess whether the chronic accumulation of lipids enhances cellular heterogeneity.
Method: PHHs isolated from four donors were incubated with a phenotyping 5-probe cocktail (Sanofi-Aventis[5]) using the so-called "cocktail approach." In order to mimic the hepatic steatosis occurring in NAFLD, hepatocytes were loaded with free fatty acids, resulting in intracellular lipid accumulation. Subsequently, cells were incubated with the five-drug cocktail. After 72 h in culture, hepatocytes were collected and single-cell RNA-sequencing was performed using a droplet-based approach.
Results: Four subgroups of hepatocytes were identified consistently, independently of the treatment condition, and across all four donors. These subgroups displayed differential gene expression upon cocktail treatment, and xenobiotic metabolism-related specialization. Furthermore, lipid accumulation was found to increase transcriptional variability in two subgroups of hepatocytes, and to differentially affect the expression of genes involved in lipid metabolism. In particular, intracellular fat accumulation was shown to diminish the drug-related metabolic capacity of hepatocytes.

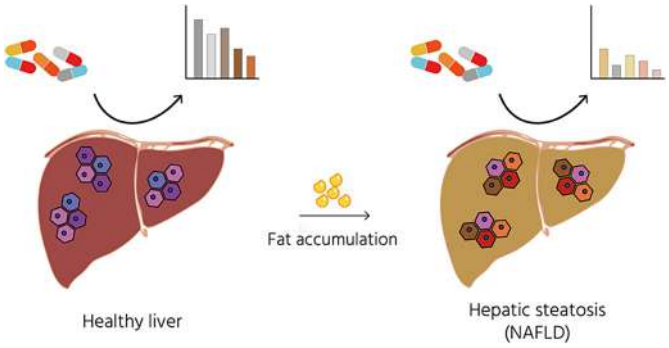

Figure: Graphical abstract summarizing the hypothesis stated.

Conclusion: Our results demonstrate that, upon a metabolic challenge such as exposure to drugs or intracellular fat accumulation, hepatocyte subgroups exhibit heterogeneous transcriptomic responses.

Management of severe, steroid-resistant and steroid-refractory hepatotoxicity in patients treated with checkpoint inhibitor immunotherapy

Nashla Hamdan[1], Marco Iafolla[2], Yada Kanjanapan[2], Marcus Butler[2], Lillian Siu[2], Philippe Bedard[2], Kendra Ross[2], Keyur Patel[1], Anna Spreafico[2], Jordan Feld[1], Morven Cunningham[1]. *[1]University Health Network, Toronto Centre for Liver Disease, Toronto, Canada; [2]University Health Network, Princess Margaret Cancer Centre, Toronto, Canada*
Email: morven_c@hotmail.com

Background and aims: Checkpoint inhibitor immunotherapy (ICI) has revolutionized cancer care and is increasingly used in a range of primary malignancies. Treatment is associated with immune-related toxicities which may require ICI discontinuation and immunosuppressive therapies (IST). Management of severe ICI hepatotoxicity is not well defined, especially for patients who respond poorly to initial corticosteroids. We sought to better understand management of severe ICI hepatotoxicity and responses to IST.
Method: Patients receiving ICI in early phase clinical trials at Princess Margaret Cancer Centre, or treated at the Toronto Centre for Liver Disease for ICI hepatotoxicity, were included. Patients with CTCAE Grade (G)3/4 ICI hepatotoxicity (ALT >5 × ULN) were identified and clinical records reviewed for management and outcomes.
Results: From Aug 2012-Oct 2021, 25 patients with G3/4 ICI hepatotoxicity were identified. Most (17; 68%) had metastatic melanoma. Eleven received anti-CTLA-4/PD-1; 9 anti-PD-1, and 5 anti-CTLA-4 monotherapy. All patients initially received corticosteroids for hepatotoxicity (1–2 mg/kg/day prednisone equivalent). Figure 1 shows response to corticosteroids and sequence of additional IST. 13 patients (52%) were steroid-refractory (no response after 48–72 hours) or steroid-resistant (rebound ALT upon steroid

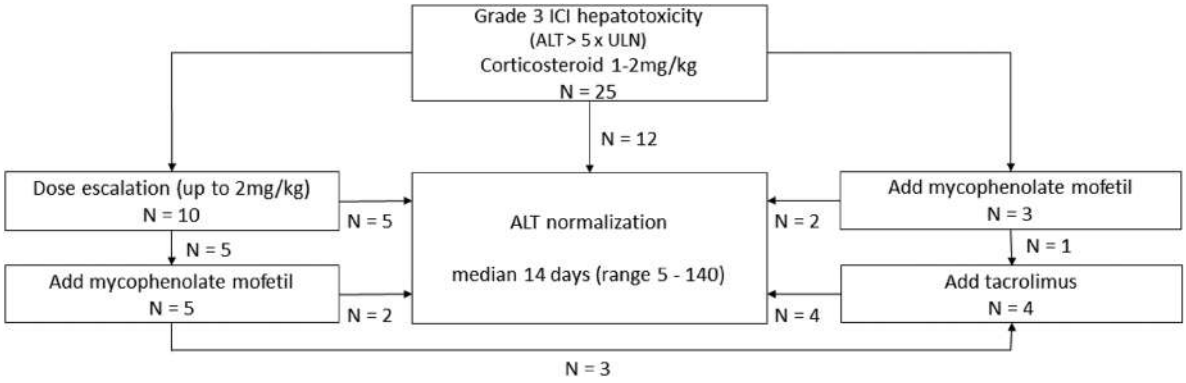

Figure: (abstract: FRI010)

taper). Ten received steroid dose escalation (up to 2 mg/kg/day) with sustained response in five (50%). Eight (32%) received 2nd line IST with mycophenolate (MMF) for steroid resistant/refractory hepatotoxicity, after median 17.5 days of steroid treatment (IQR 9–21). Four (50%; 16% of total cohort) did not respond to MMF and required 3rd line IST (Tacrolimus; dose targeting trough level of 4–6). Age, sex, liver metastases, prior ICI exposure or peak ALT did not predict need for 2nd or 3rd line IST. ALT normalized in all, after median 14 days (IQR 10–27). Patients on corticosteroid alone had shorter total time on IST than those with additional IST (median 86 days, IQR 41–123) vs 113 days (85–235), p = 0.03). In those given additional IST, rate of ALT improvement tended to be faster with Tacrolimus than MMF (25.5 IU/day (IQR 22–29.5) vs 10.5 IU/day (IQR −3 to 29.5), p = ns in this small cohort). IST-related adverse events occurred in two patients (vertebral fracture; hyperglycaemia). Over median follow up of 30.6 months (range 2.3–81.5), 12 patients died. No patients died of complications of hepatotoxicity.

Conclusion: Up to a third of patients with severe (G3/4) ICI hepatotoxicity may not respond adequately to corticosteroids and require additional IST. MMF is not consistently effective as 2nd line IST. To expedite resolution and minimize IST exposure, Tacrolimus should be considered 2nd line IST alternative. These results will assist development of treatment algorithms for severe ICI hepatotoxicity, for further prospective evaluation.

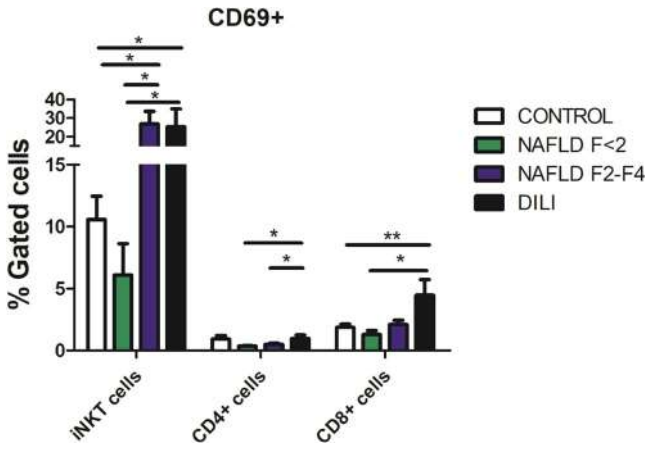
Email: edugf1@gmail.com

Background and aims: Activation of the immune system is involved in both non-alcoholic fatty liver disease (NAFLD) and idiosyncratic drug-induced liver injury (DILI). We aimed to identify activation markers in invariant natural killer T (iNKT) and CD4/CD8+ T cells to better understand the pathophysiology of these disorders.

Method: We analyzed the activation profile (CD69, CD25 and HLA-DR) and NKG2D on iNKT cells, and CD4/CD8 T cells by flow cytometry in peripheral blood mononuclear cells from NAFLD, with or without significant liver fibrosis, and DILI patients.

Results: There was an increase in iNKT cells in NAFLD patients compared to DILI or control subjects ($p = 0.035$ and $p = 0.031$, respectively). Regarding the cellular activation profile, NAFLD with significant liver fibrosis ($F \geq 2$) displayed higher levels of CD69 + iNKT cells compared to NAFLD with none or mild liver fibrosis ($F \leq 1$) ($p = 0.040$) and control patients ($p = 0.031$). CD69 + iNKT positively correlated with insulin resistance, liver fibrosis indexes FIB4 and APRI, and AST levels. DILI patients showed an increase in CD69+ and HLA-DR+ in both CD4+ and CD8+ T cells, detecting the most relevant difference in the case of CD69 + CD8+ T cells.



Conclusion: CD69 + iNKT may be a biomarker to assess liver fibrosis progression in NAFLD. CD69 + CD8+ T cells were identified as a potential distinctive biomarker for distinguishing DILI from NAFLD. These results support the involvement of the immune system on NAFLD with significant liver fibrosis and DILI development.

FRI012

Natural antibodies are required for necrotic cell debris clearance and liver repair during necrotic liver injury

Matheus Mattos[1], Sofie Vandendriessche[1], Sara Schuermans[1], Romy Mittenzwei[2], Ari Waisman[2], Pedro Elias Marques[1]. *[1]Rega Institute Ku Leuven, Leuven, Belgium; [2]Institute for Molecular Medicine, University Medical Center of the Johannes Gutenberg-University Mainz, Mainz, Germany*
Email: pedro.marques@kuleuven.be

Background and aims: Acetaminophen (APAP) poisoning is the most common cause of acute liver failure cases in Europe. Administration of N-acetyl cysteine within the first 12 hours is the best treatment

available; if this early deadline is not met, liver transplantation becomes the only life-saving alternative. APAP overdosage causes hepatocyte death by necrosis, a catastrophic event characterized by plasma membrane rupture and deposition of intracellular contents (debris) in the tissue, where it acts as a powerful inducer of inflammation. Prolonged permanence of debris in the liver can lead to excessive inflammation, further tissue damage and impairment of liver regeneration. One critical step towards liver repair is the clearance of necrotic cell debris, creating room for new hepatocytes, shaping the immune response towards resolution and rescuing liver function. Despite its relevance in liver diseases, the mechanisms underlying the clearance of necrotic debris *in vivo* are poorly understood. It is postulated that debris are phagocytosed by innate leukocytes, however, owing to its varied composition, the recognition and internalization of necrotic debris is still elusive. We hypothesize that phagocytes take advantage of polyreactive Natural Antibodies (NAbs) as adaptors for recognition and phagocytosis of necrotic debris.

Method: C57BL/6J wild-type (WT), Rag2-/- and IgMi-/- mice received an oral overdose of APAP (600 mg/Kg). Liver injury/repair, deposition of natural antibodies, and inflammation were assessed by immunofluorescence, intravital microscopy and flow cytometry. We also used an *in vitro* hepatocyte debris assay to evaluate binding of NAbs to hepatocyte debris.

Results: WT mice challenged with APAP rapidly developed liver injury, as assessed by increased levels of serum ALT, extensive centrilobular necrosis and massive liver inflammation, including neutrophil (6 h–48 h) and monocyte (24 h–72 h) recruitment. We demonstrated that both IgM and IgG NAbs become deposited in the necrotic areas early after liver injury (6 h), and in necrotic hepatocytes *in vitro*. The antibody deposits disappear with liver recovery (72 h). In both Rag2 -/- and IgMi -/- mice (which lack NAbs), we observed significantly increased liver injury, hepatic inflammation and impairment of liver repair, as compared to their WT littermates. Adoptive transfer of WT serum to these mice rescued the deposition of NAbs in necrotic areas, causing also a reduction in serum ALT levels, centrilobular necrosis, and improvement in liver recovery.

Conclusion: The binding of NAbs to the necrotic cell debris in the liver is central for a quick and effective liver repair, and to reduce the inflammatory response to injury. Our data suggests that NAbs may be used therapeutically to reduce liver injury after acute insults (e.g. drug-induced liver injury) and to improve liver repair in necrotic diseases.

FRI013

Human paracetamol hepatotoxicity is mitigated by the gut-liver axis in vitro

Katie Morgan[1], Martin Vandeputte[1], Kay Samuel[2], Steven Morley[1], Natalie Homer[3], Martin Waterfall[4], Jonathan Fallowfield[1,5], Peter Hayes[1], John Plevris[1]. *[1]University of Edinburgh, Hepatology Dept, Edinburgh, United Kingdom; [2]Scottish National Blood Transfusion Service, The Jack Copland Centre 52 Research Avenue North, Edinburgh, United Kingdom; [3]University of Edinburgh, Mass spectrometry core, Edinburgh, United Kingdom; [4]University of Edinburgh, Flow Cytometry Core Facility, Edinburgh, United Kingdom; [5]University of Edinburgh, Centre for Inflammation Research, Edinburgh, United Kingdom*
Email: katie.morgan@ed.ac.uk

Background and aims: The gut liver axis is a bidirectional system communicating via signals from the microbiome, immune system, dietary and genetic influences. We have previously shown in vitro that APAP disrupts tight junctions in hepatic HepaRG cells in a concentration dependant manner.[1] The aim of this study, was to develop a model of enterohepatic circulation of paracetamol (APAP) *in vitro* and establish whether intestinal barrier has a hepatoprotective effect in the context of APAP toxicity.

Method: We used the Caco-2 human colorectal adenocarcinoma cell line to represent gut and the human hepatic HepaRG line to represent liver. Caco2 cells were incubated with 0, 5, 10 and 20 mM of APAP for 24 hours. Supernatant was transferred onto fresh HepaRG cells for a further 24 hours. Cell cultures were monitored in real time using the ECIS Zθ, an impedance based cellular assay, using multiple frequencies to measure tight junctions, adhesion (4 kHz) and cell membrane integrity (64 kHz). Viability was assessed using PrestoBlue, to monitor cell metabolism, and Promega Celltiter glo for a measure of total ATP. Percentage of APAP metabolized by Caco2 cells was measured using LC-MS/MS. IL-8, IL-1b, IL-6, IL-10, TNF, and IL-12p70 were measured using the CBA Human Inflammatory Cytokines kit flow-cytometry bead assay.

Results: ECIS measurements showed an increase in tight junctions/adhesion in a concentration dependent manner on Caco2 cells. In contrast to previously published work,[1] when using Caco2 preconditioned media, toxicity to HepaRG cells was mitigated with no loss of tight junctions. LC-MS/MS showed that Caco2 cells metabolize 64–68% of total APAP without any adverse effect on their viability. IL-6 and IL-8 produced by HepaRG cells was appropriately reduced suggesting an anti-inflammatory effect of APAP.

Conclusion: We have shown that intestinal cells are capable of removing 2/3 APAP within the intestinal barrier with no compromise of viability or tight junctions mitigating toxicity to hepatic cells. Based on these observations, the intestine is an effective barrier protecting the liver from APAP hepatotoxicity therefore parenteral administration of APAP should be avoided and if no other option intravenous dose should be adjusted accordingly.

A new score to predict mortality at baseline in patients not fulfilling KCH criteria for non acetaminophen induced liver failure-The "SAFE" score (Severity of ALF in emergency)

Harshvardhan Tevethia[1], Rakhi Maiwall[1], Shalini Thapar[2], Roshan Koul[3], Prashant Mohan Agarwal[4], Guresh Kumar[5], Ashok Choudhury[1], Shiv Kumar Sarin[6]. *[1]Institute of Liver and Biliary Sciences, Hepatology, Delhi, India; [2]Institute of Liver and Biliary Sciences, Radiology, Delhi, India; [3]Institute of Liver and Biliary Sciences, Neurology, Delhi, India; [4]Institute of Liver and Biliary Sciences, Critical Care, Delhi, India; [5]Institute of Liver and Biliary Sciences, Biostatistics, Delhi, India; [6]Institute of Liver and Biliary Sciences, Hepatology, Delhi, India*
Email: harshvardhantevethia@gmail.com

Background and aims: Prognostic scores in ALF such as King's College Hospital (KCH) Score have limited sensitivity in stratifying patients for liver transplant especially related to non-acetaminophen etiology, leading to delayed listing and poor outcomes. The MELD score also has limitations with the use of creatinine which is not a true representative of liver injury. We studied ALF patients not fulfilling KCH criteria; for their clinical course, outcomes, liver volume, markers of cerebral edema like Optic Nerve Sheath Diameter (ONSD) to develop a new score to predict mortality at baseline.

Method: Patients diagnosed to have ALF and not fulfilling KCH criteria at admission were enrolled and electronic data was retrieved [from June 2010 to May 2021] from the HIS using a predefined format. All patients underwent CT imaging (Non contrast) of both Brain and abdomen at admission. The Liver volume was calculated (CT) along with changes of cerebral edema were recorded. Baseline parameters were correlated along with predictors of outcome, need for liver transplant, KCH and MELD scores. Cox regression analysis was done at baseline for prediction of mortality.

Results: A total of 75 patients were screened of which 49 (65.5%) patients did not fulfil the KCH criteria [mean age 33.24 ± 15.5 years,

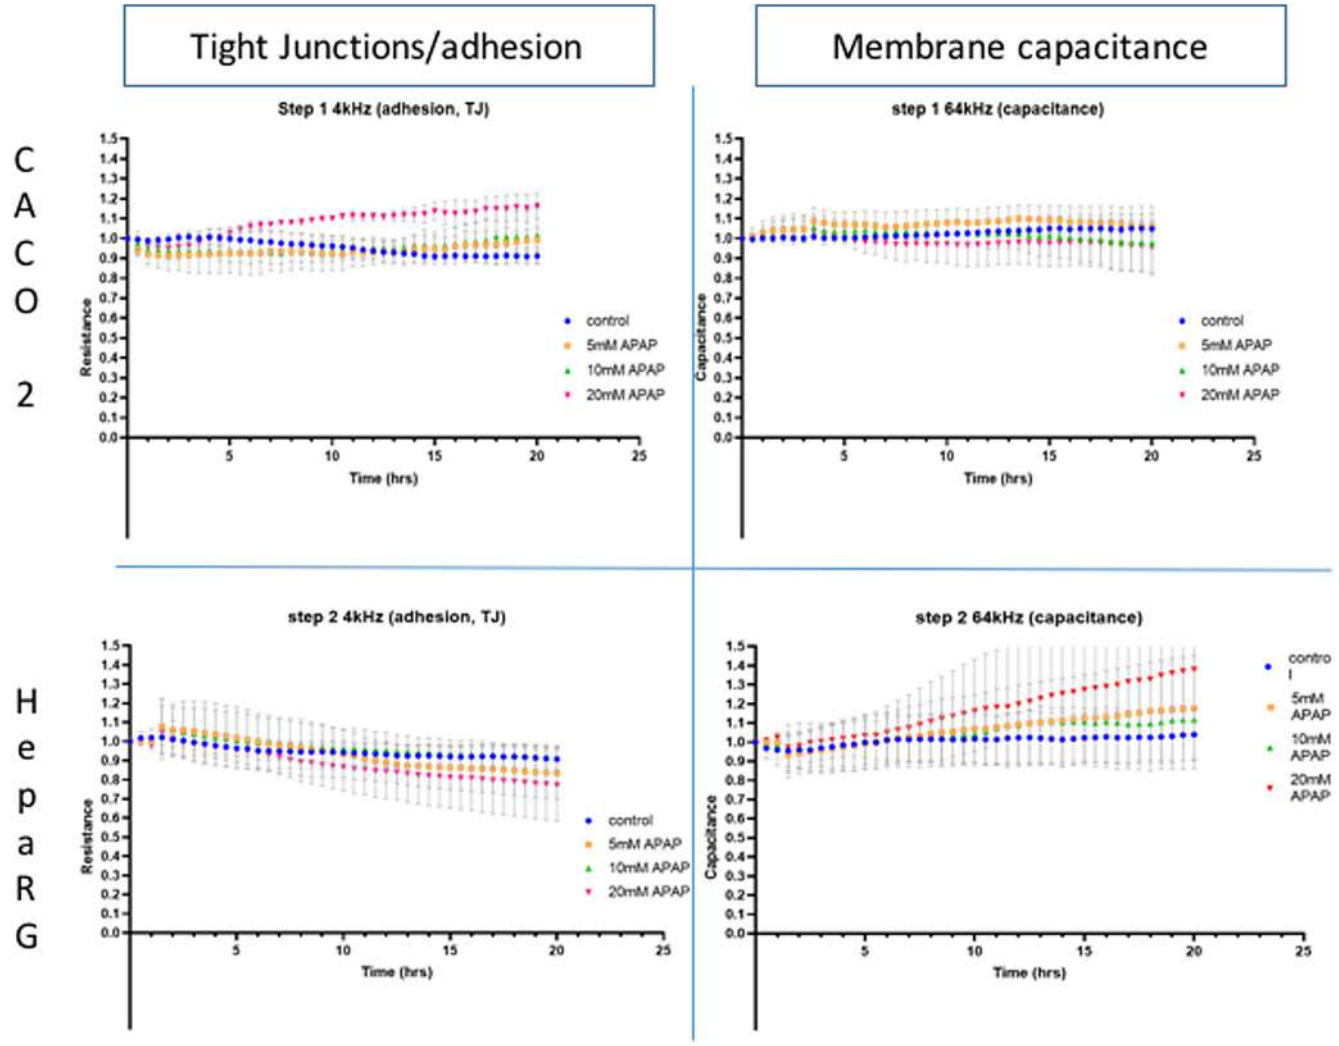

Figure: (abstract: FRI013)

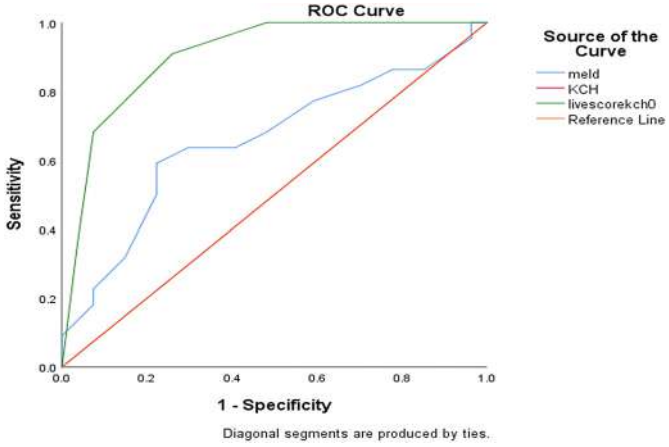
males 59.2%]. The all-cause mortality in patients not meeting the KCH criteria was 44.8%. The most common etiology was hepatitis E (34.7%) followed by indeterminate etiology (28.6%). On the CT imaging of the brain, cerebral edema was seen in 34% patients; with significantly lower liver volume in the ALF non-survivors than survivors (765 ± 465 cm^3 vs 1265 ± 346 cm^3 $p < 0.04$). On univariate analysis Grade >3 Hepatic encephalopathy (HE), ONSD (both right/left eye) >5 mm, jaundice to HE duration >9 days and liver volume <980 cm^3 were found to be significant. On multivariate analysis, HE grade 3 (OR- 7.671, 95% C.I- 0.912–64.55), ONSD > 5 mm (OR- 22.14 95% C.I- 1.943–252.423), jaundice to encephalopathy >9 days (O.R- 24.82 95% C.I- 2.293–268.65) were found to be significant. We developed the "SAFE" score using these variables. A score of 5, gave the AUROC value of 90.9 with $p < 0.01$ (95% CI-82.9–98) with a sensitivity of 90%, specificity of 71%, positive and negative predictive values of 82% and 73% respectively with Youden index at 50%. On comparison with KCH (50, 95% C.I-33.6–64.4) and MELD score (65.9, 95% C.I -50–81.9) the SAFE score was significantly better at predicting mortality in ALF patients at baseline.



Conclusion: In patients not fulfilling the KCH criteria, the newly developed SAFE score was significantly better in predicting worse outcomes . Its variables indicate the presence of cerebral edema and low liver volume as the main causes of mortality in these subset of patients. Application of the SAFE score should be validated and a routine use of CT brain and liver be practiced for better stratification of ALF patients at baseline.

Ten-year single center experience in hepatotoxicity due to mushroom poisoning

Ozan Sarikaya[1], Ilker Turan[1], Fulya Günsar[1], Aysenur Arslan[2], Nilay Daniş[3], Ferit Çelik[1], Galip Ersoz[1], Sezgin Ulukaya[4], Murat Zeytunlu[5], Omer Ozutemiz[1], Ulus Akarca[1], Zeki Karasu[1]. *[1]Ege University, Medical Faculty, Gastroenterology, Izmir, Turkey; [2]Ege University, Medical Faculty, Internal Medicine, Izmir, Turkey; [3]Karabuk University, Gastroenterology, Karabuk, Turkey; [4]Ege University, Medical Faculty, Anesteziology, Izmir, Turkey; [5]Ege University, Medical Faculty, General Surgery, Izmir, Turkey*
Email: ulusakarca@gmail.com

Background and aims: Mushroom poisoning is quite common in Turkey. It can cause acute liver injury and acute liver failure (ALF) requiring liver transplantation. We investigated the outcomes of patients with acute hepatotoxicity due to mushroom poisoning in our cohort.
Method: We retrospectively evaluated the characteristics of patients with liver toxicity due to mushroom poisoning. We also investigated parameters related to mortality or liver transplantation.
Results: Thirty patients (17/13: F/M, median age 50.4 (22–73)) were included in the study. Twenty-seven patients presented with nausea and vomiting. In addition, fourteen patients had abdominal pain and sixteen had diarrhea. These patients were admitted to our intensive care unit within an average of 2.5 days (6 hours–8 days) after eating mushrooms from the countryside. In 15 patients (fourteen at admission, one during hospitalization), INR increased >1.5, acute liver failure developed in 4 patients (two patients at admission, hepatic encephalopathy developed in two patients during follow-up). The peak levels of ALT, AST and total bilirubin were 2109 ± 1963 U/l, 1828 ± 1675 U/L, 4.92 (0.1–28.56 mg/dl), respectively. In hospital follow-up, the highest INR levels were found to be an average of 2.29 (±1.56). All patients were treated with N-acetylcysteine (NAC). Seven patients were treated with penicillin G, six patients with silymarin, and two patients with both penicillin G and silymarin. Eight patients underwent plasmapheresis (median 6 times). Two of the four patients with ALF underwent emergency liver transplantation, and one patient died 72 days after transplantation. One patient who developed ALF recovered with medical treatment, while the other patient who could not be transplanted died. In multivariate analysis, INR and chlorine levels at hospital admission were found to be statistically significant factors for death and liver transplantation. (respectively; OR: 17.8 and p: 0.04 and OR: 0.54 and p: 0.04)
Conclusion: In our cohort, the mortality rate of mushroom liver toxicity was 10%. High INR levels and detection of hypochloremia have been associated with serious outcomes such as liver transplantation or mortality, and these parameters may be predictive of urgent liver transplantation.

CCl4-induced acute liver injury in C57/BL mice model showed elevated expressions of Na+ taurocholate cotransporting polypeptide on intestinal stellate cells

Johnny Amer[1], Reem Sbieh[1], Ahmed Salhab[1], Rifaat Safadi[1]. *[1]Hadassah Hebrew University Hospital, Liver Unit, Jerusalem, Israel*
Email: johnnyamer@hotmail.com

Background and aims: The Na+ taurocholate cotransporting polypeptide (NTCP/SLC10A1) is believed to be pivotal for hepatic uptake of conjugated bile acids. In the case of acute liver injury (ALI), NTCP is downregulated leading to hepatic and biliary injury, driving inflammatory and fibrotic processes. Several studies linked ALI to cause intestinal mucosa damaged. In this study, we aimed to evaluate whether bile acid (BAs) trafficking interfere with intestinal stellate cells in an ALI of CCl_4 mice model.
Method: C57/BL mice were *i.p* injected (1X) with CCl_4 (xxx) to induce ALI. Livers, intestinal stellate cells (ICS) isolated form intestine and serum were obtained from mice and assessed for inflammatory (H&E staining, ALT and pro-inflammatory panel of cytokines), fibrosis (Sirius red staining, a-smooth muscle actin, collagen and fibronectin) and metabolic (BAs, cholesterol, triglyceride, glucose tolerance test (GTT) and fasting blood sugar (FBS)) profiles. In addition, ICS were assessed for NTCP and membrane injury of surfactant D (SP-D) and the receptor for advanced glycation end-products (RAGE). BAs trafficking were assessed in ICS and their impact on proliferation and apoptosis were evaluated.
Results: Compared to WT mice, CCl4-induced ALI and was worsened in the histopathology outcome. In addition, serum showed elevated levels of BAs (3-fold; $P = 0.002$) associated with increased RAGE, TNF-a, MCP-1, INF-γ, IL-1, IL-6 and IL-8 ($p < 0.01$). Moreover, CCl4-induced ALI showed elevated serum levels in liver enzymes, lipids, glucose and metabolic markers ($p < 0.01$). ICS showed high expressions of aSMA and were correlated with elevated expressions of NTCP. ICS BAs intracellular concentrations were increased (2-fold) with increased SP-D (1.2-fold) as well as elevation in their apoptotic rate (2.1-fold) in the ALI mice model.
Conclusion: NTCP modulatory expressions on ICS could be an important step in the pathogenesis of ALI. Antagonizing BAs uptake may suggest a therapeutic strategy in improving liver-gut axis.

The association between chronic Colchicine use and incident decompensated cirrhosis

Michal Carmiel[1,2], Fadi Hassan[2,3], Vered Rosenberg[4], Gabriel Chodik[4,5], Mohammad Naffaa[2,3]. *[1]Galilee Medical Center, Liver Unit, Nahariya, Israel; [2]Bar-Ilan University, The Azrieli Faculty of Medicine, Safed, Israel; [3]Galilee Medical Center, Rheumatology Unit, Nahariya, Israel; [4]Maccabi Healthcare Services, Epidemiology and Database Research, Tel Aviv, Israel; [5]Tel-Aviv University, Sackler Faculty of Medicine, Tel Aviv, Israel*
Email: michalc@gmc.gov.il

Background and aims: Colchicine (COL) is an anti-inflammatory agent, prescribed as a chronic treatment in some medical conditions. Although high doses inhibits microtubule formation resulting in mitotic arrest and hepatotoxicit, in clinical practice COL is considered safe due to relatively low doses. In this study, we examined the association between chronic use of COL and the incidence of decompensated cirrhosis event.
Method: A cohort study using computerized database of 2.3-million member Maccabi Healthcare Services in Israel. All patients ≥18 y/o who initiated COL between Jan. 1 2000 and Dec. 31 2018 were included. Patients were followed until first event of decompensated cirrhosis (DC), leaving MHS, death or Dec. 31 2019. Excluded: patients with a diagnosis of cirrhosis, chronic HBV, HCV, alcoholic or biliary disease at beseline, patients who developed an event within 12 months of follow-up, patients treated <30 days, and patients treated with a mean daily treatment >3 mg/day. COL exposure was evaluated as the Proportion of Months Covered with drug (PMC) and by Mean Daily Dose (MDD). The PMC was categorized as follows: <20%, 20–40%, 40–60%, 60–80%, >80%. Cox regression models were used to calculate the hazard ratios (HR) and confidence intervals (CI) for the development of DC.
Results: A total of 21773 eligible patients initiated COL during study period. During follow-up, 129 incident cases of DC were identified (68.5/100, 000 person-years, mean follow-up 8.65 ± 5.53 years). In univariate analysis: COL PMC as well as older age, Familial Mediterranean Fever (FMF), HbA1c ≥ 6.5, BMI > 40 and Fib-4 > 1.45 at baseline were associated with an event of DC. In multivariate analysis: FMF, BMI > 40, FIB-4 > 1.45 and COL PMC were all significantly associated with incident of DC. The highest risk for developing DC (HR 3.68, 95% CI 2.23–6.07) was in '60–80%' PMC group. Restricting analysis to patients treated for >12 and >60 months, the risk for DC in the PMC group '60–80%' was higher, (HR 4.56, 95% CI 2.74–7.58) and (HR 6.69, 95% CI 3.56–12.56), respectively. Patients

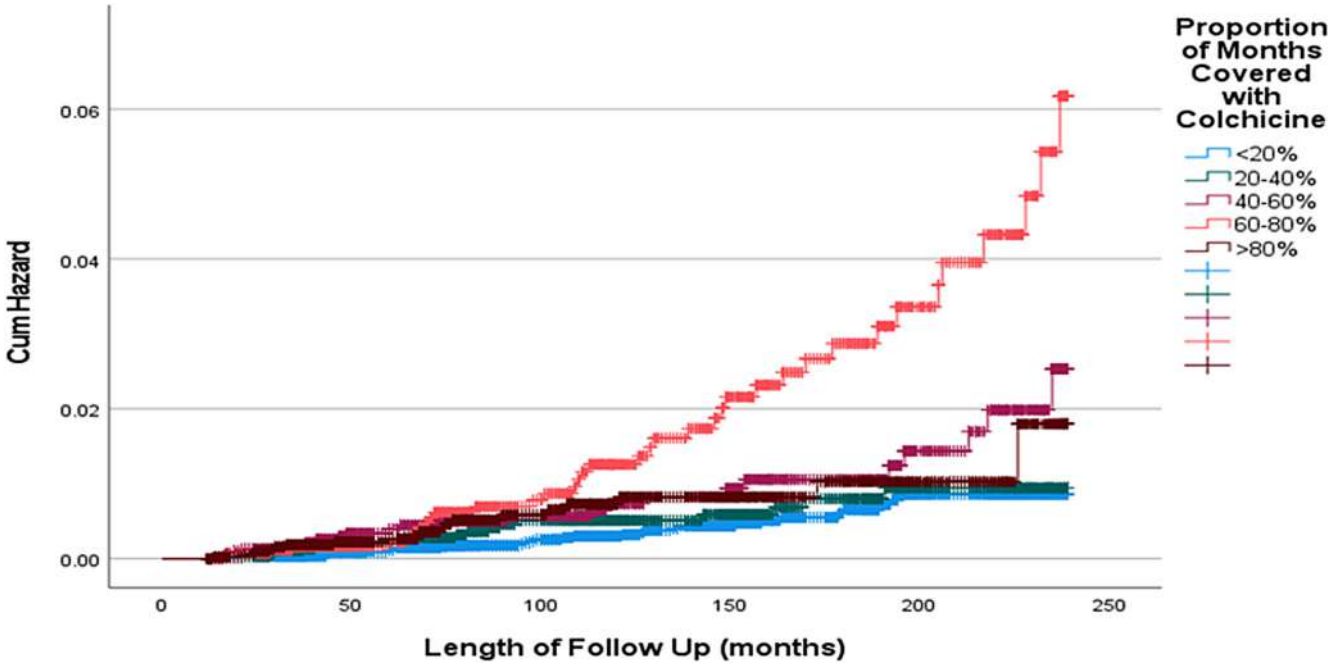

Figure: (abstract: FRI017): Kaplan-Meier analysis for cumulative hazard risk for cirrhosis decompensation related to PMC (%).

with COL PMC '60–80%' had the highest cumulative hazard risk for DC (Kaplan-Meier analysis, LogRank = 47.192, $p < 0.001$).
Conclusion: Chronic colchicine use is associated with incident DC in a cohort of new COL users.

FRI018
Inhibition of C-C motif chemokine receptor 2 (CCR2) using a novel in silico designed peptide attenuates macrophage migration in vitro and intrahepatic monocyte recruitment in vivo
Eline Geervliet[1,2], Ralf Weiskirchen[2], Ruchi Bansal[1,3]. *[1]University of Twente, Medical Cell Biophysics, Enschede, Netherlands; [2]RWTH Aachen, Institute of Molecular Pathobiochemistry, Experimental Gene Therapy and Clinical Chemistry, Aachen, Germany; [3]University of Twente, Translational Liver Research, Netherlands*
Email: ekgeervliet@gmail.com

Background and aims: Acute liver injury is a highly prevalent and a life-threatening disease. Hepatocyte injury induces activation of liver-resident Kupffer cells (KCs) and consequently activation of hepatic stellate cells (HSCs). Hepatocytes, HSCs and KCs secrete C-C motif chemokine ligand 2 (CCL2) and trigger the recruitment of C-C motif chemokine receptor 2 (CCR2) expressing circulating monocytes. This results in chronic liver inflammation that further progresses to liver fibrosis, cirrhosis and/or hepatocellular carcinoma. Blocking the CCR2, using a small molecule CCR2/CCR5 inhibitor cenicriviroc (CVC), has already been proven effective *in vitro*, *in vivo*, and in phase-I and -IIb clinical trials. However, small molecules often have limitations i.e. poor pharmacokinetics and lack of receptor specificity. We designed a CCR2 antagonizing peptide (AP2) with improved pharmacokinetics, and high receptor specificity to reduce monocyte infiltration and disease progression in acute liver injury.
Method: Receptor binding affinity of the AP2 was characterized using surface plasmon resonance imaging (SPRi) *in situ* and *in vitro*. Efficacy of AP2 on CCL2-driven chemotaxis was examined *in vitro* in mouse RAW 264.7 macrophages and human THP-1 monocytes using transwell assays, and *in vivo* in an acute carbon tetrachloride induced liver injury mouse model. To assess intrahepatic monocyte infiltration *in vivo*, liver tissues were mechanically dissociated using Tissue Grinder, and cell population such as CD45+ leukocytes, resident and monocytes-derived macrophages (MoMFs) (CD11b+/++ and F4/80+/++), and T-cells (CD3+) were analyzed using flow cytometry. Furthermore, effects of AP2 on disease progression (inflammatory and fibrosis markers) were assessed using immunohistochemistry. The effects of AP2 were compared with CVC *in vitro* and *in vivo*.
Results: AP2 ($p < 0.01$) and CVC ($p < 0.05$) showed favorable inhibition of CCL2-driven macrophage/monocyte chemotaxis. *In vivo*, flow cytometric analysis revealed that a decrease in the population of CD45+ cells and $CD11b^{++}F4/80^{+}$ MoMFs and (activated) CD11b++/F4/80++ KCs, while CD3+ T cells in CVC and AP2 treated mice were comparable to that of healthy controls. Immunohistochemical analysis evidenced decreased expression of fibrosis markers (collagen-I and alpha-smooth muscle actin) and an increase in Ki-67 positive hepatocytes in the AP2 treated mouse livers. Our data shows effective amelioration of inflammation and fibrosis by inhibition of CCR2 using CCR2-antagonizing peptide. SPRi and *in vitro* peptide binding studies are ongoing alongside with more *in vivo* analysis. The peptide will be evaluated further in a non-alcoholic steatohepatitis (NASH) mouse model.
Conclusion: Our CCR2-antagonizing peptide inhibited migration of macrophages/monocytes *in vitro* and ameliorated inflammation and fibrosis *in vivo* in an acute liver injury mouse model.

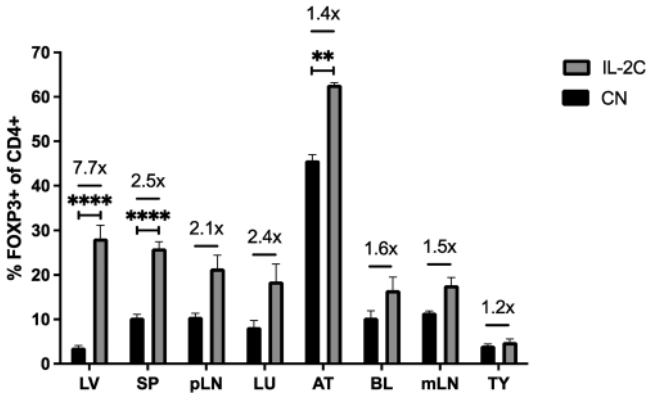
Murine intrahepatic regulatory t cells modulate acute liver inflammation by promoting a protective and restorative microenvironment

Ada Kurt[1], Karoline Strobl[2], Tonika Chester[1], Gabriel Osborn[1], Paula Ruiz[1], Elizabeth H. Gray[1], Alberto Sanchez-Fueyo[1], Marc Martinez-Llordella[1]. *[1]King's College London, Department of Inflammation Biology, London, United Kingdom; [2]Medical University of Vienna, Institute for Cancer Research, Vienna, Austria*
Email: ada_sera.kurt@kcl.ac.uk

Background and aims: CD4+CD25+Foxp3+ regulatory T cells (Tregs) exert powerful immunomodulatory effects that are essential to maintain immune homeostasis and prevent the development of immune-mediated diseases. In addition to their immunomodulatory role, recent studies have identified that depending on the tissue compartment they migrate to or reside in, Tregs acquire tissue-specific features and develop cytoprotective and regenerative functions. The liver is an organ known to be deprived in IL-2, a cytokine that is essential for the adequate function and survival of Tregs. The extent to which this affects intra-hepatic Treg phenotype and the capacity of these cells to modulate liver damage has not been adequately investigated. In this study, we aimed to explore the phenotypic and functional diversity of liver resident Tregs during homeostasis. Additionally, we investigated their role in ameliorating liver inflammation and tissue damage by depleting Tregs and increasing their pool by exogenous IL-2 complex (IL-2c) administration in murine models.

Method: Flow cytometry phenotyping and microarray analysis was performed on Foxp3-YFP intrahepatic and splenic Tregs in homeostatic conditions and with the administration of IL-2c for 3 consecutive days. Tregs were depleted in Foxp3-DTR mice by intraperitoneal (i.p) injection of 1μg diphtheria toxin and IL-2c were administered i.p. to wild-type C57BL/6 mice. The extent of liver damage following a single dose of carbon tetrachloride (CCL4) injury was investigated 24 hours later in both models.

Results: Quantification of Foxp3+CD4+ cells among different tissues showed that the liver exhibited the lowest abundance of Tregs. Analysis in homeostatic conditions revealed that, although intrahepatic Tregs exhibited the core transcriptional Treg signature, they expressed a distinct transcriptional profile. This was characterized by reduced CD25 expression and increased levels of pro-inflammatory Th1 transcripts IL1b and IFNγ. Depletion of Tregs showed that Tregs effectively reduced the magnitude of systemic and intra-hepatic inflammatory responses following CCL4 injury, but they were not directly involved in ameliorating hepatocyte necrosis. In contrast, the administration of IL-2c markedly increased the number of intrahepatic Tregs and significantly ameliorated liver damage following CCl4 administration. The cytoprotective effect observed in response to IL-2c was associated with the increased expression by Tregs of markers known to regulate their suppressive function.



Conclusion: Our results offer insight into the transcriptome and complex immune network of intrahepatic Tregs and how their number and phenotype may affect their ability to modulate liver inflammation. Strategies capable of selectively increasing the pool of intra-hepatic Tregs could constitute effective therapies in inflammatory liver diseases.

Place of steroids and prognosis factors for grade = 3 immune-checkpoint inhibitors induced hepatitis: a 6-year prospective study

Eleonora De Martin[1], Alina Lutu[1], Ariane Laparra-Ramakichenin[2], Nicolas Golse[1], Astrid Laurent Bellue[3], Caroline Robert[2], Olivier Lambotte[4], Audrey Coilly[1], Ilias Kounis[1], Edoardo Poli[1], Lea Duhaut[1], Olivier Rosmorduc[1], Catherine Guettier[3], Jean-Marie Michot[2], Didier Samuel[1]. *[1]Hôpital Paul Brousse, Centre Hépato-Biliaire, Villejuif, France; [2]Institut Gustave Roussy; [3]Hôpital Bicetre, Anatomo-pathologie, France; [4]Hôpital Bicetre, Medecine interne et Immunologie clinique*
Email: eleonora.demartin@aphp.fr

Background and aims: The management of liver toxicity of immune checkpoint inhibitors (ICI) and the role of steroids is controversial. This study aimed to provide a report of a well characterized cohort of patients with ICI-induced hepatitis and their management.
Method: In this prospective cohort study, patients treated with ICI for metastatic cancer and referred to hepatology unit for grade ≥3 hepatitis (06/2015–09/2021) were evaluated and the ones with ICI-induced hepatitis, after exhaustive causal investigations, were included. The decision to introduce steroids and/or ursodeoxycholic acid (UDCA) was at physician discretion (oncologist/hepatologist).
Results: Among 64 included patients, 29 (45%) female, median age 61 (33–83) yrs, the most common cancers were metastatic melanoma (n = 30), renal cancer (n = 12) and epidermoid carcinoma (n = 6). The ICI administered were anti-PD1 (n = 29), anti-PDL1 (n = 9), anti-CTL4 (n = 5), anti-PD1+anti-CTL4 (n = 21) and ICI+chemotherapy (ex. carboplatin, anti-EGFR) (n = 21). 20% of patients were previously exposed to another ICI. Median time between ICI introduction and first increase of liver tests (LFTs) was 1.80 (0.82–3.42) months and between ICI introduction and peak of LFTs was 2.67 (1.43–5.17) months, median number of doses was 2 (1.75–4). Forty (62%) patients had grade 3 and 24 (38%) grade 4 hepatitis, 33% were symptomatic. At peak median (IQR) LFTs were AST 481 (280–780) IU/l, ALT 320 (164–549) IU/l, total bilirubin 14.5 (10–28) μmol/l, conjugated 8.85 (5.32–19.2) μmol/l, GGT 366 (150–800) IU/l, ALP301 (134–513) IU/l, only 2 patients had increased INR. Median IgG were 10.0 (7.8–12.3) g/L, ANA was positive in 49% and ASMA in 3.5% of patients. The diagnosis was histologically confirmed in 91% of patients. Seven patients underwent biliMRI and 3 had cholangitis. No differences were found between patients with grade 3 or 4 hepatitis regarding type of cancer, type of ICI, number of doses, interval between ICI and peak of LFTs. Steroids were introduced in 32 (50%) patients and UDCA was used in 27% of patients. Doses of steroids were 0.5, 1 and 2 mg/kg/day in 8, 21 and 2 patients (not known in 1), respectively. Four patients didn't improve, 1 required increase of steroids, 3 a second immunosuppressive drug, 1 multiple drugs and died of liver failure. Use of steroids was associated with higher AST (p = 0.041), ALT (p = 0.041), total and conjugated bilirubin (p < 0.01 and 0.025) but not with type of ICI, number of doses, interval between ICI introduction and LFTs increase. Among grade 4 patients, 8 (33%) improved without steroids.

Table: Characteristics of patients treated vs not treated with steroids

	Steroids No N=32	Steroids Yes N=32	p
ALT, IU/l	388 [264; 688]	566 [354; 1295]	**0.041**
AST, IU/l	238 [132; 448]	427 [252; 750]	**0.041**
Total bilirubin, ∝mol/l	11.5 [9.10; 18.8]	20.5 [11.8; 49.2]	**<0.01**
Conjugated bilirubin, ∝mol/l	7.00 [5.05; 10.0]	12.0 [6.00; 38.0]	**0.025**
GGT, IU/l	390 [155; 659]	315 [184; 981]	0.62
ALP, IU/l	327 [118; 418]	258 [147; 585]	0.59
Interval between first ICI dose and LFTs increase, months	2.07 [0.983; 3.33]	1.38 [0.667; 3.44]	0.67
Interval between first ICI dose and LFTs peak, months	2.53 [1.85; 3.22]	3.42 [1.34; 7.08]	0.51
Number of doses	3.00 [1.50; 4.00]	2.00 [2.00; 4.00]	0.82
Anti-PD1+anti-CTLA4, n(%)	10 (31%)	11 (34%)	0.79
Anti-PD1, n(%)	16 (50%)	13 (41%)	0.45
Anti-PDL1, n(%)	5 (16%)	4 (12%)	1
Anti-CTLA4, n(%)	1 (3.1%)	4 (12%)	0.35

Conclusion: Grade ≥3 ICI-induced hepatitis was non-severe in the majority of cases. Steroid therapy was introduced in only half of the patients and was associated with higher ALT and bilirubin level. New cut off to indicate the use of steroid therapy is needed.

FRI021

The role of macrophage ETS Proto-oncogene 2 in acute-on-chronic liver failure

Lulu He[1], Qun Cai[1], Xi Liang[2], Jiaojiao Xin[1], Jing Jiang[1], Dongyan Shi[1], Keke Ren[1], Yun Li[3], Jiaxian Chen[1], Jinjin Luo[1], Jiaqi Li[1], Peng Li[1], Jun Li[1]. *[1]The First Affiliated Hospital, Zhejiang University School of Medicine, China; [2]Taizhou Central Hospital (Taizhou University Hospital), Precision Medicine Center, Taizhou, China; [3]Zhejiang University School of Medicine, Institute of Pharmaceutical Biotechnology and the First Affiliated Hospital Department of Radiation Oncology, Hangzhou, China*
Email: lijun2009@zju.edu.cn

Background and aims: Acute-on-chronic liver failure (ACLF) is a critical disease caused by acute aggravation of chronic liver disease, with poor prognosis and high mortality. The detailed mechanism of ACLF remains unclear. The purpose of this study was to investigate the value of macrophage ETS Proto-oncogene 2 (ETS2) as a prognostic marker in ACLF, and its role in mouse liver failure model induced by D-GalN/LPS.
Method: In this study, peripheral blood monocytes from 50 patients with ACLF, 19 patients with chronic liver disease and 14 healthy persons were collected for RNA-SEQ sequencing analysis. ACLF patients were divided into ETS2-high and ETS2-low expression group, and the differentially expressed genes between two groups were analysed. AAV9-ETS2-shRNA were injected to knockdown ETS2 in vivo. And then acute liver failure model of D-GalN/LPS was constructed. Serum biochemical indicators and the expression of inflammatory factors was detected by qPCR and ELISA. HE staining and TUNEL staining were used to observe the inflammatory infiltration and necrosis. Immunohistochemistry was used to detect the expression of high mobility group box 1 (HMGB1). In vitro, CRISPR-Cas9 was used to knockout ETS2 in RAW264.7 cells. The changes of inflammatory factors and related signalling pathways were detected with the intervention of HMGB1.
Results: The mRNA expression of ETS2 in peripheral blood of ACLF group was significantly increased compared with other groups. People who died within 28 days and 90 days showed increased expression of ETS2 compared with people who survived. The activation of innate immune and the suppression of adaptive immune were observed in ETS2- high expression group. In vivo experimental results showed that, ETS2 knockdown increased the liver function impairment and the expression of inflammatory factors

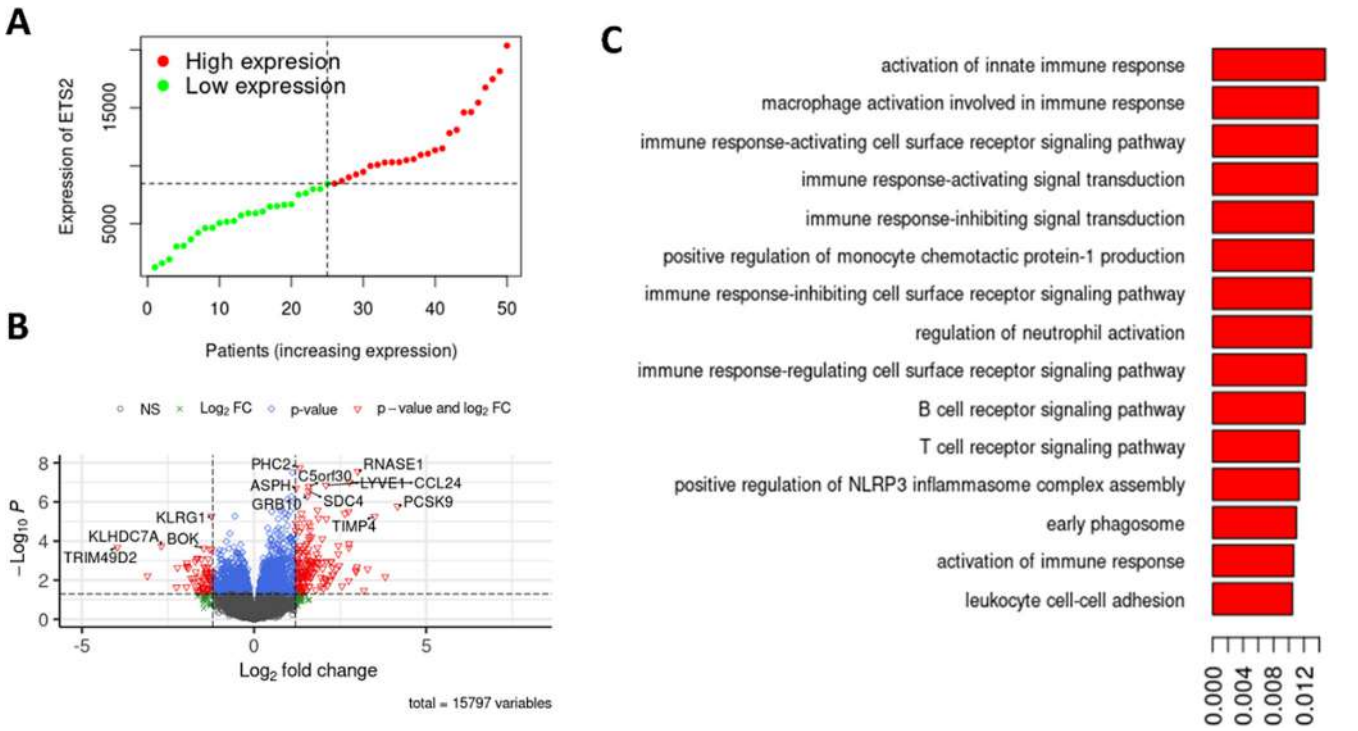

Figure: (abstract: FRI021)

significantly in acute liver failure model. The inflammatory infiltration and necrosis in liver tissue were significantly increased, and the expression of HMGB1 in liver tissue was significantly increased. In vitro results showed that D-GalN could induce HMGB1 release from hepatocytes. Knockout of ETS2 in RAW264.7 significantly increased the expression of HMGB1-induced inflammatory factors, and increased NF-kappa B phosphorylation.

Conclusion: ETS2 was a prognostic marker in ACLF and associated with the activation of innate immune. ETS2 alleviates HMGB1 induced macrophage inflammation by decreasing NF-kappa B activity. Knockdown ETS2 in vivo can increase inflammatory response and further aggravate hepatocyte injury.

Email: william.bernal@kcl.ac.uk

Background and aims: Care for patients with Acute liver injury (ALI) and Failure (ALF) has advanced significantly in recent years through critical care medical therapy and the targeted use of liver transplantation (LT). Case series have shown changes in the character of illness and its outcomes from the 1970 to early 2000s but the current outcomes are poorly characterised. We examined the changing treatment and outcomes of a large cohort of patients with ALF and ALI admitted to a single specialist ICU.

Method: consecutive patients with acute liver disease admitted over the period 1999–2021 were studied, classified in Era 1 (1999–2005), Era 2 (2006–12) and Era 3 (2013–21) and paracetamol (APAP) and non-APAP aetiologies. ALF was assigned in those with hepatic encephalopathy (HE) and ALI in those without. Severity of illness was assessed by presence of HE and laboratory measures. Data is expressed as n (%) or median (IQR). Data underwent univariate and multivariate analysis including logistic regression for the primary outcome of hospital survival.

Results: The study cohort comprised 1752 patients (median age 36 (27–48) years, 60% female, 56% APAP), of whom 1177 (68%) had/developed ALF. Mortality was 4% in those with ALI and 36% in ALF ($p < 0.001$). Era 1 comprised 628 patients, Era 2: 577 and Era 3: 547. Over the study period the proportion with HE grade 3 on admission rose from 50% to 61% ($p < 0.001$), and in both APAP and non-APAP cases measures of liver injury increased: admission INR: APAP 3.3 (2.4–4.9) in Era 1 to 5.6 (3.6–9.1) in Era 3, non-APAP 2.4 (1.6–4.3) to 3.0 (2.1–4.9) both $p < 0.001$). Survival in ALF rose from 53% in Era 1 to 70% in Era 2 ($p < 0.001$), plateauing at 71% Era 3. In parallel there was a fall in use of LT from 30% of ALF cases in Era 1 to 22% in Era 3 ($p < 0.001$). This was seen in both APAP (22% to 13%, $p < 0.001$) and non-APAP (41% to 31%, $p < 0.001$) cases. 343 patients underwent LT: post-LT survival increased from 72% in Era 1 to 91% in Era 2 and Era 3 ($p < 0.001$). Transplant-free survival (TFS) rose from 54% in Era 1 to 70% in Era 3 for APAP and from 29% to 59% in non-APAP cases (both $p < 0.001$). Non-significant increases in TFS were seen when Eras 2 and 3 were compared (APAP 66% vs. 70% $p = 0.47$, non-APAP 50% vs 59% $p = 0.14$). On multivariate analysis adjusting for age, aetiology and illness severity, Era was associated with improved overall survival: Era 1 to Era 2 (Adjusted Odds Ratio 4.1 (95% CI 2.9–5.9)) and Era 3 (4.7 (3.2–6.9), but there was no difference in between Era 2 and 3 (1.1 (0.78–1.6).

Conclusion: Survival for patients with ALF has markedly improved over the last 20 years, despite an increase in illness severity. Patient survival after LT is high, but its use has fallen, particularly in APAP ALF. TFS has progressively improved but outcomes in non-APAP ALF remain inferior. However, overall survival has now plateaued suggesting a need for new medical therapies and/or a re-evaluation of the use of transplantation.

FRI023

Human liver biopsies from people with hemophilia A who received factor VIII gene transfer with valoctocogene roxaparvovec (AAV5-hFVIII-SQ) show unremarkable histopathology and reveal interindividual variability in transgene production

Sylvia Fong[1], Bridget Yates[1], Choong-Ryoul Sihn[1], Aras Mattis[2,3], Nina Mitchell[1], Su Liu[1], Chris Russell[1], Benjamin Kim[1], Adebayo Lawal[1], Savita Rangarajan[4], Will Lester[5], Stuart Bunting[1], Glenn Pierce[6], K. Email: sfong@bmrn.com

Background and aims: Hemophilia A is an X-linked bleeding disorder caused by deficiency in factor VIII (FVIII), a cofactor in the intrinsic pathway of the coagulation cascade. Factor VIII is made predominantly in liver sinusoidal endothelial cells but gene therapy efforts using adeno-associated viruses (AAV) have targeted heterologous expression in hepatocytes. Factor VIII gene transfer with a single intravenous infusion of valoctocogene roxaparvovec (AAV5-hFVIII-SQ) has been shown to confer clinical benefit through at least 5 years in people with severe hemophilia A. Molecular mechanisms underlying sustained AAV5-hFVIII-SQ-derived FVIII expression in hepatocytes have not been studied in humans.
Method: In a substudy of the phase 1/2 clinical trial (NCT02576795), liver biopsy samples were collected from five participants 2.6–4.1 years after AAV5-hFVIII-SQ gene transfer. The objectives of the substudy were to examine effects on liver histopathology, determine the transduction pattern and percentage of hepatocytes transduced with AAV5-hFVIII-SQ genomes, characterize and quantify episomal forms of vector DNA, and quantify transgene expression (hFVIII-SQ RNA and hFVIII-SQ protein). Separately, we compared patterns and efficiencies of hepatocyte transduction in mice, monkeys, and humans who had all received AAV5-hFVIII-SQ to assess translatability of preclinical findings.
Results: Histopathological examination of human samples revealed no dysplasia, architectural distortion, fibrosis or chronic inflammation. No endoplasmic reticulum stress was detected in hepatocytes expressing hFVIII-SQ protein. Hepatocytes stained positive for vector genomes, and the number of transduced cells increased with AAV5-hFVIII-SQ dose. Molecular analysis demonstrated the presence of stable full-length circular episomal genomes that are associated with long-term expression. Interindividual differences in transgene expression were noted despite the successful administration of identical vector doses. Variability may be related to host-mediated post-transduction mechanisms of vector transcription, hFVIII-SQ protein translation, and secretion. Higher levels of vector genomes were detected in the livers of humans and monkeys than in mice; however, transcription of the vector DNA into RNA occurred more efficiently in mice.

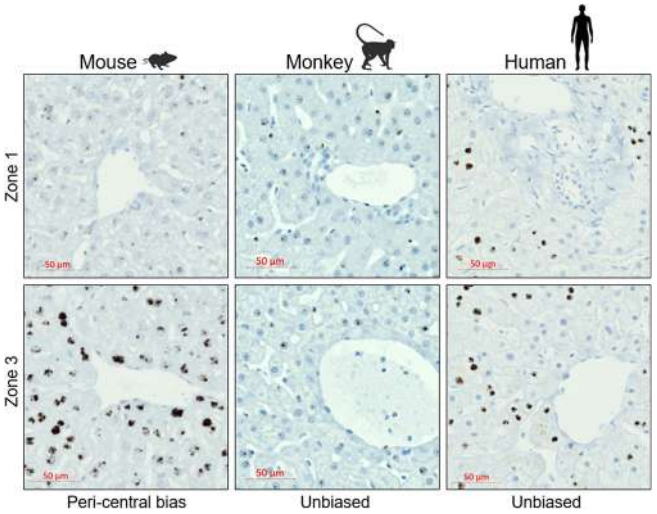

Figure: Cross species comparison of valoctocogene roxaparvovec transduction. In situ hybridization of hFVIII-SQ vector DNA (brown foci) in mouse, monkey, and human liver samples.

Conclusion: Overall, our results showed that liver histopathology was unremarkable following AAV5-hFVIII-SQ administration and that persistent episomal vector structures were formed. This work elucidates several potential mechanisms that may mediate interindividual variability in FVIII production and advances our understanding of inter-species translatability.

Email: m.scaravaglio@campus.unimib.it

Background and aims: Three cyclin-dependent kinase 4/6 inhibitors (CKIs) have shown to significantly improve the progression-free survival in patients with hormone receptor (HR)-positive, human epidermal growth factor receptor 2 (HER2)-negative advanced breast cancer (ABC). Among them, ribociclib has recently proved an overall survival benefit, emerging as a first-class option. Nevertheless, clinically significant drug induced liver injury (DILI) has been reported, leading to temporary or definitive withdrawal of antineoplastic therapy with related concerns about liver and oncologic outcomes. In a previous analysis of this cohort (manuscript in preparation) we found a significant higher risk of DILI with ribociclib compared to others CKIs. We aimed to assess characteristics and predictors of ribociclib-induced liver toxicity.
Method: All consecutive patients with ABC evaluated between June 2017 and December 2021 at the Oncology Unit of San Gerardo University Hospital, Monza, and received ribociclib for at least a complete cycle of 28 days were included in this retrospective study. Patients with hepatocellular carcinoma and/or chronic advanced liver disease were excluded.

Results: Of 122 ABC patients treated with CKIs, 43 received ribociclib and were included in the analysis, with a median treatment time of 15 months (interquartile range [IQR], 3.5 to 26.5). After a median follow-up time of 21 months (IQR, 15.5 to 30.5) an elevation of liver enzymes of any grade was reported in 13 out of 43 patients (30.2%) and 6 patients (14%) had a DILI, as defined by an ALT >5 × upper limit of normal (ULN) and/or ALp >2 × ULN. DILI episodes occurred after a median of 6 months (IQR, 3 to 8) from treatment start and all of them had a hepatocellular pattern. A single case of DILI with autoimmune features was described. Of 6 DILI patients, 1 (17%) underwent temporary and 5 (83%) definitive treatment interruption, achieving liver enzymes normalization within a median of 13 weeks (IQR, 7 to 24). Overall, the occurrence of DILI accounted for over a quarter of the total number of treatment discontinuations. No acute liver failure was reported. Fourteen of 43 patients (33%) died during the study period, none of liver-related cause. Baseline steatosis (RR 13.3, CI 4.5–39.6, $p < 0.01$) and dyslipidemia (RR 3.3, CI 0.8–13.9, $p = 0.05$) were associated with a significant higher risk of DILI. No associations were found when assessing previous exposure to antineoplastic treatments including endocrine agents, concomitant medications, presence of liver metastases, and fibrosis-4 index (FIB-4) at baseline.
Conclusion: Ribociclib is associated with a significant risk of DILI, turning in a relevant rate of antineoplastic treatment discontinuation in ABC patients. Once confirmed in larger prospective studies, baseline assessment of steatosis and dyslipidemia should be warranted to assist pre-treatment risk stratification.

FRI025

Exogenous fibroblast growth factor 7 improved hepatocyte regeneration and ameliorated CCl4-induced acute liver injury in vivo

Eline Geervliet[1,2], Ruchi Bansal[1]. [1]*University of Twente, Medical Cell Biophysics, Enschede, Netherlands;* [2]*RWTH Aachen, Institute of Molecular Pathobiochemistry, Experimental Gene Therapy and Clinical Chemistry, Aachen, Germany*
Email: ekgeervliet@gmail.com

Background and aims: During acute and chronic liver injury, hepatocyte damage instigates activation of inflammatory responses and ultimately fibrosis. Fibroblast growth factor-7 (FGF7), that binds specifically to FGFR2b (highly expressed on hepatocytes and liver progenitor cells), plays an important role in cholangiocytes/hepatocytes proliferation and liver regeneration as shown in a mouse model of cholangitis and biliary fibrosis, and partial hepatectomy. Unfortunately, during acute and chronic liver disease this ligand is insufficiently expressed resulting in lack of hepatocyte survival, and progression of liver disease. On the other hand, FGFR2b is upregulated during acute and chronic liver disease making it an excellent therapeutic target. In this research, we aim to target FGFR2b with its natural highly specific ligand FGF7 to improve survival and proliferation of hepatocytes, differentiation of liver progenitor cells, and thereby ameliorating liver disease progression in carbon tetrachloride (CCl_4)-induced acute liver injury mouse model.
Method: Acute liver injury was induced by a single injection of CCl_4. Mice were subsequently treated with vehicle or 1 µg/kg FGF7 twice a day for two days. After treatment, the mice were sacrificed, and the organs were harvested for further analysis. Hepatocyte survival and proliferation, inflammation and fibrosis were evaluated by immunohistochemical staining, and gene and protein expression.
Results: Exogenous FGF7 increased liver- and spleen-to-body weight ratio while significantly decreased the liver-to-spleen weight ratio. Immunohistochemical analysis of liver sections showed increased

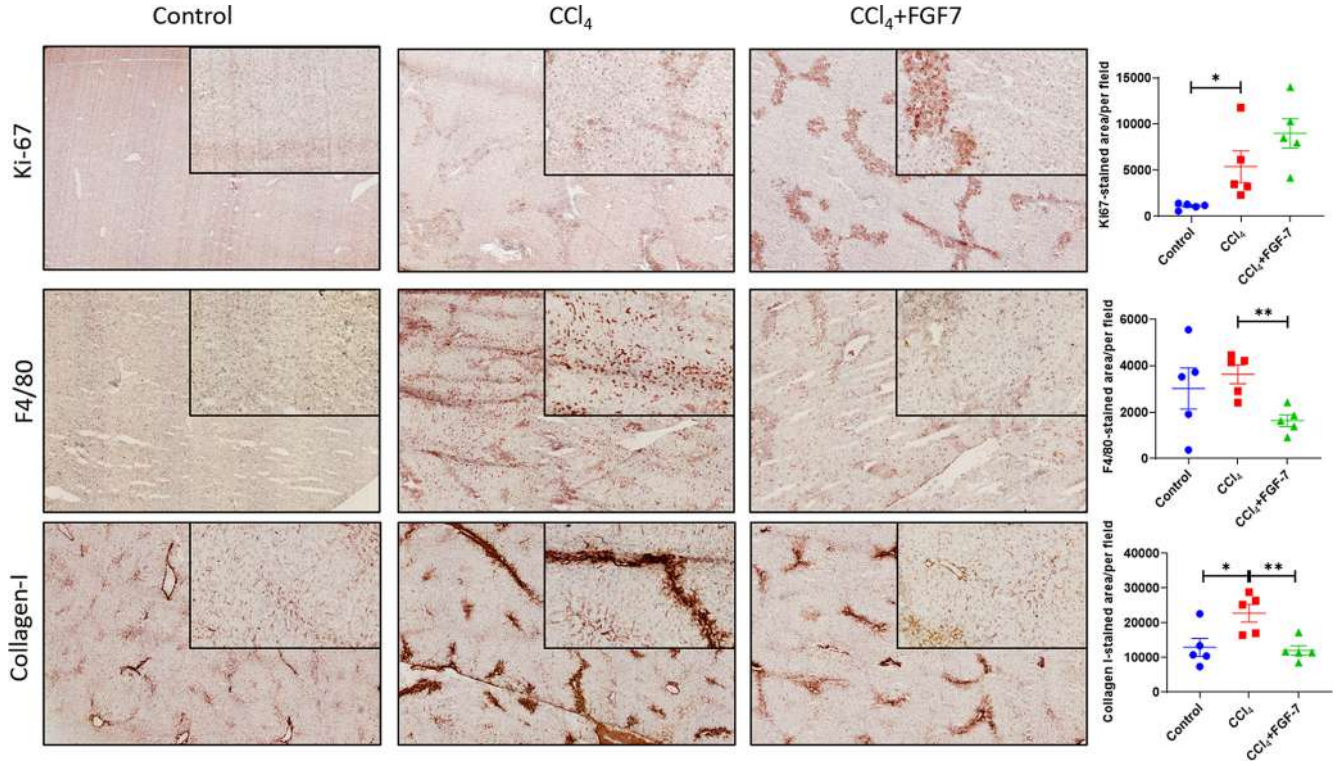

Figure 1: (abstract: FRI025): Representative microscopic images (10x) and quantitative analysis of liver sections of control (healthy, n = 5), CCl_4 (n = 5) and FGF7 (n = 5) treated mice stained with Ki67 (proliferation marker), F4/80 (macrophage marker) and Collagen-I (fibrosis marker). *$p < 0.05$ and **$p < 0.01$ denotes significance.

proliferation as determined by Ki67 expression. Furthermore, macrophage/inflammation marker, F4/80 and fibrosis marker, collagen-I were significantly decreased upon treatment, see Figure 1. Gene expression analysis of proliferation, inflammation and fibrosis markers followed the similar trend. Extensive protein analysis of hepatocyte survival pathways will be investigated using Western blot.
Conclusion: Our results show that exogenous administration of FGF7 induces hepatocyte survival and leads to amelioration of inflammatory response and fibrosis in acute liver injury. Our study demonstrates that FGF7, FGF7 derivatives or nano-engineered FGF7 may benefit patients with hepatic dysfunction.

Three COVID-19 medications-remdesivir, molnupiravir and ritonavir-boosted nirmatrelvir-and serial liver biochemistries in 22, 456 subjects

Grace Lai-Hung Wong[1], Vicki Wing-Ki Hui[1], Terry Cheuk-Fung Yip[1], Yee-Kit Tse[1], Vincent Wai-Sun Wong[1]. *[1]The Chinese University of Hong Kong, Medical Data Analytic Centre (MDAC) and Department of Medicine and Therapeutics, Hong Kong*
Email: wonglaihung@cuhk.edu.hk

Background and aims: Several medications as treatment for COVID-19 have been approved around the world. These medications have generally good safety profiles, while data concerning the liver safety of these COVID-19 medications and risk of drug-induced liver injury (DILI) are lacking. We aimed to report the serial liver biochemistries of people before and after receiving COVID-19 medications.
Method: This was a territory-wide retrospective observational cohort study in Hong Kong. We identified subjects who had received any of the three COVID-19 medications approved in Hong Kong-remdesivir, molnupiravir and ritonavir-boosted nirmatrelvir. Serial liver biochemistries at least three months before and one month after the COVID-19 medications were reported.
Results: 22, 456 subjects (5, 370 received remdesivir, 13, 127 received molnupiravir and 4, 510 received ritonavir-boosted nirmatrelvir; 551 subjects had received more than one medication) of whom 48.3% male, median age 77 years old, were included. Majority (98.7%) subjects had normal ALT (1–2 × ULN: 0.9/%; >2 × ULN: 0.4%) and total bilirubin (normal 91.3%; 1–2 × ULN: 7.2%; >2 × ULN: 1.5%) before or at the time of receiving COVID-19 medications. These parameters remained stable for up to one month after the treatment-ALT (normal 97.7%; 1–2 × ULN: 1.5%; >2 × ULN: 0.8%) and total bilirubin (normal 90.3%; 1–2 × ULN: 7.9%; >2 × ULN: 1.8%). Similar serial liver biochemistries were observed in subjects who received remdesivir, molnupiravir and ritonavir-boosted nirmatrelvir.
Conclusion: Three registered COVID-19 medications (remdesivir, molnupiravir and ritonavir-boosted nirmatrelvir) vaccines have very favourable liver safety profile in people.
Grant support: This work was supported by the Health and Medical Research Fund (HMRF)-Food and Health Bureau Commissioned Research on COVID-19 (Reference no.: COVID1903002) awarded to Grace Wong.

Trends in liver transplantation for acute liver failure. A Spanish multicenter study

Isabel Conde[1,2], Victoria Aguilera Sancho[1,2,3], Sara Martinez[4], Tommaso Di Maira[1], Maria Senosiáin[5], Rosa María Martín Mateos[6,6], Carolina Almohalla[7], Maria Luisa Gonzalez Dieguez[8], Sara Lorente Perez[4], Alejandra Otero[9], Maria Rodriguez[10], Jose Ignacio Herrero[11], Isabel Campos-Varela[12], Ainhoa Fernandez[13], Marina Berenguer[1]. *[1]La Fe University and Polytechnic Hospital, València, Spain; [2]Instituto de Investigación Sanitaria La Fe de Valencia, València, Spain; [3]ISCIII, CIBERehd, Valencia, Spain; [4]Hospital Clinico Universitario Lozano Blesa, Zaragoza, Spain; [5]Hospital Universitario Cruces, Barakaldo, Spain; [6]Hospital Ramón y Cajal, Madrid, Spain; [7]Rio Hortega University Hospital, Valladolid, Spain; [8]Central University Hospital of Asturias, Oviedo, Spain; [9]Hospital Universitario da Coruña (CHUAC), A Coruña, Spain; [10]General University Hospital of Alicantet, Alacant, Spain; [11]Clínica Universidad de Navarra, Madrid, Spain; [12]La Vall d'Hebron, Barcelona, Spain; [13]Gregorio Marañón Hospital, Madrid, Spain*
Email: icondemiel@gmail.com

Background and aims: ALF is a critical illness with high morbimortality. LT has improved outcome. Aims: to asses if there have been changes in aetiology, profile and outcomes of patients LT due to ALF in a Spanish multicenter cohort and to identify factors associated with mortality.
Method: Retrospective study of LT due to ALF cohort from 11 hospitals between 2001 and 2020. Baseline features, comorbidities, biochemical data, acute complications, early and late outcomes were recorded.
Results: 218 adults LT due to ALF (2001–2020). The cohort was subdivided in 4 time-groups (G1:2001–2005; G2:2006–2010; G3:2011–2015; G4:2016–2020). The number of ALF LT remained stable (G2: 2.5%, G3:2.2%. G4:2.7%.). Median age: 41 yrs, 62%women, AHT 11.5%, diabetes 3.7%, dyslipidaemia 8.3%, MELD 34 (29.5–38.1), 83.5% caucasic. Main LT indications were viral (26.2%), cryptogenic (26.1%), autoimmune (22.5%), and DILI (17%). 87% meet King's College criteria. 38% had severe encephalopathy, 22% renal impairment (RI) with haemodialysis, 23% required mechanical ventilation (MV). There was a trend towards an increase of LT for autoimmune (21%, 21%, 31%, 29% in G1–4 respectively, p = 0.88) and DILI (12.5%, 14%, 18%, 21% in G1–4, p = 0.72). Women seem more susceptible to ALF TH over time (58%, 53.5%, 65.6% and 67% in G1–4, p = 0.4). Complications in the early post-LT period were infections (58.7%), RI (25%) and primary dysfunction (24%). Late post-LT complications were AHT (30%), RI (20%) and diabetes (17%). 27% of patients died. Main causes of death were infections (41.5%) and liver-related (20%). Survival was 85%, 81% and 70% at 1, 5 and 10 years. Diabetes, MV, ascites and creatinine were independently associated with poorer survival (HR 4.05, p = 0.054; HR 2.74, p = 0.037; HR 2.48, p = 0.048 and HR 1.47, p = 0.007, respectively).
Conclusion: LT for ALF remained stable in the last years in Spain. Autoimmune and DILI seem to increase over time, being women more susceptible to ALF TH. Patients with diabetes, ascites, high creatinine levels, and MV were associated with poor outcomes after LT.

Hepatobiliary disease after bone marrow transplant

Maria Dezan[1,2], Marco Salvino[3,4], Alessandro Almeida[3,5], Hugo Silva[6], Lourianne Cavalcante[7,8], Helma Pinchemel Cotrim[8], Andre Lyra[7,8]. *[1]Hospital São Rafael, Gastroenterology and Hepatology, Salvador, Brazil; [2]Federal University of Bahia, Programa de Pós Graduação em Medicina e Saúde, Salvador, Brazil; [3]Hospital São Rafael, Hematology, Salvador, Brazil; [4]Hospital Universitário Professor Edgard Santos-HUPES, Hematology, Salvador, Brazil; [5]Hospital Universitário Professor Edgard Santos-HUPES, Hematology, Salvador; [6]Hospital Sao Rafael, Hematology, Salvador, Brazil; [7]Hospital São Rafael, Gastroenterology and Hepatology, Salvador, Brazil; [8]Hospital Universitário Professor Edgard Santos-HUPES, Gastroenterology and Hepatology, Salvador, Brazil*
Email: aclyra@live.com

Background and aims: Post-bone marrow transplantation (BMT) hepatobiliary complications (C-HEPBILI) may occur in up to 80% of the cases. We evaluated the frequency and clinical characteristics of C-HEPBILI in patients undergoing BMT at a referral center.
Method: This is a cross-sectional study that analyzed patient data from 2017 to 2021, including demographics, the period between BMT and C-HEPBILI diagnosis, outcome, and length of hospital stay. Drug-induced liver disease (DILI), sepsis-associated liver injury (SALI), sinusoidal obstruction syndrome (SOS), graft versus host disease (GVHD), hypoxic hepatitis (HH), and fulminant hepatitis (FH), among others, were evaluated. We diagnosed DILI according to EASL guidelines. For SALI, we considered the infectious context and a total bilirubin ≥2 mg/dL and ALP or ALT ≥2 × ULN. We used the EBMT, Seattle, and Baltimore criteria to diagnose SOS and considered hepatic GVHD when patients had skin and or intestinal GVHD and increased liver enzymes that improved after treatment. For alterations that did not meet the previous criteria, we defined liver enzymes elevation as an increase ≥1.5 ULN, named this condition isolated liver enzymes elevation (ILEE), and linked them to a possible etiology whenever clinically pertinent.
Results: Thus far, the study comprised 297 patients, 52% men. The mean age of the total population and the C-HEPBILI patients was 49.6 (±14.1) and 48.7 (±13.6) years, respectively; 164 of 297 patients (55%) had C-HEPBILI; 91 of them (55%) were women. Table 1 describes all detected C-HEPBILI. Most patients had ILEE that probably was associated with drugs or infection. We analyzed 201 autologous, 47 allogeneic haploidentical, and 49 allogeneic full-match BMT; C-HEPBILI occurred in 53%, 74%, and 47% of the cases, respectively, and was more frequent among patients with acute lymphoid leukemia. DILI occurred in 15% of patients with C-HEPBILI (44% had cholestatic DILI pattern, 44%, hepatocellular, and 12% mixed). The commonest conditioning regimens among patients with DILI used Melphalan. Nine out of 15 SOS patients died. The mean post-BMT hospital stay among C-HEPBILI patients was 25.8 days, while patients without these complications stayed for 17.9 days (mean). Twenty-two of 27 deaths occurred in C-HEPBILI patients, especially among SALI subjects.

Table 1: C-HEPBILI frequency in BMT patients*

	N	Total Population (N = 297)	C-HEPBILI Population (N = 164)
ILEE	120	40, 4%	73, 1%
DILI	25	8, 4%	15, 2%
SOS	15	5, 1%	9, 1%
HH	6	2, 0%	3, 6%
SALI	5	1, 7%	3, 0%
FH	2	0, 7%	1, 2%
GVHD	1	0, 3%	0, 6%

*Some patients progressed with more than one C-HEPBILI.

Conclusion: C-HEPBILI is frequent after BMT, is more common in women, and is associated with considerable morbidity, as well as an increase in the hospital stay. DILI was a relevant complication. Allogeneic haploidentical BMT was the most associated with C-HEPBILI.

FRI029

FOXA2 prevents hyperbilirubinemia through maintaining apical MRP2 expression in acute liver failure

Sai Wang[1], Rilu Feng[2], Shanshan Wang[3], Hui Liu[4], Chen Shao[4], Yujia Li[1], Frederik Link[1], Stefan Munker[5], Roman Liebe[6], Christoph Meyer[1], Elke Burgermeister[2], Matthias Ebert[2], Steven Dooley[2], Huiguo Ding[7], Honglei Weng[2]. *[1]Medical Faculty Mannheim, Heidelberg University, Department of Medicine II, Mannheim, Germany; [2]Medical Faculty Mannheim, Heidelberg University, Department of Medicine II, Mannheim, Germany; [3]Beijing You'an Hospital, Capital Medical University, Beijing Institute of Hepatology, Beijing, China; [4]Beijing You'an Hospital, Affiliated with Capital Medical University, Department of Pathology, Beijing, China; [5]University Hospital, LMU Munich, Department of Medicine II, Mannheim, Germany; [6]Saarland University Medical Center, Saarland University, Department of Medicine II, Germany; [7]Beijing You'an Hospital, Affiliated with Capital Medical University, Department of Gastroenterology and Hepatology, China*
Email: honglei.weng@medma.uni-heidelberg.de

Background and aims: Multidrug resistance protein 2 (MRP2) is a bottleneck in bilirubin excretion. Its loss is sufficient to induce hyperbilirubinemia, a prevailing characteristic of acute liver failure (ALF), that is closely associated with clinical outcome. This study scrutinizes the transcriptional regulation of MRP2 under different pathophysiological conditions.
Method: Thirty-six patients, 14 with quiescent liver cirrhosis and 22 with ALF, were enrolled. Hepatic MRP2, FXR, and FOXA2 expression were examined by immunohistochemistry. Clinicopathologic association was analysed. MRP2 regulatory mechanisms were investigated in primary hepatocytes, $Fxr^{-/-}$ mice and LPS-treated mouse model.å
Results: In normal hepatocytes, homeostatic MRP2 transcription is mediated by the nuclear receptor FXR/RXR complex. $Fxr^{-/-}$ mice lack apical MRP2 expression and rapidly progress into hyperbilirubinemia. In ALF patients, hepatic FXR expression is undetectable, however, the patients without infection maintain apical MRP2 expression and do not suffer from hyperbilirubinemia. These patients express robust FOXA2 in hepatocytes. FOXA2 upregulates MRP2 transcription through binding to its promoter. Physiologically, nuclear FOXA2 translocation is inhibited by insulin. In ALF, high levels of glucagon and TNF-α induce FOXA2 expression and nuclear translocation in hepatocytes. Impressively, ALF patients with sepsis express few FOXA2, lose MRP2 expression, and show severe hyperbilirubinemia. In this case, LPS inhibits FXR expression, induces FOXA2 nuclear exclusion, and thus destroys the compensatory MRP2 upregulation. In both $Fxr^{-/-}$ and LPS-treated mice, ectopic FOXA2 expression restored apical MRP2 expression and serum bilirubin levels.
Conclusion: Upregulation of FOXA2 to maintain MRP2 is an efficient strategy to prevent hyperbilirubinemia.

NAFLD: Diagnostics and non-invasive assessment

Machine learning encoding of liver biopsy images enables prediction of molecular measurements in a NASH F3/F4 fibrosis clinical cohort

Michael D. Bereket[1], Francesco Paolo Casale[1], Rohit Loomba[2], Arun Sanyal[3], Stephen Harrison[4], Zobair Younossi[5], Catherine Jia[6], David Lopez[6], Li Li[6], Robert Myers[6], David Breckinridge[6], Andrew Billin[6], Eilon Sharon[1], Matthew Albert[1], Theofanis Karaletsos[1], Daphne Koller[1]. *[1]Insitro, South San Francisco, United States; [2]University of California San Diego, La Jolla, United States; [3]Virginia Commonwealth University, Richmond, United States; [4]University of Oxford, Radcliffe Department of Medicine, United Kingdom; [5]Inova Fairfax Medical Campus, Falls Church, United States; [6]Gilead Sciences, Inc., Foster City, United States*
Email: research_operations@insitro.com

Background and aims: Machine learning (ML) models of biopsy images have the potential to improve the characterization of liver state by identifying biologically relevant phenotypes that are not captured by standard histological endpoints. To explore this possibility, we develop and compare ML models that predict transcriptomic and genetic endpoints based on standard histology readouts or ML derived histological features. We focus our genetic analysis on the PNPLA3 I148M genotype, which has been robustly linked to NAFLD/NASH risk through GWAS studies (Romeo et al, 2008; Anstee et al, 2020).
Method: Pathologist scores (NASH CRN and Ishak fibrosis scores), quantitative microscopy measurements (alpha-SMA, collagen, and fat content), H&E-stained biopsy images, liver bulk RNA-seq, and PNPLA3 I148M genotypes are curated from the STELLAR3, STELLAR4, and ATLAS clinical trial F3/F4 fibrosis cohorts. We use self-supervised ML methods (trained with no clinician annotations) to generate quantitative embeddings that represent histological phenotypes. We fit generalized linear models to predict the molecular endpoints from the standard and ML-derived biopsy features, training on a random split of half the data and predicting on held-out samples. All genetic association testing focuses on subjects of European ancestry due to population stratification concerns and considers 10 genotype principal components, age, and sex as covariates.
Results: Predictions of gene expression are improved with the ML biopsy embeddings relative to the standard histological endpoints (A). While the I148M variant is enriched in this cohort relative to the general population (allele frequency G = 0.46 vs G = 0.22 in gnomAD EUR samples), we do not observe any association between pathologist or quantitative microscopy measurement and I148M genotype ($p > 0.05$). Similarly, genotype predictions from these measurements are not significantly associated with the I148M genotype. However, genotype predictions using the self-supervised ML biopsy embeddings are significantly associated with I148M genotype in the held out samples ($p = 4E\text{-}9$, $n = 378$; B). Tiles that influence these genotype predictions are visualized in C.
Conclusion: ML models of H&E biopsy images identify histological features that improve predictions of molecular endpoints relative to standard histological readouts. Notably, we identify a histological phenotype associated with PNPLA3 I148M genotype in F3/F4 fibrosis NASH patients that is not captured by standard histological endpoints. This result supports the potential for ML models to provide orthogonal characterizations of histological state, enabling novel insights on the interplay of clinical phenotypes, transcriptomic state, and genetic backgrounds in NASH patients.

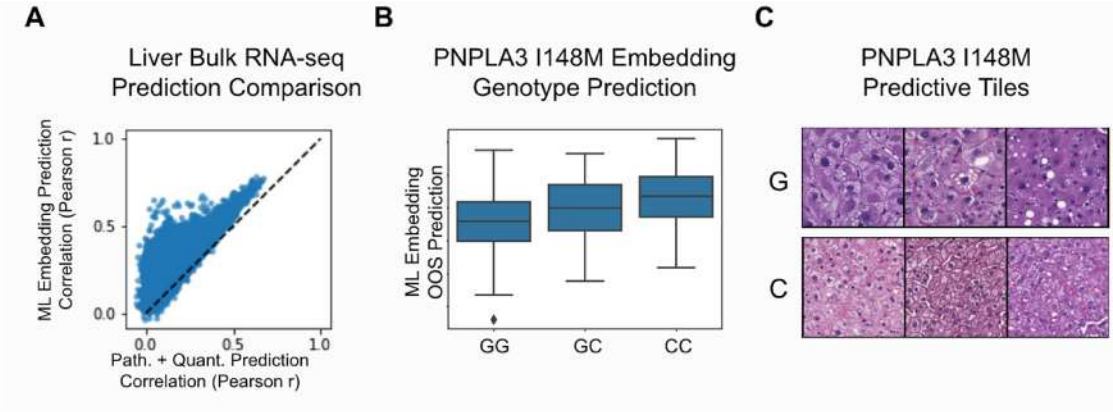
Validation of AI-assisted method of liver fat measurement in adults with type 2 diabetes

Athena Dworakowski[1], Wenjie Pang[1], Sherif Boulos[1], Sofie De Meyer[1], Jian Yeo[2], Gaurav Gulsin[2], Abhishek Dattani[2], Emer Brady[2], Joanna Bilak[2], Sarah Ayton[2], Alastair Moss[2], Michael House[3], Tim St Pierre[3], Gerry McCann[2]. *[1]Resonance Health, Burswood, Australia; [2]University of Leicester, Department of Cardiovascular Sciences, United Kingdom; [3]The University of Western Australia, School of Physics, Crawley, Australia*
Email: sofied@resonancehealth.com

Background and aims: Type 2 diabetes (T2D) is strongly associated with the development of non-alcoholic fatty liver disease (NAFLD), which is an emerging independent risk factor for cardiovascular



Prediction of molecular endpoints from histological features. A) Scatter plot of correlations between predicted and observed gene expression using standard histological endpoints (pathologist and quantitative microscopy measurements) or self-supervised ML-derived biopsy embeddings as input features; 3040 / 17648 genes have a difference of at least 0.2 in prediction correlation. B) Box plot of PNPLA3 I148M genotype predicted from self-supervised ML biopsy embeddings. C) Biopsy tiles that most strongly influence the PNPLA3 embedding model predictions.

Figure: (abstract: FRI030)

dysfunction. Hepafat-AI® is a software device developed using artificial neural networks (ANN) and provides rapid (less than one minute) automated liver fat quantification from magnetic resonance images without the need for labour-intensive manual image analysis. The aims of this study were to compare HepaFat-AI against the histologically validated HepaFat-Scan® technique as a reference standard in a cohort of asymptomatic adults with T2D.

Method: One hundred and thirty-three adults (97% T2D, mean age 62.6 ± 7.6 years, 60% male) underwent magnetic resonance imaging (MRI) of the liver and heart. Nineteen were excluded due to incorrect imaging parameters or breathing artifacts, leaving a sample of 114 subjects. Volumetric liver fat fraction (VLFF) was analysed twice, first manually with HepaFat-Scan based on the 3-point Dixon principle and then automatically processed using HepaFat-AI. HepaFat-AI was previously trained on 889 individual HepaFat-Scan datasets from both 1.5 T and 3 T scanners and generates a report comprising VLFF measurements, proton density fat fraction (PDFF), and steatosis grade. Bland-Altman analysis was performed to determine the 95% limits of agreement between the two methods of measuring VLFF. The diagnostic performance of HepaFat-AI for predicting HepaFat-Scan steatosis grade 1 or above was also analysed in terms of sensitivity, specificity, and accuracy.

Results: Bland-Altman analysis showed that on average HepaFat-AI yields slightly higher VLFF results with a bias of +0.42 (95%CI 0.10–0.74)%VLFF against HepaFat-Scan. The 95% limits of agreement between the two methods were -3.02 and +3.85%VLFF. The sensitivity and specificity of HepaFat-AI for predicting HepaFat-Scan determined steatosis grade of 1 or above were 0.97 (95% CI 0.84–0.99) and 0.88 (95% CI 0.64–0.99) respectively. With HepaFat-Scan as the reference standard, HepaFat-AI had an accuracy of 0.90 (95% CI 84–95) for grading steatosis above or below the grade 0/1 boundary.

Conclusion: HepaFat-AI provides a rapid and automated liver fat quantification analysis of MR images which has important implications for cost and may provide a fast alternative point-of-care testing for patients. The adoption of ANNs in clinical settings has the potential to enhance diagnostic efficiency and medical intervention for T2D adults with liver disease.

Identifying advanced liver disease in asymptomatic patients in primary care: an evaluation of patient outcomes 24 months after implementing a primary care liver pathway and community liver service

Tina Reinson[1], Chris Byrne[2], Mead Mathews[3], Janisha Patel[4].
[1]*University of Southampton, Primary Care, Population Sciences and Medical Education, Southampton, United Kingdom;* [2]*University of Southampton, Human Development and Health, Southampton;* [3]*St Mary's Surgery, Southampton, United Kingdom;* [4]*University Hospital Southampton, Hepatology, Southampton*
Email: t.reinson@soton.ac.uk

Background and aims: In 2019, Southampton Clinical Commissioning Group implemented a liver guidance pathway and community liver service to help early detection and reduce the number of deaths from liver disease. The liver guidance pathway supports primary care clinicians identify patients at risk of liver disease to access early intervention before developing to advanced liver disease. The community liver service provides vibration controlled transient elastography (VCTE) assessment to patients who, after following the liver guidance pathway, have been identified as having severe liver fibrosis. This study aims to evaluate the patient outcomes 24 months after implementing the liver pathway and VCTE service.

Method: All patients referred to the Southampton community liver service between January 2019 and December 2020. Demographics recorded included: Age, sex, body mass index (BMI), alcohol consumption (high or low), VCTE reading (kPa), diagnosis (alcohol related liver disease, non-alcoholic fatty liver disease or both) and patient outcomes (stay in primary care or refer to secondary care for clinical management).

Results: 527/632 patients referred to the community liver service received a VCTE assessment.16.6% ($n = 105$) did not attend their appointment and for 0.9% ($n = 5$), no valid VCTE reading was obtained. The median (IQR) age of patients was 58 (46–65) years, 58.6% were male; median (IQR) BMI was 30.5 (27.1–35.1) kg/m^2 and alcohol

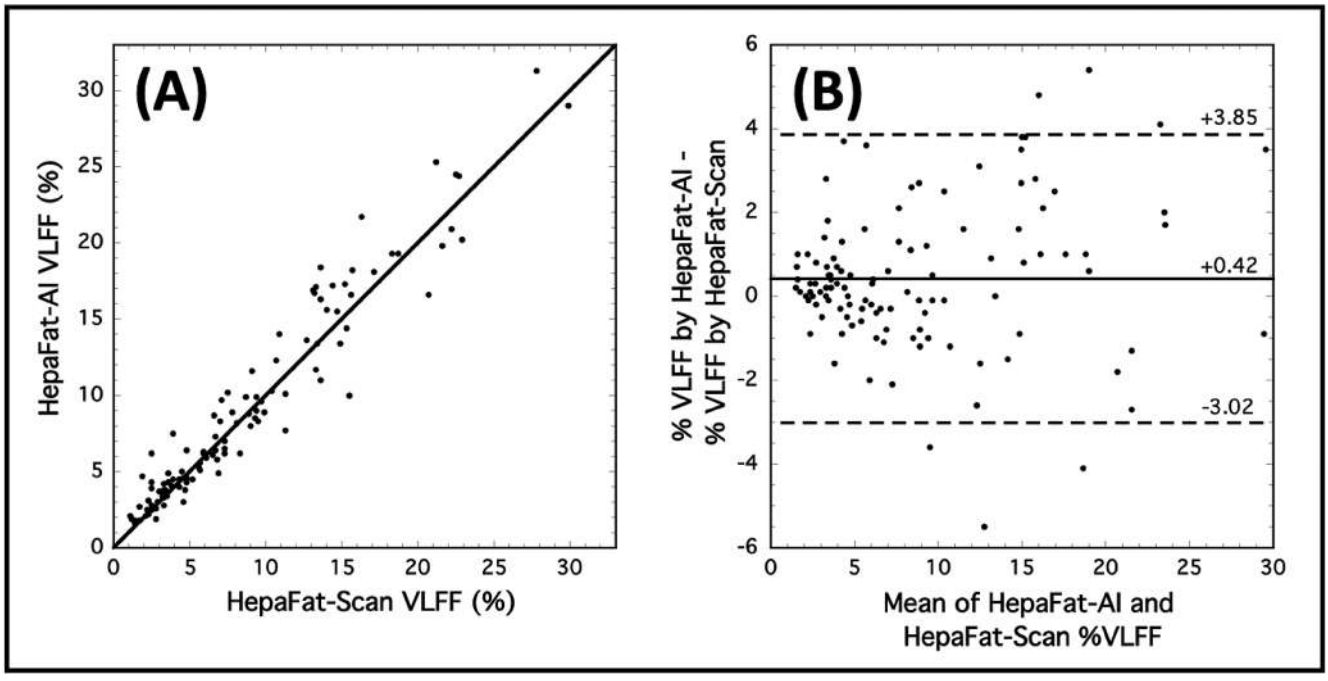

Figure: (abstract: FRI031): (A) VLFF from manual processing (HepaFat-Scan) vs automated processing (HepaFat-AI) with line of equivalence. (B) Bland-Altman plot showing the differences between the HepaFat-AI and HepaFat-Scan VLFF measurements. The solid line shows the mean difference and the dashed lines show the upper and lower 95% limits of agreement between the two methods.

consumption in 23.9% (*n* = 126) was graded as high (defined as drinking more than the UK recommended alcohol guidelines). Mean (SD) VCTE was 9.5 (9.2) kPa, of whom 8% (*n* = 42) had a reading of >20.0 kPa. 77.4% (*n* = 408) were diagnosed with non-alcoholic fatty liver disease (NAFLD); 15.7% (*n* = 83) with alcohol related liver disease (ARLD) and 6.8% (*n* = 36) with both NAFLD and ARLD. 27.9% (*n* = 147) of patients were found to have a liver fibrosis stage of F3/F4 (9.7 kPa–13.5 kPa/>13.6 kPa) and were referred to secondary care. 71.0% (*n* = 374) had a liver fibrosis stage of F0-F2 (between 3.0 kPa and 9.6 kPa) and were referred back to primary care for repeat VCTE assessment in 3 years time.

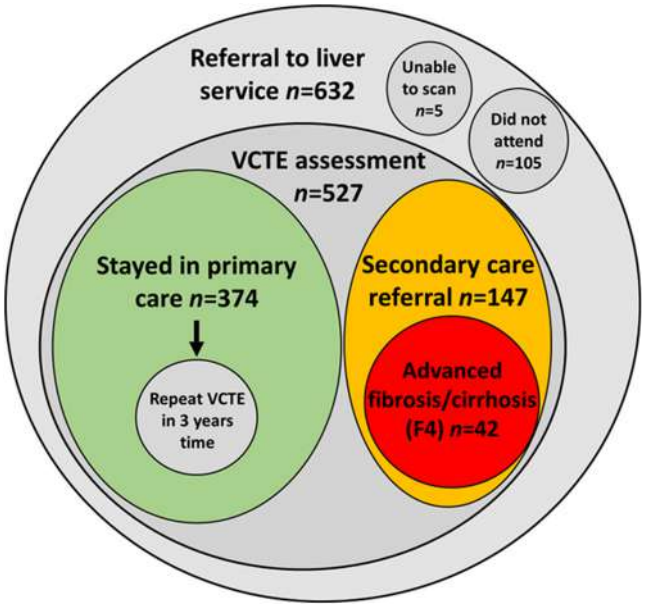

Figure: Summary of patient pathway through the community-based liver scanning service.

Conclusion: 8% asymptomatic patients identified as having advanced liver disease/cirrhosis and ~20% identified as being at risk of developing progressive liver fibrosis, are now being monitored by secondary care. The remaining patients (71%) are being monitored in primary care and will be referred for repeat VCTE assessment in 3 years time. This evaluation demonstrates the usefulness of providing primary care clinicians with a liver guidance pathway with access to VCTE assessment, a service that is still predominantly only accessible in secondary care.

Predictive survival-time modelling of Non-Alcoholic Steatohepatitis (NASH) fast progressors using real-world evidence

Nils Svangård[1], Christen Gray[2], Ally Taylor[3], Taylor Cohen[4], Bret Sellman[4], Claire Donoghue[2], Faisal Khan[5], Christopher Rhodes[6], Philip Ambery[7], Shameer Khader[5], John Dillon[3]. *[1]AstraZeneca, Data Science & Artificial Intelligence, Sweden; [2]AstraZeneca, Data Science & Artificial Intelligence, Cambridge, United Kingdom; [3]University of Dundee, United Kingdom; [4]AstraZeneca, Microbiome Discovery, Gaithersburg, United States; [5]AstraZeneca, Data Science & Artificial Intelligence, Gaithersburg, United States; [6]AstraZeneca, Early CVRM, Gaithersburg, United States; [7]AstraZeneca, Clinical Metabolism, Gothenburg, Sweden*
Email: nils.svangard@astrazeneca.com

Background and aims: Evidence suggests that a subset of patients with Non-Alcoholic Fatty Liver Disease (NAFLD) may progress faster to end stage liver disease via Non-alcoholic Steatohepatitis (NASH). There is a need for methods to identify such sub-populations of fast progressors in order to improve patient care and enable more effective clinical trials. Prior machine learning based approaches to identify progressors, e.g. using binary prediction of progression types, did not consider censored events due to death, transfer out of data source, or end of study period, which can reduce accuracy of the results. The aim of this study is to develop a machine learning *survival-time prediction* model that can identify NAFLD and NASH patients at risk of fast progression to end stage liver disease based on real-world data, taking censoring of events into account.
Method: We retrospectively evaluated patients in Optum® Clinformatics® Data Mart (de-identified US electronic health records, 2007–2021) aged ≥18 with the index-time being the first diagnosis of NAFLD or NASH based on ICD- codes with no prior liver disease. Progression time was defined as the time between index date and the first hard endpoint of NASH or censored at death, transfer out of data source, or end of study period. Progression times were predicted using a machine learning survival-time model robust to missing data, trained on sparse data and 80% of the subjects. Model performance was evaluated using the cumulative dynamic area-under-the-curve on the remaining subjects and compared with five single biomarker baseline models. The most important features were visualized using Shapley Additive exPlanations (SHAP).
Results: A final cohort of 260,180 patients matched the inclusion and exclusion criteria, 3% of the patients had a severe endpoint observed, and the median progression time for these patients was 14 months. The predictive model had an *average cumulative dynamic AUC of 0.76* for predicting progression times from index to the end of the study period, compared with 0.64 for the best performing baseline model, the AST/ALT ratio.
Conclusion: The predictive survival-time model outperforms individual biomarkers at characterizing NASH fast progressors both at index time and continuously until the time of event. Future research of the model should include validation in other datasets, including patients in a range of geographic regions, of different ethnicities and with biopsy confirmed NASH.

Online education significantly improved gastroenterologists' knowledge of the diagnostic and monitoring techniques used in liver fibrosis

James White[1], Elaine Bell[1], Briana Betz[2], Jörn Schattenberg[3].
[1]*Medscape Global Education, London, United Kingdom;* [2]*Medscape LLC, New York, United States;* [3]*University Medical Center Mainz, I. Department of Medicine , Mainz, Germany*
Email: jrwhite@webmd.net

Background and aims: Non-alcoholic steatohepatitis is a leading cause of liver fibrosis. Progression of liver fibrosis to advanced stages is linked to severe outcomes and increased healthcare costs. Non-invasive techniques, including biomarkers and elastography, improve the diagnosis and monitoring of liver fibrosis. Unmet educational needs are one barrier in the use of non-invasive techniques. We assessed whether online continuing medical education (CME) could improve physicians' knowledge and confidence of appropriate diagnostic and monitoring techniques in liver fibrosis.

Method: Gastroenterologists (n = 220) participated in a chapterised video activity entitled "Evolution of Diagnosis and Monitoring for Liver Fibrosis" which covered guideline recommendations, identification of patients at risk of progression, and non-invasive pathways for identifying advanced fibrosis. Educational effect was assessed using a repeated-pair design with pre-/post-assessment. 3 multiple choice questions assessed knowledge and 1 question, rated on a Likert-type scale, assessed confidence. A paired samples t-test was conducted for significance testing on overall average number of correct responses and for confidence rating, and a McNemar's test was conducted at the question level (5% significance level, $p < 0.05$). Cohen's d with correction for paired samples estimated the effect size of the education on number of correct responses (<0.20 modest, 0.20–0.49 small, 0.59–0.79 moderate, ≥0.80 large). Data were collected from 04/01/21 to 09/03/21.

Results: Results showed significant overall improvement in average percentage of correct responses for gastroenterologists (45% pre- to 63% post-education, $p < 0.001$, Cohen's d = 0.56). The percentage of gastroenterologists that answered all questions correctly improved from 9% pre-, to 30% post-education.

Whilst 23% improved and 27% reinforced their knowledge regarding which set of markers is included in the Enhanced Liver Fibrosis (ELF) score, 50% of gastroenterologists still lack this information after education ($p < 0.001$).

Post-activity, 41% of gastroenterologists had a measurable increase in confidence in using non-invasive techniques in clinical practice to identify patients with advanced fibrosis ($p < 0.001$), with an average confidence shift of 58%.

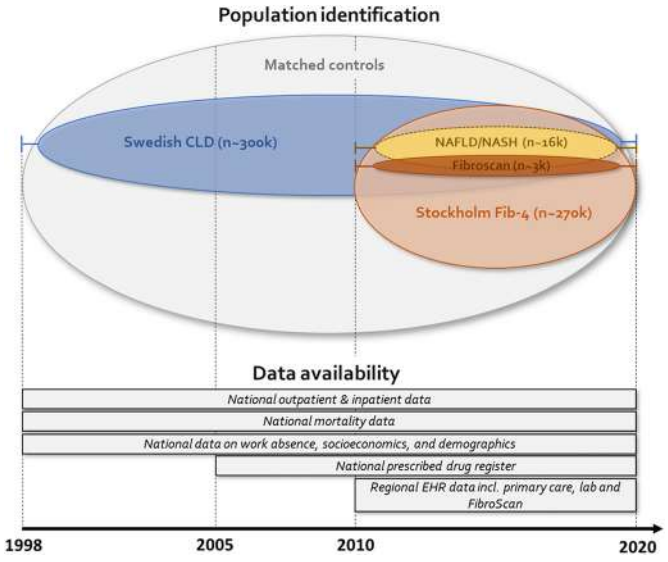
Conclusion: Participation in an online chapterised video activity significantly improved physicians' knowledge and confidence of appropriate diagnostic and monitoring techniques in liver fibrosis. Despite this, further education regarding the markers included in the ELF score is needed for gastroenterologists.

FRI035

Health outcomes and risk assessment in chronic liver disease (HERALD): a large Swedish research platform

Emilie Toresson Grip[1,2], Oskar Ström[1,2], Hannes Hagström[1,3,4].
[1]Karolinska Institutet, Department of Medicine Huddinge, Sweden; [2]Quantify Research AB, Stockholm, Sweden; [3]Karolinska University Hospital, Division of Hepatology, Department of Upper GI Diseases, Stockholm, Sweden; [4]Karolinska Institutet, Clinical Epidemiology Division, Department of Medicine Solna, Stockholm, Sweden
Email: emilie.toresson.grip@ki.se

Background and aims: The 'HEalth outcomes and Risk Assessment in chronic Liver Disease' (HERALD) study is a multi-stakeholder Swedish research-platform linking national and regional registries to investigate the epidemiology and risk factors of liver outcomes, resource-use and costs, in patients with chronic liver diagnoses (CLD) or liver-related laboratory tests. HERALD is also planned to include data from the National Diabetes Register and other countries during 2022, and is open to international collaboration.
Method: A CLD cohort will consist of all patients ≥18 years with ≥1 CLD diagnosis (ICD-10) in the Swedish Patient Register, or primary care from the Stockholm region. A Fib-4 cohort will consist of patients with laboratory tests (AST, ALT and platelets), required for estimating the non-invasive Fibrosis-4 (Fib-4) score in all care settings in Stockholm. All patients will be linked with longitudinal data on diagnoses, comorbidities, healthcare utilization, prescribed medicines, mortality, work absence, socioeconomic status and demographics. For a subset, other laboratory data and data on transient elastography (FibroScan) are extracted from electronic health records (EHR) and FibroScan-devices, respectively. High-risk subgroups and costs will be compared with matched controls from the general population.
Results: A feasibility study was completed in 2020 and ethical approval for HERALD was granted in August, 2020. During 2001–2019, the number of patients with NAFLD was 16, 285, with at least 46, 122 patient years of follow-up. The number of patients with chronic HCV, AIH or PBC were n = 53, 602, n = 5, 337 and n = 5, 247, respectively. 200, 000 to 300, 000 patients with CLD are expected, partly overlapping with the ~270, 000 patients expected in the Fib-4 cohort.



Conclusion: This study is the result of a research collaboration between academia and analytical and pharmaceutical industry. HERALD will be the largest data collection to date to estimate a contemporary prevalence of liver disease and advanced fibrosis in a broad, unselected population of healthcare-seeking individuals in Sweden. Furthermore, HERALD will utilize clinical and non-clinical information to characterize patients with different risk profiles and to estimate long-term societal burden associated with severe liver outcomes in clinical practice over a 20-year period.

FRI036

Impact of alcohol use on the diagnostic performance of serum-based indices for fatty liver disease

Oscar Danielsson[1], Markku Nissinen[1], Katja Pahkala[2,3,4], Terho Lehtimäki[5,6], Olli Raitakari[2,3,7], Fredrik Åberg[8]. *[1]Clinic of Gastroenterology, Helsinki University Central Hospital and University of Helsinki, Helsinki, Finland, Finland; [2]Centre for Population Health Research, University of Turku and Turku University Hospital, Turku, Finland, Finland; [3]Research Centre of Applied and Preventive Cardiovascular Medicine, University of Turku, Turku, Finland, Finland; [4]Paavo Nurmi Centre, Unit of Health and Physical Activity, University of Turku, Turku, Finland, Finland; [5]Department of Clinical Chemistry, Fimlab ltd., Finland, Finland; [6]Faculty of Medicine and Health Technology, Finnish Cardiovascular Research Center-Tampere, Tampere University, Tampere, Finland, Finland; [7]Department of Clinical Physiology and Nuclear Medicine, Turku University Hospital, Turku, Finland, Finland; [8]Transplantation and Liver Surgery, Helsinki University Central Hospital and University of Helsinki, Finland*
Email: oscar.danielsson@hus.fi

Background and aims: Non-alcoholic fatty liver disease (NAFLD) and alcohol-related liver disease (ARLD) frequently co-exist, and recently proposed diagnostic criteria for metabolic-dysfunction associated fatty liver disease (MAFLD) have removed strict cut offs for alcohol use. While several indices exist for detection of NAFLD, there is paucity of study on how alcohol use possibly impact their diagnostic performance. We analysed the effect of various level of alcohol use on the performance of several indices for detecting fatty liver disease (FLD).
Method: From the Cardiovascular Risk in Young Finns study, we included participants who underwent abdominal ultrasound (US) in 2010–2012 for detection of FLD and had serum analyses available from the same time for calculation of the Fatty Liver Index (FLI), Hepatic Steatosis Index (HSI) and Lipid Accumulation Product (LAP). Alcohol use was assessed by questionnaires. Predictive performance for FLD was assessed by AUROC, logistic regression, sensitivity, specificity, and positive and negative predictive values (PPV and NPV) according to alcohol consumption.
Results: Study comprised 1426 individuals (mean age 42.1 years, 42.6% males, mean BMI 26.3 kg/m², mean alcohol use 9.4 g/day), of which 234 (16%) had FLD by US. High risk index-scores were observed in 27.2%, 24.7% and 54.8% (FLI, HSI and LAP, respectively) of the study population. When daily alcohol consumption was <50 grams, all indices discriminated FLD with AUROCs of 0.82–0.88. Among heavy drinkers (>50 g/day), AUROCs were 0.61–0.66. Alcohol use correlated weakly with both FLI (r = 0.09) and LAP scores (r = 0.16, both p-values <0.001), no significant correlation for HSI.

Index	Alcohol/day, g	PPV	NPV
FLI		31.0/45.6%	97.5/94.6%
	<10	28.2/44.6%	97.7/96.0%
	10-20/30*	32.7/45.0%	99.3/93.2%
	20/30-50*	48.5/54.5%	100.0/87.1%
	>50	43.5/53.8%	69.2/69.6%
HSI		23.5/41.5%	97.6/92.4%
	<10	35.1/37.2%	98.5/94.4%
	10-20/30*	21.2/47.7%	97.0/90.1%
	20/30-50*	35.9/62.5%	100.0/88.6%
	>50	44.0/62.5%	70.0/66.7%
LAP		26.6%	96.1%
	<10	23.1%	97.6%
	10-20/30*	32.1%	95.3%
	20/30-50*	43.3%	87.0%
	>50	38.5%	60.0%

Values shown for **lower/higher** cut off values

*Alcohol use categorized using different cut off values for men and women

Conclusion: With alcohol consumption below 50 g/day, FLI, HSI and LAP perform well for detection of FLD, all with comparable performance. With higher alcohol consumption, their diagnostic performance is reduced substantially.

FRI037

Liver stiffness on magnetic resonance elastography and liver-related outcomes in nonalcoholic fatty liver disease: a systematic review and meta-analysis of individual participants

Veeral Ajmera[1], Kun Yang[1], Beom Kyung Kim[1], Abdul Majzoub[2], Nobuharu Tamaki[3], Atsushi Nakajima[4], Ramazan Idilman[5], Mesut Gumussoy[5], Digdem Kuru Öz[5], Ayse Erden[5], Natalie Quach[6], Xin Tu[6], Xinlian Zhang[6], Mazen Noureddin[7], Alina Allen[8], Rohit Loomba[6]. *[1]University of California San Diego; [2]Conemaugh Memorial Medical Center; [3]Musashino Red Cross Hospital, Japan; [4]Yokohama City University Medical Center; [5]Ankara University, Turkey; [6]University of California San Diego, United States; [7]Cedars Sinai Medical Center, United States; [8]Mayo Clinic, United States*
Email: v1ajmera@ucsd.edu

Background and aims: Magnetic resonance elastography (MRE) is a reproducible, accurate, continuous biomarker of liver fibrosis, however, limited data characterize its association with outcomes. We conducted a systematic review and pooled analysis of individual participant data from published studies and additional identified cohorts to evaluate the association between liver stiffness on MRE and liver-related outcomes.

Method: A systematic search identified 6 cohorts of adults at risk for NAFLD who underwent MRE and were assessed for liver-related outcomes. In a pooled analysis, logistic regression and Cox proportional hazards models were used to assess the association between liver stiffness on MRE and liver-related outcomes including a composite primary outcome defined as varices needing treatment, ascites and hepatic encephalopathy. Secondary outcomes included hepatocellular carcinoma (HCC) and death. Cumulative incidence curves evaluated time to first event for the primary outcome.

Results: Our pooled analysis included 2275 patients (54% women) with a mean age 57.5 (±15) years and mean MRE at baseline of 4.01 (±2.17) kPa. A total of 948 events occurred in 458 participants. Each 1 kPa increase in liver stiffness was associated with OR = 1.22 (95% CI:1.16–1.29, $p < 0.001$) increased odds of the primary outcomes at baseline. Among 1983 patients with a median (IQR) of 3 (4.14) years of follow up time the 1- and 3-year risk of the primary outcome was 0.6% and 1.5% for MRE <5 kPa, 7.2% and 16.6% for 5–8 kPa and 8.5% and 18.8% for MRE >8 kPa respectively (Figure). The hazard ratio (HR) for the primary outcome, HCC and death for MRE 5–8 kPa were HR = 11.9 (95% CI:7.58–18.96, $p < 0.001$), HR = 14.8 (95%CI:5.53–39.6, $p < 0.001$) and HR = 2.37 (95%CI:1.68–3.34, $p < 0.001$) respectively and for >8 kPa HR = 17.3 (95% CI:10.1–29.7, $p < 0.001$), HR = 23.3 (95%CI:7.94–68.2, $p < 0.001$) and HR = 4.84 (95%CI:3.22–7.27, $p < 0.001$) respectively, compared to <5 kPa. The MEFIB index defined as positive when MRE ≥3.3 kPa and FIB-4 ≥1.6 had a strong association with the primary outcome HR = 21.8 (95% CI:11.0–43.2, $p < 0.001$) and excellent negative predictive value for hepatic decompensation (Figure).

Conclusion: Liver stiffness assessed by MRE is associated with liver-related outcomes and death and the combination of MRE and FIB-4 has excellent negative predictive value for hepatic decompensation.

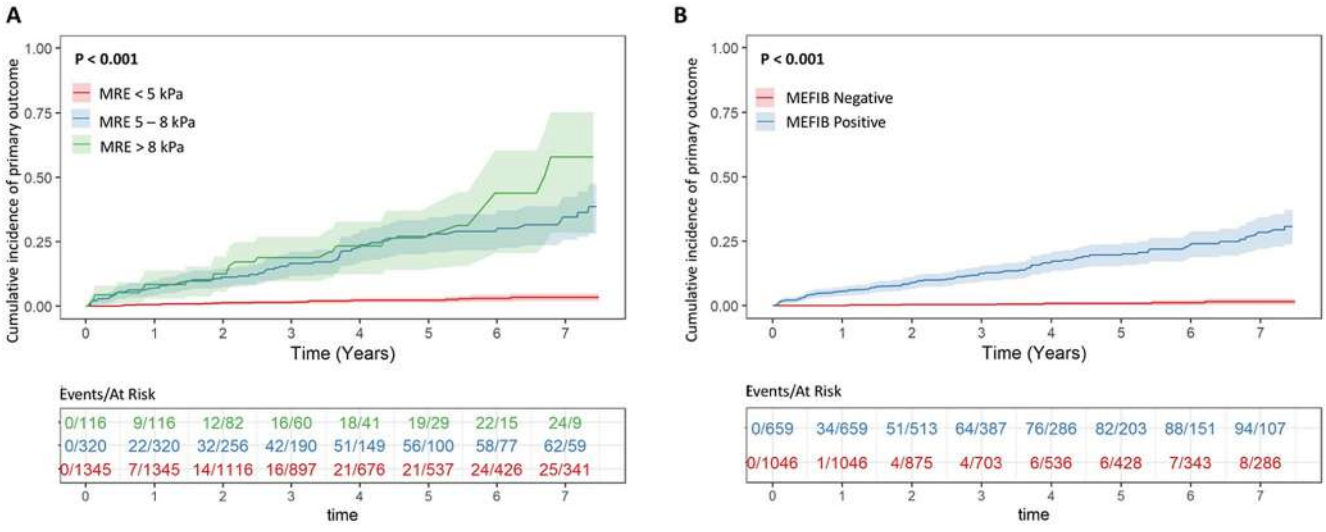


Figure: (abstract: FRI037): Cumulative incidence curves for primary outcome by (a) MRE <5 kPa vs 5–8 kPa and >8 kPa and (b) MEFIB Index.

FRI038

Utilising features of metabolic syndrome to cost-effectively improve metabolic dysfunction-associated fatty liver disease diagnosis rates

Cassandra Baiano[1], Jennifer Nobes[1], Iain Macpherson[1], Callum Livingstone[1], Madeleine Caven[1], Paul Brennan[1], Ellie Dow[2], John Dillon[1]. [1]*School of Medicine-University of Dundee, United Kingdom;* [2]*NHS Tayside, United Kingdom*
Email: cbaiano@dundee.ac.uk

Background and aims: The international consensus currently defines Metabolic Dysfunction-associated Fatty Liver Disease (MAFLD) as obesity, multiple metabolic risk factors, or type 2 diabetes mellitus plus hepatic steatosis on imaging. To facilitate the diagnosis of liver diseases, like MAFLD, in the community, an algorithm-based diagnostic tool (intelligent liver function testing, iLFT) that uses biochemical tests and clinical information has been developed. 22% of iLFT results are initially descriptive (i.e. isolated raised ALT) with no definitive aetiology but are identified as MAFLD after costly, prolonged investigations. This study aimed to identify whether features of the metabolic syndrome could be used to cost-effectively increase MAFLD diagnosis in the community while decreasing the need for imaging or liver clinic attendance.
Method: A retrospective analysis of iLFT patients from 2018 to 2020 was conducted. Medical records were used to identify BMI, features of metabolic syndrome, and steatosis on ultrasound scan (USS). Logistic regression analyses assessed which features of metabolic syndrome could predict USS steatosis. New MAFLD diagnostic pathways within iLFT were modelled with a cost-benefit analysis.
Results: 2720/6791 patients had no cause for deranged liver function tests identified by iLFT or had suspected MAFLD, of which 646 had sufficient health data for analysis.
While glucose impairment is the only statistically significant feature to predict USS steatosis across BMIs ($p < 0.000$, Sen = 41%, PPV = 88%), prediction can be optimised by stratifying patients into three BMI categories (≤26, 27–34, ≥35). In patients with BMI ≥35 (n = 114), any one feature of metabolic syndrome is a strong enough predictor of USS steatosis that MAFLD can be diagnosed and managed in the community, and USS and liver clinic can be avoided ($p < 0.003$, Sen = 85%, PPV = 91%). In BMI 27–34 (n = 275), glucose impairment is a strong enough predictor of USS steatosis that MAFLD can be diagnosed and managed in the community, and USS and liver clinic can be avoided ($p < 0.007$, Sen = 35%, PPV = 89%). In patients with a high NAFLD fibrosis score or BMI ≤26 (n = 257), both ultrasound and liver clinic are still required for assessment.
The expert liver team reviewed a sub-cohort of 144/646 patients and found that new MAFLD diagnostic pathways based on this stratification produce the correct MAFLD diagnosis or a fail-safe next step in 96% (n = 138) of cases. The new pathways offer a savings of £36.22 for every £1 spent.
Conclusion: New MAFLD diagnostic pathways that stratify patients by BMI and include features of metabolic syndrome to predict fatty infiltration on USS could cost-effectively increase MAFLD diagnosis in the community and reduce referral to USS by 26% while reducing referral to liver clinic by 24% (Sen = 100%, PPV = 98%).

FRI039

Non-invasive assessment of type VII collagen degradation is related to NAFLD activity but not fibrosis stage

Mette Juul Nielsen[1], Peder Frederiksen[1], Morten Karsdal[1], Diana Leeming[1], Jörn Schattenberg[2]. [1]*Nordic Bioscience A/S, Herlev, Denmark;* [2]*University Medical Centre of the Johannes Gutenberg-University Mainz, Mainz, Germany*
Email: mju@nordicbio.com

Background and aims: Type VII collagen is an anchoring fibril collagen crucial for the function and stability of the extracellular matrix (ECM) by linking basement membrane and interstitial matrix collagens together. Remodeling of the basement membrane is observed in early stage pericellular fibrosis, whereas accumulation

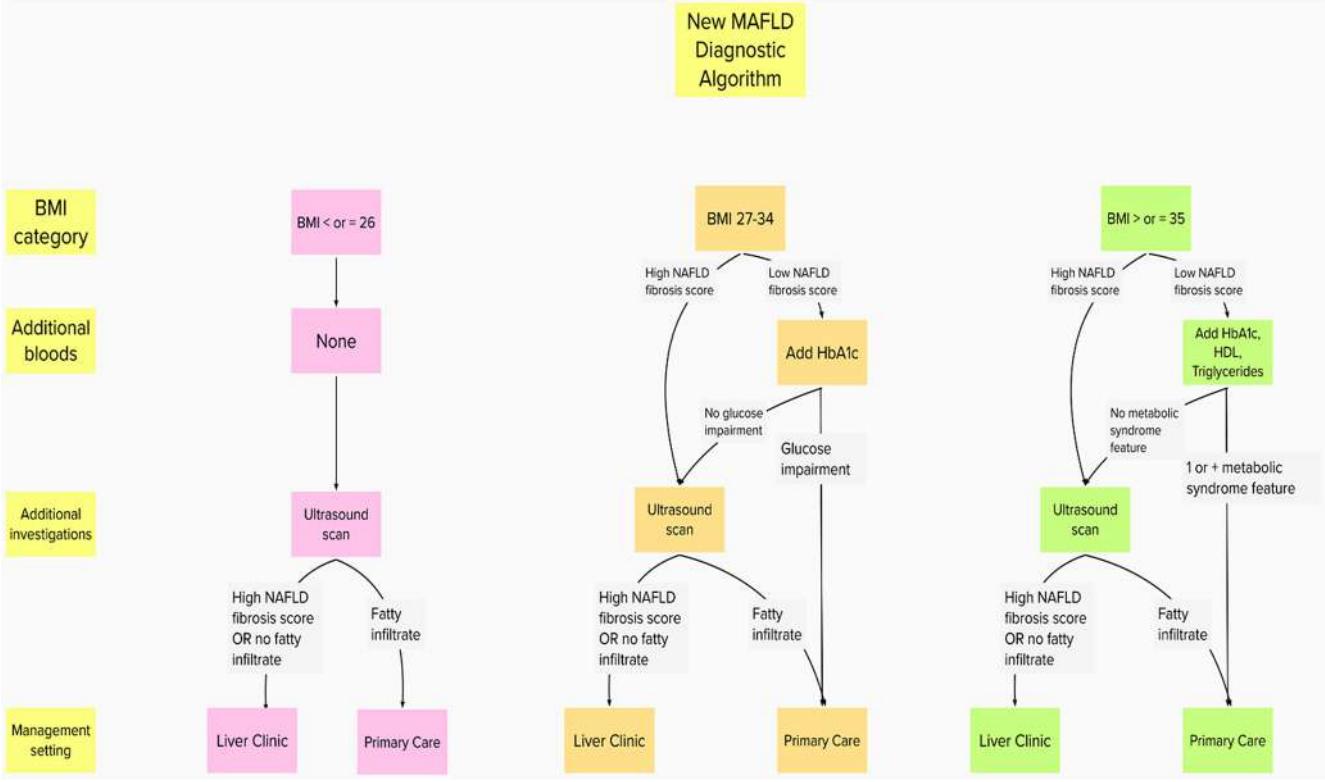

Figure: (abstract: FRI038)

of interstitial matrix collagens is observed during advanced fibrosis. The role of type VII collagen in liver fibrosis is unknown. The aim of this study was to investigate the role of type VII collagen using a collagen neoepitope technology in relation to fibrosis development in NAFLD patients.

Method: Degradation of type VII collagen was assessed by the novel neoepitope marker, C7M, developed by Nordic Bioscience A/S, in serum samples from 140 NAFLD patients with biopsy confirmed liver fibrosis F0-F4 and NAS 0–7 in a cross-sectional study design. Histopathological staging of fibrosis, steatosis, hepatocyte ballooning and lobular inflammation was scored according to the Kleiner scoring system.

Results: Patients had median age of 53.5 (IQR 43–60) years and median BMI of 32.2 kg/m^2 (IQR 29.0–36.1) of which 74 (53%) were male (p = 0.499). Serum C7M significantly correlated with the NAS (r = 0.255; p = 0.003), the grade of hepatocyte ballooning (r = 0.278; p = 0.001), and steatosis (r = 0.285; p < 0.001), but not the degree of lobular inflammation (r = 0.161; p = 0.065) or the histological fibrosis stage (r = –0.005; p = 0.962). C7M was significantly elevated in patients with NAS ≥3 compared to NAS ≤2 (p < 0.001). A 30% and 18% increase in C7M was observed from hepatocyte ballooning grade 0 to 1–2 (p = 0.001) and from steatosis grade 0–1 to 2–3 (p = 0.004), respectively. In the same cohort, the levels of the fibrogenic collagen marker, PRO-C3, was increased in the population with advanced vs early fibrosis (p < 0.0001), as well as in patients with steatosis (p = 0.0001), hepatocyte ballooning (p = 0.0001), and lobular inflammation (p < 0.0001).

Conclusion: Degradation of type VII collagen may be an early indicator of increased protease activity, related to linkage disruption of the ECM structure between basement membrane and interstitial matrix collagens in liver fibrosis development in patients with NAFLD.

FRI040

Reliability of histologic disease activity measures in non-alcoholic fatty liver disease (NAFLD) and development of an expanded NAFLD activity score

Email: roloomba@ucsd.edu

Background and aims: In clinical trials of non-alcoholic steatohepatitis (NASH), the Non-alcoholic Steatohepatitis Clinical Research Network (NASH CRN) histologic scoring system is the current gold standard histology assessment but has demonstrated intra- and inter-observer variability. An expert panel determined in a prior Research and Development/University of California Los Angeles (RAND/UCLA) process that existing histologic scoring systems do not fully capture NASH disease activity and fibrosis. We evaluated the intra- and inter-rater reliability of histologic disease activity measures and correlated these measures with a disease activity visual analogue scale (VAS) to propose an exploratory expanded non-alcoholic fatty liver disease (NAFLD) activity score (NAS) index comprising optimized items.

Method: Four liver pathologists assessed 40 liver biopsies representing the full spectrum of NAFLD. These central readers were blinded to clinical information, completed standardized training, and scored each histologic measure twice, with ≥2 weeks between each assessment. Scored measures included existing histologic indices, the component items of these indices, and additional items identified in the prior RAND/UCLA study. Reliability was assessed using intra-class correlation coefficients (ICCs).

Results: The ICCs for existing NAFLD activity indices demonstrated substantial to almost perfect intra-rater reliability (ICC, 0.80–0.85) and moderate to substantial inter-rater reliability (ICC, 0.60–0.72). Ballooning degeneration items (ICC, 0.68–0.79), including those that extended scores from 0 to 2 to 0–4, and steatosis items (ICC, 0.72–0.80) had substantial inter-rater reliability. Fibrosis measures demonstrated substantial to almost perfect inter-rater agreement (ICC, 0.70–0.87). Items for ballooning degeneration and Mallory-Denk bodies (MDBs) had large correlations with the disease activity VAS (r = 0.66–0.96) and were used to develop an expanded NAS (intra-rater ICC, 0.90; inter-rater ICC, 0.80). Steatosis items were poorly correlated with the disease activity VAS (r = –0.02 to 0.12).

Conclusion: Histologic indices, including the expanded NAS, had almost perfect intra-rater reliability and moderate to substantial inter-rater reliability. Ballooning degeneration and MDBs were used for the expanded NAS based on their strong correlations with disease activity. Future evaluation of the responsiveness of these measures is needed.

FRI041

Evaluating future risk of NAFLD fibrosis in adolescents: prediction and decision curve analysis

Kushala Abeysekera[1,2], Julian Hamilton-Shield[1], James Orr[2], Fiona Gordon[2], Laura Howe[1], Jon Heron[1], Matthew Hickman[1]. *[1]University of Bristol, United Kingdom; [2]Bristol Royal Infirmary*
Email: k.abeysekera@bristol.ac.uk

Background and aims: Elevated body mass index (BMI) is the major risk factor for nonalcoholic fatty liver disease (NAFLD) development. Using data from the Avon Longitudinal Study of Parents and Children (ALSPAC), we sought to investigate whether other variables from adolescence could improve prediction of future NAFLD fibrosis risk at 24 years, above BMI.

Method: Aged 24 years, 4018 ALSPAC participants had transient elastography (TE) using Echosens 502 Touch. 513 participants with harmful alcohol consumption were excluded. 2.7% had ≥F2 equivalent fibrosis. Logistic regression models examined which factors that were measured at age 17 were predictive of NAFLD fibrosis in young adults. Predictors included sex, BMI, central adiposity, lipid profile, blood pressure, liver function tests, homeostatic model assessment for insulin resistance (HOMA-IR), and steatosis at 17 years (based on ultrasound). A model including all these variables reflected "standard of care" (SoC). Models were compared using area under the receiver operator curve (AUROC) and Bayesian Information Criterion (BIC), analysis, which penalises model complexity. Models were tested in participants with overweight and obese standardised BMIs (BMI SDS) centiles at the 17-year time point. A decision curve analysis (DCA) was performed to evaluate the clinical utility of models at 17-years predicting NAFLD fibrosis at a threshold probability of 0.1. Datasets were imputed up to the number of available TE outcomes.
Results: In adolescents with overweight/obese BMI SDS centiles, the SoC model had the highest AUROC (AUROC 0.84 [SD 0.03]). However following BIC analysis, BMI SDS at 17 years was the best predictor of NAFLD fibrosis at 24 years. A DCA examining overweight/obese adolescent participants demonstrated the model that had greatest net benefit, above a treat all assumption, was the SoC model although the net benefit was marginal (0.0054 [IQR 0.0034–0.0075]). This was equivalent to 5 more NAFLD fibrosis cases being detected per 1000 patients.
Conclusion: SoC measurements are not superior to BMI SDS in adolescence at predicting NAFLD fibrosis development in young adulthood. Additional SoC measurements provide incremental but small benefit in detecting true positive fibrosis cases. Thus, with the agenda of reducing long term morbidity and mortality associated with fibrosis, providing targeted interventions to overweight and obese adolescents is important to prevent progression to fibrosis.

Background and aims: Non-alcoholic fatty liver disease (NAFLD) is becoming a major health problem, resulting in hepatic, metabolic and cardio-vascular morbidity. Our study aims at evaluating new ultrasonographic tools to detect and measure hepatic steatosis.
Method: After local approval and patient consent, we included 73 patients addressed to a hepatology consultation for NAFLD suspicion or follow-up. They underwent ultrasonographic measurement of liver sound speed estimation (SSE) and attenuation coefficient (AC) using Aixplorer MACH 30 (Supersonic Imagine, France), and continuous Controlled Attenuation Parameter (cCAP) using Fibroscan (Echosens, France). Hepatic steatosis was then classified according to MRI proton density fat fraction (PDFF). Receiver operating curve (ROC) analysis was performed to evaluate the diagnostic performance in the diagnosis of steatosis.
Results: Our 73 patients (35 males and 38 females) had high mean age, BMI, weight, and waist circumference, respectively 60 years, 29.4 kg/m^2, 85 kg and 104 cm. 67% had a metabolic syndrome and 15% significant liver fibrosis. According to PDFF, 18 (24.7%) patients had no steatosis (PDFF <6.5%, S0), 30 (41.1%) suffered from mild steatosis (6.5 <PDFF <16.5%, S1), 8 (10.9%) from moderate steatosis (16.5 <PDFF <22%, S2), and 17 (23.3%) from severe steatosis (PDFF >22%, S3). SSE, AC and cCAP correlate with PDFF, with respective Spearman correlation coefficient of –0.50, 0.51 and 0.65 ($p < 0.01$).

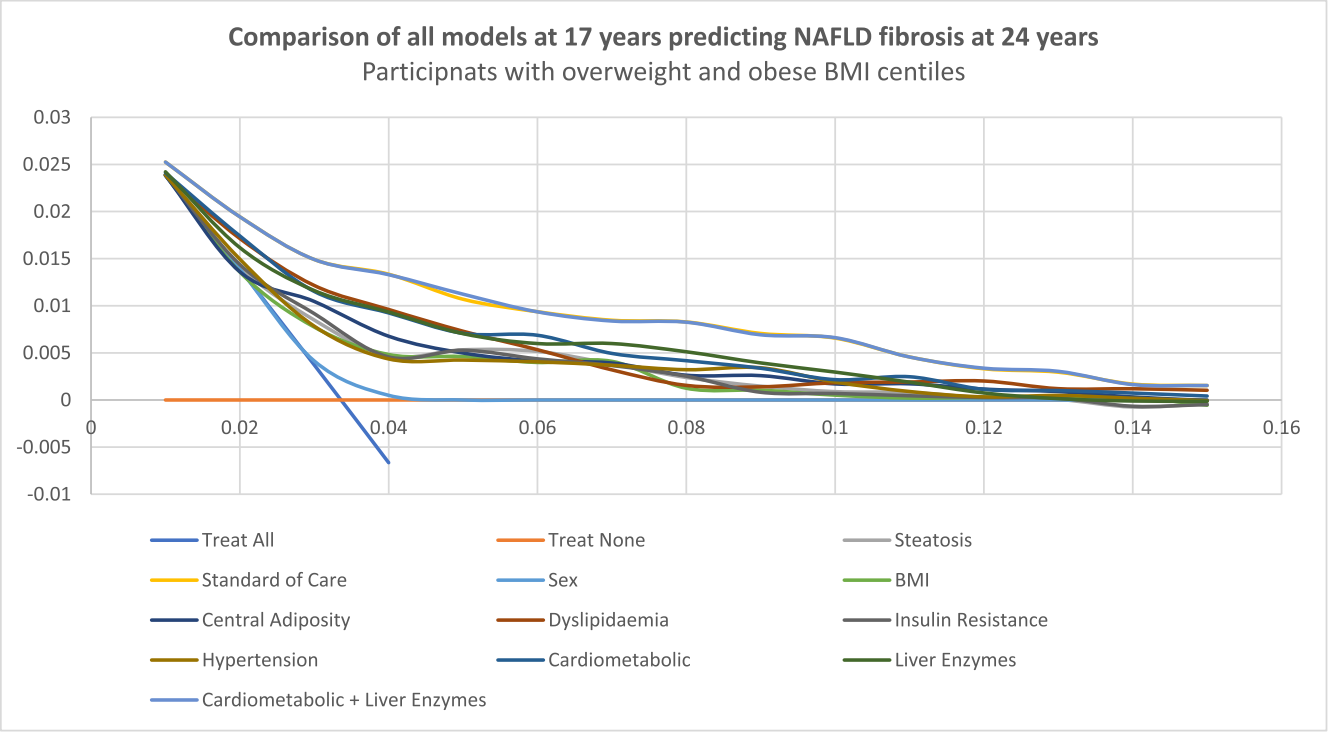

Figure: (abstract: FRI041): Decision curve analysis of different models to predict NAFLD Fibrosis at 24 years in 17 years with overweight or obese BMI centiles.

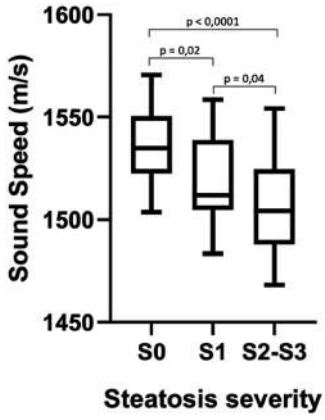
Mean SSE, AC and cCAP values significantly differ between non-steatotic and steatotic patients (S1–S3). SSE values also differs between S1 and S2–S3 steatosis ($p = 0.04$). An SSE threshold of 1524 m/s had a sensitivity of 69% and a specificity of 74% for the diagnosis of steatosis (S1–S3). The corresponding area under the ROC curve (AUC) was 0.77 (95% CI 0.66–0.88, $p < 0.01$). An AC threshold of 0.41 dB/cm/MHz had a sensitivity of 91% and a specificity of 79% for the diagnosis of steatosis (S1-S3). The corresponding AUC was 0.91 (95% CI 0.84–0.98, $p < 0.01$). An cCAP threshold of 263 dB/m had a sensitivity of 82% and a specificity of 78% for the diagnosis of steatosis (S1–S3). The corresponding AUC was 0.92 (95% CI 0.86–0.98, $p < 0.01$). The EASL-suggested threshold of 275 dB/m has a sensitivity of 75% and a specificity of 94%.



Conclusion: SSE and AC, simultaneously measured using Aixplorer MACH 30 system, demonstrate their reliability to detect liver steatosis. AC has high sensitivity for all-grade steatosis detection, with AUC >0.90, despite having more than 40% of our patients suffering from mild steatosis (S1).
To be noted that mean SSE values significantly differ between S1 and S2–S3 patients, maybe allowing for future ultrasonographic steatosis grading.
cCAP has good overall performances, but optimal thresholds are yet to be determined, and is not able to distinguish between different grades of steatosis.

FRI043

Community NAFLD screening programme in patients with type 2 diabetes mellitus indicates high burden of undiagnosed liver disease

Emma McCormick[1], Noelle Cullen[1], Suzanne Norris[1], Oonagh O'Hagan[2]. [1]*St James's Hospital, Hepatology, Dublin, Ireland;* [2]*Meaghers Pharmacy Group, Dublin, Ireland*
Email: emmamccormick@rcsi.ie

Background and aims: NAFLD is the most common liver disease in Western countries, affecting 1 in 4 adults, with prevalence mirroring that of obesity and T2DM. The presence of hepatic fibrosis is an important predictor of premature mortality and liver-related morbidity and mortality. Vibration-controlled transient elastography (VCTE) is a validated non-invasive test with NPV >90% for detection of advanced fibrosis/cirrhosis, but is largely confined to specialist centres. The lack of optimised public health screening strategies to detect liver fibrosis in adults remains a healthcare challenge.
The aim of this study was to assess the feasibility of VCTE as a screening method to detect hepatic fibrosis in patients with identified risk factors for NAFLD in a community healthcare setting.
Method: 206 patients (94 male, 112 female,) with risk factors for NAFLD were identified via dispensing records in community pharmacies and invited to register for VCTE appointment. VCTE assessments were performed in 4 community pharmacies over 14 dates between June and July 2021 and results sent to patients' GPs. Patients with liver stiffness measurements (LSM) >8.2 kPa were referred to a specialist Hepatology clinic for follow up.
Results: The median age was 63 years (range 27–84). 88% of patients had T2DM and 53% had a BMI >30. The median CAP score was 291 dB/m (range 160–400), and 45% of patients had a CAP score ≥300 dB/m. The median LSM was 5.8 kPa. 31% of patients had LSM ≥7.1 kPa, 15% had LSM ≥9.1 kPa and 6.7% had LSM ≥12.5 kPa. Only 19% of patients had both a normal CAP and LSM.
Conclusion: This is the first study to assess VCTE screening for hepatic fibrosis beyond traditional healthcare settings, and demonstrates that community-based risk-stratified screening leads to earlier identification of patients with liver fibrosis. Community pharmacy is a readily accessible healthcare setting in which access to non-invasive assessments of liver fibrosis outside of the hospital setting could be offered with potential significant cost savings to the healthcare system.

FRI044

Non-alcoholic fatty liver disease in patients with type-2 diabetes mellitus in Greenland

Rasmus Hvidbjerg Gantzel[1,2], Abdullah Ghassan Farik Muhammad[1,3], Frederik Orm Hansen[1,3], Karsten Fleischer Rex[3], Gerda Elisabeth Villadsen[1], Henning Grønbæk[1,2], Michael Lynge Pedersen[3,4]. [1]*Aarhus University Hospital, Department of Hepatology and Gastroenterology, Århus N, Denmark;* [2]*Aarhus University, Department of Clinical Medicine, Århus N, Denmark;* [3]*Steno Diabetes Center Greenland, Nuuk, Greenland;* [4]*Institute of Nursing and Health Science, Greenland Center for Health Research, Nuuk, Greenland*
Email: ragant@rm.dk

Background and aims: Non-alcoholic fatty liver disease (NAFLD) is the liver manifestation of the metabolic syndrome with a close relation to type-2 diabetes mellitus (T2DM). The prevalence of T2DM is increasing in the Greenlandic population. However, due to genetic variants, diabetic complications may occur less frequently in Greenlanders than non-Greenlanders. We aimed to characterize the prevalence and severity of NAFLD in patients with T2DM in Greenland.
Method: We included 1619 patients with T2DM living in Greenland in a register-based cross-sectional study. 1436 patients were born in Greenland and 183 were born in Denmark. In the absence of histopathology and radiological data, we used alanine aminotransferase (ALAT) as surrogate marker of steatosis and estimated the degree of liver fibrosis with the FIB-4 score. Linear regression analyses were performed to assess associations between steatosis and the severity of the metabolic syndrome. A diagnosis of metabolic syndrome required ≥3 of the criteria: T2DM, BMI >30 kg/m^2, triglycerides >1.7 mmol/l or antilipidemic treatment, HDL <1.0/1.3 mmol/l for men/women or antilipidemic treatment, and systolic/diastolic blood pressure >130/85 mmHg or antihypertensive treatment.
Results: Despite higher BMI and plasma lipid levels, Greenlanders had a better glycemic control with lower HbA1c and a lower proportion on anti-diabetic treatments compared with Danes. The median ALAT was similar, though ALAT was elevated in a larger proportion of Greenlanders (21%) compared with Danes (11%). The median ALAT was statistically significantly higher in Greenlanders with metabolic syndrome compared with Greenlanders without metabolic syndrome (51 vs. 39 U/L, $p < 0.001$). Further, ALAT increased with 8.0% (95% CI: 5.2–10.9, $p < 0.001$) for each metabolic syndrome criteria fulfilled. The Danes had a higher FIB-4 score than Greenlanders (median 0.97 vs. 0.91, $p = 0.048$). 84% of Greenlanders and 80% of Danes had a FIB-4 score <1.45 with a very low risk of significant fibrosis, while 13% of Greenlanders and 18% of Danes had a FIB-4 score of 1.45–2.67 with an intermediate risk of fibrosis. Only 2% in both ethnic groups had a FIB-4 score >2.67 suggesting advanced fibrosis.

Conclusion: ALAT elevations are more frequent in Greenlanders than in Danes with T2DM, and ALAT increases with 8.0% for each metabolic syndrome criteria fulfilled. Accordingly, ALAT may be a useful and easily accessible tool to monitor NAFLD in patients with T2DM in Greenland. The median FIB-4 score is lower in Greenlanders compared with Danes, suggesting a lower degree of liver fibrosis. These findings need further evaluations preferably including comparisons with histopathology.

FRI045

A baseline signature of metabolites involving the gut-liver axis predicts MRI-PDFF response to FASN inhibitor TVB-2640: results from the FASCINATE-1 study

Rohit Loomba[1], Marie O'Farrell[2], Eduardo Martins[2], Katharine Grimmer[2], Alithea Zetter[2], Cristina Alonso[3], Ibon Martínez-Arranz[3], George Kemble[2], Stephen Harrison[4]. *[1]UC San Diego School of Medicine, Dept of Gastroenterology, La Jolla; [2]Sagimet Biosciences, San Mateo, United States; [3]OWL Metabolomics, Derio, Spain; [4]Pinnacle Clinical Research, San Antonio, United States*
Email: roloomba@ucsd.edu

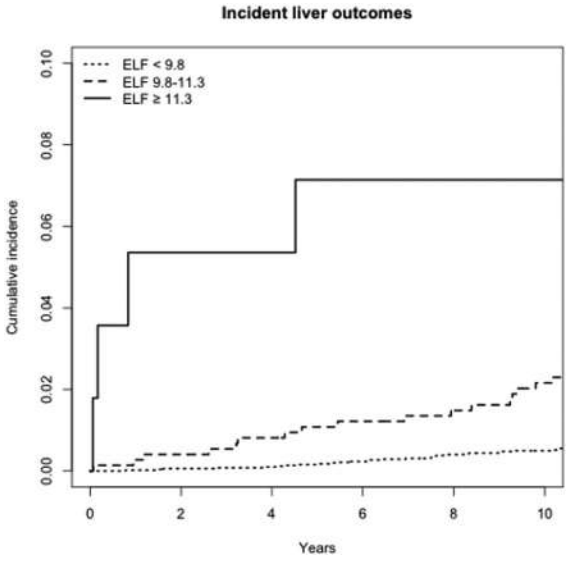
Background and aims: TVB-2640 is a potent FASN inhibitor in Ph2b development for NASH. FASN is an attractive target because de novo lipogenesis drives steatosis, causes lipotoxicity, and is necessary for fibrogenesis. A 12 wk Ph2a study FASCINATE-1 was completed and met its primary endpoint. TVB-2640 reduced liver fat by 28.1% (p = 0.001) at 50 mg with a 61% MRI-PDFF response rate (decrease >30%, p = 0.001), and decreased biomarkers including ALT, PRO-C3, PIIINP, CK-18 and lipotoxins. NASH clinical studies are often confounded by high pbo but relatively low drug response rates. The objective of this work was to identify predictive biomarkers of MRI-PDFF response using metabolomic and SNP profiling of baseline blood samples from patients in FASCINATE-1.
Method: Metabolomic plasma profiling of ~460 species was performed on the OWL platform for pbo, 25 mg, 50 mg. Two machine learning approaches, Random Forest (RF) and Support Vector Machine were applied to baseline data. Using% change in MRI-PDFF as a continuous variable, a signature was developed using 50% of samples and tested using the other 50% with extensive cross-validation for sample size. Genotyping of SNPs relevant to NAFLD was completed for 19 patients to date (6 pbo, 13 on 50 mg, 79% Hispanic). Correlative analysis included metabolomics, genomics and other NASH biomarkers.
Results: A 6-metabolite signature was identified that enriches for MRI-PDFF response to TVB-2640. This showed 79% accuracy, 88% positive predictive value and 63% negative predictive value by the RF method. The components are ursodeoxycholic acid, glycoursodeoxycholic acid, DL-2-Aminocaprylic acid, Sarcosine, D (-)-2-Aminobutyric acid and phosphatidyl choline (O-18:0/22:4). The composition of several bile acid derivatives suggests a role for the gut liver axis in TVB-2640 response. Overall, secondary bile acids increased after 12 wk of TVB-2640 across several classes and 9/10 species tested although not statistically significant. Analysis of pbo and independent validation is ongoing to refine this signature.
SNP analysis showed allele variants in PNPLA3 rs738409, TMF6SF2 rs58542926 and MBOAT7 rs641738 in 68%, 16% and 53% of patients respectively, consistent with literature. MRI-PDFF responders included patients with wild type, hetero- or homozygous PNPLA3 rs738409. The effect of PNPLA3 genotype on baseline metabolomic profile will be assessed. Additional predictive signatures are under development using a combination of metabolomics and genomic profiling.
Conclusion: TVB-2640 decreased liver fat and markers of inflammation, lipotoxicity and fibrosis. Plasma metabolomics identified a baseline predictive signature of MRI-PDFF response to FASN inhibition, which indicates a role for the gut-liver axis. The Ph2b FASCINATE-2 study will incorporate microbiome analysis and the signature will be retrospectively tested and extended to histology analysis.

FRI046

Enchanced Liver Fibrosis test in predicting severe liver-related outcomes in the general population

Kustaa Saarinen[1,2], Martti Färkkilä[1,2], Antti Jula[3], Iris Erlund[3], Terhi Vihervaara[3], Annamari Lundqvist[3], Fredrik Åberg[4]. *[1]Helsinki University Hospital, Abdominal Center, Helsinki, Finland; [2]University of Helsinki, Helsinki, Finland; [3]Finnish Institute for Health and Welfare, Helsinki, Finland; [4]Helsinki University Hospital, Transplantation and Liver Surgery Clinic, Finland*
Email: kustaasaarinen@gmail.com

Background and aims: Liver fibrosis is the most important prognostic factor for liver-related morbidity and mortality in liver diseases in population including non-alcoholic fatty liver disease and alcohol-related liver disease. Existing methods for liver fibrosis assessment are either not suitable or show suboptimal performance for fibrosis screening in unselected populations. The Enhanced Liver Fibrosis (ELF) test, a composite score based on three serum-based markers of matrix turnover tissue inhibitor metalloproteinase 1 (TIMP-1), human procollagen type III amino terminal propeptide (PIIINP) and hyaluronic acid (HA) can detect advanced fibrosis and predict liver-related outcomes in various types of chronic liver diseases, but studies in large general population cohorts are lacking. We evaluated the performance of the ELF test in predicting liver related outcomes at the population level.
Method: ELF was measured at baseline from frozen serum samples of adult (age >30 years) participants of the Finnish Health 2000 study, a population-based epidemiological survey conducted in year 2000–2001. Subjects with baseline liver disease were excluded. Data were linked with national healthcare registers for hospitalization, cancer and death related to severe liver disease.
Results: The cohort comprised 6040 individuals (46% men, mean age 52.7 ± 15 years, BMI 26.9 kg/m^2, median alcohol use 74.9 g/week, 10% with diabetes). ELF was <9.8 in 5243 (87%), 9.8–11.3 in 741 (12%), and ≥11.3 in 56 (0, 9%). During a median follow-up of 13.1 years, 67 severe liver-related outcomes occurred. By age- and sex-adjusted Cox regression, hazards ratios (HRs) for liver outcomes were 6.44 (95%CI 3.37–12.29) with ELF 9.8–11.3, and 24.37 (95% CI 8.55–69.50) with ELF ≥11.3, compared to ELF <9.8. Corresponding cumulative Aalen-Johansen incidences are shown in the figure. The C-statistic of ELF for predicting liver outcomes was 0.82 (95% CI 0.72–0.91) at 5 years and 0.73 (0.65–0.81) at 10 years.



Conclusion: The ELF test predicts severe liver-related outcomes in the general population. The ELF test could thus be used for initial stratification of the population regarding risk for future liver disease.

FRI047

Radiowater perfusion PET of the liver, and its value as a biomarker to discriminate between NAFLD and NASH, and activity and fibrosis grade

Olof Eriksson[1], Kerstin Heurling[1], Paul Hockings[1], Edvin Johansson[1], Alkwin Wanders[2], Håkan Ahlström[1], Lars Johansson[1], Johan Vessby[3], Fredrik Rorsman[3], Mark Lubberink[4]. *[1]Antaros Medical AB, Sweden; [2]Aalborg University Hospital, Aalborg, Denmark; [3]Uppsala University Hospital, Sweden; [4]Uppsala University Hospital, Uppsala, Sweden*
Email: olof.eriksson@ilk.uu.se

Background and aims: The lack of non-invasive, biopsy free and repeatable assessments for fibrosis and activity stage in NAFL and NASH is a significant hurdle in respect to clinical diagnosis and evaluation of novel interventions. Radiowater PET has been shown to be a sensitive technique to quantify blood flow and identify perfusion defects in e.g. cardiology and neurology. We hypothesized that pathological changes in liver perfusion and arterial and portal blood flow could be detected by radiowater PET. The aim of this clinical study was to assess the value of radiowater PET for distinguishing between NAFL and NASH, as well as predicting activity and fibrosis grade in direct comparison with established biomarkers.
Method: A subset of patients with suspected NAFL/NASH (N = 30) recruited within the NASH AM-02 study was examined by radiowater PET/MRI, as well as transient elastography (FibroScan), in addition to sampling for established biomarkers of liver fibrosis. NAFL/NASH diagnosis as well as activity and fibrosis grade were verified by hepatic biopsy. Dynamic radiowater PET data of the liver was used to assess total hepatic blood flow, portal vein flow, hepatic arterial flow and portal flow fraction. The ROC AUC, the Youden cut-off and sensitivity/specificity were calculated for discrimination between (a) NAFL vs NASH, (b) activity grade 0–1 vs 2–4 and (c) fibrosis grade 0–1 vs 2–4. The correlation between parameters and activity grade 0–4 and fibrosis grade 0–4 was estimated by Spearmańs correlation coefficient.
Results: In total 30 patients were examined in this sub-study and diagnosed with NAFL (n = 11) or NASH (n = 19), fibrosis grade 0–1 (n = 17) or 2–4 (n = 13) and activity grade 0–1 (n = 11) or 2–4 (n = 19). The ROC UAS as well as the Spearmańs correlation coefficient for each parameter is reported in Table 1.
Conclusion: Radiowater PET has similar value as biomarker for distinguishing between NAFL/NASH and identifying activity grade, but not fibrosis grade, as transient elastography and established plasma markers.

FRI048

The combination of the ELF and FIB-4 scores have high predictive performance for significant fibrosis in patients with NAFLD

Zobair Younossi[1,2], Sean Felix[2], Thomas Jeffers[2], Elena Younossi[2], Fatema Nader[3], Andrei Racila[1,2], Brian Lam[2], Maria Stepanova[3]. *[1]Inova Health System, Medicine Service Line, Falls Church, United States; [2]Betty and Guy Beatty Center for Integrated Research, IHS, Falls Church, United States; [3]Center for Outcomes Research in Liver Disease, Washington DC, United States*
Email: zobair.younossi@inova.org

Background and aims: Patients with nonalcoholic fatty liver disease (NAFLD) and fibrosis of stage 2 or greater (clinically significant fibrosis) are at risk for adverse outcomes, and are commonly considered to be candidates for clinical trials. Although non-invasive tests (NITs) for fibrosis have good negative predictive value (NPV), they tend to have suboptimal positive predictive value (PPV) for determining significant fibrosis. Our aim was to use a combination of two NITs to rule in and to rule out significant fibrosis among patients with NAFLD.
Method: Data were collected from patients with confirmed NAFLD diagnosis. Serum and liver biopsies were obtained for all patients. The Enhanced Liver Fibrosis (ELF) and FIB-4 NITs were calculated. Liver biopsies were read by a single hepatologist and scored according to the NASH CRN criteria, from stage 0 (no fibrosis) to 4 (cirrhosis). Significant fibrosis stage was defined as stage F2–F4.
Results: There were 463 NAFLD patients included: 48 ± 13 years old, 31% male, 35% type 2 diabetes. Of included patients, 39% had significant fibrosis; mean ELF score was 9.0 ± 1.2, mean FIB-4 score was 1.22 ± 1.05. Patients with significant fibrosis were older, more commonly male, had lower BMI but more components of metabolic syndrome (type 2 diabetes, hypertension, hyperlipidemia), higher ELF and FIB-4 scores ($p < 0.0001$). The performance of the two NITs in identifying NAFLD patients with significant fibrosis was as follows: AUC (95% CI) = 0.78 (0.74–0.82) for ELF, 0.79 (0.75–0.83) for FIB-4. A combination of ELF score ≥9.8 and FIB-4 ≥1.96 returned PPV of 95% which can reliably rule in significant fibrosis (sensitivity 22%, specificity >99%), while an ELF score ≥7.7 and FIB-4 ≥0.30 had NPV of 95% which can be used to rule out significant fibrosis (sensitivity 98%, specificity 22%); based on the latter, a rule to rule out significant fibrosis could be rewritten as follows: ELF <7.7 or FIB-4 <0.30.
Conclusion: The combination of ELF and FIB-4 can provide an easy algorithm with both high NPV and high PPV to rule out or rule in significant fibrosis in NAFLD. These data can be used to risk-stratify NAFLD patients in clinical practice as well as identify those who could be candidates for clinical trials.

Association of the biological age and the level of global deoxyribonucleic acid methylation with metabolic parameters in patients with non-alcoholic fatty liver disease

Olena Kolesnikova[1], Anastasiia Radchenko[1], Valentina Galchinskaya[2]. [1]*L.T. Mala Therapy National Institute of the National Academy of Medical Sciences of Ukraine, Department of Study of Aging Processes and Prevention of Metabolic-Associated Diseases, Kharkiv, Ukraine;* [2]*L.T. Mala Therapy National Institute of the National Academy of Medical Sciences of Ukraine, Laboratory of Immuno-Biochemical and Molecular-Genetics Researches, Kharkiv, Ukraine*
Email: anastasha.radchenko@gmail.com

Background and aims: Changes in the metabolic phenotype occur with age in patients with non-alcoholic fatty liver disease (NAFLD), however, the time of their occurrence and the connection with the processes and markers of aging remain not fully understood. Our aim was to establish the relationship between biological age (BA) and the global methylation level (GML) with metabolic parameters in patients with NAFLD.
Method: Our study included 106 patients with NAFLD with a mean age of 51.4 ± 8.9 years (62.3% women). All patients were divided into groups according to age: group 1-young patients (<45 years), group 2-middle-aged (45–59 years), group 3-the elderly (>60 years). The diagnosis of NAFLD was based on the fatty liver index and fibrosis-4 index. Anthropometric and biochemical parameters were determined in all patients. The GML that is the content of 5-methylcytosine in the DNA of mononuclear blood cells was detected with ELISA as a marker of aging. BA was calculated according to the method of A.G. Gorelkin, B. B. Pinkhasov.
Results: Analysis of anthropometric, lipid profile and liver parameters in patients with NAFLD depending on age revealed significant differences in the level of triglycerides (TG) (p = 0.043), BA (p = 0.002) between groups 1 and 2, and in BA (p = 0.002) between groups 1 and 3. There was a significantly higher proportion of young patients with an increased percentage of body fat (FAT) (χ^2 = 4.011; p = 0.045) compared to middle-aged patients. Correlation analysis in group 1 showed a positive association between calendar age (CA) and visceral fat (VIS) (p = 0.023) and negative one between CA and alkaline phosphatase (AP) (p = 0.017), BA was associated with VIS (p = 0.016), and the GML-with ALT (p = 0.036). In group 2 there was no relationship between CA and the observed parameters, while BA was positively associated with FAT (p = 0.012), VIS (p = 0.002), aspartate aminotransferase (AST) (p = 0.045), TG (p = 0.019), very low-density lipoprotein cholesterol (VLDL-C) (p = 0.019) and had a negative relationship with the percentage of skeletal muscle (MUS) (p = 0.021) and AP (p = 0.042). The GML in this group was associated with body mass index (BMI) (p = 0.040), TG (p = 0.002), VLDL-C (p = 0.003). In group 3, CA had a direct association with VIS (p = 0.021) and a reverse one with total cholesterol (TC) (p = 0.005), BA was not associated with indicators that were not used for calculation, the GML was directly related to hip circumference (HC) (p = 0.035) and AP level (p = 0.011).
Conclusion: BA has been associated with anthropometric, lipid and liver parameters in middle-aged patients with NAFLD. The GML has been related to the levels of HC, BMI, TG, VLDL-C, ALT, AP, mainly in middle-aged patients with NAFLD, which may be associated with more pronounced changes in the metabolic profiles of this age group. The data obtained can be useful for the prevention of accelerated aging rates in patients with NAFLD.

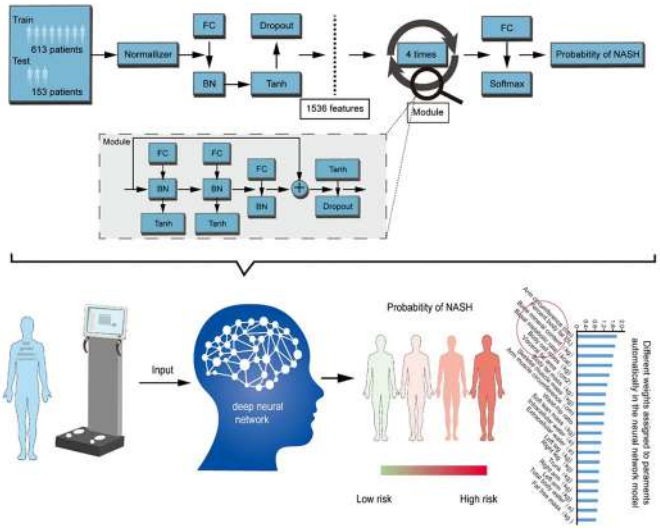
Email: zhengmh@wmu.edu.cn

Background and aims: There is an unmet need for accurate non-invasive methods to diagnose non-alcoholic steatohepatitis (NASH). Since impedance-based measurements of body composition are simple, repeatable and have a strong association with non-alcoholic fatty liver disease (NAFLD) severity, we aimed to develop a novel and fully automatic machine learning algorithm, consisting of a deep neural network based on impedance-based measurements of body composition to identify NASH (the LEARN algorithm, bioeLectrical impEdance Analysis foR Nash).
Method: 1, 259 consecutive subjects with suspected NAFLD aged 12–75 years were screened from six medical centers across China from 2016 to 2021. 766 patients with biopsy-proven NAFLD were included in the final analysis. Patients were randomly divided into the training and validation groups, in a ratio of 4:1. The LEARN algorithm (utilizing impedance-based measurements of body composition along with age, sex, history of hypertension and diabetes) was developed in the training group to identify NASH, and subsequently, tested in the validation group.
Results: The LEARN algorithm showed good discriminatory ability for identifying NASH in both the training and validation groups (AUROC: 0.81, 95%CI 0.77–0.84 and 0.80, 0.73–0.87, respectively). This algorithm performed better than serum cytokeratin-18 neoepitope M30 level or other non-invasive NASH scores (including HAIR, ION, NICE) for identifying NASH (p-value <0.001). Additionally, even in a condition of partial missing the data of body composition, LEARN algorithm performed well in identifying NASH (AUROC: 0.82, 95%CI 0.72–0.92). Subgroup analysis showed that the LEARN algorithm performed well in different subgroups.



Conclusion: The LEARN algorithm, utilizing simple easily obtained measures, provides a fully automated, simple, non-invasive method for identifying NASH.
Keywords: NAFLD, NASH, LEARN algorithm, body composition.

FRI051
Head to head comparison between MEFIB versus MAST for identification of high-risk patients with NAFLD
Beom Kyung Kim[1,2], Nobuharu Tamaki[1,3], Jinho Jung[1], Nancy Sutter[1], Claude Sirlin[1], Atsushi Nakajima[4], Rohit Loomba[1]. *[1]University of California San Diego; [2]Yonsei University College of Medicine; [3]Musashino Red Cross Hospital; [4]Yokohama City University Graduate School of Medicine*
Email: roloomba@ucsd.edu

Background and aims: Nonalcoholic fatty liver disease (NAFLD) patients with ≥stage 2 fibrosis are at an increased risk for developing liver-related morbidity and mortality. We performed a head-to-head comparison to evaluate the diagnostic test accuracy and predictive performance of MAST (magnetic resonance imaging-aspartate aminotransferase) versus MEFIB (the combination of magnetic resonance elastography [MRE] and FIB-4).
Method: NAFLD patients with a liver biopsy and MRE were analyzed from two prospective cohorts, the University of California San Diego (n = 414) and Yokohama City University (n = 314). Diagnostic performances for significant fibrosis (stage ≥2) were assessed using area under receiver operating characteristic curves (AUROCs).
Results: The mean age was 55.3 years and 48.1% were male. Significant fibrosis was observed in 46.4%. MEFIB was superior than MAST with AUROCs of categorized MEFIB (rule-in, intermediate, and rule-out) and MAST (>0.242, 0.165~0.242, and <0.165) being 0.889 (95% confidence interval [CI] 0.864~0.914) and 0.769 (95% CI 0.733~0.805), respectively (p < 0.001). Positive predictive value for significant fibrosis of MEFIB rule-in criteria was significantly higher, compared to MAST >0.242 (94.2% versus 88.2%, respectively; p = 0.031). Negative predictive value for significant fibrosis of MEFIB rule-out criteria was also significantly higher, compared to MAST <0.165 (89.8% versus 73.3%, respectively; p < 0.001). When MAST was analyzed as a continuous variable, its AUROC improved to 0.890 (95% CI 0.866~0.914).
Conclusion: For the identification of high-risk patients with NAFLD, MEFIB is significantly superior to categorized MAST. As continuous MAST score had high AUROC, the optimal cutoffs should be modified. Conversely, MEFIB, as a simple and easy algorithm, has practical advantages with a more reliable diagnostic performance as well as a better rule-in/-out ability.

Key words: NAFLD, significant fibrosis, MEFIB, FAST, MAST, diagnosis, validation

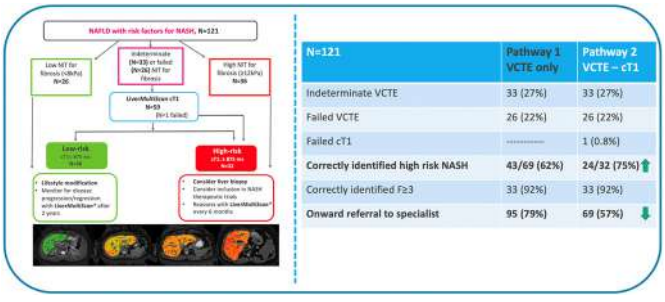
MRI assessment (cT1) with LiverMultiScan following VCTE improves the diagnostic yield for high-risk NASH
Naim Alkhouri[1], Andrea Dennis[2], Atsushi Nakajima[3], Stephen Harrison[4], David J. Breen[5], Daniel Cuthbertson[6], Mazen Noureddin[7]. *[1]Arizona Liver Health, Chandler, United States; [2]Perspectum, United Kingdom; [3]Department of Gastroenterology and Hepatology, Yokohama City University School of Medicine, Japan; [4]Division of Cardiovascular Medicine, Department of Medicine, University of Oxford, Oxford, United Kingdom; [5]University of Southampton, United Kingdom; [6]Institute of Ageing & Chronic Disease, Faculty of Health & Life Sciences, University of Liverpool, United Kingdom; [7]Karsh Division of Gastroenterology and Hepatology, Comprehensive Transplant Center, Cedars Sinai Medical Center, Los Angeles, CA, USA, United States*
Email: andrea.dennis@perspectum.com

Background and aims: In the diagnostic pathway for NAFLD, EASL recommends the use of non-invasive tests (NITs) for assessing fibrosis. However, NASH, independently of fibrosis stage, is also associated with poor outcomes and thus high costs of care. Accordingly, recent EASL and NICE guidance recommend diagnosis and management of this patient group. As an MRI-derived measure, cT1 is an excellent biomarker to diagnose NASH, shown to predict clinical outcomes, and has become a leading NIT for stratifying patients based on high-disease risk. We compared a clinical pathway using cT1 for stratifying high-risk NASH to the current recommendation using NITs for advanced fibrosis only, to explore diagnostic accuracy and appropriate further referral to specialist care.
Method: We studied NAFLD patients who had undergone NITs; liver stiffness (kPa) from vibration controlled transient elastography (VCTE, FibroScan®), and MRI-derived cT1 (ms) with Liver*MultiScan*®. All had liver fat ≥5% (Liver*MultiScan*® PDFF) and had histologically confirmed NAFLD with liver biopsy. We compared two diagnostic approaches: (1) Utilising VCTE results only, to exclude low risk individuals and identify those with advanced fibrosis suitable for onward referral; (2) VCTE followed by cT1 (for NASH risk stratification). We assessed the number of failed and indeterminate results,% positive predictor value (PPV) for high-risk NASH cases correctly identified, and number referred onto specialist care. Correct identification of fibrosis was based on F≥3; "high-risk NASH" was NAS≥4 and F≥2; established (EASL guidelines) VCTE thresholds were <8 kPa rule out and ≥12 kPa rule in; cT1 threshold was ≥875 ms.
Results: Using data from N = 121 patients (60 yrs., 40% female, 59% BMI ≥27 kg/m^2). The second pathway (VCTE followed by cT1) increased the PPV for high-risk NASH from 62% (43/69 with VCTE≥8 kPa) to 75% (24/32 with cT1 ≥875 ms) and reduced subsequent referrals from 95 to 69 individuals. This was driven by better stratification of failed or indeterminate cases, and greater specificity for the identification of those with high-risk NASH by incorporating cT1 (Figure 1).



N=121	Pathway 1 VCTE only	Pathway 2 VCTE – cT1
Indeterminate VCTE	33 (27%)	33 (27%)
Failed VCTE	26 (22%)	26 (22%)
Failed cT1	----------	1 (0.8%)
Correctly identified high risk NASH	43/69 (62%)	24/32 (75%) ↑
Correctly identified F≥3	33 (92%)	33 (92%)
Onward referral to specialist	95 (79%)	69 (57%) ↓

Conclusion: Investigating suspected advanced fibrosis using positive NIT results, with combined TE and MRI assessment of cT1 increased the diagnostic accuracy of high-risk NASH by 21% and reduced liver biopsy by 28%. Screening tests based on NITs for fibrosis alone are inadequate for risk stratification and diagnosis of NASH. Inclusion of MRI-assessed cT1 in NAFLD/NASH clinical diagnostic pathways improves diagnostic accuracy and reduces the need for biopsy and for specialist referral, which would result in downstream cost savings.

FRI053

The PNPLA3 (rs738409) G/G-genotype is associated with presence of NASH and increased long-term risk of cirrhosis in NAFLD

Magnus Holmer[1], Robin Zenlander[1], Axel Wester[1], Mattias Ekstedt[2], Patrik Nasr[2], Stergios Kechagias[2], Stefano Romeo[3], Per Stal[1], Hannes Hagström[1]. [1]*Karolinska Institutet, Department of Medicine, Huddinge, Stockholm, Sweden;* [2]*Linköping University, Division of Diagnostics and Specialist Medicine, Department of Health, Medicine and Caring Sciences, Linköping, Sweden;* [3]*University of Gothenburg, Department of Clinical and Molecular Medicine, Gothenburg, Sweden*
Email: magnus.holmer@ki.se

Background and aims: Mutations in several genes are linked to a worse histopathological profile in patients with nonalcoholic fatty liver disease (NAFLD). It is unclear if these genotypes impact long-term outcomes. Here, we investigated the prognostic importance of PNPLA3, TM6SF2, MBOAT7 and GCKR genotypes on the development of cirrhosis, liver related events (LRE) and all-cause mortality in a well-defined cohort of patients with NAFLD.
Method: DNA samples were collected from 546 patients with NAFLD. Presence of advanced fibrosis was established through liver biopsy (stage 3–4) or elastography (≥15 kPa), while presence of nonalcoholic steatohepatitis (NASH) was defined only by histology. A total of 5396 controls matched by age, sex and municipality were identified from the Swedish population. Outcome of cirrhosis, LRE and overall mortality were collected from national registries. Cox regression models were used to estimate adjusted hazard ratios (aHR) for these outcomes.
Results: In patients with NAFLD, the G/G genotype of PNPLA3 (*rs738409*) was associated with a higher prevalence of NASH at the time of biopsy (OR 3.67 [95% CI = 1.66–8.08]), but not with advanced fibrosis (OR 1.81 [95% CI = 0.79–4.14]). In NAFLD subjects without advanced fibrosis at baseline, the G/G genotype was associated with a higher risk of developing cirrhosis and LRE (aHR 2.41 [95% CI = 1.02–5.71], Figure 1) after adjustments for age, sex, body mass index and type 2 diabetes during a median follow-up of 18.1 years. However, no increased risk was found for patients with advanced fibrosis at baseline (aHR 0.67, [95% CI = 0.13–3.43]). Compared to controls, NAFLD cases had a higher rate of developing cirrhosis and the increased risk correlated to PNPLA3 and GCKR genotypes. Mortality was not affected by any genetic variant.

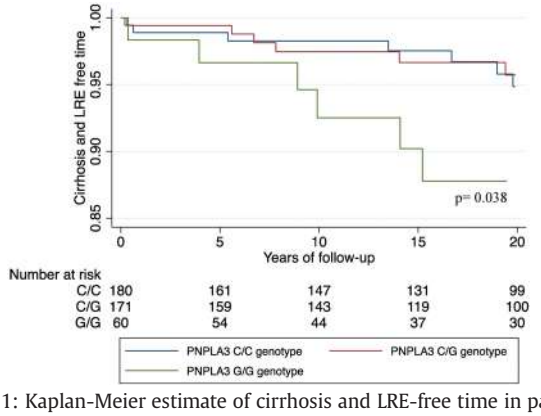


Figure 1: Kaplan-Meier estimate of cirrhosis and LRE-free time in patients with NAFLD without advanced fibrosis at baseline. LRE = Liver related events.

Conclusion: The G/G genotype in PNPLA3 is associated with an increased risk of progression to cirrhosis in NAFLD. This was confined to patients without advanced fibrosis at baseline. Our results suggest that assessment of PNPLA3 genotype can be of clinical relevance in non-cirrhotic patients with NAFLD to individualize monitoring and therapeutic strategies.

FRI054

Hepatic expression of secreted calcium-binding protein 2 by hepatic stellate cells is associated with human non-alcoholic fatty liver disease progression

Frederik Larsen[1], Mike Terkelsen[1], Sofie Bendixen[1], Daniel Hansen[1], Charlotte Wernberg[2], Mette Lauridsen[2], Tina Di Caterino[3], Fabio Avolio[1], Majken Siersbæk[1], Vineesh Indira Chandran[1], Jonas Graversen[1], Aleksander Krag[1,3], Lars Groentved[1], Kim Ravnskjaer[1]. [1]*University of Southern Denmark, Odense, Denmark;* [2]*Sydvestjysk Sygehus, Esbjerg, Denmark;* [3]*Odense University Hospital, Odense, Denmark*
Email: tibert@bmb.sdu.dk

Background and aims: Non-alcoholic fatty liver disease (NAFLD) and its progressive form, non-alcoholic steatohepatitis (NASH), is the hepatic manifestation of obesity-induced metabolic syndrome. Activated Hepatic stellate cells (aHSCs) play a pivotal role in hepatic fibrosis, a defining process of NAFLD pathogenesis. Thus, secreted aHSC-specific proteins may hold promise as non-invasive biomarkers for diagnosis of NASH. Histological assessment of liver biopsies is the golden standard in diagnosis of NASH. Liver biopsy, however, is associated with risk for the patient and does not fully capture the tissue heterogeneity of the fibrotic liver.
Method: RNA sequencing was performed on liver needle biopsies from a histopathological characterized severely obese (BMI >35) discovery cohort (n = 30). Bioinformatical analysis was used to identify potential biomarkers and their hepatocellular origin. Detection of mRNA in liver tissue and protein levels in plasma was performed using single molecule fluorescence *in situ* hybridization (smFISH) and ELISA, respectively.
Results: Hepatic expression of secreted modular calcium-binding protein 2 (*SMOC2*) was upregulated in NASH patients compared to healthy obese patients (padj <0.001). Single-cell RNA sequencing data indicated hepatic *SMOC2* expression by quiescent and aHSCs exclusively, which was validated using smFISH. Moreover, plasma [SMOC2] was elevated in NASH patients compared to healthy obese patients (p <0.001) with a predictive accuracy of AUROC 0.88 (steatosis activity score >2).
Conclusion: Plasma [SMOC2] shows promise as a non-invasive biomarker for diagnosis of NASH. Linkage of plasma [SMOC2] to aHSCs, moreover, may directly reflect key cellular changes associated with NASH progression.

FRI055

Clinicians' perspectives on barriers and facilitators for the adoption of non-invasive liver tests: a mixed-method study

Yasaman Vali[1], Roel Eijk[2], Timothy Hicks[3], Will Jones[3], Jana Suklan[3], Vlad Ratziu[4], Adriaan G. Holleboom[5], Miranda Langendam[1], Quentin Anstee[6], Patrick Bossuyt[1]. *[1]Amsterdam UMC, University of Amsterdam, Department of Epidemiology and Data Science, Amsterdam, Netherlands; [2]Athena Institute, VU University Amsterdam, Faculty of Science, Amsterdam, Netherlands; [3]NIHR Newcastle In Vitro Diagnostics Co-Operative, Newcastle University, Newcastle upon Tyne, United Kingdom; [4]University Paris-Diderot, Assistance Publique-Hôpitaux de Paris, hôpital Beaujon, Paris, France; [5]Amsterdam University Medical Centres, Department of Internal and Vascular Medicine, Amsterdam, Netherlands; [6]Newcastle University, The Newcastle Liver Research Group, Translational & Clinical Research Institute, Faculty of Medical Sciences, Newcastle upon Tyne, United Kingdom*
Email: y.vali@amc.uva.nl

Background and aims: Multiple non-invasive tests (NITs) have been developed to evaluate NAFLD patients. However, the availability of NITs varies from country to country, and little is known about their implementation and adoption in clinical practice. This study aimed to explore clinicians' perspectives on barriers and facilitators that influence the adoption of NITs.

Method: This cross-sectional study was performed using an exploratory mixed-methods approach. Twenty-seven clinicians from different countries, with a wide age range (from 30 to 63), specialties, and years of experience, were purposefully sampled. All participants filled in a questionnaire; 16 of those participated in a follow-up semi-structured interviews. Qualitative and quantitative data were collected and summarized using the recently published Non-adoption, Abandonment, Scale-up, Spread, and Sustainability (NASSS) framework for new medical technologies in healthcare organizations on seven domains: 1) the condition, 2) the technology, 3) the value proposition, 4) the adopters, 5) the organization, 6) the wider system, and 7) embedding and adaptation over time (see Figure 1).

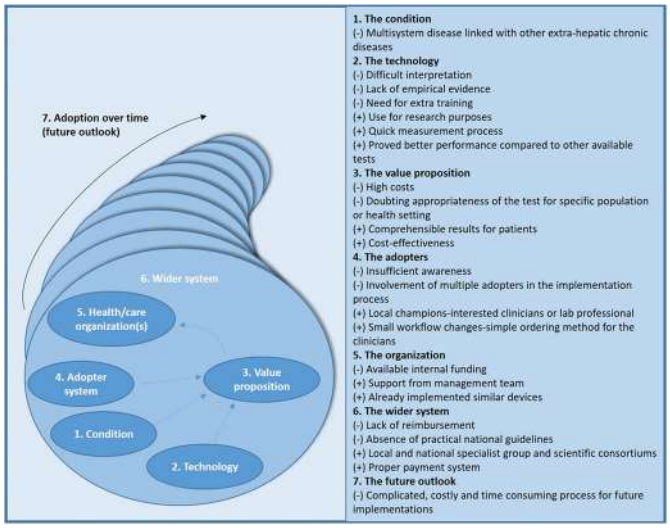

Figure: NASSS (Non-adoption, Abandonments, Scale-Up, Spread, and Sustainability) framework and the main barriers (–) and facilitators (+) of NAFLD tests' adoption in each domain.

Results: Several influencing factors were reported in different domains of the NASSS framework (see Figure 1). Among those, insufficient knowledge and limited awareness, impractical practice guidelines not yet built upon robust evidence for specific patient populations and care settings, need for extra training to perform the tests, difficult interpretation, and absence of sufficient reimbursement systems were perceived as the most important barriers. Other factors were indicated as important facilitating factors: ease of use and quick measurement process, evidence showing better performance compared to other available tests, local champions (clinicians with special interest in and knowledge about the new test), proper functional payment system and existence of resources in academic hospitals.

Conclusion: Adoption of new diagnostic NAFLD tests is a complex process and can be promoted or restricted by several factors, such as robust evidence, practical guidelines, a proper payment system, and local champions. As this study was restricted to clinicians, future studies could explore other stakeholders' perspectives necessary to improve the adoption of new biomarker-based NITs into clinical practice.

FRI056

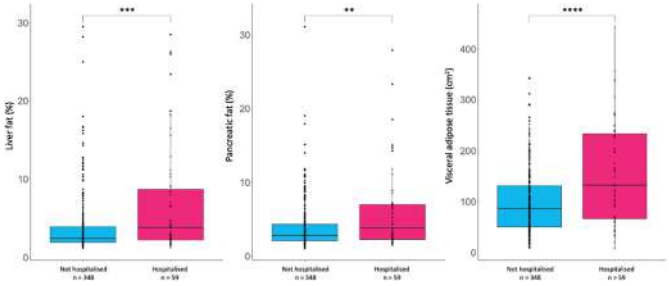
Ectopic fat deposition in the liver and pancreas and the presence of excess visceral adipose tissue significantly increase hospitalisation risk following COVID-19

Tom Waddell[1,2], Adriana Roca-Fernandez[2], John McGonigle[2], Arun Jandor[2], Valentina Carapella[2], Helena Thomaides-Brears[2], Andrea Dennis[2], John Michael Brady[2], Rajarshi Banerjee[2]. *[1]The University of Oxford, Department of Engineering Science, Oxford, United Kingdom; [2]Perspectum Ltd, Oxford, United Kingdom*
Email: tom.waddell@perspectum.com

Background and aims: In patients with COVID-19, obesity may increase risk of hospitalisation, use of mechanical ventilation and patient mortality. High liver fat, body mass index (BMI) and male sex are significant predictors of hospitalisation risk following COVID-19. However, BMI is a poor indicator of body fat distribution. Here, we studied ectopic fat accumulation within the liver and pancreas and body composition through multiparametric magnetic resonance (mpMR) and compared participants with and without hospitalisation for COVID-19.

Method: Participants with laboratory-confirmed or clinically suspected SARS-CoV-2 infection were recruited to the COVERSCAN study (NCT04369807; median time from initial symptoms = 177 days) and underwent a multi-organ mpMR scan (CoverScan, Perspectum Ltd). Measures of liver and pancreatic fat (PDFF), liver fibroinflammation (cT1) and body composition [visceral adipose tissue (VAT), subcutaneous adipose tissue (SAT), skeletal muscle index (SMI)] were analysed. Differences between participants hospitalised (n = 59) and not hospitalised (n = 348) for COVID-19 were assessed using Wilcoxon signed-rank tests. Univariate and multivariate analyses were performed on all biomarkers to assess the hospitalisation risk. Data presented are median values.

Results: Approximately 6-months after initial symptoms, participants hospitalised following COVID-19 had significantly elevated pancreatic fat (3.8% vs 2.8%, $p < 0.01$), liver fat (3.8% vs 2.4%, $p < 0.01$) and liver cT1 (735 ms vs 706 ms, $p < 0.01$) compared to those who convalesced at home. Though hospitalised participants had a significantly elevated BMI (27 kg/m^2 vs 25 kg/m^2, $p = 0.014$), it was VAT, but not SAT, that was significantly elevated (132 cm^2 vs 86 cm^2, $p < 0.01$). Univariate analysis revealed that male sex, advanced age and elevated BMI, VAT, pancreatic fat, liver fat, and liver cT1 were all significantly predictive of hospitalisation following COVID-19. In multivariate analysis, only age remained significantly predictive of hospitalisation. In hospitalised people with obesity (≥30 kg/m^2), VAT, liver cT1 and liver fat, but not BMI nor pancreatic fat, remained significantly elevated [VAT: 220 cm^2 vs 152 cm^2, $p = 0.01$ (Figure 1); liver fat: 9.9% vs 4.2%, $p = 0.003$; liver cT1: 782 ms vs 742 ms, $p = 0.012$].



Conclusion: mpMR revealed significantly elevated visceral and ectopic fat deposition within the liver and pancreas in hospitalised participants following COVID-19. In obese participants, BMI was not significantly different in hospitalised, and non-hospitalised patients, whereas visceral fat, liver fibroinflammation and liver fat were significantly elevated. Our work highlights body fat distribution an important consideration for COVID-19 risk profiling, which cannot be sufficiently evaluated based on BMI alone.

FRI057

Genomic and metabolomic profiles and their correlations with preclinical signs of endothelial dysfunction measured by peripheral arterial tonometry in non-alcoholic fatty liver disease

Mario Masarone[1], Jacopo Troisi[2,3], Benedetta Maria Motta[1], Martina Lombardi[2,3], Pietro Torre[1], Roberta Sciorio[1], Marco Aquino[1], Marcello Persico[1]. *[1]University of Salerno, Internal Medicine and Hepatology Unit, Department of Medicine, Surgery and Odontostomatology "Scuola Medica Salernitana", Baronissi (Salerno), Italy; [2]Theoreo srl, Montecorvino Pugliano (Salerno), Italy; [3]University of Salerno, Department of Chemistry and Biology, "A. Zambelli", Fisciano (Salerno), Italy*
Email: mario.masarone@gmail.com

Background and aims: NAFLD is associated with insulin resistance, metabolic syndrome (MS) and diabetes and it is an independent CVD risk factor. Endothelial Dysfunction (ED) plays a central role in the pathogenesis of CVD. Preclinical ED can be detected by vascular reactivity studies, such as Peripheral Arterial Tonometry (PAT). Genome Wide Studies (GWAS) identified Single Nucleotide Polymorphisms (SNPs) associated to NAFLD progression. Some of them (ie TM6SF2) have been postulated to influence CVD risk. The use of specific biomarkers related to ED presence in NAFLD may allow an early identification of CVD risk and provide crucial insights into its pathophysiology. This could be addressed through untargeted metabolomics and genomic approaches. Aims: to identify metabolomics signatures able to discriminate the presence of ED by combining data provided by metabolomics analyses with those from PAT, and to correlate them with anthropometric, laboratory and genomic profiles of NAFLD subjects.
Method: Serum was collected from 107 subjects with biopsy-proven NAFLD (55.9% NAFL; 26.6% NASH; 17.5% NASH-Cirrhosis) without clinically evident CVD. Metabolomics analysis was performed by mass spectrometry. The resulting profiles were correlated with PAT scores, revealed by an EndoPAT-2000 device, and with genomic profiles of 4 SNPs of NAFLD (PNAPL3; TM6SF2; GKR; MBOAT).
Results: Class separation in metabolomics profiles between patients with and without ED (EndoPAT cut-off = 0.51) was obtained through a "Partial Least Square Discriminant Analysis" (PLS-DA), which was also used to identify the discriminating metabolites. According to the PLS-DA score plot, two metabolomics profiles were identified, significantly different, in the two groups ($R2 = 0.98$, $p < 0.001$). The metabolites profiles are presented in figure 1. By comparing PAT scores of patients with simple steatosis (NAFL) (n:61, 19 with ED), NASH (n:29, 12 with ED), and NASH-cirrhosis (n:17, 9 with ED) no significant difference was observed ($p = 0.34$), suggesting that CVD risk is not associated with the degree of liver disease. Moreover, the clinical and genetic parameters associated to ED were type 2 diabetes, MS and BMI (directly) and TM6SF2 dominant model (CC + CT) (inversely) at the univariate and only MS at a multivariate analysis.

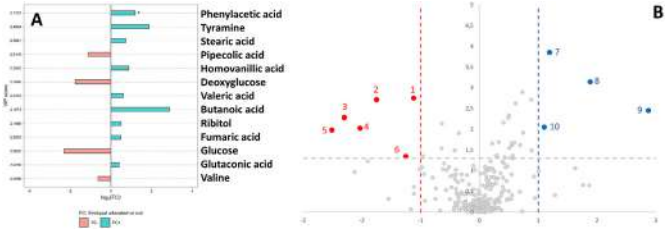


Figure: Metabolomic profiles of NAFLD patients with and without ED. Panel A: Impaired Metabolites. Panel B Volcano plot of impaired metabolites.

Conclusion: NAFLD patients with and without ED exhibit significant differences in their metabolomics profiles, demonstrating that they could be a useful early diagnostic tool for assessing CVD risk and providing an in-depth understanding of its underlying mechanisms. Among the NAFLD associated SNPs, only TM6SF2 mutation was correlated to a reduced prevalence of ED, but the only independent factor for ED was MS presence.

FRI058

Determinants of liver stiffness measurements in patients with NAFLD-an individual patient data meta-analysis

Email: ferenc.mozes@cardiov.ox.ac.uk

Background and aims: Liver stiffness measurements (LSM) performed with FibroScan are used in the clinical assessment of patients with non-alcoholic fatty liver disease (NAFLD). Fibrosis is the main determinant of LSM, but the contribution from other determinants and how they vary in patient subgroups is less well studied. Our aim was to describe the dependence of LSM on histological, demographic and laboratory parameters.
Method: Data sets including LSM, demographics, histology- and lab parameters were reported in 2768 patients. Parameters with correlation r >0.15 with LSM were selected as possible determinants of LSM in the entire patient group. Linear regression models were built by adding one predictor at a time to a base model including the log-transformed LSM and fibrosis stages as indicator variables. Partial R^2 values were compared to evaluate the contribution of each variable in explaining the variability of log-transformed LSM. A separate analysis evaluated the interaction between age and fibrosis stage.
Results: NASH CRN fibrosis stage, lobular inflammation and ballooning grades, age, aspartate aminotransferase (AST), platelet count (Plt), gamma-glutamyltransferase (GGT), BMI and presence of T2DM correlated with LSM with r >0.15. Mean age was 51 years, mean BMI was 30 kg/m^2, 41% of patients had T2DM. Fibrosis stage explained most of the variance (R^2 = 0.411) in log-transformed LSM, followed by BMI (partial R^2 = 0.051), GGT (partial R^2 = 0.023), and AST (partial R^2 = 0.022) (see Table). Furthermore, including an interaction term between fibrosis stage and age explained log-transformed LSM better than only considering the main effect of fibrosis stage (F-statistic = 3.171, p = 0.007).

Model predictors	Partial R^2
Age	0.0018
BMI	0.0514
Plt	0.0068
AST	0.0221
GGT	0.0232
T2DM	0.0183
Ballooning grade	0.0119
Lobular inflammation grade	0.0132

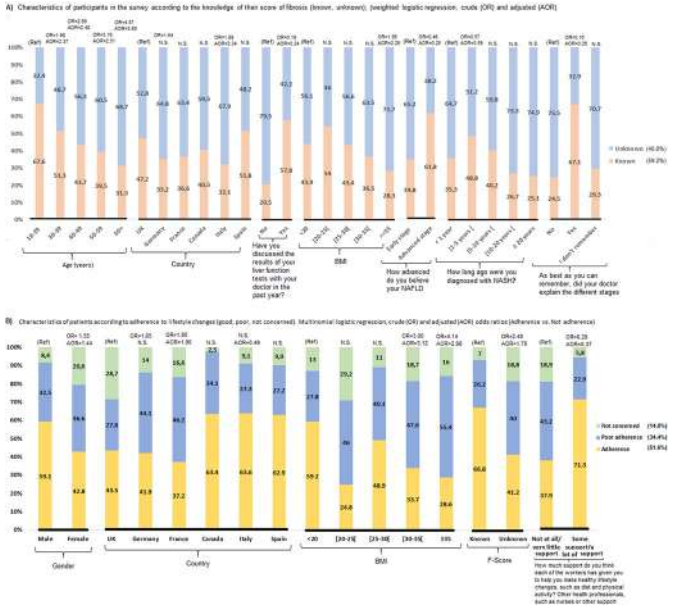
Conclusion: Our data confirm that fibrosis is the main determinant of LSM in patients with NAFLD, with BMI, GGT and AST explaining most of the remaining variance. However, LSM was less dependent on fibrosis stage in younger patients-a result that deserves further exploration. Our findings should be taken into account when interpreting LSM results from these patients.

FRI059

Knowledge of liver fibrosis stage among adults with non-alcoholic fatty liver disease/non-alcoholic steatohepatitis improves adherence to life style changes

Carrieri Patrizia[1], Abbas Mourad[1], Fabienne Marcellin[2], José Luis Calleja Panero[3], Camelia Protopopescu[1], Jeffrey Lazarus[4,5].
[1]Aix Marseille Univ, Inserm, IRD, SESSTIM, Sciences Economiques & Sociales de la Santé & Traitement de l'Information Médicale, ISSPAM, Marseille, France; [2]Aix Marseille Univ, Inserm, IRD, SESSTIM, Sciences Economiques & Sociales de la Santé & Traitement de l'Information Médicale, ISSPAM, Marseille, France; [3]Department of Gastroenterology, Hospital Universitario Puerta de Hierro de Majadahonda, Madrid, Spain; [4]Barcelona Institute for Global Health (ISGlobal), Hospital Clínic, University of Barcelona, Barcelona, Spain; [5]University of Barcelona, Faculty of Medicine, Barcelona, Spain
Email: abbas.mourad@inserm.fr

Background and aims: Non-alcoholic fatty liver disease (NAFLD) continues to rise in many countries, paralleling the epidemic of obesity worldwide. NAFLD can evolve into non-alcoholic steatohepatitis (NASH) depending on age, lifestyle, and metabolic risk factors. Both diseases are managed with lifestyle interventions, but unawareness of liver disease severity may compromise adherence. An international survey of people living with NAFLD/NASH was conducted for the first time to identify correlates of a lack of knowledge about fibrosis status, and to assess whether this unawareness was associated with poor adherence to lifestyle changes.
Method: We recruited 1411 adults living with NAFLD/NASH in Canada, France, Germany, Italy, Spain, and the United Kingdom who were registered on the online patient community platform Carenity. Weighted binary and multinomial logistic regressions were performed to estimate the effect of explanatory variables on unawareness of fibrosis stage and poor adherence to lifestyle changes, respectively, in univariable and multivariable analyses.
Results: In the study group, men accounted for 54.1%, 15.5% of the participants had obesity, and 75.3% of NAFLD patients reported being in an early fibrosis stage. Of the total, 59.2% were unaware of their fibrosis stage, and 34.4% reported non-adherence to lifestyle changes. After multiple adjustments (Figure 1), older people were found to be at more risk of not knowing their fibrosis stage. Individuals who were aware of their fibrosis stage were more likely to have discussed their liver tests with their physicians throughout the previous year (AOR = 0.24; 95%CI: 0.16–0.36), and to have been diagnosed throughout the 5 years preceding the survey (AOR = 0.59; 95%CI: 0.38–0.91). Individuals with a body mass index (BMI) ≥35 were over twice as likely to not know their fibrosis stage (AOR = 2.26; 95%CI: 1.37–3.40). Unawareness about fibrosis stage was significantly associated with poor adherence to lifestyle changes (AOR = 1.70; 95%CI: 1.14–2.41). Individuals with obesity (BMI ≥30) had a threefold higher risk of having poor adherence to lifestyle changes (AOR = 3.12; 95%CI: 1.74–5.60). People reporting having received support from nurses and other health staff were more likely to be adherent to lifestyle changes (AOR = 0.37; 95%CI: 0.25–0.54).



Conclusion: As fibrosis stage is becoming the main predictor of NAFLD progression, patients' knowledge of their fibrosis stage should become a priority to improve liver health. Given the seriousness of NASH-related morbidity and mortality, improving patient-provider communication, especially for people with obesity, about liver fibrosis stage, its associated risks, and how to mitigate them, is essential. Training healthcare professionals and promoting patient educational programs to support behavior changes should also be included in the liver health agenda.

FRI060

The MRI and AST (MAST) score is correlated with noninvasive and histologic markers of fibrosis in patients with advanced fibrosis due to NASH

Background and aims: The MAST Risk score is a noninvasive tool that includes AST and MRI-based assessments of liver stiffness (LS) by elastography (MRE) and steatosis by proton density fat fraction (MRI-PDFF), for the identification of patients at risk of progressive NASH. Our aims were to evaluate the effects of cilofexor (CILO) and firsocostat (FIR) on MAST, and associations between treatment-induced changes in MAST with histologic and noninvasive test (NIT) responses in patients with advanced fibrosis due to NASH.

Method: NASH patients with histologically-confirmed, advanced fibrosis (NASH CRN F3–F4) in the phase 2b ATLAS trial were treated with regimens including CILO 30 mg (n = 40), FIR 20 mg (n = 40), CILO + FIR (n = 78), or placebo (n = 39), once daily for 48 weeks (W48). Liver histology was evaluated by a central reader and a machine learning (ML) approach (PathAI; Boston, MA). Endpoints included a ≥1-stage improvement in fibrosis without worsening of NASH (primary endpoint [PE]), ≥2-pt reduction in NAFLD Activity Score (NAS response [NAS-R]), and LS by vibration-controlled transient elastography (VCTE) and ELF responses (ELF-R), defined as ≥25% and ≥0.5-unit reductions from baseline (BL) to W48, respectively. Changes in MAST were evaluated using Wilcoxon rank sum and Fisher's exact tests.

Results: At BL, 56% of patients had cirrhosis (F4); median MAST Risk score was higher in those with F4 vs F3 fibrosis (0.36 vs 0.24; p = 0.003). Across study groups, BL MAST was significantly correlated with ELF score (ρ = 0.53), LS by VCTE (ρ = 0.48), hepatic collagen content (ρ = 0.37) and α-SMA expression by morphometry (ρ = 0.26), serum bile acids (ρ = 0.44), ML NASH CRN fibrosis score (ρ = 0.39), and proportionate areas of NASH CRN F4 (ρ = 0.38), portal inflammation (ρ = 0.36), and hepatocellular ballooning (ρ = 0.27; all p < 0.05), but not proportionate areas of steatosis or lobular inflammation. Compared with placebo (median change in MAST from BL to W48: −0.04), greater improvements in MAST at W48 were observed with FIR (−0.23; p = 0.03); differences with CILO (-0.06, p = 0.46) and CILO +FIR (−0.05; p = 0.68) were not statistically significant. Compared to non-responders, greater improvements in MAST from BL to W48 were observed in patients with NAS-R and LS by VCTE-response, but not ELF or PE response (Figure).

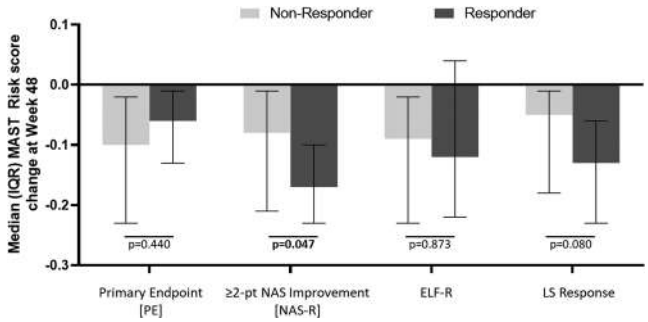

Figure: Change in MAST Risk Score by Histologic and Noninvasive Test Response at Week 48.

Conclusion: In patients with advanced fibrosis due to NASH, the MAST Risk score is correlated with noninvasive and histologic measures of fibrosis and may be a useful marker of treatment response beyond conventional histologic methods.

FRI061

Independent determinants of CAP values in healthy individuals with dysmetabolism

Cristiana Bianco[1], Serena Pelusi[1], Eleonora Giacopuzzi Grigoli[2], Luigi Santoro[1], Francesco Malvestiti[1,3], Melissa Tomasi[1], Ilaria Marini[1], Sara Margarita[1], Rossana Carpani[1], Daniele Prati[1], Luca Valenti[1,3].
[1]*Precision Medicine, Department of Transfusion Medicine and Hematology-Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico;* [2]*Università degli Studi di Milano;* [3]*Università degli Studi di Milano, Department of Pathophysiology and Transplantation*
Email: biancocristiana.md@gmail.com

Background and aims: Controlled attenuation parameter (CAP) values determined during vibration controlled transient elastography correlate with hepatic fat content and can non-invasively assess the presence of fatty liver with moderate accuracy. Aim of the study was to examine the clinical and metabolic determinants of CAP in a cohort of apparently healthy individuals with dysmetabolism.
Method: We assessed CAP in 953 consecutive blood donors with ≥3 dysmetbolism features (hypertension, hyperglicemia, overweight/obesity, low HDL/high tryglicerides), who participated in a primary prevention program (LIVER-BIBLE cohort up to July 2021). CAP determinants were assessed by generalized linear models.
Results: Mean age was 53.9 ± 6.3 yrs, BMI 28.5 ± 3.0 Kg/m^2, 158 (16.6%) participants were females, 35 (3.7%) diabetics, 704 (73.9%) had hypertension and 383 (40.2%) dyslipidemia, 463 (48.6%) had fatty liver (CAp >275 db/m), and 17 (1.8%) liver stiffness measurement (LSM) ≥8 kPa. CAP correlated with LSM ($p < 10^{-16}$). CAP was associated with older age ($p = 0.02$), higher BMI, abdominal circumference, glucose, insulin, ferritin ($p < 0.01$ for all), and lower HDL ($p = 0.03$). No consistent association with CRP, hypertension, diet or lifestyle factors was detected, except for alcohol consumption ($p = 0.003$). At multivariable analysis (Table), abdominal circumference was the main determinant of CAP ($p < 10^{-9}$), with insulin ($p < 10^{-6}$), HbA1c ($p = 0.006$), ferritin ($p = 0.04$) and HDL levels ($p = 0.04$). Independent determinants of CAP ≥275 dB/m were confirmed to be abdominal circumference ($p < 10^{-5}$), insulin ($p = 0.0003$), HDL, HbA1c, BMI and alcohol consumption ($p < 0.05$ for all). Fatty liver index predicted CAP ≥275 dB/m with low-moderate accuracy (AUROC = 0.70), whereas ALT with low accuracy (AUROC = 0.60). In the subset of the latest 352 enrolled participants for whom the information was available, we found an independent association between CAP and lower TSH levels (estimate −5.06 ± 2.22, $p = 0.02$).

	Overall LIVER-BIBLE Cohort			Subgroup with TSH determination (n=352)		
	Estimate	SE	P value	Estimate	SE	P value
Sex, F	1.99	1.84	0.28	3.33	2.76	0.23
Age, years	0.37	0.19	0.06	0.35	0.32	0.27
BMI, kg/m^2	0.79	0.62	0.21	0.42	0.95	0.66
Abdominal circumference, cm	1.41	0.22	$1.1*10^{-10}$	1.60	0.34	$1.9*10^{-6}$
HbA1c, mmol/mol	0.81	0.30	$6.4*10^{-3}$	0.31	0.45	0.49
Insulin, uU/ml	0.70	0.14	$2.8*10^{-7}$	0.95	0.22	$2.0*10^{-5}$
HDL, mg/dl	-0.25	0.13	$4.9*10^{-2}$	-0.15	0.20	0.45
Ferritin, log ng/ml	2.91	1.45	$4.4*10^{-2}$	1.88	2.40	0.43
Alcohol drinks, n/week	0.33	0.22	0.12	0.90	0.34	$8.0*10^{-3}$
TSH, mU/l	-	-	-	-5.06	2.22	$2.2*10^{-2}$

Figure: Independent predictors of CAP values in the LIVER-BIBLE cohort. F: female; BMI: body mass index; HbA1c: glycate hemoglobin; TSH: thyroid stimulating hormone; SE: standard error.

Conclusion: In healthy individuals with dysmetabolism, CAP values were most strongly associated with the severity of hyperinsulinemia and abdominal adiposity. The association between activation of the pituitary-thyroid axis and fatty liver is being evaluated in the whole updated cohort.

FRI062

Performance of liver-related clinical scores in the SAPHIR study

Lorenz Balcar[1,2], Georg Semmler[1,2,3], Stephan Zandanell[1], David Niederseer[4], Sophie Gensluckner[1], Alexandra Feldman[1], Christian Datz[3], Bernhard Paulweber[1], Elmar Aigner[1]. [1]*Paracelsus Medical University of Salzburg, First Department of Medicine, Salzburg, Austria;* [2]*Medical University of Vienna, Division of Gastroenterology and Hepatology, Department of Internal Medicine III, Vienna, Austria;* [3]*General Hospital Oberndorf, Department of Internal Medicine, Oberndorf bei Salzburg, Austria;* [4]*University Hospital Zurich, Department of Cardiology, Zurich, Switzerland*
Email: e.aigner@salk.at

Background and aims: There are several established clinical scores for patients with chronic liver diseases; however, the prognostic value of these scores in the general population is unclear. Therefore, our study aimed to evaluate the value of liver-related risk-scores in a population-based cohort with a 20-year follow-up.
Method: We included participants from the SAPHIR study from the city of Salzburg, Austria. We calculated Cox regression models for (i) overall mortality, (ii) malignancy-related-, (iii) major adverse cardiovascular (CV)-, and (iv) composite CV events (minor/major adverse CV events).
Results: Overall, 1646 patients were included (mean age 52 ± 6 years; 63% male). Mean BMI was 27 ± 4 kg*m^{-2} and 15% of patients had metabolic syndrome (MetS) at baseline. Mean Framingham risk score (FRS) was 12 ± 4 points, indicating an intermediate risk for developing CV diseases within 10 years. Median follow-up was 18.7 years (IQR: 15.4–20.5).
In univariable analyses, APRI was associated with overall mortality (hazard ratio [HR]: 5.01 [95% confidence interval (95%CI): 1.27–19.78)]; $p = 0.021$), as was FIB-4 (HR: 1.53 [95%CI: 1.18–1.99]; $p = 0.002$), the MetS (HR: 1.28 [95%CI: 1.11–1.49]; $p < 0.001$), the Forns- (HR: 1.24 [95%CI: 1.08–1.42]; $p = 0.002$), and the FLI- (HR: 1.03 [95% CI: 1.01–1.04]; $p = 0.002$), but not the BARD-score (HR: 1.16 [95%CI: 0.97–1.38]; $p = 0.097$). The FLI-score (HR: 1.02 [95%CI: 1.01–1.03]; $p = 0.006$) and the MetS (HR: 1.17 [95%CI: 1.07–1.28]; $p < 0.001$) were univariably associated with malignant events. For major adverse CV events, results were similar (FLI-score: HR: 1.03 [95%CI: 1.02–1.05]; $p < 0.001$; MetS: HR: 1.50 [95%CI: 1.31–1.73]; $p < 0.001$). Furthermore, the Forns- (HR: 1.13 [95%CI: 1.04–1.23]; $p = 0.005$), as well as the FLI-score (HR: 1.03 [95%CI: 1.02–1.04]; $p < 0.001$) and the MetS (HR: 1.32 [1.21–1.43]; $p < 0.001$) were associated with a combined CV endpoint. In multivariable analyses including age, BMI, mean arterial pressure, FRS, and respective scores significantly associated in univariable analyses, none of the scores remained independently associated with overall mortality and malignant outcomes. Interestingly, the MetS remained independently associated with major adverse CV events (aHR: 1.36 [95%CI: 1.11–1.65]; $p = 0.003$) and the FLI-score for combined CV endpoints (aHR: 1.02 [1.01–1.04]; $p = 0.010$).
Conclusion: While specific liver-related scores (i.e., FIB-4, APRI) are strongly associated with outcomes in liver diseased patients, their prognostic value is limited in the general population. Most of the scores of interest were univariably associated with overall mortality; however, these associations vanished when adjusting for other variables. Importantly, the MetS as well as the FLI-score showed independent associations with CV events, suggesting a strong correlation of fatty liver disease and rate of CV outcomes in the general population.

FRI063

Correlations of 2D-Shear wave and transient elastography liver stiffness measurements in patients with non-alcoholic fatty liver disease

Dimitrios Karagiannakis[1], Georgios Markakis[1], Dimitra Lakiotaki[1], Elisavet Michailidou[1], Paraskevi Fytili[1], Evangelos Cholongitas[1], Ioannis Vlachogiannakos[1], George Papatheodoridis[1]. [1]*Laiko General Hospital, Medical School, National and Kapodistrian University of Athens, Greece*
Email: d_karagiannakis@hotmail.com

Background and aim: The performance of transient elastography (TE) has been widely assessed, while 2D-shear wave elastography (2D-SWE) is a newer elastographic technique. The aim of the study was to investigate if liver stiffness measurements (LSM) of 2D-SWE are correlated with LSM of TE for the evaluation of liver fibrosis in patients with non-alcoholic fatty liver disease (NAFLD).
Methods: In total, 552 consecutive patients with NAFLD were included [median age: 55 (range:19–87) years, Males: 288 (52.5%)]. Mean waist circumference was 105 ± 13 cm and median BMI 28.7 (17.3–79.7) kg/m^2 [Normal BMI (<25): 94 (17%), Overweight (BMI = 25–30): 94 (17%), Obese (BMI > 30): 192 (34.8%)]. Liver fibrosis was assessed by TE (M/XL probe) and 2D-SWE at the same time. CAP was performed for the estimation of the degree of liver steatosis.
Results: Median LSM of TE was 5.5 (2.8–75) kPa and of 2D-SWE 62 (3.7–46.2) kPa. TE (and CAP) and 2D-SWE were not feasible in 18 (3.3%) and 26 (4.7%) patients respectively. Mean CAP value was 290 ± 54 db/m. One hundred and twenty eight patients (23.2%) had mild steatosis (CAP < 250 db/m) and 406 (73.6%) had moderate/severe steatosis (CAP≥250 db/m). LSMs by TE and 2D-SWE were correlated in normal BMI (r: 0.774; p < 0.001), overweight (r:0.774; p < 0.001) and obese (r: 0.75; p < 0.001) patients, as well as in patients with CAP ≤250 db/m (r = 0.63; p < 0.001) and CAp >250 db/m (r = 0.743; p < 0.001). According to TE measurements, patients were sub-classified to those without moderate fibrosis (F0–F1; LSM by TE <7 kPa; n = 388 or 70.3%), moderate/severe fibrosis (F2/F3; LSM:7–13 kPa; n = 117/19.3%) and cirrhosis (F4; LSM>13 kPa; n = 57/10.3%). A significant correlation between TE and 2D-SWE was found in all these subgroups (r:0.458; r:0.624; r:0.696, respectively; all p < 0.001). The accuracy of 2D-SWE for detecting patients with moderate/severe fibrosis diagnosed by TE was 89.7% (LSM cut-off 6.87 kPa: 87% sensitivity, 81.2% specificity for discrimination between moderate/severe (F2/F3) and no moderate fibrosis (F0–F1). The accuracy of 2D-SWE for diagnosing patients with cirrhosis diagnosed by TE was 99.1% (LSM cut-off 12.16 kPa: 90.4% sensitivity, 95.9% specificity).
Conclusion: LSMs by 2D-SWE correlate with those of TE and therefore 2D-SWE can reliably substitute TE in the evaluation of liver fibrosis in patients with NAFLD. Similar LSM cut-off values of TE and 2d-SWE can be applied in order to classify NAFLD patients into fibrosis stages.

FRI064

Performance of the Enhanced Liver Fibrosis (ELF) test in real world practice versus clinical trials of non-alcoholic steatohepatitis

Maria Stepanova[1,2,3,4], Sean Felix[2,3], Thomas Jeffers[2,3], Elena Younossi[2,3], Brian Lam[2,3], Linda Henry[1,2,3,4], Zobair Younossi[1,2,3]. [1]*Inova Health System, Medicine Service Line;* [2]*Betty and Guy Beatty Center for Integrated Research, IHS;* [3]*Inova Health System, Center for Liver Disease, Department of Medicine;* [4]*Center for Outcomes Research in Liver Disease*
Email: zobair.younossi@inova.org

Background and aims: The ELF score is calculated using three direct markers of fibrosis [hyaluronic acid (HA), amino-terminal propeptide of type III collagen (PIIINP), tissue inhibitor of matrix metalloproteinase 1 (TIMP-1)]. In NAFLD, advanced stage of fibrosis is the most important predictor of long-term clinical outcomes. Our aim was to assess performance of ELF for identification of advanced fibrosis in patients with NAFLD enrolled in clinical trials and in patients seen in a real-life hepatology clinic.
Method: Data collected from two non-overlapping samples of NAFLD patients were used in this study (Group 1: real world hepatology practice, Group 2: enrollees from NASH Clinical trials). Both groups were matched according to presence of advanced fibrosis. Clinical data, liver biopsy, and serum were collected for each included patient. ELF scores were calculated using an ADVIA Centaur XP analyzer. Liver biopsies were scored by a single hepatopathologist 0–4 using CRN criteria; advanced fibrosis was defined as stage 3 (bridging fibrosis) or 4 (compensated cirrhosis). Performance of ELF for predicting advanced fibrosis was assessed in both groups.
Results: A total of 1, 379 subjects were available [Group 1: N = 467, age 48 ± 13 years old, 31% male, 35% type 2 diabetes, 24.6% advanced fibrosis, mean (SD) ELF score was 9.0 ± 1.2; based on published cutoffs, 78% had ELF <9.8 (low-risk), 17% 9.8 ≤ ELF <11.3 (moderate risk), and 5% ELF ≥11.3 (high-risk), Group 2: N = 912, age 54 ± 11 years old, 43% male, 55% type 2 diabetes, 26% advanced fibrosis; mean (SD) ELF 9.6 ± 1.0 including 61% with low-risk, 33% moderate risk, 6% high-risk ELF scores]. Area under the ROC curve (AUC) (95%) for predicting advanced fibrosis by ELF was 0.81 (0.77–0.85) in Group 1. The cutoff of ELF ≥9.8 returned sensitivity 57% (47%–66%), specificity 89% (86%–92%), positive predictive value (PPV) 63% (54%–70%), negative predictive value (NPV) 86% (83%–89%); in addition, the cut-off of ELF ≥11.3 returned specificity 99% (98%–100%), sensitivity 19% (12%–28%), PPV 88% (69%–96%), NPV 79% (77%–80%). In Group 2, ELF had AUC (95% CI) = 0.80 (0.77–0.82) for predicting advanced fibrosis which was identical to that seen in Group 1. The cutoff of ELF ≥9.8 returned sensitivity 74% (68%–79%), specificity 74% (70%–77%), positive predictive value (PPV) 50% (45%–55%), negative predictive value (NPV) 89% (86%–91%); in addition, the cut-off of ELF ≥11.3 returned specificity 98% (97%–99%), sensitivity 17% (12%–22%), PPV 77% (66%–89%), NPV 77% (74%–80%).
Conclusion: The non-invasive serum-based ELF test performs well in identifying high risk NAFLD patients in both real-life and clinical trial settings.

FRI065

Machine learning using simple non-invasive tests of fibrosis and B-mode ultrasound for the prediction of adverse liver-related outcomes in NAFLD

Heather M. Kosick[1,2], Chris McIntosh[3,4], Mina Fakhriyehasl[3], Chinmay Bera[5], Oyedele Adeyi[6], Kartik Jhaveri[3], Keyur Patel[5]. [1]*University of Toronto, Toronto, Canada;* [2]*University Health Network, Toronto, Canada;* [3]*University Health Network, Joint Department of Medical Imaging, Toronto, Canada;* [4]*University Health Network, Peter Munk Cardiac Centre and Joint Department of Medical Imaging, Canada;* [5]*University Health Network, Gastroenterology & Hepatology, Toronto, Canada;* [6]*University of Minnesota, Department of Laboratory Medicine and Pathology, Minneapolis, United States*
Email: heather.evans@medportal.ca

Background and aims: Advanced fibrosis (F3–4) in non-alcoholic fatty liver disease (NAFLD) increases the risk of adverse liver-related outcomes. Serum-based non-invasive tests (NIT) alone are still not yet able to reliably predict NAFLD outcomes. Our aims were to explore the role of machine learning (ML) algorithms based on simple NIT combined with B-mode ultrasound (US), for prediction of adverse liver-related outcomes.
Method: Retrospective observational single center cohort study which included NAFLD patients with biopsy between 2010–2018. Demographics, anthropometric measurements, clinical outcomes, NIT, including FIB-4 and NFS, and US data, including liver/spleen size, steatosis, and features of advanced liver disease, were collected. ML algorithms were generated using the random forest technique to create predictive models for each clinical outcome, including hepatic decompensation, hepatocellular carcinoma (HCC), liver transplant, all-cause and liver-related mortality.

Results: 389 NAFLD patients were included with F3–4 prevalence 48.6%, 54.5% male, mean age 48.5±13.2 years, diabetes in 30.1%, and BMI 32.4 ± 7.0 kg/m^2. Overall, 51 (13.1%) patients had an adverse liver-related outcome over median 3.14 years, and included hepatic decompensation in 9.5%, HCC 4.1%, liver transplant 5.4%, mortality 2.6% and liver-related mortality 2.1%. AUC measures for the ML predictive models were: hepatic decompensation 0.958, HCC 0.770, liver transplant 0.931, all-cause mortality 0.831, and liver-related mortality 0.859. ML feature importance for predictive variables was determined for each outcome. FIB-4, AST:ALT ratio, and age had the greatest feature importance for NIT and clinical variables respectively. US-based parameters did not have significant feature importance for liver-related outcomes compared to clinical or biochemical features.

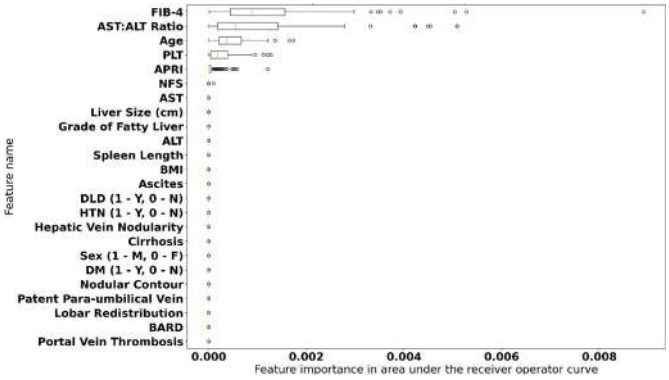

Figure: Feature Importance Box Plot for Machine Learning Algorithm Prediction of Hepatic Decompensation.

Conclusion: ML models based on readily available clinical, biochemical, and US-based variables were able to accurately predict adverse liver-related outcomes in a tertiary cohort of biopsy-proven NAFLD patients. Age, AST:ALT ratio, and FIB-4, but not US-based parameters, contributed significantly to ML predictive models for clinical outcomes.

FRI066

Incorporating a two-tiered liver fibrosis assessment into annual diabetes review in primary care-3 year follow up study

Rajan Bhandari[1], Dina Mansour[1]. [1]*Q E hospital Gateshead, United Kingdom*
Email: dmansour299@yahoo.co.uk

Background and aims: We previously presented the outcome of a pathway incorporating 2-tiered fibrosis assessment into annual diabetic reviews in primary care. This 3 year follow up study looks at
Outcomes in patients referred into secondary care with moderate-advanced fibrosis
Ongoing service delivery requirements after the first year of case finding
Effectiveness of the pathway in detecting patients with advanced disease, by looking at the number of patients missed in the pathway presenting with advanced disease.
Method: All patients aged >35 years with T2DM attending annual review at two primary care practices in North East England between April 2018 and September 2019 (n = 467) had a Fib-4 requested, followed by transient elastography (TE) if the Fib-4 was above the high sensitivity threshold. Those with a liver stiffness >8 kPa were reviewed in secondary care. This pathway was continued in both practices after the end of the initial study period. We reviewed the outcomes of all patients referred to secondary care; the number of patients referred in the subsequent years with ongoing case-finding; and any patients missed from initial screening presenting with decompensated/symptomatic disease.
Results: Of 467 patients in the initial study, 58 were referred for TE, 25 had a LSM>8 kPa and 20 had advanced disease (on imaging/biopsy/endoscopy). 6/20 (30%) patients with advanced disease have died- 2/20 liver related deaths (hepatocellular carcinoma (HCC) and decompensated cirrhosis); 1 patient diagnosed with HCC was treated with curative transarterial chemoembolisation; 3 patients had varices on OGD (2 started on carvedilol for primary prophylaxis); 12 remain under follow up. In all patients with LSM >8 kPa (n = 25): 8/25 (32%) died (3/8 from COVID-19); 24% (6) LSM improved, 8% (2) LSM deteriorated; 32% (8/25) lost weight. No patients missed by the pathway presented with decompensated disease. Serial FIB-4 at annual screening 2019–2021: 4 patients new raised Fib-4 scores-1 DNA, 1 TE is awaited, 1 LSM <8 kPa (discharged), 1 advanced disease (LSM 17.1 kPa).
Conclusion: Incorporation of a two-tiered liver fibrosis assessment into primary care annual diabetic screening significantly improves identification of advanced liver disease and no patients have presented with advanced disease out-with the pathway. It allows for early detection and interventions against the complications associated with advanced liver disease. Mortality in patients with advanced liver disease remains high. Referrals for TE and into secondary care dramatically reduce after the initial year of case finding.

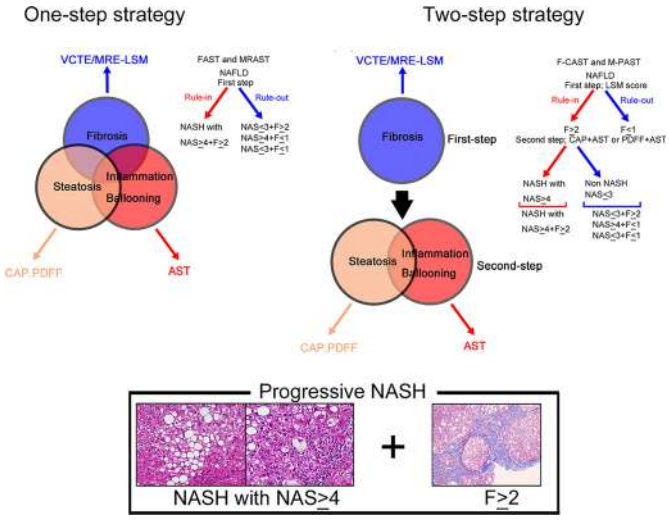
Email: kento318@yokohama-cu.ac.jp

Background and aims: Clinical trials enroll patients with elevated non-alcoholic fatty liver disease (NAFLD) activity score (NAS≥4) and significant fibrosis (F≥2); however, screening failure rates are often high following biopsy. We aimed to develop a new score to identify non-alcoholic steatohepatitis (NASH) with NAS≥4 and F≥2 using magnetic resonance imaging (MRI).
Method: We undertook a prospective primary study of 176 patients and a retrospective validation study of 169 patients with liver biopsy proven NAFLD at three liver centers. Liver stiffness measurement (LSM) by magnetic resonance elastography (MRE), proton density fat fraction (PDFF) measured by MRI, and aspartate aminotransferase (AST) were combined to develop a simple index (MRI with AST; MRAST score) for NASH with NAS≥4 and F≥2, as in FibroScan-AST (FAST) score (One-step strategy).
Results: MRAST score was generally equivalent to FAST (an area under the ROC curve (AUROC) = 0.780) for the detection of NASH with NAS≥4 and F≥2 with an AUROC of 0.756, with consistent results in the validation cohort (AUROC = 0.812 [MRAST] vs 0.779 [FAST]). We then examined a two-step strategy, VCTE-LSM or MRE-LSM as first-step, following CAP+AST or PDFF+AST as second-step. When used as

the rule-in criteria, the positive predictive value (PPV) was 71.6% for FAST, 74.2% for MRAST, 82.6% for F-CAST, and 78.1% for M-PAST in combined cohort. When used as the rule-out criteria, negative predictive value (NPV) was 85.2% for FAST, 88.8% for MRAST, 85.3% for F-CAST, and 87.3% for M-PAST. Indeterminate patients by the FAST, MRAST, F-CAST and M-PAST were 48.5%, 49.9%, 32.5% and 28.1%, respectively.



Conclusion: MRAST has equal diagnostic accuracy with FAST for NASH with NAS≥4 and F≥2. In addition, our results supported the higher utility of a two-step strategy using F-CAST and M-PAST over one-step method (FAST and MRAST) for detecting NASH with NAS>4 +F > 2.

FRI068

Impact of artificial intelligence assistive tool on the histopathologic review of fibrosis in non-alcoholic steatohepatitis patients

Aileen Wee[1], Wei Qiang Leow[2], Gwyneth Soon[3], Elaine Chng[4], Dean Tai[4], Yayun Ren[4], Jia Ling Chong[4], Yee Chen Ng[4], Feng Liu[5], Lai Wei[6], Arun Sanyal[7]. *[1]Department of Pathology, Yong Loo Lin School of Medicine, National University of Singapore, Singapore; [2]Department of Anatomical Pathology, Singapore General Hospital, Singapore and Duke-NUS Medical School, Singapore; [3]Department of Pathology, National University Hospital, Singapore; [4]HistoIndex Pte. Ltd., Singapore; [5]Peking University People's Hospital, Peking University Hepatology Institute, Beijing Key Laboratory of Hepatitis C and Immunotherapy for Liver Diseases, Beijing, China; [6]Hepatopancreatobiliary Center, Beijing Tsinghua Changgung Hospital, Tsinghua University, Beijing, China; [7]Virginia Commonwealth University, Richmond, Virginia, USA*
Email: patweea@nus.edu.sg

Background and aims: Inter-observer variability for categorical scores of liver fibrosis among pathologists ranges from fair to moderate weighted kappa. Artificial intelligence (AI) and advances in digitised whole-slide images (WSI) facilitated the use of an AI-assistive tool in pathology to improve histopathologic interpretation. Second harmonic generation/two-photon excitation fluorescence (SHG/TPEF) microscopy with AI can provide standardised evaluation. This pilot study aims to explore the impact of AI tools on the overall agreement on fibrosis assessment between pathologists.
Method: Unstained sections of liver biopsies from 50 non-treated patients with NASH (F0–F4) were taken from Peking University People's Hospital and fibrosis was quantitated using SHG/TPEF microscopy (qFibrosis). To evaluate performance metrics for assisted and unassisted reads, pathologists interpreted images in both modalities in 2 sessions separated by a wash-out period of at least 3 weeks. H&E and MT-stained images were digitised and uploaded onto a WSI platform, and the assisted reads included an additional SHG image with qFibrosis stage and continuous values. 3 pathologists participated in this study, with experiences ranging from 5 to 40 years.
Results: The qFibrosis AI tool has been validated in studies, showing >95% agreement. When assisted by the qFibrosis AI tool, the concordance rate between pathologists improved to near perfect agreement, with 0.82 linear weighted kappa, as compared to 0.72 for the unassisted review. Mean overall percentage agreement between pathologists improved from 89.38% to 92.93% ($p = 0.032$). Mean linear weighted kappa for intra-observer agreement is also higher, achieving 0.91 kappa compared to 0.79 for unassisted reads. The effect of AI assistance on fibrosis assessment consistency was examined by reviewing the percentage of patients who remained staged between F1-F3 after the initial reads. Using qFibrosis, 95.3% of the patients were retained versus 82% for the unassisted review.

Table: Mean percentage agreement and weighted kappa (linear) for assisted and unassisted reads.

		Unassisted	Assisted
Inter-observer	Mean Percentage Agreement	89.38%	92.92%
	Mean Weighted Kappa (Linear)	0.7157	0.8163
Intra-observer	Mean Percentage Agreement	92.08%	96.46%
	Mean Weighted Kappa (Linear)	0.7861	0.9081

Conclusion: qFibrosis as an AI assistive tool can improve inter-pathologist weighted kappa to near perfect agreement with 93% agreement and 95% retention rate. qFibrosis has been well validated and enable pathologists with varying experience to establish similar performance in fibrosis evaluation. This has important implications in the development of drugs for NASH treatment.

FRI069

PRO-C3 based sequential algorithm can screen high-risk NASH and severe fibrosis in asian NAFLD population

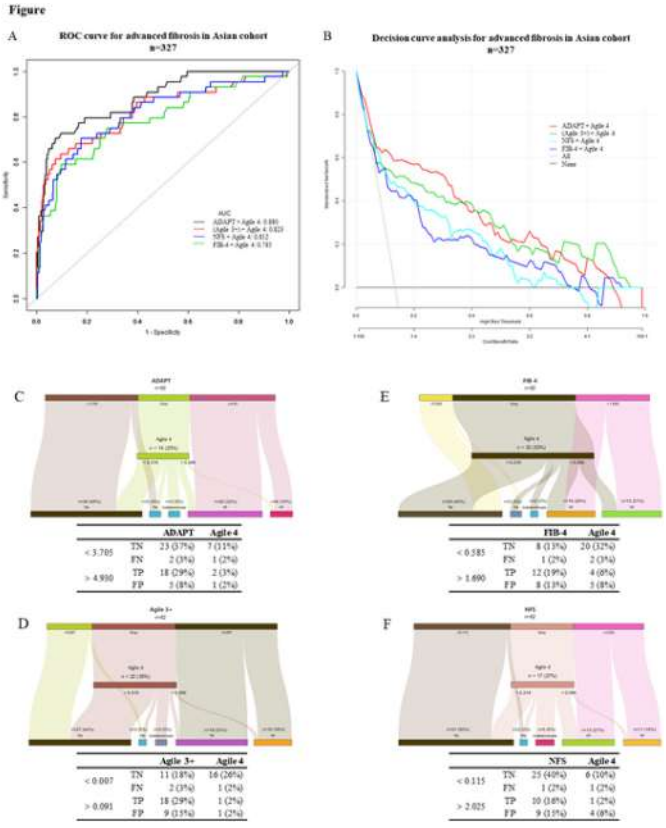
Liang-Jie Tang[1], Gang Li[1], Mohammed Eslam[2], Pei-Wu Zhu[3], Sui-Dan Chen[4], Howard Ho-Wai Leung[5], Ou-Yang Huang[1], Grace Lai-Hung Wong[6,7], Yu-Jie Zhou[8], Morten Karsdal[9], Diana Leeming[9], Chris Byrne[10], Giovanni Targher[11], Jacob George[2], Vincent Wai-Sun Wong[6,7], Ming-Hua Zheng[1,12,13]. *[1]The First Affiliated Hospital of Wenzhou Medical University, NAFLD Research Center, Department of Hepatology, Wenzhou, China; [2]Westmead Hospital, Westmead, and University of Sydney, Storr Liver Centre, Westmead Institute for Medical Research, Sydney, Australia; [3]The First Affiliated Hospital of Wenzhou Medical University, Department of Laboratory Medicine, Wenzhou, China; [4]The First Affiliated Hospital of Wenzhou Medical University, Department of Pathology, Wenzhou, China; [5]The Chinese University of Hong Kong, Department of Anatomical and Cellular Pathology, Hong Kong, China; [6]The Chinese University of Hong Kong, Department of Medicine and Therapeutics, Hong Kong, China; [7]The Chinese University of Hong Kong, State Key Laboratory of Digestive Disease, Hong Kong, China; [8]Shanghai Jiao Tong University, Division of Gastroenterology and Hepatology, Key Laboratory of Gastroenterology and Hepatology, Shanghai, China; [9]Nordic Bioscience Biomarkers and Research A/S, Herlev, Denmark; [10]University Hospital Southampton, Southampton General Hospital, Southampton National Institute for Health Research Biomedical Research Centre, Southampton, United Kingdom; [11]University and Azienda Ospedaliera Universitaria Integrata of Verona, Section of Endocrinology, Diabetes and Metabolism, Department of Medicine, Verona, Italy; [12]Wenzhou Medical University, Institute of Hepatology, Wenzhou, China; [13]Key Laboratory of Diagnosis and Treatment for the Development of Chronic Liver Disease in Zhejiang Province, Wenzhou, China*
Email: zhengmh@wmu.edu.cn

Background and aims: With non-alcoholic fatty liver disease (NAFLD) incidence and prevalence increasing, there is an urgent

need for non-invasive diagnostic tests to accurately screen high-risk patients for liver inflammation and fibrosis. We evaluated the diagnostic performance of a new sequential algorithm for assessing liver inflammation and fibrosis in NAFLD.

Method: Data from two prospective Asian cohorts (327 biopsy-confirmed patients with NAFLD [262 from Wenzhou, 65 from Hong Kong]) were studied. The area under the receiver operating characteristic curve (AUROC) was used to test the diagnostic performances of FAST, ADAPT, Agile 3+ and Agile 4, and for comparison with other widely used non-invasive fibrosis scores.

Results: For progressive non-alcoholic steatohepatitis (NASH) patients (NASH + NAFLD activity score (NAS) ≥4 + F ≥2), the AUROC of FAST score was 0.801 (95% confidence interval (CI): 0.739–0.863), and the negative predictive value (NPV) was 0.951. For advanced fibrosis (F3) and cirrhosis (F4), the AUROC of ADAPT, Agile 3+ and Agile 4 were 0.879 (95% CI: 0.825–0.933), 0.805 (95% CI: 0.725–0.886) and 0.943 (95% CI: 0.892–0.994), and the NPV was 0.972 and 0.992, respectively. A new sequential algorithm of ADAPT + Agile 4 combination was better than other combinations (AUROC = 0.88, 95% CI: 0.824–0.935). This new combination algorithm approach can more accurately screen out high-risk patients (i.e. the number of true positive (TP) groups has increased from 21%, 26%, and 31% to 32%), while reducing the number of patients requiring liver biopsy (including false positive (FP)), false negative (FN) and indeterminate groups from 29% and 26% to 20%) (Figure). At the same time, in all subgroup analyses (stratifying by sex, age, diabetes, NAS, BMI and ALT), ADAPT + Agile 4 had good diagnostic performance.



Conclusion: The new sequential algorithm reliably assesses inflammation and fibrosis in NAFLD patients, making it easier to exclude low-risk patients and recommending high-risk patients for referral treatment, while reducing the need for liver biopsy.

FRI070

Real-world use of the FIB-4 calculator in primary care workflows to screen for advanced non-alcoholic fatty liver disease in a large US health system

George Therapondos[1], Anna Thomas[2], Douglas T. Dieterich[3], Nigel Girgrah[1], Philip Oravetz[4]. *[1]Ochsner Health, Multiorgan Transplant, New Orleans, United States; [2]NASHNET; [3]Icahn School of Medicine, Department of Medicine, New York, United States; [4]Ochsner Health, Population Health, New Orleans, United States*
Email: gtherapondos@ochsner.org

Background and aims: Non-alcoholic fatty liver disease (NAFLD) affects about 25% of the global population. Early identification is needed to appropriately direct patients to expected new therapies. Ochsner Health is a large health system located in Louisiana, USA. The FIB-4 calculation was integrated into the Ochsner Health electronic health record (EHR) to better understand the burden of disease and real-world implications of its use for NAFLD.

Method: The FIB-4 calculation was integrated within the EPIC EHR in Summer 2021 but is not yet available for use by primary care providers. The data presented here are aggregated for exploratory analyses to understand the impact of its use in primary care. The following FIB-4 cut offs were used: if FIB-4 ≥2.67, then high-risk; if FIB-4 from 1.0-2.67 and below 35 years or 1.3–2.67 and 35 to 65 years, or 2.0–2.67 and above 65 years, then medium risk; if FIB-4 <1.0 and below 35 years or <1.3 and 35 to 65 years or below 2.0 and over 65 years, then low risk. Data from 2016–2021 were aggregated and a provider-facing dashboard was generated to show patient demographics, comorbidities and FIB-4 scores.

Results: Out of 606, 906 patients, FIB-4 scores were able to be calculated in 283, 880 (46.77%) of these patients. Average age was 52.4 years (60.23% male, 29.71% female). 53.05% identified as White/Caucasian, 37.22% as African American/Black, 0.50% as Asian, and 3.50% as Hispanic or Latino. Prevalence of comorbidities was as follows: obesity (43.45%), diabetes (26.01%), hypertension (24.16%), heart disease (21.83%), hypercholesterolemia/hyperlipidemia (16.21%), and renal disease (9.27%). 60.51% of the total population had two or more comorbidities. Rates of comorbidities amongst the 50 lowest income zip codes in Louisiana were significantly higher than the general population.

20, 013 patients were classified as high-risk for advanced liver fibrosis, and 55, 265 were classified as medium risk. However, only 2.46% of the total population had been referred to hepatology. This trend remained true across multiple subpopulations, including patients with obesity (11.45% were medium/high-risk, 2.35% actually referred), diabetes (9.75% were medium/high-risk, 3.25% referred), heart disease (8.92% were medium/high-risk, 3.24% referred), hypercholesterolemia/hyperlipidemia (6.57% were medium/high-risk, 4.65% referred) and hypertension (9.39% were medium/high-risk, 3.23% referred).

Conclusion: The gap in patients classified as medium and high-risk to the actual rate of referral to hepatology suggests that many patients at-risk for NAFLD are not being identified. This study identified 75, 278 patients who need further hepatology investigation. The implications of this large number of NAFLD patients on the delivery of liver services needs to be further investigated. Additional analysis is needed to understand the impact of health disparities on NAFLD patients.

FRI071

In silico identification and validation of plasma Ficolin-2 (FCN-2) as non-invasive biomarker of fibrosis in Non-alcoholic Fatty Liver Disease (NAFLD)

Pablo J. Giraudi[1], Noel Salvoza[1,2,3], Natalia Rosso[1], Claudio Tiribelli[1], Deborah Bonazza[4], Biagio Casagranda[5], Nicolo de Manzini[5,6], Michela Giurucin[5], Silvia Palmisano[6,7]. *[1]Fondazione Italiana Fegato Onlus, Basovizza, Italy; [2]University of Trieste, Trieste, Italy; [3]Philippine Council for Health Research and Development, Taguig, Philippines; [4]Cattinara Hospital, Surgical Pathology Unit, Trieste, Italy; [5]Cattinara Hospital, Surgical Clinic Division, Trieste, Italy; [6]University of Trieste, Department of Medical, Surgical and Health Sciences, Trieste, Italy; [7]Cattinara Hospital, Trieste, Italy*
Email: noel.salvoza@fegato.it

Background and aims: Non-alcoholic fatty liver disease (NAFLD) covers a spectrum of diseases from simple steatosis (SS) to non-alcoholic steatohepatitis (NASH), with a significant risk of progressing to fibrosis. Fibrosis is considered as the most important predictive factor in the prognosis and mortality of NAFLD patients. Liver biopsy is widely accepted as the gold standard for its diagnosis and reliable non-invasive methods are unavailable. We investigated the diagnostic performance of plasma Ficolin-2 (FCN-2), identified by an *in silico* approach for the diagnosis of fibrosis in NAFLD.
Method: For the *in silico* analysis, a biological network was built to identify proteins related to fibrogenesis using molecular databases and bioinformatic tools. Of the several markers identified, FCN-2 met the criteria as one of the most interesting candidates that follows the fibrotic process aside from being secreted in the plasma. For the validation phase, 76 morbidly obese (MO) subjects with biopsy-proven NAFLD were stratified according to fibrosis stage (minimal F0-F1, n = 43; moderate-advanced F2-F3-F4, n = 33). Plasma FCN-2 levels were determined by enzyme-linked immunoabsorbent assay and the diagnostic performance was assessed.
Results: Although FCN-2 did not differentiate the steatosis stage of NAFLD, plasma FCN-2 levels significantly decreased when liver damage progresses from minimal to moderate/advanced fibrosis ($p < 0.0001$). Interestingly, FCN-2 levels correlated inversely with lobular inflammation ($p = 0.0002$) and portal inflammation ($p = 0.0007$) histological features of NAFLD. When stratified according to sex, the FCN-2 plasma levels are similar between males and females. The diagnostic performance of plasma FCN-2 in detecting F≥2 fibrosis was higher than those of other current fibrosis' indexes (FORNS, FIB-4) (AUROC 0.76, 0.72, and 0.67, respectively). Furthermore, when combined with other tests (GGT and APRI), the score index yield an excellent discrimination power with AUC of 0.80 in identifying advanced fibrosis.
Conclusion: Plasma FCN-2 can be used as potential biomarker for discriminating moderate/advanced from minimal fibrosis in the context of NAFLD. Validation in larger cohorts will be required for its clinical utility. The use of FCN-2 alone or in combination with other tests may provide an alternative to minimize the need for biopsies to detect fibrosis in NAFLD patients.

FRI072

A lower cut-off of liver stiffness measurement (8/13) kPa performs better than Baveno 6 criteria for advanced chronic liver disease in patients with non-alcoholic fatty liver disease

Sagnik Biswas[1], Manas Vaishnav[1], Piyush Pathak[1], Himanshu Narang[1], Shubham Mehta[1], Amit Goel[2], Shalimar[1]. *[1]All India Institute of Medical Sciences, New Delhi, Gastroenterology and Human Nutrition, New Delhi, India; [2]Sanjay Gandhi Post Graduate Institute of Medical Sciences, Gastroenterology, Lucknow, India*
Email: drshalimar@yahoo.com

Background and aims: Patients with ≥F3 fibrosis are grouped as compensated advanced chronic liver disease (cACLD). Baveno six consensus recommended the rule in and out liver stiffness measurement (LSM) cut-offs for diagnosing compensated advanced chronic liver disease (cACLD) as 10 kPa and 15 kPa. Baveno seven suggested lowering the cACLD cut-off for NAFLD, though it is supported by scanty data. We aimed to identify the LS cut-off for cACLD in people with non-alcoholic fatty liver disease (NAFLD).
Method: Included 330 patients with biopsy proved NAFLD (male 173 [52.4%]; age, median [interquartile range] 39 [33–47] years; body mass index 32.6 (25.6–44.4) kg/m^2); diabetes 102 (30.9%). All the LS measurements were done by a single operator, after overnight fasting using a standard measurement technique. All the LS measurements were done within four weeks of liver biopsy.
Results: Liver biopsy revealed ≥F3 fibrosis, i.e., cACLD, in 70 (21.2%). Measured LS were <10, 10 to <15 and ≥15 kPa in 230 (69.7%), 46 (13.9%) and 54 (16.4%), respectively. Baveno six criteria achieved a sensitivity (rule out) and specificity (rule-in) of 72.9% and 93% for cACLD. The area under receiver operator characteristic (AUROC) curve of LSM for predicting cACLD was 0.862 (0.810–0.914). The LS <8, 8 to 13, and >13 kPa were present in 182 (55.2%), 82 (24.8%) and 66 (20.0%), respectively. A new cut-off at 8 KPa and 13 KPa showed sensitivity and specificity of 90% each. Univariate analysis identified age, diabetes, and LS as independent predictors of cACLD, but platelet count and albumin were not statistically significant. On multivariate analysis, only LS (OR, 1.201, 95% CI, 1.139–1.267) and diabetes (OR, 2.592, 95% CI, 1.298–5.179) were independent predictors of cACLD. The AUROC for the model with LSM and diabetes was 0.863 compared with 0.862 for LSM alone (Delong test, P = 0.934). The AUROC for predicting cACLD with BMI <25 kg/m^2 and ≥25 kg/m^2 was 0.945 (0.886–1.000) and 0.844 (0.784–0.904), respectively.
Conclusion:LS cut-offs set at <8 and >13 kPa perform better to diagnose cACLD than the Baveno 6 criteria. The presence of diabetes and body mass index needs to be accounted for while interpreting the cut-offs.

FRI073

High prevalence of multi-organ steatosis and fibroinflammation, identified by multi-parametric magnetic resonance imaging, in people with type 2 diabetes

Nicole Eichert[1], Karyna Gibbons[2], Azlinda Hamid[3], Vashist Deelchand[4], Jinny Woolgar[1], Rob Suriano[1], Helena Thomaides-Brears[1], Rajarshi Banerjee[1], Graham Kemp[5], Sarah Ali[4], Gaya Thanabalasingham[2], Daniel Cuthbertson[3,5]. *[1]Perspectum Ltd., Oxford, United Kingdom; [2]Oxford University Hospitals NHS Foundation Trust, Oxford Centre for Diabetes, Endocrinology and Metabolism; [3]Liverpool University Hospitals NHS Foundation Trust, University Hospital Aintree, United Kingdom; [4]Royal Free London NHS Foundation Trust, United Kingdom; [5]University of Liverpool, United Kingdom*
Email: nicole.eichert@perspectum.com

Background and aims: Type 2 diabetes (T2D) is a multi-system disease characterized by a high prevalence of micro- and macro-vascular complications, like diabetic nephropathy and cardiovascular disease, and co-morbidities, like metabolic-associated fatty liver disease. These are often only detected at a late stage, particularly when they become clinically manifest. Early detection provides a window to potentially prevent and reverse disease progression, and improve outcomes. The aim of this study was to provide comprehensive assessment of multi-organ health and pre-clinical detection of diabetes-related organ damage with a single, efficient, 30 min non-contrast magnetic resonance imaging (MRI) scan in patients with T2D.
Method: Overall, 138 adults with T2D [62 yr (54–70); 60% male; BMI of 31 kg/m^2 (28–35); HBa1c 60 mmol/L (51–70); 92% on metformin, T2D duration 11 yr (6–11)] were recruited to the MODIFY study (*NCT04114682*). MRI data were acquired to derive organ-specific measures of size, fat deposition, fibroinflammation, body composition (visceral adipose tissue, VAT; subcutaneous adipose tissue, SAT; skeletal muscle index, SMI) and aortic distensibility (CoverScan®, Perspectum Ltd.). Normative values of MRI metrics were based on 92

healthy volunteers [44 yr (32–53); 66% male; BMI 23 kg/m^2 (21–25)] and published literature, and the prevalence of abnormalities for each organ was assessed using Fisher's exact tests. Statistical significance of co-prevalence was assessed by simulation assuming that values were independently binomially distributed.

Results: In this cohort of established T2D patients, characterised by abnormal body composition (high SAT and VAT, low SMI), there was a high prevalence of multi-organ abnormality (86% with at least 2 organs affected). There was evidence of fatty infiltration and/or fibroinflammatory changes in the liver (72% of patients), co-occurring with abnormality in pancreas (38%), spleen (44%), kidney (64%), and aorta (71%). High-risk non-alcoholic steatohepatitis (NASH) was significantly more prevalent in the obese ($p < 0.005$). Prevalence of low SMI and elevated pancreatic fat were associated with duration of T2D ($p < 0.05$). Aortic stiffness was significantly associated with organ steatosis ($p < 0.05$, Figure).

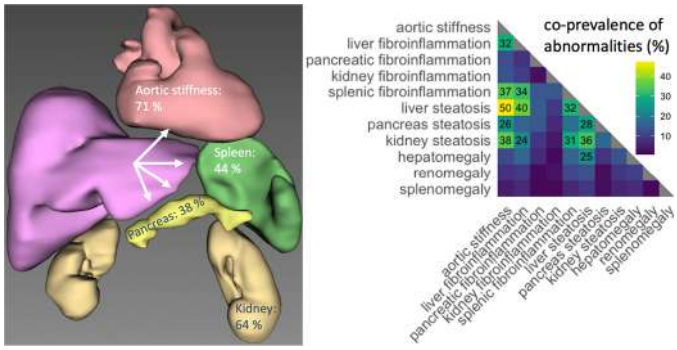


Figure: Left: Co-prevalence of organ abnormality in T2D patients with liver abnormality. Right: Co-prevalence of all abnormalities; pairs with co-prevalence exceeding the significance threshold for association indicated by numeric values.

Conclusion: Elevated levels of fat and fibroinflammation were highly prevalent in the liver, pancreas, spleen, and kidney with evidence of atherosclerosis and sarcopenia in most patients with T2D. The use of glucose-lowering therapies associated with weight loss, such as GLP-1 receptor agonists and SGLT2 inhibitors, are likely to have a beneficial effect on mobilising ectopic fat.

FRI074

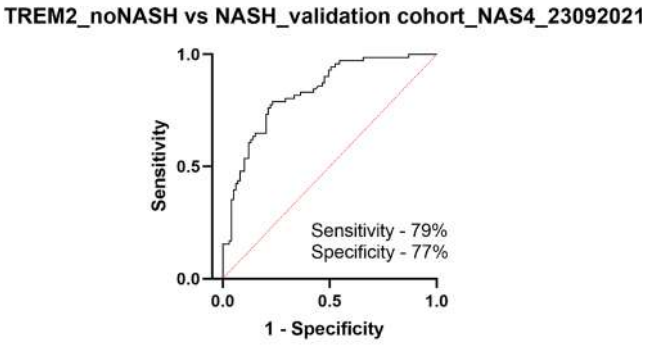
Plasma TREM2, a novel non-invasive biomarker for diagnosis of NASH in NAFLD patients with elevated liver stiffness

Charlotte Wernberg[1,2], Vineesh Indira Chandran[3], Mette Lauridsen[2], Frederik Larsen[4], Maria Kløjgaard Skytthe[3], Camilla Dalby Hansen[1], Majken Siersbæk[4], Tina Di Caterino[5], Sönke Detlefsen[5], Yaseelan Palarasah[3], Kim Ravnskjaer[4], Lars Groentved[4], Søren Kragh Moestrup[3], Maja Thiele[1], Jonas Graversen[3], Aleksander Krag[1]. *[1]Odense University Hospital, Centre for Liver Research, Department of Gastroenterology and Hepatology, Odense, Denmark; [2]University Hospital of South Denmark, Department of Gastroenterology and Hepatology, Esbjerg, Denmark; [3], Department of Molecular Medicine, Odense C; [4]University of Southern Denmark, Department of Biochemistry and Molecular Biology, Odense, Denmark; [5]Odense University Hospital, Department of Clinical Pathology, Odense, Denmark*
Email: charlotte.wilhelmina.wernberg@rsyd.dk

Background and aims: Non-invasive markers of non-alcoholic steatohepatitis (NASH) is still an unmet clinical need, but also represent a key barrier in NASH clinical trials. Here we investigate the diagnostic accuracy of soluble plasma Triggering Receptor Expressed on Myeloid cells 2 (plasma TREM2) as a circulating biomarker for NASH in patients with NAFLD and elevated liver stiffness.

Method: A cross-sectional design with a derivation (n = 48) and a validation cohort (n = 170) among patient with suspected NAFLD, a valid liver biopsy and liver stiffness measure (LSM) >7.9 kPa, was applied. Soluble TREM2 in plasma was measured by quantitative immunoassay. Since patients with low fibrosis score are not eligible for clinical trials, we excluded patients with LSM <8.0. At risk NASH was defined as patients with non-alcoholic fatty liver disease (NAFLD) activity score (NAS) ≥4.

Results: Plasma TREM2 levels were significantly elevated in the derivation cohort in at-risk NASH patients with NAS≥4 as compared with NAS<4 subjects, with an area under the receiver operating characteristics curve (AUROC) 0.92 (95% CI: 0.84–0.99). Plasma TREM2 level was 2.1-fold increased in at-risk NASH patients and a strong diagnostic accuracy was confirmed in the validation cohort with an AUROC 0.83 (95% CI: 0.77–0.89, $p < 0.0001$). TREM2 level was associated with histologic features i.e., steatosis, lobular inflammation, and ballooning ($p < 0.0001$) but not fibrosis. Clinical cut-offs for rule-in and rule-out (90% sensitivity and 90% specificity) were settled and TREM2 values <38 ng/ml was found to be the optimal rule-out cut-off (sensitivity 90%, specificity 51%) whereas TREM2 level >65 ng/ml was the optimal rule-in cut off for at-risk NASH (sensitivity 89.9% and specificity 52%).



Area	0.8306
Std. Error	0.03105
95% confidence interval	0.7698 to 0.8915
P value	<0.0001

Conclusion: Plasma TREM2 is a promising novel blood-based single biomarker that can rule out or rule in presence of NASH with high accuracy.

FRI075

Unbiased clustering of exhaled breath profiles in metabolic dysfunction-associated fatty liver disease identifies a patient phenotype at higher risk of disease progression

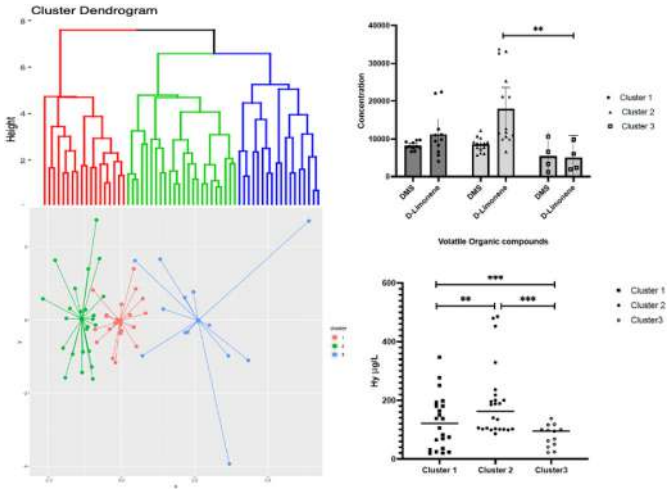
Rohit Sinha[1], Paul Brinkman[2], Khalida Ann Lockman[1], Alan Jaap[3], Peter Hayes[1], John Plevris[1]. *[1]Hepatology Laboratory and Centre of Liver and Digestive Diseases, The University of Edinburgh, Edinburgh, United Kingdom; [2]UMC Amsterdam, The Department of Respiratory Medicine, Amsterdam, Netherlands; [3]Edinburgh Centre for Endocrinology & Diabetes, Royal Infirmary of Edinburgh, Edinburgh, United Kingdom*
Email: rohit.sinha@nhs.net

Background and aims: Human breath contains numerous volatile compounds which reflect the metabolic activity. Electronic nose (eNose) technology can distinguish metabolic dysfunction-associated fatty liver disease (MAFLD) from healthy with reasonable confidence [1, 2]. We hypothesised breath prints obtained from eNose could identify patient subgroups at higher risk for progression within the MAFLD spectrum.

Method: The study was a prospective single-centre cohort study (ClinicalTrials.gov: NCT02950610). eNose is a custom-made device made up of five-sensor arrays, each containing four sensors, previously validated in respiratory and liver disease [1, 3]. eNose on the exhaled breath was performed on well characterised MAFLD patients (n = 60)-Child's A MAFLD cirrhotics (n = 30) and non-

cirrhotic MAFLD (n = 30), previously described [1]. Data were analysed using R studio (v 2.3.2) and SPSS 21. An unbiased machine learning clustering technique was applied. First hierarchical ward clustering, combined with similarity profile analysis, was used to assess the number of significant cluster groups. Between-cluster comparisons and Games-Howell post hoc analyses of clinical variables at baseline were performed using the Kruskal-Wallis test for continuous data and the chi-square test for categorical data.

Results: Data reduction to 3 principal components (PCs) explained 97.8% of the total variance. Three groups of patients with MAFLD disease were delineated solely based on their exhaled breath profiles. Three clusters were identified; cluster 1 consists of 23 patients, cluster 2 consists of 24 patients, and cluster 3 consists of 13 patients. The clusters were comparable in clinical phenotyping. Cluster 2 was identified as a higher risk group with significant differences in serum hyaluronic acid levels ($p = 0.001$), endoscopic evidence for portal hypertension ($p = 0.003$) and exhaled breath concentration of dimethyl sulphide ($p = 0.041$) and D-limonene ($p = 0.015$).



Conclusion: This study shows that unbiased clustering of exhaled breath profiles captured using eNose technology identifies three phenotypes within the MAFLD spectrum. One of the three clusters included most patients with more advanced liver disease. These results warrant prospective studies on the potential of exhaled breath fingerprinting using eNose technology as point-of-care diagnostics in the surveillance of patients with established metabolic dysfunction-associated fatty liver disease.

FRI076

The pericellular basement of the hepatocytes is highly affected by bariatric surgery in obese patients with non-alcoholic fatty liver disease

Ida Lønsmann Lønsmann[1,2], Pierre Bel Lassen[3,4], Diana Leeming[2], Morten Karsdal[2], Mette Juul Nielsen[2], Karine Clément[3,4]. *[1]University of Southern Denmark, Faculty of Health Research, Odense, Denmark; [2]Nordic Bioscience A/S, Biomarkers and Research, Herlev, Denmark; [3]Sorbonne Université, INSERM, Paris, France; [4]Assistance Publique Hôpitaux de Paris, Nutrition Department, Paris, France*
Email: Ilc@nordicbio.com

Background and aims: Bariatric surgery decreases the severity of non-alcoholic fatty liver disease (NAFLD) in patients with severe obesity by improving liver histology and liver function tests. Nevertheless, there is a need for non-invasive biomarkers for monitoring treatment efficacy in NAFLD. The extracellular matrix (ECM) of the liver is subject to major changes during disease progression. The ECM basement membrane (BM) consists of mainly type IV collagen produced by hepatocytes. Changes in BM has been associated with early liver injury, repair mechanisms and pericellular fibrosis. The aim of this study was to investigate changes in biomarkers targeting two distinct epitopes reflecting BM remodeling of type IV collagen (PRO-C4 and C4M) after bariatric surgery (BS) as well as in relation to baseline liver histology.

Method: 60 weight stable patients with severe obesity (BMI >35 kg/m^2) were examined at baseline and 12 months after BS-induced weight loss. Liver biopsies were performed during BS. Serological levels of PRO-C4 and C4M were measured using competitive ELISAs and change from baseline to 12-months follow-up were evaluated using a linear mixed effect model adjusted for type of surgery. Linear regression models adjusted for age, sex, BMI and type 2 diabetes were used to evaluate the association of PRO-C4 and C4M with hepatocyte ballooning, steatosis, lobular inflammation and fibrosis at baseline.

Results: The cohort consisted of 56.7% females with a mean age of 46 and BMI of 49.0 kg/m^2. 66.7% of the patients were F2. Interestingly, baseline levels of both PRO-C4 and C4M decreased with increasing hepatocyte ballooning ($p < 0.0001$) and PRO-C4 decreased with increasing lobular inflammation ($p = 0.022$), while this association was borderline significant for C4M ($p = 0.055$). No significant associations were observed for collagen type IV remodeling with liver steatosis or fibrosis at baseline. Furthermore, median PRO-C4 and C4M levels decreased significantly from baseline to 12-months post BS by 21% ($p = 0.01$) and 14% ($p < 0.001$), respectively.

Conclusion: Hepatocytes are embedded in the BM, and changes in hepatocyte health is reflected by remodeling of the adjacent ECM. This study shows that BM remodeling is associated with liver histopathology. Consequently, serological biomarkers of type IV collagen remodeling could be used as markers of treatment efficacy in NAFLD patients.

A re-appraisal of the diagnostic performance of ultrasonography for fatty liver disease

Chul-min Lee[1], Eileen Yoon[2], Jonghyun Lee[3], Mi Mi Kim[1], Bo-Kyeong Kang[1], Dae Won Jun[2], Hyunwoo Oh[4], Hyo Young Lee[4], Sang Bong Ahn[5], Joo Hyun Sohn[6], Huiyul Park[7]. *[1]Hanyang University College of Medicine, Department of Radiology, Seoul, Korea, Rep. of South; [2]Hanyang University College of Medicine, Department of Medicine, Seoul, Korea, Rep. of South; [3]Hanyang University College of Engineering, Department of Medical and Digital Engineering, Seoul, Korea, Rep. of South; [4]Uijeongbu Eulji Medical Center, Department of Medicine, Gyeonggi-do, Korea, Rep. of South; [5]Nowon Eulji Medical Center, Eulji University School of Medicine, Department of Medicine, Seoul, Korea, Rep. of South; [6]Hanyang University Guri Hospital, Department of Medicine, Gyeonggi-do, Korea, Rep. of South; [7]Uijeongbu Eulji Medical Center, Department of Family Medicine, Gyeonggi-do, Korea, Rep. of South*
Email: bluefish010@naver.com

Background and aims: Previous studies showed that ultrasonography (USG) has high specificity but low sensitivity for diagnosing fatty liver. Especially, the diagnostic performance of USG for mild fatty is low. We tried to re-appraisal the diagnostic performance of USG for fatty liver disease at this point.

Method: We performed a retrospective, multi-nation, multi-center, cross-sectional, and observational study. We included subjects who underwent both the USG and magnetic resonance proton density fat fraction (MR PDFF) within the six-month interval. The diagnostic performance of USG for fatty liver was evaluated as MR PDFF reference standard using sensitivity, specificity, positive and negative predictive value (PPV and NPV), diagnostic accuracy, and area under the receiver operating characteristics curve (AUC).

Results: We included a total of 5056 subjects in this study. The USG showed a sensitivity of 89.1%, specificity of 81.0%, and AUC of 0.850 for diagnosing any fatty liver (MR PDFF ≥6.5%). Furthermore, the sensitivity, specificity, and AUC of USG for diagnosing mild fatty liver (6.5%≤MR PDFF ≤14%) were 83.4%, 81.0%, and 0.822,

respectively. The mean hepatic fat contents on MR PDFF were significantly different according to the USG fatty liver grading ($p < 0.05$). There was acceptable inter-institution variability of USG for diagnosing fatty liver among six centers.
Conclusion: The USG showed good diagnostic performances for any fatty liver and mild fatty liver, higher than previously known.

Email: mazen.noureddin@cshs.org

Background and aims: The American Association for the Study of Liver Disease does not recommend screening for non-steatohepatitis (NASH) among patients with type 2 diabetes (T2DM) while the European Association of the liver (EASL) recommends screenings. Both organizations have called for cost effective analysis (CEA) which has been recently published from the US population. Our aim was to assess the value of screening for NASH with significant fibrosis (fibrotic NASH) in five separate European populations.
Method: We performed cost-utility analyses of four separate fibrotic-NASH screening strategies using third-party, public sector payer perspectives for five European countries, each for two separate hypothetical populations initially aged 55 years with either T2DM and fibrotic-NASH, or fibrotic-NASH and no T2DM, and compared it to the strategy of not screening these populations for fibrotic-NASH. Screening methods involved combinations of Fibrosis-4 (FIB-4) followed by Fibroscan® or liver biopsy for detecting fibrotic NASH indicated per recent EASL guidelines. An incremental cost-effectiveness ratio (ICER) of ≤50, 000 local currency units per incremental quality-adjusted life year was considered cost-effective.
Results: When screening T2DM+ fibrotic-NASH patients aged 55 years first with FIB-4 followed by Fibroscan®, and then treating detected fibrotic NASH patients with an intensive lifestyle intervention, this is shown to be a cost-effective strategy in all of the country-specific analyses when compared to not screening these patients (Figure 1). These outcomes hold steady both in the base case assessment and in the sensitivity analyses of the model. Screening approaches involving liver biopsy were found non cost-effective in all studied countries. The results have not changed when we assessed the analysis starting screening at age 40.

Treatment	Country	Incremental costs	Incremental utilities	Incremental cost effectiveness ratio (ICER)
ILI	UK*	£274	0.0177	£15, 459
	Germany	€90	0.0177	€5, 093
	Italy	-€82	0.0177	-€4, 643
	France	€148	0.0177	€8, 383
	Spain	€109	0.0177	€6, 153

*'UK' denotes England and Wales National Health Service (NHS)

Figure: Base case results when screening T2DM+ Fibrotic NASH patients aged 55 years

Conclusion: Screening for fibrotic-NASH in T2D persons over the age of 55 as well as younger patients (over 40 years) is cost effective in European countries. Given the increasing burden of NAFLD/NASH and the expected approved medications, we recommend screening patients with T2D for fibrotic-NASH in Europe.

FRI079
Free Light Chains as a potential biomarker of inflammation and fibrosis in non-alcoholic steatohepatitis

Email: lig.antonio91@gmail.com

Background and aims: Non-alcoholic fatty liver disease (NAFLD) is the most common chronic liver disease worldwide. Almost 20-30% of NAFLD patient develop steatohepatitis (NASH) characterized by hepatocyte ballooning, lobular inflammation and progressive fibrosis. Inflammation process in NASH is known to be associated with overexpression of pro-inflammatory biomarkers (IL1-beta, IL6, TNF-alfa).
Polyclonal free light chains (FLC) reflect B cell activation and could give insight into the activity of the adaptive immune system in a variety of inflammatory conditions. The aim of this study is to evaluate the potential role of FLC as biomarker of inflammation and fibrosis in NAFLD/NASH.
Method: We enrolled 187 patients with metabolic liver disease at Liver Outpatient clinic at Policlinico A. Gemelli: 48 with NAFLD, 85 with NASH and 54 with cirrhosis. Diagnosis of NASH was histologically assessed. Medical and pharmacological anamnesis, anthropometric measurements and laboratory tests (FLC included, lambda and kappa) were obtained for all patients.
Results: Total FLC (lambda + kappa) were significantly higher in patients with cirrhosis than in patients with NAFLD or NASH (125.2 vs 32.7 mg/L $p < 0.01$). Total FLC, lambda and kappa were higher in NASH patients than in NAFLD although non significantly (respectively 34.5 vs 32.4 mg/L $p = 0.2$, 15.0 vs 13.2 mg/L $p = 0.2$, 19.9 vs 19.1 mg/L $p = 0.8$). In patients with NASH, total FLC are higher in patients with advanced fibrosis (F >2, 39.0 vs 30.3, $p = 0.03$). Total FLC are associated to advanced fibrosis independently from age, sex, BMI and diabetes (OR1.04, CI 1.00-1.08, $p = 0.04$).
Conclusion: In this study we highlight that FLC concentration is significantly higher in patients with cirrhosis than in patients with NAFLD or NASH. In NASH patients, advanced fibrosis is associated with higher serum concentration of total FLC. Serum FLC may represent a useful tool in grading and staging non-alcoholic fatty liver disease.

Email: jadine.scragg@phc.ox.ac.uk

Background and aims: Nonalcoholic fatty liver disease (NAFLD) is associated with inflammation and hepatocellular death, leading to activation of fibroblasts and progressive hepatic fibrosis-the single most important factor determining liver-related clinical outcomes and mortality. A range of non-invasive biomarker tests (NITs) are used in drug trials to measure biological response to therapy including routine biochemistry (ALT, AST), markers of necrosis/apoptosis (CK18-M65), and fibrosis (ELF, PRO-C3, and Fibroscan (VCTE)). Although sustained weight loss >10% has been shown to improve histological fibrosis, little is known about its acute effects on NITs.
Method: 26 non-cirrhotic NAFLD patients were prescribed a 12-week very low calorie diet (VLCD) (800kcal/day). Fasted blood samples were taken at weeks 0, 1, 3, 5, 7, 9 and 12 and VCTE measured at weeks 0 and 12. Routine labs as well as hyaluronic acid (HA), TIMP-1, PIIINP, PRO-C3, PRO-C4, PRO-C5, CK18-M65 were serially measured and ELF, ADAPT and FIB4 scores calculated. Patients were stratified by weight loss at 12 weeks into <5%, 5–7% and >7% of initial body weight and NIT change from baseline assessed.
Results: After 12-weeks VLCD, 4 patients had lost <5%, 4 had lost 5–7% weight and 18 had lost >7% body weight. No significant difference in NIT values were evident between weight loss groups at baseline. Rapid reductions in multiple collagen biomarkers were apparent after a week of VLCD. At 12-weeks, significant reductions in ELF (ANOVA p = 0.040, −5.3 ± 1.8% at >7% weight loss), driven by PIIINP (ANOVA p = 0.004, −23.7 ± 3.9% at >7% weight loss), and CK18-M65 (ANOVA p = 0.023, −43.5 ± 7.6% at >7% weight loss) were seen in patients who lost >7% weight. Similar trends were observed in ALT, AST, PRO-C3, and ADAPT but no difference was seen in FIB4 or VCTE.

Variable	Weight loss group	Baseline NIT value	Significance between baseline NIT values, by weight loss grouping	Percentage change in NIT	Significance of % NIT change from baseline, by weight loss grouping
ELF	<5%	9.4±0.4	0.579	-3.4±2.2	0.040*
	5-7%	9.5±0.2		-2.8±2.5	
	>7%	9.8±0.2		-5.3±1.8*	
PIIINP (ng/ml)	<5%	9.7±1.7	0.787	-14.4±17.4	0.004*
	5-7%	9.8±1.3		-3.6±5.6	
	>7%	10.9±1.0		-23.7±3.9*	
TIMP (ng/ml)	<5%	263.1±11.8	0.941	-4.6±6.9	0.463
	5-7%	260.4±45.4		-8.2±3.5	
	>7%	272.1±17.1		-11.4±2.3	
HA (ng/ml)	<5%	67.2±38.6	0.638	-23.5±12.1	0.232
	5-7%	57.6±10.6		-38.5±29.4	
	>7%	105.6±28.3		-39.8±16.9	
ADAPT	<5%	4.9±0.4	0.190	-6.1±8.4	0.458
	5-7%	5.3±0.6		-10.8±6.0	
	>7%	6.1±0.3		-13.9±2.4	
PRO-C3 (ng/ml)	<5%	11.8±2.6	0.666	-10.6±15.4	0.268
	5-7%	11.6±1.6		-24.5±11.7	
	>7%	13.4±1.1		-27.9±3.4	
M65 (IU/L)	<5%	319.4±153.1	0.159	4.6±10.9	0.023*
	5-7%	203.1±35.9		-4.8±26.3	
	>7%	568.0±96.8		-43.5±7.6*	

Conclusion: A 12-week VLCD intervention induced significant weight loss of a level reported to reduce hepatic fibrosis if sustained. Rapid changes in NITs were observed within a week of commencing VLCD. Significant weight-loss associated improvements in markers of NASH-associated necrosis/apoptosis (CK18-M65), and some but not all markers of fibrogenesis (PIIINP, ELF) were present at week-12. These were of a magnitude similar to those reported in Phase 2 drug trials. Changes occurred too rapidly to reflect a drop in hepatic fibrosis stage, suggesting that NITs are sensitive to changes in disease activity and fibrogenesis that precede fibrosis resolution.

FRI081

Signature of circulating hepatic proteins detects fibrosing-steatohepatitis in progressive non-alcoholic fatty liver disease

Email: olivier.govaere@ncl.ac.uk

Background and aims: Non-alcoholic fatty liver disease (NAFLD) is considered as the hepatic manifestation of the metabolic syndrome and changes in circulating blood proteins have been associated with advanced NAFLD. Yet, it is still unclear which proteins originate from the liver and how these alter during disease progression.
Method: The cohort comprised 256 patients from the European NAFLD Registry with histologically proven NAFLD identified at four specialist centres. The histological semi-quantitative NASH CRN system was used to score the biopsies. 191 plasma and 65 serum samples were processed for proteomics analysis using the SomaScan™ platform. In a subset of 51 cases, snap-frozen liver biopsies underwent high-throughput RNA sequencing (RNAseq). Integrative analysis of these data with publicly available single-cell RNAseq data was used to identify cell of origin. Binary logistic modelling was implemented to predict disease activity.
Results: Comparing patients with advanced fibrosis (F3–4) to mild disease (F0–2) in the discovery cohort of 191 plasma samples identified 156 differentially expressed proteins, while stratifying based on a NAFLD Activity Score (NAS) ≥4 identified 79 proteins. Of these, 34 proteins were common to both analyses, including AKR1B10, APOF, THBS2 and TREM2. To determinate which proteins originate from the liver, we performed a correlation analysis between plasma proteins identified by the F3-4/NAS≥4 analyses and mRNA within 51 patients, finding 40 proteins/mRNAs reaching the significance threshold. Deconvolution by single-cell RNAseq data indicated the different hepatic cellular changes during disease progression, such as *AKR1B10*, *APOF* and *GDF15* to originate from epithelial cells, *ADAMTSL2* and *THBS2* from fibroblasts and TREM2 from macrophages. Finally, to assess potential utility within a non-invasive diagnostic pathway to detect fibrosing-steatohepatitis defined as the presence of NASH, NAS≥4 and F≥2, we performed logistic regression analysis. Backward elimination of variables identified a composite model that could predict NASH+NAS≥4+F≥2 with an Area Under the Curve of 0.878 based on markers including circulating ADAMTSL2, AKR1B10, CFHR4 and TREM2. Performance of the model was validated in a cohort of 65 serum samples with an AUC = 0.851 compared to 0.678 for the FIB4 score.
Conclusion: We showed that circulating proteomic changes reflect grade of steatohepatitis and stage of fibrosis that may be used to assess disease severity.

FRI082

Peripheral blood mononuclear cells mitochondrial copy number and adenosine triphosphate inhibition test in non-alcoholic fatty liver disease

Eileen Yoon[1], Dae Won Jun[1], Sang Bong Ahn[2], Huiyul Park[3], Hyo Young Lee[4], Hyunwoo Oh[4], Chul-min Lee[5], Mi Mi Kim[5], Bo-Kyeong Kang[5], Joo Hyun Sohn[6]. *[1]Hanyang University College of Medicine, Department of Medicine, Seoul, Korea, Rep. of South; [2]Nowon Eulji Medical Center, Eulji University School of Medicine, Department of Medicine, Seoul, Korea, Rep. of South; [3]Uijeongbu Eulji Medical Center, Department of Family Medicine, Gyeonggi-do, Korea, Rep. of South; [4]Uijeongbu Eulji Medical Center, Department of Medicine, Gyeonggi-do, Korea, Rep. of South; [5]Hanyang University College of Medicine, Department of Radiology, Seoul, Korea, Rep. of South; [6]Hanyang University Guri Hospital, Hanyang University College of Medicine, Department of Medicine, Gyeonggi-do, Korea, Rep. of South*
Email: noshin@hanyang.ac.kr

Background and aims: Non-alcoholic fatty liver disease (NAFLD) is known to be associated with mitochondrial dysfunction. The purpose of this study was to develop biomarkers for the assessment of mitochondrial dysfunction in patients with NAFLD.
Method: Mitochondrion-associated transcriptome analysis was performed from the NAFLD and healthy control liver. Peripheral blood mononuclear cells obtained from 88 patients with NAFLD and healthy controls were used to measure mitochondrial DNA (mtDNA) copy number. Mitochondrial inhibition substrate test (ATP assay) was performed in HepG2 cells using patients' serum. Cellular ATP concentration was measured in patient serum was applied at the same quantity as the media.
Results: Hepatic mRNA transcriptome analysis showed that patients with NAFLD exhibited upregulated expression of genes related to mitochondrial tricarboxylic acid (TCA) cycle (E2F1, E2F2, and ORC6) and those related to the mitochondrial envelope (E2F1, MAPK4, and CYP2K6) compared to healthy controls. Gene set enrichment analysis revealed upregulated expression of genes related to the pathways of TCA cycle and DNA replication in patients with NAFLD as compared to that in healthy controls. The mtDNA copy number in the peripheral blood mononuclear cells was 1.28-fold lower in patients with NAFLD than in healthy controls ($p < 0.0001$). Cellular adenosine triphosphate (ATP) concentration decreased 1.2-fold times in NAFLD patients than in healthy controls ($p < 0.0001$). The mtDNA copy number and ATP inhibition test showed negative correlation with degree of hepatic steatosis. And ATP concentration showed positive correlation with mtDNA copy number.
Conclusion: Peripheral blood mononuclear cells mitochondrial copy number and ATP inhibition test can be used biomarkers for the assessment of mitochondrial dysfunction in patients with NAFLD.

Comparison of diagnostic performance between FIB-4 and NFS in metabolic-associated fatty liver disease era

Dae Won Jun[1], Eileen Yoon[1], Sang Bong Ahn[2], Huiyul Park[3], Hyo Young Lee[4], Hyunwoo Oh[4], Joo Hyun Sohn[5], Bo-Kyeong Kang[6], Mi Mi Kim[6], Chul-min Lee[6]. *[1]Hanyang University College of Medicine, Department of Medicine, Seoul, Korea, Rep. of South; [2]Nowon Eulji Medical Center, Eulji University School of Medicine, Department of Medicine, Seoul, Korea, Rep. of South; [3]Uijeongbu Eulji Medical Center, Department of Family Medicine, Gyeonggi-do, Korea, Rep. of South; [4]Uijeongbu Eulji Medical Center, Department of Medicine, Gyeonggi-do, Korea, Rep. of South; [5]Hanyang University Guri Hospital, Hanyang University College of Medicine, Department of Medicine, Gyeonggi-do, Korea, Rep. of South; [6]Hanyang University College of Medicine, Department of Radiology, Seoul, Korea, Rep. of South*
Email: sonjh@hanyang.ac.kr

Background and aims: Fibrosis-4 index (FIB-4) and non-alcoholic fatty liver disease (NAFLD) fibrosis score (NFS) are the two most widely used non-invasive tools for screening of advanced fibrosis in subjects with NAFLD. Since metabolic dysfunction-associated fatty liver disease (MAFLD) has been proposed as a new category of fatty liver disease, we aimed to compare the diagnostic performance of FIB-4 and NFS in subjects with MAFLD and in various subgroups.
Method: This study was designed as cross-sectional study. Data from 6, 775 subjects who underwent magnetic resonance elastography (MRE) and abdominal ultrasonography at the same time during a health check-up at 13 various health check-up centers were retrospectively reviewed. Advanced fibrosis was defined as an MRE value of ≥3.6 kPa.
Results: The area under the receiver operating characteristic curves (AUROCs) of FIB-4 and NFS for diagnosing advanced fibrosis were similar in subjects with MAFLD. However, the AUROC of NFS was lower than that of FIB-4 in the diabetic subgroup of MAFLD (0.809 in FIB-4 vs. 0.717 in NFS, $p = 0.002$). The performances of both FIB-4 and NFS were poor in the subgroup of MAFLD with significant alcohol intake.
Conclusion: The overall diagnostic performance of FIB-4 and NFS for diagnosing advanced fibrosis did not differ among subjects with MAFLD. However, the performance of NFS was lower in the diabetes subgroup of MAFLD. The diagnostic performance of FIB-4 was better for fibrosis in various subgroups of MAFLD.

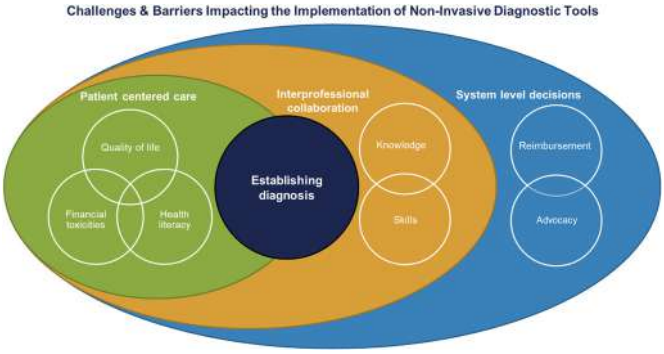
FRI084

Assessing the applicability of non-invasive diagnostic tests (NITs) in non-alcoholic fatty liver disease: an international qualitative study

Maja Thiele[1], Sophie Péloquin[2], Luca Valenti[3], Patrice Lazure[4], Mounia Heddad Masson[5], Alina Allen[6], Jeffrey Lazarus[7], Mazen Noureddin[8], Mary Rinella[9], Frank Tacke[10], Suzanne Murray[2], Emmanuel Tsochatzis[11]. *[1]Center for Liver Research, Odense University Hospital and University of Southern Denmark, Odense, Denmark; [2]AXDEV Group Inc., Canada; [3]Università degli Studi di Milano, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy; [4]AXDEV Group Inc.; [5]EASL, Geneva, Switzerland; [6]Mayo Clinic, Rochester, MN, United States; [7]Barcelona Institute for Global Health (ISGlobal), Hospital Clínic, University of Barcelona, Barcelona, Spain; [8]Cedars Sinai Medical Center, Los Angeles, CA, United States; [9]Northwestern University Feinberg School of Medicine, Chicago, IL, United States; [10]Charité Universitätsmedizin Berlin, Dept. of Hepatology and Gastroenterology, Berlin, Germany; [11]UCL Institute for Liver and Digestive Health, Royal Free Hospital and UCL, London, United Kingdom*
Email: lazurep@axdevgroup.com

Background and aims: The use of non-invasive tests (NITs) in the field of non-alcoholic fatty liver disease (NAFLD), non-alcoholic steatohepatitis (NASH), and advanced fibrosis has the potential to improve patient care by simplifying the diagnostic process, providing comprehensive data, and reducing the need for biopsies. We assessed the challenges to implementation of NITs in Germany, Italy, the United Kingdom, and the United States.
Method: We conducted a two-phase qualitative assessment consisting of interviews (n = 29) followed by an expert workgroup discussion (n = 8). Interviews allowed for exploration of challenges with diabetologists, hepatologists, primary care providers (PCPs), patient advocates, clinical/basic researchers, and healthcare administrators/payers. The expert working group discussion included internationally recognized clinicians and researchers in NAFLD and liver fibrosis from the four selected countries. They were asked to review, validate, and expand on the identified challenges and collaboratively discuss potential solutions. Transcripts from both phases were analyzed thematically.
Results: The main challenges related to the implementation of NITs are shown in Figure 1. First, we identified a lack of awareness about NITs and the importance of early detection of NAFLD, NASH, and advanced fibrosis among PCPs and diabetologists. Second, respondents described a need for NITs with more specificity and for their automation to build effective and efficient referral pathways. Some

first phase participants reported that, in the absence of available therapeutic agents, there was no need for novel diagnostic tools. In the opinion of experts, more effort should be made to demonstrate the impact of early diagnosis through NITs. This would help in enhancing patient motivation for improved metabolic health, slowing or halting disease progression and establishing surveillance for the timely detection or prevention of liver related complications. Liver disease was reported to be of low priority among non-hepatologists. This challenge is unlikely to change unless the cost-effectiveness of the more costly NITs and their impact on patient outcomes can be demonstrated.



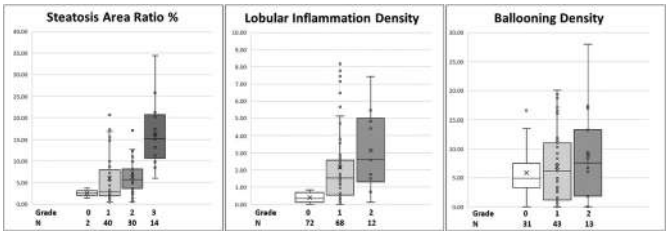
Conclusion: The results of this qualitative study should inform the development of awareness campaigns and targeted educational interventions focused on diagnosis and risk stratification with NITs. This will facilitate early diagnosis and care and help to raise NAFLD as a public health issue.

FRI085

Evaluation of the performance of a novel digital pathology method for the continuous quantification of steatosis, ballooning and inflammation in liver biopsies and its correlation with NASH-CRN scores in patients with NASH

Louis Petitjean[1], Li Chen[1,2], Aras Mattis[3], Mojgan Hosseini[4], Michael Goedken[5], Cynthia Behling[4], Arun Sanyal[6], Mathieu Petitjean[1]. *[1]PharmaNest, Princeton, United States; [2]PharmaNest Inc, Princeton, United States; [3]University of California San Francisco, San Francisco, United States; [4]University of California San Diego, La Jolla, United States; [5]Rutgers University, New Brunswick, United States; [6]Virginia Commonwealth University, Richmond, United States*
Email: mathieu.petitjean@pharmanest.com

Background and aims: We have previously shown that the Phenotypic Fibrosis Composite Score calculated by the FibroNest Quantitative Image analysis and AI methods correlate with the NASH-CRN histological fibrosis stages and steatosis grades established from collagen-stained histology slides. Here, we report the performance of the FibroNest method to quantify Ballooning, Inflammation and Steatosis from digital images of H&E human liver biopsy sections.
Method: This retrospective study comprised a cohort of 87 patients with NASH diagnosed by histologic assessment of liver biopsy according to NASH-CRN criteria with Lobular Inflammation grades of 0 (N = 7), 1 (68), and 2 (12), hepatocyte ballooning grades of 0 (N = 31), 1 (43) and 2 (13), and steatosis grades of 0 (N = 2), 1 (40), 2 (30) and 3 (14). Formalin-fixed, paraffin embedded biopsy sections were H&E stained and imaged with an Operio CS2 scanner at 20X in white light. Quantitative image analysis was performed by FibroNest™ to extract individual features of inflammation (stained nuclei) and tissue texture quantitative layers from the calibrated and normalized images. A subset of 21 representative images was used to develop a machine learning (ML) predictive model using 2.3 K annotations for lobular inflammation, 5.62 K for portal and periportal inflammation, 1.41 for "false" lobular inflammation such as isolated ducts or microscopic necrosis, 1.08 for ballooning and 787 for balloon mimics made by 4 hepatopathologists familiar with the NAS scoring system. The predictive ML model established topographical probability maps for lobular, total inflammation, and hepatocellular ballooning. Confidence thresholds are defined to identify histological features of interest, which are then quantified by several continuous and normalized parameters (biopsy area ration, density count, and 200XFOV normalized count).
Results: The Lobular Inflammation composite score exhibits moderate correlation with the histological grades. Significant disagreement in the assessment of grade 1 lobular inflammation is driven by "confusion" with portal inflammatory features which degrades the specificity between grades 1 and 2 (p = 0.187). The mean values of the Ballooning Density correlate with the histological assessment, but p-values between grades are poor. The mediocre performance of the ML model is driven by the lack of agreement in the annotations provided by pathologists. The steatosis proportion area is in fair agreement with steatosis grades. Disagreement is driven by the fact that the NASH-CRN criteria is based on percent hepatocytes with fat rather than fat area ratio (in full tissue area).



Conclusion: As reported by other teams, liver biopsy Digital Pathology methods based on supervised ML and annotation provided by pathologists (H&E stains, Inflammation, Ballooning) result in continuous quantification methods of moderate performance.

FRI086

Can combination of M2BPGi and APRI help endocrinologists refer patients with advanced hepatic fibrosis to hepatologists?

Mi Mi Kim[1], Bo-Kyeong Kang[1], Chul-min Lee[1], Huiyul Park[2], Hyo Young Lee[3], Hyunwoo Oh[3], Sang Bong Ahn[4], Dae Won Jun[5], Eileen Yoon[5], Joo Hyun Sohn[6]. *[1]Hanyang University College of Medicine, Department of Radiology, Seoul, Korea, Rep. of South; [2]Uijeongbu Eulji Medical Center, Department of Family Medicine, Gyeonggi-do, Korea, Rep. of South; [3]Uijeongbu Eulji Medical Center, Department of Medicine, Gyeonggi-do, Korea, Rep. of South; [4]Nowon Eulji Medical Center, Eulji University School of Medicine, Department of Medicine, Seoul, Korea, Rep. of South; [5]Hanyang University College of Medicine, Department of Medicine, Seoul, Korea, Rep. of South; [6]Hanyang University Guri Hospital, Hanyang University College of Medicine, Department of Medicine, Gyeonggi-do, Korea, Rep. of South*
Email: msbbogri@naver.com

Background and aims: Although the non-invasive tests (NITs, ex. FIB-4, NAFLD fibrosis score (NFS), AST to platelet ratio index (APRI)) are widely used to diagnose advanced hepatic fibrosis, there is a considerable intermediate zone and diagnostic performance decreased in diabetes subjects. The purpose of this study is to figure out whether combination of M2BPGi with various NITs can help endocrinologist screening for advanced hepatic fibrosis in clinic.
Method: A total of 1, 129 subjects visiting endocrinology clinic of tertiary hospital and performed M2BPGi were included (mean age: 53.7 ± 14.8 years). NFS, FIB-4, and APRI were calculated for all subjects. Advanced fibrosis was defined by transient elastography (TE≥8.0 kPa). Sensitivity analysis was also performed.
Results: This study included 426 (37.7%) were diabetes and 703 (62.3%) were non-diabetes who visited the endocrinology

department. Mean age was 53.7 ± 14.8 years. Diagnostic performance of predicting advanced hepatic fibrosis was highest in APRI (the area under the receiver operating characteristics curve (AUROC) = 0.811), followed by M2BPGi (0.720) and FIB-4 (0.718). M2BPGi at a cutoff of 0.8 showed similar diagnostic performance to lower cutoff of other NITs (sensitivity: 72.9% in M2BPGi vs. 77.4–82.8% in other NITs; specificity: 57.3% vs. 43.1–65.9%). Diagnostic performance of APRI in diabetes was comparable to non-diabetes group (0.832 vs. 0.811, P = 0.393). When the combination of M2BPGi (cutoff of 0.8) and APRI (cutoff of 0.5 and 1.5), the sensitivity and specificity for advanced hepatic fibrosis were 67.4% and 80.4% in endocrinology clinic and 68.9% and 79.2% in diabetic subjects, respectively.
Conclusion: Combination of M2BPGi and APRI can help screening for advanced hepatic fibrosis in endocrinology clinic.

FRI087
The relationship between foetal head circumference growth trajectories and nonalcoholic fatty liver disease in adolescents
Jeffrey Lee[1], Ashish Yadav[2], Trevor Mori[2], Rae-Chi Huang[3], Leon Adams[4], Lawrence J. Beilin[2], Elizabeth McKinnon[3], John Olynyk[1], Oyekoya Ayonrinde[1]. *[1]Fiona Stanley Hospital; [2]The University of Western Australia; [3]Telethon Kids Institute; [4]Sir Charles Gairdner Hospital*
Email: jeffreyjlee18@gmail.com

Background and aims: Intrauterine and childhood factors are associated with nonalcoholic fatty liver disease (NAFLD) in adolescents and adults. Previous studies have associated intrauterine growth restriction (IUGR), small for gestational age (SGA) and intrauterine exposures such as smoking in pregnancy, and gestational weight gain, with NAFLD in offspring. Maternal factors and intrauterine influences determine foetal growth patterns and birth weight. Serially measured foetal head circumference (HC) provide a useful measure of foetal growth patterns and IUGR. We aimed to examine associations between foetal HC growth trajectories and subsequent NAFLD during adolescence.
Method: Repeated antenatal ultrasound with foetal morphometry was measured in 1440 pregnant women (Gen1) in the Raine Study, between 16 weeks gestation and delivery. Using standard deviation scores or z-scores for the HC measurements, five foetal HC trajectories were developed (Figure 1). Offspring (Gen2) birth weight was recorded and IUGR, SGA and large for gestational age (LGA) were determined for the live-born neonates. As part of the 17-year follow up of the Gen2 cohort, lifestyle questionnaires, anthropometry, blood tests and liver ultrasound, were performed. A subset of 576 adolescents had both liver ultrasound and foetal ultrasound HC trajectories data.

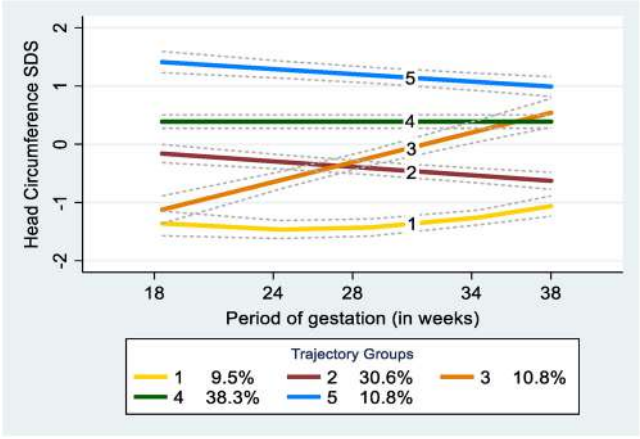


Figure: Head Circumference trajectory groups: 1 Low-stable, 2 Average-falling, 3 Low-rising, 4 Average-stable, 5 High-stable. SDS-standard deviation scores, Dotted lines represent 95% confidence intervals, Percentages represent individual group membership.

Results: NAFLD was diagnosed in 92 of 576 (16%) adolescents (52% male). Adolescents with NAFLD had higher body mass index (BMI), waist circumference, suprailiac skinfold thickness, alanine aminotransferase (ALT), gamma glutamyl transpeptidase, triglycerides, total and low density lipoprotein cholesterol, leptin and Homeostasis Model Assessment for Insulin Resistance (HOMA-IR), but lower high density lipoprotein cholesterol and adiponectin levels compared with those without NAFLD (p < 0.05 for all). Birth weight, gestational age, IUGR, SGA and LGA were not associated with NAFLD. Using multivariable logistic regression analysis, low-stable HC trajectory group 1 (OR 3.54; 95% CI, 1.21–10.35, p = 0.02), suprailiac skinfold thickness (OR 1.09, 95% CI 1.05–1.13, p < 0.001), ALT (OR 1.03, 95% CI 1.01–1.06, p = 0.02) and leptin (OR 1.03, 95% 1.02–1.05, p = 0.001) were associated with NAFLD.
Conclusion: The low-stable HC trajectory associated with a persisting small HC through pregnancy, but not birth characteristics, was associated with increased risk of subsequent NAFLD in adolescents. The association of a low foetal HC trajectory with NAFLD in adolescence supports the Developmental Origins of Health and Disease (DOHaD) hypothesis linking early life events with subsequent disease.

FRI088
Liver stiffness assessed by transient elastography predicts clinical events in patients with T2DM and NAFLD
Jesús Rivera[1], Monica Pons[1], Alejandra Planas[2], Rafael Simo Canonge[2], Jordi Bañeras[3], Ignacio Ferreira[3], Joan Genesca[1], Juan Manuel Pericàs[1]. *[1]Vall d'Hebron Hospital Universitari, Liver Unit, Barcelona, Spain; [2]Vall d'Hebron Hospital Universitari, Diabetes and Metabolism Research Unit, Spain; [3]Vall d'Hebron Hospital Universitari, Cardiology Department, Spain*
Email: jesusriveraest@gmail.com

Background and aims: Non-alcoholic fatty liver disease (NAFLD) and type 2 diabetes (T2DM) are intimately related entities. T2DM is a major predictor of cardiovascular events (CVE) in NAFLD patients, whereas the role of NAFLD on CVE in T2DM as well as the impact of T2DM on liver-related events (LRE) in NAFLD remain poorly known. The aim of this study was to evaluate the role of NAFLD on the onset of clinical outcomes among T2DM patients.
Method: Prospective cohort with case-control analysis comprising 200 T2DM subjects with no history of CV disease (CVD) and 60 non-diabetic subjects matched by age with available transient elastography (TE) data. Patients were selected from the Outpatient Diabetes Clinic of Vall d'Hebron Hospital and the Primary Healthcare centres within its catchment area (North Barcelona). Overall clinical events (CE) were composed by CVE (coronary, cerebrovascular or peripheral arteriopathy), LRE (liver decompensation or hepatocellular carcinoma) and all-cause mortality. NAFLD was defined as Controlled Attenuation Parameter (CAP) ≥275 dB/m and/or Fatty liver index (FLI) ≥60 after exclusion of the other liver diseases and alcohol consumption over 30 gr/day in males and 20 gr/day in females. A value of coronary arterial calcium score (CACs) ≥400 Agatston units (AU) was considered indicative of high risk of CVD. Cox regression analysis to predict CE was performed.
Results: Overall, 34 (18.2%) T2DM patients presented any CE vs 4 (7.0%) controls (p 0.042) during a median follow-up of 5.6 years. Among patients with T2DM and NAFLD (n = 134), 21 (28.4%) CVE were reported, being coronary events the most frequent outcome (11/134; 8.2%). One subject (0.7%) presented LRE and 8 (6%) patients died, 25% of which due to CVD and 37.5% each for malignancy and infectious diseases. T2DM-NAFLD patients with CE showed higher rates of diabetes complications (42.9% vs 22.1%; p 0.04 and 61.9% vs 34.2%; p 0.017 for diabetic retinopathy and nephropathy, respectively), high-risk CVD (CACs ≥400 52.6% vs 19.3%, p 0.002) and higher median liver stiffness (6.7 vs 5.4 kPa, p 0.007) than those without CE. No differences were found between groups in terms of T2DM control (fasting glucose; HbA1c) or metabolic syndrome determinants rates

(high blood pressure or obesity). In Cox analysis, development of clinical events among T2DM-NAFLD patients was associated with a higher liver stiffness (HR = 1.05; 95%CI 1.01–1.09, p 0.003) and male gender HR = 4.02; 95%CI 1.29–12.50, p 0.016). No statistical association was found for diabetes complications or CACs ≥400.

Cox regression analysis			
	Hazard Ratio	**95% CI**	**p**
Liver stiffness	1.05	1.01-1.09	**0.003**
Male gender	4.02	1.29-12.50	**0.016**
Age	1.08	0.99-1.19	0.07
CAC ≥ 400 AU	0.42	0.14-1.19	0.10
Diabetic nephropathy	0.41	0.15-1.11	0.82
Diabetic retinopathy	0.46	0.17-1.24	0.12

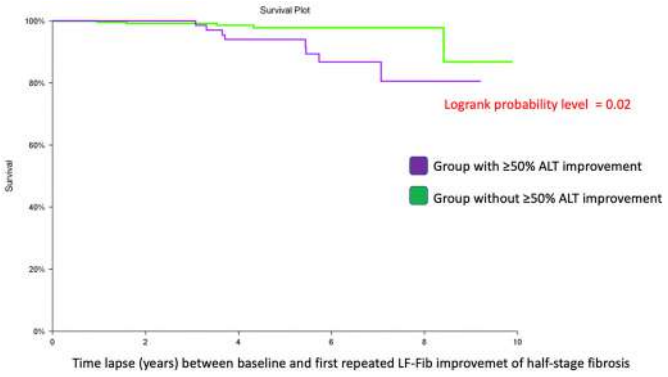
Conclusion: Our results suggest that severity of NAFLD is associated with clinical events in patients with T2DM independently of CV disease or T2DM complications. TE might help stratifying T2DM patients with NAFLD at higher risk of developing clinical events and therefore shall be recommended in all T2DM patients.

FRI089

Repeated noninvasive liver biopsy surrogate LIVERFASt correlates with BMI and liver enzyme improvements

Marie Decraecker[1], Hiriart Jean-Baptiste[1], Marie Irles-Depe[1], Faiza Chermak[1], Juliette Foucher[1], Victor de Lédinghen[1]. [1]*CHU BORDEAUX, Pessac, France*
Email: marie.decraecker@gmail.com

Background and aims: MAFLD-related morbi-mortality is increasing worldwide due to epidemics of obesity and type 2 diabetes (T2D). LIVERFASt (LF, Fibronostics, US) is a new point-of-care proprietary technology to assess quantitatively (score from 0.00 to 1.00) liver fibrosis (LF-Fib) in MAFLD pts, with prognostic value for liver-related events and overall mortality (Hepatology Suppl.2021).
To assess repeated LF-Fib performance for liver fibrosis regression rate (LFR) reflected with significant improvement in clinical endpoints, body mass index BMI≥10% and liver enzymes ALT ≥50% from baseline.
Method: Pts with repeated LF-Fib were prospectively included. Significant improvements in clinical endpoints were: BMI decrease of ≥10% and ALT decrease ≥50% from baseline. Half fibrosis stage improvement was considered with each 0.15 of LF-Fib score. Statistics were descriptive and FPR time dependent using hazard ratios HR (95%CI).
Results: 500 MAFLD patients from a tertiary center were pre-included with LF-Fib at baseline and 401 were included with at least one repeated LF-Fib during follow up; 87 pts had 7 repeated LF-Fib during 9.9 years follow up. 44.3% were female, median (range) age 56 (21–77) yrs, distribution of fibrosis 45%F0, 29%F1, 6%F2, 12%F3 and 8% F4, respectively. 13/401 (3.24%) regressed liver fibrosis as per LF-Fib ≥0.15 from baseline score. 109 (27.2%) patients had an ALT regression of ≥50% from baseline during FU. 75 (18.7%) experienced an improvement in BMI ≥10% during FU. Median LF-FIB was 0.27 and median (range) FU between baseline and last repeated LF-Fib was 3.57 yrs (3–9.9).
Occurrence of half-stage liver fibrosis improvement as per LF-Fib was more probable among those that achieved ALT regression of ≥50% from baseline: Cox Mantel Hazard Ratios [HR (95%CI)] 3.47 (1.08–11.19) versus 0.29 (0.09–0.93) in those without ≥50% ALT decrease (logrank probability level 0.02) (Figure 1).



HR (95%CI) for LF-Fib half-stage improvement (0.15 score) in the group with BMI improvement of ≥10% was 1.78 (0.38–8.39) vs 0.56 (0.12–2.64) in the group that not achieved a BMI improvement of ≥10% (logrank probability level = 0.37).
Conclusion: LF-Fib improvement of half-stage was significantly more prevalent in patients that achieved ALT decrease ≥50% from baseline and a trend was observed in patients that had ≥10% decrease in BMI from baseline. LF-Fib correlates with clinical endpoints and, therefore can be used for long-term monitoring of MAFLD patients.

FRI090

Increased liver stiffness on vibration controlled transient elastography (Fibroscan) as a predictor of all-cause mortality in people with fatty liver disease

Michael Braude[1,2], Ammar Majeed[2,3], Stuart Roberts[2,3], Stephen Bloom[2,4], Paul Gow[5,6], Anouk Dev[1,2], William Sievert[1,2], William Kemp[2,3]. [1]*Monash Health-Clayton Hospital Main Entrance, Gastroenterology and Hepatology, Clayton, Australia;* [2]*Monash University Clayton Campus, Clayton, Australia;* [3]*The Alfred, Melbourne, Australia;* [4]*Eastern Health, Box Hill, Australia;* [5]*Austin Hospital, Heidelberg, Australia;* [6]*Melbourne University-Swanston St, Parkville, Australia*
Email: mrh.braude@gmail.com

Background and aims: Fatty liver disease, which is often asymptomatic and progressive, is a multi-system, condition which is becoming the leading cause of liver-related morbidity, mortality, and liver transplant. Ascertaining liver disease severity is therefore important to guide management and prognosis. Several studies have shown a correlation between mortality and progressive liver fibrosis on both histopathology and blood-based fibrosis predictive tests. We aimed to assess vibration-controlled transient elastography (VCTE) as a predictor of mortality.
Method: VCTE studies for a primary indication of non-alcoholic fatty liver disease (NAFLD) were collated from consecutive outpatients across 4 Australian tertiary referral centres between July 2008 and April 2019. Patients with VCTE data were linked to Victorian Death Index (VDI) and the Victorian Admitted Electronic Dataset (VAED) via the Centre for Victorian Data Linkage (CVDL). Comorbidity data was derived from International Classification of Diseases 10th Revision (ICD-10) coding within the VAED. Cause of death (COD) was analysed using descriptive statistics. Liver stiffness measurement (LSM, kPa) was analysed as a predictor of all-cause mortality using Cox-proportional regression analysis with multivariable adjustment for age, gender, and comorbidities, including the Charlson Comorbidity Index (CCI).
Results: A total of 7079 individual VCTE records were identified, 6341 of which were matched via data linkage, and 5857 were represented in the VAED. The median follow-up period from VCTE to death/censorship was 3.6 (IQR 2.1–5.5, range 0.2–11.0) years. Mean age at VCTE across the 7079-patient cohort was 55.4 ± 13.6 years, median LSM was 6.1 kPa (IQR 4.7–9.3) and mean controlled attenuation

parameter (CAP) (n = 3789) was 287.7 ± 68.7 db/m. In the linked cohort of 6341 patients, 217 deaths occurred during follow-up. Median age of death was 72.3-years (IQR 64.4-79.0). Sepsis (n = 41, LSM 12.0 kpa, IQR 5.8–20.2), followed by decompensated liver disease (n = 33, LSM 32.2, IQR 18.8–49.1) and non-gastrointestinal malignancy (n = 25, LSM 13.9, IQR 6.2–23.9) were the most common primary COD, accounting for 18.9%, 15.2%, and 11.5% of deaths respectively. Hepatocellular carcinoma (HCC) was either a primary or comorbid COD in 8.8% (n = 19, LSM 22.8 kPa, IQR 11.7–31.5) of individuals. CAP was not associated with mortality in univariable analysis (HR = 1.00, CI 1.0–1.0, p = 0.488). In a multivariable analysis, n = 5857 records, increased LSM (HR 1.02, CI 1.01–1.03, p < 0.001), increased CCI (HR 1.32, CI 1.27–1.38, p < 0.001) and advanced age (HR 1.05, CI 1.03–1.07, p < 0.001), but not gender, were associated with increased mortality.

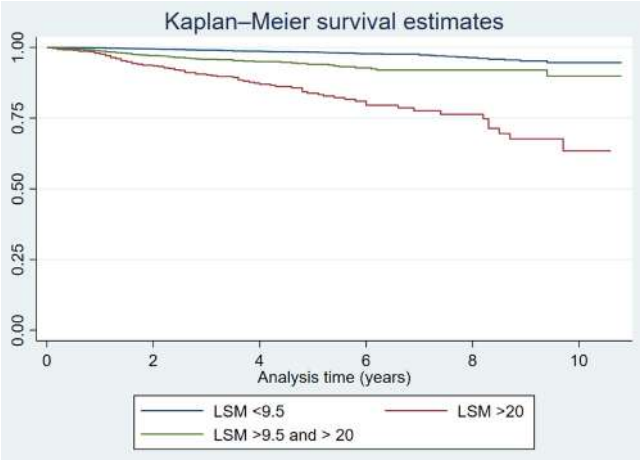


Figure: Kaplan-Meier survival curves based on LSM (kPa).

Conclusion: LSM based on VCTE is independently associated with all-cause mortality in fatty liver disease.

FRI091

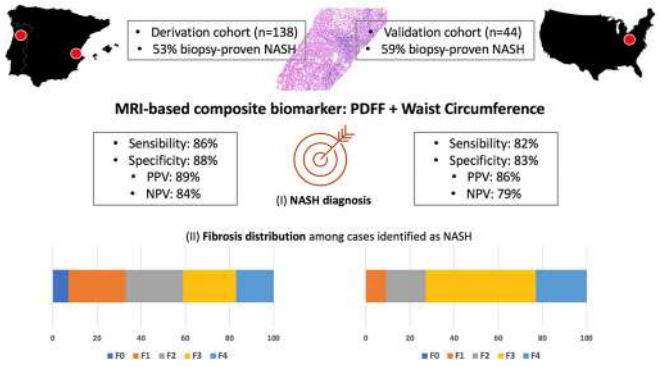
Magnetic resonance imaging-based biomarker accurately identifies patients with nonalcoholic steatohepatitis and significant liver fibrosis: a multicentre, international, validation study

David Marti-Aguado[1], Joud Arnouk[2], Jaideep Behari[2], Alessandro Furlan[3], Ramon Bataller[2], Maria Manuela Franca[4], Ana Gallen[5], Victor Merino[1], Clara Alfaro-Cervello[6], Judith Pérez[7], Salvador Benlloch[5], Victoria Aguilera Sancho[8], Desamparados Escudero-García[1], Ana Jimenez-Pastor[9], Angel Alberich-Bayarri[9], Miguel Serra[1], Luis Marti-Bonmati[9]. *[1]Clinic University Hospital, Valencia, Spain, Department of Gastroenterology and Hepatology, Valencia, Spain; [2]University of Pittsburgh Medical Center (UPMC), Hepatology Department, United States; [3]University of Pittsburgh Medical Center (UPMC), Radiology Department, Pittsburgh, United States; [4]Centro Hospitalar Universitário do Porto, Radiology Department, Porto, Portugal; [5]Hospital Arnau Villanova, Hepatology Department, Valencia, Spain; [6]Clinic University Hospital, Pathology Department, Valencia, Spain; [7]Hospital Universitario y Politécnico La Fe, Pathology Department, Valencia, Spain; [8]Universitario i Politecnic de La Fe, Hepatology Department, Valencia, Spain; [9]Universitario i Politecnic de La Fe , Radiology Department, Valencia, Spain*
Email: davidmmaa@gmail.com

Background and aims: Liver fibrosis is the only histological feature predictive of nonalcoholic steatohepatitis (NASH) progression to cirrhosis and liver-related complications. Currently, the FDA requires the inclusion of patients with biopsy-proven NASH-related fibrosis for therapeutic trials. We aimed to assess the accuracy of simple and available magnetic resonance imaging (MRI) for the detection of NASH with fibrosis.

Method: We performed a cross-sectional international study that included subjects with NAFLD from three countries evaluated between 2017 and 2021. The training cohort included 138 consecutive patients with contemporaneous MRI and biopsy-proven NAFLD from Spain and Portugal and a validation cohort of 44 patients from USA. Patients with Fibrosis-4 index >4.63 and NAFLD fibrosis score >1.57 were excluded due to high pretest probability of cirrhosis (98% specificity). Disease severity was estimated using the histology NAFLD activity score (NAS), defining NASH as NAS≥4 and significant fibrosis as F≥2. Performance parameters of sensitivity, specificity, positive predictive value (PPV) and negative predictive value (NPV) were calculated.

Results: NASH was diagnosed on liver biopsy in 53% of the European and 59% of the US cohorts, while significant fibrosis was found in 50% and 82% patients in the two cohorts, respectively. In the training cohort, MRI-Proton Density Fat Fraction (MRI-PDFF; OR: 1.57; 95%CI 1.31–1.86) and MRI-determined waist circumference (WC; OR: 1.004; 95%CI 1.001–1.007) were imaging biomarkers independently associated with NASH (adjusted for sex, age, height and liver fibrosis). A median MRI-PDFF >11% combined with a WC >96 cm in women and >107 cm in men, showed 86% sensitivity, 88% specificity, 89% PPV and 84% NPV for the diagnosis of NASH. Among patients that were above these cut-offs, 90% had fibrosis and 63% demonstrated significant fibrosis. In the validation cohort, the combined image biomarkers had 82% sensitivity, 83% specificity, 86% PPV, and 79% NPV for the diagnosis of NASH. All selected patients had fibrosis, including 81% with significant fibrosis.



Conclusion: An MRI-based composite biomarker of PDFF+WC identified patients with NASH and liver fibrosis with high specificity and PPV. This finding offers clinical utility in the management of NAFLD and patient selection for NASH clinical trials.

FRI092

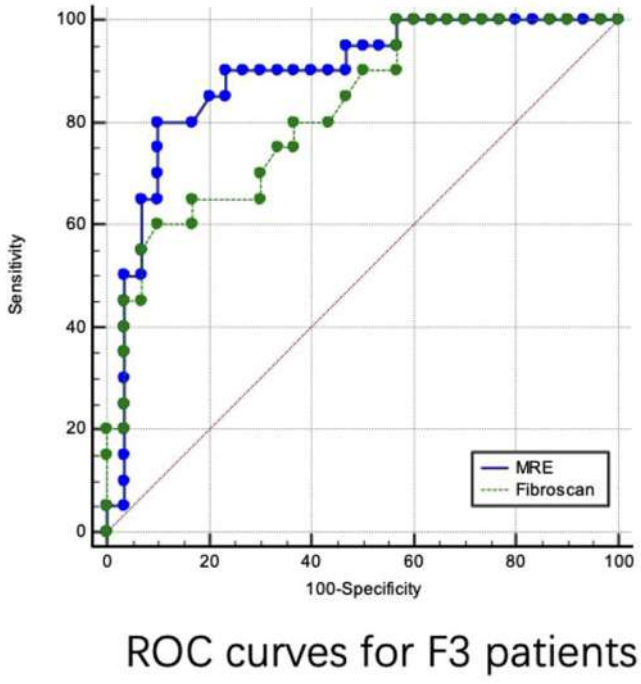
Diagnostic accuracy of MRE for staging hepatic fibrosis in patients with NAFLD

Carmen Lara Romero[1,2], Jia-xu Liang[3], Isabel Fernández-Lizaranzu[4], Javier Ampuero[1,2], Javier Castell[3], Manuel Romero Gomez[1,2]. *[1]Hospital Universitario Virgen del Rocío, Department of Digestive and Liver Diseases; [2]Institute of Biomedicine of Seville, Seville, Spain; [3]Hospital Universitario Virgen del Rocío, Department of Radiology; [4]Universidad de Sevilla, Interdisciplinar Physics Group, Seville, Spain*
Email: mromerogomez@us.es

Background and aims: To evaluate the diagnostic accuracy of magnetic resonance elastography (MRE) instaging hepatic fibrosis in patients with histologically confirmed nonalcoholic fatty liver disease (NAFLD) and analyze possible confounding factors of MRE.

Method: 54 subjects were prospectively enrolled. Liver stiffness measured by MRE and by transient elastography (Fibroscan ®) was correlated with the grade of fibrosis determined by liver biopsy.

Patients in our cohort were classified according to the cut-off values obtained from another Meta-analysis of individual patient data (2.61 kpa for F1, 2.97 kpa for F2, 3.62 kpa for F3, 4.69 kpa for F4). We also made an analysis to identify those variables that could underestimate (MRE result lower than biopsy result), overestimate (MRE result higher than biopsy results) or achieve concordance (MRE result consistent with biopsy result).
ANOVA, Kruskal-Wallis test were used for continuous variables and chi-square test or Fisher's exact test for categorical variables. ROC (receiver operator characteristic) curves for diagnostic accuracy were evaluated, and Spearman's correlation was performed to compare histologic liver fibrosis with MRE elastography and Fibroscan.
Results: The area under the ROC curve (AUROC) of MRE for ≥F2 was 0.886 vs Fibroscan AUROC 0.842 ($p = 0.48$). MRE AUROC for F3 was 0.887 vs Fibroscan AUROC 0.820 ($p = 0.27$). Spearman's correlation coefficient of liver fibrosis and Fibroscan was 0.651 ($p < 0.0001$) whereas correlation coefficient of liver fibrosis and MRE elastography was 0.704 ($p < 0.0001$).
Variables that could overestimate MRE accuracy were AST ($p = 0.0005$), ALT ($p = 0.0032$) and inflammation activity ($p = 0.008$). BMI, weight, or DM did not affect diagnostic accuracy ($p = 0.732$, $p = 0.816$, $p = 0.521$, respectively).



ROC curves for F3 patients

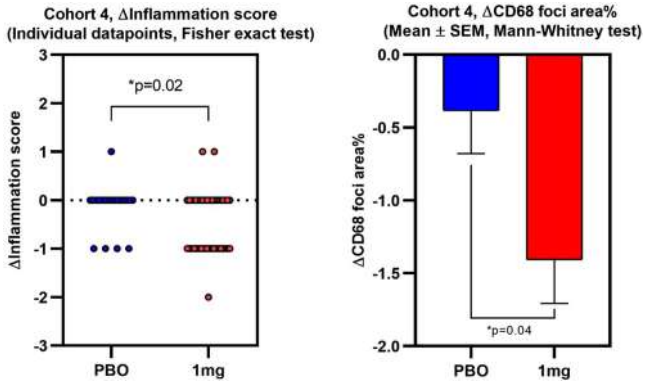
Conclusion: MRE is an effective, non-invasive method for detecting/staging hepatic fibrosis in NAFLD. Although we did not reach statistical significance, MRE showed a higher diagnostic accuracy than transient elastography in discriminating significant and advanced fibrosis. The liver inflammation grade may affect the diagnostic accuracy of MRE in staging hepatic fibrosis in NAFLD patients, but BMI or DM did not.

FRI093

Aldafermin quantitatively improves inflammation in a 24-week clinical trial in patients with nonalcoholic steatohepatitis

Tian Lan[1], Luong Ruiz[1], Wenhui Liu[1], Amir Ashique[1], Harry Chen[1], Jiping Zha[2], Alex DePaoli[1], Igor Mikaelian[1], Cynthia Guy[3], Eugenia Henry[4], Corinne Foo-Atkins[4], William Chang[4], Hsiao Lieu[4].
[1]NGM Biopharmaceuticals Inc., Translational Science, South San Francisco, United States; [2]Adagene Inc., Clinical Development, San Diego, United States; [3]Duke University Medical Center, Pathology, Durham, United States; [4]NGM Biopharmaceuticals Inc., Clinical Research, South San Francisco, United States
Email: tlan@ngmbio.com

Background and aims: Pathologist-based scores are the standard for assessing efficacy in nonalcoholic steatohepatitis (NASH) clinical trials, but are limited by variability in interpretation and insensitivity to small changes, especially for lobular inflammation. Lobular inflammation scores reflect the number of inflammatory foci per microscopic field, which are in part contributed by macrophages. Samples from a Phase 2 clinical trial with aldafermin (NGM282), an engineered fibroblast growth factor 19 analogue, were used to develop and test novel image analysis readouts for liver inflammation based on CD68, a macrophage lysosomal marker.
Method: Liver biopsies were from a 24-week clinical trial with aldafermin: NCT02443116 (Cohort 4, placebo (PBO), n = 18; 1-mg NGM282, n = 47). Biopsies and blood for non-invasive biomarkers were collected at baseline and at the end of treatment. A 6-plex immunohistochemistry (IHC) panel that included CD68 was developed to enable two image analysis endpoints: (1) "Type 1 macrophages" (M1 s) based on CD68 expression and cell shape; and (2) "Macrophage foci" to account for focal accumulations of M1 s.
Results: NGM282 decreased lobular inflammation measured by the NASH Clinical Research Network (CRN) criteria ($p = 0.02$) and the inflammation measured by the IHC macrophage foci (PBO vs. 1-mg, −0.39% vs. −1.41%, $p = 0.04$). The decrease of M1 s did not reach statistical significance in this relatively small study ($p = 0.18$). Inflammation reads by CRN criteria and by image analysis did not correlate robustly with the circulating biomarkers, including AST and ALT (r-squared ≈ 0.2).



Conclusion: Quantified IHC readouts can identify histological changes in an automated manner. These histological endpoints do not correlate well with current circulating biomarkers.

FRI094

Clinical and economic evaluation of community-based preventative screening strategies for non-alcoholic fatty liver disease in people with Type-2 diabetes melllitus

Roberta Forlano[1], Tijana Stanic[2], Sahan Jayawardana[2], Benjamin H. Mullish[1], Michael Yee[1], Mark Thursz[1], Elias Mossialos[2,3], Pinelopi Manousou[1]. [1]*Department of Metabolism, Digestion and Reproduction, Imperial college London, London, UK, United Kingdom;* [2]*Department of Health Policy, London School of Economics and Political Science, London, UK, United Kingdom;* [3]*Centre for Health Policy, The Institute of Global Health Innovation, Imperial College London, London, UK*
Email: r.forlano@imperial.ac.uk

Background and aims: The exact prevalence of Non Alcoholic Fatty Liver Disease (NAFLD) in type 2 diabetes (T2DM) is unknown. We aimed to determine the prevalence and develop a risk stratification and cost analysis for a screening policy in T2DM in primary care. We compared the cost-effectiveness of 5 screening strategies vs standard of care (SoC).

Method: Consecutive T2DM patients underwent blood tests, ultrasound (US) and liver stiffness measurement (LSM). Significant fibrosis and advanced fibrosis were defined by LSM≥8.1 kPa and ≥12.1 kPa. Diagnosis of cirrhosis was clinical, histological or radiological. Markov model included 3 health states: NMD-: no NAFLD; NMD+: NAFLD with LSM≤8 kPa; significant liver disease (SLD: LSM≥8.1 kPa); compensated cirrhosis (CC) (Fig 1).

The probability of progressing was assumed reduced for those at risk of NAFLD (NMD+) or diagnosed with SLD (SLD+) compared to those at lower risk (NMD−), or with undiagnosed disease (SLD−). The effect of earlier identification, diagnosis and treatment was based on the reduction of transition probabilities for NMD+/SLD+ vs NMD−/SLD−. The base-case analysis was conducted over a lifetime horizon and generated the cost per quality-adjusted life year (QALY) gained. We calculated average cost-effectiveness and the incremental cost-effectiveness ratio (ICER) vs SoC. Life expectancy, lifetime costs, and number of correct diagnoses were estimated. A cost-effectiveness threshold was set at £20, 000/QALY gained, as per NICE.

Results: Of 300 patients enrolled, 287 were included; 13 withdrew: 184 (73%) had NAFLD, 28 (10%) other causes of liver disease (alcohol, HBV) and 75 (26%) no liver disease. Significant fibrosis and advanced fibrosis due to NAFLD were 17% (50/287) and 11% (31/287) respectively. The prevalence of cirrhosis was 3% (8/287). Based on predictors of significant fibrosis, the BIMAST score (BMI and AST) performed better for diagnosing significant (AUROC 0.81, p < 0.0001) and advanced fibrosis (AUROC 0.84, p < 0.0001) (Fig 2). Five screening strategies were compared: 1) US + liver function tests (LFTs), 2) FIB-4, 3) NAFLD fibrosis score, 4) BIMAST score, 5) fibroscan. In a Markov model, NAFLD screening improved the rate of correct diagnoses by 8–15%, with an exception of the NAFLD fibrosis score strategy, which led to a 2% decrease in correct diagnoses. All screening strategies were associated with QALY gains, ranging from 121–148 years, with fibroscan resulting in the most substantial gains. In all screening strategies, ICER compared to SoC was between £1, 970 (BIMAST score) and £2, 480 (fibroscan) per QALY gained (Tab 1).

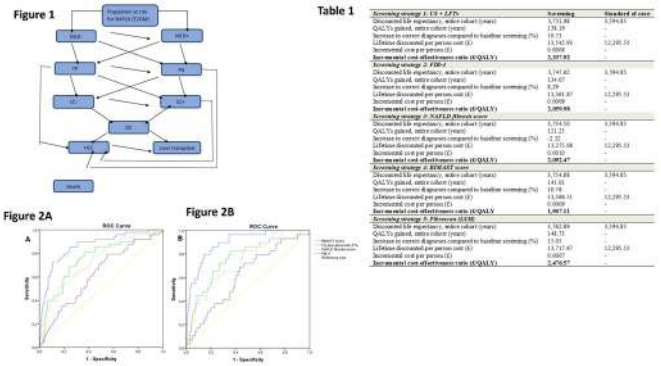


Figure 1. Markov model for the economic evaluation of screening interventions for non-alcoholic fatty liver disease. Abbreviations: - : undiagnosed; + : diagnosed; NAFLD: non-fatty liver disease; T2DM: type-2 diabetes mellitus; NMD: no/mild liver disease (no NAFLD or NAFLD with LSM ≤ 8 kPa); SLD: significant liver disease (NAFLD ≥8.1 kPa); CC: compensated cirrhosis (clinical diagnosis of cirrhosis); DC: decompensated cirrhosis; HCC: hepatocellular carcinoma.

Figure 2. BIMAST score vs conventional screening methods for predicting significant (LSM ≥ 8.1 kPa, Figure 2A) and advanced (LSM≥ 12.1 kPa, Figure 2B) fibrosis in the diabetic primary care population.

Table 1. Base-case cost-effectiveness analysis of NAFLD screening strategies versus standard of care (baseline screening).

Conclusion: Screening for NAFLD in T2DM improved diagnostic outcomes and was cost-effective in all evaluated scenarios within NICE's cost-effectiveness threshold. Fibroscan followed by BIMAST was the screening strategy associated with the greatest clinical gains.

FRI095

Confounding factors in diagnostic performance of magnetic resonance elastography for staging liver fibrosis in patients with non-alcoholic fatty liver disease: an individual patient data meta-analysis

Email: mromerogomez@us.es

Background and aims: We conducted an individual patient data meta-analysis to assess potential confounding factors influencing diagnostic accuracy of magnetic resonance elastography in staging liver fibrosis and to determine specific diagnostic cutoff values in patients with non-alcoholic fatty liver disease.

Method: A review of the literature identified studies containing MRE data for grading liver fibrosis in NAFLD patients with liver biopsy as reference standards. The original database was obtained in Excel form the corresponding authors. Pooled diagnostic cutoff value for the

various fibrosis stages were determined in a two-stage meta-analysis as the primary outcome. Multilevel modelling methods were used to analyses potential confounding factors influencing diagnostic accuracy of MRE in staging liver fibrosis.

Results: 6 independent cohorts comprising 483 patients were included in the meta-analysis, yielding liver stiffness cutoffs of 2.77 kPa (area under the receiver operating characteristic curve 0·86 [0·83–0·89]) for any fibrosis (≥F1), 3.09 kPa (0·90 [0·87–0·92]) for significant fibrosis (≥F2), 3.41 kPa (0·93 [0·91–0·96]) for advanced fibrosis (≥F3) and 4.10 kPa (0·91 [0·88–0·93]) for cirrhosis (F4). Notably, cases with mild fibrosis stage (F0–1) with moderate to severe inflammatory activity (A3–4) had exhibited greater stiffness than matched cases of the same fibrosis stage with none to mild inflammation activity. Similarly, higher liver inflammatory activity was an independent variable predicting reduced diagnostic accuracy of MRE [OR (95% CI) = 0.404 (0.220–0.740), p < 0.01], whereas steatosis degree, BMI, ALT, and AST did not affect the diagnostic accuracy of MRE (Table).

Table: GLMM (generalized linear mixed model) explore variables associated with prediction failure

Variables	OR	95% CI	Estimated (SE)	Z-value	p-value
BMI	1.001	(0.950-1.054)	0.001 (0.026)	0.03	0.97
Age	0.997	(0.972-1.022)	-0.003 (0.013)	-0.24	0.81
Sex (M vs F)	0.898	(0.500-1.612)	-0.108 (0.299)	-0.36	0.72
Population (Asian vs non-Asian)	1.178	(0.636-2.185)	0.164 (0.315)	0.52	0.60
T2DM (yes vs no)	0.788	(0.437-1.422)	-0.238 (0.301)	-0.79	0.43
ALT	0.998	(0.990-1.007)	-0.002 (0.004)	-0.41	0.68
AST	1.002	(0.992-1.012)	0.002 (0.005)	0.36	0.72
platelet	1.002	(0.998-1.006)	0.002 (0.002)	0.84	0.40
Steatosis					
S1	0.703	(0.083-5.924)	-0.353 (1.088)	-0.32	0.75
S2	0.638	(0.069-5.861)	-0.450 (1.132)	-0.40	0.69
S3	0.544	(0.054-5.513)	-0.609 (1.182)	-0.52	0.61
Inflammation activity (Lower vs higher)	0.404	(0.220-0.740)	-0.907 (0.309)	-2.93	<0.01
MRI-PDFF	0.980	(0.940-1.022)	-0.020 (0.021)	-0.94	0.35

Conclusion: MRE has excellent diagnostic performance for determining significant, advanced fibrosis and cirrhosis in patients with NAFLD. Accuracy was not influenced by anthropometric, biochemical, or steatosis degree, but could be influenced by high inflammatory activity.

FRI096

Is it possible to identify nonalcoholic steatohepatitis and the associated degree of fibrosis by noninvasive methods in patients with MAFLD?

José López González[1], Marta Casado[1], Teresa Maria Jordan Madrid[1], Almudena Porcel Martin[1], José Luis Vega Sáenz[1]. [1]*Torrecárdenas University Hospital, Almería, Spain*
Email: pepe_1993_17@hotmail.com

Background and aims: Non-alcoholic steatohepatitis (NASH) is a chronic and progressive form of metabolic associated fatty liver disease (MAFLD). NASH diagnosis requires histological evaluation after liver biopsy. Therefore, it is necessary to develop non-invasive diagnostic alternatives to identify NASH and the associated degree of fibrosis. The aim of this study is to analyze the presence of NASH and NASH with advanced fibrosis (AF) in patients with MAFLD and increased liver stiffness (LS), and to identify those associated factors with AF.

Method: We included a prospective cohort of all patients with clinical and ultrasound diagnosis of MAFLD, treated in our department since January 2019, with LS >8 kPa, measured by transient elastography. Presence of NASH and the degree of fibrosis, were evaluated after histological analysis of a liver biopsy. Epidemiological, clinical, analytical, elastographic and histological variables were collected. Patients were classified according to the presence of AF in the liver specimen (grade 3–4) or mild fibrosis (MF) (grade 1–2 or absence).

Results: Our study included 40 patients, whose characteristics are shown in Table 1. Histological analysis demonstrated NASH in 36 patients (90%), 14 patients with AF (35%), and two of them with F4 grade fibrosis. GGT and LS were significantly higher in patients with NASH and AF vs patients with MF, (161.86 ± 115 vs 90.6 ± 56, p = 0.04, 15.9 ± 8.6 vs 10 ± 1.48, p = 0.02). 42% of patients with MF had APRI<0.5 and 57% had APRI between 0.5–1. No patient with MF had APRI>0.5. Likewise, 50% of patients with AF had APRI >0.5, and 50% of them, had APRI >1.5 (p = 0.026). All patients with APRI >1 and LS >12.1 kPa had AF, and only 29% of patients with AF did not meet both criteria (p = 0.037). In addition, all patients with APRI>1.5 and GGT>115.6 IU/ml had AF, compared to 29% of patients with AF who did not meet both analytical criteria (p = 0.037).

VARIABLE		RESULTS (n = 40)
AGE		59.78 ± 8.5
SEX (%)	MALE	20 (50%)
	FEMALE	20 (50%)
AHT (%)		30 (75%)
DYSLIPIDEMIA (%)		25 (62.5%)
DIABETES (%)		27 (67.5%)
OBESITY (%)		40 (100%)
AST		47.4 ± 28.2 U/L
ALT		56.1 ± 33.5 U/L
GGT		115.6 ± 88 U/L
HEMOGLOBIN A1c		6.5 ± 1.27%
CHOLESTEROL		202 ± 33.4 mg/dL
TRIGLYCERIDES		190.4 ± 95 mg/dL
ADVANCED FIBROSIS (%)		14 (35%)
LIVER STIFFNESS (kPa)		12.1 ± 5.8 kPa
CAP (n = 23)		334.4 ± 32.4
FIB-4 (%)	<1.33	13 (32.5%)
	1.33–2.66	22 (55%)
	>2.66	5 (12.5%)
FIB-4		1.8 ± 1.04
APRI (%)	<0.5	18 (45%)
	0.5–1.5	19 (47.5%)
	>1.5	3 (7.5%)
APRI		0.66 ± 0.49

Conclusion: Most patients with MAFLD and RH >8 kPa have NASH, one-third of them have AF. Increased GGT, APRI index, and LS were associated with a higher probability of having NASH with AF. LS and APRI combination or APRI and GGT combination, can identify patients with NASH and FA. Therefore, it seems possible to identify patients with MAFLD and high risk of NASH and NASH with AF with non-invasive methods. Nevertheless, further prospective studies are needed to confirm these preliminary results.

FRI097

The potential role of fatigue in identifying patients with NASH and advanced fibrosis who experience disease progression

Zobair Younossi[1,2,3], Maria Stepanova[1,2,4], Robert Myers[5], Reem Al Shabeeb[3], Issah Younossi[4], Linda Henry[1,2,4]. [1]*Inova Health System, Medicine Service Line, Falls Church, United States;* [2]*Betty and Guy Beatty Center for Integrated Research, IHS, Falls Church, United States;* [3]*Center for Liver Diseases, Department of Medicine, Falls Church, United States;* [4]*Center for Outcomes Research in Liver Disease, Washington DC, United States;* [5]*Gilead Sciences, Inc., Foster City, United States*
Email: zobair.younossi@inova.org

Background and aims: Fatigue is common in patients with advanced liver disease. We aimed to investigate the association of fatigue with the risk of progression among patients with NASH and advanced fibrosis.

Method: In this post hoc cohort study, enrolled subjects were required to have a liver biopsy consistent with NASH and bridging fibrosis (F3) or compensated cirrhosis (F4), and were followed up for up to two years. Fatigue was quantified using the fatigue domain of the CLDQ-NASH instrument completed by subjects at baseline (score range 1–7, lower score indicates worse fatigue). Cox proportional hazard model was used to determine the relationship between the

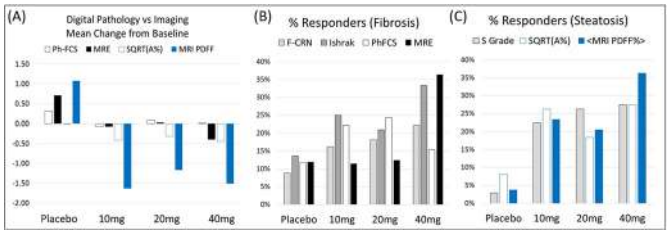
baseline fatigue score and the time to liver-related clinical events (progression to histologic cirrhosis for F3, developing hepatic decompensation for F4).
Results: There were 1679 advanced NASH patients (N = 802 F3 and 877 patients F4, age 58 ± 9 years, 40% male, 74% type 2 diabetes). During median follow-up of 16 months (IQR 14–18 month, max 26 months), 123 (15%) of F3 patients and 31 (3.5%) F4 patients experienced liver-related clinical events. The mean baseline CLDQ-NASH fatigue score was 4.77 ± 1.36 in F3 and 4.56 ± 1.44 in F4. In both F3 and F4 cohorts, patients with liver-related events in follow-up had higher baseline AST, lower platelet count, and elevated non-invasive test scores for fibrosis (APRI, FIB-4, ELF, Fibrotest, NAFLD Fibrosis Score) in comparison to patients who remained stable in follow-up (all $p < 0.01$). Their baseline fatigue scores were also significantly lower: 4.47 ± 1.36 in progressed F3 vs. 4.83 ± 1.35 in stable F3 ($p = 0.0091$); 3.74 ± 1.31 in progressed F4 vs. 4.59 ± 1.43 in stable F4 ($p = 0.0011$). In multivariate analysis, the association of lower fatigue scores (more fatigue) with the risk of liver-related events was significant: hazard ratio (HR) per 1 fatigue point = 0.84 (0.75–0.93), $p = 0.0012$, in all patients; HR = 0.85 (0.75–0.96), $p = 0.0088$, in F3; HR = 0.67 (0.53–0.85), $p = 0.0014$, in F4. These associations remained significant after adjustment for clinico-demographic confounders: adjusted HR = 0.79 (0.70–0.89), 0.85 (0.74–0.97), and 0.62 (0.48–0.81), respectively (all $p < 0.02$).
Conclusion: Lower baseline fatigue scores were associated with adverse clinical events in patients with advanced NASH. A combination of baseline clinical and fatigue parameters can inform clinicians of which patients with advanced fibrosis due to NASH are at risk of adverse clinical outcomes.

FRI029

Novel digital pathology quantitative image analysis and AI method detects the treatment effects of NASH drug candidates with a performance that benchmarks imaging-based measurements

Li Chen[1], Elizabeth Brown[2], Anne Minnich[2], Vipul Baxi[2], Dimple Pandya[2], Shuyan Du[2], Edgar Charles[2], Zachary Goodman[3], Mathieu Petitjean[1], Arun Sanyal[4]. *[1]PharmaNest, Inc, Princeton, United States; [2]Bristol Myers Squibb, Princeton; [3]Inova Health Systems, Falls Church, United States; [4]Virginia Commonwealth University, Richmond, United States*
Email: mathieu.petitjean@pharmanest.com

Background and aims: Manual histological evaluation of liver biopsy is the gold standard method for fibrosis and steatosis staging in Non-Alcoholic Steatohepatitis (NASH), but it is limited by its inter and intra-reader variability. Quantitative Digital Pathology image analysis and AI (FibroNest™) as well as quantitative MRI signal analysis methods have the potential to overcome the current limitation of standards. This exploratory post-hoc analysis compared FibroNest digital pathology scoring methods with NASH-CRN categorical stages and imaging-based scores in patients with NASH from the phase 2b FALCON1 study (NCT348699).
Method: Eligible adults were 18–75 years of age (N = 197) with NASH diagnosed by histologic assessment of liver biopsy according to NASH CRN criteria and stage 3 fibrosis. During the 48-week double-blind treatment period, patient received 10 mg, 20 mg, or 40 mg PGBF subcutaneous or placebo once weekly. Liver biopsies were obtained six months before or during screening and at week 24. Most patients underwent imaging resulting in Mean Liver Stiffness (MRE) and Mean Proton Density Fat Fraction (MRI-PDFF) measurements. Formalin-fixed, paraffin embedded sections of the liver biopsies where stained with Masson Trichrome and imaged at 40X. Quantitative image analysis was performed to extract single-fiber quantitative traits (qFTs, N = 315) from the fibrosis histological phenotype. A previously validated selection of principal qFTs were normalized and combined into a fibrosis severity score (Ph-FCS, 1 to 10). The non-fibrotic/scar parenchymal tissue area fat ratio (A%) is measured, and its square root is used as an exploratory marker SQRT (A%). Each digital image was evaluated for quality along 20 dimensions (tissue processing, staining, and scanning) to generate a Digital Biopsy Adequacy Score (DBA).
Results: Patients with biopsies with a DBA lower than 5 (non-adequate, ~10% of the cohort) were not included in the results. Groups sizes ranged from 27 to 45 patient per group. The quantification of the antifibrotic effect of the treatments was similar using the mean change from baseline of the Ph-FCS and MRE. SQRT (A%) was highly correlated to PDFF ($R^2 = 0.660$, N = 334) and demonstrated same anti-steatotic effects as PDFF for each group (Fig. A). Responders were identified with a relative reduction from baseline of MRE, Ph-FCS, PDFF and SQRT (A%) of ≥15%, ≥25%, ≥30% and ≥30% respectively, and with a 1-unit reduction for the histological stage. The agreement between quantitative digital pathology and imaging methods is illustrated in Fig. B, C.



Conclusion: Combined to AI algorithms, quantitative digital pathology image analysis generates continuous scores that enhance conventional histological staging methods. They detect the antifibrotic and anti-steatosis effect of treatment such as PGBF with a performance that benchmarks imaging-based measurements.

FRI099

Translational fibrosis phenotypes between the 3D human NASH spheroidal model and clinical NASH samples

Louis Petitjean[1], Simon Ströbel[2], Li Chen[1,3], Francisco Verdeguer[2,4], Radina Kostadinova[2], Arun Sanyal[5]. *[1]PharmaNest, Inc, Princeton, United States; [2]InSphero AG, Shlieren, Switzerland; [3]PharmaNest Inc, Princeton, United States; [4]University of Zurich, Zürich, Switzerland; [5]Virginia Commonwealth University, Richmond, United States*
Email: louis.petitjean@pharmanest.com

Background and aims: The use of 3D human spheroidal model for efficacy testing of anti-fibrotic compounds for Non-Alcoholic Steatohepatitis (NASH) has led to the need to understand the relevance of the fibrosis histological phenotypes and their clinical translational relevance. Here, a novel digital pathology quantitative image analysis and AI platform, FibroNest™, was used to measure quantifiable Fibrosis Traits (qFTs) in 3D human NASH models and natural cohort of patients diagnosed with NASH.
Method: 3D liver tissues were either treated for 10 days with free fatty acids and LPS or not to generate NASH (n = 14 tissues) and lean (n = 17 tissues) conditions respectively. The clinical cohort was retrospective and consisted of 104 patients with NASH diagnosed by histologic assessment of liver biopsy according to NASH CRN criteria by pathologists F0 (26), F1 (24), F2 (28), F3 (20), F4 (6). 4 μm FFPE spheroid and liver biopsies sections were stained with Picro Sirus Red, and scanned (40X and 20X) with bright-light whole slide imaging scanners. FibroNest™, was used to quantify the fibrosis histological phenotype including 32 traits for collagen content, fiber morphometry, and architecture, generating 315 qFT. Principal qFTs were automatically detected to best describe the progression of the fibrosis in both models. A Venn diagram approach was used to identify those traits that describe histological fibrosis severity in both models.
Results: The Venn Diagram identifies 97 shared traits between the two fibrosis progression models. qFTs are normalized to their initial

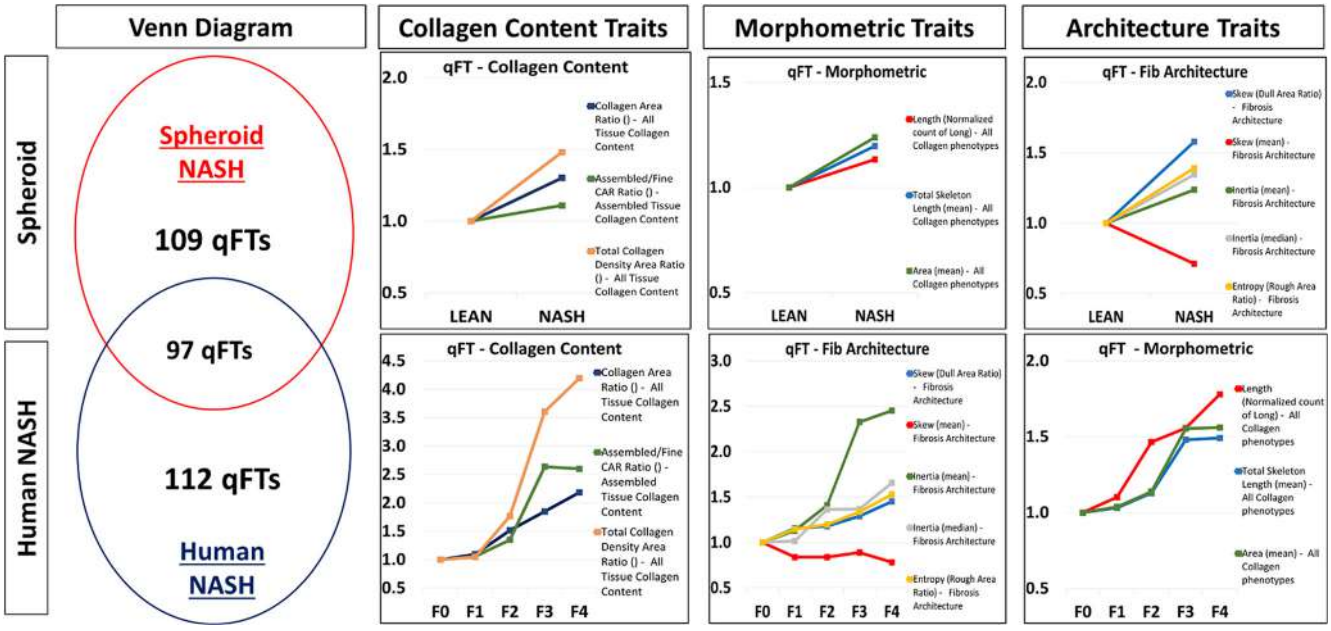


Figure: (abstract: FRI099)

value and their folds describe relative levels of progression benchmarked from a model to another. 10 traits described collagen features such as collagen area ratio, assembled/fine collagen fibers area ratio, and density area ratio (Figure). 61 traits described common morphometric features, such as the proportion of long collagen fibers, the mean fiber skeleton length, and the mean fiber area. 26 traits described common architectural features. The 3D human NASH spheroidal model cannot be directly associated to a specific NASH CRN score, but specific qFTs can be associated with either F2 or F3 stages using their fold values.

Conclusion: We identified 97 histological traits of fibrosis severity phenotype that can be translated from the 3D NASH spheroid model to clinical F2 or F3 NASH CRN stages. These traits will be used to evaluate the anti-fibrotic compounds effect in 3D NASH model to predict their effect in human.

FRI100

Shear wave elastography, transient elastography and enhanced liver fibrosis test use in the assessment of non-alcoholic fatty liver disease (NAFLD) in real- world practices

Sean Felix[1], Elena Younossi[1,2], Thomas Jeffers[2], Evis Hudson[3], Nagashree Gundu Rao[3], Z. Chris[3], Amish Gandhi[3], Maria Castillo-Catoni[3], Maria Ramirez[3], Mehreen Husain[3], Evangeline Delgado[3], Ambika Baru[3], Merica Shrestha[3], Romona Satchi[3], Yemsrach Gami[3], Pegah Golabi[3], Andrei Racila[4], Fatema Nader[5], Maria Stepanova[3,5], Zobair Younossi[3]. *[1]Inova Fairfax Medical Campus, Department of Medicine, Falls Church, United States; [2]Inova Fairfax Hospital, Falls Church, United States; [3]Inova Health System, Medicine Service Line, Falls Church, United States; [4]Inova Fairfax Medical Campus, Falls Church, United States; [5]Center for Outcomes Research in Liver Diseases, Washington, United States*
Email: zobair.younossi@inova.org

Background and aims: Risk stratification of NAFLD patients using non-invasive tests can be challenging. In this context, correlation of different radiologic and blood-based NITs to each other can be clinically informative. We aimed to assess the correlation of different NITs to identify high-risk NAFLD/NASH patients seen at real-world primary care provider (PCP) and endocrinology (ENDO) practices and link them to a GI or hepatology practice for specialized care.

Method: Using the electronic health records (EHRs), patients seen at PCP and ENDO clinics were screened for the presence of NASH risk factors. Patients with a diagnosis of type 2 diabetes or those with >2 other components of metabolic syndrome (hypertension, hyperlipidemia, or obesity) were eligible for the second round of assessment using FIB-4. Patients with FIB-4 score ≥1.45 were referred to a hepatology practice for transient elastography (TE) by FibroScan™ (Echosens, Paris, France: liver stiffness [LSM] and fat assessment by controlled attenuation parameter [CAP]), shear-wave elastography (SWE) by ACUSON Sequoia Ultrasound System (Siemens Healthineers, Erlangen, Germany: LSM by Point Shear Wave Elastography [pSWE] and ultrasound-derived fat fraction [UDFF]), and the Enhanced Liver Fibrosis (ELF) Test (Siemens Healthineers, Tarrytown, NY, USA).

Results: 13, 953 patients were screened (53% from ENDO practices, 47% from PCP). Of those, 4, 269 (30%) met the criteria for the second round of screening with FIB-4: 1, 286 (30%) agreed to enroll. Based on the FIB-4 risk cut-off, 328 (25%) patients were considered eligible for linkage to hepatology care, of whom 177 (53%) agreed to undergo linkage assessment. Patients who underwent linkage assessment were 67 ± 10 years of age, 52% male, 61% white, 23% black, 4% Hispanic, and 8% Asian, mean BMI was 31.6 ± 6.4 kg/m^2, 90% had clinical history of hyperlipidemia, 79% hypertension, 62% type 2 diabetes, and 23% reported having coronary artery or cardiovascular disease. Mean (SD) FIB-4 score: 1.95 ± 0.74; ELF score: 9.55 ± 0.83, LSM by TE: 7.0 ± 4.0 kPa, CAP 287 ± 64 dB/m, LSM by SWE: 3.98 ± 1.55 kPa, UDFF: 13.4 ± 8.6%, and FAST score: 0.25 ± 0.24. Of these patients, based on published or recommended by manufacturers cut-offs, 3% were considered high-risk by ELF, 17% by TE, and 8% by SWE; and additional 64% by ELF, 68% by TE, and 84% by SWE were considered low-risk. The correlations among the two stiffness measures (TE and SWE) and ELF were significant: Spearman's rho = +0.51 ($p < 0.0001$) between stiffness by TE and SWE; +0.40 ($p < 0.0001$) between stiffness by SWE and ELF; +0.25 ($p = 0.0028$) between stiffness by TE and ELF.

Conclusion: High-risk NASH patients can be identified by applying a simple clinical algorithm using electronic heath records and point-of-care NITs.

FRI101

Diagnostic performance of AGILE 3+ score for identification of advanced fibrosis and prediction of liver-related events in patients with non-alcoholic fatty liver disease

Grazia Pennisi[1], Ciro Celsa[1], Marco Enea[1], Alessandra Pandolfo[2], Michela Antonucci[3], Carlo Ciccioli[1], Giuseppe Infantino[1], Claudia La Mantia[1], Stefanie Parisi[1], Adele Tulone[1], Vito Di Marco[1], Antonio Craxi[1], Calogero Camma[1], Salvatore Petta[1]. *[1]Section of Gastroenterology and Hepatology, Department of Health Promotion, Mother and Child Care, Internal Medicine and Medical Specialties (PROMISE), University of Palermo, Italy; [2]University of Palermo; [3]University of Palermo, Dipartimento di Biomedicina, Neuroscienze e Diagnostica avanzata (BIND)*
Email: salvatore.petta@unipa.it

Background and aims: We aimed to assess the diagnostic accuracy of AGILE 3+, a recently developed score based on the combination of AST/ALT ratio, platelet count, diabetes status, sex, age and LSM, respect to FIB-4 and LSM, for the diagnosis of advanced fibrosis and for the prediction of liver-related events (LRE) occurrence in patients with non-alcoholic fatty liver disease (NAFLD).
Method: 614 consecutive patients with biopsy-proven NAFLD or clinical diagnosis of NAFLD-related compensated cirrhosis were enrolled. LRE were recorded during follow-up. FIB-4, LSM by TE and AGILE 3+ were measured. The diagnostic performance of noninvasive criteria for advanced fibrosis and for the prediction of LRE was assessed by AUROC curve and by decision curve analysis (DCA).
Results: In patients with biopsy-proven NAFLD (n = 520), LSM and AGILE 3+ had higher AUROC than FIB-4 (0.88 for LSM and AGILE 3+ vs 0.78 for FIB-4; $p < 0.001$) for advanced fibrosis, and AGILE 3+ exhibited the lower rate of indeterminate area of the test (25.2% for FIB-4, vs 13.1% for LSM, vs 8.3% for AGILE 3+). In the entire cohort AGILE 3+ had significantly higher AUC for predicting LRE respect to LSM (36-month AUROC 0.95 vs 0.93, $p = 0.008$; 60-month 0.95 vs 0.92, $p = 0.006$; 96-month 0.97 vs 0.95, $p = 0.001$). DCA showed that all scores had modest net benefit for ruling-out advanced fibrosis at the risk threshold of 5%–10% of missing advanced fibrosis. At the risk threshold of 5% of false negative or false positive LRE at 36-, 60-, 96- and 120-month, AGILE 3+ outperformed both FIB-4 and LSM for ruling-out LRE.
Conclusion: AGILE 3+, according to resource availability, clinical setting and the risk scenarios is an accurate and valid alternative to FIB-4 and LSM for the noninvasive assessment of disease severity and prognosis in NAFLD patients.

FRI102

Diagnostic accuracy of non-invasive tests for cirrhotic NASH-an individual participant data meta-analysis

Ferenc Mozes[1], Jenny Lee[2], Yasaman Vali[2], Emmanuel Selvaraj[1], Arjun Jayaswal[1], Jerome Boursier[3], Elisabetta Bugianesi[4], Ramy Younes[5], Monica Lupsor-Platon[6], Salvatore Petta[7], Toshihide Shima[8], Takeshi Okanoue[8], Sanjiv Mahadeva[9], Wah-Kheong Chan[9], Gideon Hirschfield[10], Peter Eddowes[11], Philip N. Email: ferenc.mozes@cardiov.ox.ac.uk

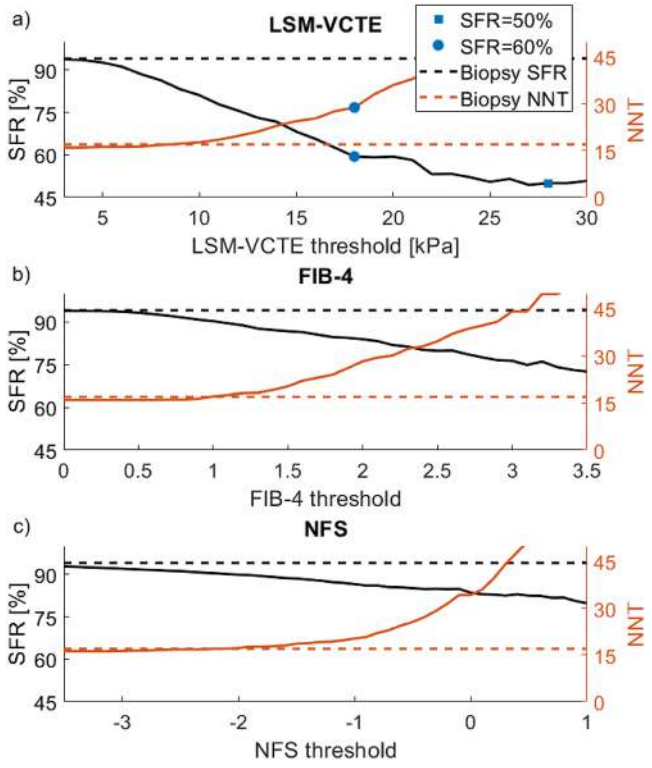
Background and aims: Screening for non-alcoholic steatohepatitis with cirrhosis (NASH+F4), identified by regulators as an unmet medical need, is done by liver biopsy. Given the low prevalence of the condition in typical clinical populations, risk stratification using non-invasive tests (NITs) is desirable to reduce the number of unnecessary liver biopsies. The aim of this study was to evaluate the diagnostic performance of vibration-controlled transient elastography (LSM-VCTE), fibrosis-4 index (FIB-4) and NAFLD fibrosis score (NFS) as screening tests for NASH+F4.
Method: This was an individual participant data meta-analysis of studies evaluating NITs against liver histology. NASH was defined as NAS>4 with at least grade 1 in each of the components. Diagnostic accuracy was assessed by the area under the receiver operating curve (AUROC). The relationship between NIT cut-off and screen failure rate (SFR) and the number of patients that needed to be tested (NNT) to identify 1 positive case was explored visually. We report on cut-offs that achieved 90% sensitivity, 90% specificity and maximised the Youden-index as well as cut-offs that achieved screen failure rate of 50% and 60%. Sequential combinations of serum NITs followed by LSM-VCTE were also evaluated.
Results: We included 2738 individual patient data from 25 primary studies (43% female, median age 52 years, median BMI 29 kg/m^2; 41% had type 2 diabetes; 57% had NASH, 6% had NASH + F4). LSM-VCTE had AUROC = 0.90, higher than 0.80 for FIB-4 and 0.78 for NFS (both $p < 0.001$). Cut-offs for 90% sensitivity, 90% specificity and maximum

Youden-index were 10.2 kPa (Sp 76%, SFR 80%, NNT = 18), 14.6 (Se 68%, SFR 69%, NNT = 24), and 10.4 kPa (Se 89%, Sp 77%, SFR 79%, NNT = 18) for LSM-VCTE; 1.16 (Sp 52%, SFR 89%, NNT = 18), 2.73 (Se 41%, SFR 79%, NNT = 39) and 1.35 (Se 88%, Sp 61%, SFR 87%, NNT = 18) for FIB-4; – 1.637 (So 53%, SFR 89%, NNT = 18), 0.473 (Se 32%, SFR 82%, NNT = 50) and –0.878 (Se 77%, Sp 69%, SFR 86%, NNT = 21) for NFS (Figure 1). A cut-off combination of FIB4 1.16 or NFS –1.637 followed by LSM VCTE of 16 kPa yielded Se 59%, Sp 93%, SFR 62%, and NNT = 27 and only 10% of the entire patient group would have to undergo liver biopsy while also reducing the number of LSM-VCTE exams to 51%.



Conclusion: Only LSM-VCTE achieved SFR of 50% and 60% which was at the cost of high NNT. Sequential combinations can achieve similar diagnostic accuracy while potentially reducing the number of LSM-VCTE exams and biopsies being performed, which could have favorable cost implications.

FRI103

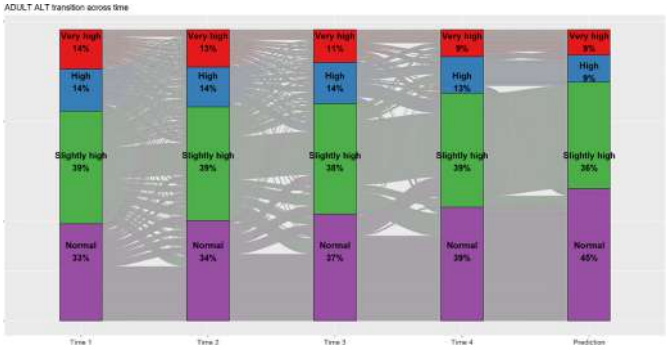
Longitudinal ALT trajectories are generally stable among patients with non-alcoholic fatty liver disease (NAFLD): an investigation using artificial recurrent neural networks

Michael Fried[1], Breda Munoz[1], Jamie Wu[1], Kenneth Cusi[2], Vincent Wai-Sun Wong[3], Peter Mesenbrink[4], Marcos Pedrosa[4], Andrea Mospan[1], Miriam Vos[5], Rohit Loomba[6], Arun Sanyal[7]. *[1]Target RWE, Durham, United States; [2]University of Florida, Gainsville, United States; [3]The Chinese University of Hong Kong, Hong Kong, China; [4]Novartis, East Hanover, United States; [5]Emory University, Atlanta, United States; [6]University of California at San Diego, San Diego, United States; [7]Virginia Commonwealth University Medical Center, Richmond, United States*
Email: mfried@targetrwe.com

Background and aims: Serum alanine aminotransferase (ALT) is a biomarker used to monitor liver injury. Little is known about ALT fluctuations over short intervals or the influence of patient characteristics on ALT trajectory in patients with NAFLD. This study modelled longitudinal variability in ALT and estimated the probability of a patient transitioning from their baseline level.

Method: TARGET-NASH is a longitudinal study of patients managed for NAFLD in usual clinical practice. Data from patients enrolled in the US with ≥3 ALT measures were included. Liver transplant, cholecystitis, liver cancer, sepsis were excluded. ALT categories: normal (≤30 U/L), slightly high (1–2X normal), high (2–3X normal), very high (>3X normal). Using available data, the transition between ALT categories was modelled using a recurrent neural network. 80%–20% data split into training-testing approach was utilized to fit the model and assess accuracy. Age, sex, body mass index (BMI), race/ethnicity, ALT date, hypertension, diabetes, cardiovascular disease and statin use were identified a priori.

Results: 3, 664 adult patients were followed over a median of 38.2 months (range: 1.7–87) with 3.9 months (range: 0.5–54.2) between ALT measures. Median age: 59; non-Hispanic (85%), White (76%), BMI 32 kg/m^2, history of hypertension (74%), type 2 diabetes (54%), cardiovascular disease (22%), statin use (46%); diagnosed with NASH (44.3%), cirrhosis (40.4%), NAFLD (15.3%). Patients in higher ALT categories at baseline were younger with a greater percentage of Hispanic or Latino participants vs. lower ALT categories. At baseline, 33%, 38%, 15%, 14% of patients had normal ALT, slightly high, high, very high ALT levels, respectively. In the unadjusted model, 39% with normal ALT at baseline remained in that category during follow up. Among those with slightly high ALT at baseline, 18% remained within that stratum; 5% and 18% of those with high and very high ALT, respectively, at baseline remained in the same strata. Probability of transitioning from normal or slightly high to very high ALT level was 2% and 6%, respectively, suggesting that transition from low to high ALT levels is uncommon. Risk of transition was higher in NH Whites (24%) and Hispanics (24%), followed by NH Black (21%), Asians (19%). Statin use did not influence transition. Accuracy of the neural network on training and testing data sets was 99% and 82%, respectively. Accuracy of the testing data set improved when limiting to phenotype at baseline: 89% (NAFLD), 84% (NASH), 84% (cirrhosis).



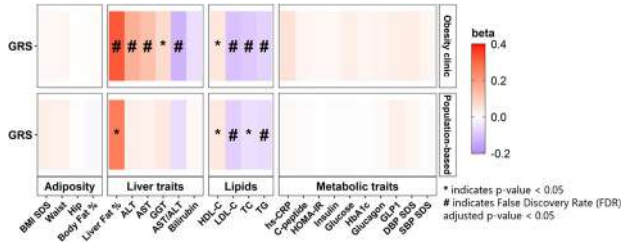
Conclusion: Longitudinal ALT trajectories remained relatively stable among patients with NAFLD. Understanding the course of ALT fluctuations is important for helping to differentiate natural variation from potential hepatotoxic or beneficial effects of therapeutics. Next steps include exploration of ALT trends associated with probability of clinical outcomes.

FRI104

An adult-based genetic risk score for hepatic fat associates with liver and lipid traits in Danish children and adolescents

Yun Huang[1], Sara Stinson[1], Helene Bæk Juel[1], Morten Lund[2,3], Louise Aas Holm[1,3], Cilius Esmann Fonvig[1,3,4], Niels Grarup[1], Oluf Pedersen[1], Michael Michael Christiansen[2,5], Aleksander Krag[6,7], Stefan Stender[8], Jens-Christian Holm[1,3,9], Torben Hansen[1]. *[1]University of Copenhagen, The Novo Nordisk Foundation Center for Basic Metabolic Research, København, Denmark; [2]University of Copenhagen, Department of Biomedical Sciences, Denmark; [3]Copenhagen University Holbæk Hospital, Department of Pediatrics; [4]Kolding Hospital a part of Lillebælt Hospital, Department of Pediatrics; [5]Statens Serum Institute, Department for Congenital Disorders; [6]Odense University Hospital, Department of Gastroenterology and Hepatology; [7]University of Southern Denmark, Institute of Clinical Research; [8]Rigshospitalet, Department of Clinical Biochemistry; [9]University of Copenhagen, Faculty of Health and Medical Sciences*
Email: torben.hansen@sund.ku.dk

Background and aims: Several genetic variants that associate with hepatic fat content in adults have been identified in genome-wide association studies. Their effects in children and adolescents remain unclear. The aims of this study were to test the effect of genetic variants known to associate with hepatic fat in adults, individually and combined as a genetic risk score (GRS), with cardiometabolic traits, and to investigate the predictive ability of the GRS for hepatic steatosis in children and adolescents.
Method: Children and adolescents with overweight/obesity from an obesity clinic cohort (n = 1, 843, median age 11.7 years, body mass index standard deviation score [BMI SDS] 2.85, 45.2% male) and a population-based cohort of children and adolescents (n = 2, 271, median age 11.6 years, BMI SDS 0.26, 40.1% male) were included. Anthropometrics and biochemical parameters were measured in both cohorts. Liver fat content was measured by magnetic resonance spectroscopy in 539 individuals. We calculated a weighted GRS based on eight genetic variants known to associate with hepatic fat content in adults. Associations of individual genetic variants and the GRS with cardiometabolic traits were tested using multiple linear and logistic regression models. Receiver operating characteristic (ROC) curve analysis was performed on models based on risk factors for hepatic steatosis, defined as hepatic fat ≥5%, and area under the curve (AUC) was calculated to evaluate model performance.
Results: Variants in *PNPLA3, TM6SF2, GPAM,* and *GCKR* were significantly associated with higher liver fat content ($p < 0.01$) and with distinct patterns of circulating lipids. The GRS was associated with higher liver fat content and alanine transaminase (ALT), as well as lower LDL-cholesterol and triglycerides in the obesity clinic and population-based cohorts. The GRS was not associated with adiposity or other metabolic traits. The GRS was associated with higher prevalence of hepatic steatosis (odds ratio [OR] per 1-unit GRS-increase: 2.18, p = 1E-8), and with lower prevalence of dyslipidemia (OR 0.90, p = 0.02). A prediction model for hepatic steatosis including GRS alone yielded cross-validated AUC of 0.76 (95% CI 0.69–0.83). The addition of the GRS to a model containing clinical risk factors for hepatic steatosis (BMI SDS, ALT, homeostatic model assessment of insulin resistance [HOMA-IR]) increased AUC slightly from 0.87 (95% CI 0.82–0.92) to 0.89 (95% CI 0.84–0.94).



Conclusion: The adult-based GRS for hepatic fat was associated with liver fat content, liver enzymes and lipid profiles, but was not associated with adiposity and other metabolic traits in children and adolescents. The GRS could serve as a predictor of the risk for hepatic steatosis in addition to clinical risk factors and could be used for early preventative initiatives.

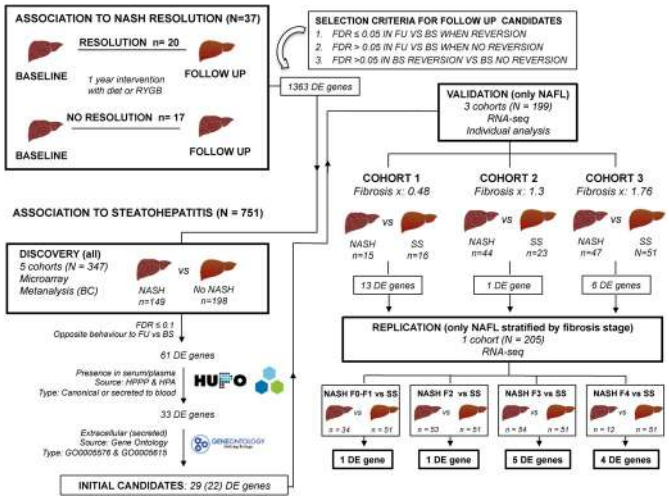
Identification of new potential biomarkers to follow steatohepatitis in patients with non-alcoholic/metabolic-associated fatty liver disease

Douglas Maya[1,2,3], Rocío Gallego-Durán[1,2,3], María del Rosario García-Lozano[1,2], Rocio Munoz Hernandez[1,3,4], Angela Rojas Alvarez-Ossorio[1,2,3], Antonio Gil-Gomez[1,2,3], Javier Ampuero[1,2,3,4], Manuel Romero Gomez[1,2,3,4]. *[1]Institute of Biomedicine of Seville, Hepatic, Digestive and Inflammatory Diseases, Sevilla, Spain; [2]Centro de Investigación Biomédica en Red en el Área temática de Enfermedades Hepáticas, Spain; [3]Hospital Universitario Virgen del Rocío, Gastroenterology and Hepatology, Sevilla, Spain; [4]Facultad de Medicina, Universidad de Sevilla, Sevilla, Spain*
Email: mromerogomez@us.es

Background and aims: To integrate different liver gene-expression datasets to identify novel potential serological biomarkers to follow-up steatohepatitis in NAFLD patients.
Method: Initial candidates were obtained by comparing the gene expression of paired liver biopsies coming from NAFLD patients that were able (n = 20) or not (n = 17) to resolve steatohepatitis at the end of a dietary or a surgical intervention of 1 year (section 1). Association of candidates to steatohepatitis was initially explored in 6 microarray gene expression datasets (n = 317) in which patients were classified as NASH or No NASH according to the SAF score and analysed as a single cohort after batch normalization. Selected candidates were filtered through a series of public datasets to retain exclusively secreted proteins able to reach the bloodstream. Candidates were validated independently in three additional RNA-seq additional datasets in which patients with Bland Steatosis (SS) were compared against patients with steatohepatitis (NASH (Cohort 1: N = 31 15 SS/16 NASH) (Cohort 2 N = 67 23 SS/44 NASH) (Cohort 3 N = 99 51 SS/47 NASH)) introducing age (Cohorts 2 and 3) and sex as covariables in the analysis (all 3). These candidates were further explored in a recently published gene expression (*Govaere et al. 2020*) in which 163 NASH patients were stratified by fibrosis stage (F0–F1 n = 34; F2 n = 53; F3 n = 54; F4 n = 12) and compared against patients with bland steatosis with no or mild fibrosis (SS n = 51).
Results: Paired liver biopsy analysis identified 1363 genes that significantly change their behaviour specifically in patients achieving NASH resolution. 61 or them showed a positive or a negative association to steatohepatitis in the integrative multiarray comparison in the microarray multicohort dataset. 22 of them are secreted and can reach the bloodstream. Only one of them, IL-32, replicated its behaviour in the microarray cohort (Fold Change (FC): 1.43, p-value 1.3×10^{-9}, FDR:1.3×10^{-6}) and in all three RNA-seq analysis (*Cohort 1* FC: 2.47, p-value 6.2×10^{-4} FDR 1.0×10^{-2}; *Cohort 2*: FC: 1.59, p-value 8.3×10^{-5}, FDR: 9.7×10^{-2}; *Cohort 3* FC: 2.11, p-value 1.15×10^{-7}, FDR: 3.2×10^{-6}). This protein also replicated its behaviour in the last dataset independently from fibrosis stage (*NASH F0-F1 vs NAFL* FC: 1.64, p-value: 3.78×10^{-6}, q-value: 9.99×10^{-4}) (NASH *F2 vs NAFL* FC: 1.69, p-value: 5.62×10^{-5}, q-value: 2.90×10^{-2}) (*NASH F3 vs NAFL* FC: 2.03, p-value: 4.81×10^{-8}, q-value: 8.52×10^{-6}) (N*ASH F4 vs NAFL* FC: 2.16, p-value: 4.80×10^{-5}, q-value: 1.83×10^{-3}).



Conclusion: IL-32 expression in the liver shows the most robust and dynamic association to steatohepatitis and might constitute a useful biomarker for its detection and follow-up in patients.

FRI106

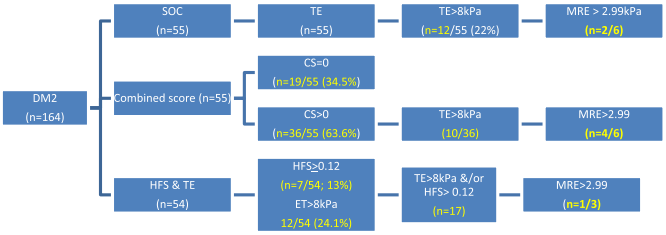
NASH patient's itinerary: Comparison of strategies for screening, referring and management

Roque-Cuéllar[2,4], Inmaculada Dominguez[7], Ioanna-Panagiota Kalafati[8], Sabine Kahl[9], Pedro Pablo García-Luna[7,10], Jörn Schattenberg[11], Michael Roden[12], George Dedoussis[8], Jeffrey Lazarus[13]. *[1]Digestive Diseases Department, Virgen del Rocío University Hospital; [2]Institute of Biomedicine of Seville; [3]CIBERehd; [4]Virgen del Rocío University Hospital; [5]Centro de Salud El Porvenir, Seville, Spain; [6]Endocrinology and Nutrition Department, Virgen del Rocío University Hospital; [7]Clinical Biochemistry Department, Virgen del Rocío University Hospital; [8]Harokopio University Athens; [9]Deutsches Diabetes-Zentrum; [10]University of Seville; [11]University Medical Center Mainz; [12]German Diabetes Center; [13]Barcelona Institute for Global Health (ISGlobal), Hospital Clínic, University of Barcelona*
Email: mromerogomez@us.es

Background and aims: Non-alcoholic fatty liver disease (NAFLD) is a highly prevalent, underdiagnosed, health system burden and impacts on quality of life including comorbidities in the affected population. Cost-effective strategies focusing on clinical pathways to detect and refer patients to care are needed. The aim of this study is to build a stepwise algorithm combining non-invasive freely available methods (FIB-4, NFS, HFS alone or combined) and vibration-controlled transient elastography (VCTE) in diabetic patients from primary care and endocrinology units.

Method: One-hundred sixty-four diabetes patients were recruited from January 2021 to February 2022 and randomized to one of three arms: Arm A (n = 55) patients referred following standard of care; Arm B (n = 55) patients referred due to altered combined fibrosis score (CFS) (FIB4>1.3 or NFS >−1.456 or HFS>0.12); and Arm C (n = 54) patients referred due to HFS>0.12 or VCTE>8 KPa. Patients at risk of NAFLD-fibrosis (VCTE>8 kPa) underwent magnetic resonance elastography (MRE).

Results: Age average was 55 ± 10 y, 54.3% males, and 66.5% obese (BMI>30 Kg/m^2). Transient elastography >8 kP was found in 35/164 (21.3%); >10 kPa 22/164 (13.4%) and >15 kPa 12/164 (7.3%). No statistical differences were seen among these three arms in biochemical, anthropometric or clinical features. All patients from Arm A were referred and 12/55 showed VCTE>8 kPa and 7 underwent MRE. In Arm B, 36 patients were referred and 10/36 showed VCTE>8 kPa and 9 underwent MRE. In Arm C, 17 were referred and 4 underwent MRE. Two out of six, four out of six and one out of three patients in each arm showed MRE>2.99 kPa (significant fibrosis) in five patients MRE was not valid. Estimated cost for NAFLD patient referral to the liver unit was approximately €570, 78 (Sánchez-Torrijos et al. REED 2019), VCTE €120 and CFS €0.59 per patient with T2DM: cost in Arm A was €31, 392.9; cost in Arm B was €24, 90053 and in Arm C was €16, 215.12



Conclusion: The prevalence of advanced fibrosis in a diabetic cohort reached 7.3% confirmed by transient elastography and MRE. A stepwise algorithm in the management of patients with type 2 diabetes with combined score and VCTE was cost-effective, allowing to save 50% of the budget compared to the standard of care.

Peformance of fibrometer-derived biomarker panels for assessment of fibrosis stage in NAFLD: NIMBLE stage 1 and the NASH CRN collaborative Study

Rohit Loomba[1], Sudha Shankar[2], Katherine Yates[3], Clayton Dehn[4], James Bolognese[5], Brent Tetri[6], Kris Kowdley[7], Raj Vuppalanchi[8], Cynthia Guy[9], James Tonascia[3], Anthony Samir[10], Claude Sirlin[11], Sarah Sherlock[12], Kathryn Fowler[11], Helen Heymann[13], Tania Kamphaus[13], Roberto Calle[14], Arun Sanyal[15]. *[1]University of California at San Diego, San Diego, United States; [2]Astrazeneca, United States; [3]Johns Hopkins University, Bloomberg School of Public Health, United States; [4]P-value LLC, United States; [5]Cytel, United States; [6]Saint Louis University, Department of Gastroenterology and Hepatology, United States; [7]Liver Institute Northwest, United States; [8]Indiana University, Division of Gastroenterology and Hepatology, United States; [9]Duke University, Department of Pathology, United States; [10]Massachusets General Hospital, Department of Radiology, United States; [11]University of California at San Diego, Department of Radiology, United States; [12]Pfizer, United States; [13]Foundation for the National Institutes of Health (FNIH), United States; [14]Regeneron Pharmaceuticals, United States; [15]Virginal Commonwealth University, Division of Gastroenterology, Hepatology and Nutrition, Department of Internal Medicine, United States*
Email: roloomba@ucsd.edu

Background and aims: The intent of the current collaborative study between NIMBLE & the NASH CRN was to further evaluate the performance of Fibrometer-based biomarker panels, including those developed for NAFLD or other liver diseases, with & without VCTE for identification of fibrosis strata in those with NAFLD. This cross-sectional study evaluated the diagnostic-test performance characteristics of four Fibrometer-based biomarker panels for assessing fibrosis in a well-characterized cohort of patients with biopsy-confirmed NAFLD with description of sensitivity & specificity at Youden's cutoff for their intended diagnostic use in a large, multicenter US cohort of patients with NAFLD/NASH.

Method: The performance of Fibrometer Virus (FM-VIRUS), Cirrhometer Virus (CM-VIRUS), Fibrometer NAFLD (FM-NAFLD) & Fibrometer VCTE-Light (FM-VCTE-Light) was evaluated for the assessment of fibrosis. Blood-based parameters were tested from aliquots of the same blood sample from each patient obtained within 90 days of a liver biopsy demonstrating NAFLD of varying activity &

stages (Stages 0–4). VCTE measurements were performed in a subgroup of trial participants within this time window. In order to minimize spectrum bias, the cohort was selected a priori to have a similar distribution of fibrosis stages across its entire range. The primary hypothesis was that the AUROC for each panel for its intended use was numerically >0.7 & significantly superior to 0.5. The secondary hypothesis was that the AUROC for each panel for fibrosis was significantly greater than that for FIB-4 (as the common reference).

Results: 1073 patients with biopsy-proven NAFLD including NAFL (n = 220) & NASH (n = 853) were evaluated. The number of patients with fibrosis stages 0, 1, 2, 3 & 4 were 222, 114, 262, 277 & 198, respectively. The dataset for Fibrometer VCTE-Light was smaller as VCTE data were available in only 393 patients. The AUROCs, Youden's cutoff with its sensitivity/specificity are provided below: All 4 panels met criteria for intended use for diagnosis of fibrosis stage ≥2, advanced fibrosis, & cirrhosis. Compared to FIB-4, FM-VIRUS & FM-NAFLD met criteria for diagnosis of advanced fibrosis but not for fibrosis stage ≥2 or cirrhosis, while CM-VIRUS was not superior to FIB-4 for any of the intended uses. In contrast, FM-VCTE-Light was significantly superior to FIB-4 for all three intended uses.

	FIB4	FM-VIRUS	CM-VIRUS	FM-NAFLD	FM-VCTE-Light
Parameters	Age, ALT, AST, PLT	Age, sex, A2M, AST, BUN, GGT, INR, PLT	Age, sex, A2M, AST, BUN GGT, INR, PLT	Age, weight, AST, ALT, FER, GLU, PLT	Age, sex, A2M, AST, GGT, LSM, PLT
Diagnostic test characteristics	AUROC (Youden cut-off value) [Sensitivity, Specificity]				
F stage ≥ 2	0.796 (1.4) [65.4,80.8]	0.801 (0.4) [69.2,77.4]	0.723 (0.0) [65.2,69.9]	0.809 (0.4) [67.7,80.0]	0.836** (0.4) [71.6,81.1]
F stage ≥ 3	0.793 (1.4) [75.1, 68.6]	0.808* (0.4) [76.4,69.9]	0.764 (0.0) [76.2,63.0]	0.805* (0.4) [77.9,67.0]	0.854** (0.4) [89.9,65.3]
F stage 4	0.81 (1.5) [85, 63.4]	0.826 (0.6) [75.0,73.2]	0.822 (0.1) [65.6,81.5]	0.800 (0.5) [76.7,68.0]	0.899* (0.7) [94.2,74.7]

A2M: alpha2 macroglobulin, AST: aspartate aminotransferase; ALT: alanine aminotransferase, BUN: blood urea nitrogen, FER: ferritin, GGT: Gamma-glutamyl transferase, GLU: fasting glucose, INR: international normalized ratio, LSM: liver stiffness by VCTE, PLT: platelets count.
*p< 0.05 for comparison with FIB-4 for their intended use
**p< 0.001 for comparison with FIB-4 for their intended use
All AUROCs are statistically significant and superior to AUROC=0.5 (p<0.001)

Conclusion: FM-VCTE-Light consistently outperformed FIB-4 for stratification of fibrosis across a spectrum of fibrosis stages. FM-VIRUS & FM-NAFLD appear to be better than FIB-4 for detecting advanced fibrosis but not for other fibrosis stages. These data will be helpful in informing trial design for future studies using these Fibrometer-based non-invasive tools across various intended use populations.

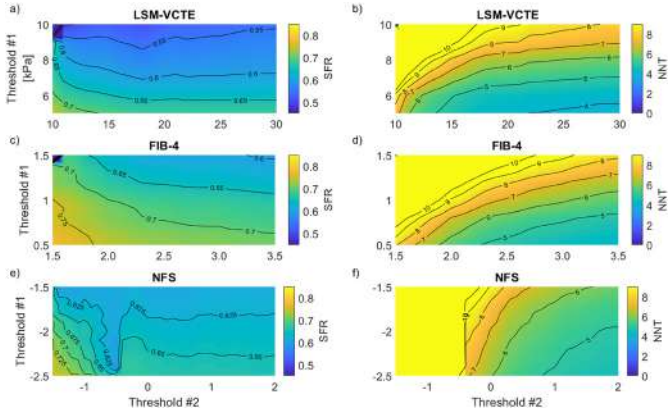
Email: ferenc.mozes@cardiov.ox.ac.uk

Background and aims: Histological assessment to confirm non-alcoholic steatohepatitis with significant fibrosis (NASH+F2–3) is needed prior to enrolment in clinical trials. Non-invasive testing (NIT) strategies to identify those with high risk for the target condition are needed to reduce screen failure rates (SFR). Our aim was to evaluate liver stiffness measurements by vibration-controlled transient elastography (LSM-VCTE), alone or in combination with the fibrosis-4 score (FIB-4) and the NAFLD fibrosis score (NFS) in such screening strategies.

Method: This was an individual participant data meta-analysis of studies evaluating LSM-VCTE against liver histology. The target condition was NASH+F2–3. NASH was defined as NAS≥4 with at least grade 1 in each of the components. Upper and lower cut-offs were used, with patients with NIT cut-offs between these two thresholds being selected for liver biopsy. Diagnostic performance was tested over a range of lower and upper NIT thresholds for single NITs, and sequential combinations of serum NITs and LSM-VCTE.

Sensitivity (Se), specificity (Sp), SFR, and number of patients that need to be tested to identify one true positive case (NNT) are reported.

Results: We included 2738 individual patient data from 25 primary studies (43% female, median age 52 years, median BMI 29 kg/m^2; 41% had type 2 diabetes; 57% had NASH, 28% had NASH+F2–3). Threshold combinations and corresponding SFR and NNT for single NIT strategies are shown in Figure 1. Visual inspection of the SFR and NNT distributions showed that increasing the upper NIT thresholds above 20 kPa, 3.0 and 1.0 for LSM-VCTE, FIB-4 and NFS, respectively, does not improve diagnostic performance, so these were chosen as upper cut-offs. LSM-VCTE thresholds of 6 kPa and 20 kPa (Se 80%, Sp 44%, SFR 64%, NNT 4) had higher sensitivity, higher SFR and lower NNT, than thresholds 10 kPa and 20 kPa (Se 39%, Sp 83%, SFR 53%, NNT 9). FIB-4 thresholds 0.7 and 3.0 (Se 73%, Sp 33%, SFR 67%, NNT 6), only differed in sensitivity and specificity from thresholds 1.0 and 3.0 (Se 58%, Sp 53%, SFR 67%, NNT 6). NFS thresholds −3.0 and 1.0 (Se 79%, Sp 34%, SFR 68%, NNT 5), and −2.6 and 1.0 (Se 73%, Sp 43%, SFR 66%, NNT 5) had similar diagnostic performances.



Sequential combinations of NITs could perform similarly to single NITs, with fewer individuals needing LSM-VCTE and liver biopsy. FIB-4 with cut-offs 0.7 and 4.63 followed by LSM-VCTE with cut-offs 6 and 20 kPa had Se 68%, Sp 59%, SFR 60%, NNT 5. NFS with cut-offs −3.272 and 1.766 followed by LSM-VCTE with cut-offs 6 and 20 kPa had Se 70%, Sp 56%, SFR 62%, NNT 5.

Conclusion: The major benefit of employing a sequential testing strategy was the reduced number of liver biopsies. Additionally, we noticed no further gain in diagnostic accuracy for the upper threshold of NITs above a certain level, suggesting that a judicious choice of thresholds can lead to a reduction in testing costs.

FRI109

Multiparametric MRI biomarker corrected T1 as a prognostic marker in chronic liver disease

Naim Alkhouri[1], Cayden Beyer[2], Anneli Andersson[2], Elizabeth Shumbayawonda[2], Michael Pavlides[3], Arjun Jayaswal[3], Matt Kelly[2], Stephen Harrison[3]. *[1]Arizona Liver Health, Fatty Liver Program, Chandler, United States; [2]Perspectum, Innovation, United Kingdom; [3]Oxford Centre for Magnetic Resonance (OCMR), Headington, United Kingdom*
Email: cayden.beyer@perspectum.com

Background and aims: Liver biopsy is an imperfect reference test for non-alcoholic fatty liver disease (NAFLD) and non-alcoholic steatohepatitis (NASH), due to its invasive nature, 2.4% major complication rate, high intra- and inter-reader variability and sampling error. The utility of non-invasive technologies (NITs) as alternative tools for NASH prognosis are assessed by their ability to predict clinical outcomes. Non-invasive multiparametric magnetic resonance imaging (mpMRI) with Liver*MultiScan,* and specifically corrected T1 (cT1), has previously been shown to predict clinical outcomes. With this study we investigate the association of increasing cT1 thresholds with clinical outcomes.

Method: Imaging and outcomes data were collected at two tertiary centers in the UK between May 2011 and July 2017 from patients referred to clinically indicated biopsy or known liver cirrhosis diagnosis. Clinical outcomes data were collected as a composite endpoint comprising ascites, variceal bleeding, hepatic encephalopathy, hepatocellular carcinoma (HCC), liver transplantation and mortality, more details described by Jayaswal et al. *Liver Intl* (2020) and in NCT01543646. Cox proportional hazard analysis was used to calculate hazard ratios (HRs) for the continuous and grouped variables. Probability of clinical outcome for cT1 as a continuous variable was used as reference and the HRs for each cut-off were used as scaling factors.

Results: 182 patients, including 54% with NAFLD, with 620 years follow up were included in the analysis where 13 patients had liver event occurrences, suggesting the overall risk of complications of 7% within the <72 months follow-up time. The events were ascites (5), variceal bleeding (1), hepatic encephalopathy (2), HCC (3) and mortality (9), with some patients having multiple events. cT1 had a 0.7% increased risk of clinical event for every 1 ms increase in cT1 (HR = 1.007, 95% CI: 1.003–1.011, p = 0.0010), which is equivalent to 91% increase of risk per 100 ms (HR 1.91). Patients with cT1 greater than 875 ms had 3.42 [95% CI: 1.05–11.11, p < 0.05] times higher risk to experience an event before those with cT1 below or equal to 875 ms. The cumulative probability of clinical events over time was higher for patients with cT1 of greater than 875 ms, compared to those with intermediate (800–875 ms) and low (<800 ms) cT1 (Fig. 1).

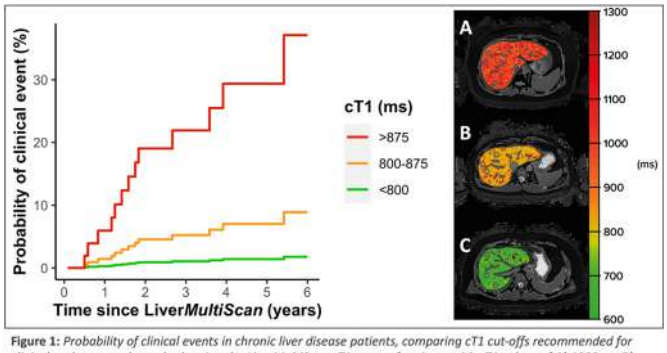


Figure 1: *Probability of clinical events in chronic liver disease patients, comparing cT1 cut-offs recommended for clinical pathways and a scale showing the LiverMultiScan cT1 maps of patients with cT1 values of* ***A)*** *1000ms,* ***B)*** *833ms and* ***C)*** *653ms.*

Conclusion: This study demonstrates that cT1 above 875 ms is not only able to identify high-risk NASH patients, but also predicts who is at higher risk for clinical events by evaluating patient health records and clinical outcomes. These results show the potential impact non-invasive mpMRI biomarkers can have to inform public health strategies and mitigate the impact of the growing burden of NAFLD.

Results of the Non-invasive Biomarkers of Metabolic Liver Disease (NIMBLE) study 1.1 on the reproducibility and repeatability of shear-wave and transient elastography in non-alcoholic fatty liver disease

Theodore Pierce[1,2], Arinc Ozturk[1,2], Sarah Sherlock[3], Guilherme Cunha[4], Xiaohong Wang[5], Qian Li[1,2], Marian Martin[1], Hannah Edenbaum[1], Kathleen Corey[2,5], Yesenia Covarrubias[4], Sudha Shankar[6], Helen Heymann[7], Tania Kamphaus[7], Roberto Calle[8], Nancy Obuchowski[9], Arun Sanyal[10], Rohit Loomba[4], Claude Sirlin[4], Kathryn Fowler[4], Anthony Samir[1,2]. *[1]Massachusetts General Hospital, Radiology, Boston, United States; [2]Harvard Medical School, Boston, MA; [3]Pfizer; [4]University of California San Diego, La Jolla; [5]Massachusetts General Hospital, Fatty Liver Clinic; [6]AstraZeneca; [7]Foundation for the National Institutes of Health (FNIH), North Bethesda, United States; [8]Regeneron, United States; [9]Cleveland Clinic; [10]Virginia Commonwealth University*
Email: asamir@mgh.harvard.edu

Background and aims: The regulatory qualification of non-invasive tests (NITs) for liver fibrosis severity assessment is a major unmet need in non-alcoholic fatty liver disease (NAFLD). Ultrasound-based methods such as shear-wave elastography (SWE) and vibration-controlled transient elastography (VCTE) have the potential, through repeated use, to assess disease response and progression. However, this application has been limited by a paucity of reproducibility data across device manufacturers in the population at risk. The aim of this study from the imaging workstream of the FNIH NIMBLE consortium (NCT04828551), was to address this knowledge gap and contribute to the evidence needed for qualification of ultrasound-based methods.
Method: A prospective two-center study of adults with suspected or established NAFLD stratified by FIB-4 (≤1.3, >1.3 < 2.67, ≥2.67) to reduce spectrum bias was performed. Each participant underwent 6 examinations on different ultrasound systems and VCTE on two days, each day by a different operator, less than a week apart. Sonographers and clinical investigators were blinded and a pre-specified data chain of custody was maintained. For uniformity, VCTE and SWE measurements were reported and analyzed in units of meters per second by an independent statistician. The primary end point was pooled different-day, different-operator reproducibility coefficient (RDC_{DDDO}). Secondary endpoints included scanner-specific RDC_{DDDO}, same-day/same-operator repeatability coefficient (RC_{SDSO}), and between-vendor RDC_{SDSO}. The study was powered to detect a 95% RDC_{DDDO} upper bound ($UB_{95\%}$) of ≤35%.
Results: 40 participants (mean age 60 years, 60% female) with low (17), intermediate (15), and high (8) FIB-4 scores were recruited. Mean body mass index was 30.9 kg/m^2. RDC_{DDDO} was 30.7% ($UB_{95\%}$ 34.4%) for SWE and 35.6% ($UB_{95\%}$ 43.9%) for VCTE. SWE vendor-specific RDC_{DDDO} varied from 24.2%–34.3%. RC_{SDSO} was 21.0% for SWE (13.9%–35.0%, by scanner) and 19.6% for VCTE. Between-vendor RDC_{SDSO} was 52.7% ($UB_{95\%}$ 64.7%).

	Number of Observations	RDC_{DDDO}	Upper 95% Confidence Bound	RC_{SDSO}	Upper 95% Confidence Bound
Vendor 1	24	31.9%	42.0%	19.0%	25.0%
Vendor 2	24	24.2%	32.1%	13.9%	18.3%
Vendor 3	24	29.9%	39.4%	14.2%	18.7%
Vendor 4	24	32.3%	42.5%	14.9%	19.6%
Vendor 5	24	34.3%	45.2%	35.0%	46.1%
Pooled SWE	**40**	**30.7%**	**34.4%**	**21.0%**	**23.5%**
VCTE	39	35.6%	43.9%	19.6%	24.1%

Conclusion: SWE demonstrated good RDC_{DDDO}, with slightly higher RDC_{DDDO} observed for VCTE. Considerably higher SWE variability is observed with measurements on different vendor platforms. These estimates are likely to inform ultrasound-based NIT qualification by (1) defining expected variability, (2) establishing that serial examination variability is lower when performed on the same vendor platform, and (3) informing future clinical trial design, including NIMBLE stage 2.

FRI111

Independent association of physical activity with nonalcoholic fatty liver disease and alanine aminotransferase levels

Jun Kyu Lee[1]. *[1]Dongguk University Ilsan Hospital, Internal Medicine, Goyang, Korea, Rep. of South*
Email: jeromee1971@yahoo.co.kr

Background and aims: The aim of the current study was to examine the independent association of physical activity with nonalcoholic fatty liver disease (NAFLD) and aminotransferases while adjusting for obesity and diet.
Method: A data from 32, 391 participants aged ≥20 years in the Korea National Health and Nutrition Examination Surveys (KNHANES) was analyzed by logistic regression models and general linear models. Physical activity was assessed from the questionnaire by health-enhancing physical activity (HEPA).
Results: The physical activity was negatively associated with NAFLD after adjustment for multiple factors with an odds ratio of 0.66 (95% CI, 0.57–0.76) comparing the most active (HEPA active) and the least active (inactive) participants. Among the participants with NAFLD, physical activity also showed an independent negative association with alanine aminotransferase (ALT) levels but not with aspartate aminotransferase levels. These independent associations were not observed when comparing the minimally active and inactive participants.

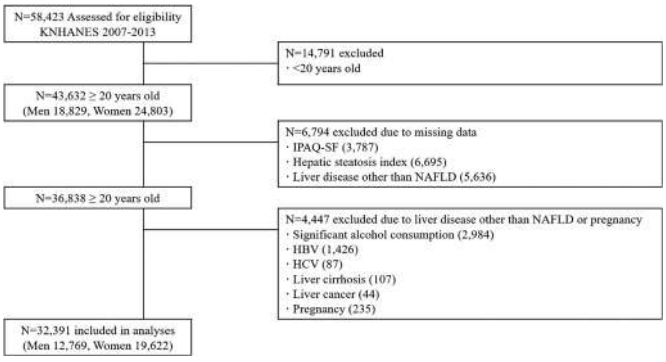

Fig. 1. Flow diagram of participant inclusion and exclusion in the current study using data from Korea National Health and Nutrition Examination Surveys (KNHANES IV, V and VI).

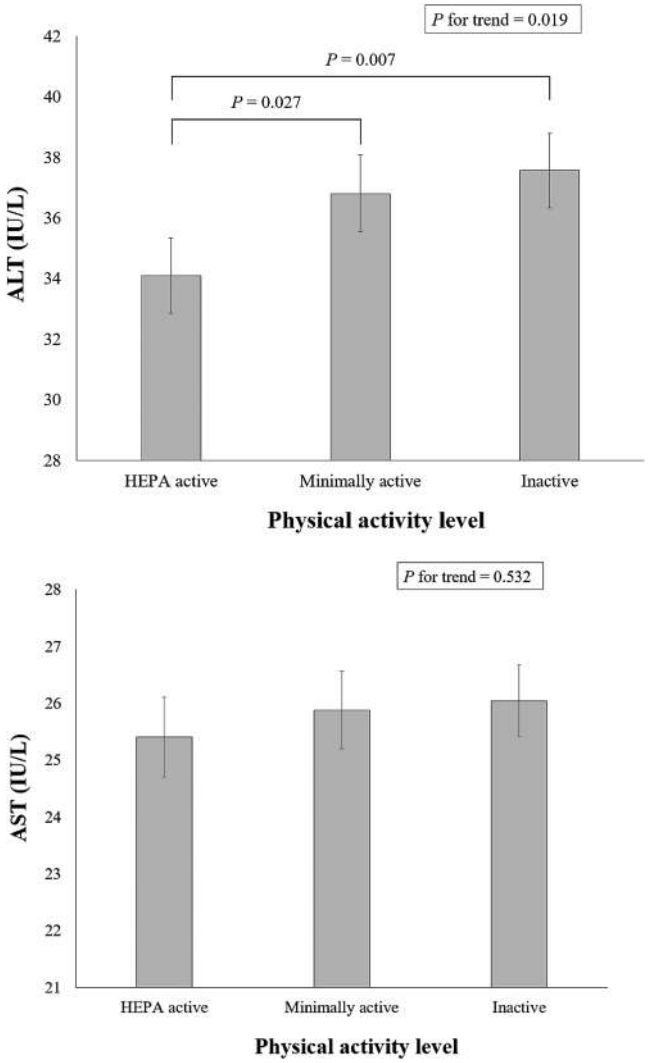

Fig. 2: Adjusted weighted means of ALT (upper) and AST (lower) by the physical activity level among participants with NAFLD (n = 6, 968).

Conclusion: Physical activity is independently associated with the degree of hepatocellular injury in patients with NAFLD as well as the risk of NAFLD in the general population. Sufficiently active physical activity greater than a minimally active level may be needed to lower the risk of NAFLD and ALT levels.

FRI112

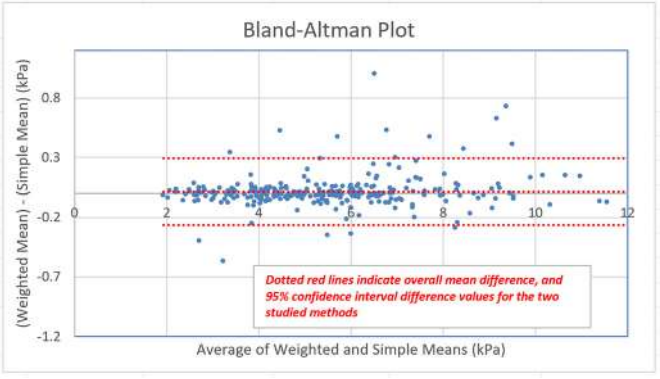
In a nonalcoholic steatohepatitis (NASH) clinical trial, baseline and screen failure magnetic resonance elastography (MRE) liver stiffness values calculated as weighted means were not different from values calculated as simple means

Michael Middleton[1,2], Mark Becker[3], Walter Henderson[1], Claude Sirlin[1]. [1]*University of California, San Diego, Radiology, San Diego, United States;* [2]*Quantix Bio, Lewes, United States;* [3]*Intercept Pharmaceuticals, Inc., San Diego, United States*
Email: msm@ucsd.edu

Background and aims: Magnetic resonance elastography (MRE) liver stiffness, a quantitative imaging biomarker of hepatic fibrosis, is commonly used in nonalcoholic steatohepatitis (NASH) clinical treatment trials. Typically, four images are acquired through the liver, and means of liver stiffness, weighted based on region-of-interest size are calculated to generate a single representative liver stiffness value for each exam. This is an appropriate method to use in clinical trials, but anecdotally it has been suggested that obtaining simple, rather than weighted means for routine clinical care is easier and may suffice. The Quantitative Imaging Biomarker Alliance (QIBA) has considered this question as part of their efforts to provide guidelines on how MRE exams should be acquired and analyzed. Data from drug development clinical trials are in many ways ideal to study this kind of question, given that typically such studies are conducted at large numbers of clinical sites using a wide variety of MR scanners of different styles and field strengths, from different MR scanner vendors. Hence, we undertook an analysis of MRE baseline and screen failure imaging data from a clinical trial testing a potential new treatment drug for NASH (NCT03439254; in progress) to determine whether liver stiffness values differed as to whether weighted, or simple means were used to generate final liver stiffness values for each exam.

Method: 308 baseline and screen failure MRE exams were obtained between October 2017 and December 2019 from 49 imaging sites worldwide. 19 MR scanner styles were represented, including 1.5 T and 3 T scanners from GE, Siemens, and Philips, with each exam using either a 2D GRE or a 2D SE-EPI pulse sequence. After exclusion of 13/308 (4.2%) of exams that were not analyzable, and 6/308 (1.9%) of exams for which incorrect images were acquired, 289/308 (93.8%) of exams were included in this analysis. Weighted and simple liver stiffness means were calculated, and compared using regression, Bland Altman, and Student t test analyses.

Results: Weighted liver stiffness means were not different from simple means (5.51 ± 1.97 kPa vs. 5.50 ± 1.94 kPa, respectively; p = 0.11). On regression analysis, slope was 0.986, intercept was 0.07 kPa, and the R^2 value was 0.995. On Bland Altman analysis, weighted and simple means differed by 0.01 ± 0.14 kPa. This difference is small compared to typical variability due to inter-scanner reproducibility, and is not clinically meaningful.



Conclusion: In a multi-center NASH clinical trial in which sites were trained and site protocols qualified by a central analysis center before study exams were acquired, no difference was observed between baseline weighted and simple mean MRE liver stiffness values across four acquired slices. This data will help inform ongoing work by QIBA in qualifying MRE liver stiffness as a quantitative imaging biomarker of hepatic fibrosis.

FRI113

Influence of pregnancy on NAFLD-associated lipidomic signatures

Tatyana Kushner[1], Ibon Martínez-Arranz[2], Marco Arrese[3], Mazen Noureddin[4], Rhoda Sperling[1], Keith Sigel[1], Scott Friedman[1], Pablo Ortiz[2], Cristina Alonso[2]. [1]*Icahn School of Medicine at Mount Sinai;* [2]*OWL Metabolomics, Spain;* [3]*Pontificia Universidad Catolica de Chile;* [4]*Cedars Sinai*
Email: tatyana.kushner@mssm.edu

Background and aims: Although NAFLD-associated lipidomic signatures have been defined in the general population, there is limited data on the influence of pregnancy on NAFLD-associated

lipidomic changes. In this study, we elucidate the deregulated lipidomic serum landscape of pregnant women with NAFLD.
Method: We prospectively screened for NAFLD at 18–22 weeks gestation in pregnant women. Pregnant woman with NAFLD (n = 6) and without NAFLD (n = 7) were matched 1:1 with retrospectively collected cases from non-pregnant woman with and without NAFLD (n = 13) based on age-, BMI- and disease-stage. Lipidomic analysis of serum samples collected under fasting conditions was performed using ultra-high performance liquid chromatography-mass spectrometry, covering lipid species across classes of glycerolipids, glycerophospholipids (phosphatidylinositol, acyl- and ether-linked phosphatidylethanolamine (PE) and phosphatidylcholine (PC)), sphingolipids (ceramides, monohexosylceramides and sphingomyelins), fatty acids and sterols (cholesteryl esters, steroids and bile acids). Lipidomic profiles in pregnant females with vs. without NAFLD and in pregnant females vs. non-pregnant matched female controls were compared.
Results: Pregnant women with NAFLD had higher PE, lysoPE and lower ceramides compared to non-pregnant women with NAFLD (see Figure). Pregnant women with NAFLD had lower triglycerides compared to non-NAFLD pregnant women; non-pregnant females with NAFLD had higher triglycerides compared to non-pregnant females without NAFLD. Pregnant women without NAFLD were significantly more likely to have lower saturated (SFA), monounsaturated (MUFA), and polyunsaturated fatty acids (PUFA) ($p < 0.05$), but have significantly higher triglyceride levels than non-pregnant women with NAFLD ($p < 0.05$). Non-NAFLD pregnant women also had lower ceramides and ether linked-lysoPC compared to non-pregnant women.

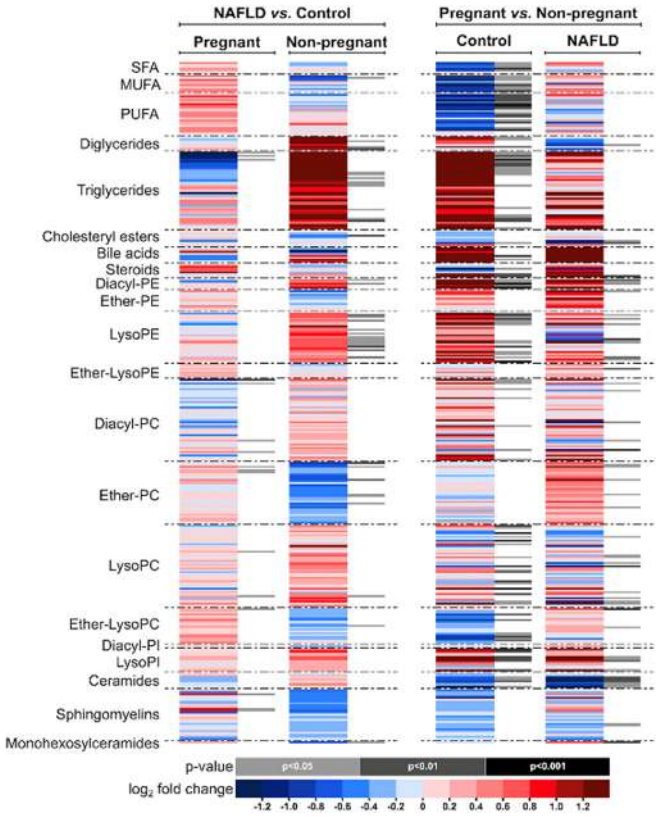


Figure: Heatmaps of lipidomic profiles in pregnant women (with and without NAFLD) compared to non-pregnant controls (with and without NAFLD).

Conclusion: Our findings suggest that NAFLD associated lipidomic signatures may be significantly impacted by pregnancy. NAFLD in pregnancy appears to be associated with a depletion in serum triglycerides and ceramides. Further workup should evaluate pregnancy-trimester specific changes as well as the role these lipid changes may play on NAFLD-associated adverse pregnancy outcomes such as gestational diabetes or effects on the newborn.

FRI114

Plasma sgp130 is an independent predictor of non-alcoholic fatty liver disease severity

Aysim Gunes[1,2,3], Laurent Bilodeau[4], Catherine Huet[4], Assia Belblidia[4], Cindy Baldwin[1], Jeanne-Marie Giard[5], Laurent Biertho[6,7], Annie Lafortune[6,7], Christian Couture[6,8], Bich N. Guyen[9], Eithan Galun[10], Chantal Bemeur[11,12], Marc Bilodeau[12], Mathieu Laplante[3,6,13], An Tang[4], May Faraj[1,3,11], Jennifer Estall[1,2,3].

Email: a.gkizil@gmail.com

Background and aims: Nonalcoholic steatohepatitis (NASH) is a metabolic disease associated with liver failure and cancer. Monitoring of advancing NASH is challenging. Since liver inflammation is a main driver of fibrosis, we investigated relationships between circulating components of the interleukin-6 signaling pathway (IL-6, sIL-6R and sgp130) and liver pathology in subjects with NAFLD and NASH.
Method: Predictive performance of plasma IL-6, sIL-6R and sgp130 were investigated in two independent cohorts: 1) patients with biopsy-confirmed NASH ($n = 49$), where magnetic resonance spectroscopy (MRS), imaging (MRI) and elastography (MRE) assessed liver fat, volume and stiffness; and 2) patients with morbid obesity ($n = 245$) undergoing bariatric surgery where histological staging of steatosis, activity, and fibrosis assessed NASH severity. Correlations were evaluated between IL-6, sIL-6R, sgp130 and anthropomorphic characteristics, plasma markers of metabolic disease or liver pathology.
Results: In patients with NASH, plasma IL-6 and sgp130 strongly correlated with liver stiffness, which for sgp130 was independent of age, sex, BMI, diabetes, hyperlipidemia, hypertension or history of HCC. Plasma sgp130 was the strongest predictor of liver stiffness compared to common biomarkers and risk scores. Plasma sIL-6R correlated with liver volume independent of age, sex, and BMI. In stepwise regression analysis, plasma sgp130 followed by NAFLD fibrosis score and plasma globulin, predicted up to 74% of liver stiffness. In patients with morbid obesity, circulating sgp130 correlated with advanced liver fibrosis.

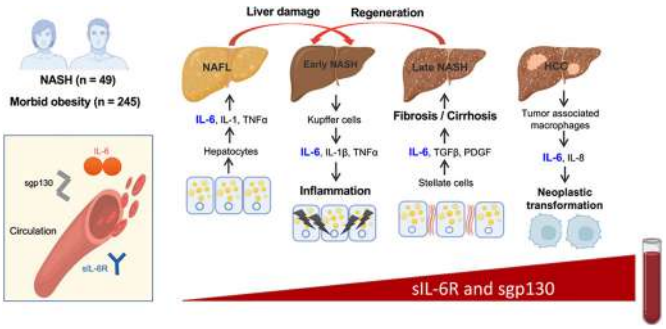

Figure: Advanced NASH is associated with liver failure and cancer; however, its detection in early stages is limited due to lack of non-invasive biomarkers. Interleukin-6 is an important player in NAFLD at all stages, involving multiple signaling mediators that circulate in blood. In biopsy-confirmed NASH, plasma sgp130 was the best predictor of liver stiffness and sIL-6R correlated with liver volume (MRI/MRE). In a second population, high sgp130 was detected in subjects with advanced fibrosis (histology). Circulating sgp130 may be a sensitive biomarker across all stages of NASH linked to metabolic disease independent of sex, age and BMI in progressive NAFLD.

Conclusion: Levels of circulating sgp130 can predict progressing NASH and may be used alone or in combination with other biomarkers as a non-invasive measure of liver disease severity.

FRI115

FIB-4 outperforms other serum non-invasive fibrosis tests in metabolic associated fatty liver disease

Nikoletta Maria Tagkou[1], Giulia Magini[1,2], Laurent Spahr[1], Francesco Negro[1,3], Jean-Louis Frossard[1], Nicolas Goossens[1,2].
[1]Hôpitaux Universitaires de Genève (HUG), Division of Gastroenterology and Hepatology, Genève, Switzerland; [2]Hôpitaux Universitaires de Genève (HUG), Division of Transplantation, Genève, Switzerland; [3]Hôpitaux Universitaires de Genève (HUG), Division of Clinical Pathology, Genève, Switzerland
Email: tagkounikoletta@gmail.com

Background and aims: Metabolic associated fatty liver disease (MAFLD) is a recently proposed terminology to replace non-alcoholic fatty liver disease (NAFLD) but non-invasive fibrosis scores have not been validated in this population. Additionally, MAFLD definition broadens the disease spectrum by including the overlap with alcohol related liver disease (MAFLD-ALD). We therefore aimed to determine the diagnostic performance of non-invasive fibrosis scores in MAFLD and whether the coexistence of alcohol abuse affects their performance.

Method: We retrospectively collected data of 409 consecutive MAFLD patients undergoing liver biopsy at our institution from 2007 to 2021. We stratified our patients by excessive alcohol consumption defined as >20 g/day in females and >30 g/day in males. The following scores were calculated with previously published cutoffs: NFS, FIB4, APRI and BARD. Advanced fibrosis was considered as F3–4 and cirrhosis as F4 fibrosis on liver biopsy. Diagnostic performance was assessed by analysis of the area under receiver operating characteristic curve (AUROC) and sensitivity/specificity calculations.

Results: Among 409 patients, 277 (66.4%) had pure MAFLD and 132 (31.7%) had MAFLD-ALD. Baseline characteristics in pure MAFLD vs MAFLD-ALD were: age (51.2 vs 58.2, $p < 0.001$), male sex (49.5 vs 87.9%, $p < 0.001$), BMI (36.9 vs 30.4 kg/m^2, $p < 0.001$), diabetes (51.1 vs 69.2%, $p = 0.001$), advanced fibrosis (27.7 vs 71.2%), cirrhosis (17.5 vs 63.6%), NASH (37.3 vs 32.6%, $p = 0.406$) and median steatosis proportion (50 vs 30%, $p < 0.001$). In pure MAFLD, the AUROCs of FIB4, NFS, APRI, and BARD for advanced fibrosis were 0.88, 0.74, 0.78 and 0.73, respectively (Table). The same AUROCs for predicting cirrhosis were 0.94, 0.82, 0.8 and 0.79, respectively. When comparing the AUROCs, FIB4 performed significantly better than the other non-invasive scores ($p < 0.001$) for the prediction of both advanced fibrosis and cirrhosis in pure MAFLD. However, FIB4 performed less well for the prediction of cirrhosis in patients with MAFLD-ALD compared to pure MAFLD (AUROC 0.83 vs 0.94, $p = 0.005$), while the other scores performed similarly.

Table: Comparison of the diagnostic performance of non-invasive fibrosis scores in MAFLD

Non-invasive score	AUROC	95% CI	Cut-offs	Sensitivity (%)	Specificity (%)
Advanced fibrosis					
FIB4	0.88	0.83–0.93	1.3	79	75
			2.67	49	98
NFS	0.74*	0.66–0.81	−1.455	90	29
			0.676	43	89
APRI	0.78*	0.72–0.84	0.5	68	72
			1.5	12	97
BARD	0.73*	0.66–0.8	2	84	43
			4	42	90
Cirrhosis

*$p < 0.05$ significantly different to FIB4.

Conclusion: FIB4 performs better than other serum non-invasive tests for the prediction of advanced fibrosis and cirrhosis in MAFLD patients, however its performance for the prediction of cirrhosis is reduced in the presence of alcohol abuse.

FRI116

Presence of auto-antibodies has no impact on histological parameters in non-alcoholic fatty liver disease

Ajeet Singh Bhadoria[1], Kavita Jain[2], Archana Rastogi[2], Chhagan Bihari[2]. *[1]All India Institute of Medical Science Rishikesh, Community and Family Medicine, Rishikesh, India; [2]Institute of Liver and Biliary Sciences, New Delhi, India*
Email: ajeetsinghbhadoria@gmail.com

Background and aims: Presence of auto-antibodies have been documented with liver diseases like viral hepatitis, drug induced hepatitis and non-alcoholic fatty liver disease (NAFLD). However, significance and impact of these autoantibodies on histological severity of NAFLD yet needs to be explored. Previous reports on association of autoantibodies with histological severity in other cohorts have revealed inconsistent results. Therefore, this study was undertaken to document the impact of auto-antibodies on histological parameters of NAFLD.

Method: All cases with histological diagnosis of NAFLD during Jan 2016–Jan 2021 were included in the study. Laboratory parameters were recorded and histological assessment was done utilizing Ishak's modified system. Positivity of autoimmune markers was defined as presence of either Anti-nuclear Antibody (ANA; titre of >1:80), anti-smooth muscle antibodies (ASMA), or anti-liver-kidney-microsomal antibodies (LKM-1; titre of >1:40). Demographic, biochemical, serologic and histological characteristics were compared between cases with and without any antibody positivity. Serum levels of CK18-M30 and PIIINP were evaluated by ELISA to assess the subtle changes in necro-inflammatory activity and fibrosis.

Results: Out of 1149 NAFLD cases screened, complete autoantibody status was known for 683 cases. Autoantibodies were present in 281/683 (41.1%, 95% CI 37.4–44.9) patients. ANA, ASMA, ANA plus ASMA was seen in 20.9% (95% CI 17.9–24.2), 14.5% (95% CI 11.9–17.4) and 5.7% (95% CI 4.1–7.7) cases, respectively. LKM-1 was not seen in any case. No significant difference was noted between the two groups in

terms of age, gender, body mass index, platelet levels, serum IgG, liver function parameters, ferritin, fasting glucose, fasting insulin, and HbA1c and lipid profile (p > 0.05). No significant difference was noted in histological parameters between the groups. However, mean CK18-M30 and PIIINP showed a rising trend with NAFL, NASH, NASH+AIH (χ^2 *trend p < 0.001)*. Mean CK18-M30 between cases with negative autoantibody, ANA positivity, ASMA positivity and combined positivity of autoantibody were 178.2 ± 81.8, 161.6 ± 63.7, 153.2 ± 70.3 and 169.8 ± 42.9, respectively (*p = 0.57*).

Conclusion: Auto antibodies were present in more than one third of NAFLD cases, with ANA positivity in one fifth and presence of ASMA in more than one in ten cases. No significant necro-inflammatory activity or fibrosis was seen with presence of auto-antibodies. However, CK-18-M30 and PIIINP showed a significant rising trend from NAFL to NASH to NASH+AIH.

FRI117

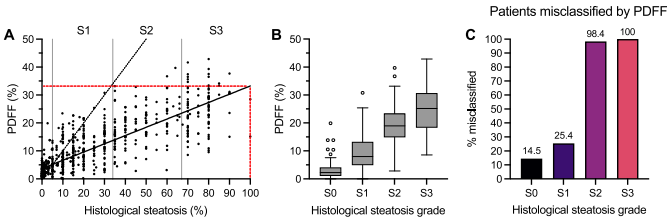
Marked underestimation of liver fat content as measured by magnetic resonance versus histology—a systematic review and meta-analysis

Sami Qadri[1,2], Kimmo Porthan[1,2], Anne Juuti[3], Anne Penttilä[3], Juhani Dabek[1,2], Tiina E. Lehtimäki[4], Wenla Seppänen[4], Johanna Arola[5], Perttu Arkkila[6], Hannele Yki-Järvinen[1,2]. *[1]University of Helsinki and Helsinki University Hospital, Department of Medicine, Helsinki, Finland; [2]Minerva Foundation Institute for Medical Research, Helsinki, Finland; [3]University of Helsinki and Helsinki University Hospital, Department of Gastrointestinal Surgery, Abdominal Centre, Helsinki, Finland; [4]Helsinki University Hospital, HUS Medical Imaging Centre, Helsinki, Finland; [5]University of Helsinki and Helsinki University Hospital, Department of Pathology, Helsinki, Finland; [6]Helsinki University Hospital and University of Helsinki, Department of Gastroenterology, Abdominal Centre, Helsinki, Finland*
Email: hannele.yki-jarvinen@helsinki.fi

Background and aims: Magnetic resonance spectroscopy (MRS) and imaging (MRI) measure liver fat via the proton density fat fraction (PDFF), which reflects the tissue volume fraction of hepatic triacylglycerols. Intuitively, PDFF would be predicted to give lower values of steatosis compared to histology, which estimates the percentage of lipid droplet-laden hepatocytes out of all hepatocytes. We conducted a systematic review and meta-analysis of patient-level data to characterise the linearity and agreement between PDFF and histological steatosis across the full spectrum of fatty liver.

Method: Following the PRISMA guideline, we searched PubMed, Scopus, Web of Science, and the Cochrane Library until February 20, 2022, to identify all studies showing data on histological macrovesicular steatosis percentage and MRS/MRI-PDFF in adults with non-alcoholic fatty liver disease (NAFLD) or in living liver donor candidates. We invited authors to submit individual patient data for pooled analysis. Linearity between PDFF and histological steatosis was assessed using Pearson's correlation, linear regression, and mixed-effects models. Agreement was assessed using Bland-Altman analysis and intraclass correlation coefficient (ICC) for continuous data and Cohen's kappa for graded classification. Risk-of-bias was assessed using QUADAS-2.

Results: The eligible studies numbered 11 (3 with MRI-PDFF and 8 with MRS-PDFF; N = 755). The relationship between PDFF and histological steatosis was highly linear (r = 0.82, p < 0.0001), and their values were fairly similar at low levels of liver fat (<5–10%). However, the higher the liver fat, the more PDFF underestimated steatosis as compared to histology (Fig. A). On the average, histological steatosis was 2.7-fold higher than PDFF, and the fractional underestimation by PDFF tended to increase from low to high levels of liver fat. A histological steatosis of 100% corresponded to an average PDFF of 33% (Fig. A). The ICC for absolute agreement between the measures was 0.43, denoting poor reliability, and for consistency between the measures 0.52, denoting moderate reliability. Use of the common NAFLD grading of steatosis (S0: <5%; S1: 5–33%; S2: 34–66%; S3: >66%) for PDFF resulted in gross misclassification of especially those patients with histological steatosis above grade S1 (kappa = 0.32; Fig. B-C). Median PDFF values corresponding to each steatosis grade were 2.2% for S0, 8.0% for S1, 18.9% for S2, and 25.2% for S3.



Conclusion: Histological and PDFF measurements of liver fat are fundamentally different. While they are in reasonable agreement at levels around the diagnostic threshold for NAFLD (~5%), histological steatosis far surpasses PDFF in patients with moderate-to-severe fatty liver. This difference should be acknowledged in guidelines for NAFLD to prevent misjudgement of the clinical status or treatment effect in patient care.

FRI118

Disease severity assessment of metabolic dysfunction-associated fatty liver disease in Taiwan

Jee-Fu Huang[1,2,3], Pei-Chien Tsai[1], Ching-I Huang[1,3], Ming-Lun Yeh[1,3], Chung-Feng Huang[1,3], Chia-Yen Dai[1,3], Ming-Lung Yu[1,3], Wan-Long Chuang[1,3]. *[1]Kaohsiung Medical University Hospital, Hepatobiliary Division, Department of Internal Medicine, Kaohsiung, Taiwan; [2]Kaohsiung Medical University Hospital, Hepatitis Center, Kaohsiung, Taiwan; [3]Kaohsiung Medical University, Faculty of Internal Medicine, College of Medicine, Kaohsiung, Taiwan*
Email: waloch@kmu.edu.tw

Background and aims: Disease severity in metabolic dysfunction-associated fatty liver disease (MAFLD) has rarely been investigated in Asians. The study aimed to assess the fibrosis stages of MAFLD in a community-based cohort in Taiwan. We also aimed to compare the differences of features between different definitions as well as the interaction between metabolic factors and viral factors.

Method: The retrospective case-control study was performed in adult subjects participating liver disease screening in Southern Taiwan. The items of liver disease screening included HBsAg, anti-HCV, transaminases, and metabolic profiles in a voluntary basis. Abdominal sonography was performed for those who had viral hepatitis or elevated transaminase levels. According to the MAFLD diagnostic criteria we stratified the subjects into: group A for type 2 diabetes, group B for BMI>23 kg/m^2, and group C of BMI≤23 kg/m^2 subjects who carried at least 2 metabolic items, respectively. Disease severity was assessed by non-invasive Fibrosis-4 (FIB-4) Index. Advanced fibrosis was defined as FIB-4 value>3.25.

Results: From 2009 to 2020, there're 5, 180 subjects who had fatty liver index (FLI)>60 and has fatty liver on sonography. We recruited 1, 948 subjects (mean age = 51.5 ± 13.4 years, females 52.1%) who met the diagnostic criteria of MAFLD and had completed results for fibrosis assessment. The study pool included 1, 470 (75.5%) NBNC NAFLD subjects and 478 subjects possessing concomitant liver diseases such as viral hepatitis infections and alcoholism. There were 395 (20.3%) of Gr A, 1, 818 (93.3%) of Gr B, and 44 (2.3%) subjects of Gr C, respectively. Advanced fibrosis on FIB-4 was observed in 79 (4.1%) subjects. The subjects of Gr C had a significantly higher percentage (20.5%, 9/44) of advanced fibrosis than Gr A (4.1%, 16/395) and Gr B (3.6%, 65/1, 818) (p < 0.001). Excluding those who had concomitant liver diseases, the subjects of Gr C still had a significantly higher percentage (15%) of advanced fibrosis than Gr A (1.8%) and Gr B (1.4%) (p = 0.003). Multivariate regression analysis demonstrated that HBV/HCV co-infection (OR = 16.74, 95% CI = 4.62–60.67, P <

0.001), HCV infection (OR = 8.83 95% CI = 4.79–16.30, P < 0.001), Gr C (OR = 6.94, 95% CI = 2.65–18.15, P < 0.001), and age (OR = 1.08, 95% CI = 1.05–1.11, P < 0.001) were significant factors for predicting the subjects with advanced fibrosis.
Conclusion: Lean MAFLD Taiwanese subjects carrying metabolic abnormalities had a higher chance of advanced fibrosis than others in a community-based setting.

FRI119
Optical analysis of liver magnetic resonance images (MRI) 3 T to detect steatohepatitis features: the program DeMILI 3.0.
Isabel Fernández-Lizaranzu[1,2], Emilio Gomez-Gonzalez[2], Sheila Gato Zambrano[1], Rocío Montero-Vallejo[1], Enrique Claudio Fernandez[3], Juan Carlos Diaz Martin[3], Rebeca Sigüenza[4], Rocío Aller[4], Maria Angeles Martin Prats[5], Manuel Romero Gomez[6]. *[1]Institute of Biomedicine of Seville, Seville, Spain; [2]Universidad de Sevilla, Higher Technical School of Engineering (ETSI), Group of Interdisciplinary Physics (GFI), Seville, Spain; [3]Virgen del Rocio University Hospital, Department of Radiology, Spain; [4]Hospital Clínico Universitario de Valladolid, Spain; [5]Universidad de Sevilla, Department of Electronic Engineering, Spain; [6]Institute of Biomedicine of Seville, Seville, Spain*
Email: ifernandez14@us.es

Background and aims: DeMILI in MRI 1.5 T has been proved as useful to detect steatohepatitis in patients with non-alcoholic fatty liver disease (NAFLD) (Gallego-Durán et al. Sci Rep 2016). The aim of this study was to evaluate the potential of optical processing methods applied to non-enhanced contrast liver 3 T MRI to predict steatohepatitis in NAFLD patients.
Method: Seventy-nine biopsy-proven NAFLD patients recruited between October 2019 and December 2021 at 'Virgen del Rocío' University Hospital (HUVR, n = 68) and Valladolid Clinical University Hospital (HCUV, n = 11). Main characteristics: 50.6 % female, 21.5% <45 years old and 32.9% >65 years old, 55.6% showed steatohepatitis in the liver biopsy. 3.0 T MRI was conducted using a whole-body Philips® scanner without contrast medium. 3 different sequences were performed in axial plane: SSFSE-T2 (Single Shot Fast Spin Echo T2-weighted), FAST-STIR (Fast Short inversion Time Inversion Recovery) and DYNAMIC. The entire liver was imaged and 6 consecutive slices, per each sequence, were manually selected covering the whole organ. 84 physical and mathematical feature descriptors (estimators) were computed from every image. Principal Component Analysis was performed to extract the main estimators related to steatohepatitis and two logistic regressions (LR) were built: The first one (DeMILI 3.0-v1) used estimators E63, E12 and E21, n = 43 HUVR patients for training, and n = 36 patients (25 HUVR + 11 HCUV) for validation. The second LR (DeMILI 3.0-v2) was built with estimators E70, E12 and E21 and the same cohort in different subsets: training n = 64 from HUVR, and validation n = 15 (4 HUVR + 11 HCUV). Receiver operating characteristic (ROC) curves were obtained.
Results: ROC curves for DeMILI 3.0-v1 and DeMILI 3.0-v2 are shown in Figure 1. The area under the ROC curves (AUROC) obtained were: i) for DeMILI 3.0-v1, AUROC = 0.7378 for training set and AUROC = 0.7307 for validation set, and ii) for DeMILI 3.0-v2, AUROC = 0.7958 for training set and AUROC = 0.6071 for validation set.

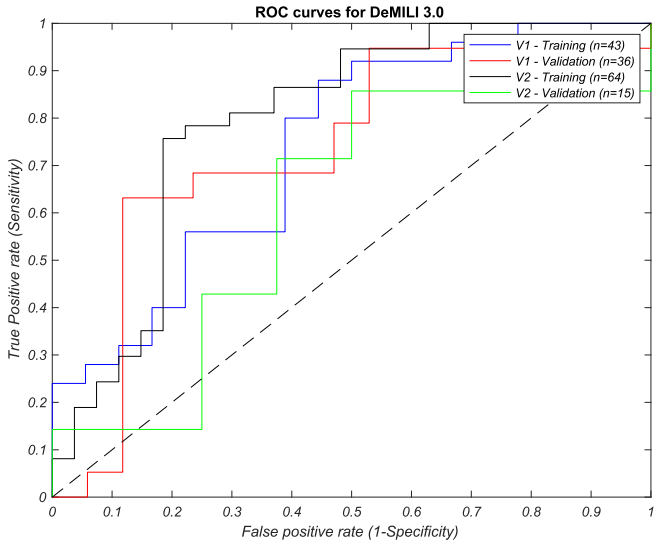


Figure: ROC curves of LRs (v1 and v2) for training and validation subsets.

Conclusion: Initial results with limited cohorts show that DeMILI 3.0 detects steatohepatitis in patients with NAFLD with a diagnosis accuracy of 0.73 (DeMILI 3.0-v1). Validation cohorts include patients from other center than training. DeMILI 3.0-v1 yields results close to DeMILI using 1.5 T MRI.

FRI120
The fibrosis-4 cut-off value for significant fibrosis is dependent on the type of non-alcoholic fatty liver disease patients
Leen Heyens[1,2,3], Wouter Robaeys[1,2], Christophe Van Steenkiste[4,5], Sven Francque[5,6], Geert Robaeys[1,2,7]. *[1]Hasselt University, Faculty of Life Sciences and Medicine, Hasselt, Belgium; [2]Ziekenhuis Oost-Limburg, Gastro-enterology and Hepatology, Genk, Belgium; [3]Maastricht University, Faculty of Health, Medicine and Life Sciences, Maastricht, Netherlands; [4]Maria Middelares, Gastro-enterology and Hepatology, Gent, Belgium; [5]University of Antwerp, Gastro-enterology and Hepatology, Antwerpen, Belgium; [6]Antwerp University Hospital, Gastro-enterology and Hepatology, Edegem, Belgium; [7]UZ Leuven Gasthuisberg Campus, Gastro-enterology, Leuven, Belgium*
Email: leen.heyens@uhasselt.be

Background and aims: Non-alcoholic fatty liver disease (NAFLD) has become the most frequent cause of chronic liver disease. The fibrosis stage has been identified as the most important predictor of prognosis. The Fibrosis-4 (FIB-4) is an easy-to-use non-invasive score to predict fibrosis based on routine blood parameters. However, we previously showed that the 1.3 FIB-4 cut-off value had a low performance to detect significant fibrosis (≥F2) in a primary care (PC) population. We aimed to determine whether NAFLD-group-specific optimal FIB-4 cut-off values can be determined to identify patients with a high likelihood of ≥F2, considered an at-risk population to be referred for further management.
Method: In a prospective study in the Belgian regions of Limburg, East-Flanders, and Antwerp, patients were screened in seven PC practices. Type 2 diabetes mellitus patients (T2DM) were screened in the hospital of Ziekenhuis Oost-Limburg. As a proxy of the fibrosis stage, liver stiffness was determined using Vibration Controlled Transient Elastography (VCTE) by FibroScan® (Echosens, France) and used as the reference method. The FIB-4 was calculated based on recent laboratory data from the electronic patient file. The Youden Index (J) was used to determine the optimal cut-off value for detecting ≥F2 (>7.9 kPa for the M-probe and >7.2 kPa for the XL-probe) in three populations: PC (unselected all-comers), T2DM screened in PC (T2DM-PC, PC subgroup), T2DM screened in a hospital (T2DM-H).

Results: Of the 816 (424 (52.0%) PC, 103 (12.6%) T2DM PC, and 289 (35.4%) T2DM-H) screened patients, 534 (65.4%) had FIB-4 values and no other causes of steatosis but NAFLD. Of these, 275 (51.5%) were male, median age was 63 (26–71) years, median BMI 29.8 (26.2–33.46) kg/m^2, median waist circumference 104.0 (97.0–113.0) cm for men and 98.0 (86.1–110.0) cm for women, and 276 (51.9%) had T2DM. The number of patients with ≥F2 was 30 (11.8%), 20 (30.3%), and 96 (45.7%) for the PC, T2DM-PC, and T2DM-H cohorts. Using logistic regression, both FIB-4 ($p < 0.05$) and the type of NAFLD-group significantly ($p < 0.05$) contributed to ≥F2. The area under the operating curve (AUROC) of the model was 0.76 compared to an AUROC of 0.61 using only FIB-4. The maximum J was 0.40461 and corresponded to a sensitivity of 0.61 and specificity of 0.80. Using the linear predictor, the optimal cut-off value per population was 4.3 for the PC cohort, 2.3 for the T2DM-PC, and 0.66 for the T2DM-H cohort. These cut-off values were not influenced by age or the grade of steatosis as measured by controlled attenuation parameter (CAP).

Conclusion: The optimal cut-off value of the FIB-4 score for detecting NAFLD-associated significant fibrosis depends on the patient groups' characteristics, potentially resulting from the different prevalence of the condition in the respective groups. However, the cut-off values were not influenced by age or the severity of the steatosis.

FRI121

Developing an algorithm to predict NAFLD in clinical trial volunteers-interim report NCT04873258

Jörg Täubel[1,2,3], Dominic Pimenta[4], Aviva Petrie[5], Lydia Sulaiman[6], Ulrike Lorch[3], Kevin Moore[5]. *[1]St George's University of London, United Kingdom; [2]Richmond Research Institute, London, United Kingdom; [3]Richmond Pharmacology, United Kingdom; [4]Richmond Research Institute, London, United Kingdom; [5]University College London, United Kingdom; [6]King's College London, United Kingdom*
Email: d.pimenta@richmondresearchinstitute.org

Background and aims: Non-alcoholic fatty liver disease (NAFLD) affects around 1 in 4 of the global adult population, and ranges in severity from benign fatty liver infiltration, to hepatitis, cirrhosis and hepatocellular carcinoma. NAFLD has important implications for clinical trial volunteers as an occult co-morbidity. NAFLD may modulate drug metabolism, and studies have suggested that Grade III/IV liver reactions are 4x commoner in healthy volunteers with probable NAFLD than without. We therefore aimed to develop a non-invasive tool, utilizing new technology, to predict NAFLD in this population. This is our interim report (NCT04873258)
Method: This is an ongoing observational cross-sectional study design. Volunteers attend the unit for a single day of biomarker assessment, including bioimpedance vector analysis (%visceral fat, total body fat% and skeletal muscle %), anthropometric measurement (BMI, waist circumference), and lab bloods. A FibroScan is performed as a pragmatic gold standard 'outcome' for NAFLD, and E (fibrosis) and CAP (steatosis) scores are recorded. Traditional multivariate linear and logistic regression is performed, correlating biomarkers with linear E and CAP scores, and 'significant' disease (≥F2, E >7.5 kPa and ≥S2, CAp >260 dB) respectively. Alongside this machine learning models are trained (Python {sklearn, TensorFlow}) and performance compared.
Results: Interim results: 290 individuals (of extended target 1500) with demographics as follows; 61% male, 51.5% Caucasian, average age of 39.4 years, 40% of the cohort had diabetes. The overall prevalence of significant fibrosis (E score ≥7.5 kPa) was 11.4% and the prevalence of significant steatosis (CAP ≥260 dB) was 35.6%. A logistic regression model was trained for E and CAP scores, identifying key features in the dataset as waist circumference and GGT. A prototype clinical score was derived, with an AUC of 0.81 for E and 0.89 for CAP scores. Machine learning models were compared, with the best performing model being Gaussian Naïve Bayes for E (AUC 0.82) and Decision Tree for CAP (0.79). A clinical tool based on a score derived from logistic regression coefficients was created (Figure) for use by physicians to gauge the risk of NAFLD in volunteers, using two variables (GGT and waist circumference), with high sensitivity and acceptable specificity (E score sensitivity 90%, specificity 45%, CAP score sensitivity 85.5%, specificity 81.9%).

Figure: Prototype NAFLD clinical tool (Alpha).

Conclusion: Our early interim analysis shows promising results, sufficient to prototype a clinical tool with high sensitivity and acceptable specificity for screening out individuals in clinical trials at high probability of occult NAFLD and/or fibrosis. Future work to develop the underlying model, advance machine learning models to further improve performance, and deliver to clinic is underway.

FRI122

Correlation of ultrasound derived fat fraction (UDFF) with MRI (PDFF): possibilities and analysis of confounding factors

Reinhard Kubale[1,2], Marcin Krawczyk[3,4], Paul Lessenich[1], Arno Bücker[1], Aaron Engel[5], Andrzej Milkowski[5], Guenther Schneider[2]. *[1]Saarland University Hospital, Homburg, Germany; [2]Saarland University, Saarbrücken, Germany; [3]Saarland University Hospital, Department of Internal Medicine II-Gastroenterology, Hepatology, Endocrinology, Diabetology, and Nutritional Medicine, Homburg, Germany; [4]Innere II, Homburg/Saar, Germany; [5]Siemens Healthineers, Forchheim, Germany*
Email: kubale@mac.com

Background and aims: Ultrasound derived Fat fraction (UDFF) is a quantitative sonographic method based on a combination of attenuation and backscatter coefficients. Aim of the study was to evaluate feasibility and correctness in correlation with MRI (PDFF: Proton density fat fraction) and to analyze confounding factors.
Method: Examinations were done with 2 US-machines (Sequoia and S2000: Siemens) with 5C1, DAX and 6C1 transducers with an algorithm based on a phantom corrected combination of attenuation (AC) and backscatter coefficient (BSC). Measurements of a ROI of 9 cm^2 were correlated with MRI PDFF values of the whole liver and a ROI in the right liver lobe (RLL) in the same position (Vida, Siemens-LiverLab®). To test the reproducibility we examined in a pilot study 20 patients with two UDFF-measurements on different days. The effect of fasting state was tested by performing UDFF before, 1, 3 and 5 hours after a standard meal. The main study consists of 194

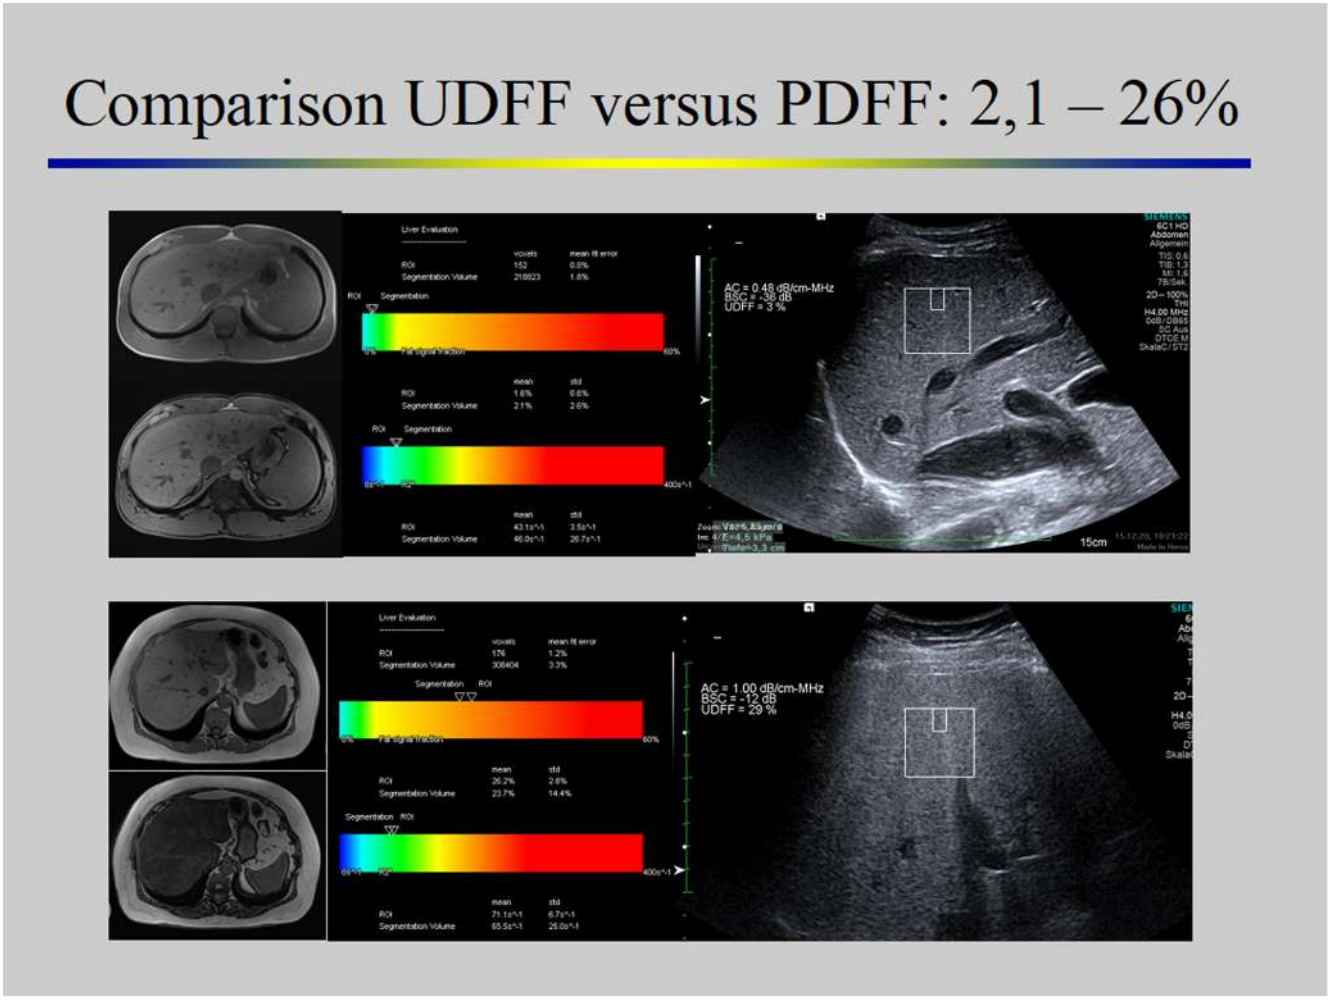

Figure: (abstract: FRI122): Comparison of Multiparametric Assessment of UDFF with PDFF in patients with 2, 1 % and 26%.

consecutive patients (112 male, 82 female), who received a liver MRI for clinical reasons.

Results: In the pilot study (Study I) PDFF of the whole liver (10.3 ± 9.4%), was significantly higher than in the corresponding ROI (8.65 ± 9.6%). The correlation of PDFF-measurements with scan heads (5C1, DAX, 6C1) were r = 0.94/0.91 and 0.85. Repeated measurements showed values of r = 0.99/0.97 and 0.89 with best reproducibility of the DAX. Measurements before, 1, 3 and 5 hours after meal showed no significant differences between the time points (Friedmann-Test).

The main study shows a significant difference in PDFF-measurement of the whole liver (11.6 ± 9.1%) and the ROI (8.9 ± 9.5%). Although AC and BSC are not linear related to PDFF the model with both parameters shows a significant correlation between UDFF and PDFF of the whole liver and the corresponding ROI and Voxel for all patients r = 0.80/0.7 and 0.6 (6C1). Bland-Altmann shows, that main confounding factors are severe liver cirrhosis with a small RLL, chemotherapy/lipiodol application, sarcoidosis and amyloidosis. Problems in MRI arose in severe Hemochromatosis, patients over 150 kg due to artifacts.

Conclusion: UDFF shows a strong positive correlation with PDFF. Confounding factors could be identified hypothetically allowing for improvement in the future. UDFF could be a screening tool for early diagnosis of NAFLD and a biomarker for therapy control.

FRI123

ELF to identify NASH and fibrosis in non-alcohol related fatty liver disease

Richard Parker[1], Peter Eddowes[2], Natasha McDonald[3], Philip N. Newsome[2], Gideon Hirschfield[4], Jonathan Fallowfield[3], Ian Rowe[5]. *[1]Leeds Teaching Hospital Trust, Leeds Liver Unit, Leeds, United Kingdom; [2]University of Birmingham, Centre for Liver Research, Birmingham, United Kingdom; [3]MRC/University of Edinburgh Centre for Inflammation Research, Queen's Medical Research Institute, Edinburgh, Edinburgh, United Kingdom; [4]University of Toronto, Division of Gastroenterology, Toronto, Canada; [5]University of Leeds, Leeds Institute for Medical Research, Leeds, United Kingdom*
Email: richardparker@nhs.net

Background and aims: The current paradigm for eligibility for trials in NAFLD requires the presence of NASH and fibrosis of particular severity. We examined whether the ELF score could be repurposed to predict both NASH and fibrosis.

Method: A cohort of 240 patients with biopsy-proven NAFLD was used. Treatment threshold was NAS ≥4 (as per the FLIP algorithm) and fibrosis grade of greater than 2. The cohort was split 60:40 into modelling and validation groups. Internal validation of modelling was done using 2000 bootstrapped samples. Test performance was evaluated with AUROC analysis. Low and high cut-offs at 90% sensitivity or specificity respectively were calculated in the modelling cohort, and negative and positive predictive values (NPV, PPV) and positive and negative diagnostic likelihood ratios (PDLR, NDLR)

calculated. The model was calibrated graphically in the validation cohort and test performance confirmed. All statistical tests were done in R using pROC, rms and ggplot2 packages.

Results: The average age of the cohort was 55 years, 117 (66%) were male. All components of the ELF score correlated with NAS and were significantly different between patients with NAS <4 or ≥4. A model ('ELF-t') that included all of the ELF parameters (HA, P3P and TIMP-1) performed best to identify cases suitable for trials or treatment (AUROC 0.74). At a low cut-off ELF-t had a NPV of 91% and the high cut-off gave a PPV of 92%. NDLR was 0.27 (0.12–0.607), PDLR 2.47 (1.15–5.31). Calibration was good in the validation cohort with similar test performance (AUC 0.79, NPV 91%, PPV 93%).

Conclusion: The constituent markers of the ELF test can be repurposed to assess the likelihood of NAFLD with sufficient activity and scarring to meet common eligibility criteria for clinical trials, which are likely to translate into a paradigm for treatment as new drugs come to market. This provides a non-invasive method for assessing patients as an alternative to liver biopsy.

FRI124

Performance of the Steatosis-Associated Fibrosis Estimator (SAFE) to predict F2 fibrosis and higher in a cohort of South Korean patients with non-alcoholic fatty liver disease (NAFLD)

Vivek Charu[1], Allison Kwong[1], Ajitha Mannalithara[1], Eileen Yoon[2], Dae Won Jun[2], W. Ray Kim[1]. *[1]Stanford University School of Medicine, Stanford, United States; [2]Hanyang University College of Medicine, Korea, Rep. of South*
Email: vcharu@stanford.edu

Background and aims: The Steatosis-Associated Fibrosis Estimator (SAFE) score is a recently developed scoring system to categorize NAFLD patients by their risk of having significant liver fibrosis (F2 or higher). Here we evaluate the performance of the SAFE score in predicting F2 fibrosis based on transient elastography (FibroScan) measurements in a cohort of South Korean patients with NAFLD.

Method: We identified a cohort of adult patients with a clinical diagnosis of NAFLD who underwent FIbroScan at Hanyang University from 2020 to 2022. Using the available laboratory information, we calculated SAFE, Fibrosis-4 (FIB-4) and the NAFLD fibrosis score (NFS) for each patient. Our outcome of interest was F2 fibrosis or higher, and a FibroScan threshold of greater than 7 kPa was used. We computed the area under the receiver operating curves (AUROC) to quantify the performance of each non-invasive score to predict F2 fibrosis or greater. We calculated the sensitivity, specificity, positive predictive value and negative predictive values of the SAFE score using an apriori determined threshold of greater than or equal to 100.

Results: We identified 749 patients with a clinical diagnosis of NAFLD who underwent FibroScan testing with clinical/laboratory data to generate SAFE, FIB-4 and NFS scores (Table). SAFE, FIB-4 and NFS were strongly correlated with each other in this cohort (pairwise Spearman's correlations: SAFE-FIB4: 0.83; SAFE-NFS: 0.80; FIB4-NFS: 0.84). We estimated the AUROC for each fibrosis estimator (Table), and found that the AUROC for the SAFE score (0.76) was significantly higher than that for FIB-4 (0.64) and NFS (0.63) (p-values for DeLong's tests: SAFE-FIB4, <2.2e-16; SAFE-NFS, 6.352e-16). FIB-4 and NFS scores had similar AUROC (0.64 and 0.63, p-value for DeLong's test: 0.5822). Using a threshold for the SAFE score of greater than 100 to identify high-risk patients would result in a sensitivity of 0.66 (95%CI: 0.58–0.73), specificity of 0.74 (95%CI: 0.70–0.78), positive predictive value of 0.42 (95%CI: 0.36–0.48) and negative predictive value of 0.88 (95%CI: 0.85–0.91) for predicting F2 fibrosis or higher based on FibroScan measurements.

Table. Clinical/demographic data; fibrosis estimator performance

Sex (N; %)	Male	372 (49.6%)
	Female	377 (50.4%)
Age (median; IQR [years])		55.0 (40.0-63.0)
BMI (median; IQR [kg/m^2])		25.3 (22.9-28.3)
Diabetes (N; %)	Yes	218 (29.1%)
	No	531 (70.9%)
AST (median; IQR [u/L])		36.0 (26.0-53.0)
ALT (median; IQR [u/L])		36.0 (21.0-68.0)
Total Protein (median; IQR [g/dL])		7.7 (7.4-8.0)
Albumin (median; IQR [g/dL])		4.5 (4.3-4.6)
Globulin (median; IQR [g/dL])		3.2 (2.9-3.5)
Platelets (median; IQR [x10^9/L])		236.0 (196-279)
Fibroscan (median; IQR [kPa])		5.4 (4.3-6.8)
Fibroscan (N; %)	>7.0 kPa	168 (22.4%)
	<=7.0 kPa	581 (77.6%)
Fibrosis scores		
SAFE (median; IQR)		57.6 (-4.2-133.8)
FIB-4 (median; IQR)		1.33 (0.88-2.05)
NFS (median; IQR)		-1.94 (-3.08- -0.82)
AUROCs		
SAFE (estimate; 95%CI)		0.76 (0.72-0.81)
FIB-4 (estimate; 95%CI)		0.64 (0.59-0.69)
NFS (estimate; 95%CI)		0.63 (0.58-0.68)

Conclusion: In a cohort of Korean adults with NAFLD, the SAFE score performs better than FIB-4 or NFS to predict F2 fibrosis or higher based on FibroScan measurement. A SAFE threshold of greater than 100 has reasonable, but not perfect, negative predictive value for identifying F2 fibrosis or greater in this cohort (0.88). Evaluating the performance of the SAFE score in additional diverse cohorts is essential to assess its utility in identifying patients at low risk of having clinically significant fibrosis.

FRI125

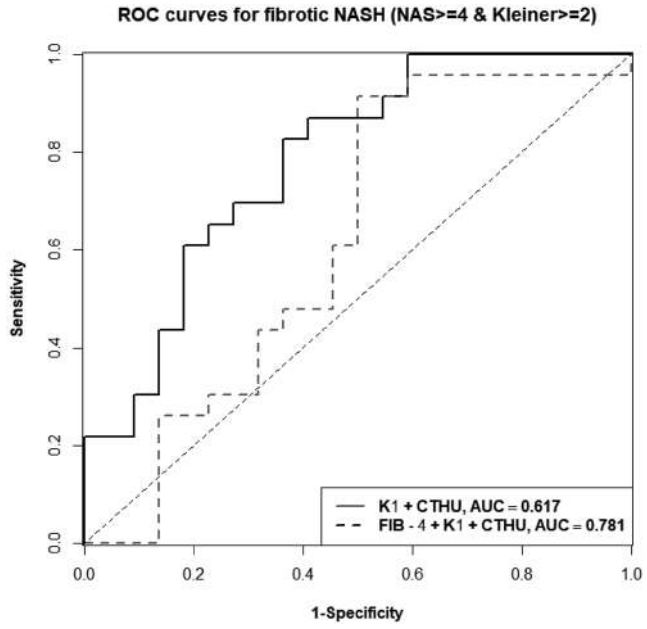
FIB-4 combined with positron emission tomography biomarkers detects fibrotic NASH

Sean Romeo[1], Connie Chan[2], Blake Shaw[3], Karen Matsukuma[4], Michael Corwin[5], Victoria Lyo[6], Shuai Chen[3], Guobao Wang[5], Souvik Sarkar[1,7]. *[1]University of California, Davis, Internal Medicine/Gastroenterology and Hepatology, United States; [2]UC Davis School of Medicine, Sacramento, United States; [3]University of California, Davis, Public Health Sciences/Biostatistics, United States; [4]University of California, Davis, Pathology and Laboratory Medicine, United States; [5]University of California, Davis, Radiology, United States; [6]University of California, Davis, Surgery, United States; [7]Florida Research Institute, Lakewood Ranch, United States*
Email: ssarkar@ucdavis.edu

Background and aims: Non-alcoholic steatohepatitis (NASH) is a severe form of non-alcoholic fatty liver disease (NAFLD) that is associated with liver cirrhosis and hepatocellular cancer. Methods for diagnosing NASH without liver biopsy are limited, therefore presenting an urgency to noninvasively detect NASH by characterizing features: steatosis, inflammation, and fibrosis. We combined the well-established non-invasive fibrosis-4 (FIB-4) measurement with a recent ^{18}F-fluorodeoxyglucose (FDG) positron emission tomography/computed tomography (PET/CT) imaging approach for NASH to elucidate imaging determinant of fibrotic NASH.

Method: The study was approved by the institutional review board. Patients ≥18 years with NAFLD who had undergone liver biopsy were enrolled. FDG transport rate (K_1) by dynamic PET and CT Hounsfield units (CTHU) were determined from liver regions-of-interest (ROI) as previously defined, while FIB-4 was calculated from serum by an established criterion. Liver biopsies were scored per NASH-CRN (Clinical Research Network) criteria. Fibrotic NASH was defined as NAFLD activity score (NAS) ≥4 with Kleiner fibrosis stage ≥2. Severe fibrotic NASH was defined as NAS ≥5, plus fibrosis stage ≥3. Correlations among parameters were calculated using the

Spearman correlation. Receiver operating characteristics (ROC) analyses were performed with cut-off selected based on Youden's Index, where FIB-4, K_1 and CTHU were combined using logistic regression.
Results: Of 45 enrolled patients, 31 were female, 54 ± 13 years, and BMI 34.0 ± 5.7 kg/m^2; 16% of patients had inflammation >3, while 58% had NAS >4 and 29% with fibrosis ≥3. FIB-4 correlated with fibrosis significantly (r = 0.58, p < 0.001), as expected, but not with NAS (r = 0.2, p = 0.178). K_1 and CTHU showed significant correlations with NAS. As shown prior, the dual-variate model of K_1+CTHU could detect clinical NASH but not fibrotic NASH. When FIB-4 score was combined in the model it was able to detect fibrotic NASH with an AUC of 0.781 (Figure 1) and severe fibrotic NASH with an AUC of 0.845. The triple variate model of 1.46001*K1–0.04009*CTHU + 1.27309*FIB-4 ≥1.574408, was able to predict fibrotic NASH with a sensitivity of 83% and a specificity of 64%. While 3.27447*K1 + 0.00597*CTHU + 0.99330*FIB-4 ≥−1.296305 predicted severe fibrotic NASH with a sensitivity of 91% and specificity 68%.



Conclusion: Combination of non-invasive serum and imaging tests enabled detection of clinical fibrotic NASH. Studies in larger and diverse cohorts will enable establishing this tool for determination of clinical changes in NAFLD patients.

FRI126
Mitochondria-derived methylmalonic acid is associated with advanced fibrosis risks in metabolic dysfunction-associated fatty liver disease (MAFLD): results from the NHANES 1999–2004
Qi Huang[1], Li Li[1], Linjian Yang[1], Linong Ji[1], Xiantong Zou[1]. [1]*Peking University People's Hospital, China*
Email: evazou@bjmu.edu.cn

Background and aims: Methylmalonic acid (MMA) is related to mitochondrial dysfunction, which is a key process of fatty liver disease. This study aimed to investigate the association between MMA and metabolic dysfunction-associated fatty liver disease (MAFLD) using large epidemiological data.
Method: We included 12, 494 individuals from the National Health and Nutrition Examination Survey (NHANES) 1999–2004. MAFLD was diagnosed with Fatty Liver Index (FLI) ≥60 or USFLI≥30, and participants with advanced fibrosis risks were identified with elevated non-alcoholic fatty liver disease fibrosis score (NFS), fibrosis-4 (FIB4) or aspartate aminotransferase (AST): platelet ratio (APRI). Participants were divided into four groups according to MMA levels (<120, 120–175, 175–250 or >250 (nmol/L)).
Results: The prevalence of MAFLD was 38.3, 40.6, 42.1 and 39.8% (p = 0.068) and the prevalence of participants with advanced fibrosis risk was 2.0, 3.5, 5.6, 10.6% (p < 0.001) in four consecutive MMA groups. Compared with participants with lower MMA levels, higher MMA levels had a higher prevalence of diabetes, hypertension and dyslipidaemia, increased ALT, and decreased vitamin B12, RBC and platelet counts. Higher MMA levels were not independently associated with NAFLD (p for trend: 0.997). MMA>250 nmol/L independently increased the risk of advanced fibrosis by one fold in MAFLD patients (OR 95% confidence interval:2.05 (1.37, 3.08)), but not in non-MAFLD participants (OR 95%CI:1.81 (0.93, 3.54)). The association between MMA and fibrosis was consistent among different subgroups stratified by alcohol intake, BMI, blood glucose, pressure or lipids (p for interaction >0.05). The area under the receiver operator characteristics curve (ROC AUC) of MMA in detecting fibrosis in MAFLD was 0.658 (0.658, 0.658), which was higher than that of C-reactive protein 0.540 (0.540, 0.540) (p < 0.001).
Conclusion: MMA was independently associated with advanced fibrosis risks in MAFLD, and this association was unaltered in subgroups stratified by different metabolic profiles or lifestyles. This finding indicated a possibility of using MMA as a novel candidate non-invasive biomarker and therapeutic target for fibrosis in MAFLD.

Hepatic angiocrine HGF attenuates liver fibrogenesis via modulation of PDK1/AKT axis
Jianye Wang[1], Sarah Schulze[1], Victor Olsavszky[2], Kai Schledzewski[2], Cyrill Géraud[2], Helmut Friess[1], Norbert Hueser[1], Daniel Hartmann[1]. [1]*Klinikum rechts der Isar der Technischen Universität München, München, Germany;* [2]*Medical Faculty Mannheim, Heidelberg University, Mannheim, Germany*
Email: jianye.wang@tum.de

Background and aims: Hepatocyte growth factor (HGF) is a complete hepatic mitogen and is believed to play a role in liver fibrogenesis and hepatocarcinogenesis. Liver sinusoidal endothelial cells (LSEC) can recruit inflammatory cells by releasing angiocrine signals to produce HGF in the process of liver fibrosis and cirrhosis, but the precise contributions of HGF from LSEC to liver fibrosis remain elucidated.
Method: To investigate the effects of hepatic angiocrine HGF on liver fibrogenesis, Stab2-Cre^{tg} HGF$^{fl/fl}$ (HGF$^{LSEC-KO}$) mice, in which HGF is specifically switched off in LSEC, were used. Carbon tetrachloride (CCl_4) injection was performed in these mice and the kinetics of the ratio of liver to body weight, immunohistochemistry for liver fibrosis, Western blot and RT-PCR for fibrotic markers, HGF/c-MET signaling pathways and cell cycle-associated genes were determined after initiation of cirrhosis.
Results: We found that HGF$^{LSEC-KO}$ mice showed no difference in the liver-to-body-weight ratio compared to the control group after early-stage CCl_4 treatment. After fibrogenesis, HGF$^{LSEC-KO}$ mice had a higher expression of collagen 1A1 and alpha-SMA and the proliferation of hepatocytes was significantly impaired in HGF$^{LSEC-KO}$ mice. In addition, the LSEC-specific HGF deficiency reduced the c-met level and thus deactivated the PDK1 (3-phosphoinositide-dependent protein kinase-1)/Akt pathway while hepatic angiocrine HGF did not alter immune cell infiltration.
Conclusion: The hepatic angiocrine HGF signaling pathway plays a crucial role in the early stages of liver fibrogenesis. The hepatic angiocrine HGF signaling pathway is essential not only for liver

recovery during fibrogenesis, but also for the growth of the liver and even the entire organism.

Key words: hepatocyte growth factor (HGF), liver sinusoidal endothelial cells (LSEC), hepatocytes, liver, fibrogenesis, liver cirrhosis

Bisphosphonate-loaded nanogels attentuate liver fibrosis by repolarization of M2-type macrophages

Leonard Kaps[1], Anne Huppertsberg[2], Niklas Choteschovsky[1], Adrian Klefenz[1], Feyza Durak[3], Barbara Schoers[3], Mustafa Diken[3], Emma Eichler[1], Sebastian Rosigkeit[1], Sascha Schmitt[2], Christian Leps[4], Friedrich Foerster[1], Ernesto Bockamp[1], Bruno Degeest[5], Federico Marini[6], Kaloian Koynov[7], Stefan Tenzer[4], Detlef Schuppan[1], Lutz Nuhn[7]. [1]*University Medical Center Mainz, Institute of Translational Immunology and Research Center for Immune Therapy, Mianz, Germany;* [2]*Max Planck Institute for Polymer Research, Mainz, Germany;* [3]*University Medical Center Mainz, TRON-Translational Oncology, Mainz, Germany;* [4]*University Medical Center Mainz, Institute of Immunology, Mainz, Germany;* [5]*Ghent University, Department of Pharmaceutics and Cancer Research Institute Ghent (CRIG), Belgium, Belgium;* [6]*University Medical Center Mainz, Institute of Medical Biostatistics, Epidemiology and Informatics, Mainz, Germany;* [7]*Max Planck Institute for Polymer Research, Mainz*
Email: nuhn@uni-mainz.de

Background and aims: In liver fibrosis, M2-type macrophages promote the replacement of functional parenchyma by collagen-rich scar tissue. Bisphosphonates impaired the polarization towards M2-type macrophages and demonstrated an anti-fibrotic/-tumor effect in murine models of mesothelioma and liver cancer [V. JD *et al.*, Br J Cancer. 2010; T. L. Rogers *et al.*, J Transl Med. 2011]. But, pharmacokinetics of bisphosphonates are poor for liver targeting as they are rapidly excreted by the kidneys after intravenous (iv) application. Here, we aimed to treat liver fibrosis by repolarizing liver M2-type macrophages towards an antifibrotic M1-type via a biocompatible, pH-degradable, nanogel carrier system conjugated to the bisphosphonate alendronate (AL).

Method: In primary murine macrophages, AL/NP (~30 µM AL) induced no cytotoxic effect and repolarized M2-type polarized macrophages towards a M1-type, increasing the expression of the M1-type related markers TNF-α, CCL-2 and downregulated the M2-type markers IL-10 and chitinase YM-1 on the transcript and protein level as determined via qPCR and flowcytometry (FACS).

Results: After iv injection in CCl_4 fibrotic Balb/c mice, more than 80% of near-infrared fluorescence labeled (CS800)-AL/NP rapidly accumulated in the liver, whereas CS800-AL were instantly cleared via the kidneys. On the cellular level, CS800-AL/NP were effectively engulfed by non-parenchymal cells (e.g. liver macrophages), while the AL/NP's uptake was significantly lower in parenchymal cells (hepatocytes) as determined by FACS. CS800-AL/NP were well tolerated and showed no overt toxicity. For fibrosis induction, Balb/c mice were gavaged with CCl_4 for 5 weeks. At week 4, mice received two iv injections of AL/NP (~2 mg/kg or 4 mg/kg AL) per week while control groups received equal concentrations of AL or NP, respectively. At the end of week 5, mice were sacrificed and liver collagen and the surrogate marker α-SMA were significantly reduced to physiological levels in AL/NP treated vs. control mice as determined by HYP quantification, Sirius Red readout and immunohistochemistry, while free AL and NP had no significant effect. Transcriptomic and proteomic data from total liver tissue of AL/NP (~4 mg/kg AL) treated vs. control mice (n = 3) revealed an upregulation of proinflammatory pathways and an enrichment of M1-type macrophages related genes in the treated mice, suggesting that AL/NP treatment triggers a switch from M2- to M1-type macrophages. In addition, we showed a downregulation of the M2-type markers YM-1, CD206 and IL-10 in the treated vs. control fibrotic liver both on the transcript and protein expression level.

Conclusion: This nanogel platform and the presented delivered drug conjugate AL/NP may serve as a novel, highly effective tool to treat liver fibrosis and possibly other diseases that are dominated by M2-type macrophages.

FRI148

Preclinical evaluation of the calpain inhibitor BLD-3051 as a therapeutic strategy for liver fibrosis

C. Wong[1], J.-X. Huang[1], W. Yu[1], P. Ibrahim[1], Ravi Rajagopalan[1]. [1]*Blade Therapeutics, Inc, South San Francisco, United States*
Email: rrajagopalan@blademed.com

Background and aims: Calpains are a family of non-lysosomal intracellular calcium-dependent cysteine proteases that perform limited proteolytic cleavage of its substrates that in turn modulate a variety of signaling pathways controlling phenotypic effects like cell proliferation, migration, differentiation, and apoptosis. Elevated dimeric calpain activity levels are implicated in a variety of disease pathologies including fibrotic diseases. Additionally, calpain knock-outs and small molecule dimeric calpain inhibitors are efficacious in animal models of fibrosis. We have generated multiple calpain inhibitors with significantly improved potency, protease selectivity, and ADMET properties that may represent important new anti-fibrotic agents. Here, we describe the properties of BLD-3051, a small molecule dimeric calpain inhibitor and characterize its activity in a therapeutic model of liver fibrosis.

Method: 8-week-old C57BL/6 mice were fed a choline-deficient, L-amino acid, high fat diet (CDAHFD) for the entire 10-week study duration. Oral gavage dosing of BLD-3051 was initiated on week 5 of CDAHFD and continued for 6 weeks. Once daily (QD) doses of 60 and 200 mg/kg and twice daily (BID) doses of 30 and 100 mg/kg were evaluated. Body and liver weight and liver enzyme panel data were collected. Histopathology by modified NAFLD activity score (NAS) and liver hydroxy-proline levels were used to assess anti-fibrotic efficacy.

Results: BLD-3051 reduced NAS scores and liver hydroxy-proline levels in a dose-dependent manner with BID dosing being more efficacious. The lowering of NAS by BLD-3051 is largely driven by an anti-fibrotic effect.

Conclusion: BLD-3051 is a potent, selective, orally bioavailable calpain inhibitor that when dosed therapeutically shows robust anti-fibrotic effects against multiple endpoints in a CDAHFD induced model of liver fibrosis. BLD-3051 is currently in preclinical development.

FRI149

Experimental fibrosis alters matrix-bound vesicles cargo that do not revert after histologic recovery

Toshifumi Sato[1,2], Bashar Matour[3], Jiang Li[2], Michael Merchant[4], Daniel Wilkey[4], Kenichi Ikejima[1], Stephen Badylak[3,5], George Hussey[5,6], Melanie Scott[3,7], Gavin Arteel[2,7]. *[1]Juntendo University Hospital, Gastroenterology, Bunkyo City, Japan; [2]University of Pittsburgh-Department of Medicine, Gastroenterology, Pittsburgh, United States; [3]University of Pittsburgh, Surgery, Pittsburgh, United States; [4]University of Louisville, Medicine, Louisville, United States; [5]University of Pittsburgh, McGowan Institute for Regenerative Research, Pittsburgh, United States; [6]University of Pittsburgh, Pathology, Pittsburgh, United States; [7]Pittsburgh Liver Research Center, University of Pittsburgh, Pittsburgh, United States*
Email: tosato@juntendo.ac.jp

Background and aims: Although it is now understood that hepatic fibrosis can resolve, potential therapies to enhance fibrosis resolution are lacking. MBV are nanometer-sized vesicles bound within the ECM collagen network. Changes in MBV cargo may contribute, at least in part, to the phenotypic changes driven by fibrosis and recovery.
Method: Fibrosis was induced by injecting male C57Bl/6J mice with CCl_4 (1 ml/kg 2 × /wk 4wks); animals were sacrificed 1–28 days later. Liver injury and fibrosis was monitored by clinical chemistry, histology and gene expression. MBV were extracted from the livers of mice and the trypsinized MBV proteome cargo was analyzed by LC-MS/MS analysis using a Proxeon EASY-nLC 1000 UHPLC and nanoelectrospray ionization into an Orbitrap Elite mass spectrometer. Feature data were extracted and analyzed using Proteome Discoverer v2.4. Hierarchical clustering of significantly-changed MBV proteins was performed using StringDB and KEGG classification. To investigate the effect of MBV on the recovery of liver fibrosis, normal MBV from porcine urinary bladder (30 mg/mouse i.p.) were injected for up to 2 weeks after cessation of CCl_4.
Results: Fibrosis caused by CCl_4 rapidly resolved after cessation, reverting to almost normal histology and expression after 28 d recovery. The amount and type of proteins associated with the MBV tended to decrease in fibrosis, which was not reversed even after fibrosis recovery. StringDB and KEGG analysis indicated that the proteins lost in fibrosis/recovery were predominantly RNA-binding proteins associated with the ribosome, which may also impact the RNA cargo of the MBV. Some mice injected with normal MBV accelerated the fibrotic resolution.
Conclusion: Liver MBV alter their protein cargo in response to experimental fibrosis. Importantly, these changes do not revert to baseline levels even after almost complete histological recovery of fibrosis. These data suggest MBV may be a novel prospect for mechanistic insight into hepatic disease progression and recovery.

FRI150

Hepatocyte cell-specific deletion of cathepsin D does not affect liver inflammation and fibrosis during cholestatic-induced liver fibrosis

Maria Fernandez-Fernandez[1,2], Paloma Ruiz-Blazquez[2,3], Valeria Pistorio[3,4], Susana Núñez[2,5], M. Carmen Garcia-Ruiz[2,5,6,7], José Fernandez-Checa[2,5,6,7], Anna Moles[2,3,6]. *[1]Institute of Biomedical Research of Barcelona (IIBB-CSIC), Experimental Pathology, Barcelona, Spain; [2]CiberEHD, Spain; [3]Institute of Biomedical Research of Barcelona (IIBB-CSIC), Experimental Pathology, Barcelona, Spain; [4]University of Naples Federico II, Italy; [5]Institute of Biomedical Research of Barcelona (IIBB-CSIC), Cell Death and Proliferation, Barcelona, Spain; [6]IDIBAPS, Barcelona, Spain; [7]USC Research Center for ALPD, United States*
Email: anna.moles.fernandez@gmail.com

Background and aims: During liver fibrosis proteolytic activity is regulated in a timely manner in infiltrating and liver-resident cells depending on the cellular demands and controls not only matrix turnover but also, the activation and repression of growth factors and chemokines. Despite our growing understanding of the roles played by lysosomal proteases, cathepsins, in liver fibrosis, our knowledge of their specific targets and signaling networks remains limited. Thus, the aim of this study was to analyse cathepsin D (CtsD) cell-specific role in hepatocytes during liver fibrosis.
Method: To study the cell-specific role of CtsD we generated a novel knock-out mouse strain by breeding Albumin Cre (hepatocytes) mice with CtsD floxed mice. CtsD cell-specific deletion was confirmed by CtsD WB in primary mouse hepatocytes and dual IF (F4/80-CtsD) in liver sections. Fibrosis was established using bile duct ligation (BDL) for 14 days or chronic administration of CCl_4 (0.5 µl/g) twice a week for 8 weeks in $CtsD^{F/F}$ and $CtsD^{\Delta Hep}$ mice. Liver damage was determined by serum ALT and H&E staining in liver sections. CtsD was assessed by enzymatic activity assay and RTPCR. Fibrosis was analysed by Sirius Red staining α-SMA IHP and α-SMA, Col1A1 and TGF-beta RTPCR. Liver inflammation was determined by NIMP and F4/80 IHP and TNF-α, CCL2 and CCL3 RTPCR.
Results: First we determined CtsD expression in mouse fibrotic livers, demonstrating CtsD presence in hepatocytes and macrophages. CtsD cell-specific deletion in hepatocytes was validated by CtsD WB in primary mouse hepatocytes and dual IF (F4/80-CtsD) in liver section from $CtsD^{F/F}$ and $CtsD^{\Delta Hep}$ mice. Of note, CtsD expression remained unaffected in liver non-parenchymal cells. In addition, adult unchallenged $CtsD^{\Delta Hep}$ mice displayed normal liver damage determined by ALT and H&E staining in liver sections. Next, fibrosis was established for 14d using BDL. CtsD deletion in $CtsD^{\Delta Hep}$ livers was confirmed by CtsD activity assay and gene expression. CtsD deletion in hepatocytes, did not affect liver damaged (ALT) and liver fibrosis as determined by Sirius red staining, α-SMA IHP and hepatic α-SMA, Col1A1 and TGF-beta gene expression. Furthermore, liver inflammation was also not significantly affected in $CtsD^{\Delta Hep}$ mice after BDL as assessed by NIMP and F4/80 IHP and TNF-α, CCL2 and CCL3 gene expression. In agreement, no significant changes in liver damage, fibrosis and inflammation were observed after chronic CCl_4 administration between $CtsD^{F/F}$ and $CtsD^{\Delta Hep}$ mice supporting our results in the BDL model.
Conclusion: CtsD expressed in hepatocytes does not play an essential contribution to liver fibrosis development after cholestatic-induced liver injury.

FRI151

The therapeutic potential of alpha v integrins in liver fibrosis

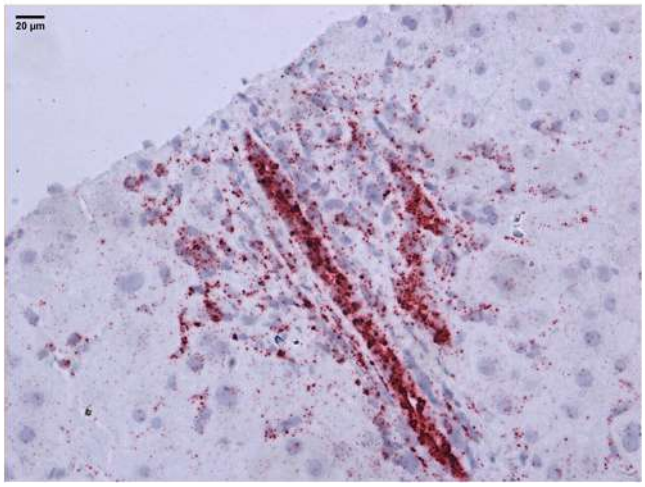
Syedia Rahman[1,2,3], Guruprasad Aithal[1,3], Jane Grove[1,3], K. Tao Pun[4], James Roper[4], Andrew Bennett[1,2,3]. *[1]NIHR Nottingham Biomedical Research Centre, Nottingham University Hospitals NHS Trust and University of Nottingham, Nottingham, United Kingdom; [2]FRAME Alternatives Laboratory University of Nottingham Medical School, Life Sciences, Nottingham, United Kingdom; [3]Nottingham Digestive Diseases Centre, Medicine, Nottingham, United Kingdom; [4]GlaxoSmithKline, Novel Human Genetics Research Unit, United Kingdom*
Email: syedia.rahman@nottingham.ac.uk

Background and aims: Hepatic stellate cells (HSC) are the primary effector cells in liver fibrosis and they secrete inactive transforming growth factor beta (TGFbeta) which, when activated through proteins known as alpha v integrins, contributes to liver fibrosis. These integrins are composed of beta 1, 3, 5, 6 and 8 subunits. Specific inhibitors which target alpha v integrins and their particular beta subunit have shown to reduce fibrosis progression in mouse models but their role has not been explored in human liver disease. We aimed to assess integrin expression on activated human HSCs and the level of integrin expression in human liver samples from patients with varying degrees of fibrosis. Subtype selective integrin inhibitors were tested to determine their capability to inhibit HSC activation and their effect on TGFbeta activity. This has previously never been performed before using human samples.
Method: HSCs were isolated from healthy individuals, integrin gene and protein expression was measured using qPCR and western blot. Tissue expression of integrins on fibrotic human liver tissue was

examined using a novel technique known as RNAscope®. To assess TGFbeta activity in HSCs, HSCs were co-cultured with mink lung epithelial TGFbeta reporter cells which were used to detect levels of active TGFbeta.

Results: There was gene and protein expression of alpha v, beta 1, 3 and 5 integrins with the exception of beta 6 on activated human HSCs. There was high gene expression of alpha v, beta 1, 3, 5 and 8, normalized to beta-actin. We show, for the first time, an identical pattern of integrin expression observed in fibrotic human liver tissue which showed increased expression compared to healthy controls. In co-culture assays, antibodies to alpha v, beta 1 and beta 3 integrins inhibited the increase in active TGFbeta, while antibodies to beta 5 and beta 6 integrins did not have any effect. From the subtype selective compounds tested, a beta 1 inhibitor, prevented the TGFbeta increase in a dose-dependent manner while a beta 6 inhibitor did not.

Fibrotic human liver tissue stained with haematoxylin and RNAscope® probe detecting B1 integrin



Conclusion: In activated HSCs, there was gene and protein expression of integrins beta 1, 3 and 5 with similar integrins expressed on fibrotic human liver tissue, not reported previously. A beta 1 integrin inhibitor compound successfully inhibited TGFbeta activation in a dose-dependent manner. This shows the exciting potential of beta 1 integrin specifically being a successful treatment target for liver fibrosis.

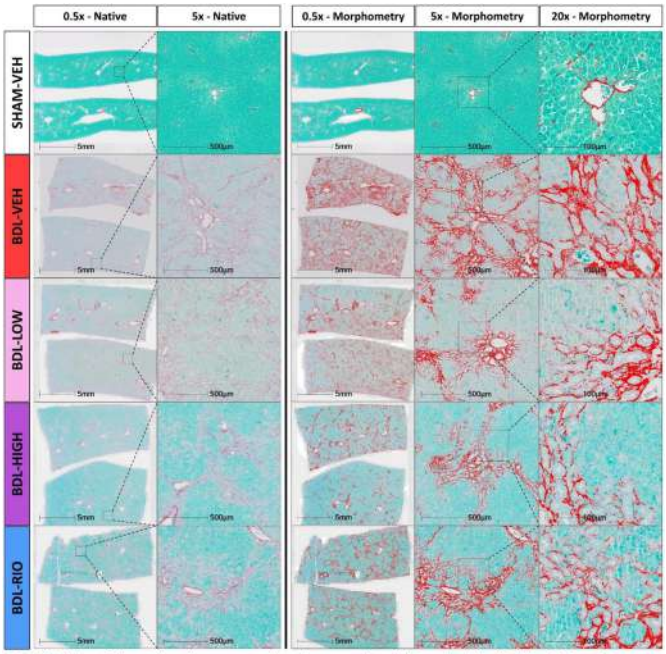
Email: elefebvre@pliantrx.com

Background and aims: Transforming growth factor-beta (TGF-beta) signalling is a key driver of liver fibrosis. In primary sclerosing cholangitis (PSC), integrins overexpressed on injured cholangiocytes (alpha-v/beta-6) and myofibroblasts (alpha-v/beta-1) regulate TGF-beta activity; they bind and activate latent TGF-beta thereby promoting liver fibrosis. We investigated the effects of PLN-75068, a tool alpha-v/beta-6 and alpha-v/beta-1 inhibitor compound, on liver fibrosis and portal hypertension in rats with cholestatic biliary cirrhosis.

Method: Male Sprague Dawley rats underwent bile duct ligation (BDL) or sham operation (SHAM). Two weeks post-surgery, BDL rats received PLN-75068 100 mg/kg (BDL-LOW), 300 mg/kg (BDL-HIGH), riociguat ([RIO], BDL-RIO; positive control) 0.5 mg/kg or vehicle ([VEH], BDL-VEH), and SHAM rats received VEH (SHAM-VEH) twice daily via oral gavage for 2 weeks. Portal pressure (PP), mean arterial pressure (MAP), heart rate and splanchnic/portal blood flow were measured at end of treatment. Alanine transaminase (ALT), aspartate transaminase (AST), alkaline phosphatase (ALP) and bilirubin (BIL) were assessed. Fibrosis was quantified by automated morphometry of collagen proportionate area (CPA) on Picro-Sirius red-stained full liver lobe sections and assessment of hydroxyproline (HP).

Results: Cirrhotic vehicle control rats (BDL-VEH) showed significantly higher values of PP (12.2 ± 1.9 vs 6.8 ± 0.9 mmHg; $p < 0.001$) and CPA (13.8 ± 4.3 vs 1.1 ± 0.2%; $p < 0.001$) compared with SHAM-VEH. Elevated PP in BDL rats was lowered with treatment: BDL-LOW (−10%; $p = 0.009$), BDL-HIGH (−9%; $p = 0.26$) and BDL-RIO (−10%; $p = 0.02$). MAP was significantly reduced in all treated groups (BDL-LOW: −22%; BDL-HIGH: −27%; BDL-RIO: −24%; all $p < 0.001$) vs BDL-VEH. CPA was decreased with treatment: BDL-LOW (−28%; $p = 0.04$), BDL-HIGH (−41%; $p = 0.003$) and BDL-RIO (−29%; $p = 0.03$) compared with BDL-VEH (Figure). HP levels were comparable across all BDL rats (VEH: 489 ± 163 ug/g; LOW: 508 ± 111 ug/g; HIGH: 473 ± 114 ug/g; RIO: 476 ± 174 ug/g). ALT was significantly lower with treatment: BDL-LOW (63 ± 10 U/L; −26%), BDL-HIGH (58 ± 12 U/L; −32%) and BDL-RIO (59 ± 9 U/L; −31%) all $p < 0.001$, compared with BDL-VEH (85 ± 17 U/L). Treatment with RIO significantly reduced AST ($p = 0.03$), but ALP and BIL remained unchanged in all treated animals compared with BDL-VEH. Weight loss was observed in BDL-HIGH but was not statistically significant.



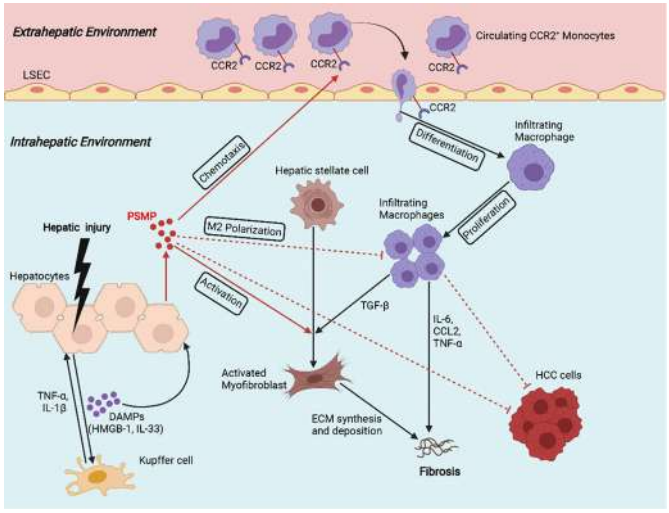
Quantification of fibrosis by collagen proportionate area on Picro-Sirius red-stained full liver lobe sections.
SHAM-VEH, sham operated rats administered vehicle; BDL-VEH, bile duct ligated rats administered vehicle; BDL-LOW, bile duct ligated rats administered PLN-75068 100 mg/kg; BDL-HIGH, bile duct ligated rats administered PLN-75068 300 mg/kg; BDL-RIO, bile duct ligated rats administered riociguat 0.5 mg/kg.

Conclusion: In rats with biliary cirrhosis, dual alpha-v/beta-6 and alpha-v/beta-1 inhibition by PLN-75068 ameliorated portal hypertension, exerted dose-dependent anti-fibrotic effects as assessed by CPA and significantly reduced ALT levels. A multinational Phase 2a evaluation of PLN-74809 in participants with PSC is ongoing (INTEGRIS-PSC; EudraCT: 2020–001428-33; NCT04480840).

FRI153
Dual roles of PSMP/MSMP in the progression of hepatic fibrosis and hepatocellular carcinoma

Shaoping She[1], Liying Ren[2], Pu Chen[1], Dongbo Chen[1], Hongsong Chen[1]. [1]*Peking University People's Hospital, Peking University Hepatology Institute, Beijing Key Laboratory of Hepatitis C and Immunotherapy for Liver Diseases, Beijing, China;* [2]*Affiliated Hospital of Guilin Medical University, Laboratory of Hepatobiliary and Pancreatic Surgery, Guilin, China*
Email: chenhongsong@bjmu.edu.cn

Background and aims: Chemokines are a family of cytokines that orchestrate the migration and positioning of immune cells within tissues and are critical for the function of the immune system. PC3 secreted microprotein (PSMP) or microprotamine (MSMP) is a novel chemotactic cytokine discovered through genome-wide bioinformatics analysis and chemoattractant platform screening, which can act as a CCR2 ligand to recruit peripheral blood monocytes and lymphocytes. CCR2 participates in liver pathology, including acute liver injury, chronic hepatitis, fibrosis/cirrhosis and tumor progression, by mediating the recruitment of immune cells to inflammation and tumor sites. In the present study, we investigated the expression and role of PSMP in liver fibrosis/cirrhosis and hepatocellular carcinoma (HCC).
Method: PSMP expression was studied in patients and murine models of fibrosis/cirrhosis and HCC. The role of PSMP *in vivo* was evaluated in PSMP gene knockout mice. The direct effects of PSMP on macrophages, hepatic stellate cells and tumor cells were studied *in vitro*.
Results: In this study, we found that PSMP is highly expressed in fibrotic/cirrhotic tissues from patients with multiple etiologies. PSMP is also overexpressed in human liver cancer-adjacent tissues, and its expression level is positively correlated with patients' survival. PSMP deficiency ($Psmp^{-/-}$) resulted in a marked amelioration of hepatic fibrosis, but promoted liver tumor growth in mice. Damage-associated molecular patterns molecules HMGB-1 and IL-33 significantly induced hepatocytes to produce PSMP. In CCl_4-induced hepatic injury, the infiltration of $CCR2^+$ monocytes and macrophages into the liver is significantly decreased in $Psmp^{-/-}$ mice. In HCC, knockout of PSMP can inhibit the infiltration of tumor-infiltrating $CD8^+$ lymphocytes and promote M2-polarization of tumor-associated macrophages (TAMs) in mice. At the cellular level, we found that PSMP can directly promote the M1 polarization of bone marrow-derived macrophages and the activation of LX-2 cells, and also inhibit the proliferation and migration of HCC cells.



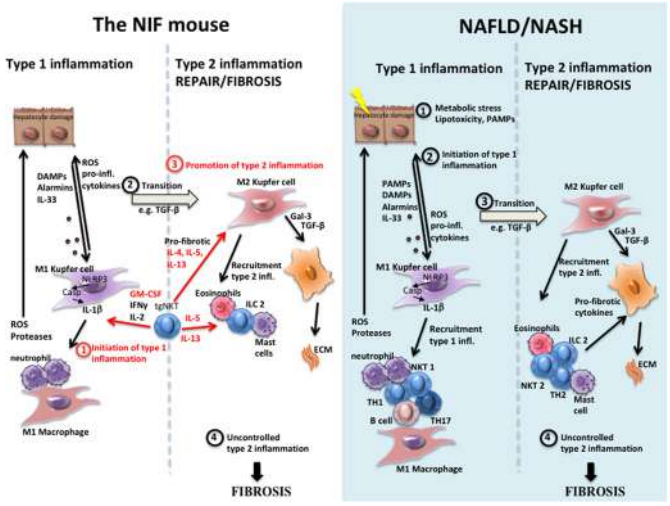
Conclusion: In conclusion, PSMP can promote liver fibrosis, while inhibit liver carcinogenesis. These results indicate that PSMP may play different or even opposite functions in different stages of liver disease, suggesting that PSMP is a potential target for the treatment of chronic liver disease and HCC.

FRI154
NKT cells promote both type 1 and type 2 inflammatory responses in the non-obese diabetic inflammation and fibrosis (NIF) mouse model

Julia Nilsson[1,2], Maria Hörnberg[1], Kajsa Linde[1], Dan Holmberg[1,2], Sofia Mayans[1]. [1]*InfiCure Bio AB, Umeå, Sweden;* [2]*Lund University, Experimental Medical Science, Malmö, Sweden*
Email: sofia.mayans@inficurebio.com

Background and aims: Sterile liver inflammation and fibrosis are associated with many liver disorders of different etiologies. Both type 1 and type 2 inflammatory responses have been reported to contribute to liver pathology and the mechanisms controlling the balance between these responses are largely unknown. Here we use the non-obese diabetic inflammation and fibrosis (NIF) mouse model for chronic liver inflammation and fibrosis to investigate the role of NKT cells in the different phases of sterile liver inflammation.
Method: Transgenic mice overexpressing a NKT cell population in the presence or absence of an adaptive immune system was analyzed and the role of this population in the generation of chronic liver inflammation and fibrosis was examined.
Results: We demonstrate that transgenic NKT cells, when developing in an immunodeficient $Rag2^{-/-}$ genetic background (the NIF mouse), expresses a mixed Th1/Th2 cytokine profile, which induces IL-1β production through the NLRP3 pathway that initially result in the development of chronic liver inflammation. This phase is followed by the development of a type 2 inflammatory response including the

expression of the IL-33 alarmin, production of anti-inflammatory/profibrotic cytokines, the activation of the TGFβ pathway, and recruitment of activated hepatic stellate cells (HSC) which results in the development of liver fibrosis. This process is controlled by the adaptive immune system since littermate controls carrying one functional *Rag2* allele and developing a normal adaptive immune system, fail to develop chronic liver inflammation and fibrosis.



Conclusion: Our data illustrates how plasticity in NKT cells can drive an initial type 1 inflammatory response and promote the transition into a type 2 inflammatory response thus overlapping key cellular and molecular events characterizing human liver diseases such as e.g. NAFLD/NASH. Further, the data suggests that this process is controlled by some component (s) of the adaptive immune system. The observed mechanistic overlap with human liver disease suggest that the NIF mouse model represents a unique tool for drug efficacy tests in liver inflammation and/or fibrosis with large translational potential as illustrated in the figure.

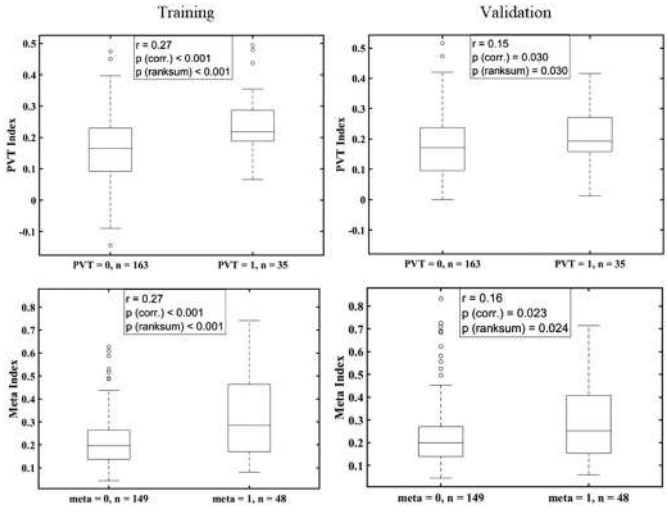
Email: skyntuh@gmail.com

Background and aims: Stromal remodelling in tumor microenvironment plays an important role in cancer progression. It is featured by collagen realignment in the stromal compartment, collagen fibers and basal membrane. There remains a lack of studies addressing the stromal background and fibrosis features and its prognostic value in liver cancer. qFibrosis is a system of second harmonic generation and two photon emission (SHG/TPE) microscopy which can identify, quantify and visualize the fibrosis features from biopsy samples. qFibrosis has been validated for its application in diagnosis and prognosis of hepatitis B and non-alcoholic steatohepatitis. In this study, we aim to establish a prognostic estimation model by using qFibrosis analysis in liver cancer.
Method: Total of 198 patients with HCC underwent curative tumor resection were included. Their disease status, survival time, and clinical outcomes of whether portal vein thrombosis (PVT) and metastasis (Meta) developed during follow-up after surgery were analyzed. Liver tissue and liver tumor from the 198 patients were imaged and assessed using qFibrosis system, and generated a total of 33 and 156 collagen parameters from liver tissue and tumor part, respectively. We used these collagen parameters to build two models, PVT-index and Meta-index, to differentiate the patient's clinical outcome of PVT and Meta, respectively. The models were validated using leave-one-out method.
Results: Both developing PVT and metastasis were significant indicators for poor prognosis. Seven parameters were selected from the parameters of liver tissue and tumor part to build the PVT-index and Meta-index, respectively. The PVT-index well differentiates patients developing PVT ($p < 0.001$ for training, $p = 0.030$ for validation, Figure), and the Meta-index also well differentiate patients developing metastasis during follow-up ($p < 0.001$ for training, $p = 0.024$ for validation, Figure).



Boxplot for PVT-index and Meta-index.

Conclusion: Prognostic estimation models consist of collagen parameters in qFibrosis system could be built to predict HCC patient's clinical outcomes of developing PVT and Meta during follow-up after radical treatment. Our results demonstrated the potentials of using qFibrosis system to transform the histopathological features into quantifiable data that could be used to correlate with patient outcome as other clinical biomarkers.

Multi-target engagement effect of a novel long-acting Glucagon/GIP/GLP-1 triple agonist, HM15211, in animal model of NASH/fibrosis

Jong Suk Lee[1], Jung Kuk Kim[1], Seonmyeong Lee[1], Yohan Kim[1], Jaehyuk Choi[1], Hyunjoo Kwon[1], Eun Jin Park[1], Sung Min Bae[1], Sang Hyun Lee[1], In Young Choi[1]. [1]*Hanmi Pharm.Co., Ltd., Seoul, Korea, Rep. of South*
Email: iychoi@hanmi.co.kr

Background and aims: Although its benefits were confirmed for NASH resolution, semaglutide failed to improve fibrosis in human. Recently, benefits of glucagon and GIP in addition to GLP-1 have been suggested beyond metabolism such as fibrosis. Thus, optimal use of these incretins simultaneously could be a promising strategy for NASH and fibrosis treatment. For this purpose, a novel long-acting Glucagon/GIP/GLP-1 triple agonist, HM15211, was developed. Here, beneficial effect of HM15211 via multi-target engagement was evaluated in animal models of NASH/fibrosis.
Method: AMLN-diet induced NASH mice and CDA-HFD induced nash.fibrosis mice were administered either with HM15211 or acylated GLP-1, GLP-1/GIP, or GLP-1/Glucagon agonist. Choline-deficient, L-amino acid-defined, and high fat diet (CDA-HFD)

induced NASH and fibrosis mice were also utilized. After treatment for 8 ~ 12 weeks, histologic analysis including NAFLD Activity Score (NAS) and hepatic hydroxyproline (HP) were determined. Liver transcriptome analysis was performed to investigate differentially expressed genes (DEGs) for diverse biological pathways.

Results: In AMLN mice, HM15211 treatment led to greater reduction in each component and composite NAS (6.1, 4.9, 3.6, 4.9, 2.0 for vehicle, acylated GLP-1, GLP-1/GIP, GLP-1/Glucagon, HM15211) than incretin analogs, and more NASH resolution achievement were confirmed for HM15211. In CDA-HFD mice, HM15211 treatment was consistently associated with greater reduction of NAS than incretin analogs. More reduction in hepatic HP and collagen contents (−4.2, −10.0, 7.1, and −26.5% *vs.* vehicle for acylated GLP-1, acylated GLP-1/GIP, acylated GLP-1/Glucagon, and HM15211) than incretin analogs were confirmed, indicating potential benefits of HM15211 for liver fibrosis. To understand underlying mechanisms for improved therapeutic effects of HM15211 on NASH and fibrosis, DEG analysis was performed and compared to acylated GLP-1, HM15211 treatment was associated with more favourable DEG signature in diverse pathways including bile acid metabolism, inflammation and fibrosis in addition to lipid metabolism, highlighting its multi-targeting MoA for the treatment of NASH and fibrosis.

Conclusion: In NASH/fibrosis animal models, more therapeutic benefits of HM15211 over other incretins were demonstrated. Notably, DEG analysis supports the basis for multi-target engagement effects of HM15211. Thus, HM15211 might be a novel therapeutic option for NASH and fibrosis. Human study is ongoing to assess the clinical relevance of these findings.

FRI157

Direct anti-inflammatory and anti-fibrotic effects of a novel long-acting Glucagon/GIP/GLP-1 triple agonist, HM15211, in thioacetamide-induced mouse model of liver injury and fibrosis

Jung Kuk Kim[1], Jong Suk Lee[1], Yohan Kim[1], Seonmyeong Lee[1], Jaehyuk Choi[1], Hyunjoo Kwon[1], Eun Jin Park[1], Sung Min Bae[1], Dae Jin Kim[1], Sang Hyun Lee[1], In Young Choi[1]. [1]*Hanmi Pharm.Co., Ltd.*
Email: iychoi@hanmi.co.kr

Background and aims: HM15211 is a novel long-acting triple agonist consisting of rationally designed Glucagon/GIP/GLP-1 triple agonist conjugated to human IgG FC fragment via short PEG linker. Previously, therapeutic benefits of HM15211 were demonstrated in diet-induced animal models of NASH and/or fibrosis. Here, we evaluate direct anti-inflammatory and -fibrotic effects of HM15211 in TAA (thioacetamide)-induced liver injury and severe fibrosis mouse, and investigate underlying MoA.

Method: To induce liver injury and liver fibrosis, escalating doses of dose of TAA was injected to mouse for 12 weeks. HM15211 was administered during last 10 weeks. Hepatic hydroxyproline (HP) contents were measured and Sirius red staining was conducted. qPCR was performed to evaluate relevant marker gene expression. Multiplex assay was performed to measure blood level of pro-inflammatory cytokines. For mechanistic study, THP-1 cell and LX2 cell were used.

Results: HM15211 treatment significantly reduced HP content (−51% *vs.* Veh., $p < 0.01$), Sirius red positive area (−65% *vs.* Veh., $p < 0.001$), and fibrosis score (0.7 for HM15211 *vs.* 3.0 for Veh., $p < 0.001$) in TAA mice. Considering baseline fibrosis score at week 2 (1.0), HM15211 could confer both potential reversal effect on pre-existing fibrosis and prevention effect on fibrogenesis. Consistently, expression of hepatic marker genes for fibrosis (i.e. collagen) and inflammation (i.e. F4/80 and TNF-alpha) were significantly reduced in HM15211-treated group. Furthermore, multiplex analysis revealed that HM15211 treatment was associated with robust reduction across pro-inflammatory cytokines such as TNF-alpha, IL-1beta, IL-6, and etc. Significant reduction in blood level of liver enzymes was also confirmed. Mechanistically, PMA/LPS-induced THP-1 cell adhesion and subsequent cytokine secretion were significantly attenuated by HM15211. TGF-beta-induced collagen production was also reduced in LX2 cell. Based on *in vitro* results, observed benefits in TAA mice might primarily results from direct anti-inflammatory and -fibrotic effects of HM15211.

Conclusion: HM15211 markedly improved liver inflammation and fibrosis in TAA mice, and related MoAs were elaborated by *in vitro* studies. Together with previous results, generalized anti-inflammatory and -fibrotic effects of HM15211 were corroborated. Thus, HM15211 could be a novel therapeutic option for fibrosis due to NASH. Human study is ongoing to assess the clinical relevance of these findings.

Email: michael.trauner@meduniwien.ac.at

Background and aims: Loss of BSEP/ABCB11 was shown to protect mice from acquired cholestasis due to preconditioning with a hydrophilic bile acid (BA) pool, with tetrahydroxylated BAs as the most prominent species. In this study we aimed to investigate whether loss of BSEP and subsequent increase in hydroxylation/detoxification of BAs protects mice from development of carbon tetrachloride (CCl_4) induced hepatic fibrosis.

Method: BSEP WT and KO mice were injected every other day with CCl_4 for 8 weeks as model of hepatic fibrosis. *In vitro,* the hepatic stellate cell line LX2 was challenged with TGF-beta with and without cotreatment of tetrahydroxylated BAs. RNA profiling was performed by RT-PCR. Liver histology/immunohistochemistry (IHC), immunofluorescence (IF) and immunoblot were assessed.

Results: In contrast to WT mice, serum parameter ALT and AST were not elevated in BSEP KO mice by CCl_4 injection. In line, mRNA expression of inflammatory markers *Cxcl1, Cxcl2, Ccl2, Ccl5* remained unchanged in BSEP KO mice injected with CCl_4, while in WT CCl_4 mice these markers were significantly increased (3fold, 20fold, 20fold, 2fold, respectively). Accordingly, numbers of MAC-2 positive cells were significantly lower in BSEP KO CCl_4 injected mice when compared to CCl_4 WT mice. Fibrotic markers *Col1a1, Col1a2* as well as Sirius red were significantly reduced in BSEP KO CCl_4 mice compared to WT CCl_4 mice (by 40%, 60%, 65% respectively). Accordingly, alpha-SMA (marker of activated hepatic stellate cells) (IF) remained at basal levels in BSEP KO CCl_4 mice. Mechanistically, we could demonstrate that hepatic protein expression of pJNK (known to be involved in development of CCl_4 induced hepatic fibrosis) was reduced in BSEP KO CCl_4 mice in comparison to challenged WT mice. In vitro, activated phenotype of LX2 cells was ameliorated with treatment of tetrahydroxylated BAs, as reflected by significant reductions of alpha-SMA and Col1a1 gene expression.

Conclusion: Loss of BSEP and subsequent hydroxylation of the bile pool protects mice from CCl_4 induced hepatic fibrosis via suppression of hepatic pJNK signalling and attenuation of HSC activation.

Email: wolfgang.mikulits@meduniwien.ac.at

Background and aims: The expression of the receptor tyrosine kinase Axl and the release of its cleavage product soluble Axl (sAxl) are highly elevated in hepatocellular carcinoma (HCC), advanced fibrosis, and cirrhosis. Recent studies suggest that the expression of Gas6, the high affinity ligand of Axl, is also enhanced during liver fibrogenesis and HCC. In this study, we evaluated the diagnostic accuracy of sAxl and Gas6 in a large cohort of patients with HCC, liver fibrosis and end-stage liver disease.
Method: Levels of sAxl and Gas6 were analyzed by enzyme-linked immunosorbent assays (ELISAs) in serum samples of patients with HCC, cholangiocarcinoma, colorectal liver metastases, chronic liver disease of all fibrosis stages, end-stage liver disease, and healthy controls from five centers in Europe. ELISAs were optimized to exclusively analyze either free sAxl or bioactive Gas6 levels.
Results: A total of 1111 patients (median age 57.8y, 67.3 % male) was included in the study. sAxl, Gas6 as well as their albumin (alb) ratios showed high diagnostic accuracy for the detection of HCC in comparison to healthy controls (AUC 0.765–0.942). sAxl/alb was confirmed as an accurate biomarker of advanced liver fibrosis and cirrhosis, and was even outperformed by Gas6/alb, which showed good accuracy (AUC 0.818–0.897) comparable to ELF™ test for the detection of liver cirrhosis. sAxl, Gas6 and their albumin ratios detected hepatic decompensation (Gas/alb: AUC 0.878), and were predictors of transplant-free survival.
Conclusion: Gas6/alb shows high accuracy for the detection of significant to advanced fibrosis and liver cirrhosis, as well as decompensated liver cirrhosis superior to sAxl/alb.

Multispectral analysis of liver biopsies from patients with chronic hepatitis C reveals unique macrophage phenotypes and spatial interactions associated with fibrosis progression

Omar Saldarriaga[1], Santhoshi Krishnan[2], Morgan Oneka[2], Arvind Rao[3], Joseph Gosnell[1], Daniel Millian[1], Timothy Wanninger[1], Jingjing Jiao[4], Laura Beretta[4], Heather Stevenson[1]. *[1]University of Texas Medical Branch, Department of Pathology, Galveston, United States; [2]Rice University, Department of Electrical and Computer Engineering, Houston, United States; [3]University of Michigan, Department of Computational Medicine and Bioinformatics, Ann Arbor, United States; [4]University of Texas MD Anderson Cancer Center, Department of Molecular and Cellular Oncology, Houston, United States*
Email: omsaldar@utmb.edu

Background and aims: Despite availability of direct-acting antivirals, viral hepatitis C (HCV) still impacts ~58 million people world-wide and ~70% progress to chronic infection. Chronic hepatitis develops after the virus restricts pro-inflammatory macrophage activation necessary to control infection, contributing to T cell disfunction and viral persistence. Intrahepatic macrophages represent ~20% of non-parenchymal cells and greatly impact the hepatic microenvironment, host immune response to liver injury and the development of fibrosis. We hypothesized that variations in the heterogeneity of macrophages determine disease progression in HCV + patients.
Method: We used multispectral imaging to phenotype and quantify resident Kupffer cells (CD68 +), monocyte-derived macrophages (Mac387 +), pro-fibrogenic macrophages (CD163 +), and co-expression of pro-inflammatory (CD14) and anti-inflammatory (CD16) in patients with minimal (fibrosis stage: 0/6; n = 5) or advanced (fibrosis stage: 6/6; n = 6) fibrosis. Next, we compared differences in the spatial distribution of the identified phenotypes (i.e., enrichment or depletion) within the hepatic microenvironment. Multiplex stained liver biopsies were scanned with a spectral imaging microscope (Vectra 3, *Akoya Biosciences*) and multi-component TIFF images and cell_seq_data files were analyzed to determine the heterogeneity of these various cell phenotypes. Both phenotype matrices and t-distributed stochastic neighbour embedding plots (t-SNE) were used (*Visiopharm®; MATLAB 2020a, MathWorks inc.)*. Phenotypes that were significantly enriched were selected for spatial proximity analysis using G-function calculations.
Results: Phenotype matrix analysis revealed the enrichment of unique pathogenic macrophage phenotypes (CD163 + CD16 +, CD68 +, CD68 + MAC387 +) in the HCV + patients with advanced fibrosis ($p < 0.05$). Increased CD68 +, CD68 + MAC387 + macrophage populations, in certain individuals, correlated with poor clinical outcome (increased prothrombin time and decreased platelet counts). Spatial analysis showed significant ($p < 0.05$) enrichment of CD14 +, CD68 + CD14 + CD163 +, CD68 + MAC387 +, and MAC387 + macrophage populations near CD68 + cells and depletion of CD163 + CD16 + population to CD14 + cells. Enriched interactions between MAC387 + and CD163 + MAC387 + positive macrophages were exclusively observed in the HCV + patients with advanced fibrosis.
Conclusion: Multispectral imaging with spatial analysis enabled detailed evaluation of intrahepatic macrophages and their relationship with neighbouring cells phenotypes. Unique phenotypes and interactions were observed among HCV patients with advanced fibrosis and in those that had disease progression. This approach identified novel potential targets for inhibiting fibrosis development and development of future personalized medicine approaches.

Neutrophil-specific NLRP3 activation triggers liver inflammation and fibrosis

Benedikt Kaufmann[1,2], Yanfang Peipei Zhu[1], Aleksandra Leszczynska[1], Agustina Reca[1], Laela M. Booshehri[1], Alexander Wree[3], Helmut Friess[2], Daniel Hartmann[2], Hal M. Hoffman[1], Ben Croker[1], Ariel Feldstein[1]. *[1]Department of Pediatrics, University of California San Diego, La Jolla; [2]Department of Surgery, TUM School of Medicine, Klinikum rechts der Isar, Technical, University of Munich; [3]Charité, Campus Virchow Klinikum and Charité, Campus Mitte, Department of Hepatology and Gastroenterology, Universitätsmedizin Berlin*
Email: benedikt_kaufmann@hotmail.com

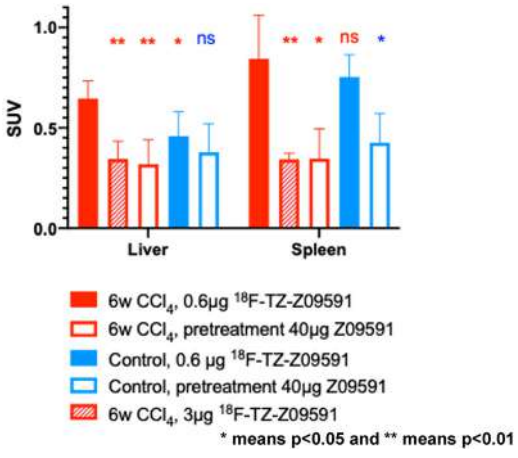
Background and aims: Neutrophils have a key role in the acute inflammatory response during liver inflammation and fibrosis and are hypothesized to promote chronic inflammation and liver fibrosis if they are not efficiently cleared by macrophages. The NLRP3 inflammasome is crucial in liver inflammation and fibrogenesis. In this study the role of neutrophil-specific NLRP3 inflammasome over-activation in liver pathobiology was investigated.
Method: Neutrophil-specific mutant NLRP3 knock-in mice were generated by crossing Nlrp3 knock-in mouse strains with the presence of an intronic floxed neomycin resistance cassette with mice expressing Cre recombinase under the control of Calcium-binding protein A8. Liver tissue and bone marrow were analysed by immunohistochemistry, flow cytometry, and real-time quantitative polymerase chain reaction.
Results: Mutant mice with neutrophil-specific NLRP3 activation showed shortened survival, poor growth, and severe liver inflammation. Furthermore, neutrophil-specific NLRP3 activation resulted in systemic changes in hematopoiesis and an accumulation of inflammatory neutrophils, the key cells in the initial phase of inflammation, in the liver. Infiltrative inflammatory neutrophils were identified by elevated CD162 (PSGL-1) and increased expression of CD16/32 (FcγRIII/II) analyzed by flow cytometry as well as increased positive myeloperoxidase staining in the liver of mutant mice. Inflammation of liver tissue in mutant mice resulted in a decrease of resident macrophages evident by reduced CLEC4f and F4/80 expression in both IHC staining and qRT-PCR. In contrast, pro-inflammatory macrophage population was increased in mutant mice demonstrated by Ly6C staining and upregulation of inducible nitric oxide synthase 2 (iNOS2). Sirius Red staining revealed liver fibrosis in mutant mice, whereas WT mice showed a healthy liver. The expression of the pro-fibrotic genes metalloproteinases 1 (TIMP1) and connective tissue growth factor (CTGF) was upregulated in the liver tissue of mutant mice.
Conclusion: Neutrophil-specific NLRP3 overactivation resulted in severe liver inflammation with accumulation of inflammatory neutrophils and pro-inflammatory macrophage polarization. Furthermore, it induced liver fibrosis and a pro-fibrotic gene expression pattern. This data provides novel insights into the complex relationship between liver neutrophil-driven inflammation, macrophage polarization and liver fibrosis.

FRI162

Imaging of fibrosis in metabolic associated liver disease by a radiolabeled affibody targeting PDGFRB

Olivia Wegrzyniak[1], Johanna Rokka[2], Bo Zhang[1], Maria Rosestedt[1], Bogdan Mitran[1,3], Pierre Cheung[1], Emmi Puuvuori[1], Sofie Ingvast[4], Frederik Ponten[4], Frederik Frejd[5], Olle Korsgren[4], Jonas Eriksson[1,6], Olof Eriksson[1,7]. *[1]Uppsala University , Department of Medicinal Chemistry, Uppsala, Sweden; [2]Uppsala University , Department of Public Health and Caring Sciences, Uppsala, Sweden; [3]Antaros Medical AB, Mölndal, Sweden; [4]Uppsala University , Department of Immunology, Genetics and Pathology, Uppsala, Sweden; [5]Affibody AB, Solna, Sweden; [6]Uppsala University Hospital, PET Center, Uppsala, Sweden, [7]Antaros Tracer AB, Mölndal, Sweden*
Email: olivia.wegrzyniak@ilk.uu.se

Background and aims: The pathological formation of fibrosis, is an important feature in liver in Metabolic Associated Fatty Liver Disease (MAFLD) as well as in many different other diseases. Platelet-derived growth factor receptor beta (PDGFRB) is a known biomarker of activated hepatic stellate cells, and thus play a key role in fibrosis in MAFLD. Today, the treatment and monitoring of hepatic fibrosis is hampered by the lack of suitable methods for detecting and diagnosing the disease. Therefore, it is of crucial importance to develop non-invasive methods in order to detect, diagnose, stage and study fibrosis. Herein, we report the preparation, characterization, and evaluation of fluorine-18-labelled Affibody molecule Z09591, in a mouse model of non-alcoholic steatohepatitis (NASH).
Method: Affibody molecule Z09591 was labelled with fluorine-18 via tetrazine/trans-cyclooctene click chemistry. ^{18}F-TZ-Z09591 was evaluated in a 6 weeks CCl_4 treatment mouse model of liver fibrosis by a PET study, including *ex vivo* biodistribution and autoradiography. Binding results were correlated to staining and PDGFRB immunohistochemistry (IHC) on *post-mortem* biopsies.
Results: Affibody molecule Z09591 was successfully radiolabelled with fluorine-18 with high purity and reproducible yield. PET studies demonstrated that liver uptake of ^{18}F-TZ-Z09591 was higher in mice with induced hepatic fibrosis compare to healthy liver (Figure). The liver binding could also be blocked by pre-treatment with Z09591 in excess, indicating receptor specific binding. *Ex vivo* autoradiography demonstrated high signal intensity in positive hepatic sinusoids affected by fibrosis, as confirmed by Sirius red staining and PDGFRB IHC.



Conclusion: We describe the radiolabelling and evaluation of the PDGFRB binding affibody Z09591. ^{18}F-TZ-Z09591 exhibited specific binding to hepatic fibrotic lesions. ^{18}F-TZ-Z09591 is a promising tool for PET imaging of fibrosis in MAFLD. The use of such a tracer clinically could represent a non-invasive diagnostic, prognostic as well as predictive tool for MAFLD patients.

FRI163

Liver complications in greek patients with sickle cell disease: a multicenter retrospective analysis from eight thalassemia and sickle cell units across Greece

Konstantinos Manganas[1], Sophia Delicou[1], Aikaterini Xydaki[1], Alexandra Kourakli[2], Loukia Evliati[3], Euthimia Vlahaki[4], Evangelos Klironomos[5], Michail Diamantidis[6], Ioannis Lafiatis[7], Antonis Kattamis[8], Ioannis-Georgios Koskinas[1]. *[1]Ippokrateio General Hospital of Athens, Athens, Greece; [2]General University Hospital of Patras, Rio, Greece; [3]Evangelismos General Hospital, Athens, Greece; [4]Ippokrateio-General Hospital of Thessaloniki, Thessaloniki, Greece; [5]Venizeleio General Hospital, Heraklion, Greece; [6]General University Hospital of Larissa, Larissa, Greece; [7]General Hospital of Mytilene, Mytilene, Greece; [8]Agia Sofia Children's Hospital, Athens, Greece*
Email: kmagganas92@gmail.com

Background and aims: Sickle cell disease (SCD) is one of the most common monogenic disorders worldwide and liver complications, acute and chronic, are common in this group of patients. Our study aims to highlight the prevalence and predisposing factors of liver fibrosis in SCD patients.
Method: Eight Thalassemia and Sickle Cell Units across Greece and 219 patients enrolled in our study and history of liver related disease complications was recorded, as well as a full laboratory and imaging analysis concerning their liver function. Patients were divided in two groups, those with indications of advanced liver fibrosis (Fibroscan >13.5 kPa or Fib-4 >3.25 or APRI >1.5) and those without indications of advanced liver fibrosis.
Results: The prevalence of significant liver fibrosis in SCD patients in our study was 10.7%. The presence of liver fibrosis was significantly correlated with advanced age, male gender, cholelithiasis and higher LDH, γ-GT, INR, direct and indirect bilirubin levels. Noteworthy, patients with advanced liver fibrosis had suffered significantly more acute liver crises, acute liver sequestration crises and acute intrahepatic cholestasis in the last five years, while these patients were also receiving transfusion therapy more often and for a longer period of time and had higher Liver Iron Concentration (LIC) levels, but without statistical significance. No correlation was observed with ultra-sound findings of right hearth failure or previous viral hepatitis.

	Patients with no significant fibrosis	Patients with significant fibrosis	p < 0.05
Hb (g/dl)	9.50 (1.37)	9.03 (1.09)	0.045**
HbS (%)	60.2% (14.5%)	63.9% (10.5%)	0.252*
HbF (%)	11.57% (8.3%)	13.39% (8.1%)	0.334*
PLTs (x10^9/L)	337.7 (178.81)	183.0 (145.50)	<0.001*
Ferritin (ng/ml)	772.02 (1432.02)	771.86 (1018.94)	0.668**
AST (U/L)	35.78 (15.15)	55.15 (30.42)	0.007**
ALT (U/L)	27.69 (16.18)	35.21 (30.36)	0.994**
γ-GT (U/L)	44.19 (52.89)	72.33 (115.93)	0.042**
LDH (U/L)	386.21 (124.33)	568.76 (224.02)	0.000**
Direct bilirubin (mg/dl)	0.67 (0.35)	1.25 (0.83)	0.002**
Indirect bilirubin (mg/dl)	1.57 (1.40)	2.77 (1.95)	0.003**
CRP (mg/l)	5.43 (8.92)	2.50 (2.76)	0.336**
INR	1.17 (0.41)	1.33 (0.57)	0.003**
Albumin (g/dl)	4.33 (0.52)	4.17 (0.61)	0.228*
MRI T2* (LIC-mg Fe/gr dry weight)	4.96 (7.19)	6.16 (7.04)	0.865**
Age (years)	46.75 (13.48)	52.56 (12.12)	0.05*
Duration of transfusions (years)	7.85 (13.22)	8.71 (13.34)	0.443**
Transfusions (PRBC/year)	6.06 (8.72)	7.95 (8.95)	0.124**
Acute liver crises (per 5 years)	0 (0.00)	0.16 (0.50)	0.000**
Acute intrahepatic cholestasis (per 5 years)	0 (0.00)	0.11 (0.45)	0.010**
Liver sequestration crises (per 5 years)	0.06 (0.278)	0.38 (0.88)	0.046**

Conclusion: Our study shows that advanced liver fibrosis is a significant cause of morbidity in patients with SCD and is primarily associated acute vaso-occlusive phenomena and chronic intravascular hemolysis of the disease itself.

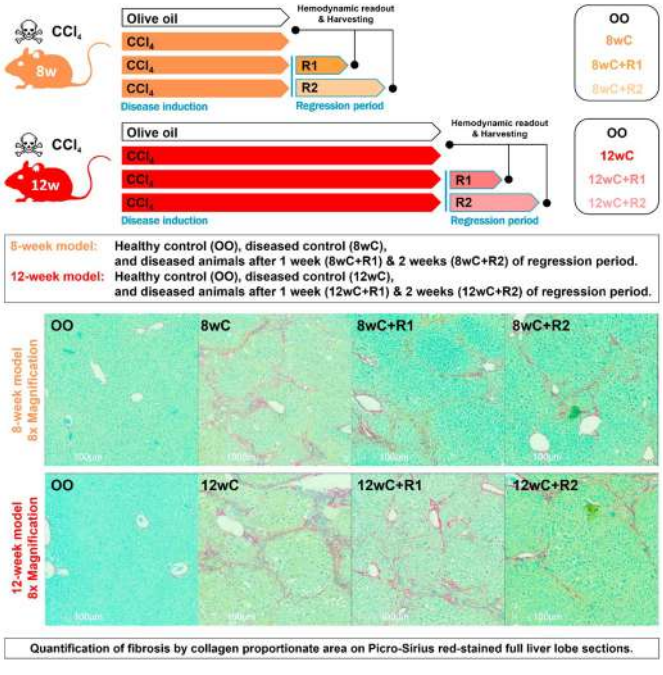
Hemodynamic, molecular, and histological characterization of a toxic liver fibrosis regression model

Philipp Königshofer[1,2,3,4,5], Ksenia Brusilovskaya[1,2,3,4,5], Benedikt Hofer[1,2,3], Benedikt Simbrunner[1,2,3,4,5], Oleksandr Petrenko[1,2,3,4,5], Hubert Scharnagl[6], Tatjana Stojakovic[6], Michael Trauner[1], Philipp Schwabl[1,2,3,4,5], Stefan Günther Kauschke[7], Larissa Pfisterer[7], Thomas Reiberger[1,2,3,4,5]. *[1]Division of Gastroenterology and Hepatology, Department of Internal Medicine III, Medical University of Vienna, Vienna, Austria; [2]Vienna Experimental Hepatic Hemodynamic lab (HEPEX), Medical University of Vienna, Vienna, Austria; [3]Christian Doppler laboratory for Portal Hypertension and Liver fibrosis, Vienna, Austria; [4]Ludwig Boltzmann Institute for Rare and Undiagnosed Diseases (LBI-RUD), Vienna, Austria; [5]CeMM Research Center for Molecular Medicine of the Austrian Academy of Sciences, Vienna, Austria; [6]Clinical Institute of Medical and Chemical Laboratory Diagnostics, University Hospital Graz, Graz, Austria; [7]Boehringer Ingelheim Pharma GmbH, Biberach, Germany*
Email: thomas.reiberger@meduniwien.ac.at

Background and aims: Portal hypertension (PH) results from 'static' liver fibrosis and 'dynamic' vascular components. Liver disease regression depends on cessation of liver injury to allow liver fibrosis regression and functional regeneration. We aimed to establish a toxic liver disease regression model to investigate the 'regressive' course of PH and fibrosis.
Method: Male C57BL/6JRj mice were exposed to CCl_4 for eight (8 w) or twelve (12 w) weeks (2 µL/g in olive oil, 3x/week, per oral), respectively, to induce moderate (8 wC) and severe liver fibrosis (12 wC)-followed by one (+R1) or two (+R2) weeks of regression period, respectively (Figure). Healthy control groups received olive oil only (OO). Portal pressure (PP) was measured at end of each timeline. Blood parameters were assessed. Fibrosis was quantified by collagen proportionate area (CPA) in %. Matrix- and inflammation-related gene-expression was measured in bulk liver tissue.



Results: Diseased animals developed PH with PP (8wC: 8.5 ± 1.3 mmHg vs OO: 4.9 ± 0.8 mmHg; 12 wC: 10.0 ± 1.2 mmHg vs OO: 5.2 ± 0.2 mmHg; all p < 0.001) and liver fibrosis with CPA% (8 wC: 8.5 ± 5.0 % vs OO: 1.6 ± 0.9 %; 12 wC: 16.9 ± 3.9 % vs OO: 0.8 ± 0.2 %; all p < 0.001). In both models, PP regressed after one (8wC + R1: −31 %, p < 0.001; 12wC + R1: −16 %, p = 0.01) and after two weeks (8 wC + R2: −29 %, p < 0.001; 12wC + R2: −21 %, p = 0.002), respectively. Fibrosis regressed in the 8-weeks (8 wC + R1: −1 %, p < 0.99; 8 wC + R2: −37 %, p = 0.24) and significantly in the 12-weeks (12 wC + R1: −16 %, p = 0.002; 12 wC + R2: −21 %, p < 0.001) setting. AST and ALT levels significantly decreased after 1 week of regression (8 wC/12 wC+R1: −99 %) and after 2 weeks of regression, transaminases were similar to healthy controls (p < 0.001). Expression of fibrogenesis-related genes was significantly reduced: *Col1a1* (8 wC + R1/2: −85/-91 %; 12 wC + R1/2: −83/−74 %), *Tgf-beta* (8 wC + R1/2: −71/−80 %; 12 wC + R1/2: −62/−27 %), and *alpha-Sma* (8 wC + R1/2: −86/−85 %; 12 wC + R1/2: −70/−42 %). Matrix-metalloproteinase activity was promoted by decreased *Timp1* (8 wC + R1/2: −94/−95 %; 12 wC + R1/2: −92/−85 %) expression. Pro-inflammatory *Tnf-alpha* (8 wC + R1/2: −69/−74 %; 12 wC + R1/2: −70/−69 %) expression was also decreased.
Conclusion: The characterization of this toxic model of liver disease regression suggests that the two-week regression period following 12-weeks of CCl_4 exposure includes a suitable therapeutic window to investigate treatments to promote regression of PH and liver fibrosis.

FRI165
The upper limit of normal of alanine aminotransferase (ALT) in diagnosing liver disease and fibrosis by the Intelligent Liver Function Test (iLFT) system
Jeremy Lee[1], John Dillon[1], Iain Macpherson[1]. [1]*University of Dundee, School of Medicine, Dundee, United Kingdom*
Email: jjslee@dundee.ac.uk

Background and aims: There is an increasing prevalence of liver disease in the UK, and mortality from liver disease continues to rise. Liver function tests (LFTs) are often used to investigate for liver disease, but there remains a significant number of patients with undiagnosed liver disease who could benefit from early detection and intervention. The intelligent LFT (iLFT) system is designed to cascade further tests in patients with abnormal LFTs, generating a probable liver diagnosis. This increased the rate of diagnosis of liver disease by 43%. One parameter used by iLFT is serum alanine aminotransferase (ALT) level, using an upper limit of normal (ULN) of 30 U/L, given recent evidence suggesting a lower ULN of ALT to diagnose liver diseases. This study aims to determine the frequency of liver disease and fibrosis at ALT level 31–55 U/L, compared to ALT >55 U/L, and provide evidence for using an ULN of ALT of 30 U/L in the iLFT system.
Method: A retrospective analysis was done on patients undergoing iLFT in 2018–19, comparing ALT levels to iLFT and fibrosis outcomes.
Results: 672 iLFT diagnoses were made in the ALT 31–55 U/L group, with 148 (22.0%) alcoholic liver disease (ALD) diagnoses, 74 (11.0%) non-alcoholic fatty liver disease (NAFLD) diagnoses, 30 (4.5%) combined NAFLD and ALD diagnoses, 15 (2.2%) hepatitis B or C diagnoses, 74 (11.0%) metabolic or autoimmune liver diseases. 1041 diagnoses were made in the ALT >55 U/L group, which is significantly higher (p < 0.05) compared to the ALT 31–55/L group. There were 137 (20.4%) fibrosis diagnoses in the ALT 31–55 U/L group, compared to 311 (29.9%) in the ALT >55 U/L group.

iLFT fibrosis outcomes	ALT 31-55U/L	ALT >55U/L	p-value
ALD with significant fibrosis.	33	68	<0.05
Abnormal ALT, ALP, GGT, negative liver screen, abnormal fibrosis biomarkers.	11	31	<0.05
Abnormal ALT, negative liver screen, abnormal fibrosis biomarkers.	10	32	<0.05
NAFLD-NASH with significant fibrosis.	48	110	<0.05
NAFLD and ALD with abnormal fibrosis biomarkers.	24	38	0.075
Abnormal ALT, ALP, negative liver screen, abnormal fibrosis biomarkers.	1	1	-
Abnormal ALT, GGT, negative liver screen, abnormal fibrosis biomarkers.	10	31	<0.05

Figure: Frequency of fibrosis according to aetiology between both ALT groups.

Conclusion: There is a significant proportion of patients with ALT 31–55 U/L who have underlying liver disease or fibrosis. Lowering the ULN of ALT has increased the detection rate of liver disease and fibrosis in these patients.

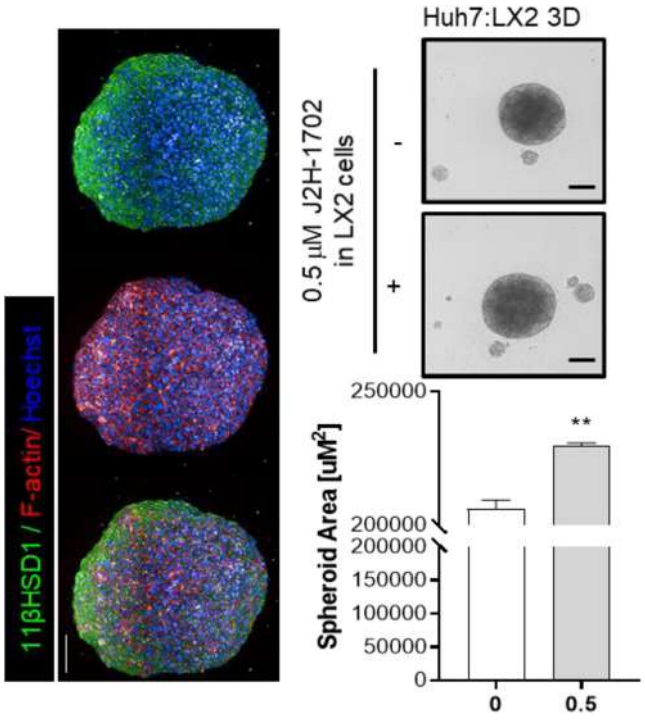
Inhibition of 11beta-hydroxysteroid dehydrogenase 1 relieves fibrosis through depolarizing of hepatic stellate cell in NASH
Su-Yeon Lee[1], Hyung Chul Rhu[2], Sanghwa Kim[1], Yeonhwa Song[1], Inhee Choi[3], Namjeong Kim[1], Jee Woong Lim[2], Hyo Jin Kang[2], Jason Kim[2], Haeng Ran Seo[1]. [1]*Institut Pasteur Korea, Advanced Biomedical Research Lab, Seongnam-si, Korea, Rep. of South;* [2]*J2H Biotech Inc., R&D Center, Suwon-si, Korea, Rep. of South;* [3]*Institut Pasteur Korea, Medicinal Chemistry, Seongnam-si, Korea, Rep. of South*
Email: shr1261@ip-korea.org

Background and aims: 11-beta-hydroxysteroid dehydrogenase type 1 (11betaHSD1) is a key enzyme that catalyses the intracellular conversion of cortisone to physiologically active cortisol. Although 11betaHSD1 has been implicated in numerous metabolic syndromes, such as obesity and diabetes, the functional roles of 11betaHSD1 during progression of nonalcoholic steatohepatitis (NASH) and consequent fibrosis have not been fully elucidated.
Method: the effects of J2H-1702 on steatosis and fibrogenesis were investigated in both multicellular hepatic spheroids (MCHSs) in vitro systems and in vivo mouse models.
Results: We found that pharmacological and genetic inhibition of 11betaHSD1 resulted in reprogramming of hepatic stellate cell (HSC) activation via inhibition of p-SMAD3, alpha-SMA, Snail, and Col1A1 in a fibrotic environment and in multicellular hepatic spheroids (MCHSs). We also determined that 11betaHSD1 contributes to the maintenance of NF-kappaB signalling through modulation of TNF, TLR7, ITGB3, and TWIST, as well as regulating PPAR-alpha signalling and extracellular matrix accumulation in activated HSCs during advanced fibrogenesis in MCHSs. Of great interest, the 11betaHSD1 inhibitor J2H-1702 significantly attenuated hepatic lipid accumulation and ameliorated liver fibrosis in diet- and toxicity-induced NASH mouse models.



Conclusion: Together, our data indicate that J2H-1702 is a promising new clinical candidate for the treatment of NASH.

Anti-fibrotic effects of microRNA-9-5p and microRNA-122

Dana Eidelshtein[1], Eithan Galun[1], Jonathan Axelrod[1]. [1]*Hadassah University Hospital-Ein Kerem, The Goldyne Savad Institute of Gene and Cell Therapy, Jerusalem, Israel*
Email: dana.eidelshtein@mail.huji.ac.il

Background and aims: Liver fibrosis is the final consequence of many chronic liver injuries and is an increasingly crucial health problem. MicroRNA's (miR's) are short single-stranded RNAs that regulate post-transcriptional mRNA expression by binding to complementary mRNA sequences, resulting in translational repression and gene silencing. In this *in vitro* study, we sought to identify potential miRNAs that could serve as potential therapeutic targets through which to ameliorate liver fibrosis. We identified and validated fibrosis-reducing miRNAs based on their ability to suppress two key fibrogenic pathways: 1) NADPH Oxidase 4 (NOX4), which maintains stellate cells activation by generation of reactive oxygen species (ROS)-induced oxidative stress and DNA damage; and 2) TGF-beta, a central molecular signaling pathway in fibrosis.
Method: Potential miR candidates were identified by bioinformatics screening for miR seed sequences in the *NOX4* 3′UTR. Candidate miRNA's were evaluated for anti-fibrotic activity by transfection of synthetic mimic-miRs into LX-2 cells, an established activated human stellate cell (HSC) line, and assessed for reduction of smooth muscle actin (alpha-SMA) protein levels by flow cytometry. Target-sequence specificity of candidate miRs was validated by co-transfection into LX-2 or HEK293 cells of mimic-miRs with a PmiRGLO vector (Promega) containing a cloned NOX4-3′UTR (PmiRGLO-Nox4) or mutant control (PmiRGLO-mutNox4) sequence and analysis of luciferase activity.
Results: Bioinformatics screening identified miR-9-5p and miR-96-5p miRs as having the highest predicted binding potential to NOX4 3′ UTR seed sequences and highest potential for NOX4 expression inhibition. miR-9-5p was also predicted to target TGF-beta receptor (TGFbR2) as was miR-122, an important regulator of hepatic metabolism. Co-transfection experiments in HEK293 demonstrated that mimic-miR-9-5p, but neither miR-96-5p nor miR-122, effectively suppressed PmiRGLO-Nox4 directed luciferase expression, but not that of PmiRGLO-mutNox4. miR-96-5p transfection similarly suppressed both NOX4 and TGFbR2 mRNA levels in LX-2 cells. In contrast, both miR9-5p and miR-122, but neither miR-96-5p nor a scrambled control-miR, effectively suppressed alpha-SMA expression in transfected LX-2 cells. Preliminary evidence suggests that LX-2 cells may also inherently express and perhaps secret both miR-9-5p and miR-122.

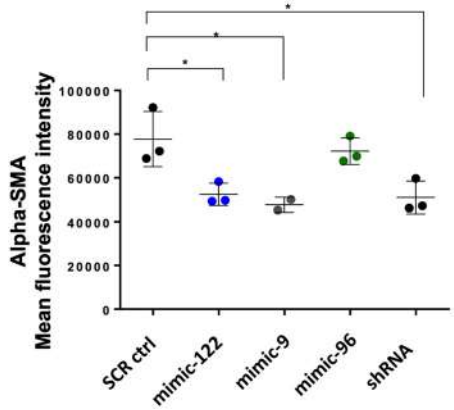

Figure: miR-9-5p and miR-122 suppress alpha-SMA in HSCs in vitro. Transfection of LX-2 cells with miRNAs, miR-9-5 and miR-122 decreases alpha-SMA protein expression. *p < 0.05 by two-way Student's t test.

Conclusion: Our *in vitro* findings demonstrate an anti-fibrotic therapeutic potential of miR-9-5p and miR-122 in activated human stellate cells and liver fibrosis.

FRI168

Higher daily Aramchol dose results in higher effect size in fibrosis improvement in the ARMOR study open label part

Vlad Ratziu[1], Yusuf Yılmaz[2], Don Lazas[3], Scott Friedman[4], Liat Hayardeny[5], Shaul Kadosh[6], Tali Gorfine[5], Arun Sanyal[7]. Email: vlad.ratziu@inserm.fr

Background and aims: Aramchol is a partial inhibitor of hepatic stearoyl-CoA desaturase (SCD1) with direct anti-fibrotic activity demonstrated in pre-clinical models. In a 52-week phase 2b study, improvement in fibrosis by ≥1 stage without NASH worsening was observed in 17.5%, 21.3% and 29.5%, in the placebo, Aramchol 400 and 600 mg, respectively. A 53% higher exposure is achieved when dividing 600 mg QD Aramchol to 300 mg BID. Since this higher exposure was expected to improve efficacy, Aramchol 300 mg BID was selected for a phase 3 study in patients with NASH and fibrosis. An Open-Label Part is designed to explore the kinetics of histological outcome measures and non-invasive tests as a function of treatment duration
Method: 150 patients with histologically confirmed NASH and fibrosis are being enrolled to receive Aramchol 300 mg BID in the Open-Label Part of the study. Patients are randomized 1:1:1 to perform a post-baseline liver biopsy at weeks 24, 48 or 72. The primary efficacy endpoints are the kinetics of fibrosis improvement without NASH worsening and NASH resolution without fibrosis worsening. Biopsies are read by 3 independent pathologists, followed by a consensus reading
Results: Herein we report the results from the first 20, F1-3 patients that received Aramchol in whom the scheduled post-baseline biopsy was performed. At baseline, mean age ± SD was 58.5 ± 8.7 years; 70% were females; 75% White; mean BMI 33.5. ± 3.6 kg/m^2; 90% had type 2 diabetes; 13 patients had stage 3 fibrosis; 4 stage 2, and 3 stage 1; Mean NAS was 4.8 ± 1.3. Post-baseline biopsies were performed for 9 patients at 24 weeks, 9 at 48 weeks and 2 at 72 weeks. Altogether 12/20 patients (60%) showed fibrosis improvement by ≥1 stage (5/9 after 24 weeks, 6/9 after 48 weeks and 1/2 after 72 weeks). 19/20 patients were either stable or reduced fibrosis measured by liver biopsy. In 5 patients, fibrosis was reduced by 2 points. In 9/20 (45%) patients there was fibrosis improvement without NASH worsening. Statistically significant reductions in ALT, AST and biomarkers associated with liver fibrosis Fib-4 and ProC-3 were also observed corroborating the histological effects. Reductions of a similar magnitude are seen in a cohort of the first 20 patients for which paired biopsy have been analyzed, a cohort of 50 patients for which biomarker data was analyzed (ARCON Cohort) and a cohort of 139 of which ALT, AST and FIB-4 were analyzed. Aramchol showed excellent safety and tolerability. Updated data from the open label study will be presented.
Conclusion: 60% of the 20 patients treated with Aramchol 300 mg BID showed fibrosis improvement. Data is corroborated by congruent changes in fibrosis biomarkers and by a biochemical response in aminotransferases. The data presented here, albeit preliminary, is aligned with the hypothesis that higher Aramchol exposure results in an improved efficacy profile and a direct anti-fibrotic effect may be manifested as early as 24 weeks.

FRI169

Development of a high precision liver biopsy method to improve the accuracy of fibrosis staging and collagen profiling

Morten Christensen[1], Ida Villesen[1], Mette Juul Nielsen[1], Morten Karsdal[1], Diana Leeming[1]. [1]*Nordic Bioscience, Fibrosis Research, Herlev, Denmark*
Email: moc@nordicbio.com

Background and aims: Liver biopsy is the gold standard for diagnosis and staging of hepatic fibrosis, however it is associated with limitations such as the pathologist's inter-variability, small sample size, and patient discomfort. Currently, liver biopsy is required as a primary regulatory outcome in clinical trials on non-alcoholic steatohepatitis (NASH), which has increased the need for regulatory approved biomarkers as clinical endpoints. Additionally, hepatic fibrosis is characterized by the excessive accumulation of extracellular matrix (ECM) proteins such as collagens. Quantifying the ECM might improve the precision of fibrosis staging in the liver biopsy. The aim of this proof-of-concept study was to develop a high precision biopsy method to effectively quantify the fibrosis in the liver of bile duct ligated (BDL) rats using serological collagen degradation biomarkers.
Method: Sprague Dawley rats underwent BDL surgery and were terminated after 2 weeks. Post termination, 160 µg of snap frozen liver tissue was cleaved with matrix metalloproteinase (MMP) -2 and -9 for 3, 24 and 72 hours, and protease activity halted by addition of 1 µM EDTA. MMP-2 and -9 degradation fragments of type III, IV, and VI collagen were measured in the tissue extract by neo-epitope specific competitive ELISAs (C3M and C6M, respectively) based on monoclonal antibodies. The activity of MMP-2 and MMP-9 was confirmed by their ability to cleave carboxymethylated transferrin and visualized by Coomassie blue staining.
Results: Conditioned medium C3M increased significantly with increasing incubation time with MMP-2, thus a 78-fold increase with3 hour incubation that increased to, 128-fold at 72 hours of incubation. In comparison, MMP-9 showed an increase of 43-fold at 3 hours to, 150-fold at 72 hours. This was significant when compared to tissue extract with no MMP added ($p < 0.0001$). A significant increase was also seen in C6M levels at incubation times of 24 hours (MMP2: 66-fold and MMP9: 103-fold) and 72 hours (MMP2: 14-fold and MMP9: 46-fold) ($p < 0.0001$). MMP-2 and MMP-9 proved successful in cleaving carboxymethylated transferrin.
Conclusion: A proof-of-concept high precision ex vivo model was established in BDL treated rodents showing MMP-2 and MMP-9 degraded collagen type III and VI was released from the liver tissue to the conditioned medium as assessed by C3M and C6M. The high precision biopsy holds potential to improve the current liver biopsy evaluation by providing a quantifiable measurement of liver fibrosis.

FRI170

MAIT cell inhibition promotes liver fibrosis regression by reprogramming macrophage phenotype

Morgane Mabire[1], Hegde Pushpa[1], Hammoutene Adel[1], JingHong Wan[1], Manon Allaire[1], Al Sayegh Rola[1], Tristan Thibault-Sogorb[1,2], Emmanuel Weiss[1,2], Valérie Paradis[1,3], Pierre de la Grange[4], Hélène Gilgenkrantz[1], Sophie Lotersztajn[1]. Email: morgane.mabire@inserm.fr

Background and aims: Mucosal-Associated Invariant T (MAIT) cells are non-conventional T cells restricted by the non-classical MHC-1b molecule MR1 that display altered functions during chronic liver diseases. We recently reported that hepatic MAIT cells are activated during fibrosis in human liver samples and in mice models and display profibrogenic properties (*Nat Commun* 2018). Here, combining studies in human precision-cut liver slices (PCLS) and experimental models, we investigated whether and how targeting MAIT cell activation may impact fibrosis regression.
Method: Liver PCLS were generated from patients with end-stage fibrosis and cultured *ex vivo* with or without the MAIT cell antagonist Acetyl-6-formylpterin (Ac-6-FP) for 48 hrs. Fibrogenic and inflammatory gene expression was evaluated by RT-qPCR and α-SMA by immunostaining. Liver fibrosis was induced in mice by repeated carbon tetrachloride (CCl_4) injections for 4 weeks. For fibrosis regression, CCl_4 injections were discontinued and mice were daily administered with Ac-6-FP for up to 4 days. Comparison of genes differentially regulated by Ac-6-FP in $Ly6C^{high}$ profibrogenic macrophages and $Ly6C^{low}$ restorative macrophages was performed by RNA sequencing.
Results: Human PCLS from patients with end-stage fibrosis exposed to Ac-6-FP showed significant reduction in the expression of fibrogenic genes such as *TGFB*, *ACTA2*, *COL1A1* and *COL1A2*. Concordantly, the number of α-SMA+ cells was reduced in PCLS exposed to Ac-6-FP. Moreover, inhibiting MAIT cells decreased *CCL2* and its receptor *CCR2* expressions. Mice chronically exposed to CCl_4 and daily injected with Ac-6-FP showed accelerated fibrosis regression associated with a decrease in CCR2+ $Ly6C^{high}$ and an increase in $Ly6C^{low}$ macrophages. RNAseq analyzes performed on $Ly6C^{high}$ and $Ly6C^{low}$ macrophages in Ac-6-FP- and vehicle-exposed mice showed reprogramming of macrophage signature by Ac-6-FP. Apoptosis was the most significant pathway deregulated by Ac-6FP, with upregulation of apoptotic genes in $Ly6C^{high}$ macrophages while induction of survival genes was mainly observed in $Ly6C^{low}$. Genes of the autophagy pathway, an anti-inflammatory and antifibrogenic mechanism in the liver, were also induced in both populations by Ac-6-FP, together with an increase in the number of LC3II+cells.
Conclusion: Inhibiting MAIT cell activation may offer new perspectives for antifibrogenic therapy, by promoting fibrosis resolution via reprogramming of macrophage profile.

Email: katrine.prier.lindvig@rsyd.dk

Background and aims: Significant liver fibrosis is the precursor of progressive liver disease and predicts the risk of liver-related complications. We aimed to generate a decision aid for general practitioners, to evaluate which patients to refer to secondary care, by developing a multivariable model for diagnosis of significant fibrosis in a biopsy-controlled cohort.
Method: We derivated the LiverPRO score in a derivation cohort of high-risk patients with an alcohol overuse and biopsy-controlled fibrosis stage (F0–F4). Univariable logistic regression followed by decision tree analysis detected nine routine liver blood markers and age as predictors of significant fibrosis (≥F2). From these, we built the final model as a software combining multiple algorithms derived from fractional polynomial regression that predicts the risk of

significant fibrosis in a score range of 0–100%. We validated the LiverPRO score in a screening study of randomly invited Danish citizens at risk of NAFLD or alcohol-related liver disease, using a liver stiffness measurement ≥8 kPa as outcome. Finally, we compared the diagnostic accuracy of the LiverPRO score with the serum markers ELF-test and FIB-4.

Results: The derivation cohort included 463 patients, 75% male, with a median age of 57 years (IQR 14). The majority (197/463, 55%) had significant liver fibrosis (≥F2), and 94 (20%) had advanced liver fibrosis (≥F3). The LiverPRO score diagnosed significant fibrosis with good diagnostic accuracy (AUC 0.84; 95% CI 0.81–0.88), similar as the ELF-test (AUC 0.84; 0.80–0.88), and superior to the FIB-4 (AUC 0.77; 95% CI 0.73–0.83). The same was observed for advanced fibrosis (LiverPRO AUC 0.92; 0.88–0.95 versus ELF-test AUC 0.92; 0.89–0.95 versus FIB-4 AUC 0.84; 95% CI 0.79–0.89).

The validation cohort included 4.722 participants, 49% male, median age 57 years (IQR 11), and 299 (6%) had a TE ≥8 kPa, of those 50% had risk factors for ALD, 46% for NAFLD and 4% had no risk factors for fatty liver disease. In this low prevalence cohort, the LiverPRO score detected TE ≥8 kPa with moderate accuracy (AUC 0.75; 95% CI 0.72–0.77), comparable to the ELF test (AUC 0.74; 95% CI 0.71–0.78) and superior to FIB-4 (AUC 0.64; 95% CI 0.59–0.68).

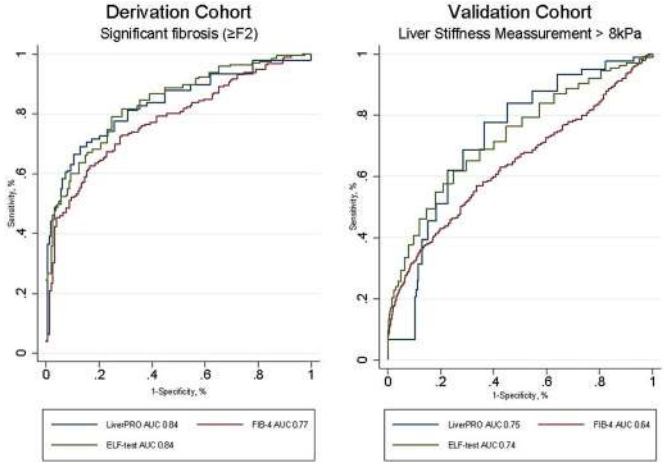

Figure: Overall diagnostic performance for Significant liver fibrosis and Liver Stiffness Measurement >8 kPa of the LiverPRO score, FIB-4 and ELF-test in the derivation and validation cohort.

Conclusion: The LiverPRO score accurately predicts significant and advanced liver fibrosis in both a high prevalence and a low prevalence cohort. Combined with a very low cost of the routine liver blood markers and an easy interpretable score from 0 to 100%, the score may be a useful screening tool and decision aide for primary care referral pathways.

FRI172

The protective effect of time-caloric restriction in liver fibrosis induced by nitrosamines in rat model

Christian Molina-Aguilar[1,2], Fernanda Arriaga-González1[1,2], Felipe Castañeda[1,3], Kevin Villa-Malagon[4,5], Irving Simonin-Wilmer[1], Obed Ramírez Sánchez[1], Emilio Calderón Garza[6], Mayra López Azuara[2], Osiel Ledesma Juárez[7], Martín del Castillo Velasco-Herrera[8], David Adams[8], Mauricio Díaz-Muñoz[9], Carla Daniela Robles-Espinoza[1].

Email: cmolina@liigh.unam.mx

Background and aims: Liver fibrosis is the first stage in the progression of cirrhosis and hepatocellular carcinoma (HCC). Around 80% of people with HCC developed cirrhosis as a previous stage, being chronic inflammation a key factor in these maladies' progression. Fibrosis is the only reversible stage of the liver injury progression; however, the cellular and molecular mechanisms of this stage are not fully understood. A better understanding of fibrotic would represents an unprecedented opportunity to avoid complications (cirrhosis and HCC) in patients. It would also help improve patient survival and ease the significant burden on the national health system by reducing drastically the number of HCC patients, which would also lower healthcare costs in many countries. In recent years, our group has explored the beneficial effects that calorie restriction (T-CR) without malnutrition has in rats treated with diethylnitrosamine (DEN), a hepatotoxic that allows us to recapitulate fibrosis-cirrhosis-HCC sequence to characterized better the liver damage and identify potential therapeutic targets. We showed in 2017 that T-CR, in the HCC stage, avoided liver chronic inflammation, the cirrhosis where established in early-stage preserving the hepatic functions, and finally although HCC tumors developed, these had a slower evolution, all compared with rats Ad Libitum (24 h of food access)

Method: Forty male Wistar rats (with an initial weight of 240 ± 20 g) were randomly assigned into one of four experimental groups. AL: Control rats without DEN and 24 h of food access. AL + DEN: Rats with 24 h of food access and DEN treatment weekly during 10 weeks to induce fibrosis. T-CR: Rats with only 2 h of food access per day and without DEN. T-CR+DEN: Rats treated weekly for 10 weeks with DEN and only 2 h of food access.

Results: A) T-CR and T-CR+DEN groups had a reduction of 30 and 37 percent in food intake in comparison with the AL, inducing less corporal weight gain but with normal nutritional state. B) Histopathology, through Ishak stage estimation and blood chemistry assessments, revealed that DEN induces fibrosis and light tissue damage (seen in both groups treated with DEN), but was less aggressive when rats are under caloric restriction. C) Preliminary results suggested a lower "basal chronic inflammatory state" was induced by caloric restriction in both healthy (T-CR) and fibrotic (T-CR +DEN) groups evidenced in total Leucocytes levels. To complement these results, we are analyzing RNAseq data from all these groups and the results will be presented at the congress.

Conclusion: Our results so far suggest that T-CR maintains its beneficial effects at a physiological level despite the damage caused by DEN in fibrosis, and that one of the mechanisms of this effect is through a decrease in the basal inflammatory state of the liver.

FRI173

Macrophage MerTK promotes a profibrogenic cross-talk with hepatic stellate cells via soluble mediators

Mirella Pastore[1], Chiara Raggi[1], Nadia Navari[1], Benedetta Piombanti[1], Giovanni Di Maira[1], Elisabetta Rovida[1], Marie-Pierre Piccinni[1], Letizia Lombardelli[1], Federica Logiodice[1], Krista Rombouts[2], Salvatore Petta[3], Fabio Marra[1]. [1]*University of Florence, Firenze, Italy;* [2]*University College London, United Kingdom;* [3]*Università degli Studi di Palermo, Palermo, Italy*
Email: fabio.marra@unifi.it

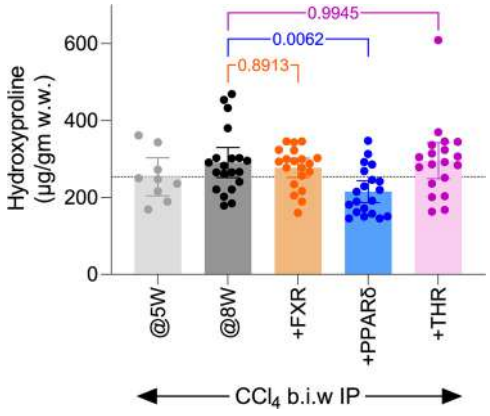
Background and aims: Activation of Kupffer cells and recruitment of monocytes are key events in fibrogenesis. These cells release soluble mediators which induce the activation of hepatic stellate cells (HSC), the main fibrogenic cell type within the liver. Mer tyrosine kinase (MerTK) signaling regulates multiple processes in macrophages and has been implicated in the pathogenesis of NASH-related fibrosis. In this study, we explored if MerTK activation in macrophages influences the profibrogenic phenotype of HSCs.
Method: M2c-like ($MerTK^+/CD206^+/CD163^+/CD209^-$) macrophages were differentiated from peripheral blood monocytes using M-CSF and IL-10. The role of MerTK was assessed by stimulation with the ligand Gas-6 and by pharmacologic inhibition with UNC569.
Results: $MerTK^+$ macrophages exhibited activation of STAT3, ERK1/2, and p38 and increased expression of VEGF-A. Exposure of $MerTK^+$ macrophages to Gas-6 increased activation of MerTK and downstream pathways. These events were reverted by pretreatment with UNC569. *MERTK* and *Gas-6* mRNA levels were gradually increased during macrophage polarization towards a M2c-like phenotype and were significantly greater in Kupffer cells than in peripheral blood monocytes. Gas-6 was released both by M2c-like macrophages and Kupffer cells. Activation of MerTK in macrophages induced a secretome which caused a significant increase in migration, proliferation, viability and expression of profibrogenic factors in HSCs. Conditioned medium of Gas-6-stimulated $MerTK^+$ macrophages also induced a significant increase in phosphorylation of STAT3 and p38 in HSCs, and upregulation of IL8 expression. These effects were specifically related to MerTK activity in macrophages, as indicated by pharmacologic inhibition.
Conclusion: MerTK activation in M2c-like macrophages modifies the secretome to promote HSC profibrogenic features, indicating that this receptor may be implicated in the pathogenesis of hepatic fibrosis.

FRI174

Comparative fibrosis-reducing activities of farnesoid X receptor (FXR), peroxisome-proliferator activated receptor delta (PPAR) and thyroid hormone receptor (THR) agonists in the carbon tetrachloride mouse model

Edward Cable[1], Jeffrey Stebbins[1], Yun-Jung Choi[1], Jiangao Song[1], Prasad Manchem[2], Sanjay Pandy[2], Charles McWherter[1]. [1]*CymaBay Therapeutics Inc., Newark, United States;* [2]*Triangulum Biopharma, Carlsbad, United States*
Email: ecable@cymabay.com

Background and aims: Fibrogenesis is a key first step toward cirrhosis in the liver, independent of etiology. A limited number of nuclear receptor agonists that have been tested in diseases with liver fibrosis. The AIM of the current study is to test three of these agonists in established fibrosis in the mouse CCl_4 model. These three selected agonists are: the FXR agonist, obeticholic acid; the PPARd agonist, seladelpar, and the THRb agonist, resmetirom. This model's mechanism of liver injury is via the trichloromethyl radical, which is likely harsher than any human disease. The rationale for selecting this model is that fibrosis can be established prior to initiation of treatment and the ability of these receptor agonists can be stringently tested for reduction of established fibrosis.
Method: Male C57B/6 mice were treated with 1 mL of CCl_4 per g BW via IP injection twice per week for 8 weeks. Concurrent with treatment initiation at week 5, a set of animals (n = 10) was sacrificed to assess the fibrosis levels. Animals (n = 20/group) were dosed daily with OCA (30 mg/kg), seladelpar (10 mg/kg), resmetirom (1 mg/kg) or vehicle in 0.5% CMC, PO for an additional 3 weeks while continuing CCl_4 administration. Liver histology assessments (H&E and PSR) and hydroxyproline content were analyzed as measures of liver fibrosis.
Results: Average hydroxyproline content at treatment start was 253 mg/g liver. Additional 3 weeks of CCl_4 treatment increased the average hydroxyproline to 290 mg/g. Neither FXR nor THR agonists decreased hydroxyproline content (277 and 291 mg/g, respectively) while PPARd decreased hydroxyproline to 215 mg/g. In addition to the reduction in total hydroxyproline, the PSR staining demonstrated a reduction in bridging fibrosis with seladelpar compared to both the vehicle at 8 weeks and the starting levels at 5 weeks. No apparent changes in fibrosis staining were observed with the other treatments.



Conclusion: The CCl_4 mouse model may be used to test for molecular targets that will reduce established fibrosis. The combination of total biochemical and histologic measurements are important to assess the topographic changes. Reduction of the PSR positive fibrotic cords between the veins is generally considered beneficial and readily observable in this model. We believe that this 8-week model can be used to dissect some of the molecular mechanisms for fibrogenesis, fibrolysis after cessation of CCl_4, and fibrolysis in the presence of CCl_4. Is treatment-related fibrolysis in the presence of CCl_4 just a reduction in the CCl_4 mediated fibrogenesis or are there separate processes? This model can be used to attempt to answer these questions and build on the findings that PPARd agonists reduce established fibrosis in the dietary NASH mouse, the *foz/foz* mouse, and the NIF mouse models.

FRI175

A novel role for serine protease Kallikrein 8 in liver fibrosis through cleaving complement C3 and hepatic macrophage polarization

Cichun Wu[1], Yao Liu[1], Ying Li[1], Wei Zhang[1], Lei Fu[1], Xin Ni[2], Shifang Peng[1]. [1]*Xiangya Hospital Central South University, Department of Infectious Diseases, Changsha, China;* [2]*Xiangya Hospital Central South University, International Collaborative Research Center for Medical Metabolomics, Xiangya Hospital Central South University, Changsha, China*
Email: sfp1988@csu.edu.cn

Background and aims: Kallikrein 8 (KLK8), an emerging serine protease in the family of Kallikrein-related peptidases (KLKs), has been implicated in myocardial and renal fibrosis. To date, it remains unknown whether and how KLK8 is involved in liver fibrosis. In this study, we aimed to determine the role of KLK8 in liver fibrosis and the underlying molecular mechanisms.
Method: KLK8 expression and localization were examined in liver tissues from fibrotic human subjects and rodent models. *In vivo* and *in vitro* silencing or overexpression of KLK8 was used for functional

studies. The natural substrates of KLK8 were screened and characterized in the liver. Mechanistic studies were performed to identify the involving KLK8-dependent molecular pathways.

Results: Hepatocyte KLK8was significantly increased in liver fibrotic patients and rodents, and the greater levels were correlated with the higher degree of liver fibrosis. Notably, liver fibrosis occurred spontaneously in transgenic-mediated overexpression of KLK8 in rats, suggesting apro-fibrotic effect. With hepatocyte-specific silencing of KLK8 in rodent models, we found that liver fibrosis was significantly attenuated compared with controls. Using immunoprecipitation in combination with mass spectrometry, we identified complement C3 as the natural substrate of KLK8. Furthermore, *in vitro* and *in vivo* mechanistic studies reveled that KLK8 promoted liver fibrosis through cleaving complement C3 to its active fragment C3a, which subsequently induced the macrophage polarization toward M2 phenotype and secretion of transforming growth factor (TGF)-β1, leading to an indirect activation of hepatic stellate cells.

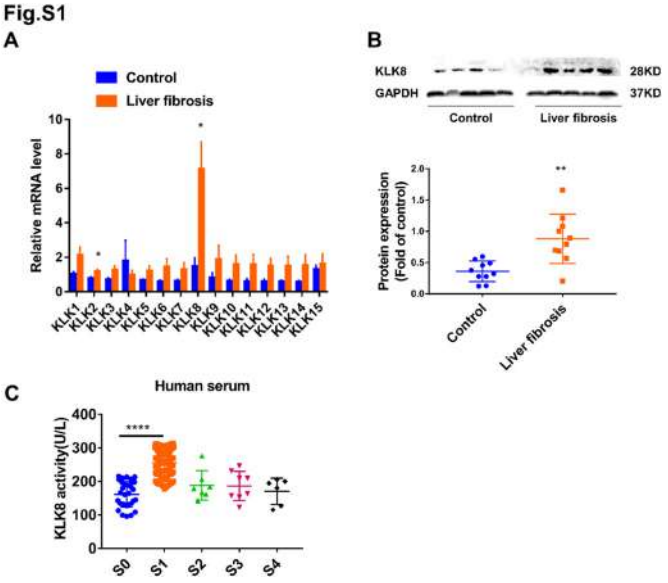


Figure S1. Expression levels of human hepatic KLK8 in liver fibrosis and control. (A) qRT-PCR analysis of themRNA expression levels of KLK1–KLK15 in the liver fibrosis group (n = 8) and the healthy control group (n = 6); (B) Western blot analysis of KLK8 protein levels in the liver fibrosis group (n = 10) and healthy control group (n = 10); (C) Serum KLK8 in patients with liver fibrosis (n = 108) and healthy control individuals (n = 31); Data are expressed as means ± SEM; *P < 0.05; **P < 0.01; ***p < 0.001; ****P < 0.0001 vs control.

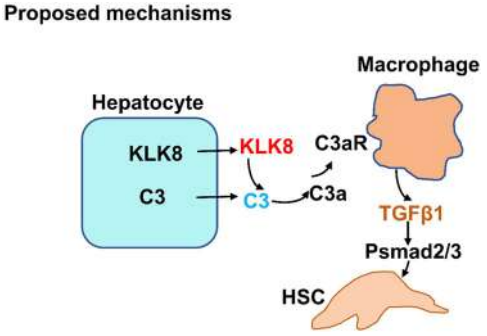

Proposed mechanisms. During liver injury, KLK8 secreted by hepatocytes releases the active fragment C3a by shearing complement C3, which in turn activates macrophages to secrete TGFβ1 and promotes the development of liver fibrosis through the TGFβ1/smad2/3 signaling pathway

Conclusion: This study has delineated a novel role for KLK8in liver fibrosis. As such, the new findings may advance our understanding of KLK8, and eventually help unleash its therapeutic potential in the development of novel treatments.

FRI176

The modulation of NADPH oxidases by tyrosol-derived phenolic compounds prevents hepatic fibrogenesis

Daniela Gabbia[1], Sara Carpi[2,3], Samantha Sarcognato[4], Ilaria Zanotto[1], Beatrice Polini[2], Katia Sayaf[5], Paola Nieri[2], Francesco Paolo Russo[5], Maria Guido[4], Sara De Martin[1]. *[1]University of Padua, Department of Pharmaceutical and Pharmacological Sciences, Padova, Italy; [2]University of Pisa, Department of Pharmacy, Pisa, Italy; [3]CNR PISA, NEST, Pisa, Italy; [4]University of Padua, Department of Medicine, Padova, Italy; [5]University of Padua, Department of Surgery, Oncology and Gastroenterology, Padova, Italy*
Email: sara.demartin@unipd.it

Background and aims: Hepatic NADPH oxidases (NOXs) are devoted to the production of reactive oxygen species (ROS), thus regulating inflammatory and fibrotic processes. Exaggerated NOX expression and activation, particularly of NOX1 and NOX4, have been related to the activation of hepatic stellate cells (HSCs) and the trigger of fibrogenesis. Therefore, compounds modulating the expression and activity of NOXs may represent promising agents for the management of hepatic fibrosis. In this study we investigated the antifibrotic and antioxidant action of the two phenolic compounds tyrosol and hydroxytyrosol, known for their cardioprotective activity, with the aim of unravelling their effect in vitro and in vivo on NOX-related fibrogenetic pathways.

Method: We evaluated tyrosol and hydroxytyrosol activity by means of LX2 and HepG2 cells, used as in vitro models of HSCs and hepatocytes, respectively. A mouse model of liver fibrosis was induced by a 4-week IP CCl_4 administration to 6 Balb/C mice; 6 untreated mice were used as controls. Tyrosol and hydroxytyrosol were administered daily by oral gavage. Levels of hepatic NOX1/4, alphaSMA, COL1A1, IL-6, IL-10 were assessed by qPCR and Western blot. Hepatic miR-181-5p, miR-221, miR-29b-3p and miR-101 were measured by qPCR.

Results: Tyrosol significantly decreased the production of ROS by HepG2 cells, and the mRNA levels of NOX1/4, alphaSMA and COL1A1 in TGFbeta1-activated LX2 cells, displaying an antifibrotic and antioxidant activity comparable to the prototypical NOX1/4 inhibitor GKT136901. An increase of hepatic ROS ($p < 0.0001$), alphaSMA, COL1A1, IL-6 and IL-10 mRNA levels ($p < 0.05$) were observed in fibrotic mice, as well as a slight increase in NOX1/4 expression. Tyrosol and hydroxytyrosol were able to counteract these effects, by significantly downregulating alphaSMA, COL1A1, NOX1/4, IL-6 and IL-10 with respect to fibrotic mice. The profibrotic miRNAs miR-181-5p and miR-221 were downregulated by tyrosol, whereas the expression of antifibrotic miRNAs miR-29b-3p and miR-101 was restored to physiological level by both tyrosol and hydroxytyrosol. Liver histology confirmed a reduction of fibrosis in treated mice.

Conclusion: The phenolic compounds tyrosol and hydroxytyrosol ameliorate hepatic fibrosis by reducing hepatic oxidative stress and inflammation and modulating the hepatic expression of miRNAs involved in fibrogenesis. Tyrosol-derived molecules should be evaluated as promising antifibrotic candidates.

FRI177

Exploring gender-related differences in liver fibrosis and regeneration through a new experimental carbon tetrachloride protocol in mice

Katia Sayaf[1], Ilaria Zanotto[2], Daniela Gabbia[2], Dafne Alberti[3], Giulia Pasqual[3], Sara De Martin[2], Francesco Paolo Russo[1]. [1]*University of Padova, Department of Surgery, Oncology and Gastroenterology, Padova, Italy;* [2]*University of Padova, Department of Pharmaceutical and Pharmacological Sciences, Padova, Italy;* [3]*University of Padova, Department of Surgery, Oncology and Gastroenterology, Padova, Italy*
Email: francescopaolo.russo@unipd.it

Background and aims: The incidence of chronic liver diseases (CLDs) is two-fold higher in men than women and they display clinically relevant differences. Thus, understanding the mechanistic gaps between females and males by pre-clinical studies is fundamental to increase the awareness on gender influence in the pathophysiological and regenerative mechanisms underlying liver fibrosis.
Method: A new experimental protocol based on increasing doses of carbon tetrachloride (CCl_4) has been developed and performed in female and male Balb/C mice, by intraperitoneal injections for 12 weeks, followed by a washout period of 8 weeks. Mice were sacrificed at different timepoints (6, 12 and 20 weeks). Flow cytometry experiments were performed on fresh liver tissues to evaluate the amount of recruited monocytes-derived macrophages (MoMFs). Liver histology was assessed by Masson's trichrome staining, and liver function was evaluated by the hydroxyproline assay. The gene and protein expression of collagen, growth factors, and pro inflammatory elements were evaluated by qPCR and immunohistochemistry, respectively.
Results: Both female and males developed a progressive liver fibrosis during CCl_4 treatment and showed liver regeneration during the washout period. After 6 weeks of treatment, male mice showed more fibrotic areas ($p < 0.05$) and more activated stellate cells (HSCs) than female mice ($p < 0.05$). Furthermore, a higher inflammatory status within male liver was confirmed during the acute damage by the intensive recruitment of pro-inflammatory $Ly6C^{high}$ $F4/80^{med\ to\ high}$ $CD11b^{high}$ MoMFS, together with higher levels of gene expression of pro-inflammatory growth factors than females. On the other hand, females developed a worse hepatic condition after 12 weeks of CCL_4 treatment, showing a higher hydroxyproline content, more activated HSCs than males, and elevate amounts of $Ly6C^{high}$ $F4/80^{med\ to\ high}$ $CD11b^{high}$ MoMFS. During the washout period, female mice showed less fibrotic areas than males ($p < 0.05$) and the presence of small amounts of MoMFs, while some activated HSCs but no pro-inflammatory MoMFs were detected in males.
Conclusion: This new model of fibrosis obtained with increasing doses of CCl_4 led to the development of liver damage without adaptive responses of the liver to the injury. We observed gender-related differences in liver damage and regeneration, due to the fact that gender influences the recruitment of pro-inflammatory MoMFs and the activation of hepatic stellate cells.

FRI178

Multicenter external validation of FIB-6: a novel, machine-learning, simple bedside score to rule out severe liver fibrosis and cirrhosis in patients with MAFLD

Gamal Shiha[1], Reham Soliman[1], Nabiel Mikhail[2], Khalid Alswat[3], Ayman Abdo[3], Faisal Sanai[4], Necati Ormeci[5], George Dalekos[6], Amir Anushiravani[7], Mai Mabrouk[8], Samir Marzouk[9]. Email: g_shiha@hotmail.com

Background and aims: Non-invasive tests (NITs) are urgently required to evaluate hepatic fibrosis in MAFLD. We previously developed and validated a non-invasive diagnostic index based on routine laboratory parameters for predicting the stage of hepatic fibrosis in patients with chronic hepatitis C (HCV) called FIB-6 through machine learning with random forests algorithm using retrospective data of 7238 biopsy proven chronic hepatitis C (CHC) patients. Our aim is to validate this novel score in patients with MAFLD.
Method: Performance of the new score was externally validated in cohorts from one site in Egypt (n = 674) and in 5 different countries (n = 1798) in Iran, KSA, Greece, Turkey and Oman). Biopsy samples were scored by experienced pathologists who used the METAVIR scoring system. Results were also compared with three established tools (FIB-4, APRI, and AAR).
Results: In this study, 2472 patients met the criteria, and their liver biopsy results were included for analysis. Using the optimal cutoffs in the data of FIB-6 indicated a reliable performance in diagnosing cirrhosis, severe fibrosis, and significant fibrosis. Results indicated good sensitivity and NPV. Sensitivity = 70.5%, specificity = 62.9%. PPV = 15.0% and NPV = 95.8% for diagnosis of cirrhosis. For diagnosis of severe fibrosis (F3 and F4), the results were 86.5%, 24.0%, 15.1% and 91.9% respectively, while for diagnosis of significant fibrosis (F2, F3 and F4), the results were 87.0%, 16.4%, 24.8% and 80.0%). Comparing of the results of FIB-6 rule-out cutoffs with those of FIB-4, APRI, and AAR showed that in ruling out severe fibrosis and cirrhosis, FIB-6 gave the highest sensitivity and NPV (97.0% and 94.7%), as compared to FIB-4 (71.6% and 94.7%), APRI (36.4% and 90.7%), and AAR (61.2% and 90.9%).

Table: (abstract: FRI178): Diagnostic performance of FIB-6 optimal cutoffs in all cohorts compared to the liver biopsy results

	Cutoff	Sensitivity	Specificity	PPV	NPV
Cirrhosis (F4 vs. F0123)	2.3159	70.5 (64.0–76.2)	62.9 (60.9–64.9)	15.0 (12.9–17.4)	95.8 (94.7–96.7)
Severe fibrosis (F34 vs. F012)	1.8992	86.5 (82.5–89.8)	24.0 (22.3–25.9)	15.1 (13.6–16.8)	91.9 (89.4–93.9)
Significant fibrosis (F234 vs. F01)	1.7720	87.0 (84.1–89.5)	16.4 (14.8–18.1)	24.8 (23.0–26.7)	80.0 (75.7–83.7)

Table: Diagnostic performance of FIB-6 rule-out cutoffs for severe fibrosis (F3) or cirrhosis (F4) in all cohorts compared with that of FIB-4, APRI, and AAR

	Cutoff	Sensitivity	NPV
FIB-6	1.5023	97.0 (94.6–98.4)	94.7 (90.4–97.1)
FIB-4	1.45	71.6 (66.6–76.2)	94.7 (93.6–95.7)
APRI	0.70	36.4 (31.5–41.7)	90.7 (89.5–91.8)
AAR	1.00	61.2 (55.9–66.3)	90.9 (89.3–92.3)

Conclusion: FIB-6 score is an accurate, simple, noninvasive test for ruling out advanced fibrosis and liver cirrhosis in patients with MAFLD better than APRI, FIB-4 and AAR.

FRI179

A bioengineered approach to re-create and study the extracellular matrix-immune cell crosstalk in normal and fibrotic liver

Sara Campinoti[1], Claire McQuitty[1,2], Lorenzo Caciolli[1], Bruna Almeida[1], Lai Wei[1,2], Luca Zanieri[3], Antonio Riva[1,2], Alessandro F. Pellegata[4], Paola Bonfanti[3,5], Sara Mantero[4], Shilpa Chokshi[1,2], Luca Urbani[1,2]. *[1]The Roger Williams Institute of Hepatology, London, United Kingdom; [2]King's College London, Faculty of Life Sciences & Medicine, United Kingdom; [3]The Francis Crick Institute, Epithelial Stem Cell Biology & Regenerative Medicine Lab, United Kingdom; [4]Politecnico Di Milano, Department of Chemistry, Materials and Chemical Engineering "Giulio Natta", Italy; [5]University College of London, Division of Infection and Immunity, Royal Free Hospital, United Kingdom*
Email: luca.urbani@researchinliver.org.uk

Background and aims: Liver fibrosis is caused by progressive accumulation of extracellular matrix (ECM) coupled with chronic inflammation. Bioengineering allows for the development of disease models to study complex diseases, such as liver fibrosis, where both cellular and extracellular microenvironment components contribute to the pathology. Bioengineered liver models have been developed by combining decellularised liver scaffolds with liver cells. However, the lack of an immune compartment is an important drawback given the role of inflammation in fibrosis. This study aims at establishing a bioengineered liver model to study the immune cell-ECM crosstalk in fibrosis.
Method: We developed two custom-made bioreactors for whole rat livers or human tissue segment culture (WL and HuTS bioreactor respectively). Decellularised normal and fibrotic rat and human livers were obtained following established protocols (detergent-enzymatic treatment). Human peripheral blood mononuclear cells (PBMCs) from healthy donors, were perfused in WL or HuTS bioreactor in absence or presence of decellularised normal or fibrotic liver scaffolds. Viability, phenotype, and cytokine production in the medium were assessed (via FACS and Luminex) in comparison to static culture conditions. Gene expression and cell phenotype of PBMCs present in the scaffolds were examined via qPCR and immunofluorescence.
Results: The bioreactors allowed for perfusion of PBMCs through decellularised rat and human liver scaffolds. Circulated PBMCs maintained cell viability and cell population frequency comparable to static culture conditions. When PBMCs were perfused through decellularised liver scaffolds, a portion of cells infiltrated the matrix, with different cell types and frequency between normal and fibrotic liver scaffolds. In fibrotic scaffolds, the number of circulating T cells decreased, while more liver infiltrating monocytes were found in respect to healthy condition. Cytokine analysis revealed that the ECM triggers the release of innate and adaptive immune system cytokines and those related to pro-regenerative immune response.
Conclusion: Here we show the validation of two bioreactor-based systems which allow to perfuse immune cells through decellularised liver matrix. This perfusion system proved to be suitable for the study of immune cell interaction with normal or fibrotic ECM, and more in general, with bioengineered constructs, and showed that mechanisms of chronic inflammation observed in fibrosis can be replicated in vitro.

FRI180

Clinical and genetic factors associated with regression of fibrosis in ACLD after etiological therapy

Yuly Mendoza[1,2], Mojgan Masoodi[3], Sofia Tsouka[3], Jaime Bosch[2], Annalisa Berzigotti[1,2]. *[1]Department of Visceral Surgery and Medicine, Inselspital, Bern University Hospital, University of Bern, Switzerland; [2]Department for BioMedical Research, Visceral Surgery and Medicine, University of Bern, Switzerland; [3]Institute of Clinical Chemistry, Bern University Hospital, Bern, Switzerland*
Email: yuly.mendozajaimes@insel.ch

Background and aims: Liver fibrosis is the main determinant of clinical outcomes in advanced chronic liver disease (ACLD) of any etiology. The introduction of effective etiological therapies has shown that liver fibrosis and even cirrhosis is reversible after eliminating the cause of ACLD. However, not all patients experience fibrosis regression, evidencing that other factors modulate this process. In order to better understand the genetic and molecular mechanisms controlling fibrosis regression we analysed the genetic and transcriptomic pathways in ACLD with or without regression of fibrosis using high-throughput technologies.
Method: We conducted a case-control pilot study of 60 patients with ACLD of different etiology, 30 with histological and/or clinical evidence of regression (Regressors, Re) and 30 without (Non-regressors, NRe), after a minimum of 24 months of etiological therapy. In all patients we performed genotyping (TaqMan assay) of gene variants associated with liver fibrosis (PNPLA3, TM6SF2, SERPINA1, GCKR, TMC4, HSD17B13). Transcriptomic analysis (RNAseq) was done in 30 frozen paired liver biopsies (before and after therapy) of 15 patients. Differentially Expressed Genes (DEGs) analysis were determined using DESeq2 and selected for FDR <0.05. The enrichment of biological pathways was determined with KEGG.
Results: Lack of regression was associated with higher frequency of GCKR-rs1260326 CT-Allele (NRe 63.3% vs Re 36.7%; OR: 0.240, p = 0.020), obesity (63.7% vs. 36.7%, p = 0.041) and higher liver stiffness (33.3 vs. 21.8 kPa, p = 0.032). These three factors remained independently associated with lower likelihood of ACLD regression on multivariate analysis (Figure). RNAseq data comparing Re vs. NRe in the post-therapy samples disclosed 109 significantly DEGs out of 17,243 genes. Downregulated DEGs in Re showed significant enrichment for the Hippo signaling pathway (p < 0.05). Other pathways identified included the PI3K-Akt signaling pathways, ECM-receptor interaction, focal adhesion and relaxin signaling pathways, already known to be involved in liver fibrosis.

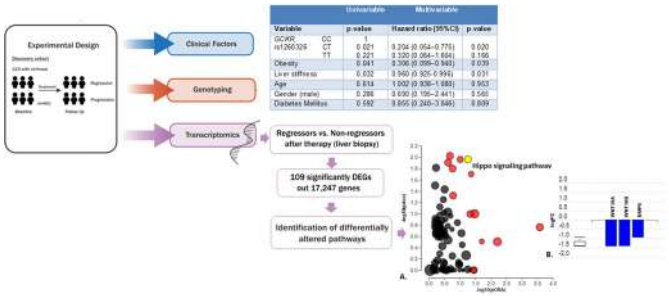

Figure. Study design and schematic illustration. A. Hippo signaling pathway (KEGG: 04390) (yellow) is shown, using negative log of the accumulation and over-representation p-values, along with the other most significant pathways. B. Gene measured expression bar plot with 3 DGEs in Hippo signaling pathway ranked based on their absolute value of log fold change, showing downregulated genes in Regressors.

Conclusion: Presence of obesity, high LSM and GCKR-rs1260326 CT-Allele decrease the likelihood of fibrosis regression of ACLD. The liver transcriptome analysis suggests that the Hippo signaling pathway, a pathway driving hepatic stellate cell activation, is involved in fibrosis

regression and may represent a novel potential therapeutic target to reverse liver fibrosis in ACLD.

Email: kleinerd@mail.nih.gov

Background and aims: A 1-stage fibrosis improvement is key for therapeutic benefit assessment in NASH trials. But in trials with a 48-week duration, most patients do not change their fibrosis stage according to the CRN system. This is due to either insufficient change in collagen amount or fibrosis distribution. qFibrosis can analyse these differential changes which has been shown to provide insights on drug effects. The generalisability in this approach beyond NASH has not been established. In this exploratory analysis, a cumulative qFibrosis score was used to identify fibrosis changes in different regions of the liver sections in treated hepatitis C (HCV) subjects who have achieved sustained virological response.
Method: Paired biopsies from 35 patients assessed to have "no-change" in fibrosis. Using qFibrosis, collagen proportionate area (CPA) of 5 pre-defined fibrosis regions [portal, peri-portal (PP), peri-central (PC), peri-sinusoidal (PS) and bridging] were quantified using second harmonic generation/two photon excitation fluorescence technology. CPA values for each region were normalized to a 0–1 range with qFibrosis total weighted score (qF-TWS) calculated as a sum of all 5 CPA values.
Results: The baseline staging of the HCV patients were F0 (n = 1); F1 (n = 2); F2 (n = 2); F3 (n = 7); F4 (n = 9); F5 (n = 2); F6 (n = 12). This cohort was reclassified by qF-TWS as those with progression (n = 9), no change (n = 7) and regression (n = 19). Changes in different regions of the tissue sections and their relationship to overall CPA response of 3 individuals from these representative groups is shown. We observed differential changes in different regions of the liver, with specific changes in the perisinusoidal region even though the conventional fibrosis stage did not change.

Figure: qF-TWS of 3 patients who have no change in fibrosis before and post-treatment. E.g., patient A showed increase in fibrosis (normalized) in 5 regions: 0.11 to 0.22 for portal, 0.17 to 0.30 for PP, 0.18 to 0.21 for PC, 0.21 to 0.33 for bridging, 0.48 to 0.36 for PS.

Conclusion: qF-TWS can differentiate subjects with fibrosis progression and regression post-treatment who were determined as no-change by pathologists' assessment. The ability of qFibrosis to assess fibrosis heterogeneity on a continuous scale provides the potential of detecting subtle fibrosis changes that cannot be captured by current system. A separate study is planned to establish correlation to clinical outcomes.

FRI182

Characterisation of the novel Galectin-3 inhibitor GB1107 on CCl4-induced liver fibrosis in mice

Alison MacKinnon[1], Ross Mills[2], Fredrick Zetterberg[3], Rob Slack[3].
[1]Galecto Inc, Edinburgh, United Kingdom; [2]University of Edinburgh, Centre for Inflammation Research, Edinburgh, United Kingdom; [3]Galecto Inc, Copenhagen, Denmark
Email: AM@galecto.com

Background and aims: Galectin-3 (Gal-3) is a pro-fibrotic β-galactoside binding lectin highly expressed in fibrotic liver (1) and implicated in hepatic fibrosis (2). GB1107 is a novel orally active anti-Gal-3 small molecule inhibitor that has high affinity and selectivity for galectin-3 as well as high oral bioavailability in mice (3).
Method: Liver fibrosis was induced by administration of CCl_4 (1:3 CCl_4:olive oil) at 1 microlitre per g or olive oil control twice weekly by intraperitoneal injection in male C57Bl/6 mice for 8 weeks. GB1107 or vehicle control was administered once daily orally (10 mg/kg) for the last 4 weeks of CCl_4 treatment. Livers were removed and fibrosis assessed by Sirius red staining of liver sections and gene sequencing. Total RNA was extracted and libraries were prepared using the NEBNEXT Ultra II Directional RNA Library Prep kit and the Poly-A mRNA magnetic isolation module. Paired-end sequencing with a read length of 100 bp was performed using a single P3 flowcell on the NextSeq 2000 platform. The raw reads were aligned to the mouse reference genome assembly GRCm39 using STAR. Pathway enrichment analysis was performed to determine enrichment of differentially expressed genes (DEGs)within Reactome pathways and Gene Ontology (GO) terms.
Results: GB1107 significantly reduced CCl_4-induced liver fibrosis (Sirius red, CCl_4-vehicle 2.70 + 0.24%; CCl_4-GB1107 1.99 + 0.10% ($p = 0.009$)). Using a false discovery rate-adjusted statistical threshold (FDR-adjusted $p < 0.05$) and a 2-fold change in expression cutoff, 1, 659 DEGs were identified with CCl_4 treatment compared to control. Comparing GB1107 treatment with CCl_4 vehicle mice 1147 DEGs were identified. Pathways strongly enriched in up-regulated genes in the CCl_4 group included those related to the extracellular matrix, and collagen biosynthesis and assembly, cell cycle and the immune system whilst pathways related to fatty acid or lipid metabolism were enriched in the down regulated genes. Principal component analysis revealed that GB1107 overlapped significantly with the control group and effectively reversed the CCl_4 induced gene changes.
Conclusion: GB1107 inhibited CCl_4-induced liver fibrosis and reversed CCl_4-induced gene changes. Small molecular weight and orally active inhibitors of galectin-3 show promise as potential new oral anti-fibrotic agents for the treatment of liver fibrosis. A first-in-human study with GB1211, an analogue of GB1107, has shown it to be both safe and well tolerated in man, demonstrating a PK profile that supports twice daily dosing (NCT03809052). GB1211 has now progressed to a phase II study in patients with liver cirrhosis (NCT05009680).

Quantitative digital pathology of 3D human NASH models establish continuous scores to evaluate the antifibrotic effects of Selonsertib, Firsocostat and Resmetiron

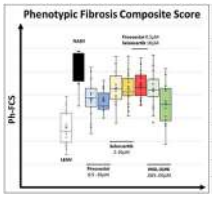
Louis Petitjean[2], Simon Ströbel[3], Li Chen[2], Eva Thoma[3], Radina Kostadinova[3]. *[1]PharmaNest, Inc, Princeton, United States; [2]PharmaNest Inc, Princeton, United States; [3]InSphero AG, Schlieren, Switzerland*
Email: louis.petitjean@pharmanest.com

Background and aims: Human in-vitro 3D NASH tissue model have the potential to accelerate the discovery of new anti-fibrotic

compounds. We have previously reported the performance of novel Digital Pathology Quantitative AI to generate automatic, continuous and direct fibrosis endpoints to quantify fibrosis severity and compound treatment response. Here, we expand this validation effort to increasing concentartions of Selonsertib, Firsocostat and resmetiron (MGL-3196) and their combinations.

Method: Human in vitro 3D InSight™ liver microtissues containing primary hepatocytes, Kupffer cells, endothelial cells and hepatic stellate cells in 96-well plates were used to model NASH progression using a defined cocktail of free fatty acids, LPS and high levels of sugars. For compound efficacy testing, the 3D NASH tissues were simultaneously treated with selonsertib (2 mM and 10 mM), firsocostat (0.5 mM and 10 mM), MGL-3196 (0.005 mM and 0.05 mM) andcombination of selonsertib (10 mM) with firsocostat (0.5 mM) for a total of 9 groups (n = 18 to 21 in each group). Liver microtissues slices were stained with Sirus Red and digitaly imaged at 40X. FibroNest™, a cloud-based quantitative image analysis and quantitative AI platform, was used to quantify the fibrosis phenotype along 32 traits for collagen content, morphometry, and architecture. Each trait is described by up to seven quantitative fibrosis traits (qFTs, 315 in total). Principal qFTs are automatically detected and combined into a normalized Phenotypic Composite Fibrosis Score (Ph-FCS). Each qFT is described individulally for relative severity (green to red) in Phenotypic Heatcharts.

Results: The Ph-FCS offers a significant detection threshold and dynamic range to evaluate the antifibrotic response the seven treatment arms (box plot chart and p-value table below). Firsocostat (10 mM) and MGL-3196 (0.05 mM) antifibrotic effects are significant and comparable. The combination of selonsertib (10 mM) with the low dose of firsocostat (0.5 mM) does not demonstrate any synergestic effect. The dose response effects are poorly detected except for the MGL-3196 arms (p = 0.075) which demonstrate that the result is driven by the compounds, not the Ph-CFS score and method. Each principal qFT is described individually for relative severity (green to red) in phenotypic heatcharts which can be used to quantified differences in the fibrosis phenotype in each group, and quantify specific effects of each drug (and dose) on the collagen distribution, collagen fibers morphometry and fibrosis architecture.



p Values	LEAN	NASH	Firsocostat 0.5µM	Firsocostat 10µM	Selonsertib 2µM	Selonsertib 10µM	Firsocostat 0.5µM Selonsertib 10µM	MGL-3196 0.005µM	MGL-3196 0.05µM
LEAN		0.000	0.000	0.000	0.000	0.000	0.000	0.000	0.000
NASH			0.000	0.000	0.010	0.000	0.000	0.000	0.000
Firsocostat 0.5µM				0.083	0.095	0.086	0.017	0.133	0.386
Firsocostat 10µM					0.002	0.001	0.001	0.033	0.669
Selonsertib 2µM						0.369	0.582	0.643	0.057
Selonsertib 10µM							0.401	0.955	0.057
Firsocostat 0.5µM Selonsertib 10µM								0.433	0.018
MGL-3196 0.005µM									0.075
MGL-3196 0.05µM									

Conclusion: The combination of FibroNest™ imaging analysis for automated quantification of histological fibrosis severity phenotype within vitro 3D InSight™ human NASHmodel provide powerful platform for anti-fibrotic drug-candidates response evaluation.

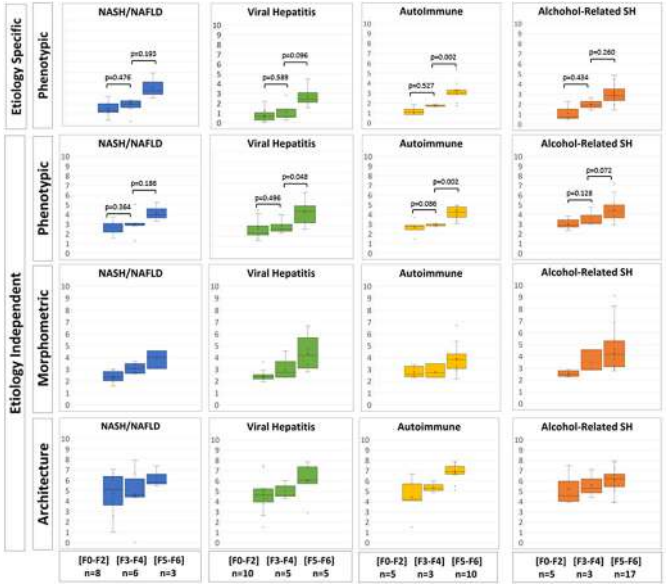
Etiology-independent fibrosis severity scoring by quantitative digital pathology image analysis

Adam Watson[1], Louis Petitjean[2], Mathieu Petitjean[2], Michael Pavlides[1]. [1]*University of Oxford, Oxford, United Kingdom;* [2]*PharmaNest, Inc, Princeton, United States*
Email: mathieu.petitjean@pharmanest.com

Background and aims: While fibrosis is the common end point of many chronic liver disease, little is known about the possible subtle histological differences between etiologies and the related performance of existing fibrosis staging system. Here, we used quantitative Digital Pathology image analysis and quantitative AI to quantify the phenotype of liver fibrosis using histological traits to describe to collagen content, collagen fiber morphometry and fibrosis architecture. The aim of this study as to identify histological traits common to a variety of liver disease aetiologies and use these to develop a new quantitative etiology-independent fibrosis severity score.

Method: Patients who had undergone liver biopsy for the assessment of diffuse liver disease were included. Liver biopsy histology slides stained with Sirius Red were digitally scanned and categorised as mild (F0–2; n = 28), moderate (F3–4; n = 17) or severe (F5–6; n = 35) fibrosis using the Ishak staging system. Disease etiology was classified as alcohol related liver disease (ARLD; n = 25), non-alcoholic fatty liver disease (NAFLD; n = 17), viral (chronic hepatitis B or C; n = 20), or autoimmune (PBC, PSC or autoimmune hepatitis; AIH; n = 18). FibroNest™ was used to describe the fibrosis phenotype of each etiological group according to quantitative fibrosis traits parameters (qFTs; n = 220) from three phenotypic layers: collagen content, fibers morphometry and fibrosis architecture. For each etiological group, qFTs that showed significant variation (>20%; $p < 0.05$) between the mild and severe groups of fibrosis were combined to produce an etiology-specific score for fibrosis severity. We also combined qFTs common to all four aetiological groups (n = 77) to produce etiology-independent score for fibrosis severity, morphometry, and architecture.

Results: Our etiology-independent fibrosis phenotypic score (2nd row of Figure 1) correlates with fibrosis stage and distinguishes mild from severe fibrosis with acceptable performance. The etiology-specific phenotypic score (1st row of Figure 1) has a superior performance for mild fibrosis. For each etiology [NAFLD, Viral, AutoImmune, AR-SH], group mean values are comparable for the Mild [2.63;2.67;2.64;3.03], Moderate [3.03;3.04;3.04;2.90] and Severe [4.17;4.26;4.33;4.47] stages. The morphometric and architectural scores (and their related qFTs) can be used to further enrich the understanding of fibrosis phenotypes.



Conclusion: Our data shows that quantitative digital pathology image analysis can phenotype fibrosis and quantify severity in multiple liver disease aetiologies. We used this technology to develop an etiology-independent score to assess the severity of fibrosis from liver biopsies.

Liver stiffness and autoimmune profile in a cohort of patients with systemic sclerosis

Davide Di Benedetto[1,2], Maria Lorena[1,2], Francesca Baorda[1,2], Giulia Francesca Manfredi[1,2], Antonio Acquaviva[1,2], Carla De Benedittis[1,2], Cristina Rigamonti[1,2], Mattia Bellan[1,2], Mario Pirisi[1,2]. [1]*AOU Maggiore della Carità, Division of Internal Medicine, Novara, Italy;* [2]*Università del Piemonte Orientale, Department of Translational Medicine, Novara, Italy*
Email: davidedibenedetto304@gmail.com

Background and aims: Systemic sclerosis (SSc) is characterized by skin fibrosis and involvement of esophagus, lungs, heart and kidneys. Liver involvement in SSc is considered rare, but reports addressing this issue are scarce. Here, we evaluated the prevalence of liver fibrosis and hepatic autoimmunity in a cohort of SSc patients.
Method: A retrospective observational study was performed on 97 patients diagnosed with SSc or mixed connective tissue disease with sclerodermic manifestations who underwent transient elastography evaluating liver stiffness (LS) and controlled attenuation parameter (CAP) due to clinical indication; a biochemistry assessment and major antibodies associated to liver autoimmunity were recorded whether performed together to clinical and demographic data.
Results: Among the 97 patients included, 16 (16.5%) had LS ≥7.5 kPa, 5 of whom had LS ≥12.5 kPa. Predictors of LS ≥7.5 were alcohol consumption, waist circumference, elevated alkaline phosphatase (ALP) levels, anti-La and anti-mitochondrial antibody (AMA) positivity. CAP values compatible with steatosis (≥280 dB/m) were observed in 6 (6.2%) patients. Waist circumference, body mass index and diabetes mellitus were significant predictors of steatosis. Out of 97 patients, 19 (19.5%) were positive for AMA, 4 (4.2%) for anti-Sp100, 1 (1%) for anti-gp210 and 7 (7.3%) were diagnosed with primary biliary cholangitis.
Conclusion: Among SSc patients, the prevalence of biomarkers of hepatic fibrosis and AMA is relatively high, suggesting the opportunity of performing a transient elastography and a screening for hepatic autoimmunity at diagnosis and/or along the course of the disease.

Email: popa.alexandru@umft.ro

Background and aims: Ultrasound based elastography techniques became in the last years reliable tools to predict the severity of liver fibrosis in chronic hepatopathies. Usually, these techniques are integrated in high-end US machines but recently they became available in medium-range ones.
To evaluate the performance ofpoint Shear-Wave Elastography from Siemens, implemented on the new ACUSON Juniper Ultrasound System, for the non-invasive assessment of liver fibrosis, and to identify liver stiffness (LS) cut-off value for predicting advanced fibrosis, using Transient Elastography (TE) as the reference method.
Method: We included 201 consecutive subjects (60% men, mean BMI = 28.7 ± 4.9 kg/m^2, mean age 59 ± 18.4 years) with or without chronic hepatopathies in whom LS was evaluated in the same session by means of 2 elastography techniques: TE and p-SWE from Siemens. Reliable LS measurements were defined for TE as the median value of 10 measurements with an interquartile range/median (IQR/M) <30%, and for p-SWE as the median value of 10 measurements acquired in a homogenous area and an IQR/M <30%. A cut-off of ≥9.5 kPa by TE was used to define advanced fibrosis (F ≥ 3).
Results: Valid liver stiffness measurements (LSM) were obtained in 97.5% of patients using both elastography methods. Therefore, 196 subjects were included in the final analysis (27.8% with TE ≥9.5 kPa). A moderate positive correlation was found between the LS values obtained by the 2 methods: r = 0.68, p < 0.0001 (Spearman correlation). LS values obtained by p-SWE were significantly lower than those obtained by TE: 8.3 kPa vs. 10.12 kPa (p < 0.0001). The best p-SWE cut-off value for advanced fibrosis (F ≥ 3) was 7.4 kPa (AUC-0.95; Se-81.5%; Sp-98%; PPV-95.7%; NPV-93.3%) (fig 1).

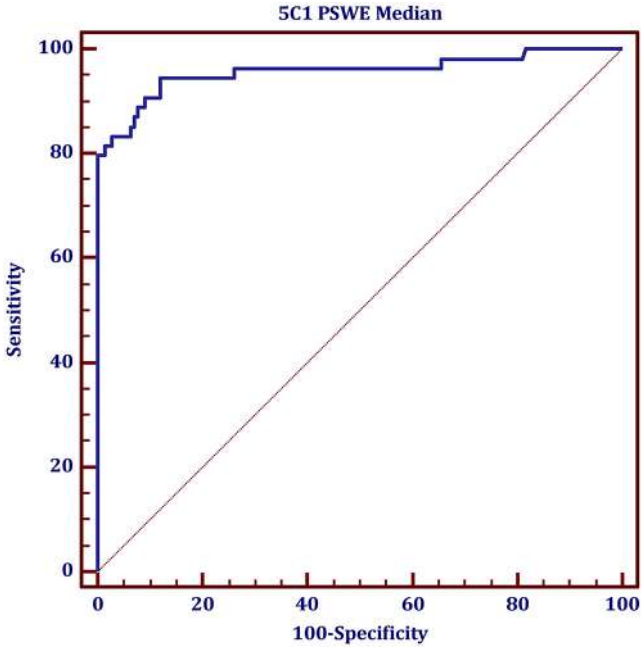

Figure 1: Performance of p-SWE for predicting advanced fibrosis (F ≥ 3).

Conclusion: Using the new US system, the best p-SWE cut-off value for predicting advanced fibrosis was 7.4 kPa.

Inhibition of tumour progression locus 2 (TPL2) halts the progression of liver fibrosis in a stringent long term choline deficient high-fat diet (CdHFD) rat model

Milessa Silva Afonso[1], Rowena Suriben[1], Natalie Sroda[1], Sowjanya Dokku[1], David Hollenback[1], Mehdi Belkhodja[1], Wesley Minto[1], Sangeetha Mahadevan[1], Grant Budas[1], Yeonju Lee[1], Kelli Boyd[1], Eda Canales[1], Bernard Murray[1], Matthew Warr[1], James Taylor[1], James Trevaskis[1], Ruchi Gupta[1]. [1]*Gilead Sciences, Inc, Foster City, United States*
Email: milessa.silvaafonso@gilead.com

Background and aims: Chronic inflammatory stimuli exacerbate liver damage and contribute to the development of fibrosis and NASH. Inhibition of TPL2, a serine-threonine kinase downstream of pattern recognition receptors, could halt or reverse NASH and liver fibrosis. Previously reduced hepatic inflammation and fibrosis was observed with a TPL2 inhibitor (TPL2i) in the rat CDHFD model. Here we explored the effect of TPL2i in an extended disease model.
Method: Male Wistar rats on CDHFD for 8 weeks were treated with TPL2i (100 mg/kg, BID), ACC inhibitor (ACCi, 10 mg/kg, QD), cenicriviroc (CVC, 100 mg/kg BID) or combinations of ACCi (10 mg/kg QD) + TPL2i (100 mg/kg BID) or ACCi (10 mg/kg QD) + FXR agonist cilofexor (CILO; 30 mg/kg BID) for 10 weeks (n = 10–15/group). Liver fibrosis was assessed by picrosirius red (PSR) and αSMA staining. Hepatic immune cell and cytokine content were assessed by immunohistochemistry and ELISA, respectively. CCR2$^+$ and Foxp3$^+$/CD3$^+$ (TReg)

cells were measured by immunofluorescence and quantified using Visiopharm.
Results: TPL2i reduced PSR by 48% and αSMA by 50% vs. vehicle (both $p < 0.001$). The combination TPL2i + ACCi reduced PSR by 63% and αSMA by 72% vs. vehicle. No improvement in these endpoints was observed with either ACCi or CVC. TPL2i reduced the expression of fibrogenic genes and hepatic content of macrophages and T-cells compared to vehicle ($p < 0.001$), but no further reductions were observed with the TPL2i + ACCi combination. A reduced number of $CCR2^+$ cells and increased proportion of TRegs were observed in liver from TPL2i-treated rats vs. vehicle. As expected, CVC reduced macrophage number (by 22%, $p < 0.01$) but did not alter T-cells. TPL2i reduced TNF-α by 64%, KC/GRO by 47% and IL-1β by 46% (vs vehicle, all $p < 0.01$). Further reductions in TNFα and KC/GRO were observed with ACCi + TPL2i combination. CVC reduced TNF-α by 48%, KC/GRO by 32%, and IL-1β by 34% (vs. vehicle, all $p < 0.05$). As a clinically relevant benchmark, the ACCi + CILO combination reduced PSR and αSMA (by 30% and 52% vs. vehicle, both $p < 0.001$), as well as macrophages and T-cells (by 28% and 32% vs. vehicle, both $p < 0.001$).
Conclusion: TPL2i improved fibrotic and inflammatory endpoints in this extended rat CDHFD model, with greater or equivalent efficacy compared to the clinically validated combination of ACCi + CILO. These results provide rationale for inhibition of TPL2 for the treatment of NASH and suggest potential for its use in novel combination therapies.

Evaluation of the antifibrotic effects of naringenin, asiatic acid and icariin by using precision-cut liver slices of mouse and human
Ke Luo[1], Yana Geng[1], Vincent de Meijer[2], Dorenda Oosterhuis[1], Peter Olinga[1]. [1]*University of Groningen, Department of Pharmaceutical Technology and Biopharmacy, Groningen, Netherlands;* [2]*University of Groningen, University Medical Center Groningen, Department of Surgery, Groningen, Netherlands*
Email: p.olinga@rug.nl

Background and aims: Fibrosis is an exaggerated wound healing response defined by excessive accumulation of extracellular matrix, which may lead to organ dysfunction or even organ failure. Therapies for liver fibrosis are lacking. Naringenin (NRG), asiatic acid (AA) and icariin (ICA) are three compounds that were reported to exert antifibrotic effects in both *in vitro* and *in vivo* animal models of liver fibrosis. However, no human data is available. Our objective was to investigate the potential antifibrotic effects of these three compounds by using the *ex vivo* mouse and human precision-cut liver slices (PCLS) model.
Method: PCLS prepared from mouse liver tissue (mPCLS), healthy human liver tissue (hhPCLS) and cirrhotic human liver tissue (chPCLS) were cultured for 48 h with or without different concentrations of the three compounds. The viability was assessed by evaluating the ATP content of PCLS to study the toxicity of the three compounds. Gene expression of the fibrotic markers alpha-1 type I collagen (*COL1a1*), heat shock protein 47, alpha-smooth muscle actin, connective tissue growth factor, plasminogen activator inhibitor-1, and inflammatory markers interleukin-1 beta, interleukin-6, tumor necrosis factor alpha were determined by qPCR. Pro-collagen 1a1 (Pcol1a1) excreted by PCLS into the culture medium was determined by an ELISA assay.
Results: NRG concentration-dependently inhibited *COL1a1* gene expression in mouse and human PCLS. The highest non-toxic concentration of NRG (300 μM in mPCLS, 200 μM in hhPCLS and chPCLS) supressed fibrosis and inflammation related genes and reduced the Pcol1a1 in the culture medium by 54 ± 21 % (mPCLS), 34 ± 23 % (hhPCLS), and 75 ± 23 % (chPCLS). The highest non-toxic concentration of AA (30 μM) decreased only in hhPCLS *COL1a1* and Pcol1a1 by 34 ± 17 %, and downregulated fibrosis-related gene expression. 25 μM of ICA, the highest non-toxic concentration, only supressed in mPCLS *col1a1* gene expression, while decreasing inflammation related genes in all PCLS types.
Conclusion: NRG showed the most promising antifibrotic potency in both mouse and human PCLS, with more profound effects in chPCLS than in the early on-set of fibrogenesis in hhPCLS. Antifibrotic effects of AA were only shown in hhPCLS. ICA only exerted antifibrotic effects on fibrosis related genes in mPCLS.

FRI189
Diagnostic efficacy of Mac-2 binding protein glycosylation isomer for predicting liver fibrosis in patients with metabolic associated fatty liver disease
Se Young Jang[1], Dae Won Jun[2], Hoon Gil Jo[3], Ki Tae Yoon[4], Young Youn Cho[5]. Email: gongori1004@gmail.com

Background and aims: The definition of metabolic associated fatty liver disease (MAFLD) has newly been proposed. We aimed to investigate the efficacy of Mac-2 binding protein glycosylation isomer (M2BPGi), non-invasive fibrosis marker, for discriminating significant and advanced fibrosis, and cirrhosis, respectively according to MAFLD and NAFLD definitions.
Method: Serum M2BPGi levels were collected and analyzed from 950 fatty liver patients in a tertiary hospital. Liver fibrosis was graded by transient elastography. Diagnostic efficacy of serum M2BPGi and other serum based liver fibrosis markers [fibrosis index based on four factors (FIB-4) and NAFLD fibrosis score (NFS)] was evaluated using correlation analysis and area under the ROC curve (AUC).

Table 1:(abstract: FRI189): Diagnostic efficacy of serum M2BPGi and other serum markers in predicting the liver fibrosis stage in patients with MAFLD.

	AUC (95% CI)	Cut-off value	Sensitivity (%)	Specificity (%)	PPV (%)	NPV (%)	P
M2BPGi							
F >1	0.706 (0.657–0.755)	1.15	48.6	81.2	35.9	88.0	<0.001
F >2	0.719 (0.662–0.776)	1.19	50.5	80.4	24.6	92.8	<0.001
F >3	0.843 (0.774–0.912)	1.31	73.7	85.6	20.1	98.5	<0.001
FIB-4							
F >1	0.703 (0.650–0.756)	1.61	68.8	66.2	30.6	90.7	<0.001
F >2	0.709 (0.643–0.774)	1.63	70.3	65.9	20.7	94.6	<0.001
F >3	0.796 (0.713–0.878)	2.40	65.8	82.8	15.8	98.0	<0.001
NFS							
F >1	0.660 (0.608–0.713)	−0.72	62.5	65.8	28.3	89.0	<0.001
F >2	0.682 (0.616–0.748)	−0.72	68.1	64.4	19.5	94.1	<0.001
F >3	0.787 (0.711–0.863)	−0.70	84.2	63.5	10.2	98.8	<0.001

Results: There were 810 patients and 687 patients by the MAFLD and NAFLD definition, respectively. Serum M2BPGi level and other liver fibrosis markers showed a positive correlation with fibrosis grade. The AUC values of M2BPGi were 0.698, 0.698, and 0.828 for predicting fibrosis (F) >1, F >2, and F >3, respectively in NAFLD group. The AUC values of M2BPGi were 0.706, 0.719, and 0.843 for predicting F >1, F >2, and F >3, respectively in MAFLD group. The AUC values of M2BPGi for predicting severity of fibrosis were greater than those of serum based liver fibrosis markers (Table 1).

Conclusion: M2BPGi showed better diagnostic efficacy for diagnosing the severity of liver fibrosis in MAFLD patients.

FRI190

Multispectral imaging analysis of liver biopsies from patients with non-alcoholic steatohepatitis reveals enrichment of pathogenic macrophage phenotypes associated with disease progression

Joseph Gosnell[1], Omar Saldarriaga[1], Santhoshi Krishnan[2], Morgan Oneka[2], Arvind Rao[3], Daniel Millian[1], Timothy Wanninger[1], Jingjing Jiao[4], Laura Beretta[4], Heather Stevenson[1]. *[1]UTMB Health-University of Texas Medical Branch at Galveston, Pathology, Galveston, United States; [2]Rice University, Houston, United States; [3]University of Michigan, Ann Arbor, United States; [4]The University of Texas MD Anderson Cancer Center, Houston, United States*
Email: jogosnel@utmb.edu

Background and aims: Non-alcoholic steatohepatitis (NASH) affects 3–6% of the US population and risk factors include obesity, dyslipidemia, metabolic disease, and type 2 diabetes. While many patients diagnosed with NASH will not progress to cirrhosis, identifying which patients will develop advanced fibrosis is a challenge. Intrahepatic macrophages are critical gate keepers in the hepatic microenvironment that assist in maintaining immune tolerance. Upon activation, they can promote a pro-fibrotic hepatic microenvironment. We hypothesized that patient variation in intrahepatic macrophage phenotypes could predict disease progression in patients with NASH.
Method: We used multiplex staining followed by multispectral imaging to phenotype and quantify resident liver macrophages (CD68+), monocyte-derived macrophages (Mac387+), pro-fibrogenic macrophages (CD163+), and their co-expression of pro-inflammatory (CD14) and anti-inflammatory (CD16) markers in the context of hepatic architecture. We compared differences in spatial distribution (i.e., in enrichment and/or depletion) of macrophage populations in patients with NASH and either minimal (n = 6; fibrosis stage: 0–1/4) or advanced (n = 5, fibrosis stage: 4/4) fibrosis. First, multiplexed stained liver biopsies were scanned with a multispectral microscope (Vectra 3, Akoya Biosciences). We then determined the heterogeneity of these various macrophage populations in the study groups using phenotype matrices and t-distributed stochastic neighbor embedding plots (t-SNE) (Visiopharm®; MATLAB 2020a). Phenotypes that were significantly increased in the patients with advanced fibrosis were selected for spatial proximity analysis using G-function equations.
Results: Phenotype matrix analysis revealed the enrichment of unique pathogenic macrophage phenotypes (MAC387+, MAC387 + CD163+, MAC387 + CD163 + CD68+, MAC387 + CD163 + CD16 + CD14 +, MAC387 + CD163 + CD16 + CD14 + CD68+) in NASH patients with advanced fibrosis when compared to those with minimal fibrosis. Pathogenic macrophage populations (MAC387+, CD163 + MAC387+, CD163+, CD68 + CD163+) correlated with poor clinical outcome (increased prothrombin time and decreased platelet counts) in two of the patients with minimal fibrosis. In patients with advanced fibrosis, spatial analysis also showed significant ($p < 0.05$) infiltration of MAC387+ macrophages near CD68+ Kupffer cells.

Conclusion: Multispectral imaging combined with spatial analysis allows characterization of distinct macrophage subpopulations that may be able to predict fibrosis progression in patients with NASH. The ability to identify at-risk patients by the presence of pathogenic intrahepatic macrophages may also lead to future precision medicine approaches.

FRI191

Diabetes, but not prediabetes, is associated with significant liver fibrosis

Byung Ik Kim[1], Yong Kyun Cho[1], Won Sohn[1]. *[1]Kangbuk Samsung Hospital*
Email: hand0827@naver.com

Background and aims: This study aimed to assess the risk of liver fibrosis between no glucose intolerance, prediabetes and diabetes in the general population.
Method: A cross-sectional study was conducted based on a cohort from a health examination program which included a magnetic resonance elastography (MRE). The participants were classified into three subgroups according to glucose tolerance: no glucose intolerance, prediabetes and diabetes mellitus. Liver fibrosis was evaluated by liver stiffness measurement (LSM) value using 2-dimensional real-time MRE. The risk of liver fibrosis was compared after adjusting for confounding factors including the presence of liver disease (non-alcoholic fatty liver disease, significant alcohol consumption and viral hepatitis).
Results: A total of 2, 090 subjects was included: no glucose intolerance (n = 889); prediabetes (n = 985); and diabetes (n = 216). The mean age was 50.6 years. The mean values of LSM in no glucose intolerance, prediabetes, and diabetes were 2.37 ± 0.43 kPa, 2.41 ± 0.34 kPa, and 2.65 ± 0.70 kPa, respectively ($p < 0.001$). The proportion of significant fibrosis (LSM ≥2.97 kPa) in no glucose intolerance, prediabetes, and diabetes was 3.1%, 4.4%, and 16.7%, respectively ($p < 0.001$). Compared with no glucose intolerance, the risk of significant fibrosis was higher in diabetes (adjusted odds ratio [aOR] 3.37, 95% confidence interval [CI] = 1.78–6.40, $p < 0.001$). However, there was no difference between prediabetes and no glucose intolerance (aOR 0.94, 95% CI = 0.54–1.64, $p = 0.940$). A subgroup analysis also showed that prediabetes is not associated with significant fibrosis unlike diabetes in subjects with or without liver disease.
Conclusion: Diabetes but not prediabetes is a risk factor for significant liver fibrosis regardless of the pressence of liver disease.

FRI192

Lysophosphatidylserine may stimmulate liver fibrosis

Takako Nishikawa[1], Makoto Kurano[2], Hitoshi Ikeda[2], Nobutake Yamamichi[1], Yutaka Yatomi[2], Kazuhiko Koike[3], Mitsuhiro Fujishiro[3]. *[1]The University of Tokyo Hospital, Center for Epidemiology and Preventive Medicine, Tokyo, Japan; [2]The University of Tokyo, Clinical Laboratory Medicine, Tokyo, Japan; [3]Graduate School of Medicine, the University of Tokyo, Japan, Department of Gastroenterology, Tokyo, Japan*
Email: kuranoma-int@h.u-tokyo.ac.jp

Background and aims: Lysophospholipids (LPLs), such as lysophosphatidic acid and sphingosine 1-phosphate are had an interest as second-generation lipid mediators. Lysophosphatidylserine (LysoPS), a phosphatidylserine-derived LPL, has recently been identified as a specific receptor, such as GPR34 and GPR174, P2Y10, and has begun to attract attention as a novel lipid mediator. In this study, we report the effect of LysoPS on liver fibrosis and their physiological roles *in vitro*.
Method: (1) The hepatic myofibroblast-like stellate cell line, CFSC-8B (CFSC), derived from a CCl_4-induced cirrhotic rat liver was utilized. The cells were incubated with the medium added various concentrations of 18: 0 and 18: 1 LysoPS. Expressions of alfa-smooth muscle actin (α-SMA) determined by western blotting. (2) Liver fibrosis was induced by intraperitoneal injection of carbon tetrachloride (CCl4) two times a week for 8 weeks in mice. (3) The tissue of liver with hepatocellular carcinoma in patient with hepatitis B virus and the plasma in patients with liver dysfunction was utilized. Expressions of

GPR34 and GPR174, P2Y10 receptor and LysoPS levels in the plasma were examined.
Results: (1) When the cells were incubated with LysoPS for 24 hours, expressions of alfa-smooth muscle α-SMA were up-regulated by 10 μM of 18: 0 and 18: 1 LysoPS treatment. Expressions of α-SMA were inhibited by inhibitors of Smad3, p38 mitogen-activated Protein kinase and Rho-associated kinase. (2) Expressions of GPR34 and GPR174, P2Y10 receptor were up-regulated along Glisson's capsule in CCl4 treated mice. 16:1 and 20:4 LysoPS levels in the plasma were increased in CCl4 treated mice. (3) Expressions of GPR34 and GPR174, P2Y10 receptor, derived from a hepatic myofibroblast-like stellate cell, were up-regulated along fibrous capsule of hepatocellular carcinoma in patient with hepatitis B virus. 16:0 and 18:2 LysoPS levels and phosphatidylserine (PS) levels, as precursor of 16:0 LysoPS, in the plasma were increased in patients with liver fibrosis.
Conclusion: In this study, it was suggested that LysoPS is involved in liver fibrosis in vitro. In vivo study, upregulation of LysoPS receptor was observed in hepatic myofibroblast-like stellate cells, suggesting that LysoPS may also be involved in liver fibrosis. Furthermore, an increase in LysoPS of some fatty acid molecular species was observed in mouse plasma, suggesting the possibility of laboratory medical application of LysoPS as a marker of liver fibrosis.

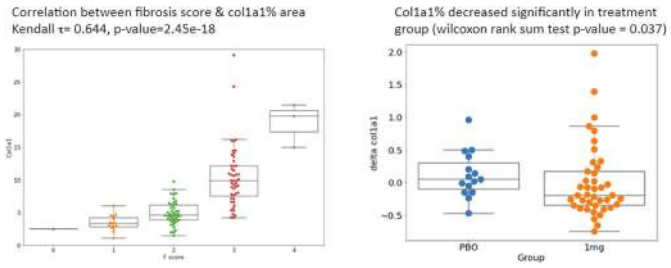
Quantitative assessment of liver fibrosis in NASH patients

Luong Ruiz[1], Tian Lan[1], Wenhui Liu[1], Amir Ashique[1], Harry Chen[1], Jiping Zha[2], Alex DePaoli[1], Igor Mikaelian[1], Cynthia Guy[3], Eugenia Henry[1], William Chang[1], Corinne Foo-Atkins[1], Hsiao Lieu[1].
[1]NGM Biopharmaceuticals Inc., Translational Sciences, South San Francisco, United States; [2]Adagene Inc, San Diego, United States; [3]Duke University Medical Center Greenspace, Department of Pathology, Durham, United States
Email: lruiz@ngmbio.com

Background and aims: The success of clinical trials for the treatment of nonalcoholic steatohepatitis (NASH) is dependent on the efficacy evaluation of the liver fibrosis endpoint. Fibrosis is currently assessed visually using the NASH Clinical Research Network (CRN) staging scheme. However the NASH CRN scheme evaluates patterns of fibrosis that are not related by a linear relationship to the quantified abundance of pathologic collagen deposition. Samples from a Phase 2 clinical trial with aldafermin (NGM282), an engineered fibroblast growth factor 19 analogue, were used to develop a novel image analysis readout for liver fibrosis.
Method: Liver biopsies were from a 24 week clinical trial with aldafermin (NGM282): NCT02443116 (placebo (PBO), n = 22; 1 mg, n = 49). Biopsies and blood for non-invasive biomarkers were collected at baseline and at the end of treatment. A 6-plex immunohistochemistry panel that included Collagen 1A1 (COL1A1) was developed. The image analysis method for COL1A1% area utilized morphological operations to eliminate normal collagen, adaptive thresholding to alleviate uneven signal intensities, and morphological erosion to remove edge effects. Parameters for the methods were tuned on a subset of images and then applied to the whole dataset.
Results: Fibrosis CRN reads correlated robustly with COL1A1% area (Kendall's t = 0.644, p-value <0.001). In addition, image analysis identified patients with decreases in COL1A1% area despite no changes in the CRN score. As a consequence, the COL1A1% area identified a statistically significant proportion of responders in the treatment arm (p = 0.037), which represented a 24% decrease in COL1A1% area compared to the PBO group, and which was not reflected by the CRN score (p = 0.12). The COL1A1% area and the CRN score correlated similarly to the non-invasive end points of serum N-terminal type III collagen propeptide and Enhanced Liver Fibrosis (ELF) score (Kendall's t ~ 0.3 with p < 0.001). Finally, the coefficient of variation for COL1A1 in consecutive liver sections was 7%.



Conclusion: In summary, immunohistochemistry-based quantitative pathology endpoints may identify drug effects that are not captured by categorical CRN endpoints.

Second harmonic generation microscopy can quantify and subclassify early stages of NASH fibrosis progression: data from a screen-failure cohort of a NASH phase 2 study

Dominique Brees[1], Dean Tai[2], Clifford Brass[3], Nikolai Naoumov[4], Elaine Chng[2], Yayun Ren[2], Andreas Sailer[1], Douglas Applegate[3], Jossy George Kochuparampil[1], Juergen Loeffler[1], Li Chen[3], Miljen Martic[1], Zachary Goodman[5], Marcos Pedrosa[1], Quentin Anstee[6]. *[1]Novartis Pharma AG, Basel, Switzerland; [2]Histoindex Pte. Ltd., Singapore; [3]Novartis Pharmaceuticals Corporation, East Hanover, NJ, United States; [4]London, United Kingdom; [5]Inova Health System, Director of Hepatic Pathology Consultation and Research, Falls Church, VA, United States, [6]Newcastle University, Translational & Clinical Research Institute, Faculty of Medical Sciences, Newcastle upon Tyne, United Kingdom*
Email: quentin.anstee@newcastle.ac.uk

Background and aims: The semiquantitative liver biopsy grading and staging systems proposed by the non-alcoholic steatohepatitis (NASH) clinical research network (CRN) are widely used in clinical trials due to regulatory authority recommendations. Other, more sensitive methods are available and have potential to provide more detailed and informative analyses of liver histology to inform our understanding of natural history and therapeutic response. Herein we describe the use of second harmonic generation/two-photon excitation fluorescence (SHG/TPEF) microscopy with computer-assisted analyses to provide a standardised and reproducible approach for precise quantitative assessment of NASH fibrosis.
Method: Liver biopsies from 138 patients with non-alcoholic fatty liver disease (NAFLD) who failed screening for a NASH phase 2 clinical trial (TANDEM, NCT03517540) were assessed for liver fibrosis using SHG/TPEF microscopy measured on a continuous scale (qFibrosis). The qFibrosis scores were converted into categorical scores (qF0–qF4) using cut-offs previously reported. qFibrosis was measured in the liver sinusoids from the portal triad to correspond to zones 1, 2, and 3 of the Rappaport acinus, where zones 1 and 3 are defined as 100 μm away from the end of collagen connected to vessel structures. Independently, all biopsies were assigned a NASH CRN fibrosis stage (F0–F4) by an expert central pathologist.
Results: qFibrosis scores (continuous [r = 0.59]; categorical [r = 0.58]) correlated moderately with NASH CRN scores (p < 0.001). The main difference in scores between NASH CRN and SHG/TPEF was in F1/qF1 and F2/qF2 patients (F1 [n = 61]; F2 [n = 7] vs qF1 [n = 25]; qF2 [n = 42]). Additionally, SHG/TPEF microscopy classified more patients with stage 3 compared to NASH CRN (F3 [n = 12]; qF3 [n = 29]). The NASH CRN scoring identified differences in the localization of fibrosis in portal, periportal and zone 1 fibrosis, but not in zone 1 alone, between F1 and F2 stages. In contrast, SHG/TPEF microscopy identified significant differences in portal, periportal and zone 1 fibrosis between qF1 and qF2 stages, as well as in zone 1 alone (Table 1). Furthermore, there were no significant differences in mean qFibrosis scores in other acinar zones.

Table 1. Quantitative fibrosis measurements by SHG/TPEF in lobular regions based on staging by SHG/TPEF microscopy and NASH CRN.

SHG/TPEF microscopy staging			
Lobular regions	**qF1, mean (n = 25)**	**qF2, mean (n = 42)**	**p value**
Portal	1.490	2.879	0.004
Periportal	0.659	1.242	<0.001
Perisinusoidal (zone 1)	0.080	0.161	0.005
Perisinusoidal (zone 2)	1.129	1.309	0.342
Perisinusoidal (zone 3)	0.093	0.096	0.881
Pericentral	0.292	0.312	0.688
Central vein	0.339	0.448	0.209

Perisinusoidal (zone 3)	0.096	0.082	0.678
Pericentral	0.318	0.372	0.549
Central vein	0.401	0.463	0.624
Portal+periportal+perisinusoidal (zone 1)	3.176	6.828	<0.001

CRN, clinical research network; F, fibrosis stage; n, number of patients in group; NASH, non-alcoholic steatohepatitis; SHG/TPEF, second harmonic generation/two-photon excitation fluorescence.

Conclusion: SHG/TPEF microscopy with computer-assisted image analyses is a sensitive and reproducible methodology that may allow categorisation of subtle changes in liver fibrosis that might otherwise not be identified using the NASH CRN staging system. Further research is needed to determine the significance of such changes and parameters to be used when evaluating therapeutic efficacy. SHG/TPEF microscopy may be a useful tool, in combination with the NASH CRN scoring system, in assessing liver fibrosis.

Abstract withdrawn

FRI196

Endothelin receptor A antagonist functionalized magnetic nanoparticles as a promising approach for the treatment of liver fibrosis

Marit ten Hove[1], Andreas Smyris[1], Carsten Höltke[2], Ruchi Bansal[1].
[1]*University of Twente, Translational Liver Research, Enschede, Netherlands;* [2]*University of Münster, Department of Clinical Radiology, Münster, Germany*
Email: r.bansal@utwente.nl

Background and aims: Hepatic injuries, caused by various etiologies such as excessive alcohol intake, fatty liver disease, viral hepatitis, or metabolic disorders, can lead to development of hepatic fibrosis. Hepatic stellate cells (HSCs) activated upon hepatic injury, that proliferate and secrete an excess of extracellular matrix (ECM), remain an attractive target for the treatment of hepatic fibrosis. During liver injury, endothelin-1 (ET-1) levels are upregulated and activate HSCs by interacting with endothelin A (ETA) receptor, which is upregulated on activated HSCs upon hepatic injury. Several studies also indicate that HSCs regulate the sinusoidal blood flow and portal hypertension via ET-1, and hence antagonism of the endothelin pathway using endothelin receptor antagonist (ERA) may offer promising results. However, antagonism of ET pathway using small-molecule ERAs can result in adverse systemic effects since high or frequent dosing will be required to achieve desired therapeutic effects.

In this study, we conjugated ERA to superparamagnetic iron oxide nanoparticles (SPIONs) to improve pharmacokinetics of endothelin receptor antagonist (ERA) and to increase hepatic uptake thereby reducing the high/frequent dosing, reducing the systemic side effects while increasing the therapeutic efficacy. SPIONS are also biocompatible and have magnetic properties, therefore can be detected using magnetic resonance imaging (MRI), making them suitable for theranostic applications.

Method: First, we analyzed the association of ET-1 and ETA with HSCs activation in vitro, and with liver fibrosis using human and murine liver tissues. Thereafter, we studied the therapeutic effects of ERA on activated HSCs *in vitro*. We then conjugated ERA on the surface of dextran-PEG coated SPIONs using EDC-NHS conjugation chemistry (see the figure). Next, we examined the therapeutic effects of ERA-SPIONs versus free ERA on activated HSCs *in vitro* and in carbon tetrachloride (CCl_4)-induced liver fibrosis mouse model *in vivo*.

Results: We confirmed the overexpression of ET-1 and ETA in activated HSCs, and human and murine liver fibrosis. ERA dose-dependently inhibited TGFβ-induced HSCs activation, collagen-I expression and contractility *in vitro*. ERA-SPIONs were synthesized and attenuated TGFβ-induced HSCs activation, ECM production, contractility via antagonizing the endothelin pathway. In CCl_4-induced liver fibrosis mouse model, ERA-SPIONs treatment, compared to ERA treatment, significantly reduced liver weight, ALT levels and inhibited collagen-I deposition indicating attenuation of liver fibrosis.
Conclusion: In this study, we demonstrate that the delivery of ERA using SPIONs is a promising therapeutic approach for the treatment of liver fibrosis that increases the therapeutic efficacy of ERA *in vitro* and *in vivo*.

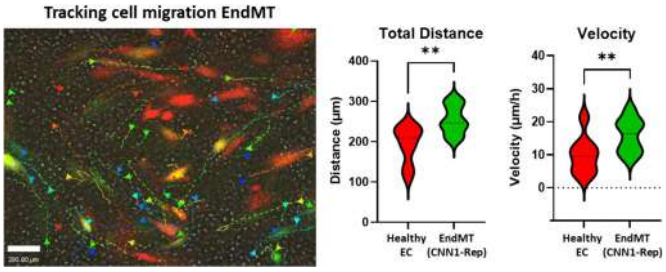
Email: radina.kostadinova@insphero.com

Background and aims: Non-alcoholic fatty liver disease (NAFLD) is a chronic liver disease, which includes hepatic steatosis that often progresses into steatohepatitis (NASH), characterized additionally by inflammation and fibrosis. We have modeled NASH using 3D human liver microtissues as a high-throughput tool for drug discovery. We present here a novel 3D human NASH model, which incorporates primary hepatocytes, Kupffer cells, liver endothelial cells, and hepatic stellate cells for high-throughput-compatible drug efficacy testing.
Method: We generated liver microtissues by culturing human primary hepatocytes, Kupffer cells, liver endothelial cells, and hepatic stellate cells in InSphero plates. Upon exposure to defined lipotoxic and inflammatory stimuli, including free fatty acids and LPS in media containing high levels of sugar and insulin, this 3D NASH model displayed pathophysiological hallmarks within 10 days of treatment. The accumulation of intracellular triglycerides (bioluminescent assay), secretion of pro-inflammatory cytokines/chemokines (Luminex), and pro-collagens type I and III (HTRF/ELISA) were measured. Quantification of fibrosis based on Sirius Red-stained tissue slices was performed using the PharmaNest imaging platform.
Results: We observed increases in intracellular triglyceride content and the secretion of proinflammatory (e. g. IL-6, IL-1b, TNF-a) and profibrotic (e.g. IL-10, GRO-a, IP-10, MCP-1) cytokines/chemokines in the NASH-treated tissues as compared to the untreated controls. Further, we detected increased fibril collagen deposition, and increased secretion of procollagen type I/III peptides under NASH conditions. Whole transcriptome analysis of NASH-treated tissues versus control revealed activation of pathways and differential regulation of genes associated with lipid metabolism, inflammation, and fibrosis induction. Treatment with the anti-TGF-β antibody and ALK5i (TGF-βRI inhibitor) concentration dependently decreased secretion of pro-collagen type I/III. Decreased deposition of fibril collagens based on quantification of fibrosis of Sirius Red-stained tissues was observed in the presence of anti-TGF-β antibody and ALK5i. The efficacy results of drug clinical candidates Selonsertib and Firsocostat were in line with clinical observations.
Conclusion: In summary, this high-throughput and compatible 3D human NASH model represents a promising approach for NASH drug candidate efficacy selection early within the drug discovery process.

FRI198
Investigating the function of Endothelial-To-Mesenchymal transition during liver fibrogenesis using a Liver-On-A-Chip platform
James Whiteford[1,2], Samantha Arokiasamy[2], Clare Thompson[1], William Alazawi[1], Neil Dufton[2]. *[1]Queen Mary University of London, United Kingdom; [2]Queen Mary University of London, Centre of Microvascular Research, London, United Kingdom*
Email: n.dufton@qmul.ac.uk

Background and aims: The plasticity of blood vessels, and particularly the cells that line them, endothelial cells (EC), are fundamental for our body's rapid response to tissue injury. During chronic disease, such as Non-Alcoholic Steatohepatitis (NASH), the specialised liver sinusoidal EC (LSEC) are replaced by the emergence of new disease-associated EC populations. Our research has identified Endothelial-to-mesenchymal transition (EndMT), whereby LSEC loss their liver-specific identity and acquire mesenchymal cell traits, as a key aspect of liver fibrogenesis. The transcriptomic signature of EndMT is now well established but the functional contribution of EndMT to the pathology of liver disease remains largely uninvestigated due to the challenges of performing high-resolution single cell imaging in viable liver tissue. This project aims to understand the cellular characteristics of EndMT by combining novel EndMT reporters with Liver-On-A-Chip (LOAC) platforms to model vascular changes in response to a NASH microenvironment.
Method: Identification, creation, and application of EndMT-specific fluorescent reporter constructs (EndMT-Reps). Transduction of EC using lentiviral packaged CNN1-eGFP construct as an inducible EndMT-Rep (CNN1-Rep) to 2D, 3D and 4D imaging techniques for fixed and live cell imaging. Combined application of live and fixed imaging technologies to measure EndMT using CNN1-Rep on LOAC platform under physiological conditions. Demonstration of the high-resolution single-cell EndMT tracking by live cell time-lapse microscopy and with post-acquisition processing (Volocity software) to perform a comparative study of CNN1-Rep and healthy LSEC within pro-fibrotic (TNFα + TGFβ2) and NASH-like (oleic and palmitic acid) LOAC microenvironment.
Results: We found CNN1-Rep was the most robust EndMT-reporter and was significantly induced in EC treatment with TNFα and TGFβ2 (1 ng/ml and 10 ng/ml respectively) for 48 h. Co-localisation of CNN1-Rep with mesenchymal marker SMA confirmed specificity of the reporter for cell undergoing EndMT. By applying CNN1-Rep within LOAC we were able to track EndMT cells for the first time for up to 24 hours. We show that EndMT cells are significantly more motile in pro-fibrotic and NASH-like than healthy EC within the same LOAC.



Conclusion: The combination of EndMT reporter, CNN1-Rep, with LOAC technology can provide us with unrivalled opportunities to understand the dynamic EndMT behaviour in homeostatic and disease liver microenvironments. Our data support the hypothesis that EndMT cells are migratory and have the potential to be an invasive cell type contributing to fibrotic cellular niche and driving fibrogenesis in the liver.

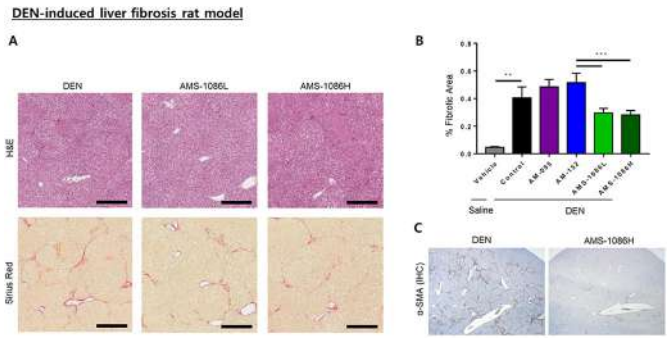
Discovery of AMS-III-1086, a novel LPA1 antagonist for the treatment of liver fibrosis and liver cirrhosis

Nakcheol Jeong[1], Peppi Prasit[1], Jung-Hee Kim[1], Misun Lee[1], Bo-Yeong Pak[2], Sojin Ahn[1], Gil Won Lee[1], Seohyun Min[1], Sanghyeok Lee[1], Yeup Yoon[3,4,5], Wonseok Kang[3,6], Hyeree Kim[3,7]. *[1]AM Sciences, Seoul, Korea, Rep. of South, [2]AM Sciences, Seoul, Korea, Rep. of South; [3]Samsung Advanced Institute for Health Sciences and Technology, Sungkyunkwan University, Department of Health Sciences and Technology, Korea, Rep. of South; [4]Institute for Future Medicine, Samsung Medical Center, Korea, Rep. of South; [5]Sungkyunkwan University, Department of Biopharmaceutical Convergence, Korea, Rep. of South; [6]Samsung Medical Center, Sungkyunkwan University School of Medicine, Division of Gastroenterology, Department of Medicine, Korea, Rep. of South; [7]Institute for Future Medicine, Samsung Medical Center, Korea, Rep. of South*
Email: njeong@amsciences.co.kr

Background and aims: Activation of the lysophosphatidic acid 1 (LPA1) receptor has been implicated in a various tissue fibrosis. LPA1 receptor antagonists have shown efficacy in a wide range of animal fibrosis models. Recently a human proof of concept in idiopathic pulmonary fibrosis (IPF) was obtained with the first generation of LPA1 antagonist in a 6-month Phase 2 clinical trial. But the compound was withdrawn from clinical development because of hepatobiliary toxicity, which was unrelated to LPAR1R antagonism but to the inhibition of bile salt export pumps (BSEP). AMS-III-1086 is a novel LPA1 antagonist designed to have a reduced risk of hepatobiliary liability by minimizing bile acids transport inhibition while its efficacy both in vitro and in vivo was improved thus providing a larger therapeutic index.

Method: The potency and selectivity of AMS-III-1086 for LPA1 receptors were determined in vitro by calcium flux and cell chemotaxis assays using B103 cells stably expressing LPA receptors and A2058 cells. LX2 cells were used for evaluating anti-fibrotic activities. Pharmacokinetic (PK) properties were assessed in rodent and non-human primates. N-nitrosodiethylamine (DEN)-induced rat fibrosis model was used for in vivo efficacy studies. BSEP inhibition was determined by BIOIVT. In vivo liver toxicity was evaluated in the cynomolgus monkeys. Human hepatotoxicity was ascertained by in vitro model using Hurel micro liver.

Results: AMS-III-1086 inhibited LPA-stimulated intracellular calcium release (IC50 = 5.3 nM) from B103 cells stably expressing human LPA1 and LPA-induced chemotaxis (A2058 cells; IC50 = 5.7 nM). AMS-III-1086 showed selective antagonism on LPA1 over the other LPA receptors. Treatment with LPA in LX2 cells induced the expressions of the LPA1 gene as well as fibrotic genes, but these were significantly reduced by AMS-III-1086. Functionally, AMS-III-1086 inhibited LPA-induced chemotaxis of LX2 cells. PK results showed good systemic exposure and high oral bioavailability in multiple species. BSEP inhibition was markedly improved, IC50 (20 uM) compared to the first-generation clinical candidates (IC50 = 5 uM). In a DEN-induced rat model of fibrosis and hepatocarcinogenesis, the therapeutic treatment of AMS-III-1086 (oral administration at 10 mg/kg once daily) resulted in the attenuation of fibrogenesis as well as the prevention of cirrhosis after 4 weeks of treatment. There were no significant changes in the levels of AST and ALT in the cynomolgus monkeys. Moreover, a cytotoxicity study using Hurel micro liver predicted that AMS-III-1086 had reduced risk of drug-induced liver injury which was corroborated in vivo in cynomolgus monkey.



Conclusion: AMS-III-1086 is a newly identified LPA1 antagonist which shows a good therapeutic index with increased efficacy and improved hepatobiliary toxicity and a favorable preclinical profile.

Integrated spatial-temporal mathematical liver lobule model for simulation of fibrotic wall formation

Seddik Hammad[1], Jieling Zhao[2,3], Mathieu de Langlard[2], Yueni Li[1], Jan G. Hengstler[3], Dirk Drasdo[2,3], Steven Dooley[1]. *[1]Heidelberg University, Molecular Hepatology Section, University Medical Center Mannheim, Medical Faculty Mannheim, Mannheim, Germany; [2]Institute National de Recherche en Informatique et en Automatique, (INRIA), Salacy, France; [3]Leibniz Research Centre for Working Environment and Human Factors at the Technical University Dortmund, Dortmund, Germany*
Email: steven.dooley@medma.uni-heidelberg.de

Background and aims: Upon different liver injuries, distinct patterns of fibrosis arise i.e. extracellular matrix (ECM) septa (fibrotic walls) connecting pericentral areas due to toxic drugs, or periportal compartments in cholestasis. Organ fibrosis is a highly coordinated and complex multi-cellular process that is difficult to capture with *experimental* models.

Method: We stepwise developed a computational two liver-lobule model that is continuously refined by iteration between modelers and experimentalists. The model permits to assess the role of biomechanics in the formation of the fibrotic scar. It for the first time integrates the orchestration of hepatocytes and non-parenchymal cells (NPC) during fibrosis development, including their interaction with the ECM network mechanics.

Results: Model predictions are quantitatively confirmed with experimental data. Pattern-characterizing model parameters, e.g. the density of hepatic stellate cells (HSC) and macrophages (Mph) were determined through analysis of experimental 2D and 3D images. A model of the ECM network, NPC and their intercellular communication were integrated as new elements into the existing computational model of the basic liver micro-architecture that already included hepatocytes, sinusoids, central and portal veins. The newly advanced model was applied to test possible mechanisms how the fibrotic scar may form during fibrosis in space and time.

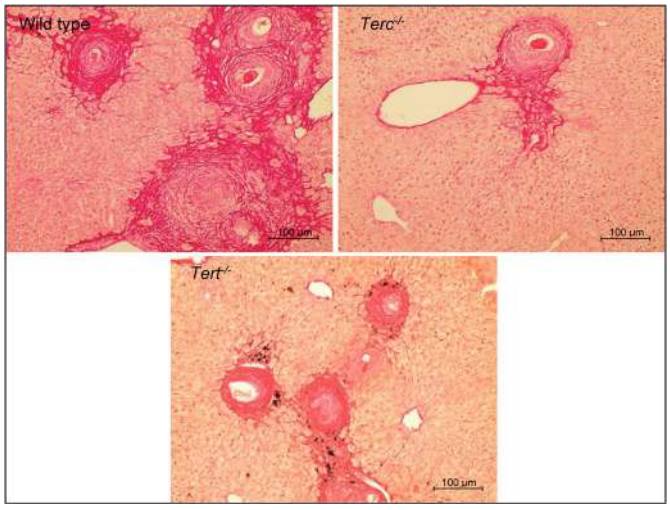
Conclusion: Using this strategy, we propose a scenario that distinguishes regeneration after a single acute toxic injury without scarring versus repeated toxic exposure leading to formation of (etiology dependent) characteristic fibrotic scar patterns, as following: (i) The spatial pattern of CYP2E1 (key metabolizing enzyme) expressing hepatocytes determines the location of ECM deposition (collagen). The tissue response is thereby mediated by the spatial-temporal pattern of certain signaling molecules provided the CYP2E1-positive damaged hepatocytes (DAMPs), leading to activation and attraction of HSC and Mph. (ii) Surviving (CYP2E1-negative) hepatocytes surrounding the CYP2E1 positive (and now damaged) region proliferate and compress the deposited collagen network into the scar like shape. The model may in the future permit us to propose targeted manipulations to reduce scar formation and the transition to cirrhosis.

FRI201

Telomerase-null mice display defective immune activation following the induction of liver fibrosis with S. mansoni

Willian Gomes[1], Vinícius Carvalho[1], Bárbara Santana[1], Leandra Naira Zambelli Ramalho[2], Rodrigo Calado[1]. [1]*Ribeirão Preto Medical School, University of São Paulo, Department of Medical Imaging, Hematology, and Clinical Oncology, Ribeirão Preto, Brazil;* [2]*Ribeirão Preto Medical School, University of São Paulo, Department of Pathology and Forensic Medicine, Ribeirão Preto, Brazil*
Email: williangomes@usp.br

Background and aims: Telomeres are structures at the end of linear chromosomes constituted by repetitive 5′-TTAGGG-3′ sequences associated to protecting proteins. Human patients with germline pathogenic variants in telomere-biology genes present critically short telomeres and usually develop bone marrow failure, but a considerable percentage also manifest pulmonary fibrosis and liver cirrhosis, although the mechanisms for disease development are still unclear. Here, we aim to investigate whether immune-mediated responses are skewed in telomerase- "knockout" (KO) mice challenged with *Schistosoma mansoni*-induced liver fibrosis.
Method: Liver fibrosis was induced by inoculation of approximately 100 cercariae to *Terc*$^{-/-}$ (n = 16), *Tert*$^{-/-}$ (n = 10) and wild-type (WT; n = 8) C57BL/6 mice, which were euthanized after 12 weeks, along with a non-infected group (*Terc*$^{-/}$n = 7^{-}, *Tert*$^{-/-}$ n = 16 and WT n = 11). Telomere length (TL) in leukocytes and liver fragments was determined by qPCR. Liver tissue samples were stained with haematoxylin-eosin (HE) and Picro-Sirius Red. Immunohistochemical (IHC) staining to F4/80, iNOS and CD206 was performed using diaminobenzidine. Bone-marrow derived macrophages (BMDM) were isolated from a second group of animals (n = 12; 4/each genotype), cultured for 7 days in RPMI and stimulated with lipopolysaccharide (LPS) or interleukin-4 (IL-4) for 24 hours. The polarization to M1 or M2-like phenotypes was determined by nitrite levels and gene expression (*IL-6*, *MMP9*, *TNF-alpha*, *CD206* and *ARG1*).
Results: TL was significantly shorter in both KO groups ($p < 0.01$). Infected animals presented hepatosplenomegaly and multiple inflammatory foci in the liver and tissue darkening. Histopathology showed the presence of granulomas surrounding *S. mansoni* eggs trapped within the tissue. *Terc*$^{-/-}$ and *Tert*$^{-/-}$ mice developed less fibrotic areas when compared to the WTs ($p < 0.05$). IHC staining revealed less macrophage infiltration within the tissue in KO animals. BMDM assay showed that the telomerase KOs impair the classical activation of macrophages, as indicated by nitrite concentrations and the differential expression of *TNF-alpha*, *IL-6,* and *MMP9.*



Conclusion: Our results suggest that the absence of telomerase causes a limited immune response following *S. mansoni* infection in mice, which mitigates the fibrotic process and cell activation. These findings also reveal that functional telomerase is critical for adequate immune response and, in patients harboring mutations in telomere-biology genes, fibrogenesis must be modulated by other inflammation signaling pathways, which deserves further investigation.

FRI202

Multiplexed digital spatial protein profiling reveals potential non-invasive biomarkers to predict advanced fibrosis

Chang Min Kim[1], Pil Soo Sung[2], Jung Hoon Cha[2], Jin Young Park[1], Yun Suk Yu[1], Hee Jung Wang[3], Eun Sun Jung[2], Si Hyun Bae[2].
[1]*Cbsbioscience, Research & Business Development, Korea, Rep. of South;* [2]*Catholic University, Korea, Rep. of South;* [3]*Inje University, Korea, Rep. of South*
Email: baesh@catholic.ac.kr

Background and aims: Innate and adaptive immune responses are critically associated with the progression of fibrosis in chronic liver diseases. Among the immune cells, intrahepatic mononuclear phagocytes are critical for the initiation and progression of liver fibrosis. In this study, using multiplexed digital spatial profiling, we aimed to develop protein signature which can be used to predict advanced fibrosis in a non-invasive approach.
Method: Snap-frozen liver tissues with various chronic liver diseases at different fibrosis stages were subjected to spatially-defined protein-based multiplexed profiling. CD3, CD68, and α-SMA markers were used to identify specific cell types. Single-cell RNA-Seq analysis was performed using GEO datasets from normal livers and cirrhotic livers. Public miRNA databse were used to find miRNA targeting protein signature.
Results: Eighty-eight portal ROIs were selected for the spatial profiling, with 24 ROIs classified into "inflammatory" (high T cell number) and 64 ROIs classified into "non-inflammatory" (low T cell number). In "non-inflammatory" ROIs, which were used for the further analyses, there were liver tissues with various fibrosis grade as F0–2 (n = 31), F3–4 (n = 33). In CD68^{+} areas, protein markers for activation of mononuclear phagocytes were detected significantly stronger in early stage fibrosis (F0, F1, and F2) than advanced fibrosis (F3 and F4). Conversely, CD68 and HLA-DR, which are known to be upregulated in SAMacs rather than KCs, were detected stronger in advanced fibrosis. Using the results from CD68^{+} area, a highly sensitive and specific, unique immune-related protein signature was developed to predict the advanced fibrosis. Combined analysis of single cell RNA-Seq data from GEO datasets (GSE136103) and spatially-defined protein-based multiplexed profiling revealed that most proteins upregulated in F0, F1 and F2 livers in portal CD68^{+} cells were specifically marked in TM (1), TM (3) and SAMacs (1) clusters, whereas proteins upregulated in F3 and F4 livers were marked in SAMacs (1), SAMacs (2), KC (1), and TM (3), highlighting the different phenotypes of portal CD68^{+} cells according to the fibrosis stages. We found the miRNAs targeting the protein signature in a public miRNA database, as the the candidate biomarkers for a non-invasive approach.
Conclusion: By establishing a GeoMx DSP method, we identified an accurate protein signature to predict advanced fibrosis. The spatially-defined protein-based multiplexed profiling demonstrated a critical difference in the phenotypes of mononuclear phagocytes between livers of early stage fibrosis and those of advanced fibrosis. Our results suggest that portal mononuclear phagocytes are critical in inflammation and fibrosis progression, and that miRNAs targeting the protein signature of those cells may be ideal non-invasive biomarker candidates.

FRI203

Sex and diagnosis-specific differences in liver elastography and attenuation

Zhi Tan[1], Marcelle Scagliotta[1], Crystal Connelly[1], Wendy Lam[1], Oyekoya Ayonrinde[1]. [1]*Fiona Stanley Hospital, Gastroenterology and Hepatology, Murdoch, Australia*
Email: oyekoya.ayonrinde@uwa.edu.au

Background and aims: Liver stiffness measurement (LSM) using Transient Elastography (TE), combined with liver attenuation measurement using controlled attenuation parameter (CAP), allows rapid, non-invasive assessment of liver fibrosis and steatosis. We examined the usefulness of TE and CAP for assessment of liver disorders in an adult hepatology outpatient population.
Method: In this cross-sectional study, we investigated the duration and findings of TE and CAP in adult outpatients with known or suspected chronic liver disease, between 2012 and 2021. LSM and CAP were measured using a FibroScan® model 502 Touch. Each procedure was performed by a hepatology nurse with experience of over 500 examinations. Patient age, sex, assessment indication, duration, LSM, CAP, and accuracy of the examination was recorded.
Results: There were 5645 examinations performed on patients with various liver disorders, mean age 55.9 (standard deviation 12.9) years, and 60.7% male. Of these, a medium (M) probe was used for 4212 (74.6%), extra-large (XL) probe for 1422 (25.2%), and small (S probe without CAP) in 11 (0.2%). The most common indications were chronic hepatitis C (CHC, 46%), chronic hepatitis B (CHB, 22%), non-alcoholic fatty liver disease (NAFLD, 15%), and alcohol-related liver disease (ALD, 6%). Median LSM in the cohort was 6.8 (IQR 4.9–11.8) kPa and CAP 252 (IQR 204–307.5) dB/m. Both LSM and CAP were higher in males, compared with females; (LSM 7.1 [5.3–12.2] kPa vs. 6.1 [4.6–10.7] kPa, $p < 0.001$) and (CAP 255 [208–309] dB/m vs. 241 [196–298], $p < 0.001$) respectively. Also, median LSM was highest with ALD (14.5 [7.5–35.3]), compared with CHC (7.6 [5.4–12.5]), NAFLD (7.6 [5.3–13.3]) and CHB (5.4 [4.3–7.1]). Median CAP was highest with NAFLD (315 [261–361] dB/m), compared with ALD (263 [211–329] dB/m), CHC (245 [203–293] dB/m) and CHB (233 [189–283] dB/m). There were sex-differences in CAP, LSM and duration of the examination, across different liver disorders (Table 1).

Diagnosis	Sex		P value
NAFLD	**Male n= 302**	**Female n=379**	
LSM (kPa)	7.6 (5.3-14.3)	7.7 (5.4-13.6)	0.75
CAP (dB/m)	323 (264-373)	306 (250-349)	0.01
Duration of exam	231 (94-478)	280 (132-546)	0.01
ALD	**Male n= 220**	**Female n=95**	
LSM (kPa)	12.7 (7.2-33.3)	21.8 (8.9-45.7)	0.06
CAP (dB/m)	273 (225-334)	246 (181-298)	0.004
Duration of exam	250 (123-448)	234 (113-490)	0.96
CHC	**Male n= 1702**	**Female n=746**	
LSM (kPa)	7.7 (5.7-13.8)	6.8 (4.9-11.5)	<0.001
CAP (dB/m)	250 (208-297)	236 (196-283)	<0.001
Duration of exam	224 (108-463)	250 (124-477)	0.03
CHB	**Male n= 701**	**Female n=524**	
LSM (kPa)	5.9 (4.6-7.8)	4.8 (4.0-6.1)	<0.001
CAP (dB/m)	240 (197-294)	219 (182-263)	<0.001
Duration of exam	177 (77-394)	172 (86-403)	0.75

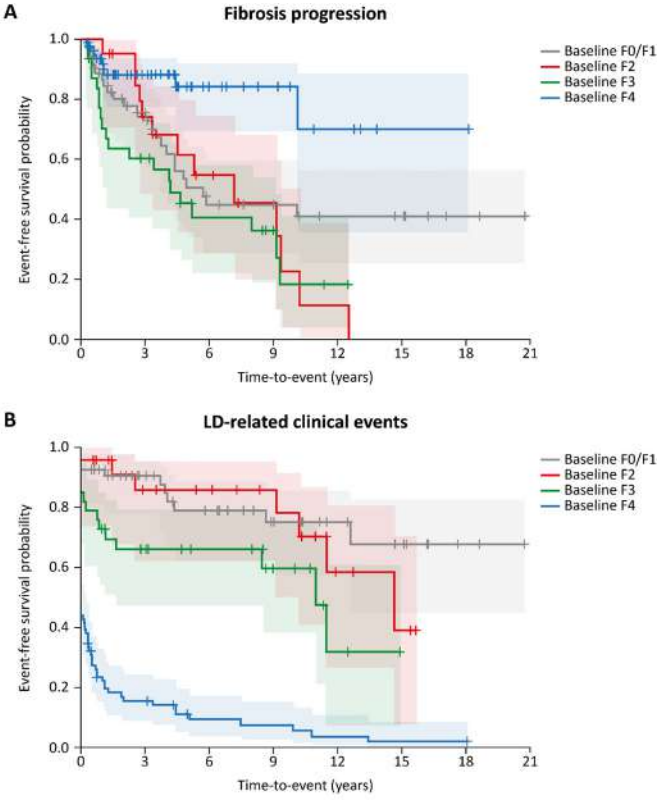
Conclusion: Across various liver disorders, CAP was significantly higher in males overall, suggesting more severe hepatic steatosis. LSM was higher in males with CHC and CHB, compared with females. Severity thresholds for CAP and LSM should consider these differences.

FRI204

Progression of liver disease among patients with a new diagnosis of protease inhibitor ZZ alpha-1 antitrypsin deficiency

Harmeet Malhi[1], Tiffany Wu[1], May Hagiwara[2], Gregory Donadio[3], Esteban Gnass[3], Will Treem[2], Kaili Ren[2], Ed G. Marins[2], Chitra Karki[2]. [1]*Mayo Clinic, Rochester, United States;* [2]*Takeda Pharmaceutical Company Limited, Cambridge, United States;* [3]*Inference, Cambridge, United States*
Email: malhi.harmeet@mayo.edu

Background and aims: Few studies have characterized disease progression in patients (pts) with alpha-1 antitrypsin deficiency-associated liver disease protease inhibitor ZZ (AATD-LD PiZZ) genotype, who may progress variably with time and may remain asymptomatic despite advanced liver fibrosis. We examined the relationship between progression of disease and LD-related clinical events (LD events) over time in this population.
Method: Data were extracted from the nFerence database (a proprietary electronic medical record database from the Mayo Clinic Healthcare System) between January 2004 and September 2021. Pts with AATD were defined by the presence of structured diagnosis (dx) codes for AATD, or an alpha-1 antitrypsin serum level of <100 mg/dL. LD was defined based on structured dx codes and surrogate measures. PiZZ genotype was defined by genotype results or unstructured data through natural language processing. Index date was defined as the first date of dx of LD. Fibrosis stage (F0–F4) was assessed at baseline (index date ± 90 days) and during follow-up using a hierarchical approach: liver biopsy (METAVIR staging), magnetic resonance elastography, Fibroscan, APRI and FIB-4. Pts with <90 days of follow-up were excluded. LD events were defined as development of ascites, spontaneous bacterial peritonitis, variceal bleeding, hepatic encephalopathy, hepatocellular carcinoma and need for liver transplantation. Outcomes were analyzed using descriptive statistics and Kaplan-Meier analysis for time-to-event.
Results: Of 685 000 pts, 6315 had a dx of AATD; of these 501 had the AATD PiZZ genotype, and 316 qualified for the study. Among pts with AATD-LD PiZZ, the mean age was 50.5 years (y), 58.4% were male, 100% were White, and 37.7% were diagnosed with chronic obstructive pulmonary disease, chronic bronchitis, bronchiectasis, or emphysema. At baseline, 197 pts had fibrosis stage: F0/F1, 53; F2, 24; F3, 33; and F4 with compensated cirrhosis (F4cc), 87 (119 pts were not categorized owing to a lack of available data). Of 316 patients with 7.4 y of median follow-up, 17.4% underwent a liver transplant: 2%, 4%, 12% and 44% among pts with baseline stage F0/F1, F2, F3 and F4cc, respectively. Disease progression (≥1 fibrosis stage) occurred in 31 pts at ≤2 y (F0/F1, 22%; F2, 5%; F3, 36%) and in 53 pts at ≤5 y (F0/F1, 49%; F2, 38%; F3, 55%) (Figure A). At any time during follow-up (median 7.4 years), LD events occurred in 50.1% of pts, with a higher number of events recorded for pts with baseline stage F4cc (98.2%) compared with F3 (68.3%) and F2 (61.0%) (Figure B).



Footnotes: Fibrosis stage (F0–F4) was defined based on liver biopsy (METAVIR staging) and other secondary measures including MELD and CTP scores, MRE, FibroScan, APRI and FIB-4 using this hierarchical order.

F4dc: MELD score increased by 15 or more from the baseline value of < 12 or CTP score increased by > 2 from the baseline; **F4cc:** MRE > 5.0 kPa, APRI > 1.5 or FIB-4 > 3.25; **F3:** 5.0 ≥ MRE > 4.0 kPa, elastography > 12.5 kPa, APRI > 0.63 or FIB-4 > 1.90; **F2:** 4.0 ≥ MRE > 3.5 kPa, elastography > 8.45 kPa, APRI > 0.43 or FIB-4 > 1.43; **F1:** 3.5 ≥ MRE ≥ 3.0 kPa.

AATD-LD PiZZ, alpha-1 antitrypsin deficiency-associated liver disease protease inhibitor ZZ; APRI, aspartate aminotransferase to platelet ratio index; cc, compensated cirrhosis; CTP; Child-Turcott-Pugh; dc, decompensated cirrhosis; FIB-4, Fibrosis-4; KM, Kaplan-Meier; LD, liver disease; MELD, model for end-stage liver disease; METAVIR, meta-analysis of histological data in viral hepatitis; MRE, magnetic resonance elastography; pts, patients.

Figure: KM estimates of fibrosis progression (A) and LD events (B) by baseline fibrosis stage in pts with AATD-LD PiZZ.

Conclusion: Almost 1/3 of F3 pts at baseline progressed to F4 and had LD events in ≤2 y, and >2/3 of F4cc pts had LD events in ≤1 y. These clinically relevant findings need validation in independent cohorts.

FRI205

Perihepatic implantation of matrix-embedded endothelial cells reduce inflammation and collagen deposition in fibrotic mice

Mireia Medrano-Bosch[1], Alazne Moreno-Lanceta[1,2], Laura Macias-Muñoz[2,3], Elazer Edelman[4,5], Wladimiro Jiménez[1,2,3], Pedro Melgar-Lesmes[1,2,4]. *[1]Department of Biomedicine, School of Medicine, University of Barcelona, Barcelona, Spain; [2]Institut d'Investigacions Biomèdiques August Pi-Sunyer (IDIBAPS), Centro de Investigación Biomédica en Red de Enfermedades Hepáticas y Digestivas (CIBERehd), Barcelona, Spain; [3]Biochemistry and Molecular Genetics Service, Hospital Clinic Universitari, Barcelona, Spain; [4]Institute for Medical Engineering and Science, Massachusetts Institute of Technology, Cambridge, MA, United States; [5]Cardiovascular Division, Brigham and Women's Hospital, Harvard Medical School, Boston, Massachusetts, United States*
Email: pmelgar@ub.edu

Background and aims: Matrix-embedded endothelial cells (MEECs) are endothelial cells grown in a 3D collagen-based scaffold that shields their immunogenicity *in vitro* and *in vivo*. This phenotype conversion minimizes stress and maximizes the secretion of anti-inflammatory and anti-fibrogenic factors. Here, we aimed to test whether the perihepatic implantation of MEECs may interfere with the inflammatory and fibroproliferative processes occurring in fibrotic mice.

Method: Fibrosis was induced in BALB/c mice (n = 12) by i.p. injection of CCl_4 diluted 1:8 v/v in corn oil twice a week for 8 weeks. Acellular matrices or MEECs were surgically implanted between the median and the right lobe in fibrotic mice. After one week, relative fibrosis area was analyzed by Sirius Red staining. Liver function was evaluated in serum samples. The expression of pro-inflammatory genes (nitric oxide synthase 2 (NOS2), ciclooxigenase-2 (COX-2), interleukin 1 beta (IL1-B)), anti-inflammatory genes (arginase 1 (ARG1), mannose receptor C-type 1 (MRC1), resistin (RETN1A)), hepatic stellate cell (HSC) activation factors (oncostatin M (OSM), platelet derived growth factor-BB (PDGFBB), transforming growth factor-beta (TGF-B)) and genes related to the extracellular matrix turnover (collagen-I (COL-I), alpha smooth muscle actin (ALPHA-SMA), tissue inhibitor of metalloproteinases-1 (TIMP1)) was quantified by Real-time PCR.
Results: Implantation of MEECs for seven days promoted a 21% reduction in the hepatic fibrosis area compared with fibrotic livers implanted with acellular matrices. These anti-fibrotic effects translated into a significant improvement of liver function reflected by the reduction of serum transaminases (ALT, 153.3 ± 15.8 vs 100.6 ± 14.5 U/L, $p < 0.05$; AST, 477 ± 50.4 vs 288 ± 54 U/L, $p < 0.05$). Perihepatic implantation of MEECs significantly reduced the hepatic expression of pro-inflammatory genes (COX-2, 1.0 ± 0.1 vs 0.6 ± 0.1 fold change (fc), $p < 0.05$; NOS2, 1.1 ± 0.3 vs 0.5 ± 0.1 fc, $p < 0.01$; IL1-B, 1.1 ± 0.1 vs 0.5 ± 0.1 fc, $p < 0.01$) and increased the hepatic expression of anti-inflammatory genes (ARG1, 1.0 ± 0.1 vs 1.6 ± 0.1 fc, $p < 0.05$; MRC1, 1.0 ± 0.1 vs 1.4 ± 0.1 fc, $p < 0.05$; RETN1A, 1.1 ± 0.1 vs 14.8 ± 4.8 fc, $p < 0.01$) on fibrotic mice. Our results also revealed that MEECs promoted a significant decrease in well-known stimulators of HSC (OSM, 1.0 ± 0.2 vs 0.35 ± 0.06 fc, $p < 0.05$; PDGF-BB, 1.0 ± 0.1 vs 0.57 ± 0.08 fc, $p < 0.01$, TGF-beta 1.0 ± 0.1 vs 0.69 ± 0.05 fc, $p < 0.05$). This reduction was associated with a fall in the hepatic expression of genes related to HSC activation (COL-I, 1.0 ± 0.1 vs 0.49 ± 0.06 fc, $p < 0.01$; ALPHA-SMA, 1.1 ± 0.2 vs 0.63 ± 0.08 fc, $p < 0.05$, TIMP-1 1.0 ± 0.2 vs 0.56 ± 0.07 fc, $p < 0.05$).
Conclusion: Perihepatic implants of MEECs display anti-inflammatory and anti-fibrotic activity in liver fibrosis. This study highlights the potential therapeutic utility of MEECs for chronic liver disease.

LncRNA XR_592974.2 and circRNA _2599 regulated hypoxic stress response in hepatic stellate cells by targeting the miRNA-145/JMY/P53 pathway

Dan Zhou[1], Jing Gao[2,3], Xiao-jun Wang[4], Yujin Li[5], Hong Chen[6], Liting Zhang[1]. *[1]The First Hospital of Lanzhou University; [2]Department of Medicine, Karolinska Institute, Stockholm, Sweden; [3]University of Helsinki, Heart and Lung Centre, Helsinki, Finland; [4]Gansu Provincial Hospital; [5]Capital Medical University, China; [6]Xi'an International Medical Center, China*
Email: lcheneye@163.com

Background and aims: Non-coding RNAs contribute to the activation of hepatic stellate cells (HSCs) and the progression of liver fibrosis. Hypoxia serves as a pivotal microenvironmental factor that facilitates the activation of HSCs. Our previous study demonstrated differentially expressed mRNAs and miRNAs in hypoxia-induced HSCs. Here, we investigated the interactions among lncRNAs/circRNAs, miRNAs, and mRNAs in HSCs under hypoxic stress.
Method: Hypoxia-induced HSCs model were treated with 400 μmol/L CoCl2 in HSC-T6 cells. The differentially expressed mRNAs, miRNA, circRNAs, and lncRNAs in hypoxia-induced HSCs were identified using whole-genome sequencing. Next, we constructed the ceRNA network based on the interactions among lncRNAs/circRNAs, miRNAs, and mRNAs in hypoxia-induced HSCs. The functional analyses were performed by the gene ontology analysis and the Kyoto Encyclopedia of Genes and Genomes pathway analysis. Finally, we performed the pathway analysis based on the public database and literature.

Results: A total of 1423 mRNAs, 54 miRNAs, 288 lncRNAs, and 60 circRNAs were differentially expressed in hypoxia-induced HSCs compared to the controls. Combined with our previous identified miRNA-mRNA regulation network in HSCs under hypoxic stress, the results presented that up regulation lncXR_592974.2 and up regulation circRNA_2599 regulated in down regulation miRNAs (miRNA-145-3p and novel 500 mature) -up regulation mRNA (Junction Mediating and Regulatory Protein (JMY, P53 Cofactor)) network, respectively. These ncRNAs/circRNAs-miRNAs- mRNAs were involved in P53 signaling pathway (Figure 1).

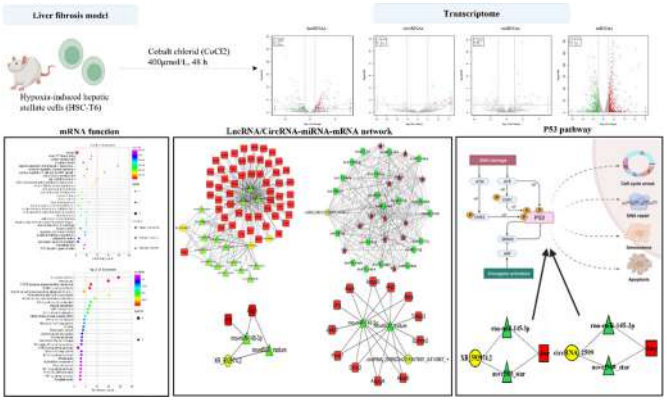

Figure: Illustration of interactions among lncRNAs/circRNAs, miRNAs, and mRNAs in hypoxia-induced hepatic stellate cells in rat.

Conclusion: Our results showed the lncRNAs XR_592974.2/circRNA_2599-miR-145-3p/novel 500 mature -Jmy-p53 regulatory axis that might participate in activated HSCs and might carry potential therapeutic targets for restraining hypoxic stress.

Email: miljen.martic@novartis.com

Background and aims: Correlation of a non-invasive test (NIT) with histology-based readouts is one of the key aspects of NIT inclusion in clinical trials and their adoption and impact on patient care. This sub-study aimed to explore correlation of different NITs with liver histology endpoints assessed by standard histology (NASH-CRN) and quantitative digital pathology (HistoIndex, HI-QDP).
Method: As part of the TANDEM NASH Phase 2 trial [NCT 03517540], the cross-sectional pre-treatment data has been collected from 269 patients with NAFLD (138 screen-failed and 131 randomized subjects). Key trial inclusion criteria were based on liver biopsy (NASH with F2 or F3 fibrosis). Only subjects who signed additional research ICF have been included in this analysis. Liver biopsies were evaluated by a central reader using NASH-CRN scoring system and analyzed by HI-QDP algorithm. ALT, AST, ELF, GGT, FIB-4 and Pro-C3 were analyzed by central laboratory, Fibroscan liver stiffness measurement (LSM) was assessed by a clinical site, while MRE LSM was assessed by a central imaging reader.
Results: Statistical analysis on the entire cohort (n = 269) revealed that MRE had the strongest correlation with both fibrosis assessments (NASH CRN and HI-QDP qFibrosis), followed by a MRI-aspartate aminotransferase (MAST) score (Figure). As MRI and MRE imaging were performed in a random subset of subjects, the MRE based dataset is smaller than for Fibroscan and soluble biomarkers. Interestingly, when correlating with qFibrosis, third and fourth ranked biomarkers were Pro-C3 and ELF, compared to FIB-4 and ELF when correlating with CR fibrosis assessment. In both cases, Fibroscan LSM and FibroScan-AST (FAST) score ranked fifth and sixth.

Correlation between histology readouts and NITs/R value (p value)		
NITs	**qFibrosis continuous**	**NASH-CRN fibrosis**
ALT (qFibrosis n = 266) (NASH-CRN n = 254)	0.07 (p = 0.23)	0.02 (p = 0.75)
AST (qFibrosis n = 266) (NASH-CRN n = 254)	0.26 (p < 0.001)	0.25 (p < 0.001)
ELF (qFibrosis n = 266) (NASH-CRN n = 255)	0.33 (p < 0.001)	0.38 (p < 0.001)
GGT (qFibrosis n = 267) (NASH-CRN n = 255)	0.22 (p < 0.001)	0.18 (p = 0.004)
PRO-C3 (qFibrosis n = 102) (NASH-CRN n = 102)	0.35 (p < 0.001)	0.08 (p = 0.44)
FIB-4 (qFibrosis n = 262) (NASH-CRN n = 251)	0.26 (p < 0.001)	0.40 (p < 0.001)
Fibroscan LSM (kPa) (qFibrosis n = 183) (NASH-CRN n = 181)	0.29 (p < 0.001)	0.21 (p = 0.004)
FAST (qFibrosis n = 151) (NASH-CRN n = 149)	0.26 (p = 0.0011)	0.28 (p < 0.001)
MRE LSM (kPa) (qFibrosis n = 32) (NASH-CRN n = 31)	0.49 (p = 0.005)	0.49 (p = 0.005)
MAST (qFibrosis n = 32) (NASH-CRN n = 31)	0.38 (p = 0.03)	0.43 (p = 0.01)

Conclusion: MRE LSM and MAST score had the strongest correlation with liver fibrosis staging (both NASH CRN and by HI-QDP qFibrosis). Additional evaluation of other individual biomarkers, as well as combination of imaging and soluble biomarkers is still ongoing and will also include separate correlations for randomized and screen failed subjects.

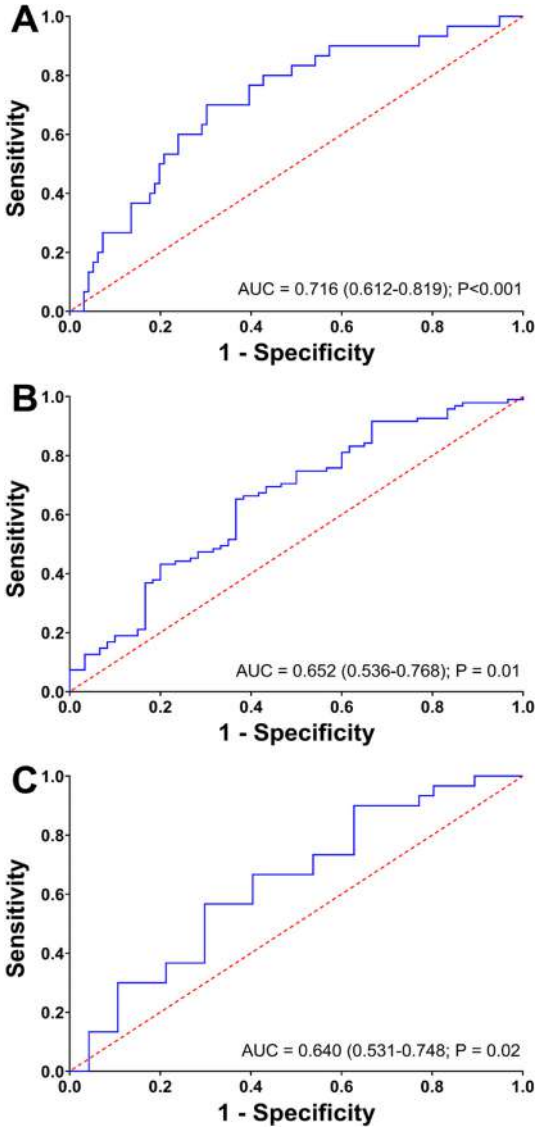
Background and aims: Approximately 40–70% of chronic HCV (CHC) patients develop an autoimmune extrahepatic disorder. IgG autoantibodies against apolipoprotein A-1 (AAA1) are a robust biomarker

of cardiovascular disease and predict all-cause mortality [1]. We previously reported the presence of AAA1 in 14/27 CHC patients [2]. Here, we evaluated AAA1 in a larger cohort of CHC patients to explore associations between AAA1, lipoproteins and severity of liver disease.
Method: Serum samples were obtained from 126 treatment naïve CHC subjects (61 genotype (GT) 1 and 65 GT3) and assayed for AAA1 and lipoprotein profiles. Subjects were classified as cirrhotic by liver imaging and/or histological assessment. Area under receiver operating characteristic curves (AUROC) were calculated for AAA1 and HDL-related parameters and used for predicting patients with cirrhosis. Fibronectin (FN) and messenger RNA (mRNA) were measured in human hepatic stellate cells (LX2) in the presence or absence of AAA1.
Results: Fifty-nine (47%) CHC patients were AAA1 positive. Twenty-one (70%) of 30 cirrhotic patients were AAA1 positive and the median magnitude of AAA1 was also significantly higher than non-cirrhotic patients (48% vs. 31%; $p < 0.001$). The AUROC for AAA1, ApoA-1 and HDL-C for predicting cirrhosis was 0.72 ($p < 0.001$), 0.65 ($p = 0.01$) and 0.64 ($p = 0.02$) (Figure A, B & C respectively). After 48 hours in the presence of AAA1, LX2 cells showed significantly increased levels of FN compared to LX2 cells alone ($p = 0.02$) and the LX2/IgG control ($p = 0.0016$). This was further confirmed by quantitating FN mRNA, LX2 cells and AAA1 showed an 80% increase in FN mRNA compared to LX2 cells alone ($p = 0.035$) and the LX2/IgG control ($p = 0.028$).



Conclusion: AAA1 are found in a subgroup of CHC patients and are found with higher incidence and magnitude in patients with advanced liver fibrosis. AAA1 are robust biomarkers for predicting cirrhosis. Human hepatic stellate cells in the presence of AAA1 showed a fibrotic phenotype. Further studies are warranted to define the role of AAA1 in the development of fibrosis and cirrhosis.

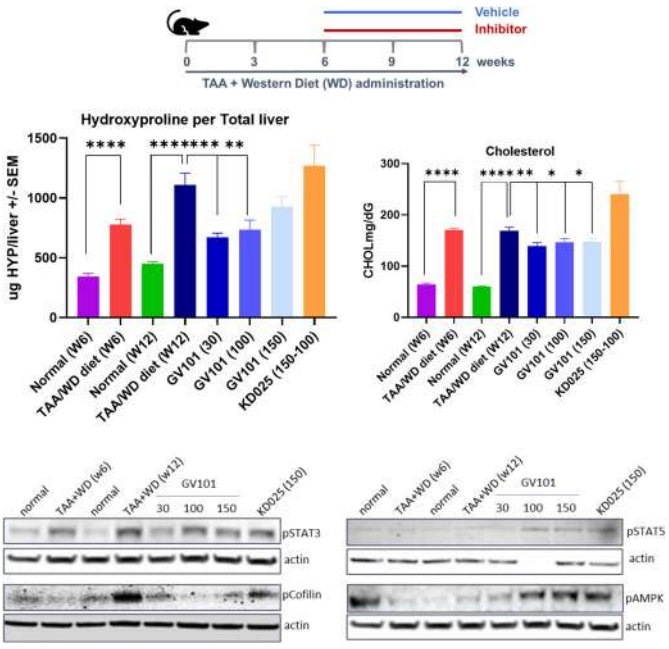
Selectivity matters: novel ROCK2 inhibitor down-regulates established liver fibrosis via concurrent targeting of inflammatory, fibrotic and metabolic pathways

Alexandra Zanin-Zhorov[1], Wei Chen[1], Melanie Nyuydzefe[1], Julien Moretti[1], Iris Zhorov[1], Rashmi Munshi[2], Malavika Ghosh[2], Kelli MacDonald[3], Bruce Blazar[4], Sam Waksal[1]. *[1]Graviton Biosciences, B.V., Translational Medicine, Amsterdam, Netherlands; [2]Aragen Biosciences, Morgan Hill, United States; [3]QIMR Berghofer Medical Research Institute, Brisbane, Australia; [4]University of MN, Masonic Cancer Center, Division of Blood & Marrow Transplant & Cellular Therapies, Minneapolis, United States*
Email: alexandra.zanin-zhorov@graviton.bio

Background and aims: The pathogenesis of hepatic fibrosis is caused and driven by dysregulated metabolism precipitated by chronic inflammation. Rho-associated coiled-coil-containing protein kinases (ROCKs) have been implicated in these processes, however the ability of selective ROCK2 inhibition to target simultaneously pro-fibrotic, pro-inflammatory and metabolic pathways was not demonstrated yet.
Method: We used the thioacetamide (TAA)-induced liver fibrosis model in combination with or without high fat diet to examine the efficacy of administration of the highly selective ROCK2 inhibitor GV101 to treat liver fibrosis, and its impact on inflammatory, fibrotic, and metabolic pathways in tissues.
Results: We found that therapeutic administration of GV101, a novel ROCK2 inhibitor with more than 1000-fold selectivity over ROCK1, attenuated established liver fibrosis induced by TAA alone or in combination with high fat diet in mice. GV101 treatment significantly reduced hydroxyproline levels in liver and serum AST/ALT ratio, which was associated with downregulation of pCofilin (pro-fibrotic), pSTAT3 (pro-inflammatory), while the levels of pSTAT5 (anti-inflammatory) and pAMPK (anti-metabolic) were increased in tissues of treated mice. In vitro experiments have shown that pharmacological selective ROCK2 inhibition, but not pan-ROCK inhibition down-regulates STAT3-dependent pro-inflammatory cytokine secretion in T cells as well as adipogenesis of both 3T3L1 mouse cells and primary human preadipocytes via AMPK-dependent mechanism.



Conclusion: All together, these data further characterize the ROCK2-specific molecular mechanism of action and highlight the therapeutic potential of highly selective ROCK2 inhibitors in liver fibrosis

FRI210

Aldafermin rebalances collagen turnover in patients with NASH and liver fibrosis in the ALPINE 2/3 study

Manal F. Abdelmalek[1], Lei Ling[2], Guy Neff[3], Naim Alkhouri[4], Charles Chen[2], Alex DePaoli[2], Hsiao Lieu[2], Diana Leeming[5], Morten Karsdal[5], Stephen Harrison[6]. *[1]Duke University, Durham, United States; [2]NGM Biopharmaceuticals, South San Francisco, United States; [3]Covenant Research, Sarasota, United States; [4]Arizona Liver Health, Tucson, United States; [5]Nordic Bioscience, Herlev, Denmark; [6]Pinnacle Clinical Research, San Antonio, United States*
Email: lling94080@yahoo.com

Background and aims: The most common method of evaluating liver fibrosis in clinical studies is by microscopic analysis of biopsies stained with Masson's trichrome or sirius red—an approach that may be too simplistic and not able to specifically differentiate among the many different collagen molecules. Recent research has demonstrated that not all collagens are created equal, and that an array of collagen-derived molecules has emerged with novel functions. Whereas the interstitial matrix collagens are increased with more severe disease, the basement membrane collagens are important for regeneration of hepatic tissue (Villesen et al., AASLD 2021). Aldafermin, an engineered analog of the human hormone FGF19, inhibits bile acid synthesis and has improved liver histology in previous phase 2 trials. Here we perform a non-invasive, more granular analysis of both the steady-state and dynamics of collagen turnover in the multicenter, randomized, double-blind, placebo-controlled, phase 2b ALPINE 2/3 study in patients with NASH.
Method: 171 patients were randomized 1:1:1:1 to receive placebo (PBO, n = 43), aldafermin 0.3 mg (n = 43), 1 mg (n = 42), or 3 mg (n = 43) SC QD for 24 weeks at 30 US study sites. Key inclusion criteria included biopsy-proven NASH with NAS≥4, stage 2 or 3 fibrosis and absolute liver fat content ≥8%. Serum concentrations of Pro-C3, Pro-C4, Pro-C6 and Pro-C8 were measured by ELISA methods.
Results: Demographic and baseline characteristics were similar across the trial groups. At week 24, the LS mean differences in the percent change from baseline in Pro-C3, a marker of interstitial matrix collagen, were −11.7% (SD 7.0%) (p = 0.049 vs PBO) in the 0.3 mg group, −13.8% (SD 7.3%) (p = 0.030 vs PBO) in the 1 mg group, and −30.2% (SD 7.1%) (p < 0.001 vs PBO) in the 3 mg group. The LS mean differences in the percent change from baseline in Pro-C8, a marker of basement membrane collagen, were +21.4% (SD 14.3%) (p = 0.07) in the 0.3 mg group, +49.2% (SD 14.7%) (p < 0.001) in the 1 mg group, and +37.6% (SD 14.4%) (p = 0.005) in the 3 mg group. In contrast, aldafermin did not reach statistical significance on the dose-dependent improvement in fibrosis on liver biopsy (19%, 31%, 15% and 30% of the patients in the placebo, 0.3 mg, 1 mg and 3 mg groups, respectively, achieved fibrosis improvement of ≥1-stage without NASH worsening).

Table 1. Percent change from baseline to week 24 in collagen turnover biomarkers

	Placebo (n=43)	Aldafermin 0.3 mg (n=43)	Aldafermin 1 mg (n=42)	Aldafermin 3 mg (n=43)
Pro-C3 (ng/mL)	4.4 (5.0)	−7.3 (5.0)	−9.4 (5.3)	−25.7 (5.2)
Difference vs placebo		−11.7 (7.0)	−13.8 (7.3)	−30.2 (7.1)
P value vs placebo		*0.049*	*0.030*	*<0.001*
Pro-C4 (ng/mL)	−3.2 (2.5)	−3.2 (2.5)	2.5 (2.7)	−0.5 (2.6)
Difference vs placebo		0 (3.5)	5.6 (3.6)	2.7 (3.6)
P value vs placebo		*0.50*	*0.06*	*0.23*
Pro-C6 (ng/mL)	10.7 (7.8)	−6.4 (7.9)	5.1 (8.3)	8.4 (8.2)
Difference vs placebo		−17.2 (11.0)	−5.7 (11.3)	−2.3 (11.2)
P value vs placebo		*0.06*	*0.31*	*0.42*
Pro-C8 (ng/mL)	−10.7 (10.1)	10.7 (10.2)	38.5 (10.8)	26.9 (10.6)
Difference vs placebo		21.4 (14.3)	49.2 (14.7)	37.6 (14.4)
P value vs placebo		*0.07*	*<0.001*	*0.005*

Values are LS means (SE). Continuous endpoints were analyzed using an analysis of covariance (ANCOVA) model with effects for treatment, baseline fibrosis stage and baseline value as covariates. Analyses were conducted using SAS software, version 9.4.

Conclusion: Our results revealed novel insights into aldafermin biology in reducing the fibrogenesis of type 3 collagen in the interstitial matrix, while strengthening type 8 collagen in the basement membrane. Given the invasive and heterogeneous nature of liver biopsy, these novel, non-invasive fibrosis markers may have the potential to obviate the limitations of liver biopsy by providing important information regarding the state of the liver and extracellular matrix turnover.

Non-invasive assessment of liver disease except NAFLD

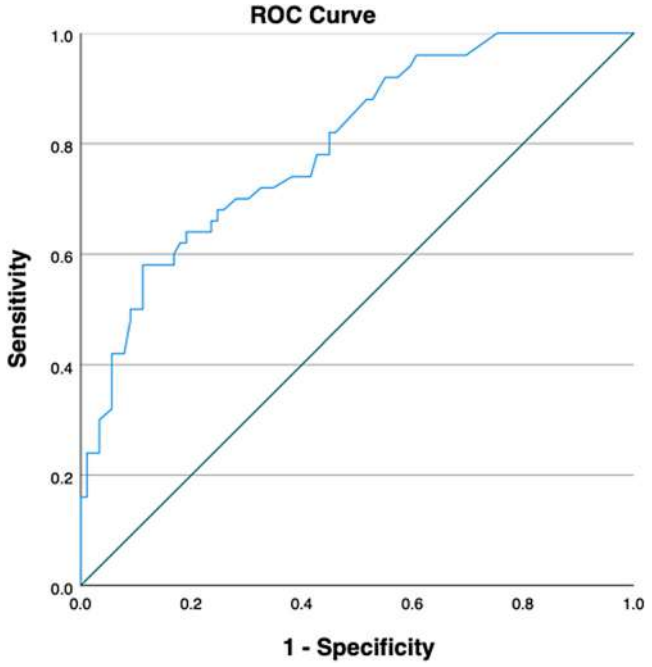
Use of the enhanced liver fibrosis test to risk stratify patients in the intelligent liver function test pathway: ruling out cirrhosis and advanced fibrosis

Madeline Pearson[1], Iain Macpherson[2], Jennifer Nobes[3], Elizabeth Furrie[3], Michael Miller[2], Ellie Dow[3], John Dillon[2].
[1]University of Dundee, School of Medicine, Dundee, United Kingdom; [2]University of Dundee, Gut Group, Dundee, United Kingdom; [3]Ninewells Hospital, Department of Blood Sciences, Dundee, United Kingdom
Email: mcpearson@dundee.ac.uk

Background and aims: The intelligent liver function testing (iLFT) pathway is an innovative automated system designed to increase detection of liver disease in primary care. Its successful roll-out within NHS Tayside significantly increased liver disease diagnosis, highlighting the need for a second 'rule-out' test to further risk stratify patients and reduce unnecessary burden on secondary care. The enhanced liver fibrosis (ELF) test comprises a panel of three direct serum biomarkers of fibrosis. In July 2020 the ELF score was incorporated into the iLFT pathway in NHS Tayside; it is automatically calculated for all samples with indeterminate or elevated fibrosis scores after an abnormal LFT, and influences recommendations for

patient management. The aim was to investigate if the ELF score could be used safely and effectively as a rule out test for cirrhosis and advanced fibrosis within the iLFT pathway.
Method: Outcomes for all patients who received an ELF test via the iLFT pathway between July 2020 and April 2021 were collected and analysed to compare ELF scores with the incidence of cirrhosis and advanced fibrosis diagnoses. A further analysis of all patients who had undergone ELF testing since its introduction in NHS Tayside, regardless of involvement with iLFT, was undertaken to compare ELF score with Transient Elastography (TE) reading.
Results: 634 patients were included in the study; 62.3% of the patients were male, with a mean age of 62.5 years and mean BMI of 31. 419 (66%) had a 'high' ELF score (≥9.8) and 219 had a 'low' ELF score. Median ELF score was 10.2 (IQR 9.5–11.1). 139 patients received TE, with a median ELF score of 10.7 (IQR 9.9–11.4)
57 patients received a clinical diagnosis of cirrhosis; 56 (98%) had a high ELF score ($p < 0.0001$). The negative predictive value (NPV) of ELF as a marker for cirrhosis is 99.5%, with a sensitivity of 98.2%. ELF score was an excellent predictor of advanced fibrosis (F3/4) on TE (AUROC 0.80, $p < 0.001$): the current cut-off value (9.8) had a sensitivity of 100% and specificity of 25%.



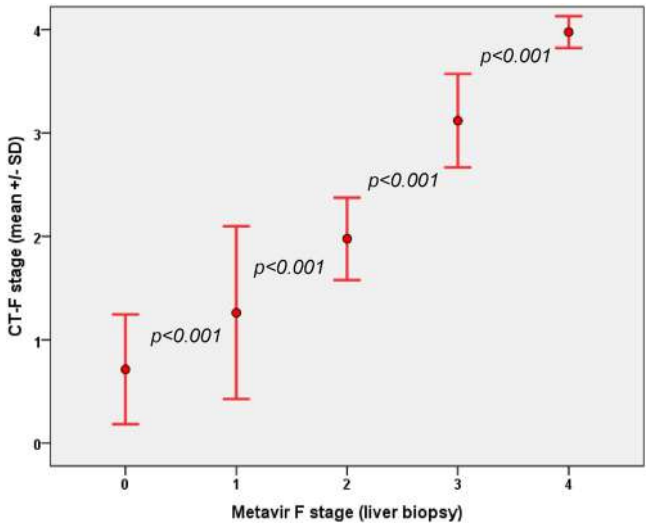
Conclusion: The high sensitivity and NPV of the ELF test for cirrhosis and advanced fibrosis confirms the safe implementation of ELF as an additional fibrosis 'rule-out' within the iLFT pathway. It allows for a streamlined, triaged referral system, ensuring that patients requiring secondary care involvement are picked up, whilst reducing unnecessary referrals amongst lower risk patients who can be safely managed in primary care.

FRI215

Comparison of CT, blood test, elastometry and their combination for non-invasive staging of liver fibrosis

Paul Cales[1], Anita Paisant[1], Clémence M. Canivet[1], Jerome Lebigot[1], Lannes Adrien[1], Carole Vitellius[1], Julien Chaigneau[1], Frédéric Oberti[1], Isabelle Fouchard[1], Sophie Michalak[1], Jerome Boursier[1], Christophe Aubé[1]. [1]*Angers University, HIFIH Laboratory, Angers, France*
Email: paul.cales@univ-angers.fr

Background and aims: The EASL 2021 guidelines on non-invasive diagnosis state that imaging does not discriminate initial stages of liver fibrosis. We sought to evaluate whether liver computed tomography (CT) imaging could discriminate Metavir fibrosis (F) stages.
Method: 111 patients with Metavir F stage by liver biopsy, CT, liver stiffness measurement (LSM), blood test (FM) or their combination (EFM) were retrospectively included. CT was prospectively evaluated by a) an expert radiologist according to the 7 usual signs of cirrhosis + CT-F stage, equivalent to Metavir; b) semi-automated quantitative morphometry (43 signs); c) 70 hepato-gastroenterologists according to CT F-stage in 10 patients (2 per Metavir F stage) for whom 4 independent diagnostic methods agreed for fibrosis stages (method without gold standard). We developed multivariate scores predictive of Metavir F stages using CT signs assessed by the expert radiologist (expert score) or by morphometry (morpho score) and by all non-invasive methods (mixed score including EFM, expert and morpho scores).
Results: 1) Characteristics in all 111 patients were, age: 54.2 ± 12.8 years, male: 60.4%, BMI: 31.2 ± 6.6 kg/m², NAFLD: 75.7%, Metavir: F0: 15.3%, F1: 34.2%, F2: 18.0%, F3: 14.4%, F4: 18.0%. Spearman correlation coefficients (Rs) with Metavir F stages were, expert score: 0.605, FM: 0.648, CT-F stage: 0.661, morpho score: 0.682, LSM: 0.737, EFM: 0.750, mixed score: 0.783. Obuchowski indexes for Metavir F stage discrimination were, expert score: 0.830, FM or CT-F stage: 0.838, morpho score: 0.855, LSM: 0.881, EFM: 0.889, mixed score: 0.909. Concerning discrimination between adjacent Metavir F stages, a significant difference was observed for the following tests, F0 vs F1: FM, LSM, EFM, expert score; F1 vs F2: all tests; F2 vs F3: LSM, EFM; F3 vs F4: CT-F stage, FM, EFM, expert and mixed scores. 2) In the 10 patients evaluated with multiple F references: the Metavir F stages were well-discriminated by CT-F stage with Rs: 0.914, Obuchowski index: 0.950 and significant differences ($p < 0.001$) between all adjacent Metavir F stages (Figure).



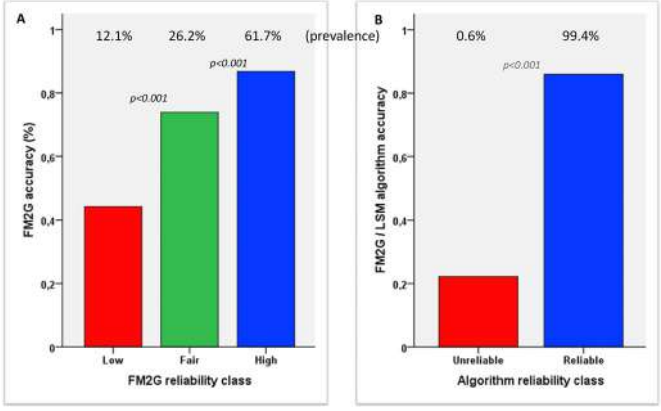
Conclusion: A CT expert score discriminates Metavir F0 to F2 stages. The best single test to discriminate all Metavir F stages from each other is a combination of a blood test and elastometry. However, combined methods (blood test, LSM and CT) offer better discrimination. Using multiple concordant F references, a simple CT semiology discriminates between all Metavir F stages very well.

FRI216

Reliability criteria of non-invasive tests for liver fibrosis

Paul Cales[1], Clémence M. Canivet[2], Lannes Adrien[3], Hunault Gilles[2], Frédéric Oberti[3], Valérie Moal[3], Isabelle Fouchard[3], Sophie Michalak[2], Jerome Boursier[2]. *[1]Angers University, Hepatology, Angers, France; [2]Angers University, HIFIH Laboratory, Angers, France; [3]Angers University Hospital, Hepatology, Angers, France*
Email: paul.cales@univ-angers.fr

Background and aims: The need for reliability studies on non-invasive tests (NITs) was underlined in the 2021 EASL guidelines. Recently, we developed intrinsic blood test reliability criteria. We sought to validate these criteria and apply them to other NITs.
Method: 6858 patients with chronic liver disease (etiologies: virus, NAFLD, alcohol) were recruited in one (cross-sectional) derivation and two (cross-sectional and longitudinal) validation sets. The main fibrosis measurements were: blood test (FibroMeter FM2G), liver stiffness measurement (LSM), Metavir F (liver biopsy) and survival. We developed a reliability score (RS) for FM2G with Metavir F as reference. It included FM2G markers + etiology and comprised 3 classes: low, fair and high reliability.
Results: 1/In the derivation set, RS estimated FM2G accuracy for fibrosis staging well (agreement coef: 0.96). Thus, cirrhosis AUROCs were, low RS: 0.686, fair RS: 0.824, high RS: 0.924, all: 0.883 ($p < 0.001$ vs each class); accuracy is detailed in the figure.
2/In the cross-sectional validation set, these significant differences were confirmed. Moreover, FM2G RS was well-correlated with the LSM AUROC (Rp: 0.83). Thus, the FM2G RS discriminated the cirrhosis AUROC of LSM better than did reliability criteria based on LSM and the IQR/LSM ratio. Also, the FM2G RS discriminated well the cirrhosis AUROCs of other blood tests (APRI, Fib4, Fibrotest, Hepascore, ELF); e.g. for Fibrotest, low RS: 0.569, fair RS: 0.680, high RS: 0.894 ($p < 0.001$ vs low). The FM2G and LSM reliability classes were complementary. Thus, we developed a sequential algorithm using first FM2G in high RS and otherwise LSM combined with FM2G. The algorithm accuracy was, according to its reliability classes, low (0.6% of patients): 22.2%, high: 86.0%, $p < 0.001$ (Figure). Its overall accuracy was 85.6% vs FM2G: 78.3% or LSM: 81.1% ($p < 0.001$).
3/In the longitudinal validation set, FM2G RS discriminated survival accuracy. Thus, logrank tests for Kaplan-Meier survival estimates of fibrosis stages were, low RS: $p = 2.10^{-7}$, fair RS, $p = 1.10^{-18}$, high RS: 3.10^{-92}. RS was thus validated independently of Metavir F.



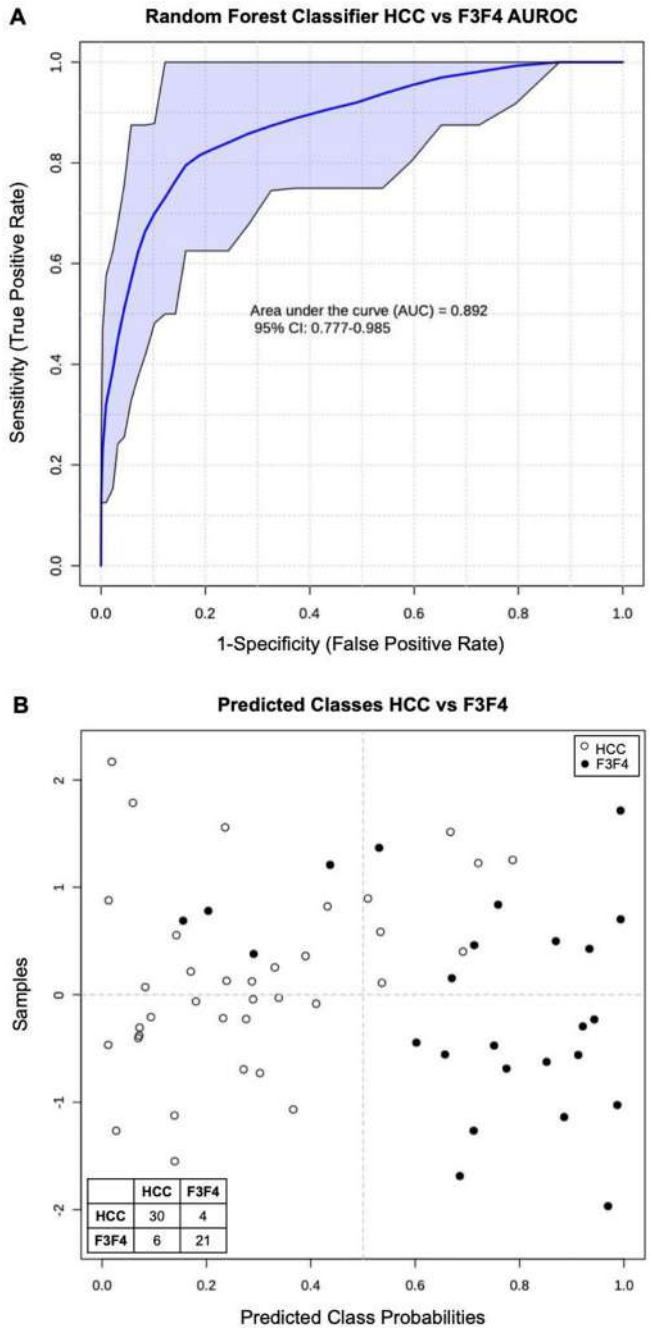
Conclusion: A blood test reliability score estimates remarkably its own diagnostic and prognostic accuracies and discriminates diagnostic performances of other NITs. The combination of blood test and elastometry reliability criteria dramatically reduces unreliable NIT prevalence (≤1%), improves accuracy and better individualizes patients with under-accuracy.

FRI217

Metabolomic profiling of capillary dry blood samples for the differential diagnoses of hepatocellular carcinoma and liver diseases

Philipp Brunnbauer[1], Jennifer Kirwan[2,3], Can Kamali[1], Christian Benzing[1], Katrin Splith[1], Karl Hillebrandt[1], Johann Pratschke[1], Moritz Schmelzle[1], Felix Krenzien[1]. *[1]Charité-Universitätsmedizin Berlin, Corporate Member of Freie Universität Berlin and Humboldt Universität zu Berlin, Department of Surgery, Experimental Surgery, Berlin, Germany; [2]Berlin Institute of Health, Core Unit Metabolomics, Berlin, Germany; [3]Max Delbrück Center for Molecular Medicine, Metabolomics, Berlin, Germany*
Email: philipp.brunnbauer@charite.de

Background and aims: Hepatocellular carcinoma (HCC) remains the second most common tumour-associated cause of death globally, in part, due to a lack of viable screening options, non-specific clinical presentation and late diagnosis. In fact, alpha-fetoprotein (AFP), the biomarker of choice, is of low diagnostic utility (sensitivity of 41–65%, specificity of 80–94%), which further deteriorates in the presence of cirrhosis or hepatitis. Herein, we present promising preliminary results of an untargeted metabolomics biomarker-discovery study, based on dry blood sampling, demonstrating robust classification accuracy, discriminating HCC (including HCC in cirrhosis) from severe fibrosis or cirrhosis.
Method: Capillary blood samples (10 uL) were collected from the earlobe of patients using a volumetric absorptive microsampling (VAMS) device. Metabolomic analysis was performed using liquid chromatography (LC) coupled to an electrospray ionisation mass spectrometry (ESI-MS). Raw LC/ESI-MS data were processed using a standard metabolomics workflow and peaks were annotated using an internal database of m/z and retention time with a 30 ppm mass accuracy. Data were further corrected for technical variation and background effects, followed by batch correction and data filtering in MATLAB (R2021a). Random forest classification was conducted in MetaboAnalyst 5.0.
Results: Having analysed dried blood samples from individuals with liver disease and healthy controls, we obtained 297 metabolites from 483 samples (162 patients), deemed suitable for statistical analysis. Although some patients presented with both, for the purpose of classification, we separated preoperative samples into two mutually exclusive groups: HCC (including HCC in cirrhosis, n = 36) and severe fibrosis/cirrhosis (F3F4, n = 25). From 43 significantly altered metabolites (fold-change ratio = 2.0, evaluated via t-test with $p < 0.05$), we selected a panel of three metabolites (IDs available on request), achieving an AUROC of 0.892 (95% CI: 0.777–0.985, Figure A), and promising predicted class probabilities and confusion matrix (Figure B).



Conclusion: Dry blood sampling can identify promising biomarker candidates that could improve HCC time-to- and stage-at-diagnosis. While our findings will be confirmed in a prospective study, focusing on age and risk factor stratification, we aim to translate our findings into an easy-to-use, low-cost population screening tool for HCC. *MS&FK share senior authorship.*

FRI218

Stable rates of cirrhosis diagnosed by Fibroscan despite changing trends in liver disease epidemiology: a single centre retrospective cohort study

Joan Ericka Flores[1,2], Anne Craigie[1], Lucy McDonald[1], Amy Edwards[1], Tim Papaluca[1,2], Michael MacIsaac[1], John Gough[1], Kate New[1], Susanne Glasgow[1], Bradley Whitton[1], Paul Desmond[1,2], Marno Ryan[1,2], Thai Hong[1], Zina Valaydon[2], Jacinta Holmes[1,2], Barbara Demediuk[1], Catherine Croagh[1], David Iser[1], Kumar Visvanathan[1,2], Swee Lin Chen Yi Mei[1], Alexander Thompson[1,2], Jessica Howell[1,2]. *[1]St. Vincent's Hospital Melbourne, Fitzroy, Australia; [2]University of Melbourne, Parkville, Australia*
Email: ericka@flores.com.au

Background and aims: Data for cirrhosis prevalence in Australia are urgently needed to plan health resourcing for hepatocellular carcinoma (HCC) surveillance and liver disease prevention programs. The aim of this study was to describe the prevalence of cirrhosis diagnosed by Fibroscan within an urban tertiary health network and linkage to specialist care.
Method: This retrospective cohort study was conducted at St Vincent's Hospital Melbourne, Australia. Raw Fibroscan data files were extracted from three machines (one static, two portable) used in hospital and community sites, and Fibroscan database. Cirrhosis was defined by aetiology specific cut offs and ≥12.5 kPa where aetiology was not available. Individuals with cirrhosis range Fibroscans were cross referenced with hospital record data to describe the proportion of patients referred for follow up. Median time intervals were reported in months (IQR). Proportions of Fibroscans in cirrhotic range and aetiologies compared with Chi square test.
Results: 10, 622 Fibroscans were performed in 8727 individuals from 9 April 2010 to 27 April 2021. Fibroscan data from 2012 was not available. Peak number of Fibroscans in 2016, coincided with availability of hepatitis C DAAs. Recorded liver disease aetiologies: 38% chronic hepatitis C (3358/8798), 25% hepatitis B (2231/8798), 15% fatty liver disease (1297/8798) and 10% alcohol (837/8798).
15% (1595/10622) of Fibroscan records were in cirrhosis range. Proportion of Fibroscans with cirrhosis range were similar over time, ranging between 15 and 19% without significant variation (p = 0.68) (Figure 1a). Proportion of fibroscans with cirrhosis due to most common aetiologies showed significant downtrend with chronic hepatitis C and chronic hepatitis B (p = 0.018 and p = 0.012, respectively). An uptrend with MAFLD (p = 0.35) and alcohol was observed, but only statistically significant for alcohol (p = 0.009).

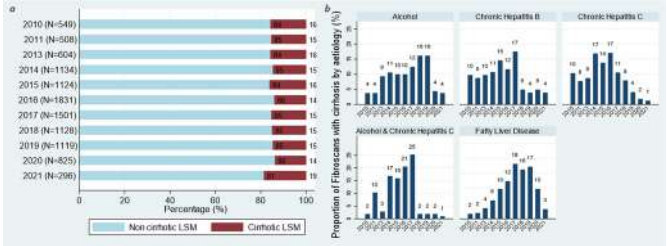


Figure 1 a) Proportion of cirrhotic range Fibroscans by year b) Proportion of cirrhotic range Fibroscans per year by aetiology

1045 patients with cirrhotic Fibroscan range had hospital records: 56% (584/1045) were known to the liver clinic at the time of Fibroscan, 20% (205/1045) were referred following Fibroscan and 24% (252/1045) had no referral. 3% (32/1045) required multiple referrals until patient attendance was recorded and 1% (13/1045) patients never attended liver clinic. Median time from Fibroscan to liver clinic referral was 13 months (IQR 3–34).
Conclusion: The proportion of patients with cirrhosis diagnosed by Fibroscan has remained stable over time, with changing trends of chronic liver disease aetiology from viral hepatitis to fatty liver disease and alcohol related liver disease. Despite this, linkage to care

of people with cirrhosis remains suboptimal. These data are limited by focusing on one hospital's liver clinic and no data of follow-up at other health services, but suggest greater resourcing streamline linkage of people diagnosed with cirrhosis by Fibroscan into specialist care is warranted.

FRI219

Comparative assessment of noninvasive methods (NIMs)-LIVERFASt, liver stiffness measurement (LSM) with transient elastography (TE, Fibroscan) ELF and FiB-4-in a prospective cohort with chronic liver diseases (CLD) from a tertiary liver center

Kawin Tangvoraphonkchai[1], Tanita Suttichaimongkol[2], Prakasit Sangaimwibool[3], Wattana Sukeepaisarnjaroen[4], Churaieat Kularbkaew. *[1]Khon Kaen University, Faculty of Medicine, Division of Gastroenterology, Department of Medicine, Thailand; [2]Khon Kaen University, Division of Gastroenterology, Department of Medicine, Thailand; [3]Khon Kaen University, Department of Pathology, Thailand; [4]Khon Kaen University, Department of Pathology, Faculty of Medicine, Thailand*
Email: kawin_tang@hotmail.com

Background and aims: CLD-related mortality in Thailand is increasing due to high prevalence of obesity and not eradicated chronic viral hepatitis B (CHB) and C (CHC). LIVERFASt (LF, Fibronostics, US) is a new point-of-care proprietary technology to assess quantitatively liver fibrosis (LF-Fib) and steatosis (LF-Ste). (Hepatology Suppl. 2020) In NAFLD pts, LF-Fib predicted liver-related events and overall mortality (Hepatology Suppl.2021).
To assess: 1/LF-Fib performance for advanced (AF) and bridging fibrosis (BF) vs LSM, FIB-4 and ELF in a prospective tertiary cohort with CLD and LB. 2/LF-Ste performance for mild (≥S1), moderate (≥S2) and marked steatosis (S3) vs. imaging methods (CAP) in NAFLD pts, including a CHC/CHB control group without steatosis (S0).
Method: Pts with simultaneous LB, blood biomarkers (LF, FIB4 and ELF) and LSM using TE were prospectively included. LB staging was as per METAVIR for CHB/CHC and NASH-CRN for NAFLD. Statistics were descriptive and using binary area under ROC [BinAUROC (95%CI)].
Results: 192 pts were included with concomitant LF, FIB4 and LSM. N = 157 patients had ELF determined along with LF and other SOC. Main characteristics were: 52.7% males, median (range) age 50 (20–69) yrs, 26.4% NAFLD, 23.9% CHB, 49.8% CHC, BMI 34.9 Kg/m^2, HbA1c 5.5, LSM 7.5 kPa, LF-Fib 0.29, LF-Act 0.29, LF-Ste 0.35, 49.5% severe NAI, 50.2% AF and 9.5% cirrhosis (F4).
Overall Bin-AUROC (95%CI) for AF were: LSM 0.70 (0.62–0.77), FIB4 0.71 (0.63–0.77) and LF-Fib 0.81 (0.67–0.85) [p = ns vs LSM and p < 0.05 vs FIB4].
In N = 157 patients with concomitant ELF determination, overall Bin-AUROC (95%CI) for AF were: LSM 0.79 (0.71–0.85), FIB4 0.69 (0.61–0.77), ELF 0.63 (0.0.53–0.71) and LF-Fib 0.77 (0.61–0.77; p = ns vs LSM and p < 0.01 vs FIB4 and ELF, respectively); for BF were: LSM 0.82 (0.71–0.88), FIB4 0.75 (0.63–0.83), ELF 0.64 (0.49–0.77) and LF-Fib 0.77 (0.65–0.85; p = ns vs all).
For ≥S1, ≥S2 and S3 steatosis-when taking into account 17 controls without steatosis (S0)- LF-Ste and CAP performances were: 0.75 (0.59–0.85)/0.75 (0.61–0.85)/0.70 (0.47–0.83) vs 0.81 (0.67–0.89)/0.81 (0.68–0.89)/0.74 (0.55–0.86), respectively, all p = ns.
Conclusion: LIVERFASt is a blood biomarker for fibrosis/steatosis staging with similar performances to TE/CAP in a tertiary cohort with CLD. In NAFLD pts, LF can be an alternative to imaging methods (e.g. CAP and LSM) for stratifying the severity of the disease.

FRI220

Diagnostic accuracy of non-invasive imaging modalities for the diagnosis of liver cirrhosis compared to histological assessment in a clinical setting

Liv Hetland[1], Mira Thing[1], Thit Kronborg[1], Beth Hærsted Olsen[2], Nina Kimer[1], Lise Lotte Gluud[1,3]. *[1]Hvidovre Hospital, Gastro Unit, Hvidovre, Denmark; [2]Hvidovre Hospital, Department of Radiology, Hvidovre, Denmark; [3]Copenhagen University, Department of Clinical Medicine, København, Denmark*
Email: livelinehetland@gmail.com

Background and aims: Diagnostic imaging including abdominal ultrasound (US) and computed tomography (CT) are important tools in the initial evaluation of patients with liver disease. We evaluated the accuracy of US and CT in diagnosing liver cirrhosis using a prospective design with histological assessment as the gold standard.
Method: This study included 369 patients from three prospective cohort studies between January 2017 and November 2021 who underwent diagnostic imaging (US or CT) and a liver biopsy based on clinical indication. Two cohorts (ProDoc, n = 34; StatLiver, n = 78) included patients with suspected cirrhosis and one cohort (FLINC, n = 257) included patients with non-alcoholic fatty liver disease (NAFLD). US and CT scans were performed by experienced radiologists and the results were re-evaluated by a second radiologist in case of inconclusive findings.
Results: The cohorts include 369 patients who underwent a liver biopsy and an US (n = 279) and/or CT scan (n = 129). In addition, 291 patients underwent a Fibroscan. In total 143 patients had histologically confirmed cirrhosis (38.7%). Of patients who underwent US, 78 were correctly diagnosed as having cirrhosis and 159 as correctly being non-cirrhotic; the sensitivity was 0.72, specificity 0.89, positive predictive value (PPV) 0.88 and negative predictive value (NPV) 0.84. Of patients who underwent CT scan, 61 were correctly diagnosed as having cirrhosis and 46 as correctly being non-cirrhotic, giving a sensitivity of 0.75, specificity of 0.96, PPV 0.97 and NPV 0.70. The PPV and NPV for Fibroscan was 0.71 and 0.91.
Conclusion: This study demonstrates that both US and CT provide important diagnostic information for ruling in cirrhosis. However, this study includes a relatively high proportion of patients with cirrhosis and the findings should therefore be re-evaluated in low risk groups.

FRI221

Use of Fibrosis-4 (FIB-4) in liver fibrosis screening: which thresholds to choose?

Denis Ouzan[1], Jeremie Corneille[2], Guillaume Penaranda[3], Jean Marie Dubertrand[4]. *[1]Arnault Institute Tzanck, Saint-Laurent-du-Var, France; [2]BIOGROUP BIOESTEREL-Laboratoire Mougins-L'espérance, Mougins, France; [3]BIOGROUP ALPHABIO-Laboratoire Européen, Marseille, France; [4]BIOGROUP BIOESTEREL-Laboratoire Mandelieu-Passero, Mandelieu-la-Napoule, France*
Email: denis.ouzan@wanadoo.fr

Background and aims: Rationale: Screening for liver fibrosis in the general population is a major public health issue. We have shown in a previous study (EASL 2020, Abs FRI225) that FIB-4, a simple score combining age, ALT/AST activity and platelet count, can detect liver fibrosis in general practice and identify a possible cause of chronic liver disease. But the optimal FIB-4 threshold that detects hepatic fibrosis remains to be defined. The FIB-4 thresholds recently proposed by a single study (1) are age-dependent: low risk if <1.30 (<65 years) and <2 (>65 years), intermediate risk between 1.3 and 2.67 (<65 years) and between 2 and 2.67 (>65 years), and high risk if >2.67. The aim of our work is to explore the simpler, age-independent FIB-4 threshold of 2 by performing a second-line ELF (Enhanced Liver Fibrosis) score after automatic calculation of FIB-4.
Method: The FIB-4 score has been automatically generated since October 1, 2020 by all city analysis laboratories in the Alpes-Maritimes French aera as soon as ALT/ASAT and platelets are

prescribed. The FIB-4 results, calculated by 80 laboratories, were analyzed. The FIB-4 thresholds used are a function of age as defined above. The ELF score was performed in the second line in a group of 183 patients at intermediate or high risk of fibrosis.
Results: During the first 3 months of the implementation of the automatic calculation of the FIB-4, 131, 861 subjects were screened, half of them were older than 65 years, 56% were women and 44% were men. The distribution of fibrosis risk observed by the FIB-4 according to age was as follows: low risk for 107, 148 subjects (81.3%), intermediate risk for 16, 297 subjects (12.4%), and high fibrosis risk for 8, 416 subjects (6.4%). An ELF score >9.8 indicative of advanced fibrosis was observed in 14/54 subjects (26%) of those with a FIB-4 score between 1.3 and 2 and in 102/129 (79%) of those with a FIB-4 >2 ($p < 0.001$).
Conclusion: The automatic calculation of the FIB-4 showed in a large cohort, a risk of hepatic fibrosis in almost 19% of the subjects: intermediate risk 12.4% and high risk of fibrosis 6.4%. The ELF test performed in the second line significantly more often confirmed the existence of advanced fibrosis in subjects with a FIB-4 >2 as compared to those with a FIB-4 between 1.3 and 2 (79 versus 26%). The threshold of 2 could significantly reduce the number of subjects in the intermediate zone of fibrosis, which is debated.

Email: macalderon@unav.es

Background and aims: Hepatocellular carcinoma (HCC) is a global health concern with increasing impact on our societies. Nowadays, there are limited diagnostic methods and most patients are diagnosed at advanced stage when current treatments have little effectiveness. Moreover, although patients in early and intermediate stages might benefit from potentially curative treatments, there is a high rate of recurrence. It is therefore essential to identify new non-invasive reliable biomarkers for the detection of HCC at an early stage and the prediction of recurrence-progression to improve patient survival. In this regard, recent advances have demonstrated that circulating tumor DNA (ctDNA) methylation has a great potential to serve as a blood-based biomarker for early diagnosis and precision treatment. In this project, we aim to identify and validate new ctDNA methylation markers for early HCC detection and HCC recurrence-progression monitoring.
Method: For *in silico* analyses we used available tissue methylation data on control and HCC patients, focusing on CpG islands and lncRNA promoter regions. We set up the protocol to isolate cfDNA from 1 ml of plasma, to treat cfDNA with bisulfite and to perform targeted sequencing. Plasma from control and HCC patients were used for validations.
Results: Using available tissue methylation data on HCC (n = 670) and control (n = 135) samples from three different studies (GSE56588, GSE54503 and TCGA-LIHC) as well as from blood leukocyte samples of healthy individuals (754 samples, GSE40279) and deep learning approaches we defined a blood-based HCC Methyl Diagnostic panel (HepaMet Panel) consisting on 27 CpG marks located within CpG islands and 2 located within lncRNA promoter regions. HepaMet Panel revealed a robust performance (accuracy of 97.3%) for control and HCC patient classification. *In silico* validation of HepaMet Panel in three independent HCC cohorts (GSE60753, GSE89852 and GSE157341) showed a sensitivity range of 97%-100%. We first set up conditions to analyze 16 of these 29 marks. Validation of this sub-panel using cfDNA from 7 early stage HCCs, 22 advanced HCCs as well as 11 healthy controls succeeded to classify 76% of HCC patients (71% early and 77% advanced).
Conclusion: We have identified a blood-based HCC Methyl Diagnostic panel that effectively classify control and HCC patients. Ongoing analyses will determine HepaMet Panel utility in the early diagnosis of HCC and HCC recurrence-progression monitoring.

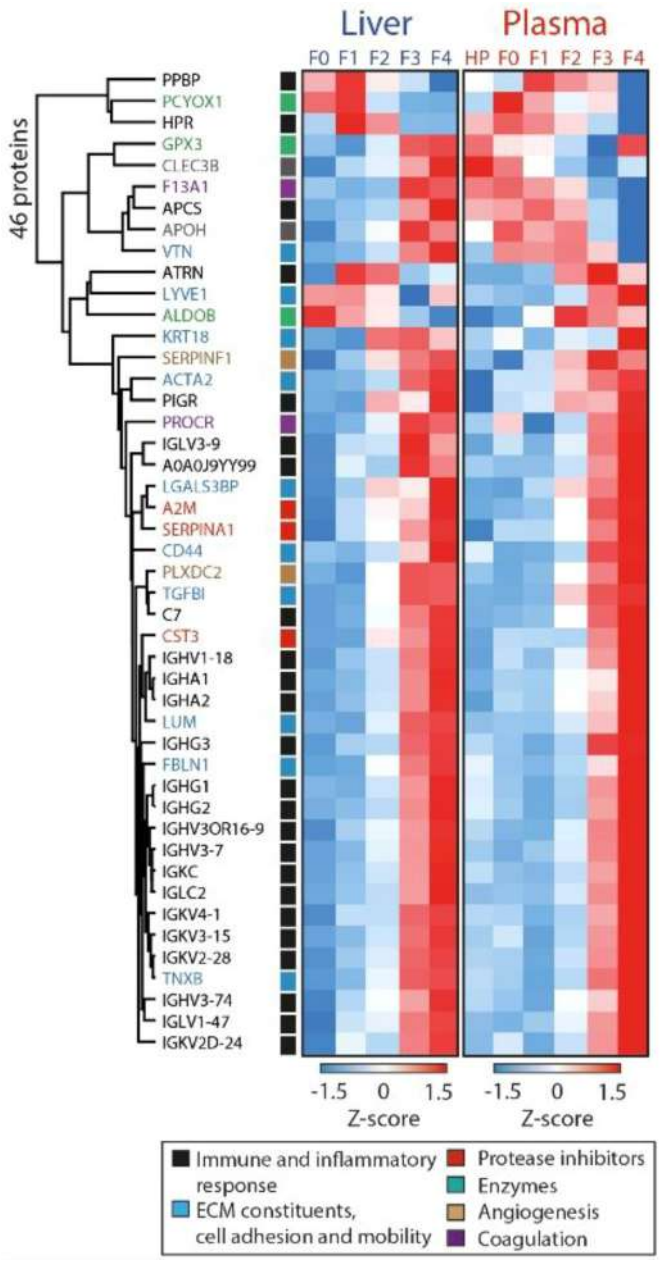
FRI223

A derivation and validation study of paired liver and plasma proteomics in 659 individuals reveals circulating biomarkers for alcohol-related liver disease

Lili Niu[1], Maja Thiele[2,3], Philipp Geyer[1], Ditlev Nytoft Rasmussen[2], Henry Emanuel Webel[1], Alberto Delgado[1], Rajat Gupta[1], Florian Meier[1], Maximilian Strauss[1], Maria Kjærgaard[2,3], Katrine Prier Lindvig[2,3], Mads Israelsen[2,3], Simon Rasmussen[1], Torben Hansen[4], Matthias Mann[1], Aleksander Krag[2,3]. *[1]University of Copenhagen, Center for Protein Research, Copenhagen, Denmark; [2]Center for Liver Research, Odense University Hospital, Department of Gastroenterology and Hepatology, Odense, Denmark; [3]University of Southern Denmark, Faculty of Health Sciences, Department for Clinical Research, Odense C, Denmark; [4]University of Copenhagen, Center for Basic Metabolic Research, Denmark*
Email: maja.thiele@rsyd.dk

Background and aims: Alcohol-related liver disease (ALD) is the most common cause of liver-related mortality, but diagnosis is often delayed due to lack of accurate, circulating biomarkers. We aimed to develop and validate diagnostic and prognostic protein marker panels of fibrosis, hepatocyte injury with inflammation, and steatosis, using paired liver and plasma proteomics.
Method: We included 459 patients with early ALD in a prospective derivation cohort, used mass spectrometry to measure plasma and liver proteome, and integrated them to determine the tissue origin of circulating proteins. We used machine learning with feature selection to derive three proteomic panels of significant fibrosis (≥F2), mild activity (sum of ballooning and lobular inflammation ≥2) and any steatosis (≥S1), and validated their ability to rule out or rule in disease in 137 healthy, age- and gender-matched controls, and 63 liver-biopsied ALD patients from an independent screening cohort. Finally, we evaluated the proteomic biomarkers' ability to predict liver-related events and all-cause mortality, and compared their diagnostic performance with 15 best-in-class existing tests.
Results: The derivation cohort consisted of 76% males, age 57 ± 13 years, 44% significant fibrosis (≥F2), 46% mild activity, 44% steatosis (≥S1). 717 unique proteins were dysregulated during disease progression, accounting for 13% of the measured liver proteome, but only half of liver proteome changes were transmitted to the circulation. Integrative analysis revealed 46 co-dysregulated proteins, representing mostly the downregulation of metabolic functions and upregulation of fibrosis signaling and immune response (figure). Feature selection found that 22 unique plasma proteins could be used in different combinations to derive three proteomic biomarker panels. The panels performed better than all comparators (including elastography, ELF, FIB-4, cytokeratin-18) for detecting significant fibrosis (AUC 0.92) and mild activity (AUC 0.87). The ≥F2 proteomic

panel ruled out significant fibrosis in 99% of the healthy controls and had the highest prognostic accuracy for liver-related events and all-cause mortality (Harrell's C 0.90 and 0.79). We successfully reproduced the excellent proteomics performance in the independent validation cohort (AUC 0.87 for significant fibrosis, and AUC 0.81 for mild activity).



Conclusion: Plasma proteomics has a great potential for the diagnosis and prognosis of overall liver health in people with a history of harmful drinking.

FRI224

Development and validation of a hepatic vascular geometrical model for noninvasive diagnosis of clinically significant portal hypertension in cirrhosis (CHESS1802)

Chengyan Wang[1], Yifei Huang[2], Changchun Liu[3], Fuquan Liu[4], Xumei Hu[5], Xutong Kuang[5], Weimin An[3], Chuan Liu[2], Yanna Liu[2], Xiaolong Qi[2]. *[1]Fudan University, Human Phenome Institute, Shanghai, China; [2]The First Hospital of Lanzhou University, CHESS Center, Institute of Portal Hypertension, Lanzhou, China; [3]Fifth Medical Center of Chinese People's Liberation Army General Hospital, Department of Radiology, Beijing, China; [4]Beijing Shijitan Hospital, Department of Interventional Therapy, Beijing, China; [5]Fudan University, Human Phenome Institute, Shanghai, China*
Email: qixiaolong@vip.163.com

Background and Aims: Noninvasive and accurate methods are needed to identify patients with clinically significant portal hypertension (CSPH). This study aims to explore the variations of hepatic vascular geometries in patients with CSPH and investigate the capability of using CT/MRI angiographic imaging-based vascular geometrical model (VGM) to identify CSPH in patients with cirrhosis.
Method: The portal vein (PV), hepatic vein (HV), hepatic artery (HA) and inferior vena cava (IVC) were segmented using a pre-trained attention-based convolutional neural network (CNN). A total of 64 vascular geometrical parameters were automatically extracted from those segmented vessels and then fed into the VGM to identify CSPH patients. A total of 853 consecutive liver cirrhosis patients from two centers who underwent contrast enhanced MRI/CT scans within 14 days of transjugular catheterization for hepatic venous pressure gradient (HVPG) measurement were included in this study. The model was trained and validated in a CT cohort (#1) containing 256 patients with cirrhosis and 267 age-matched participants without a history of chronic liver diseases, and tested on another centers including a CT cohort (#2) with 106 patients and an MRI cohort (#3) with 224 patients. CSPH was defined as HVPG $\geq$10 mmHg.
Results: In PV, significant increase of vessel diameter (from 1.50 ± 0.91 to 2.20 ± 0.69 cm) and branch vessel diameter (from 0.41 ± 0.15 vs 0.73 ± 0.56 cm) were observed in CSPH patients. In contrast, significant decrease of PV volume (from 31.01 ± 12.93 to 23.89 ± 9.68 cm^3) and tortuosity (from 0.17 ± 0.05 to 0.13 ± 0.04°) were observed in CSPH patients. In HV, significant decrease of vessel volume (from 66.52 ± 16.91 to 33.31 ± 28.05 cm^3) and length (from 812.42 ± 284.55 to 349.21 ± 185.87 mm) were observed in CSPH patients. In HA, significant increase of vessel length (from 77.26 ± 64.31 to 143.38 ± 57.2 mm) were observed, which indicates significant disruption of hepatic vascular system in CSPH patients. The AUC, accuracy, sensitivity and specificity were 0.90 ± 0.02 (95% CI, 0.88–0.93), 0.84 ± 0.01 (95% CI, 0.84–0.85), 0.87 ± 0.05 (95% CI, 0.80–0.92) and 0.83 ± 0.04 (95% CI, 0.80–0.89) for Cohort #1; 0.84 ± 0.12 (95% CI, 0.67–1), 0.88 ± 0.10 (95% CI, 0.75–1), 0.88 ± 0.10 (95% CI, 0.73–1) and 0.88 ± 0.09 (95% CI, 0.76–1) for Cohort #2; and 0.87 ± 0.11 (95% CI, 0.74–1), 0.91 ± 0.08 (95% CI, 0.8–1), 0.90 ± 0.09 (95% CI, 0.77–1) and 0.92 ± 0.08 (95% CI, 0.82–1) for Cohort #3.

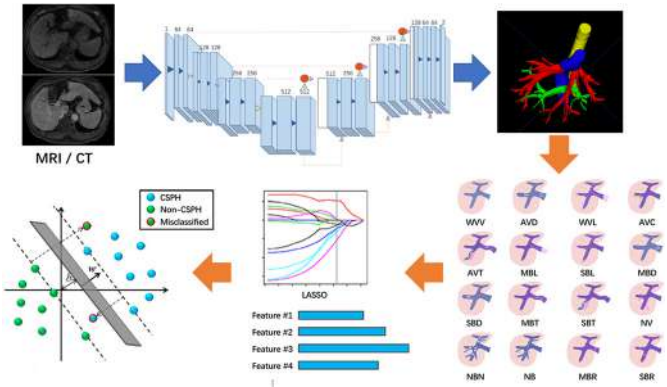


Figure 1: Workflow of the CT/MRI angiographic imaging-based vascular geometrical model.

Conclusion: This study developed and validated a contrast-enhanced CT/MRI-based VGM with good diagnostic consistency to the HVPG measurement. It provided a noninvasive and effective method for diagnosis of CSPH in patients with cirrhosis, which shows good potential for clinical applications.

FRI225

The diagnostic accuracy of ElastQ 2-D shear wave elastography for liver fibrosis risk assessment in a mixed etiology, multinational cohort

David J. M. Bauer[1,2], Annalisa De Silvestri[3], Laura Maiocchi[3], Ruxandra Mare[4], Ioan Sporea[4], Theresa Müllner-Bucsics[1,2], Giovanna Ferraioli[3], Thomas Reiberger[1,2]. Email: thomas.reiberger@meduniwien.ac.at

Background and aims: The 2-D shear wave elastography technique ElastQ (Philips) shows promise for evaluating liver fibrosis risk assessment.

Method: We prospectively recruited 875 patients for simultaneous liver stiffness measurements (LSM) by ElastQ and Vibration Controlled Transient Elastography (VCTE) in 3 European centers. IQR/median ≤30% was used as a reliability criterion. The correlation of ElastQ-LSM to VCTE-LSM was assessed by Pearson correlation. The fibrosis stage was classified by VCTE: no significant fibrosis VCTE <6 kPa, grey area/significant fibrosis VCTE 6–12 kPa, severe fibrosis/cirrhosis VCTE >12 kPa (EASL CPG 2021). This classification served as a basis for the ROC analysis and definition of 90%-specific rule-in, and 90%-sensitive rule-out cutoffs for ElastQ.

Results: Among 875 participants, ElastQ failed in 26 (2.97%) and VCTE in 7 (0.8%) and was unreliable (IQR/median >30%) in 24 (2.74%) and 6 (0.69%) participants, respectively. The final population consisted of n = 813 patients: 53.9% men (n = 438), median age: 57.0 [IQR:19] years, median BMI: 25.3 [5.8] kg/m^2. The leading etiologies were HCV (50.1%), NAFLD (16.1%), HBV (12.1%), and ALD (10.1%). Fibrosis stages were no significant fibrosis in n = 286 (35.2%), significant fibrosis in n = 290 (35.7%), and severe fibrosis/cirrhosis in n = 237 (29.2%). The Pearson correlation of VCTE and ElastQ was R = 0.64 overall, but higher in VCTE-LSM≤30 kPa (R = 0.70, Fig. 1). ElastQ-LSM ruled-out and ruled-in significant fibrosis risk at <5.3 kPa (Sens.: 91.0%) and at ≥6.8 kPa (Spec.: 91.3%), respectively (AUROC: 0.859, p < 0.001). Severe fibrosis/cirrhosis risk was ruled-out and ruled-in at <6.2 kPa (Sens.: 90.2%) and >10.2 kPa (Spec.: 90.3%), respectively (AUROC: 0.882, p < 0.001).

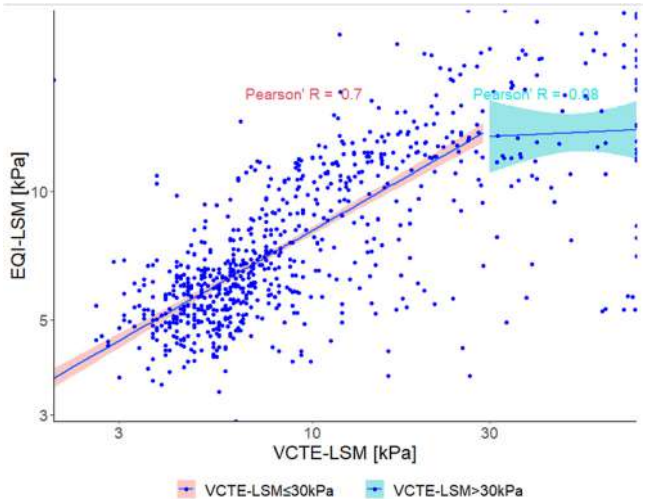

Figure 1: Scatterplot of VCTE-LSM vs. ElastQ-LSM (log10-transformed axis) with Pearson correlation separately shown for VCTE-LSM 0–30 kPa (red) and >30 kPa (turquoise). Abbreviations: ElastQ-2-D shear wave elastography technique; kPa-kilopascal, LSM-liver stiffness measurement, VCTE-Vibration Controlled Transient Elastography.

Conclusion: This prospective, multicentric study shows a moderate correlation of ElastQ -LSM to VCTE-LSM, with better correlations at VCTE-LSM≤30 kPa. ElastQ -LSM rules out significant fibrosis at <5.3 kPa and rules in advanced fibrosis/cirrhosis at >10.2 kPa.

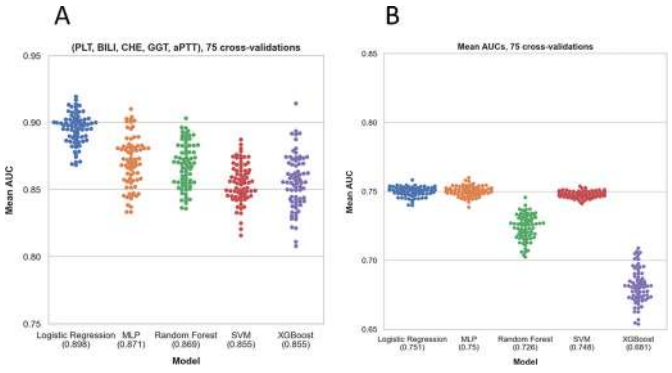
Email: thomas.reiberger@meduniwien.ac.at

Background and aims: Hepatic venous pressure gradient (HVPG) is the gold standard for evaluation of the severity of portal hypertension (PH). In this multicenter study, we investigated the diagnostic value of different machine learning models trained on standard laboratory parameters to predict severe PH in compensated advanced chronic liver disease (cACLD) patients.
Method: The training cohort included cACLD patients recruited from the prospective VICIS study (NCT03267615). Regression and classification-based prediction models were applied to identify patients with severe PH (i.e., HVPG ≥16 mmHg) based on 52 widely available laboratory parameters. After feature selection, the models were applied to an external multicenter validation cohort using a cross-validation approach with the AUC reported as the median value across 75 cross-validations.
Results: The VICIS cohort included 139 cACLD patients (35.2% with HVPG ≥16 mmHg), main etiologies were viral hepatitis (32.4%), alcohol-related liver disease (ALD; 21.6%), and non-alcoholic fatty liver disease (NAFLD; 16.5%). The external validation cohort included 834 cACLD patients (36.7% with HVPG ≥16 mmHg), with the most prevalent etiologies being viral hepatitis (38.6%), NAFLD (24.2%), and ALD (20.6%).
Recursive feature elimination identified three and five parameters as most suitable for the models.
In the VICIS cohort, internal training-validation with the 5-parameter (platelets, bilirubin, cholinesterase, GGT, aPTT) logistic regression model outperformed the other models with AUC of 0.898 for prediction of HVPG ≥16 mmHg (Figure-A).



The best 3-parameter model included platelets, bilirubin, and aPTT. After being applied to the external validation cohort, and following the training-validation split, logistic regression resulted in the highest AUC of 0.751 (Figure-B). The other 3-parameter models yielded median AUC of 0.681 (XGBoost), 0.726 (Random Forest), 0.748 (Support Vector Machine), and 0.750 (Multilayer Perceptron).
When trained on the VICIS cohort first and then applied to the external cohorts, the 3-parameter model with logistic regression resulted in AUC spread from 0.472 to 0.872 in the different centers' cohorts.
Conclusion: The VICIS-trained 5-parameter and 3-parameter model performed well to identify HVPG ≥16 mmHg in 'local' cACLD patients. However, the external applicability of the 3-parameter logistic regression model to predict HVPG ≥16 mmHg is limited-likely due to differences in laboratory assays and patient characteristics. Training and applying of the models in the subsets of the same cohort resulted in more sustained AUC. Invasive HVPG measurements are hence still needed to reliably identify cACLD with HVPG ≥16 mmHg.

FRI227

Reproducibility and applicability of spleen stiffness measurement by vibration controlled transient elastograghy in patients with and without chronic liver disease

Cristina Rigamonti[1,2], Micol Cittone[1,2], Giulia Francesca Manfredi[1,2], Andrea Sorge[3], Riccardo Moia[1,4], Maria Francesca Donato[5], Gianluca Gaidano[1,4], Mirella Fraquelli[3]. *[1]Università del Piemonte Orientale, Department of Translational Medicine, Novara, Italy; [2]AOU Maggiore della Carità, Division of Internal Medicine, Novara, Italy; [3]Fondazione IRCCS Ca' Granda-Ospedale Maggiore Policlinico, Gastroenterology and Endoscopy Unit, Milan, Italy; [4]AOU Maggiore della Carità, Division of Hematology, Italy; [5]Fondazione IRCCS Ca' Granda-Ospedale Maggiore Policlinico, Gastroenterology and Hepatology Unit, Italy*
Email: cristina.rigamonti@uniupo.it

Background and aims: Spleen stiffness measurement (SSM) by vibration controlled transient elastography (VCTE) has emerged as a promising non-invasive tool with good diagnostic accuracy for predicting the degree of portal hypertension in patients with advanced chronic liver disease (CLD). This study investigated intra-observer and inter-observer agreement and factors influencing SSM reproducibility.
Method: In this prospective multicentre study 297 patients with CLD of different aetiology (187 in Novara and 110 in Milan; 32% cirrhotics) and 123 controls (63 patients with Philadelphia negative (Ph-) myeloproliferative neoplasms in Novara and 60 heathy volunteers in Milan) consecutively underwent VCTE examination for SSM and liver stiffness measurement (LSM). SSM was blindly performed twice by two different operators. Intra-observer and inter-observer agreement was calculated using the intraclass correlation coefficient (ICC) in relationship with different patient-related covariates.
Results: A total of 922 VCTE examinations for SSM were performed in Novara and 680 in Milan, respectively, with an overall failure rate of 3.2% and 3.6%.
In CLD patients from Novara (33% cirrhotic, 26% with splenomegaly) median SSM was 24.9 kPa (IQR 20.6–36.1) and LSM was 6.8 kPa (IQR 4.9–11.3). In CLD patients from Milan (31% cirrhotics, 40% with splenomegaly) median SSM was 29.2 (IQR 16.7–34.5) and median LSM 8.3 kPa (IQR 7.1–10.8).
Median SS value was 26.6 kPa (IQR 24.3 to 36.1) in the overall CLD group, 26.3 kPa (IQR 22.3–33.6) in MPN patients and 16.1 kPa (IQR 14.6–18.7) in healthy volunteers.
In whole CLD group, SSM was significantly correlated with LSM ($r = 0.67$), spleen longitudinal diameter ($r = 0.58$), presence of cirrhosis ($r = 0.54$), and BMI ($r = 0.24$) ($p < 0.0001$ for all comparisons).
In CLD patients the overall inter-observer agreement ICC was 0.90 (0.88–0.92) and factors associated with a reduced agreement were: absence of splenomegaly (ICC0.87 *vs* 0.91), BMI >25 kg/m^2 (ICC 0.91 *vs* 0.88) and absence of cirrhosis (ICC 0.84 *vs* 0.90). Intra-observer agreement ICC for rater 1 and rater 2 respectively were 0.93 (95% CI 0.91–0.95) and 0.96 (95% CI 0.95–0.97) in Novara and 0.91 and 0.94 (95% CI 0.91–0.96) (95% CI 0.87–0.93) in Milan.
Conclusion: SSM is a highly reproducible and feasible technique for assessing SSM in patients with CLD.

FRI228

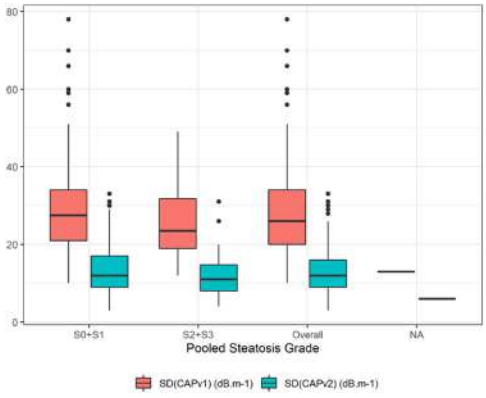
Validation of the continuous controlled attenuation parameter (CAPc) using the MRI-PDFF as reference

Nathalie Ganne-Carrié[1], Olivier Chazouillères[2], Jerome Boursier[3], Christophe Aubé[4], Yves Menu[5], Olivier Seror[6], Yves Gandon[7], Edouard Bardou-Jacquet[8]. *[1]Avicenne Hospital (AP-HP), Department of Hepatology, Bobigny, France; [2]Hospital Saint-Antoine Ap-Hp, Department of Hepato-gastroenterology, Paris, France; [3]Angers University Hospital Center, Department of Hepato-Gastroenterology and Digestive Oncology, Angers, France; [4]Angers University Hospital Center, Department of Radiology, Angers, France; [5]Hospital Saint-Antoine Ap-Hp, Department of Radiology, Paris, France; [6]Jean-Verdier Hospital Ap-Hp, Department of Radiology, Bondy, France; [7]CHU Rennes-Pontchaillou Hospital, Department of Radiology and Medical Imaging, Rennes, France; [8]CHU Rennes-Pontchaillou Hospital, Department of Liver Diseases, Rennes, France*
Email: edouard.bardou.jacquet@chu-rennes.fr

Background and aims: Controlled Attenuation Parameter (CAP) was first introduced on the FibroScan (FS) device (Echosens, France) in 2010 and has been shown to be well correlated with liver steatosis in patients with various chronic liver diseases [PMID:28039099]. A new acquisition method for CAP (continuous CAP, CAPc) has recently been introduced in order to decrease the intra examination measurement variability (IEMV) [ILC2020;poster FRI073]. The aim of this interim analysis of an ongoing study is to compare the diagnostic performances and the IEMV between CAP and CAPc.

Method: Consecutive patients, all etiologies combined, underwent FS, Magnetic Resonance Imaging (MRI) within 21 days and CAPs obtained by both methods (standard and continuous). A central reading of the MRI images was performed to assess the Proton Density Fat Fraction (PDFF) which was used as the reference to assess the steatosis grades (S >0: PDFF ≥5% and ≤10%; S >1: PDFF ≥10%). The CAPs standard deviations (SD) were compared using the unilateral Wilcoxon signed-rank test. The agreement between CAP and CAPc was assessed with the average bias, the Pearson's coefficient of correlation (CC) and the absolute agreement intraclass coefficient (AA-ICC). The CAPs performances versus the PDFF were estimated with operating characteristics curves (ROC), and their areas under the curves (AUC). AUCs were compared with Delong's bilateral test.

Results: 157 patients were included (41% female, mean BMI = 28.4 ± 5.5 kg/m^2, mean age = 55.0 ± 13.4 years, Prevalence of S >0 and S >1 were 61% and 22%, respectively). The median CAPc SD (13.1 dB/m²) was significantly lower to median CAP SD (28.4 dB/m²) (p < 0.0001). The median reduction in IEMV was 50% (Fig). The average bias between the CAP and CAPc was 7.9 dB/m. The CC and AA-ICC were 0.90 and 0.89, respectively, highlighting a strong correlation and agreement. AUCs for S >0 were 0.86 (0.79–0.92) and 0.85 (0.78–0.91) for CAP and CAPc, respectively. AUCs for S >1 were 0.85 (0.78–0.92) and 0.86 (0.79–0.93), for CAP and CAPc, respectively. AUCs of CAP and CAPc methods were not significantly different.



Conclusion: By using the continuous method, the intra examination measurement variability of the CAP is decreased with a factor 2, keeping the global performance of the CAP algorithm. Furthermore, the results of CAP and CAPc examinations are strongly correlated and in agreement. Performances of CAP and CAPc are good for S >0 and S >1.

FRI229

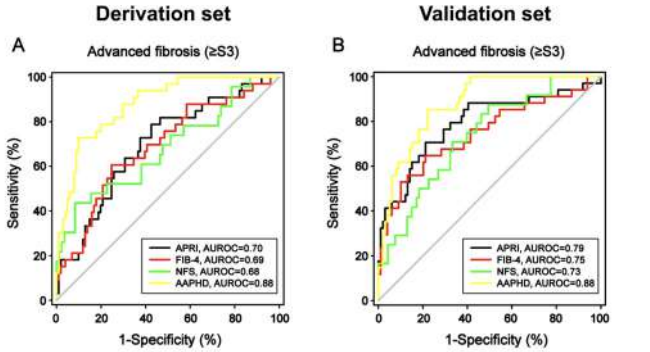
A novel non-invasive index for the prediction of liver fibrosis in chronic hepatitis B patients with concurrent nonalcoholic fatty liver disease

Jian Wang[1], Jiacheng Liu[2], Yiguang Li[3], Li Zhu[4], Minxin Mao[2], Weimao Ding[5], Yuanwang Qiu[3], Chuanwu Zhu[4], Jie Li[1], Rui Huang[1], Chao Wu[1]. *[1]Nanjing Drum Tower Hospital, The Affiliated Hospital of Nanjing University Medical School, Department of Infectious Diseases, Nanjing, China; [2]Nanjing Drum Tower Hospital Clinical College of Traditional Chinese and Western Medicine, Nanjing University of Chinese Medicine, Department of Infectious Diseases, Nanjing, China; [3]The Fifth People's Hospital of Wuxi, Department of Infectious Diseases, Wuxi, China; [4]The Affiliated Infectious Diseases Hospital of Soochow University, Department of Infectious Diseases, Suzhou, China; [5]Huai'an No. 4 People's Hospital, Department of Hepatology, Huai'an, China*
Email: dr.wu@nju.edu.cn

Background and aims: Few accurate non-invasive indexes are available to evaluate liver fibrosis in chronic hepatitis B (CHB) patients with nonalcoholic fatty liver disease (NAFLD). We aimed to establish a predictive index for advanced fibrosis in CHB patients with NAFLD.

Method: A total of 267 treatment-naïve CHB patients with NAFLD underwent liver biopsy were enrolled from four hospitals and randomly divided into a derivation set (n = 134) and a validation set (n = 133). Receiver operating characteristic (ROC) curve was used to compare predicting accuracy of different indexes.

Results: In the derivation set, alanine aminotransferase, aspartate aminotransferase (AST), prothrombin time, presence of hypertension, and type 2 diabetes were significantly associated with advanced fibrosis (≥S3). Based on these parameters, a novel index namely AAPHD for predicting advanced fibrosis was developed. The areas under the ROC curves (AUROCs) of AAPHD index in predicting advanced fibrosis was 0.88 (95%CI:0.82–0.94). The optimal cut-off value of AAPHD was −2.870, with a sensitivity of 72.73% and a specificity of 90.10%. The predicting accuracy of AAPHD for advanced fibrosis was significantly superior to AST-to-platelet ratio index (APRI) (AUROC = 0.70), fibrosis-4 score (FIB-4) (AUROC = 0.69), and NAFLD fibrosis score (NFS) (AUROC = 0.68). In the validation set, the AUROCs of AAPHD (AUROC = 0.88) remains significantly higher than that of FIB-4 and NFS, while it was comparable with APRI for predicting advanced fibrosis.



$AAPHD = -17.102 + 1.763 \times \text{hypertension (yes = 1, no = 0)} + 1.975 \times \text{diabetes (yes = 1, no = 0)} + 0.041 \times \text{AST (U/L)} + 0.965 \times \text{PT (s)} - 0.014 \times \text{ALT (U/L)}$

Figure: Receiver operating characteristic (ROC) curves of non-invasive tests for predicting advanced liver fibrosis in derivation set (A) and validation set (B).

Conclusion: AAPHD is a promising non-invasive index for predicting advanced fibrosis with high accuracy in CHB patients with NAFLD. The application of AAPHD may reduce the necessary for liver biopsy in CHB patients with NAFLD.

FRI230

Comparison between two 2D-SWE techniques using transient elastography as a reference method for liver stiffness assessment

Alina Popescu[1,2], Camelia Foncea[1,2], Raluca Lupusoru[1,2,3], Roxana Sirli[1,2], Felix Bende[1,2], Alexandru Popa[1,2], Victor Baldea[1,2], Radu Cotrau[1,2], Pascu Ariana[1,2], Ioan Sporea[1,2]. *[1]Department of Gastroenterology and Hepatology, Department of Internal Medicine II, Center for Advanced Research in Gastroenterology and Hepatology "Victor Babes" University of Medicine and Pharmacy Timisoara, Romania; [2]Center for Advanced Hepatology Research of the Academy of Medical Sciences, Timișoara; [3]Center for Modeling Biological Systems and Data Analysis, Department of Functional Sciences, "Victor Babes" University of Medicine and Pharmacy Timisoara, Romania*
Email: foncea.camelia@gmail.com

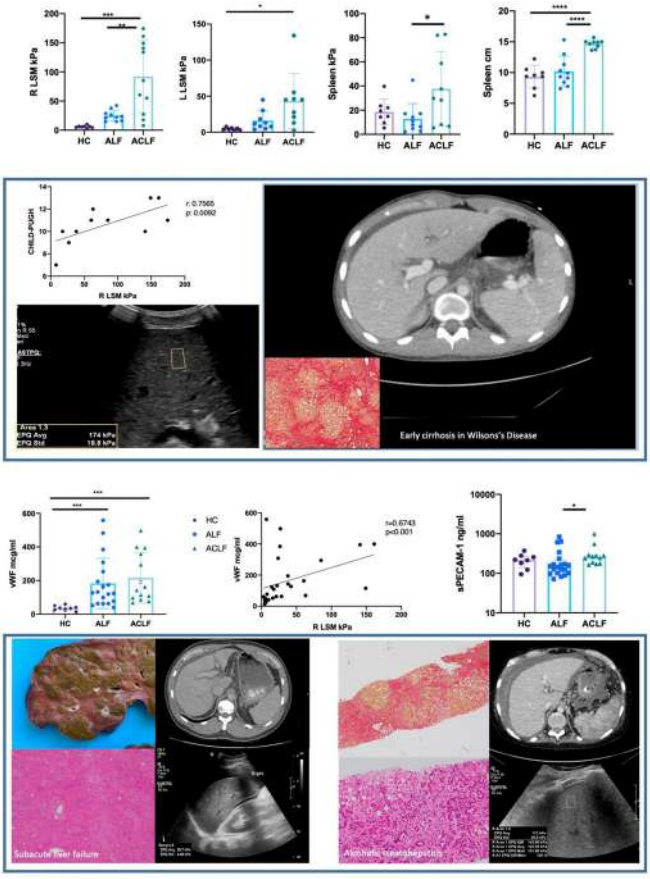
Background and aims: Ultrasound-based liver elastography techniques are non-invasive methods used for the assessment of liver stiffness (LS). In addition to Transient Elastography (TE), new methods were developed. To compare the performance of 2D-SWE technique implemented on two different ultrasound probes from different vendors for the assessment of liver stiffness measurements (LSM) using transient elastography (TE) as reference method.
Method: A prospective study was conducted in which LSM were performed in 201 consecutive patients with or without chronic liver disease, evaluated in the same session by 2D-SWE and TE implemented on the following systems: Siemens ACUSON Sequoia (5C-1 convex transducer and Deep Abdominal Transducer-DAX), Aixplorer Mach 30 (C2-1X convex transducer) and FibroScan Compact M 530 (M and XL probes). Reliable measurements were defined as the median value of 10 measurements and an IQR/M < 0.3. For significant fibrosis a cut-off value for TE of 7 kPa was used, for advanced fibrosis 9.5 kPa and for liver cirrhosis 12 kPa.
Results: From 201 patients, 198 patients had reliable measurements in all techniques and were included in the final analysis, mean age 54.8 ± 13.3 years, mean BMI 28.8 ± 5.0, 58% (116/198) men. 58.5% were without or with mild fibrosis, 14.1% had significant fibrosis, 6.2% had advanced fibrosis and 21.2% had liver cirrhosis. For significant fibrosis the performance was slightly better for 2D-SWE.SSI (AUROC = 0.89, p < 0.0001, >7.3 kPa, Se = 85.1%, Sp = 87.9%) followed by 2D-SWE.5C1 (AUROC = 0.79, p < 0.0001, >6.9 kPa, Se = 33.7%, Sp = 96.7%) and 2D-SWE.DAX (AUROC = 0.78, p < 0.0001, >6.3 kPa, Se = 36.4%, Sp = 96.7%), p = 0.01. For advanced fibrosis the best performance was slightly better by 2D-SWE.SSI (AUROC = 0.92, p < 0.0001, >8.8 kPa, Se = 92.5%, Sp = 91.9%), and by 2D-SWE.DAX (AUROC = 0.86, p < 0.0001, >7.6 kPa, Se = 38.8%, Sp = 99.3%), followed by 2D-SWE.5C1 (AUROC = 0.84, p < 0.0001, >8.6 kPa, Se = 38.8%, Sp = 96.5%), p = 0.02. For liver cirrhosis the performances were similar: 2D-SWE.SSI (AUROC = 0.91, p < 0.0001, >10.3 kPa, Se = 92.8%, Sp = 90.3%), followed by 2D-SWE.DAX (AUROC = 0.90, p < 0.0001, >10 kPa, Se = 23.8%, Sp = 98.7%) and 2D-SWE.5C1 (AUROC = 0.84, p < 0.0001, >9.9 kPa, Se = 33.3%, Sp = 96.7%), p = 0.10. The cut off values for predicting different stages of fibrosis ranged from 6.3–7.3 kPa for F2, 7.6–8.8 kPa for F3 and 9.9–10.3 for F4.
Conclusion: The performance of the evaluated 2D SWE techniques for liver fibrosis assessment was similar.

FRI231

Shear wave elastography is a useful and accurate tool to triage patients with acute liver failure syndromes

Francesca Maria Trovato[1], Florent Artru[1], Salma Mujib[1], Ellen Jerome[1], Anna Cavazza[2], William Bernal[2], Brian J. Hogan[2], Rosa Miquel[2], Mark J. W. McPhail[1]. *[1]Institute of Liver Studies, Department of Inflammation Biology, London, United Kingdom; [2]Institute of Liver Studies, London, United Kingdom*
Email: trovatofrancesca@gmail.com

Background and aims: Shear wave elastography has been largely used in chronic liver disease to assess liver stiffness non-invasively and estimate the grade of fibrosis. In acute settings, studies were inconclusive since the high stiffness is not related to fibrosis but to a combination of other factors not completely identified, including, inflammation, necrosis and micro-thrombosis. We re-evaluated the usefulness of a non-invasive anatomically directed ultrasound approach to patients with acute liver failure syndromes admitted to intensive care.
Method: 18 patients with index presentation of acute liver failure (ALF) requiring admission to liver intensive care, 3 known cirrhotics in acute on chronic liver failure (ACLF), 8 healthy controls were included in the study. After collateral history, imaging and in some case liver biopsy, acute patients were subsequently re-characterized as 10 ALF and 8 ACLF. Shear wave velocity, hepatic vascular flows, size of liver and spleen were measured using the Philips Affinity 70, and biopsy or explant histological findings were used as comparison. Platelet endothelial cell adhesion molecule-1 (sPECAM-1) and von Willebrand factor were measured in plasma by enzyme-linked immunosorbent assay (ELISA) (n: 8HC, 20 ALF, 12 ACLF).
Results: Liver stiffness measurement of the right lobe (RLSM) accurately identified healthy controls (5.9 ± 2 kPa), acute liver failure (24.87 ± 9.3) and acute on chronic liver failure (92 ± 61.8 kPa) patients. In this population with hyperdynamic circulation, the estimation of the left lobe stiffness was less accurate due to heart beat artifacts. Spleen size, but not spleen stiffness, accurately discriminate between ALF and ACLF. In ACLF, RLSM correlates with both age and severity of liver disease express by Child-Pugh score and the highest values are found in alcoholic hepatitis and Wilson's disease. sPECAM—1 correlates with bilirubin (Spearman r = 0.777, p < 0.001) and MELD (r = 0.05335, p = 0.029) in both acute liver failure syndromes but no correlation was found with liver stiffness. Conversely, vWF is highly directly correlated with RLSM, MELD and SOFA scores (p < 0.001). 3 ALF explants and 4 explants/biopsies confirming the presence of cirrhosis in ACLF patients and higher degree of cholestasis in all compartments (cytoplasmic, canalicular and ductular), had respectively a mean RLSM of 26 ± 17.6 kPa and 109 ± 60 kPa.



Conclusion: In patients with acute liver failure syndromes, shear wave elastography can help in the early clinical assessment at admission in intensive care. Plasma vWF is highly correlated RLSM and it can be speculated that the presence of platelets aggregates can be responsible of the increased values. Moreover histological analysis showed high degree of intrahepatic cholestasis in ACLF. Further studies are needed to definitely explain the high level of stiffness reported in these patients.

A novel simple and reliable 2D-shear wave elastography (SWE) and ultrasound-guided coefficient attenuation parameter (SCAP) technique for patients with chronic liver disease

Christiane Stern[1], An Ngo[2], Cristiane Villela-Nogueira[3], Dominique Thabut[1], Vlad Ratziu[1]. [1]*Hôpital Pitié-Salpêtrière, Service d'Hépato-gastroentérologie, Paris, France;* [2]*Hôpital Pitié-Salpêtrière , Service d'Hépato-gastroentérologie, Paris, France;* [3]*Federal University of Rio de Janeiro, Serviço de Hepatologia, Rio de Janeiro, RJ, Brazil*
Email: christiane.stern@gmail.com

Background and aims: Different non-invasive methods are now widely used for first line assessment of liver fibrosis and steatosis in patients with chronic liver disease. The detection of advanced fibrosis using 2D-shear wave elastography (SWE) and significant steatosis using ultraSound-guided CAP (SCAP) measured by Aixplorer MACH 30 (SS) is simple, safe and overcomes several limitations of transient elastography (TE) and CAP measured by FibroScan (FS). Nevertheless, reliability criteria have not been well described for SS. The aims of this study were to define the optimal technical procedure, the performance for the detection of fibrosis and steatosis and the reliability criteria using SS.

Method: 215 consecutive patients with chronic liver disease that underwent non-invasive tests were included. Clinical, biological and histological data within 6 months were collected. TE and CAP were performed by 2 experienced operators using the classical technique of 10 measurements at the midaxillary line. Measurements of SWE and SCAP were performed in triplicate at the mid (MAL), posterior (PAL) and anterior axillary lines (AAL) (total of 9 values). The technique the simplest to perform and most reliable has been analyzed. Performances of SWE and SCAP for the diagnosis of advanced fibrosis and significant steatosis have been defined using TE (≥9.5 kPa) and CAP (≥275 dB/m) as reference. Factors associated with discordance have been evaluated.

Results: FS and SS data from 203 patients were analyzed (12 patients excluded due to FS and/or SS failure). Baseline characteristics: mean age 56 ± 14 years; male 58%; MAFLD 59%, viral hepatitis 24%; mean BMI 28.3 ± 5.9 kg/m^2. Median TE and CAP were 6.5 kPa (2.5–66.9) and 272 dB/m (141–400). Table 1 shows the performances of SCAP according to different technique methods. The median of 3 SWE values and 3 SCAP values (1st measurement at MAL, PAL and AAL) had an AUROC of 0.96 [CI95%: 0.93–0.98] and 0.91 [CI95%: 0.86–0.95] for the diagnosis of advanced fibrosis and significant steatosis, and considered as the best technique. The accuracy of cut-off values for SWE (≥8.5 kPa) and SCAP (≥0.44) were analyzed in 54 patients with liver biopsy. There was only 1 false-negative for fibrosis (PPV = 50%, NPV = 97%) and 2 false-negatives for steatosis (PPV = 69%, NPV = 87%). The factors associated with discordance were skin-to-liver distance (SLD) ≥2.4 cm (p < 0.001), depth ≥5.5 cm (p < 0.001), stability index <70% (p = 0.009) and viscosity ≥2.4 (p = 0.026). In logistic regression, the only factor associated with discordance was SLD (p = 0.012).

Table 1. Performances of SCAP for the diagnosis of significant steatosis according to different technique methods, taking CAP measured by FibroScan as reference.

SS technique for the diagnosis of steatosis	AUROC	CI95%
SCAP measured 3 times at MAL	0.87	0.82 – 0.92
SCAP measured 3 times at PAL	0.80	0.74 – 0.87
SCAP measured 3 times at AAL	0.85	0.80 – 0.90
SCAP measured 9 times (3 MAL, 3 PAL and 3 AAL)	0.90	0.86 – 0.95
SCAP measured 3 times (1st MAL, 1st PAL and 1st AAL)	**0.91**	**0.86 – 0.95**

Conclusion: A quick and reliable non-invasive diagnosis of advanced fibrosis and significant steatosis can be obtained with the median of 3 measurements (1 mid, 1 posterior and 1 anterior axillary line) using SS. The only non-reliable criterion is skin-to-liver distance ≥2.4 cm.

Abstract withdrawn

Email: mariaazocco@hotmail.com

Background and aims: The achievement of a sustained virologic response (SVR) with direct acting antivirals (DAAs) has been shown to prevent liver-related events (LREs) in patients with chronic hepatitis C virus (HCV)-related cirrhosis. Bidimensional shear wave elastography (2D-SWE) is an effective and easy to perform technique for the early assessment of liver fibrosis during DAA treatment.
The main aim of the study was to evaluate changes in liver stiffness (LS) using 2D-SWE in patients with HCV-related cirrhosis undergoing DAA therapy. Secondary endpoint was to identify any correlation between LS, ultrasound and clinical parameters that predict the occurrence of LREs.
Method: We enrolled 229 consecutive patients who received DAAs based regimens for HCV-related cirrhosis between December 2014 and September 2016. Standard ultrasound, 2D-SWE measured LS, and clinical and laboratory data were assessed before treatment (baseline), 24 weeks after end of treatment (EOT) (T1) and 48 weeks after EOT (T2). Patients were followed up every 6 months according to international clinical practice guidelines. Any LRE was registered during follow-up. Uni- and multi-variate Cox regression analysis was performed to determine parameters associated with the development of LREs.
Results: At baseline, mean LS was 18.1 ± 6.6 kPa. Levels of LS decreased to a mean of 13.6 ± 6.1 kPa and 12.5 ± 6.1 kPa at T1 ($p < 0.0001$) and T2 ($p < 0.0001$), respectively. The median follow-up was 3.25 years (range 0.2–4.7). HCC was the most frequent LRE (30 patients, 13.1%). 13 patients (5.7%) developed ascites, 11 (4.8%) portal vein thrombosis (PVT), 8 (3.5%) hepatic encephalopathy (HE), 8 (3.5%) infections and 5 (2.2%) variceal bleeding. 9 patients died (3.9%) and 5 were transplanted (2.2%).
Male gender, bilirubin, international normalized ratio (INR), Model for End-stage Liver Disease (MELD) score, prior history of harmful alcohol intake, LS, portal velocity and a change in LS less than 20% at T2 (1-y Delta-LSM) were associated with HCC occurrence by univariate analysis. By Cox regression multivariate analysis, only MELD score (HR 1.16; CI 95% 1.01–1.33; $p = 0.026$) and 1-year Delta LSM <20% (HR 2.98; CI 95% 1.01–8.1; $p = 0.03$) were independently associated with HCC risk. Interestingly, 1-year Delta LSM <20% was independently associated with the development of ascites with significant hazard ratio (HR 5.08; CI 95% 1.03–25.14; $p = 0.04$).
Since the variables maintained their predictive value over time, we combined their HR in a simple model to estimate the probability of HCC occurrence at 24, 36, 48 and 60 months after EOT.

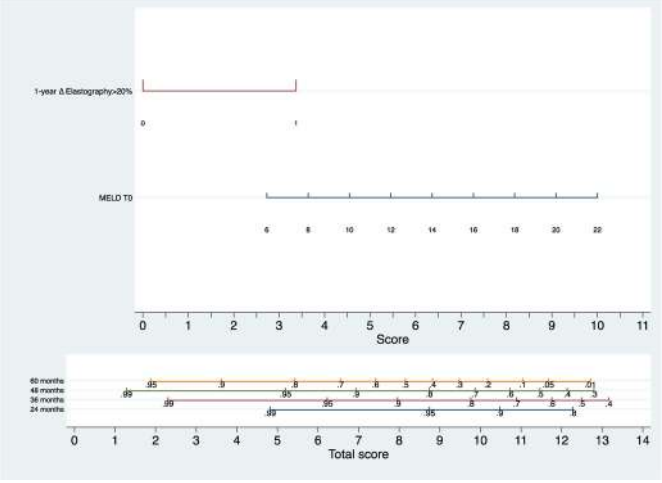

Figure: Predictive model for HCC occurrence.

Conclusion: Alone and in association with clinical and biochemical variables, dynamic changes of 2D-SWE-measured LS after DAA therapy for HCV may be a useful tool to predict HCC and ascites occurrence in cirrhotic patients.

FRI235

The concordance within one blood test improves reliability evaluation of liver fibrosis

Paul Cales[1], Clémence M. Canivet[1], Lannes Adrien[1], Frédéric Oberti[1], Isabelle Fouchard[1], Jerome Boursier[1]. *[1]Angers University Hospital, Hepatology, Angers, France*
Email: paul.cales@univ-angers.fr

Background and aims: The improved reliability of non-invasive tests of liver fibrosis is defined by agreement between a patented blood test and liver stiffness measurement (LSM) by transient elastography (TE) in 2021 EASL guidelines. The inconvenience is to require two different tests adding cost and reducing availability. Our aim was to apply this agreement rule to a single blood test targeted either for significant fibrosis (FibroMeterV2G: FM2G) or cirrhosis (CirrhoMeterV2G: CM2G) using the same markers.

Method: Patients with chronic liver disease of multiple untreated etiologies, with liver biopsy using Metavir F within 6 months of blood test, were included in a derivation (n = 2159) and a validation (n = 1476 with LSM by TE) sets. Agreement grade was calculated as the absolute difference (AD) between fibrosis (F_M) classifications of FM2G and CM2G. The main outcome was severe fibrosis (Metavir F ≥ 3). Outcome measures were AUROC and accuracy (correct diagnosis).
Results: In the derivation set, FM2G accuracy (and prevalences) were according to agreement grade: high (F_M AD ≤ 0.5): 83.1% (78.6%), fair (F_M AD = 1): 70.2% (16.3%), poor (F_M AD >1): 50.0% (5.1%), p < 0.001. CM2G accuracy was, respectively 83.1%, 67.6%, 50.9% (p < 0.001). Then, agreement was classified as concordant or not for Metavir F ≥ 3. FM2G accuracy (and prevalences) were, concordant: 83.9% (85.9%), discordant: 51.3% (14.1%), p < 0.001. FM2G AUROCs were, respectively: 0.866 and 0.519, p < 0.001. The overall accuracy of FM2G (79.3%) and CM2G (79.0%) were not different (p = 0.688) but they were complementary (kappa: 0.573). So, a CM/FM algorithm was constructed. Its accuracy was significantly increased to 82.2% (p < 0.001) vs FM2G or CM2G and different between concordant (85.1%) and discordant (64.1%, p < 0.001) blood tests. In the validation set, previous results were confirmed, e.g. CM/FM accuracy was, concordant blood tests: 79.9%, discordant: 60.5% (p < 0.001). The concordance prevalence was higher for FM2G vs CM2G (84.9%) than vs LSM (70.9%, p < 0.001). Accuracy was globally, LSM: 78.8% vs CM/FM: 77.0%, (p = 0.173) or FM2G: 75.5% (p = 0.011) but in the 70.9% of concordant FM2G/LSM it was, respectively: 88.0% vs 87.4% (p = 0.210) or 88.0% (p = 1). The accuracy in concordant tests was however higher in FM2G agreement vs LSM than vs CM2G, e.g. CM/FM: 88.0% vs 79.9% (p < 0.001).
Conclusion: The concordance within a blood test significantly increased the concordance prevalence. The limit was a reduced accuracy; the advantages were a reduced cost and liver biopsy recourse by half, and a simpler use (single time and greater ubiquity).

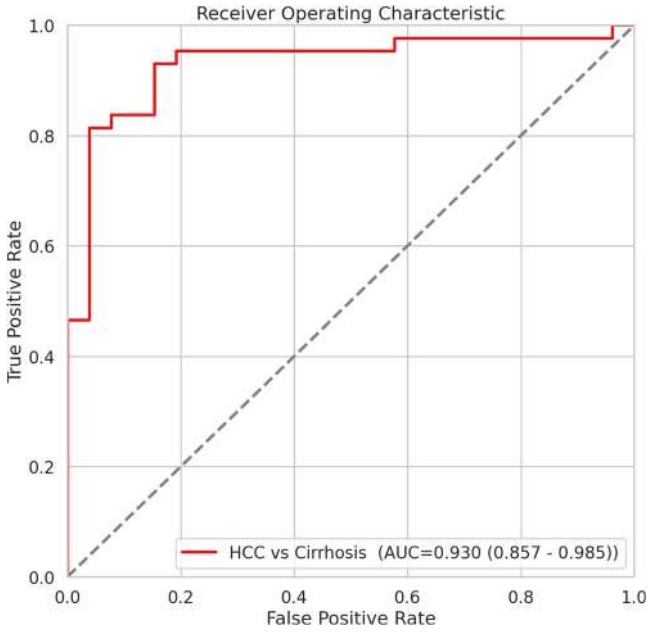
Email: ttran@glympsebio.com

Background and aims: The incidence of hepatocellular carcinoma (HCC) is rising worldwide and projected to continue increasing through 2030. HCC surveillance using ultrasound with or without AFP has suboptimal sensitivity, missing over one-third of HCC at an early stage. We previously showed a panel of biosensors that interrogate biological pathways implicated in HCC pathogenesis (tumor invasion of extracellular matrix, matrix remodeling, inflammation, and fibrinolysis) was highly effective at differentiating patients with HCC from healthy controls, with AUCs >0.94. The aim of this study was to assess accuracy of protease biosensor biomarker panel to distinguish patients with HCC from those with cirrhosis without HCC.
Method: Retrospective plasma samples were obtained from patients diagnosed with HCC (cases) and those with cirrhosis without HCC (controls). Protease biosensor cleavage was assayed from plasma by fluorimetry. The relative signal was used for classification by regularized logistic regression using 100 cross-validation (80% train, 20% validation splits). The maximum point from the Youden's J index in the training set was used to the define the optimal cut-off, which was used to calculate sensitivity and specificity for HCC detection in the validation sets.
Results: Plasma protease activity was assessed in 43 HCC cases (65% male, mean age 58 years, 49% HBV/7% HCV/44% unknown etiology) and 26 cirrhosis controls (30% male, mean age 57 years, 100% NASH etiology). Nearly three-fourths (72%) of the cases had early-stage tumors (TNM stage I or II). The most significant biosensors in the classification of HCC vs cirrhosis were substrates of MMPs, DPP4, ANPEP, ARTS-1, KLK14 and Cathepsins (L, S, K, B) and ADAM17. The panel of protease biosensors had high accuracy for differentiating patients with HCC vs those with cirrhosis (AUC = 0.93 [CI 0.86–0.98]) (Figure). Using the Youden's cut-off, sensitivity and specificity of the protease biosensor panel for HCC detection were 0.84 and 0.85, respectively.



Conclusion: Novel non-invasive biosensors measuring protease activity accurately differentiate HCC from cirrhosis and, if validated in larger biomarker studies, may serve as an alternative surveillance tool to improve early HCC detection.

FRI237
FIB-4 predicts severe hematological toxicity and 6-month mortality in older patients with cancer: ELCAPA-LIVER.

Victoire De Salins[1], Antoine Morel[2], Claudia Martinez-Tapia[2], Pierre-Emmanuel Rautou[3], Florence Canoui-Poitrine[2], Elena Paillaud[4], Johanne Poisson[5]. *[1]AP-HP, Service de Gériatrie, Hôpital Européen George Pompidou, Paris, France; [2]University Paris Est Creteil, INSERM, IMRB, F-94010 Créteil, France, Clinical Epidemiology and Ageing Unit, Institute Mondor de Recherche Biomédicale, Paris-Est University, F-94000 Créteil, France; [3]Université Paris-Cité, AP-HP, Hôpital Beaujon, Service d'Hépatologie, DMU DIGEST, Centre de Référence des Maladies Vasculaires du Foie, FILFOIE, ERN RARE-LIVER, Centre de recherche sur l'inflammation, Inserm, UMR 1149, Paris, France; [4]Université Paris-Cité, AP-HP, Service de Gériatrie, Hôpital Européen George Pompidou, Paris, France, Clinical Epidemiology and Ageing Unit, Institute Mondor de Recherche Biomédicale, Paris-Est University, F-94000 Créteil, France; [5]Université Paris-Cité, AP-HP, Service de Gériatrie, Hôpital Européen George Pompidou. Centre de recherche sur l'inflammation, Inserm, UMR 1149, Paris, France, France*
Email: poisson.johanne@gmail.com

Background and aims: The current increased life expectancy is associated with an increasing incidence of cancer in older patients. Geriatric assessment has improved the management of this heterogeneous population with thorough evaluation of physiologic systems

i.e heart, lung, renal functions for cancer treatment choice, but no study reported a comprehensive analysis of liver parameters and its impact on mortality and toxicity. Yet, aging is thought to be associated with a liver functional decline and is an important risk factor for developing chronic liver disease. FIB-4 has been shown to predict mortality in non-oncological young and older patients without known chronic liver disease. Aims of this study were to evaluate predictive value of FIB-4 for 6-months survival and treatment toxicities in patients age 70 yo or older with cancer.

Method: Patients aged 70 or older with histologically documented solid or hematological cancers and referred for geriatric assessment were included from the multicentric, French prospective open-cohort Elderly Cancer Patients (ELCAPA) from March 2015 to September 2019. In the present study (ELCAPA-LIVER), patients, at any stage, treated by chemotherapy, immunotherapy or targeted therapy in 6 different centers and for whom platelet count and serum AST and ALT measurements were available at baseline, were selected. Patients with known chronic liver diseases were excluded. Geriatric assessment was performed at baseline. FIB-4 cut-off values used to rule out or to rule in advanced fibrosis in elderly patients with liver diseases were used to classify patients into three prognostic groups (cut-offs were decided based on previous papers in older patients). Treatment toxicities (grade 0/I/II vs grade III/IV) and mortality were assessed at 6 months of follow-up.

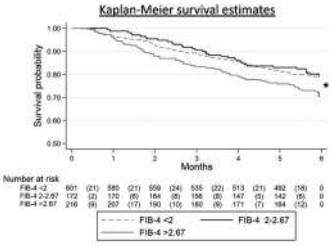
Results: 989 patients were included: median age: 81 years (IQR: 77–84); female, 58.8%; main cancer sites: digestive 29%, gynecological 28%, urinary tract 14% and lung 12%; metastasic diseases 51%. At 6 months, 763 patients were dead (77%) and 355 patients (59%) experienced grade III/IV anticancer toxicities, including 123 patients (22.4%) with hematological toxicities.

A FIB-4 index >2.67 before treatment was independently associated with hematological toxicities grade III/IV (adjusted OR = 1.92 (95% CI: 1.15–3.22), p = 0.02).

In addition, a FIB-4 index >2.67 was predictive for 6-month mortality independently of cancer site, metastasis, chronic heart failure, and C-Reactive Protein (aHR = 1.55 (1.10–2.20), p = 0.028).

Multivariate analysis for 6-months mortality (N = 989)

Variables		aHR (CI 95%)	p-value
Cancer site			
	Digestive cancer	Ref	0.014
	Gynecological cancer	0.58 (0.36 - 0.94)	
	Urinary tract cancer	0.90 (0.58 - 1.41)	
	Lung cancer	1.44 (0.90 - 2.17)	
	Other cancers	0.94 (0.58 - 1.53)	
Metastasis (N=908)		2.94 (1.92 - 4.51)	< 0.0001
Chronic heart failure (N = 976)		1.84 (1.12 - 3.02)	0.017
CRP (N = 781)		1.08 (1.05 - 1.10)	< 0.0001
FIB 4 score			
	< 2	Ref	0.028
	≥ 2 & < 2.67	0.95 (0.63 - 1.45)	
	>2.67	1.55 (1.10 - 2.20)	



Conclusion: A FIB-4 index >2.67 was an independent predictor for 6-month mortality and severe hematologic toxicity in older patients treated for cancer. This shows the importance of evaluating liver status to improve decision making in older patients with cancer.

The main thing is to be alive-exploring patients' experiences with weight gain after liver transplantation: a qualitative study

Sonja Beckmann[1,2], Patrizia Kuenzler[1,3], Kajetan Kabut[4], Oliver Mauthner[1,5]. *[1]University of Basel, Institute of Nursing Science, Basel, Switzerland; [2]University Hospital Zurich, Center Clinicak Nursing Science, Zurich; [3]Cantonal Hospital St.Gallen, Department of Gastroenterology/Hepatology and Department of Nursing, St.Gallen; [4]BDH-Klinik Elzach, Zentrum für NeuroRehabilitation, Beatmungs-, und Intensivmedizin, Germany; [5]University Department of Geriatric Medicine Felix Platter, Basel, Switzerland*
Email: sonja.beckmann@usz.ch

Background and aims: Weight gain after liver transplantation (LTx) is common, contributing to the development of new-onset obesity at 2- and 3-years post-LTx in 22% and 38% of patients. These significant weight gains prompt the question of how patients cope with this increase of weight. Unfortunately, few studies examined the patients' perspective. This study aimed to explore how patients' experienced their weight gain after LTx.

Method: Individual interviews followed a guideline with open-ended questions. Transcripts were analyzed according to the six phases of the reflexive thematic analysis approach by Braun and Clarke.

Results: The 12 participants gained 11.5 kg weight (median) over a median of 23 months after LTx. The constitutive theme "The main thing is to be alive" was a recurrent insight, captured in different facets in all three consecutive themes: "The arduous path back to living" was the emotional facet, expressing the ups and downs during the suffering from a life-threatening illness to finally being grateful for the new life. "A pleasurable new phase of life" was the legitimation, reflecting the appreciation of gaining weight and returning to a healthy appearance after having overcome the illness. "I am allowed to look like this now" was the consoling facet after a time of physical and emotional burden due to the increased weight and frustration of being unsuccessful in losing weight. Finally, the awareness of being a LTx survivor outplayed the burden of the excess weight.

Figure 1. Overview over the four themes and the seven subthemes.

Conclusion: Understanding the patients' dynamic lived experiences, beliefs and motivations on post-LTx weight gain is crucial in providing tailored care. Interventions should be offered early because the comforting insight "I am allowed to look like this now" may hinder the patient's motivation to further engage in weight loss interventions. Our suggestions on time and content of education and self-management support, based on the transtheoretical model, may guide professionals' clinical practice.

FRI239

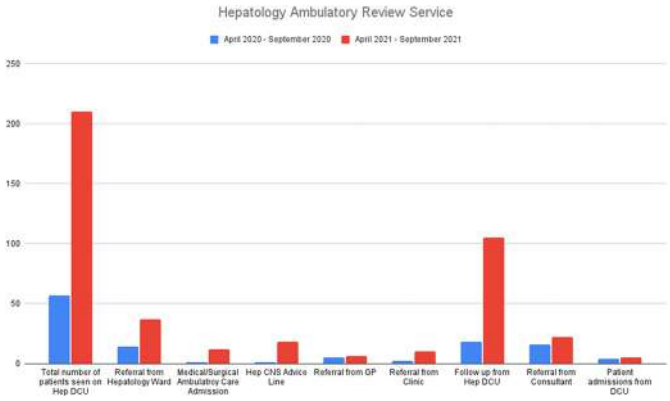
Development of a nurse led hepatology ambulatory review service

Victoria Wharton[1], Bryony Butler[1]. [1]*John Radcliffe Hospital, Hepatology, Oxford, United Kingdom*
Email: victoria.wharton@ouh.nhs.uk

Background and aims: The Liver Unit in Oxford was significantly impacted by COVID-19-highlighting a need for a nurse-led Hepatology ambulatory review service to help minimise inpatient admissions and assess patients with newly diagnosed decompensated liver disease. The Hepatology DCU were providing a nurse led abdominal paracentesis clinic and between appointments the team were able to accommodate clinical reviews. The aims for this service were to reduce Emergency Department (ED) and hospital admissions, facilitate safe and early discharges, expedite care for long term management plans and to allow a single point of access for patients and their families.

Method: Since its creation, the two founding Clinical Nurse Specialists (CNS) have collated key metrics pertaining to the patients treated by the service. These metrics included the route of referral, hospital details, date of referral, the reason for referral and whether they needed a hospital admission. Using this dataset, the effectiveness of the service has been critically assessed.

Results: Between April 2020–September 2021 the Hepatology DCU reviewed a total of 407 patients. 210 patients were seen from April 2021-September 2021; a monthly average increase of 118%, when compared to the previous year. Not included in these figures, were patients reviewed by the hepatology medical team in ED and medical/surgical ambulatory units. Of the 210 patients reviewed in DCU since April 2021, 76 patients were hepatology ward discharges reviewed by either CNS, hepatology specialist registrar or a consultant within 7–10 days of discharge. Furthermore, since starting the service just 3.9% of patients required admission from daycase. 224 (55%) of the patients seen in the ambulatory review service since April 2020 were for ascites/oedema review ± diuretic management. The ambulatory reviews are in addition to the patients' routine follow up appointments-aiding close management of their liver disease and expedition of the relevant investigations required for their long-term management, resulting in early interventions. Following completion of an Independent and Supplementary Prescribing module by the CNS, the ambulatory review service became nurse-led in September 2020.



Conclusion: Although the service is in its infancy, the number of patients reviewed has doubled since starting the hepatology ambulatory review service in April 2020. This has freed up outpatient clinic capacity and prevented delays to assessments. The Hepatology DCU currently provides a five-day service to help reduce ED attendances and reduce inpatient admissions; it is staffed by two full time band 7 CNS.

FRI240

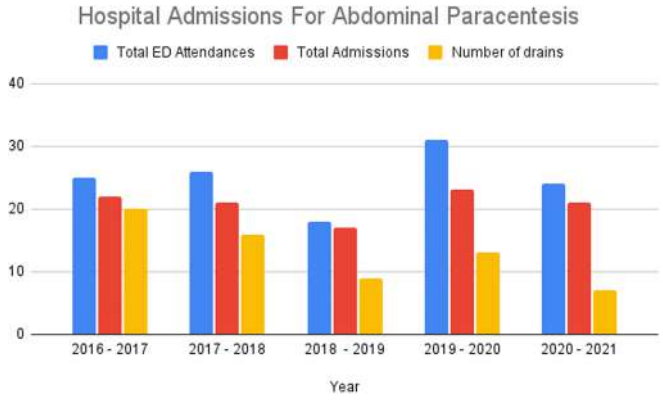
Development of a nurse led daycase abdominal paracentesis service

Victoria Wharton[1], Bryony Butler[1]. [1]*John Radcliffe Hospital, Hepatology, Oxford, United Kingdom*
Email: victoria.wharton@ouh.nhs.uk

Background and aims: Patients living with advanced liver disease often require symptomatic management of ascites with abdominal paracentesis. At Oxford University Hospitals Trust, there was previously no routine care pathway to manage the accumulation of ascites. Instead, patients would frequently present to the emergency department (ED) or to their GP in discomfort and then require emergency admission to the hepatology ward for paracentesis. This resulted in delayed care and often a lengthy hospital admission. A need was identified to provide a nurse-led, daycase paracentesis service for these patients. The aim of this service was to improve patient experience, reduce ED attendances and inpatient admissions, standardise care across the trust and build effective relationships with patients and their families.

Method: The Hepatology Day Case Paracentesis service commenced in October 2018. Initially, clinics occurred once a week, a maximum of four patients were reviewed and paracentesis was performed by a ward-based doctor. However, due to inpatient ward pressures, patients would often experience lengthy delays, when waiting for the doctor to insert their drains. This led to the development of a fully nurse delivered service. To facilitate its creation, a training programme was developed for the Clinical Nurse Specialists, in addition to postgraduate study. A 5-year dataset on patients presenting to ED with ascites (provided by clinical coders) was used to critically assess the effectiveness of the nurse-led daycase paracentesis service.

Results: Since the introduction of a fully nurse-led daycase paracentesis service in January 2020, we have performed 399 ultrasound guided paracentesis in 61 patients up to and including October 2021. Between April 2016–March 2021 a total of 124 patients presented to ED with ascites; 104 of which required an inpatient admission and 65 had a paracentesis. Furthermore, the number of patients needing admission specifically for a paracentesis fell from 20 in 2016–2017 to 7 in 2020–2021. Whilst the number of patients attending ED and requiring admission does not appear to have reduced, the number of patients admitted for paracentesis has reduced significantly.



Conclusion: The number of patients requiring admission to hospital for a paracentesis has reduced by 65% since founding a nurse-led daycase paracentesis service. The nurse-led abdominal paracentesis clinic has reduced the number of patients attending ED for ascites management alone and has provided patients with a single point of contact for managing their ascites requiring paracentesis.

FRI241

Implementing a cirrhosis order set: a qualitative analysis of provider-identified barriers and facilitators

Ashley Hyde[1], Emily Johnson[1], Michelle Carbonneau[2], Dawn Schroeder[2], Thea Luig[1], Denise Campbell-Scherer[1], Puneeta Tandon[1]. *[1]University of Alberta Faculty of Medicine and Dentistry, Edmonton, Canada; [2]Alberta Health Services, Edmonton, Canada*
Email: ac20@ualberta.ca

Background and aims: Resulting from vascular and hepatocellular injury, cirrhosis is a chronic condition that results in profound impairments in quality of life, and high rates of morbidity and mortality. Hospitalizations and readmissions become more commonplace as cirrhosis advances, with a 90-day readmission rate of 53% noted in a large North American cohort of over 1000 patients. Cirrhosis Care AB (CCAB) is a pragmatic trial which aims to address current gaps in cirrhosis care in Alberta through the implementation of a standardized order set across multiple acute care sites. Prior to implementation of such a large-scale quality improvement initiative, it is essential to understand the implementation contexts, including perceptions of the proposed intervention, and potential barriers and facilitators to implementation.
Method: We used a qualitative descriptive approach to (i) understand participant's past experiences with implementation of standardized order sets, (ii) to identify potential barriers and facilitators to implementation of the cirrhosis order set, and (iii) to develop tailored implementation strategies for each study site. We used the Consolidated Framework for Implementation Research (CFIR) and the Normalisation Process Theory (NPT) to guide development of our interview guide and coding framework. We conducted focus groups using a semi-structured interview guide. Focus groups were recorded and transcribed verbatim. A deductive content analysis approach using the core constructs of CFIR and NPT was used.
Results: We conducted a total of 8 focus groups, that were attended by 54 healthcare providers. Of the attendees, 20% were prescribers (MDs & NPs), with the remainder comprised of nurses, social workers, pharmacists, and physiotherapists. Barriers to implementation of the cirrhosis order set included the significant investment of time and resources required, the "change fatigue" of providers, and poor communication across provider groups. Facilitators included a recognized advantage of the efficiencies offered by the cirrhosis order set, the strength of the evidence on which the order set was based, leadership support of the initiative, and recognition of the need to improve care for patients with cirrhosis.
Conclusion: The findings of this study suggest that healthcare provider's perceptions of the cirrhosis order set were greatly influenced by their past experiences with the implementation of other quality improvement initiatives. Crucial to the success of the cirrhosis order set will be the use of tailored implementation strategies to promote uptake including: (i) the identification of site champions, (ii) use of implementation meetings to share learnings across study sites, and (iii) leveraging the facilitators including highlighting efficiencies in work processes that can be made possible by the cirrhosis order set.

FRI242

Quality of life in patients with advanced cirrhosis. Relationship with the development of complications

Ana Belén Rubio[1,2,3,4], Adria Juanola[1,2], Martina Perez[1,2], Marta Carol[1,2,3,4], Carlota Riba[1,4,5], Sara Martinez[1,3,4], Marta Cervera[1,2,3,4], Emma Avitabile[1,2], Ann Ma[1,2], Laura Napoleone[1,2], Octavi Bassegoda[1,2], Jordi Gratacós-Gines[1,2], Elisa Pose[1,2,3], Isabel Graupera[1,2,3], Anna Soria[1,2], Pere Ginès[1,2,3,4], Núria Fabrellas[1,2,3,4]. *[1]Hospital Clinic, Liver Unit, Barcelona, Spain; [2]University of Barcelona, Faculty of Medicine and Health Sciences, Barcelona, Spain; [3]Instituto de Investigaciones Biomédicas August Pi i Sunyer (IDIBAPS), Barcelona, Spain; [4]Centro de Investigación Biomédica en Red de Enfermedades Hepáticas y Digestivas (CIBEREHD), Madrid, Spain; [5]Fundació Clínic per la Recerca Biomèdica (FCRB), Barcelona, Spain*
Email: abrubio@clinic.cat

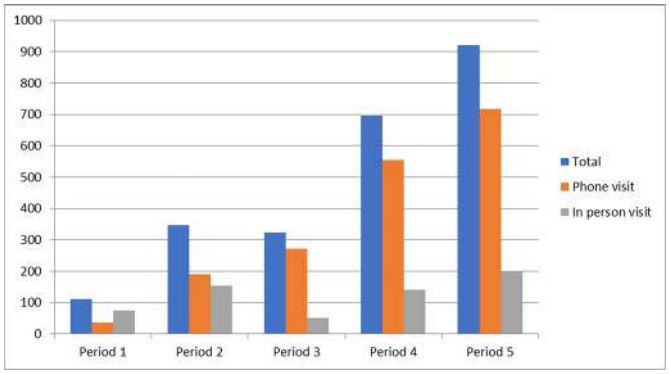
Background and aims: Liver cirrhosis causes an alteration in the Quality of Life (*QoL*) of patients that is more intense in patients in the decompensated phase. The alteration of QoL affects both the physical and mental dimensions of the patients. It is not known whether the alteration of *QoL* correlates with a higher risk of developing complications of the disease.
To investigate whether the intensity of *QoL* alteration is associated with a higher risk of developing complications of cirrhosis.
Method: This study was conducted in the cohort of patients of the *MACHT* study *(J Hepatol 2018; PMID: 30138685)*, a study investigating the effect of midodrine and albumin in patients with decompensated cirrhosis on the liver transplant waiting list. *QoL* was assessed using the Short Form Health Survey (*SF-36)* and the Chronic Liver Disease Questionnaire *(CLDQ)*. The relationship between different *QoL* parameters and the development of complications during follow-up was investigated.
Results: Under baseline conditions the two groups of patients, placebo and treatment, were similar with respect to *QoL* parameters, and were therefore considered as a single cohort. Of the 159 patients included, 53 (33%) developed complications during follow-up (median 80 days). Patients who developed complications had more marked alterations in *CLDQ* and most parameters of the physical and mental domains of *SF-36* as compared to patients who did not develop complications measured under baseline conditions. The more intense alteration of *CLDQ* and *SF-36* was also associated with a higher risk of developing hepatic encephalopathy during follow-up. In a multivariate analysis, both the mental and physical components of the *SF-36* were independent predictive factors of development of hepatic encephalopathy.
Conclusion: In patients with cirrhosis, the *QoL* parameters are not only useful to assess the degree of the patient's impairment, but also indicate a higher risk of developing complications, especially hepatic encephalopathy. These parameters provide useful clinical information for clinical practice and should be taken into account in clinical studies evaluating the efficacy of new treatments for the disease.

FRI243

Effects of the COVID-19 pandemic on the activity of an advanced practice nurse clinic on liver cirrhosis

Martina Perez[1,2,3], Ann Ma[1,3,4], Marta Cervera[1,2,3,4], Marta Carol[1,2,3,4], Ana Belén Rubio[1,3,4], Sara Martinez[1,3,4], Carlota Riba[1,3,4], Laura Napoleone[1,3,4], Jordi Gratacós-Gines[1,3,4], Anna Soria[1,3], Emma Avitabile[1,3,4], Octavi Bassegoda[1,3,4], Adria Juanola[1,3,4], Elisa Pose[1,3,4], Isabel Graupera[1,3,4], Pere Ginès[1,2,3,4], Núria Fabrellas[1,2,3,4]. *[1]Hospital Clínic de Barcelona, Liver Unit, Barcelona, Spain; [2]Facultat de Medicina-Universitat de Barcelona, Barcelona, Spain; [3]Centro de Investigación Biomédica en Red de Enfermedades Hepáticas y Digestivas (CIBEREHD), Barcelona, Spain; [4]Institut d'Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS), Barcelona, Spain*
Email: maperezgu@clinic.cat

Background and aims: Liver cirrhosis is associated with significant morbidity and mortality and is, in addition, responsible for a high number of hospitalizations, which represent a high burden for health systems. As the disease progresses, serious complications can occur, such as ascites, gastrointestinal bleeding, encephalopathy and jaundice, marking the transition to the decompensated phase. Due to the high progression rate of the disease, these complications tend to recur over time. The role of the nurse is increasingly recognized as instrumental in the management of patients with chronic liver disease, with positive impacts noted on patient education, patient independence and early detection of complications. Nevertheless, patient care was severely impacted in the year 2020 by the COVID-19 pandemic, profoundly changing the internal organisation of hospitals and the type of care we have been able to offer to patients. Therefore, the aim of this study was to evaluate the evolution of the activity of the advanced practice nurse clinic in liver cirrhosis, taking into account its recent implementation and the COVID-19 pandemic.
Method: We performed a retrospective observational descriptive study, analyzing the activity of the liver cirrhosis outpatient nurse clinic of the Hepatology Department of the Hospital Clinic in Barcelona. We included all patients visited by the specialized hepatology nurse over a period of 2.5 years, from 01/03/2019 to 31/08/2021. The data were analyzed considering five periods, each lasting 6 months. The first corresponds to the beginning of the implementation of the advanced practice nurse consultation, the third coincides with the beginning of the pandemic, the fourth and the fifth correspond to the consecutive months until August 2021.
Results: A total of 2398 visits were completed, 1772 (73.8%) by telephone and 626 (26.1%) in person. During the third period (01/03/2020–31/08/2020), face-to-face visits decreased by 30% compared to previous periods, while telephone visits increased by 50%. There was an 8-fold increase in the total number of visits in the last period compared to the first. This increase is due to an increase in telephone visits, a trend that was probably precipitated by the the COVID-19 pandemic, but that has persisted since.



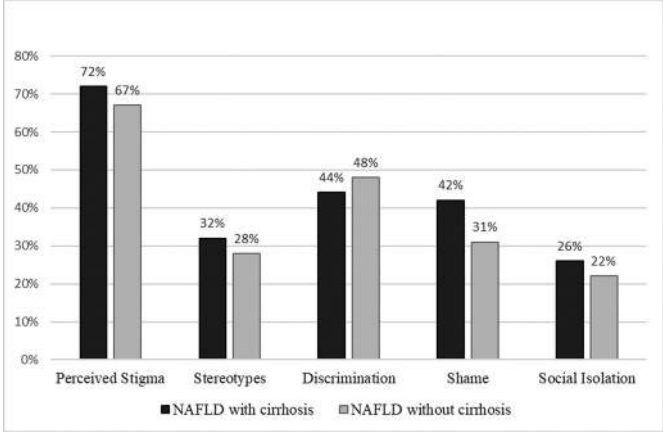
Conclusion: Despite the restrictions on face-to-face visits during the first months of the COVID-19 pandemic, visits in the advanced practice nurse clinic have continued to increase, and it has been possible to respond to patients' care needs. The specialized nurse plays a key role in the management of patients with cirrhosis and has been fundamental in responding to their needs particularly in the context of the COVID-19 pandemic.

FRI244

STIGMATIZATION IS COMMON IN PATIENTS WITH METABOLIC ASSOCIATED FATTY LIVER DISEASE AND CORRELATES WITH QUALITY OF LIFE

Marta Carol[1,2,3,4], Martina Perez[1,3,4], Elsa Solà[1,2,3,4], Marta Cervera[1,2,3,4], Sara Martinez[1,2,3], Adria Juanola[1,2,3], Carlota Riba[1,2,3], Ann Ma[1,2,3], Emma Avitabile[1,2,3], Laura Napoleone[1,2,3], Elisa Pose[1,2,3], Isabel Graupera[1,2,3], Maria Honrubia[4], Marko Korenjak[5], Ferran Torres[6,7], Pere Ginès[1,2,3,4], Núria Fabrellas[1,2,3,4]. *[1]Hospital Clínic de Barcelona, Liver Unit, Barcelona, Spain; [2]Institut d'Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS), Barcelona, Spain; [3]CIBEReHD-Centro de Investigación Biomédica en Red de Enfermedades Hepáticas y Digestivas, Madrid, Spain; [4]Universitat de Barcelona, School of Medicine and Health Sciences, Barcelona, Spain; [5]ELPA European Liver Patient Organization, Bruxelles, Belgium; [6]Institut d'Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS), Medical Statistics Core Facility, Barcelona, Spain; [7]Universitat de Barcelona, Biostatistics Unit, Faculty of Medicine, Barcelona, Spain*
Email: mcarol@clinic.cat

Background and aims: Stigmatization is a well-document problem of some diseases. Perceived stigma is common in alcohol-related liver disease and hepatitis C, but little information exists on stigma in patients with metabolic associated fatty liver disease (MAFLD). Aim of the study was to investigate frequency and characteristics of perceived stigma among patients with MAFLD.
Method: One-hundred and ninety-seven patients seen at the liver clinic were included: a study group of 144 patients with MAFLD, 50 with cirrhosis, and a control group of 53 patients with alcohol-related cirrhosis. Demographic, clinical, and laboratory data were collected. Quality-of-life was assessed by chronic liver disease questionnaire (CLDQ). Perceived stigma was assessed using a specific questionnaire for patients with liver diseases categorized in 4 domains: stereotypes, discrimination, shame, and social isolation.
Results: Perceived stigma was common in patients with MAFLD (99 patients, 69%) and affected all 4 domains assessed. The frequency was slightly higher, yet not significant, in patients with MAFLD cirrhosis vs those without (72% vs 67%, respectively; $p = 0.576$). In patients without cirrhosis perceived stigma was unrelated to stage of disease, since frequency was similar in patients with no or mild fibrosis compared to those with moderate/severe fibrosis (66% vs 68%, respectively). Among patients with cirrhosis, stigmatization was more common in alcohol-related vs MAFLD-cirrhosis, yet differences were only significant in two domains. In patients with MAFLD, perceived stigma correlated with poor quality-of-life, but not with demographic or clinical variables.



Conclusion: Perceived stigmatization is common among patients with MAFLD, is associated with impaired quality-of-life, and may be responsible for stereotypes, discrimination, shame, and social isolation, which may affect human and social rights of affected patients.

FRI245

Effect of e-health-based interventions on weight loss in patients with NAFLD: a systematic review and meta-analysis of randomized controlled trials

Ferya Celik[1], Merve Yuksel[1], Hicran Bektaş[1]. [1]*Akdeniz University, Internal Medicine Nursing, Antalya, Turkey*
Email: feryacelik@gmail.com

Background and aims: The only effective treatment is 7%–10% weight loss of non-alcoholic fatty liver disease (NAFLD). Lifestyle changes consisting of diet and physical activity are the cornerstone of weight loss. To synthesize the effect of e-health-based interventions on weight loss in patients with NAFLD.
Design: A systematic review and meta-analysis of randomized controlled trials following Cochrane methods.
Data resources: Systematic searches were conducted in Ovid, Science Direct, Web of Science, CINAHL Complete, PubMed, Cochrane Library, Scopus for studies published in English without year limitations up to January 2022.
Method: The risk of bias in eligible studies was evaluated by two researchers using the Cochrane Collaboration tool. Disagreements were resolved with the third researcher. The meta-analysis data were analyzed using the Comprehensive Meta-Analysis 3 program. PRISMA-2020 was used to report the findings.
Results: Four studies with 253 participants met the inclusion criteria. Lifestyle intervention enabled by e-health-based interventions was dietary and/or physical intervention in all studies. E-health-based interventions were applied by text messages, telephone/video calls, mobile applications. The overall effect of e-health-based interventions on weight loss was statistically significant. E-health-based interventions had a large effect on weight loss in patients with NAFLD (p = 0.03, Hedge's g = –0.91, 95% confidence interval [CI]–1.75 to –0.07) (Figure 1).

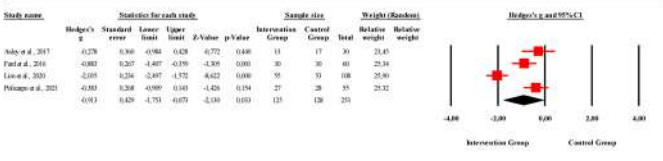


Figure 1: The results of the meta-analysis of the effect of e-health-based interventions on weight loss.

Conclusion: E-health-based interventions had a large effect on weight loss in patients with NAFLD. E-health-based interventions can assist in lifestyle change and weight loss in patients with NAFLD. In this way, liver-related complications can be reduced. Nurses can use affordable, practical and accessible e-health-based interventions to assist with weight loss in patients with NAFLD.
Keywords: e-health-based interventions, liver disease, NAFLD, nursing care, weight loss.

FRI246

Role of mutant alpha-1-antitrypsin in determining liver cell fate during embryonic development and in HCC origin

Francesco Annunziata[1]. [1]*TIGEM, Translational UNIT, Pozzuoli, Italy*
Email: f.annunziata@tigem.it

Background and aims: Alpha1-antitrypsin deficiency (AATD) is the most common genetic cause of liver disease in children. The toxic gain-of-function mutation of alpha-1-antitrypsin (ATZ) leads to its accumulation and retention in the endoplasmic reticulum (ER) of the hepatocytes resulting in liver injury and, later in life, in increased risk of hepatocellular carcinoma (HCC). Preliminary data suggest that ATZ starts to be expressed and accumulated as globules early during embryogenesis. However, it is not known whether ATZ may influence liver cell fate commitment and functionality during development. In addition, it has been speculated that globule-devoid (GD) hepatocytes may have a proliferative advantage over globule-containing (GC) hepatocytes and be responsible for HCC development and progression. However, it is not clear yet which cell has to be considered the cell of origin of HCC in AATD patients. Therefore, our aims are: *i*) study the effects of ATZ expression and accumulation in liver cells during development and differentiation to evaluate alterations in cellular identity that can be harmful during disease progression; *ii*) lineage trace liver cholangiocytes/progenitors (C/P) cells and mature hepatocytes to identify the cell of origin of HCC in AATD patients.
Method: To characterize the effects of ATZ expression on pathways demonstrated to be crucial for cell fate commitment, we performed RNA sequencing analysis at several stages over embryonic development on liver from the AATD mouse model (PiZ) and wild type (WT) mice. Histological analyses have been performed to confirm alterations in cell fate commitment.
To investigate the cell of origin of the HCC in AATD, we are performing lineage tracing experiments by using C/P- and hepatocyte- specific Cre-recombinase and reporter mouse lines. In addition, to support our *in vivo* experiments, we are investigating the capacity of both C/P cells and hepatocytes to generate liver organoids.
Results: We observed that pathways involved in cell differentiation/proliferation (e.g., Wnt and Hippo pathways) were altered in PiZ compared to WT livers. In addition, immunostainings for C/P- and hepatocyte- specific markers showed hybrid identity of liver cells in PiZ at P0. These results suggest that at very early stages during development ATZ accumulation impairs cell differentiation resulting in immature hepatocytes that are not able to play their crucial role in cell metabolism and homeostasis. Interestingly, we observed that PiZ derived hepatocytes from adult mice are not able to form cysts/organoids as the WT, while C/P form organoids faster than the WT. These results may suggest that C/P cells and not hepatocytes are involved in liver regeneration and are the cell of origin of HCC in PiZ mice.
Conclusion: In summary, our study evaluated the effects of ATZ expression and accumulation in liver cells during embryogenesis and

contribute to identify the cells responsible for HCC development in AATD.

FRI247

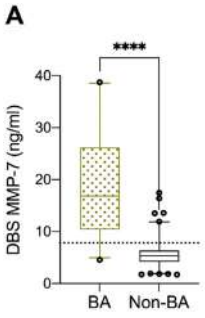
A pilot study of biliary atresia newborn screening using dried blood spot matrix metalloproteinase-7

Chee Seng Lee[1,2], Yen-Hsuan Ni[2], Huey-Ling Chen[2], Jia-Feng Wu[2], Hong-Yuan Hsu[2], Yin-Hsiu Chien[3], Ni-Chung Lee[3], Paul Wuh-Liang Hwu[3], Yu-Ju Chen[4], Yu-Lin Wang[5], Mei-Hwei Chang[2]. *[1]National Taiwan University Hospital Hsin-Chu Branch, Department of Pediatric, Hsinchu County, Taiwan; [2]National Taiwan University College of Medicine and Children's Hospital, Department of Pediatric, Taipei, Taiwan; [3]National Taiwan University Hospital, Department of Medical Genetics, Taipei, Taiwan; [4]Institute of Chemistry, Academia Sinica, Taipei, Taiwan; [5]Institute of NanoEngineering and MicroSystems, National Tsing Hua University, Hinschu, Taiwan*
Email: mhchangster@gmail.com

Background and aims: Timely diagnosis is a critical challenge and crucial to improved survival of biliary atresia (BA) patients. We aim to evaluate accuracy of Matrix Metalloproteinase-7 (MMP-7) protein as a marker for screening BA at 3 days old.

Method: Using dried blood spot screening for neonatal cholestasis patients (DBS-SCReNC), this study had enrolled pediatric patients with definite diagnosis of BA and compared with non-BA children. Children were recruited from September 12, 2018, to May 14, 2021 and followed-up until at least 6-month-old. The study was conducted in a tertiary hospital, National Taiwan University Children Hospital hepatology clinic, general pediatric clinic and well-child clinic. Stored newborn screen dried blood spot (DBS) at 3 day old of children enrolled in DBS-SCReNC study were retrieved from newborn screening (NBS) centers in Taiwan. There were 25 BA children and 107 non-BA children. MMP-7 on DBS was quantified in 2021 using a sensitive sandwich enzyme-linked immunosorbent assay.

Results: The age of the 25 children with BA (15 male, 10 female) was 3.3 ± 1.3 years, and age of 107 non-BA children (56 male, 51 female) was 2.2 ± 1.2 years old. Of the non-BA children, 3 children were diagnosed with choledochal cyst, 2 with liver hemangioma, 9 with cholestasis diseases and 93 children visited NTUH due to non-hepatobiliary diseases or for well-child visits. The time of BA patients received Kasai operation was at 43 ± 20 days old. The DBS MMP-7 level of BA children was significantly higher than that of non-BA children (19.2 ± 10.4 vs 5.6 ± 2.7 ng/ml, $p < 0.0001$). The DBS MMP-7 level showed good diagnostic accuracy with AUC of 93.7% (95% CI, 87.7%–99.7%). MMP-7 cut-off at 7.8 ng/ml has sensitivity of 92.0% (95% CI, 74.0%–99.0%), specificity of 92.5% (95% CI, 85.8%–96.7%), positive predictive value of 71.9% (95% CI, 56.3%–87.5%), negative predictive value of 98.0% (95% CI, 95.3%–100.0%) ($p < 0.001$).



B

	DBS MMP-7 > 7.8 ng/ml	DBS MMP-7 ≤ 7.8 ng/ml	Total No.
BA	23	2	25
Non-BA	9	98	107
Total No.	32	100	132

	% (95%CI)
Sensitivity	92.0 (74.0-99.0)
Specificity	92.5 (85.8-96.7)
Positive predictive value	71.9 (56.3-87.5)
Negative predictive value	98.0 (95.3-100.0)

Figure 1. (A) The newborn screening dried blood spot MMP-7 levels within 3-day-old in biliary atresia (BA) and non-biliary atresia (non-BA) children, (B) Diagnosis of BA using DBS MMP-7 at the cut-off of 7.8 ng/ml. (****: $p < 0.0001$).

Conclusion: In this study, DBS MMP-7 is able to distinguish BA from other conditions. This test allows us to screen BA children as early as 3 days old.

FRI248

In vitro rescue of nonsense variations by drug-induced readthrough of premature termination codons in progressive familial intrahepatic cholestasis type 2

Martine Lapalus[1], Elodie Mareux[1], Rachida Amzal[1], Marion Almes[1,2], Alice Thebaut[1,2], Mounia Lakli[1], Thomas Falguières[1], Sylvie Rebuffat[3], Laure Bidou[4,5], Olivier Namy[4], Emmanuel Jacquemin[1,2], Emmanuel Gonzalès[1,2]. *[1]Inserm, Physiopathogénèse et traitement des maladies du foie, UMR_S 1193, Université Paris Saclay, Hepatinov, Orsay, France; [2]Paediatric Hepatology and Paediatric Liver Transplant Department, National Reference Center for Rare Paediatric Liver Diseases, FILFOIE, ERN RARE LIVER, Assistance Publique-Hôpitaux de Paris, Faculté de Médecine Paris-Saclay, CHU Bicêtre, Le Kremlin-Bicêtre, France; [3]Muséum national d'Histoire naturelle, Centre national de la Recherche scientifique, Laboratory Molecules of Communication and Adaptation of Microorganisms (MCAM), UMR 7245 CNRS-MNHN, CP 54, Paris, France; [4]Institute for Integrative Biology of the Cell (I2BC), CEA, CNRS, Université Paris-Saclay, Gif sur Yvette, France; [5]Sorbonne Universités, Université Pierre et Marie Curie, UPMC, Paris, France*
Email: martine.lapalus@inserm.fr

Background and aims: Progressive familial intrahepatic cholestasis type 2 (PFIC2) is a severe hepatocellular cholestasis due to biallelic variations in *ABCB11* gene encoding the canalicular bile salt export pump (BSEP/ABCB11). Nonsense variations are responsible for the most severe phenotypes. We previously reported that gentamicin could partially rescue PFIC2-causing Abcb11 nonsense variations by inducing a pharmacological readthrough (RT). However, due to toxicity issues, there is a medical need to identify alternative therapies. The aim was to assess the ability of H7 (a mushroom extract), 2, 6 diaminopurine (DAP) and CDX5-1 (an aminoglycoside-induced readthrough potentiator) to induce RT of eight *ABCB11* nonsense variations (p.Y354X, p.R415X, p.R470X, p.I528X, p.R1057X, p.R1090X, p.Q1215X and p.E1302X) identified in PFIC2 patients.

Method: The RT levels of the premature termination codon (PTC) in their nucleotide environment were first quantified before and after treatment with aminoglycosides (G418, gentamicin), CDX5-1 combined to gentamicin, H7 and DAP using a dual reporter assay (luciferase/galactosidase) in NIH3T3 cells. Mutagenesis was used to reproduce nonsense variations in a plasmid encoding a rat Bsep-green fluorescent protein. The ability of the drugs to induce RT and to lead to the expression of a full-length protein was studied using immunodetection assays after transfection in human embryonic kidney (HEK293) and Can 10 cells. The function of the drug-induced full-length protein was studied by measuring the ^{3}H taurocholate transport in Madin-Darby canine kidney (MDCK) clones co-expressing Abcb11 and the rat sodium taurocholate co-transporting polypeptide (Ntcp/Slc10A1).

Results: In NIH3T3 cells, H7 and DAP induced a significant RT of p.R415X, p.R470X, p.R1057X, p.R1090X (UGA nonsense variations) while only H7 increased the RT levels of UAA nonsense variations (p.Y354X et E1302X). CDX5-1 increased the gentamicin-induced RT levels of p.R415X, p.R470X, p.R1057X and p.R1090X (UGA PTCs). H7 and DAP-induced RT levels were significantly higher than gentamicin-induced RT level. Compared to gentamicin alone, CDX5-1 combined to gentamicin, H7 and DAP treatments resulted in an increase of the full-length $Abcb11^{R1090X}$ protein expression in HEK293 and Can 10 cells, including at the canalicular membrane of Can 10 cells. Moreover, an additive effect was observed when H7 or DAP were combined to gentamicin. In MDCK cells, these tested drugs increased the bile acid transport of the full-length $Abcb11^{R1090X}$ protein.

Conclusion: Our data provide an *in vitro* proof of concept that CDX5-1 (combined to gentamicin), H7 and DAP induce a pharmacological RT leading to a full-length protein expression and increase bile acid transport of $Abcb11^{R1090X}$. These findings provide new insights for the treatment of patients with PFIC2 due to selected nonsense variations.

FRI249

Search for biomarkers and prognostic indicators of liver degeneration in glycogen storage disease type Ia

Roberta Resaz[1,2], Davide Cangelosi[3], Daniela Segalerba[1], Martina Morini[1], Maria Carla Bosco[1], Sabrina Paci[4], Annalisa Sechi[5], Daniela Melis[6], Maja Di Rocco[7], David Weinstein[8], Alessandra Eva[1].

Email: roberta.resaz@hsanmartino.it

Background and aims: Glycogen storage disease type Ia (GSDIa) is an inherited metabolic disorder caused by mutations in the enzyme glucose-6-phosphatase-alpha (G6Pase-alpha). Affected individuals develop renal and liver complications, including the development of hepatocellular adenoma/carcinoma and kidney failure. The purpose of this study was to identify potential biomarkers of the evolution of the disease in GSDIa patients. To this end, we analyzed the expression of exosomal microRNAs (Exo-miRs) in the plasma exosomes of 45 patients aged 6 to 63 years. We found that the altered expression of several Exo-miRs correlates with the pathologic state of the patients and might help to monitor the progression of the disease and the development of late GSDIa-associated complications. In addition, the Exo-miRs expression profile obtained from the patients was correlated with the liver-specific Exo-miRs profile obtained from a mouse model for GSDIa we have generated (LS-*G6pc*$^{-/-}$), to derive a common signature that could be specific and prognostic of liver degeneration and connected with biological pathways associated with tumor development and progression.
Method: We analyzed the expression of exosomal microRNAs (Exo-miRs) in the plasma exosomes of 45 patients aged 6 to 63 years. Plasma from age-matched normal individuals were used as controls. microRNAs were purified with exoRNeasy Serum/Plasma Midi kit (Qiagen) from plasma exosomes. TaqMan Array Human microRNA A cards (Thermo Fisher Scientific), enabling the quantification of 381 microRNAs each, were used to analyze exosomes-derived microRNA (ExomiR) expression.
Results: We found several deregulated Exo-miRs that correlate with the pathologic state of the liver patients. We identified microRNAs associated with liver disease and metabolic alterations of glucose and lipid pathways. We also found deregulation of microRNAs relevant in liver tumor development and, finally, several microRNAs whose altered expression has been associated with diabetic and chronic kidney diseases.
Interestingly, we found that deregulated Exo-miR profiles correlate with the altered proteome profile and the altered Exo-miR profile identified in LS-*G6pc*$^{-/-}$.
Conclusion: The altered expression of several Exo-miRs correlated with various pathologic liver states associated with the progression of the disease. Thus, our results provide evidence that the Exo-miRs profiles identified may relate to the specific affected organ gene expression and that the long-term consequences of GSDIa can be monitored through Exo-miRs assessment. In conclusion, our results may evolve into protocols to counteract both the progression of liver degeneration leading to HCA and HCC onset as well as kidney disease and failure using circulating microRNAs as biomarkers.

Background and aims: The homozygous Pi*Z mutation (Pi*ZZ genotype) in the *SERPINA1* gene results in severe alpha-1 antitrypsin deficiency (AATD) predisposing to lung and liver disease. While liver transplantation is currently the only treatment option for the liver, intravenous augmentation with purified human AAT is available for the lung. Since AAT administration displays hepatoprotective properties in mouse models of AATD and alcohol-related liver disease, we evaluated its effect on the liver phenotype in Pi*ZZ individuals.
Method: 259 non-augmented Pi*ZZ participants and 315 Pi*ZZ subjects on augmentation therapy were systemically recruited in 11 European countries and subjected to standardized clinical and laboratory evaluation as well as vibration-controlled transient elastography. Participants with hepatic comorbidities and significant alcohol consumption were excluded. Analyses were adjusted for age, sex, body mass index, diabetes mellitus, mean alcohol consumption, and recruitment center. In addition, liver biopsies of 35 non-augmented and 15 augmented Pi*ZZ subjects were evaluated.
Results: As expected, Pi*ZZ individuals on augmentation therapy presented with lower FEV1 values and increased COPD assessment test (CAT) scores. Despite higher age, augmented Pi*ZZ participants displayed lower liver stiffness measurements (LSM), had less frequently significant liver fibrosis (LSM ≥7.1 kPa), and significantly lower AST and GGT levels, as compared to Pi*ZZ individuals without augmentation.
Histological evaluation of liver biopsies revealed a lower fibrosis stage (Kleiner 2.0 vs. 4.0, p = 0.006) and lower presence of inflammation in augmented vs. non-augmented Pi*ZZ subjects (14.3 vs. 45.7 %, p = 0.043).

	Non-augmented n = 259	Augmented n = 315	p value (multivariable) *
Age (years)	50 ± 15	58 ± 10	<0.0001*
Women (%)	48.3	43.8	0.29*
BMI (kg/m^2)	24.4 ± 3.9	24.8 ± 4.5	0.96*
FEV1 (%)	78 ± 26	47 ± 18	<0.0001*
CAT (points)	12 ± 8	19 ± 7	<0.0001*
LSM (kPa)	6.5 ± 5.5	6.1 ± 3.9	0.042
LSM ≥7.1 kPa (%)	22.0	19.4	0.020
ALT (% ULN)	76 ± 45	77 ± 42	0.89
AST (% ULN)	74 ± 28	69 ± 26	<0.0001
GGT (% ULN)	92 ± 110	86 ± 74	0.021

Abbreviations: BMI, body mass index; FEV1, forced expiratory volume in 1 second; CAT, COPD assessment test; LSM, liver stiffness measurement; ALT, alanine aminotransferase; AST, aspartate aminotransferase; GGT, gamma-glutamyltransferase; ULN, upper limit of normal. *Univariate.

Conclusion: AAT augmentation therapy seems to have a beneficial association to the liver phenotype of Pi*ZZ individuals. Prospective studies are needed to confirm this observation.

FRI251

Impact of acute hepatic porphyria attack frequency on patient-reported outcomes: results from the porphyria worldwide patient experience research (POWER) study

Amy Dickey[1], Kristen Wheeden[2], Sue Burrell[3], Rocco Falchetto[4], Jasmin Barman-Aksözen[4,5], Alison Bulkley[6], Stephen Meninger[7], Stephen Lombardelli[8], Danielle Nance[9]. *[1]Massachusetts General Hospital, Boston, United States; [2]American Porphyria Foundation, Bethesda, United States; [3]Global Porphyria Advocacy Coalition, Durham City, United Kingdom; [4]Swiss Society for Porphyria, Zurich, Switzerland; [5]Stadtspital Waid and Triemli, Institute of Laboratory Medicine, Zurich, Switzerland; [6]Kantar Health, New York, United States; [7]Alnylam Pharmaceuticals, Cambridge, United States; [8]Alnylam Pharmaceuticals, Maidenhead, United Kingdom; [9]Banner Health, Gilbert, United States*

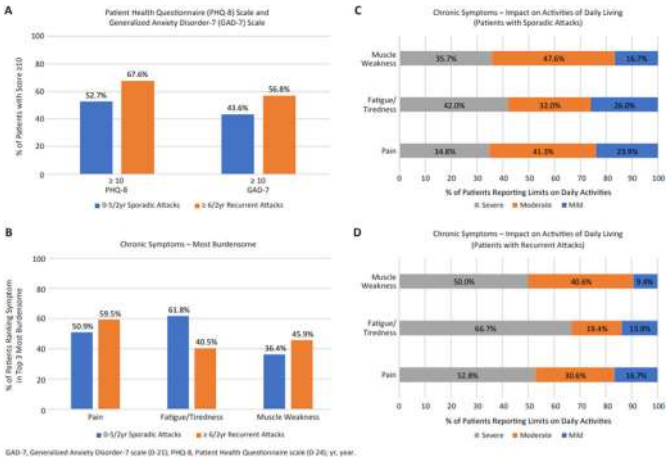
Background and aims: Acute hepatic porphyria (AHP), a group of rare genetic diseases of haem biosynthesis, is characterised by neurovisceral pain attacks. This study evaluated the impact of AHP on patient-reported outcomes (PROs) and disease burden in AHP patients who experience sporadic or recurrent attacks.
Method: Adult patients having >1 AHP attack within the past 2 years or receiving intravenous hemin and/or glucose for attack prevention were recruited from the United States, Italy, Spain, Australia, Mexico, and Brazil and administered an online survey from January 19 to April 26, 2021. Patients taking givosiran were excluded. Descriptive and bivariate analyses were performed to evaluate differences between patients with sporadic attacks (annualised attack rate [AAR], <6 within past 2 years) and recurrent attacks (AAR, ≥6). Attacks included those leading to a hospitalisation, an emergency room visit, an outpatient doctor visit, or self-management. PROs were assessed with the Generalized Anxiety Disorder-7 (GAD-7) scale (0–21) and the Patient Health Questionnaire (PHQ-8) scale (0–24). Burden of chronic symptoms was also reported.
Results: Of the 92 AHP patients who completed the survey, 55 (60%; mean age, 40.3 years) reported sporadic attacks and 37 (40%; mean age, 42.3 years) reported recurrent attacks. Most patients were female (sporadic, 92.7%; recurrent, 86.5%), and the most frequent diagnosis was acute intermittent porphyria (sporadic, 83.6%; recurrent, 59.4%). A majority of patients in the sporadic (52.7%) and recurrent (67.6%) attack groups reported a PHQ-8 score ≥10, indicating moderate to severe depression; 43.6% and 56.8% of patients in the sporadic and recurrent groups, respectively, reported a GAD-7 score ≥10, indicating moderate to severe anxiety (Figure 1A). Pain was reported as one of the top 3 most burdensome chronic symptoms in the sporadic (50.9%) and recurrent (59.5%) groups (Figure 1B). Of patients reporting their daily activities being limited by severe chronic symptoms, 83.3% of those in the sporadic (Figure 1C) and 90.6% in the recurrent group (Figure 1D) reported muscle weakness as a top 3 symptom having a moderate to severe impact.



Conclusion: While disease burden appeared greater for AHP patients experiencing recurrent attacks, both sporadic and recurrent group patients experienced a substantial impact on physical, mental, and emotional quality of life.

Email: antoon_billiet@hotmail.com

Background and aims: Polycystic liver disease (PCLD) can lead to extensive hepatomegaly, often associated with severe complaints. Indication for somatostatin-analogues (SA) or liver transplantation (LT) is in part based on subjective, patient-reported symptoms. In 2014 the PCLD-complaint-specific assessment (POLCA) score was developed as a self-report instrument to objectively capture the presence and severity of disease-specific complaints (Temmerman F, J Hepatol 2014).
The aim of this study was to validate the POLCA score and investigate the correlation with liver volume and need for volume-reduction therapy.
Method: A five year prospective multi-centric study in 21 hospitals in Belgium gathered a cohort of 266 PCLD patients. Sequential data including POLCA score, liver volumetry and the need for volume-reduction therapy were recorded. Participants were asked to complete the POLCA questionnaire, as available online

(https://www.uzleuven.be/polca). Liver volume was measured using CT-volumetry and adapted as height-adjusted total liver volume (htLV). Combined liver-kidney transplant patients (n = 9) were excluded.

Results: For 198 patients, serial POLCA scores were available. The study group consisted of young (54.8y ± 11.3), mostly female (83%) patients with predominant ADPKD (63%). Median time of follow-up was 48 months. Liver volumetry was available for 96 patients, showing a median htLV of 1967 ml.

There was a significant correlation (Spearman's rank) between POLCA severity of perceived illness (SPI) score and htLV (r = 0.48; 0.30–0.63). Patients who underwent LT had significantly higher scores on all POLCA subscales and htLV, compared to those not considered to be LT candidates (table 1). SPI score ≥16.5 predicted the need of LT with a sensitivity of 81.3% and a specificity of 88.9%.

Table: Comparison of POLCA subscales and htLV

POLCA	No LT (n = 171)	LT (n = 18)	*p* value
Severity of perceived illness	10.0 (6.0; 15.0)	23.5 (18; 26)	<0, 0001
POLCA	No LT (n = 122)	LT (n = 17)	
GERD complaints	2.0 (0.0; 5.0)	7.0 (4.5; 12.5)	<0, 0001
Impact on food intake	2.0 (0.0; 5.0)	6.0 (4.5; 9.0)	0, 0004
Perception of enlarged LV	6.0 (3.0; 8.0)	10.0 (7.5; 12.0)	<0, 0001
	No LT (n = 71)	LT (n = 16)	
htLV (ml)	1707 (1173; 2690)	3607 (2901; 4337)	<0, 0001

Longitudinal data showed a significant correlation between the change in SPI score and the change in htLV (r = 0.45; 0.26–0.61) and a significant reduction in htLV (−80 ml) by SA resulted in a decrease in SPI score (−6.0 vs +4.5).

Conclusion: This prospective study confirms the use of the POLCA score as a self-report instrument to assess the severity of PCLD-related symptoms. It is a clear reflection of both evolving symptom severity as well as objective changes in liver volume. Our findings highlight the potential of the POLCA score as a tool for longitudinal follow-up of PCLD patients and as a guide for clinicians when evaluating the need for medical or surgical intervention.

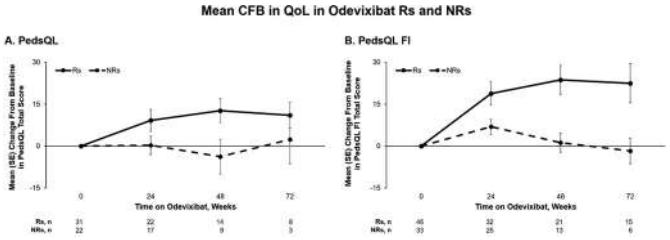
Improvements in quality of life in odevixibat responders and nonresponders: an analysis of pooled data from the PEDFIC 1 and PEDFIC 2 studies

Cara L. Mack[1], Chad Gwaltney[2], Quanhong Ni[3], Qifeng Yu[3], Velichka Valcheva[3], Lise Kjems[3], Patrick Horn[3]. [1]*Children's Hospital Colorado, University of Colorado School of Medicine, Aurora, CO, United States;* [2]*Gwaltney Consulting, Westerly, RI, United States;* [3]*Albireo Pharma, Boston, MA, United States*
Email: cara.mack@childrenscolorado.org

Background and aims: Patients with progressive familial intrahepatic cholestasis (PFIC) may have debilitating pruritus that can impact their and their families' quality of life (QoL). The phase 3 PEDFIC 1 and PEDFIC 2 studies evaluated the efficacy and safety of odevixibat, an ileal bile acid transporter inhibitor, in patients with PFIC. In these studies, odevixibat improved serum bile acids (sBAs), pruritus, and sleep; QoL was also evaluated as an exploratory endpoint. Here, using pooled data from these studies, we describe patient- and family-focused QoL changes in odevixibat responders (Rs) and nonresponders (NRs).

Method: In PEDFIC 1, children with PFIC received placebo or odevixibat (40 or 120 μg/kg/day) for 24 weeks. PEDFIC 2 is an ongoing 72—week extension study that enrolled patients from PEDFIC 1 or new patients; all patients in PEDFIC 2 receive odevixibat 120 μg/kg/day. Data from these studies were pooled from patients' first dose of odevixibat to a cut-off date of 4 December 2020. To assess QoL, caregivers of patients ≥2 years old completed the Pediatric QoL Inventory (PedsQL) and family impact (FI) questionnaires, which output total impact scores ranging from 0 to 100; higher scores indicate greater QoL. Treatment R was defined as sBA reductions of ≥70% or levels ≤70 μmol/L and/or ≥1-point drop from baseline in caregiver-reported pruritus score (on 0–4 scale) at last available assessment.

Results: In the pooled population, 49/84 (58%) met R criteria, and 35/84 (42%) were NRs. In Rs, mean age was 4.8 years and 57% were female; in NRs, mean age was 5.5 years and 37% were female. Among patients with available QoL data (PedsQL: R: n = 31, NR: n = 22; FI: R: n = 46, NR: n = 33), mean (SE) PedsQL and FI total scores at baseline indicated that both Rs (PedsQL: 56.6 [2.3]; FI: 49.9 [2.8]) and NRs (PedsQL: 55.0 [3.5]; FI: 48.9 [3.4]) had impaired QoL at least some of the time, on average. At week 72 in patients with available data, the mean (SE) change from baseline (CFB) in PedsQL total score was 11.0 (4.6) in Rs and 2.3 (8.6) in NRs; the mean (SE) CFB in PedsQL FI total score was 22.5 (7.0) in Rs and −1.7 (4.6) in NRs (Figure).



Conclusion: Odevixibat Rs and, particularly, their families, experienced QoL improvements that were sustained over time; QoL for NRs and their families was largely unchanged with up to 72 weeks of treatment. Further analysis of specific domains within PedsQL and FI that were most highly impacted in Rs is ongoing.

FRI254

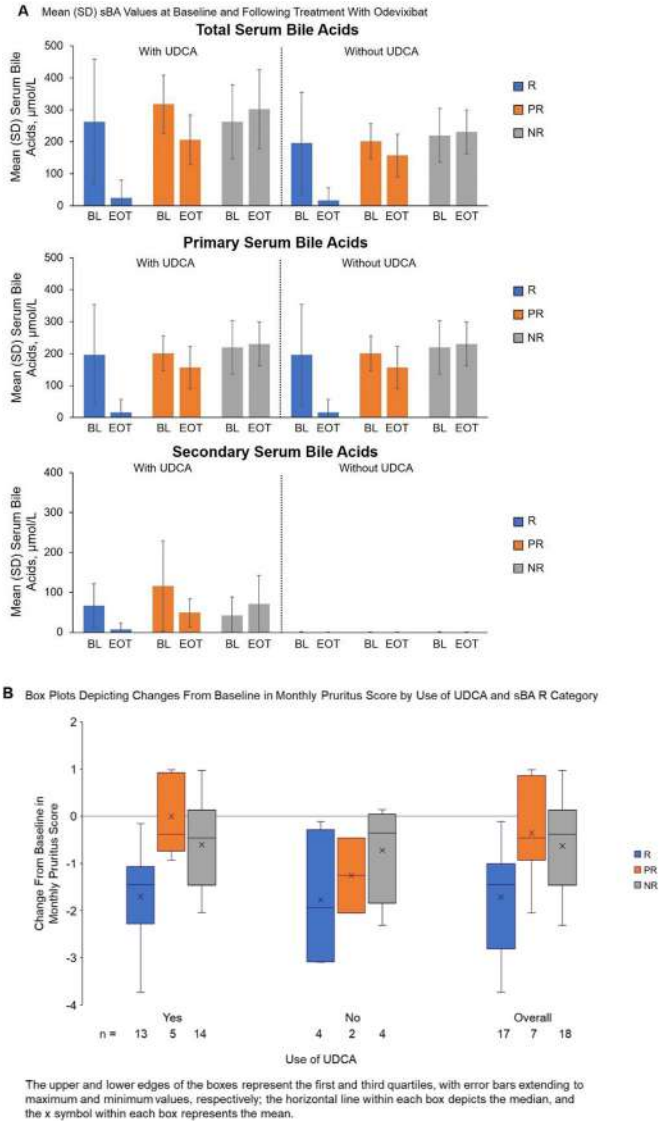
Total, primary, and secondary serum bile acid changes and pruritus improvement during odevixibat treatment in patients with progressive familial intrahepatic cholestasis

Henkjan J. Verkade[1], Folkert Kuipers[1], Quanhong Ni[2], Velichka Valcheva[2]. [1]*Department of Paediatrics, University of Groningen, Beatrix Children's Hospital/University Medical Centre Groningen, Groningen, Netherlands;* [2]*Albireo Pharma, Inc., Boston, MA, United States*
Email: h.j.verkade@umcg.nl

Background and aims: Children with progressive familial intrahepatic cholestasis who received odevixibat in the 24-week PEDFIC 1 study had significant reductions vs placebo-treated patients in total serum bile acids (sBAs) and pruritus. Here, we evaluated changes in sBAs and pruritus in patients from PEDFIC 1 categorised by sBA response (R) level and by factoring in ursodeoxycholic acid (UDCA) use.

Method: Patients eligible for PEDFIC 1 had elevated sBAs and significant pruritus at screening. Concomitant UDCA was allowed provided the patient's dose was stable. Three categories of patients among those randomised to odevixibat (n = 42) were analysed here: sBA Rs (ie, sBAs reduced ≥70% from baseline [BL] or levels ≤70 μmol/L), sBA partial Rs (PRs [ie, did not meet sBA R criteria but had sBAs reduced ≥30%), and sBA nonresponders (NRs [ie, did not meet either sBA R or PR criteria). Parameters evaluated included sBA composition (ie, total, primary, and secondary BAs, with UDCA concentration included as secondary BA) as measured by liquid chromatography–tandem mass spectrometry and pruritus as rated by caregivers (range: 0–4; higher scores indicate worse symptoms, with pruritus R defined as a ≥1-point reduction from BL); pruritus outcomes were also compared by whether patients had concomitant UDCA use and/or sBA R.

Results: Mean BL total sBAs were higher with vs without UDCA treatment in all 3 sBA R categories (Figure, A), which could be primarily accounted for by UDCA concentrations (66, 116, and 42 μmol/L, in sBA Rs, PRs, and NRs, respectively). During odevixibat treatment, sBA Rs (n = 17) had the largest decreases in total and primary sBAs, whereas sBA PRs (n = 7) had intermediate decreases, and sBA NRs (n = 18) had minimal changes. Among all odevixibat-treated patients, sBA Rs experienced greater mean reductions in monthly pruritus scores vs sBA PRs and sBA NRs (Figure, B). sBA PRs who used UDCA had smaller reductions in monthly pruritus score vs those who did not (Figure, B). Among pruritus Rs with UDCA use, the rate of sBA R, PR, and NR was 69%, 0%, and 31%, respectively; among pruritus Rs without UDCA use, these rates were 50%, 25%, and 25%.



Conclusion: UDCA treatment resulted in higher sBAs at BL, but this did not seem to affect sBA R to odevixibat. A sBA PR was not associated with a mean decrease in pruritus with concomitant UDCA use. All sBA R groups included patients for whom pruritus R did not correlate with sBA R.

FRI255

Changes in hepatic parameters, growth, sleep, and biochemical markers with odevixibat treatment across patients with various types of progressive familial intrahepatic cholestasis

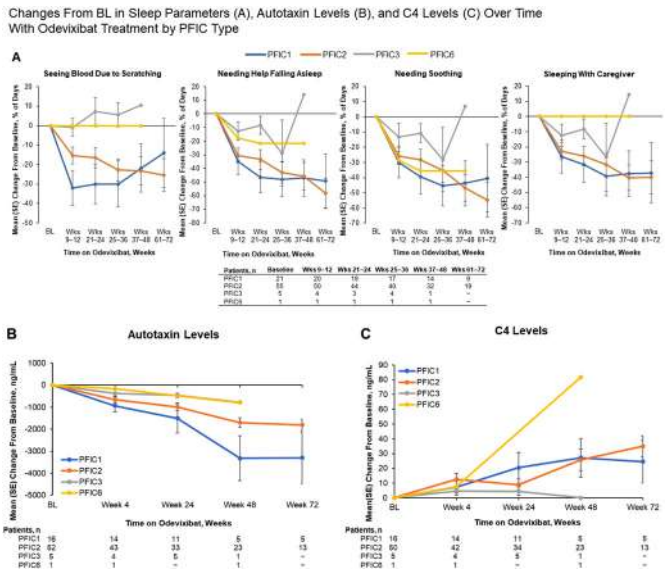
Background and aims: PEDFIC 1 and PEDFIC 2 evaluated the safety and efficacy of odevixibat, an ileal bile acid transporter inhibitor, in patients with progressive familial intrahepatic cholestasis (PFIC). Using pooled data from these studies, we analysed secondary and exploratory endpoints in patients with PFIC type 1 (PFIC1), 2 (PFIC2), 3 (PFIC3), and 6 (PFIC6).

Method: PEDFIC 1 was a 24-week, randomised, placebo-controlled study in children with PFIC1 and PFIC2. PEDFIC 2 is an ongoing 72-week extension study in patients with any PFIC type. This pooled analysis spans from patients' first dose of odevixibat to a cut-off of 4 December 2020. Assessments included changes from baseline (BL) in alanine aminotransferase (ALT), total bilirubin, growth, caregiver-reported sleep parameters, autotaxin, and 7α-hydroxy-4-cholesten-3-one (C4); data are presented to wk72 of odevixibat treatment for patients with PFIC1 and PFIC2 and to wk36 or wk48 for patients with PFIC3 and PFIC6 (who have less time on treatment vs patients with PFIC1 or PFIC2, who could have participated in PEDFIC 1).

Results: Of 84 patients in the pooled population (mean age, 5.0 years), 26% had PFIC1 (n = 22), 67% PFIC2 (n = 56), 6% PFIC3 (n = 5), and 1% PFIC6 (n = 1). With odevixibat, mean changes in ALT levels to wk72 in patients with PFIC1 (n = 6) and PFIC2 (n = 15) who reached this timepoint as of the data cut-off were −14 U/L and −85 U/L, respectively; mean changes in ALT levels to wk36 in patients with PFIC3 (n = 4) and PFIC6 (n = 1) were 67 U/L and 89 U/L. Patients with PFIC1 and PFIC2 with available data at wk72 had mean changes in total bilirubin of −6 μmol/L and −5 μmol/L, respectively; for patients with PFIC3 and PFIC6, mean changes to wk36 were 18 μmol/L and −83 μmol/L. Mean height and weight Z scores increased with odevixibat treatment across the various types of PFIC. Sleep parameters, C4, and autotaxin improved over time in almost all PFIC types (Figure). Across PFIC types, most treatment-emergent adverse events with odevixibat were mild or moderate in severity.



Conclusion: In patients with PFIC treated with odevixibat assessed to date, growth improved, autotaxin levels decreased, and C4 levels increased over time; changes in hepatic and sleep parameters in some PFIC types were more variable (eg, PFIC3, PFIC6), but these conclusions may be limited by the small size of these subgroups, particularly at later timepoints. Odevixibat was generally well tolerated.

FRI256

Analysis of quality of life, hepatic biochemical markers, and sleep in patients with progressive familial intrahepatic cholestasis who had a pruritus response with odevixibat treatment

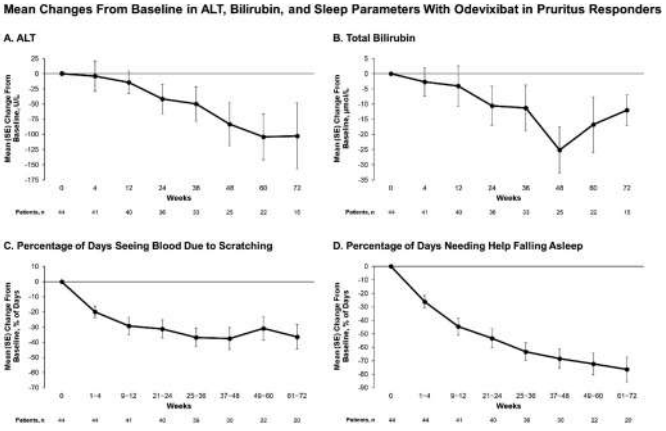
Email: t.grammatikopoulos@nhs.net

Background and aims: Patients with progressive familial intrahepatic cholestasis (PFIC), a group of rare paediatric cholestatic liver diseases, have debilitating symptoms including severe pruritus that can impact sleep and quality of life (QoL). In the phase 3 PEDFIC 1 and PEDFIC 2 studies, the ileal bile acid transporter inhibitor odevixibat reduced serum bile acids (sBAs) and improved pruritus and sleep in children with PFIC. Using pooled data from these studies, we examined secondary and exploratory efficacy endpoints and safety outcomes in patients who met criteria for a pruritus response with odevixibat treatment.

Method: PEDFIC 1 was a 24-week, randomised, placebo-controlled study in children with PFIC1 or PFIC2. PEDFIC 2 is an ongoing 72-week extension study in patients of with any PFIC type. Pruritus was rated using the Albireo observer-reported outcome instrument (range: 0–4). This pooled analysis spans from patients' first dose of odevixibat to a cut-off of 4 December 2020. We analysed sBAs, QoL (Pediatric QoL Inventory [PedsQL] and PedsQL family impact [FI] questionnaire; higher scores indicate improved QoL), alanine aminotransferase (ALT), total bilirubin, sleep parameters, and treatment-emergent adverse events (TEAEs) in patients with a pruritus response (ie, ≥1-point drop in pruritus score from baseline) following odevixibat treatment.

Results: Of 82 patients in the pooled population (of whom, 49% were female), 44 (54%) were pruritus responders. Of these 44 pruritus responders (mean age, 4.6 years), 24 (55%) were female; 23%, 68%, and 7% had PFIC 1, 2, and 3, respectively. Mean sBA levels were 247 µmol/L at baseline (n = 44) and decreased over time by 77% at weeks 70 – 72 in pruritus responders who reached this timepoint (n = 18). Mean PedsQL and FI total scores were 56 (n = 30) and 50 (n = 42) at baseline and increased by 11 (n = 8) and 24 (n = 14) at week 72, respectively, in pruritus responders. Mean ALT and total bilirubin levels decreased over time from 109 U/L and 40 µmol/L at baseline to 40 U/L and 18 µmol/L (n = 15) (Figure 1A, B), and sleep parameters improved over time in these patients (Figure 1C, D). There were no drug-related serious TEAEs.



Conclusion: Overall, patients with PFIC with a pruritus response following treatment with odevixibat experienced improvements in sBAs, QoL, hepatic biochemical markers, and sleep parameters that were sustained over time. Odevixibat was generally well tolerated.

FRI257

Longitudinal follow-up data on adults with classic, severe alpha-1 antitrypsin deficiency (Pi*ZZ genotype)

Malin Fromme[1], Samira Amzou[1], Barbara Burbaum[1], Philipp Striedl[2], Mattias Mandorfer[3], Elmar Aigner[2], Christian Trautwein[1], Pavel Strnad[1]. [1]*University Hospital RWTH Aachen, Medical Clinic III, Gastroenterology, Metabolic Diseases and Intensive Care, Aachen, Germany;* [2]*Paracelsus Medical University, First Department of Medicine, Salzburg, Austria;* [3]*Medical University of Vienna, Division of Gastroenterology and Hepatology, Vienna, Austria*
Email: mfromme@ukaachen.de

Background and aims: Homozygous Pi*Z mutation in the *SERPINA1* gene (Pi*ZZ genotype) confers a strong predisposition to lung and liver disease. Since the pace of liver disease progression and suitable prognostic factors remain unknown, we evaluated risk factors (i.e., demographics and lifestyle) and the predictive utility of non-invasive tests in the European Pi*ZZ liver cohort.
Method: 480 Pi*ZZ individuals without concomitant liver diseases or pathological alcohol consumption, decompensated liver disease, or hepatocellular carcinoma were evaluated by a standardized baseline clinical, laboratory, and elastographic assessment. 340 of them had a detailed follow-up interview at least 12 months after their baseline examination.
Results: During a median follow-up of 3.85 years, 23 Pi*ZZ individuals deceased. The main causes of fatality were lung and liver disease, each accounting for 8 deaths. 10/4 individuals received a lung/liver transplant, 3 additional Pi*ZZ individuals developed hepatic decompensation. Compared to the remaining Pi*ZZ participants, 15 individuals who developed a hepatic endpoint (liver transplant/death, or decompensated cirrhosis) presented with significantly higher body mass index (29.3 vs. 24.5 kg/m^2, p = 0.003), liver stiffness measurement (LSM, 14.0 vs. 5.2 kPa, $p = 6.3 \times 10^{-9}$), AST-to-platelet ratio index (APRI, 0.97 vs. 0.31 units, $p = 9.4 \times 10^{-7}$), fibrosis-4 index (FIB-4, 3.6 vs. 1.3, $p = 6.0 \times 10^{-6}$) and liver enzymes in their baseline examination. Multivariate Cox regression analysis revealed LSM ≥ 25 kPa (aHR 30.9, 95% CI 8.0–119.2, $p = 6.1 \times 10^{-7}$) and APRI≥1.0 units (aHR 39.6, 95% CI 10.1–154.7, $p = 1.2 \times 10^{-7}$) as strong predictors of liver-related mortality.

	Pi*ZZ without hepatic endpoint n = 325	Pi*ZZ with hepatic endpoint n = 15	P value (univariable)
Age (years)	57.5 [51.3–65.1]	57.9 [50.8–63.5]	0.828
Women (%)	47.1	20.0	0.040
BMI (kg/m^2)	24.5 [22.0–27.2]	29.3 [24.6–31.6]	0.003
Mean alcohol consumption (g/d)	2.5 [0.0–8.2]	0.0 [0.0–8.2]	0.276
LSM <15 kPa + PLT ≥ 150 (%)	88.9	33.3	8.4×10^{-10}
LSM ≥ 15 kPa (%)[1]	2.8	46.7	4.2×10^{-15}
LSM ≥ 25 kPa (%)[2]	1.2	33.3	3.7×10^{-14}
APRI ≥ 1.0 units (%)[3]	2.2	46.7	6.4×10^{-17}
FIB-4 ≥ 1.3 (%)[4]	50.6	93.3	0.001
ALT ≥ ULN (%)[5]	21.5	73.3	4.0×10^{-6}
AST ≥ ULN (%)[6]	13.2	66.7	2.4×10^{-8}
PLT <150/nL (%)[7]	9.5	60.0	3.1×10^{-9}

Abbreviations: BMI, body mass index; LSM, liver stiffness measurement; APRI, AST-to-platelet ratio index; ALT, alanine aminotransferase; AST, aspartate aminotransferase; PLT, platelet count; ULN, upper limit of normal. Adjusted Hazard ratios with 95%CI: [1]26.2 (7.4–93.2), [2]30.9 (8.0–119.2), [3]39.6 (10.1–154.7), [4]14.7 (1.6–135.9), [5]9.0 (2.4–33.5), [6]19.3 (5.2–71.8), [7]17.0 (4.6–62.0).

Conclusion: LSM and APRI accurately stratify Pi*ZZ individuals according to their risk of liver-related events. Thus, these non-invasive tests may facilitate risk stratification in clinical practice as well as patient selection for clinical trials.

Gender dependent neurological and hepatic improvement in Wilson disease patients treated with Trientine dihydrochloride: post hoc results from a prospective study

Karl Heinz Weiss[1], Isabelle Mohr[2], Carlot Kruse[3], Aurelia Poujois[4]. [1]*Salem Medical Centre, Department of Internal Medicine, Heidelberg, Germany;* [2]*Heidelberg University Hospital, Internal Medicine IV, Department of Gastroenterology, Heidelberg, Germany;* [3]*Univar Solutions B.V., Rotterdam, Netherlands;* [4]*Rothschild Foundation Hospital, Rare Disease Reference Centre "Wilson's Disease and Other Copper-Related Rare Diseases," Neurology Department, Paris, France*
Email: karlheinz.weiss@stadtmission-hd.de

Background and aims: Wilson disease (WD) is a rare autosomal recessively inherited disorder of the copper metabolism for which liver and neurological manifestations are most common. Trientine dihydrochloride (TETA-2HCl; trientine) is a well-established second line treatment for WD patients intolerant to D-penicillamine. Data on gender differences in WD progression for patients under trientine treatment are limited. The data presented are derived from a post hoc analysis of a single centre prospective study (NCT: 02426905).
Method: This study was a single centre, prospective study in adult WD patients on maintenance treatment with TETA-2HCl 300 mg (equivalent to 200 mg of trientine base) with a follow up of 12 months. All patients were previously treated with D-penicillamine. The neurological disease burden was measured by means of an investigator rated Unified Wilson's Disease Rating Scale (UWDRS) and corresponding changes from baseline to 6 months and 12 months. To investigate corresponding liver disease, the parameters analysed included alanine transferase (ALT) and aspartate transferase (AST) response.
Results: Of the 52 patients enrolled in the study, 51 (98.1%) patients were included in the full analysis set. The mean (SD) duration of trientine treatment was 13.1 (1.62) months (range: 3 to 15 months) with a mean (SD) dose of 1377.6 (368.78) mg per day (range: 150 to 2100 mg per day). The mean (SD) values for UWDRS-assessment were 11.3 (24.31) at baseline, 9.7 (23.85) at month 6 and 8.8 (22.86) at month 12. The decrease of UWDRS values over time was shown to be significant ($p < 0.01$) in a longitudinal regression model with log (UWDRS + 1) as the regressor. Analyses based on gender showed a mean UWDRS of 10.6 (n = 34) at baseline, 8.6 (n = 34) at 6 months and 8.0 (n = 34) for females and 12.6 (n = 17) at baseline, 11.9 (n = 16) at 6 months and 10.4 (n = 17) for males. The gender differences in the UWDRS decrease were significant ($p = 0.02$) in the longitudinal model extended by gender as a covariate. AST and ALT results were stable over time. There appears to be no gender difference in AST and ALT outcomes.
Conclusion: Post hoc analysis indicates that gender might have an influence on neurologic symptom regression and disease course in WD patients on trientine maintenance therapy. The trend of continuous improvement in neurological symptoms is mainly seen in female WD patients-even after long-term therapy. These findings warrant further prospective evaluation and have implications for future study designs.

FRI259

Efficacy and safety of odevixibat over 72 weeks of treatment in patients with progressive familial intrahepatic cholestasis

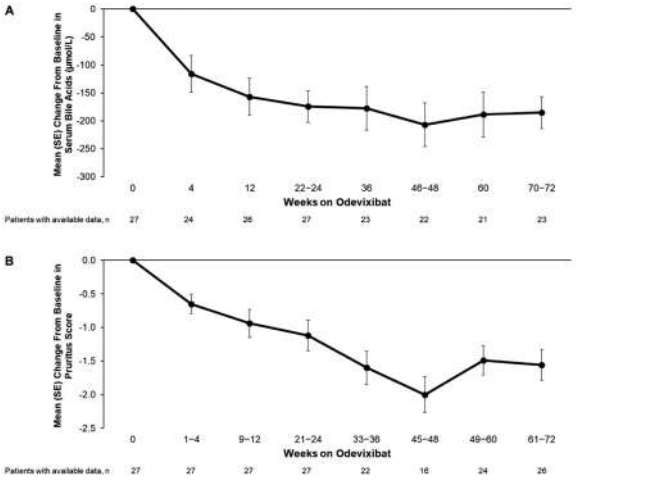
Email: richard.j.thompson@kcl.ac.uk

Background and aims: Progressive familial intrahepatic cholestasis (PFIC) is a group of paediatric cholestatic liver diseases characterised by disruption of bile production and transport, pruritus, and progressive liver disease. Here, using pooled data from two phase 3 studies in patients with PFIC (PEDFIC 1 and PEDFIC 2), we describe key long-term outcomes with odevixibat, an ileal bile acid transporter inhibitor, in the subgroup of patients treated with odevixibat for ≥72 weeks.
Method: PEDFIC 1 was a 24-week, placebo-controlled, double-blind study of odevixibat in children with PFIC1 or PFIC2. PEDFIC 2 is an ongoing, 72-week extension study in patients of any age with any type of PFIC. This pooled analysis spans from patients' first dose of odevixibat in PEDFIC 1 or PEDFIC 2 to a cut-off of December 4, 2020. The following outcomes are described over time in the subgroup of patients who had ≥72 weeks of exposure to odevixibat: serum bile acids (sBAs), caregiver-reported pruritus score (range, 0–4; higher scores indicate worse symptoms), laboratory parameters, growth, and safety.
Results: Of 84 patients in the pooled population, 27 were treated with odevixibat for ≥72 weeks (median [range], 92 [76–128] weeks). Of these 27 patients (mean age, 3 years), 52% were male, 70% had PFIC2, and 30% had PFIC1. At baseline, 82% of these 27 patients were using ursodeoxycholic acid (UDCA), 56% were using rifampicin, and 89% were using UDCA and/or rifampicin. Mean (SE) sBA levels at baseline were 291 (26) µmol/L, which decreased by −185 (28) at weeks 70–72 of odevixibat treatment (Figure). Mean (SE) pruritus score at baseline was 2.9 (0.1), which decreased by −1.56 (0.2) at weeks 61–72 (Figure). At week 72 of odevixibat treatment, decreases in alanine aminotransferase (−64.9 U/L), aspartate aminotransferase (−18.8 U/L), and total bilirubin (−5.4 µmol/L) were also observed; mean (SE) height and weight Z scores increased by 0.8 (0.1) and 0.5 (0.2), respectively. In this group of patients with ≥72 weeks of odevixibat treatment, 26 (96%) patients experienced any treatment-emergent adverse event (TEAE) and 52% experienced drug-related TEAEs. There were no TEAEs leading to discontinuation.

Change From Baseline in sBA Levels (A) and Pruritus (B) in Patients Treated With Odevixibat for ≥ 72 Weeks



Conclusion: Odevixibat was well tolerated and demonstrated durable clinical treatment benefits for up to 72 weeks in improving sBA levels, pruritus scores, hepatic parameters, and growth in patients with PFIC who were treated for at least 72 weeks.

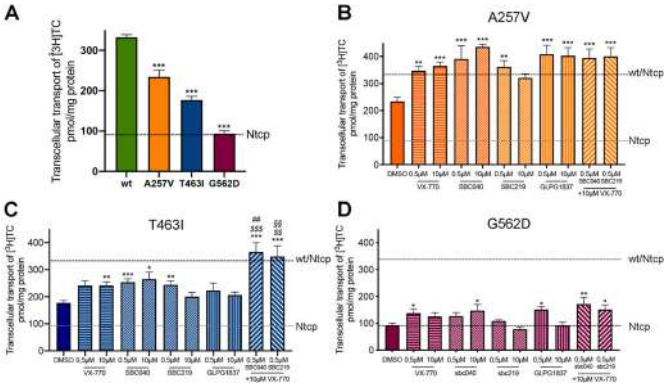
In vitro rescue of the bile acid transport function of some ABCB11 variants by CFTR potentiators: a targeted pharmacotherapy in progressive familial intrahepatic cholestasis type 2

Elodie Mareux[1], Martine Lapalus[1], Marion Almes[1,2], Pauline Adnot[1], Mounia Lakli[1], Amel Ben Saad[1], Jean-Luc Decout[3], Thomas Falguières[1], Isabelle Callebaut[4], Emmanuel Gonzalès[1,2], Emmanuel Jacquemin[1,2].
[1]Inserm, UMR_S1193 Physiopathogénèse et traitement des maladies du foie, Université Paris-Saclay, Hepatinov, Orsay, France; [2]Assistance Publique-Hôpitaux de Paris, Faculté de médecine Paris-Saclay, CHU Bicêtre, Paediatric Hepatology and Paediatric Liver Transplant Department, National Reference Center for Rare Paediatric Liver Diseases, FILFOIE, ERN RARE LIVER, Le Kremlin-Bicêtre, France; [3]CNRS, Département de pharmacochimie moléculaire, Université de Grenoble Alpes, Grenoble, France; [4]CNRS, UMR 7590, Institut de Minéralogie, de Physique des Matériaux et de Cosmochimie, Sorbonne Université, Muséum National d'Histoire Naturelle, Paris, France
Email: elodie.mareux@universite-paris-saclay.fr

Background and aims: ABCB11 is expressed at the canalicular membrane of hepatocytes and is responsible for biliary bile acid secretion. Variations in the *ABCB11* gene cause a spectrum of rare liver diseases. The most severe form is progressive familial intrahepatic cholestasis type 2 (PFIC2). Current medical treatments of these conditions have limited efficacy. Hence, the identification of alternative therapies is a major challenge.
Method: Three ABCB11 disease-causing variations identified in PFIC2 patients (A257 V, T463I and G562D) were studied by 3D structure

modelling. The variations were reproduced in a plasmid encoding a rat Bsep—green fluorescent protein. After transfection, the expression and the localisation of the variants were studied in HepG2 and Can 10 cells. Tritiated taurocholate ([^{3}H]TC) transport activity and the effect of Ivacaftor (VX-770, Kalydeco®), a clinically approved cystic fibrosis (CF) treatment, GLPG1837 in phase 2 CF clinical trials as well as SBC040 and SBC219, known as potentiators of CFTR were studied in Madin-Darby canine kidney (MDCK) clones co-expressing Abcb11 and the rat sodium taurocholate co-transporting polypeptide (Ntcp/Slc10A1).

Results: As predicted by 3D structure modelling, the three variants were correctly expressed at the canalicular membrane of HepG2 and Can 10 cells but had a defective function when studied in MDCK cells with a [^{3}H]TC transport activity ranging from 28 to 70 % of the one observed in MDCK cells expressing the wild type (wt) Abcb11 (Figure). Ivacaftor, GLPG1837, SBC040 and SBC219 increased the [^{3}H]TC transport activity of A257 V, T463I and G562D by 1.3 to 1.9-fold, allowing the [^{3}H]TC transport activity of the A257 V variant to reach the one of the wt Abcb11. Furthermore, an additive effect was observed for the T463I variant when ivacaftor was combined with SBC040 or SBC219.



Conclusion: Potentiator drugs could increase the pharmacopoeia available for patients with ABCB11 deficiency due to missense variations affecting the transport function and may delay or even suppress the need for liver transplantation in these patients.

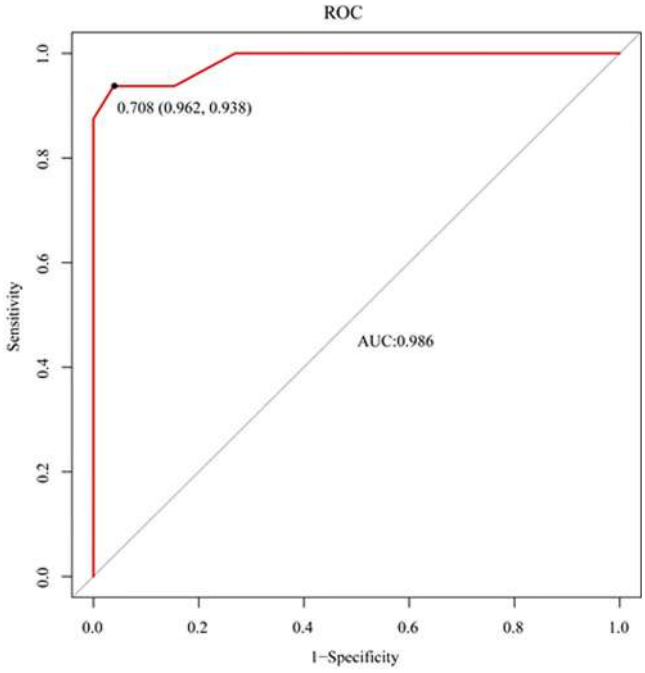
Plasma-based proteomics profiling of patients with Wilson's disease

Rui Hua[1], Jie Su[1], HaiTao Qi[2], Yonggeng Jiao[3], Lishuang Qi[2], Junqi Niu[1].
[1]*The First Affiliated Hospital of Jilin University, Hepatology, Changchun, China;* [2]*Harbin Medical University, College of Bioinformatics Science and Technology, Harbin, China;* [3]*Jilin Province FAW General Hospital, Anesthesiology, Changchun, China*
Email: huar@jlu.edu.cn

Background and aims: Wilson's disease (WD) is an inherited disorder resulting from abnormal copper metabolism. Current diagnostic criteria is inadequacy since biochemical indexes related to copper are unreliable and genetic testing is expensive. The study aimed to reveal WD-related proteomic alterations, from which protein based molecular diagnostic model was developed.

Method: We performed a LTQ-Orbitrap (LC-ESI-MS/MS) comparative quantitative proteomics analysis to reveal the differentially expressed proteins (DEPs) between 20 WD subjects (10 liver type and 10 brain type) and 10 healthy controls. Then, functional enrichment analysis of Gene Ontologyand (GO) and coexpression protein-protein interaction (PPI) network based on STRING database were performed to reveal the dysregulated biological functions. Next, eXtreme Gradient Boosting (XGboost) was used to construct an optimal classifier to distinguish liver- and brain-type WDs from healthy controls. Finally, 16 independent serum samples were collected, and detected by ELISA method to validate the disease-associated DEPs and the diagnostic classifier.

Results: Of all the identified DEPs of liver-type WD and brain-type WD, there were 62 common DEPs between the two types including 18 were up-regulated and 44 were down regulated. GO enrichment analysis revealed that the common DEPs were mainly involved in inflammation, coagulation cascade, protein transport and activation. And the coexpression PPI network showed that several DEPs interacted with many DEPs implicated in WD, such as Heparin cofactor 2 (SERPIND1), Transthyretin (TTR) and Coagulation factor IX (F9). Hereby, we constructed a classifier consisting of two down-regulated proteins (F9 and C4b-binding protein beta chain (C4BPB) with 100% accuracy. ELISA test validated the differential down-regulations of F9 and C4BPB in 16 independent WD samples when comapared with 26 healthy controls. In the independent samples, the area under the ROC curve (AUC) of the diagnostic classifier was 0.986, and its sensitivity and specificity was 93.8% and 96.2%, respectively.



Conclusion: Our study demonstrates for the first time that mass spectrometry proteomic combined with bioinformatics analysis of serum samples is a potential approach to identify candidate markers associated with WD. Further studies are warranted to evaluate the clinical utility of these biomarkers in patients with WD.

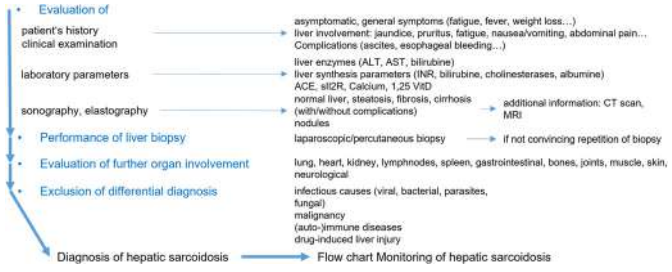
Management of hepatic sarcoidosis-multicentric approach

Janina Sollors[1], Andreas Teufel[2], Christoph Antoni[1], Matthias Ebert[2], Svetlana Hetjens[3], Yuquan Qian[1], Bernhard Schlevogt[4], Marcus-Alexander Woerns[5], Peter Galle[5], Cleo-Aron Weis[6], Raoul Bergner[7]. *[1]University Medical Center Mannheim, Department of Internal Medicine II, Mannheim, Germany; [2]University Medical Center Mannheim, Medical Faculty Mannheim, Heidelberg University, Department of Internal Medicine II, Mannheim, Germany; [3]Medical Faculty University Heidelberg, University Hospital Mannheim, Internal Medicine II, Germany; [4]University Medical Center Muenster, Department of Medicine B, Muenster, Germany; [5]University Medical Center Mainz, Department of Internal Medicine I, Mainz, Germany; [6]University Medical Center Mannheim, Medical Faculty Mannheim, Heidelberg University, Department of Pathology, Mannheim, Germany; [7]Ludwigshafen Medical Center, Division of Rheumatology, Department of Medicine A, Ludwigshafen, Germany*
Email: j.sollors@web.de

Background and aims: Sarcoidosis is systemic granulomatous disorder of unknown cause, characterized by activation of T-lymphocytes and macrophages involving multiple organs. Main manifestations are bihilar lymphadenopathy, pulmonary densification but also skin, joint and eye involvement. However, liver involvement may occur in up to 60% of all patients. As many patients experience only minor symptoms, a high number of undiagnosed cases must be assumed.
In order to successfully identify patients with hepatic sarcoidosis, a throughout characterization of these patients and their course of disease is necessary. However, the currently available evidence was mostly collected several decades ago.
Method: We collected 40 patients from four German centers to evaluate current treatment standards and course of disease. All of our patients underwent liver biopsy with histologically proven granulomatous hepatitis.
Results: Detailed characterization of these patients showed an overall benign course of disease. Treatment of these patients was very diverse with glucocorticoids for 1 year in 55% (22/40), 5–10 years in 18% (7/40), and permanently in 18% (7/40).
Other treatments included Disease-Modifying Anti-Rheumatic Drugs (DMARDs) of the conventional e.g. non-biological type (metotrexate (MTX), azathioprine (AZA), hydroxychloroquine (HCQ), sulfasalazine (SSZ), leflunomid (LEF)) in 53 %, of these, AZA 81%, MTX 46%, HCQ 10%, furthermore mycofenolatmofetil (MMF) in 10% and cyclophosphamide in 10% and biologicals in 8% of all patients in whom detailed documentation was available.



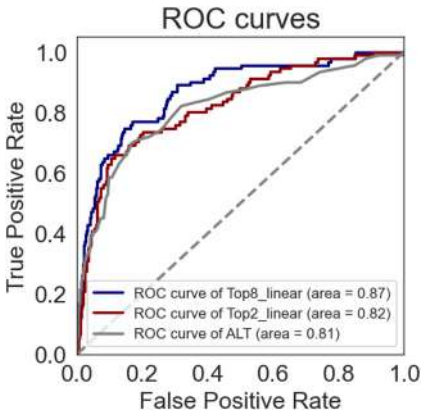
Conclusion: Despite these very diverse treatments, patients generally showed only slow progression of the disease. Only one patient died due to spontaneous bacterial peritonitis. None of our patients received liver transplantation. Based on our experience, we proposed a diagnostic work up and surveillance strategy as a basis for future, prospective register studies.

FRI263

Plasma proteomics identifies hepatic steatosis and sex differences in 2, 147 children and adolescents

Lili Niu[1,2], Sara Stinson[3], Louise Holm[3,4], Morten Lund[4,5], Cilius Fonvig[3,4], Helene Bæk Juel[3], Simon Rasmussen[1], Jens-Christian Holm[3,4,5], Torben Hansen[3], Matthias Mann[1,2]. *[1]University of Copenhagen, Novo Nordisk Foundation Center for Protein Research, Copenhagen, Denmark; [2]Max Planck Institute of Biochemistry, Department of Proteomics and Signal Transduction, Martinsried, Germany; [3]University of Copenhagen, Novo Nordisk Foundation Center for Basic Metabolic Research, Copenhagen, Denmark; [4]Copenhagen University Hospital Holbæk, The Children's Obesity Clinic, Department of Pediatrics, Holbæk, Denmark; [5]University of Copenhagen, The Faculty of Health and Medical Sciences, Copenhagen, Denmark*
Email: mmann@biochem.mpg.de

Background and aims: Childhood obesity constitutes a serious health challenge predisposing children and adolescents to cardio-metabolic- and liver diseases. In particular, the prevalence of pediatric non-alcoholic fatty liver disease (NAFLD) is estimated to be 36% in the context of obesity. Percutaneous liver biopsies are considered the gold standard for diagnosing NAFLD, but due to its invasive nature, its clinical application is limited in children. This study aims to use mass spectrometry-based proteomics to identify non-invasive biomarkers for early detection of hepatic steatosis in children and adolescents, taking into account sex-specific changes in plasma proteins during puberty.
Method: We included 2, 147 children and adolescents, aged 5 through 20, from an obesity clinic cohort and a population-based cohort in Denmark, in a cross-sectional study design. We acquired plasma proteomics data using the Evosep One liquid chromatography system coupled online to an Orbitrap Exploris 480 mass spectrometer. We performed adjusted correlation analysis to identify age-associated proteins. We then used unsupervised hierarchical clustering to identify clusters of protein trajectories changing with age. Liver fat percentage, as quantified by proton magnetic resonance spectroscopy, was available for 764 children (80% of whom were from the obesity clinic). Among these, 13.5% exhibited hepatic steatosis, defined as a liver fat percentage above 5%. We performed student's t-test (two-sided) to identify differentially abundant proteins between children and adolescents with and without hepatic steatosis. Receiver operator characteristics area under the curve (ROC-AUC) was used to identify potential biomarkers. We used the liver damage marker, alanine aminotransferase (ALT) (plasma concentrations) as a benchmark.
Results: On average, 394 proteins were quantified per sample. Among these, 70 proteins significantly correlated with age. Hierarchical clustering identified puberty-related clusters of protein trajectories, which exhibited sex-dependent differences, such as sex hormone-binding globulin. Student's t-test identified 84 significantly differentially abundant proteins, including 44 upregulated and 40 downregulated in the group with hepatic steatosis. The top 20 best-performing proteins which predicted hepatic steatosis, exhibited ROC-AUCs between 0.63 and 0.81. Combining the top two and top eight proteins resulted in an ROC-AUC of 0.82 and 0.87, respectively, which was superior to ALT.



Conclusion: Temporal plasma proteome trajectories reflect sex differences during puberty. A panel of eight proteins shows promising potential as a non-invasive diagnostic marker for hepatic steatosis in children and adolescents. This would need to be externally validated.

Pregnancy outcomes in women with Budd Chiari syndrome: a single center experience

Sagnik Biswas[1], Sabreena Sheikh[1], Manas Vaishnav[1], Anshuman Elhence[1], Naba Farooqui[2], Abhinav Anand[1], Shivanand Gamanagatti[3], Shalimar[1]. *[1]All India Institute of Medical Sciences, New Delhi, Gastroenterology and Human Nutrition, New Delhi, India; [2]Mayo Clinic, Rochester, Rochester, United States; [3]All India Institute of Medical Sciences, New Delhi, Radiodiagnosis, New Delhi, India*
Email: drshalimar@yahoo.com

Background and aims: Budd Chiari Syndrome (BCS) is associated with primary infertility and adverse pregnancy outcomes in affected females. Scant literature is available on the effect of an endovascular intervention on fertility and the outcome of future pregnancies in these patients.
Method: In this retrospective analysis, 121 female patients with BCS attending our liver clinic from 2017 to 2020 were included. Patients were categorized into three groups- no prior conception (group 1), any conception before disease onset but before completion of the family (group 2), and disease onset post completion of the family (group 3). Pregnancy outcomes (live birth, stillbirth, or abortions), mode of delivery, teratogenicity in the fetus, bleeding risk in the mother, decompensation of liver disease, or occlusion of the stent during pregnancy were assessed.
Results: BCS was diagnosed before any conception in 58 women (Group 1; median age: 22 years), during or after pregnancy but before completion of family in 39 (Group 2; median age: 27 years) and after completion of family in 24 women (Group 3; median age: 34 years). Median CTP and MELD scores of the whole cohort were 7, and 12 respectively. The primary infertility rate was 19.8% (24/121). In Group 1: 15 women with primary infertility underwent endovascular intervention with 5/15 (33%) women conceiving subsequently, resulting in 4 live births and 7 abortions. In Group 2: 5 women had developed BCS during pregnancy, and 11 in the postpartum period; 11/39 patients had a history of one or more abortions. Overall, 8/34 (23.5%) patients who underwent endovascular intervention could conceive, resulting in 4/8 (50%) live births. However, no patient developing BCS during pregnancy was able to conceive subsequently despite endovascular intervention. Group 3: No patient had any major complications during past pregnancies. Only one patient developed a TIPSS block in the postpartum period. The mode of delivery was vaginal in 88% of cases. No congenital anomaly/major bleeding episodes/decompensation/maternal mortality occurred.
Conclusion: Infertility is common in patients with BCS. Pregnancy is well tolerated in those with compensated liver disease. Normal vaginal delivery is a safe method of childbirth in these patients. No fetal malformations or major bleeding episodes were noted despite the use of oral anticoagulants.

Email: r.maan@erasmusmc.nl

Background and aims: Since the world-wide COVID19 vaccination efforts, several studies have reported on a rare side effect of ChAdOx1 nCoV-19 (AstraZeneca) with vaccine-induced immune thrombocytopenia and thrombosis (VITT). We aimed to collect consecutive new cases of splanchnic vein thrombosis (SVT) or Budd-Chiari Syndrome (BCS) following SARSCOV2 vaccination within the Vascular Liver Disease Group (VALDIG) network.
Method: This prospective international cohort study started on 01.05.2021 to include all incident cases of definite VITT (5/5 criteria: onset of symptoms 4–42 days post COVID vaccination, new thrombosis, platelets $<150 \times 10^9$, positive anti-PF4/HIT ELISA and D-dimer >4000 FEU) or otherwise vaccine-related (<5/5 criteria) SVT or BCS. Diagnosis was radiologically confirmed, and onset of symptoms was within 6 weeks after 1st or 2nd SARSCOV2 vaccination. Patients with malignancy or cirrhosis were excluded. Statistics were descriptive with frequency (%) and median (range) values. We are presenting our data until 01.11.2021.
Results: In total, 22 patients were included from 13 centers with median age 47 (21–66) and 46 % females. Median time from vaccination (AstraZeneca N = 11, Pfizer N = 9, Moderna N = 1, Johnson N = 1) to symptoms was 10 (2–32) and to diagnosis was 16 days (3–56). Patients presented with abdominal pain (86%), ascites (41%), fever (32%), elevated AST (35 U/L; 22–20100), ALT (45 U/L; 17–6928), INR (1.18; 0.88–5.1), D-dimer (6, 570 FEU; 530–63, 000), white blood cell count (10, 7×10^9/L; 4, 2–26) and decreased platelets

(160×10^9/L; 51–537). Four patients (18%) fulfilled criteria for VIIT. Location of thrombosis was portal vein in 18 (82%), hepatic vein (s) in 8 (36%), superior mesenteric vein in 15 (68%) and splenic vein in 9 (41%). Combined SVT-BCS was present in 18%, and concomitant cerebral/pulmonary/deep vein thrombosis was observed in 23%. An underlying prothrombotic cause was found in only 5 patients (23%; myeloproliferative neoplasm, antiphospholipid syndrome, protein S and antithrombin deficiency, Factor V Leiden). Eight patients (36%) were admitted to the intensive care unit. Eight patients had intestinal ischemia (36%) of whom 5 underwent bowel resection. Patients were treated with LMWH (64%), DOAC (18%) or VKA (59%). Six patients (3/6 with VIIT) received IVIG and six underwent recanalization procedures. One patient died (no VIIT).

Conclusion: Within 6 months, 22 new cases of BCS or SVT following SARSCOV2 vaccination were identified in 4 countries. Not all were AstraZeneca related. Although definite VIIT was relatively rare, most patients did not have another cause-in contrast to typical SVT or BCS. Also, these patients presented with extensive multiple site thrombosis and high rates of bowel ischemia and ICU admission. Concomitant extra-abdominal thrombosis, rare in typical BCS or SVT, was not uncommon. Further results are awaited from this expanding cohort.

FRI266

Abdominal wall hernia is a frequent complication of polycystic liver disease and associated with hepatomegaly

Thijs Barten[1], Roos-Anne Bökkerink[1], Wulphert Venderink[2], Tom Gevers[1,3], Richard ten Broek[4], J.P.H. Drenth[1]. *[1]Radboudumc, Department of Gastroenterology and Hepatology, Nijmegen, Netherlands; [2]Radboudumc, Department of Radiology, Nijmegen, Netherlands; [3]Maastricht UMC, Department of Gastroenterology and Hepatology, Maastricht, Netherlands; [4]Radboudumc, Department of Surgery, Nijmegen, Netherlands*
Email: trmbarten@gmail.com

Background and aims: Polycystic liver disease is related to hepatomegaly which causes an increased mechanical pressure on the abdominal wall. This may lead to abdominal wall herniation. We set out to establish the prevalence of abdominal wall hernia in polycystic liver disease and explore risk factors.

Method: In this cross-sectional cohort study we assessed the presence of abdominal wall hernias from polycystic liver disease patients with at least 1 abdominal computed tomography or magnetic resonance imaging scan. Abdominal wall hernia presence on imaging was independently evaluated by two researchers. Data on potential risk factors were extracted from clinical files.

Results: We included 484 patients of which 40.1% (n = 194) had an abdominal wall hernia. We found a clear predominance of umbilical hernias (25.8%, n = 125) while multiple hernias were present in 6.2% (n = 30). Using multivariate analysis, male sex (OR 2.727 p < 0.001), abdominal surgery (OR 2.575, p < 0.001) and disease severity according to the Gigot classification (Type 3 OR 2.853, p < 0.001) were identified as risk factors. Total liver volume was an independent PLD specific risk factor in the subgroup of patients with known total liver volume (OR 1.203, p = 0.001). Patients with multiple hernias were older (62.1 vs 55.1, p = 0.001) and more frequently male (22.0 vs 50.0%, p = 0.001).

Abdominal wall hernia	N (%)	Median diameter in mm (IQR) *
Overall	194 (100.0)	12 (7) n = 180
Epigastric	8 (4.1)	18 (6) n = 7
Umbilical	125 (64.4)	11 (6) n = 109
Cicatricial	3 (1.5)	26 (58) n = 3
Inguinal	67 (34.5)	13 (8) n = 53
Other hernia	4 (2.1)	10 (1) n = 2
Multiple hernias	30 (15.5)	13 (7) n = 30
Complex hernia*		
Yes	50 (25.8)	13 (6) (n = 43)
No	131 (67.5)	12 (7) (n = 109)
Unknown	13 (6.7)	Unknown

IQR = interquartile range. * N represents the number of hernias in which the diameter could be measured in two different directions (laterolateral and craniocaudal). ** Complex hernia according to Slater criteria; 13 cases were unknown because hernia repair was performed before the imaging.

Conclusion: Abdominal wall hernias occur frequently in polycystic liver disease with a predominance of umbilical hernias. Hepatomegaly is a clear disease-specific risk factor.

FRI267

MR-derived metrics have utility in identifying paediatric patients with stable autoimmune hepatitis

Piotr Pawliszak[1], Elizabeth Shumbayawonda[2], Jędrzej Sarnecki[1], Paulina Opyrchał[1], Kamil Janowski[3], Piotr Socha[3], Małgorzata Woźniak[3], Elżbieta Jurkiewicz[1]. *[1]Children's Memorial Health Institute, Radiology, Warsaw, Poland; [2]Oxford, Oxford, United Kingdom; [3]Children's Memorial Health Institute, Gastroenterology, Warsaw, Poland*
Email: pedro_pawliszak@yahoo.es

Background and aims: Paediatrics with autoimmune hepatitis (AIH) are monitored using liver biochemistry and histology, however, liver biopsy is invasive, expensive and carries the risk of pain and bleeding. Non-invasive imaging techniques (NITs) such as elastography and multiparametric MRI are showing increasing utility in supporting patient management and disease stratification, but have never been compared head-to head in children. The aim of this study was to investigate the utility of imaging markers to stratify those with stable from those with active disease and thus identify those who may not

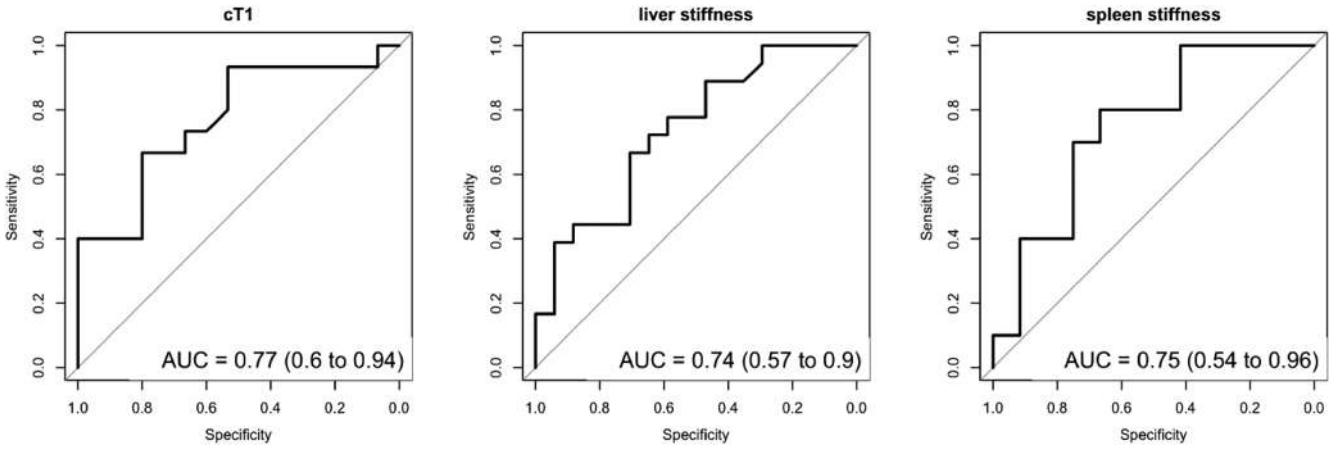

Figure: (abstract: FRI267): Diagnostic accuracy of individual imaging markers to identify AIH patients with stable disease.

require a biopsy or in whom a it may be delayed leading to improvement in cost-effectiveness of AIH patient management.
Method: N = 36 with biopsy-confirmed AIH (14 ± 3 years) and N = 16 healthy controls [HC; 14 ± 2 years) underwent non-invasive imaging to obtain liver stiffness (LS; magnetic resonance elastography), spleen stiffness (SS) and corrected T1 (cT1). All AIH patients also underwent a liver biopsy. Kruskal-Wallis test was used to compare imaging markers between HC and AIH patients, as well as those with active vs stable disease. Correlations between NITs and histological scores were performed using Spearman's rank tests. Stable disease was defined as having both lobular and portal inflammation ≤1 and Ishak fibrosis ≤2. Discrimination between active and stable disease using NITs was investigated using area under the receiver operator characteristic curve (AUC).
Results: Compared to HC, AIH patients had higher cT1 (827 ms vs 756 ms; $p < 0.001$) and LS (3 kPa vs 2.6 kPa; $p = 0.031$) but not SS (4.9 kPA vs 5.6 kPA, $p = 0.068$). N = 18 had stable disease and lower mean cT1 ($p = 0.011$), LS ($p = 0.017$) and SS ($p = 0.048$) compared to those with active disease. cT1 correlated with fibrosis ($r = 0.37$; $p = 0.049$), lobular ($r = 0.42$, $p = 0.025$) and portal inflammation ($r = 0.5$, $p = 0.005$), LS ($r = 0.42$, $p = 0.007$) and SS ($r = 0.43$, $p = 0.028$). LS correlated with fibrosis ($r = 0.47$, $p = 0.005$), SS ($r = 0.5$, $p = 0.004$) and portal inflammation ($r = 0.37$, $p = 0.029$). For predicting disease activity, cT1 had AUC:0.77 (0.6–0.94), SS had AUC:0.75 (0.54–0.96) and LS had AUC:0.74 (0.57–0.9).
Conclusion: Those with active AIH have higher fibroinflammation, liver and spleen stiffness compared to those with stable AIH. NITs have utility in identifying paediatric patients with stable disease who may not benefit from invasive liver biopsy. Further work exploring the utility of these NITs in the AIH clinical pathway is warranted.

FRI268

Development and validation of a novel ICP-MS method to quantify different copper species in human plasma from patients with Wilson disease

Tao Liang[1], Haiting Zhang[2], Linwen Zhang[1], Scott Moseley[1], Ping Guo[2], Meng Chen[1], Tracey Hall[1], Ming Li[1], Eugene Swenson[1], Wei-Jian Pan[1], Brian Meltzer[1], Ryan Pelto[1], Mark Ma[1]. *[1]Alexion, AstraZeneca Rare Disease, Boston, United States; [2]Frontage Laboratories Inc., Exton, United States*
Email: mark.ma@alexion.com

Background and aims: Wilson disease (WD) is a rare autosomal recessive genetic disorder. Functional mutation of ATP7B causes inadequate loading of copper (Cu) into ceruloplasmin (CP) and defective Cu excretion into bile, resulting in Cu accumulation in liver and other organs. Currently, WD treatment monitoring lacks reliable and fully validated bioanalytical methods. The calculated non-CP Cu (NCC) method assumes a CP-Cu:Cp ratio of 6:1 and can yield negative NCC values, which are biologically implausible. A direct assay is needed to monitor NCC, especially for patients treated with an investigational Cu-binding agent, ALXN1840 (bis-choline tetrathiomolybdate), which mobilizes tissue Cu, contributing to a non-bioavailable pool of circulating Cu.
Method: A novel method utilizing immunocapture of CP, followed by chelation and filtration to isolate different Cu fractions subject to ICP-MS analysis (Figure) was developed to fractionate and directly quantify multiple Cu species from human plasma. It permits measurement of CP-protein via LC-MS method and Cu species including CP bound Cu (CP-Cu), direct NCC, and labile bound Cu (LBC) via one workflow. Methods were validated for precision, accuracy, selectivity and stability following the FDA guidance for Bioanalytical Method Validation. A monoclonal anti-CP antibody was screened and selected for long-term assay use. Samples from healthy volunteers and from patients with WD were assessed for the Cu concentration in the CP fraction and the CP-Cu:Cp ratio.
Results: Full validations were successfully performed for each Cu fraction as well as CP-protein and showed a linear range from 5 to 1000 ng/ml (0.08–15.75 µM) for CP-Cu, direct NCC, LBC, and 5.00–800 µg/ml (0.03–5.97 µM) for CP-protein. The mean [95% confidence interval] for the CP-Cu:CP ratio was 4.68 [4.35, 5.00] in healthy volunteers and 4.09 [3.36, 4.82] in patients with WD, both being below the assumed ratio of 6.

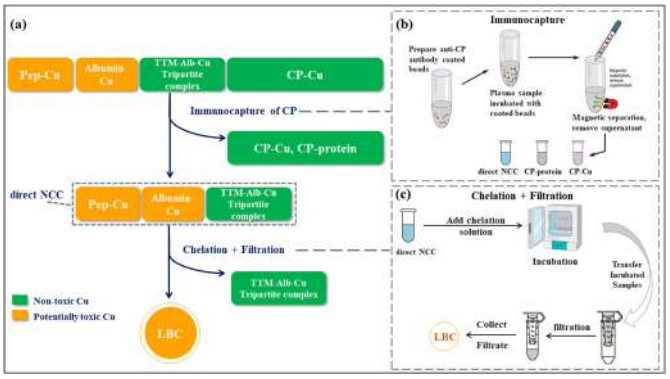

Figure: Method scheme. (a) overview of assay procedure (TTM, the active moiety of ALXN1840 which can bind to Cu and Albumin); (b) Immunocapture steps to obtain direct NCC, CP-protein, and CP-Cu fractions; (c) Chelation and filtration steps to isolate LBC.

Conclusion: Conventional calculated NCC is inaccurate and cannot be used for therapeutic guidance for WD. A novel method was developed that utilizes an immunocapture step and subsequent quantification of various fractions, including CP-Cu, direct NCC, LBC, and CP-protein. Validation data met defined acceptance criteria in terms of precision, accuracy, selectivity and stability. The assay is precise and reproducible and is valuable for accurate quantification of CP-Cu:CP-protein ratio, direct NCC and LBC, which may benefit WD therapy development.

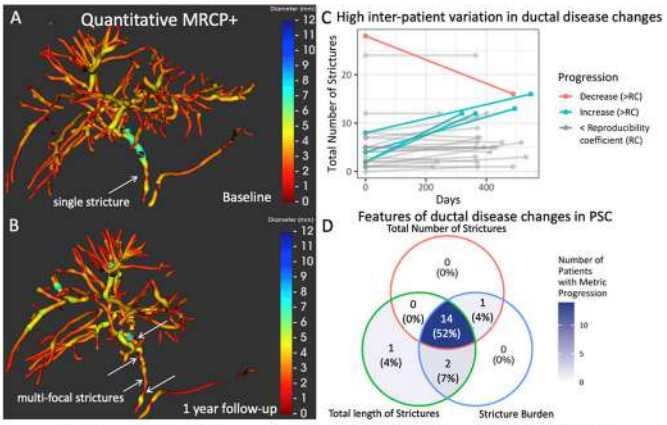
FRI269

Quantitative magnetic resonance cholangiopancreatography identifies features of ductal disease change in primary sclerosing cholangitis: a prospective observational cohort study

Palak Trivedi[1,2,3,4], Katherine Arndtz[1,2,3], Nadir Abbas[1,2,3], Alison Telford[5], Liam Young[5], Rajarshi Banerjee[5], Peter Eddowes[1,2,6,7], Kartik Jhaveri[8], Gideon Hirschfield[1,2,3,9,10]. *[1]National Institute of Health Research (NIHR) Birmingham Biomedical Research Centre (BRC), Centre for Liver and Gastrointestinal Research, University of Birmingham, Birmingham, United Kingdom; [2]Institute of Immunology and Immunotherapy, University of Birmingham, Birmingham, United Kingdom; [3]Institute of Applied Health Research, University of Birmingham, Birmingham, United Kingdom; [4]Liver Unit, University Hospitals Birmingham, Birmingham, United Kingdom; [5]Perspectum Ltd, Oxford, United Kingdom; [6]NIHR Nottingham BRC, University of Nottingham, Nottingham, United Kingdom; [7]Nottingham University Hospitals NHS Trust, Nottingham, United Kingdom; [8]Joint Department of Medical Imaging, University Health Network, University of Toronto, Toronto, Canada; [9]Toronto Centre for Liver Disease, University Health Network, Toronto, Canada; [10]Department of Medicine, University of Toronto, Toronto, Canada*
Email: liam.young@perspectum.com

Background and aims: Primary sclerosing cholangitis (PSC) is a chronic, progressive liver disease, characterised by multi-focal stricturing throughout the biliary tree. Biomarkers of parenchymal fibrosis are widely used for risk stratification. However there is a need to better characterise the extent of ductal disease involvement, its evolution over time, and the utility of quantitative biliary metrics for monitoring disease progression longitudinally. This study aimed to evaluate the utility of quantitative MRCP (MRCP+) in characterising

the extent of ductal disease involvement and monitor changes over 1 year in patients with stable biochemical and liver fibrosis readings.
Method: Patients (pts) with PSC were prospectively recruited for standardized heavily T2-weighted MRCP imaging on a Siemens Verio 3 T system at baseline and 1-year thereafter. Scans were processed with MRCP+ to enhance and quantify tubular structures using multi-scale Hessian analysis, gradient vector flow analysis, an intelligent path search algorithm and novel duct modelling algorithms. The 92 metrics generated by MRCP+ were reduced to 24 metrics expected to have clinical significance by an expert hepatopancreatobiliary radiologist. Changes in selected metrics over time were analyzed using linear mixed-effects models assuming patients as random effects.
Results: Non-cirrhotic pts with PSC were enrolled (n = 27; median age 45 yr, 70 % male) with a baseline PSC Mayo Risk Score −0.93 (IQR −1.2–0.3), ALP 142 iU/L (IQR 84–281), ALT 51 iU/L (IQR 26–91), and transient elastography score of 7.7 kPa (IQR 6.2–11.5). Intra- and extra-ductal involvement was seen in 92% and 36% pts with median modified Amsterdam cholangiographic score (MAS) of 2 (IQR 2–2) and 0 (IQR 0–2), respectively. Over a median 371-day follow-up (IQR 365–442), 67% pts manifested features of ductal disease change, evidenced by an increase in the total number of strictures (n = 15, p = 0.036, the total length of strictures (n = 17, p = 0.030), the total stricture burden (n = 17; p = 0.012), or a combination of metrics, which showed a significant dependence on time (Figure 1). Serum ALP (p = 0.51), ALT (p = 0.40), bilirubin (p = 0.39), liver stiffness values (transient elastography, p = 0.07) and biliary strictures assessed using MAS (p = 0.80) did not change significantly over time.



Sample MRCP+ biliary models from a representative PSC patient showing progression from a single stricture in the common bile duct (A) to multi-focal strictures at 1 year (B). Changes in the number of strictures for all patients (C) along with the number of patients showing changes in ductal disease through stricture metrics (D).

Conclusion: When quantitative imaging is reviewed one year apart, ductal disease change is apparent in the majority of pts with PSC, in the absence of significant variation in liver biochemistry or fibrosis values. Larger scale validation, alongside robust clinical outcome data, is essential to develop quantitative MRCP+ as a radiological toolkit for future PSC clinical trials.

FRI270

Age at diagnosis is associated with mortality in patients with hereditary hemochromatosis

Clare Foley[1], Sophie Diong[2], Fiona Colclough[2], John Ryan[2]. [1]*Beaumont Hospital, Hepatology, Gastroenterology, Dublin, Ireland;* [2]*Beaumont Hospital, Dublin, Ireland*
Email: foleyclare123@gmail.com

Background and aims: Hereditary Haemochromatosis (HH) a disorder of iron metabolism, is the most common autosomal recessive disorder in Caucasians, with Ireland having the highest prevalence in the world. Despite this, no formal screening exists for the condition. Treatment by therapeutic phlebotomy reduces morbidity and mortality.
Method: This study aimed to identify factors associated with mortality in HH patients attending a Hemochromatosis service.
Results: 1043 patients with HH were identified; 65% were male and 35% were female. Fatigue was the most common presenting complaint (37%), with family history (22%), incidental finding of raised iron studies (16%) and screening programs (13%) being other common causes of referral to the service. Homozygosity for C282Y was the most common HFE genetic mutation in this cohort (68%) with compound HFE heterozygosity accounting for 26%.
Median Ferritin at diagnosis was 332 ug/L (range 22–4655 ug/L). Mean Transferrin saturation at diagnosis: 68% (SD ± 17).
At the time of assessment, 0.03% (30/1043) of patients had died, with a median follow up time of 10 years (range 0.06–26). Of those that died, 70% were male, 43% were homozygous for C282Y, and 36% were compound heterozygotes. Median ferritin at diagnosis was 265 ug/L (dead) vs 264 ug/L (alive). Median age at diagnosis was significantly higher in those that died, 63.9 yrs vs 49.1 yrs for those alive at follow up (p < 0.0001). No significant difference was observed between groups based on gender, HFE genotype, or serum ferritin at diagnosis.
Conclusion: In a large sample of patients with patients with Haemochromatosis, age at diagnosis appears to be associated with death. Further investigation is warranted to detail the causes of death, and to determine whether HH screening in an at-risk population would reduce morbidity and mortality.

Email: LZANATTO@clinic.cat

Background and aims: Hepatoblastoma (HB), the main pediatric liver tumor, is a rare disease with few therapeutic options and increasing incidence. With chemotherapy being the only effective treatment, survivors are doomed to suffer serious side effects and new therapeutic options are urgently needed. The lack of suitable models has strongly compromised the investigation of this pediatric tumor. Here we hypothesize that patient-derived organoids may represent a novel tool to explore the mechanisms involved in HB development and to design new therapeutic options.
Method: Parental tumor (T) and non-tumor (NT) tissues collected from different Spanish hospitals were used to generate a collection of

patient-derived organoids. Organoids and primary tissues were characterized through: (i) RT-qPCR to analyze the mutation status; (ii) immunofluorescence analysis to evaluate the expression of HB biomarkers; (iii) transcriptmic studies by performing total- and small- RNA sequencing.
Results: Fourteen stable organoid lines have been successfully generated from T and NT tissues using a specific isolation protocol and have been grown in expansion media enriched in growth factors. T- and NT-organoids present differences in morphology and doubling time, with T organoids growing slower and in darker small structures compared to the NT organoids. Moreover, the T-organoids present the same mutations of the primary tissues. Additionally, T- and NT-organoids show different gene and protein expression of markers associated with hepatocyte- (HNF4) and progenitor-phenotype (KRT19, EpCAM), as well as HB-related genes, such as DLK1; and cytoplasmic localization of both GS and β-catenin. Interestingly, principal component analysis of total RNA and small RNA transcriptome revealed that HB organoids maintain general features of the tumor of origin. Finally, functional analysis has revealed conserved pathways between T- and NT-primary tissues and T- and NT-organoids, among them epigenetic regulation, proliferation, Wnt activaction and altered metabolism, indicating the maintenance of tumor features by organoids.
Conclusion: In conclusion, we have developed a new patient-derived *ex vivo* 3D system mimicking HB features, including specific gene and protein expression. Specifically, these data suggest that HB-derived organoids are a reliable model to investigate this poorly understood pediatric tumor towards the development of personalized treatments.

High rates of histological findings compatible with porto-sinusoidal vascular disease in patients with constantly elevated gamma-glutamyl transferase levels undergoing a liver biopsy

Nicola Pugliese[1], Luca Di Tommaso[1], Roberto Ceriani[1], Ludovico Alfarone[1], Elisabetta Mastrorocco[1], Maria Terrin[1], Virginia Solitano[1], Francesca Colapietro[1], Chiara Masetti[1], Ana Lleo[1], Luigi Terracciano[1], Alessio Aghemo[1]. [1]*Humanitas Research Hospital, Cascina Perseghetto, Italy*
Email: alessio.aghemo@hunimed.eu

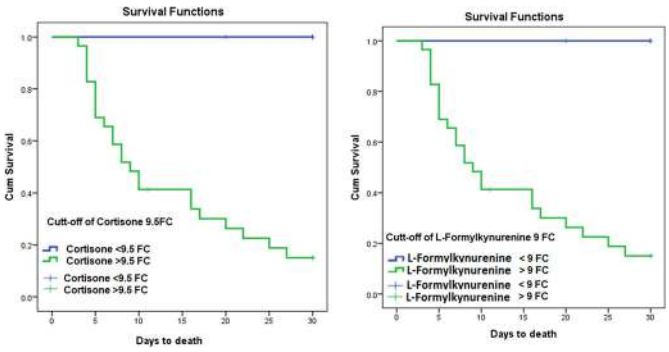
Background and aims: Isolated elevations in gamma-glutamyl transferase (GGT) levels are commonly found in patients referred to liver specialists, however their clinical impact is unknown. Data on the histological findings in these patients are scarce.
Method: All consecutive patients who underwent a liver biopsy between March 1st, 2015 and December 1st, 2020, in our Liver Unit for isolated and persistent (at least 2-fold ULN for three tests within 12 months) elevation of GGT value were retrospectively analyzed for clinical and histological features. Excluded were patients with concomitant ALT or AST elevation, intake of Hepato-toxic drugs or over the counter medications, alcohol intake >20 g/day and metabolic associated fatty liver disease (MAFLD). Data about age, gender, body mass index (BMI), comorbidities (including findings compatible with portal hypertension), smoking habit and disease severity (APRI and FIB-4), were collected. All liver biopsies were blindly reviewed by 2 experts in liver pathology.
Results: During the study period a total of 640 patients performed a liver biopsy. 29 patients (4.5%) met the inclusion criteria and were enrolled. Most of the patients were males (19/29, 65.5%) and their mean age was 49.7 ± 11.4 years (28–73). The mean BMI was 24.5 ± 2.97 (18.8–30) and only two patients presented FIB-4 suggestive of advanced liver disease. The histological findings were compatible with porto-sinusoidal vascular liver disease (PSVD) in 13/29 (45%) patients, hepatic sarcoidosis in 3/29, non-alcoholic steatohepatitis (NASH) in 3 and congenital hepatic fibrosis (CHF) in 3. Histology did not allow a definite diagnosis in 6/29 (21%) patients. Patients with PSVD were male in 10/12 (%), with a mean age of 47 ± 10.9 years (28–57), without any clinical signs of portal hypertension, in only one patient FIB-4 score was compatible with advanced liver disease. When comparing patients with PSVD to patients with any other liver etiology, we found no difference in gender, age, BMI, smoking habit, FIB-4, GGT, albumin and bilirubin values.
Conclusion: Liver histology in patients with isolated elevated GGT levels is useful as it allows to diagnose chronic liver conditions associated with a significant impact on survival. The high rate of patients with histological findings compatible with PSVD in the absence of signs of portal hypertension, requires careful assessment on how to manage these patients in the long term.

FRI273

Plasma metabolomics and machine learning characterizes metabolite signature capable of segregating patients with poor outcome in pediatric cirrhosis

Babu Mathew[1], Gaurav Tripathi[1], Vipul Gautam[2], Akhilesh Saini[1], Manisha Yadav[1], Nupur Sharma[1], Vasundhra Bindal[1], Bikrant Bihari Lal[2], Vikrant Sood[2], Rajeev Khanna[2], Jaswinder Maras[1], Seema Alam[2]. [1]*Institute of Liver and Biliary Sciences, Molecular and Cellular Medicine, New Delhi, India;* [2]*Institute of Liver and Biliary Science, Pediatric Hepatology, New Delhi, India*
Email: jassi2param@gmail.com

Background and aims: Pediatric cirrhosis is a life-threatening illness with high mortality up to 40%. Primary causes of cirrhosis in children are biliary atresia, genetic-metabolic diseases, autoimmune hepatitis, Wilson's disease and others. Development of cirrhosis in children's predisposes them to early development of sepsis and/or poor outcome. Early diagnosis of cirrhosis, sepsis and/or poor outcome in such patients may increase survival rate; therefore, development of new diagnostic methods is crucial. We investigated whether metabolomics and machine learning (ML) approaches could segregate patients with poor outcome (sepsis/mortality) in pediatric cirrhosis at baseline.
Method: Plasma metabolomics was studied using ultra-high-performance liquid chromatography and high-resolution mass-spectrometry to identify patients with poor outcome (sepsis/mortality) in pediatric cirrhosis at baseline. Altogether, 154 pediatric patients were analysed of them, 54 in derivative [40 Cirrhotics (C) and 14 Non-cirrhotics (NC)] and 100 in validation cohort [75 C, 25 NC]. Differentially expressed metabolites (DEM) with highest AUC and lowest mean decrease in accuracy were identified in cirrhotics, sepsis and were correlated with the severity (PELD score) and outcome (mortality) in pediatric patients.
Results: Of the 762 annotated features (metabolomic/biochemical/spectral databases), at baseline 120 plasma metabolites (Up-109, Downregulated-11) discriminated Cirrhotics from Non-Cirrhotics in pediatric patients (FC > 1.5, $p < 0.05$). Cirrhotics documented significant increase in Tryptophan metabolism, steroid hormone biosynthesis, purine metabolism and others ($p < 0.05$). Most importantly high L-Formylkynurenine (546 Folds), 3-Hydroxy-1H-quinolin-4-one (20 Folds), Cortisone (18 Fold), 12-Hydroxydodecanoic acid (12 Folds), L-Isoleucine (11 Folds), Hypoglycine-A (5 folds), Aminopropylcadaverine (5 Folds), 2, 3, 4, 5-Tetrahydrodipicolinate (3 Folds) and others segregated Cirrhosis from Non-Cirrhosis ($p < 0.05$). Additionally, plasma L-Formylkynurenine, 3-Hydroxy-1H-quinolin-4-one, 12-Hydroxydodecanoic acid, L-Isoleucine and Cortisone segregated sepsis and non-survivors (FC > 2, $p < 0.05$, AUC > 0.8). In validation cohort, baseline plasma L-Formylkynurenine; hazard-ratio (HR) of 3.5 (1.2–5.6), and Cortisone; HR:3 (1.5–5.2) showed high reliability [AUC > 0.95 (0.91–0.97)] for predicting non-survivors and correlated with PELD score ($r^2 > 0.5$, $p < 0.05$). L-Formylkynurenine (9.5 FC), and Cortisone (9 FC) cut-off reliably segregated non-survivors (log-rank $p < 0.01$) and showed <96% accuracy, <95% sensitivity and <95% specificity using Random Forest-based Machine-Learning model.



Conclusion: Plasma metabolite L-Formylkynurenine (>9.5 FC), and Cortisone (>9 FC) can reliably predict cirrhosis, sepsis and poor outcome in pediatric patients.

FRI274

Experience of cholestatic pruritus emphasized by patients with PBC: results from the PBC Foundation app survey

Chris Mitchell[1], James Neuberger[2], Terri Kim[3], Andrew Yeoman[4], Robert Mitchell-Thain[1]. *[1]PBC Foundation, Edinburgh, United Kingdom; [2]Birmingham Community Healthcare NHS Foundation Trust, United Kingdom; [3]Escient Pharmaceuticals, San Diego, United States; [4]Royal Gwent Hospital: Opthalmology, United Kingdom*
Email: chris@pbcfoundation.org.uk

Background and aims: Pruritus is a common symptom of cholestatic liver disease and treatment has limited efficacy. Patients with pruritus often suffer from intense itch, associated stress, and a negative effect on overall quality of life, including mental health issues.

Using PBC Foundation's App, we collected insights from Primary Biliary Cholangitis patients with pruritus, focussing on what may affect patient's daily experience of itch.

Method: An ongoing itch survey, live for over 6 months, was cross referenced with a previous survey exploring demographics and treatments. Due to cross-referencing, the number of respondents varies between questions. The main survey has 455 respondents. We defined mild, moderate and severe itch as at least 1, 4 and 7 respectively, on a numerical scale of 0 (no itch) to 10 (worse itch).

Results: Overall, similar to other studies 73% respondents suffer from itch. Over half of those itch daily and 3 in 4 patients have moderate to severe itch on their worst day.

In those aged <50 itch occurred more likely than in those >50 yr (77% vs 64%) and was more likely to be present daily (53% vs 44%). Itch occurred in the highest frequency in those within the first 5 yr of diagnosis (76%) with the lowest occurring in those >20 yr (45%).

Looking at disease modifying treatments: itch, daily itch, normal day severity and worst day severity for those on obeticholic acid were no worse than other therapies.

Information was only available for those taking cholestyramine, antihistamines or emollients and shows that itch is not present daily while on these therapies suggesting potential benefit. However itch on the worst day was almost exclusively severe and only partially ameliorated by therapy.

Conclusion: This study has a number of limitations, e.g. cross referencing different surveys taken at different times, and the risk of only itch-affected patients engaging. These surveys show that whilst some of the treatments may decrease the incidence of pruritus on a daily basis, severity of pruritus on a normal day is only slightly improved compared to the severity on the worst day. Pruritus can affect anyone within the PBC patient population and does so often and with profound effect.

Table: (abstract: FRI274).

Cancer risk in acute hepatic porphyria: a nationwide matched cohort study in 1, 245 individuals

Mattias Lissing[1,2], Daphne Vassiliou[3,4,5], Ylva Floderus[4,6], Jacinth Yan[7], Hannes Hagström[1,2], Eliane Sardh[3,4,5], Staffan Wahlin[1,2]. *[1]Karolinska University Hospital, Dept of Upper GI Diseases, Sweden; [2]Karolinska Institutet, Dept of Medicine, Huddinge, Sweden; [3]Karolinska University Hospital, Dept of Endocrinology, Sweden; [4]Karolinska University Hospital, Centre for Inherited Metabolic Diseases (CMMS), Porphyria Centre Sweden, Sweden; [5]Karolinska Institutet, Dept of Molecular Medicine and Surgery, Sweden; [6]Karolinska Institutet, Dept of Medical Biochemistry and Biophysics, Sweden; [7]Karolinska Institutet, Division of Biostatistics, Institute of Environmental Medicine, Sweden*
Email: mattias.lissing@ki.se

Background and aims: The acute hepatic porphyrias (AHP) are associated with a high risk of hepatocellular carcinoma (HCC). Patients with AHP-associated liver cancer typically do not have a well-defined underlying liver diseases or cirrhosis. Although the carcinogenic mechanisms are unknown, a strong association between HCC and biochemical AHP-activity with elevated porphyrin precursors 5-aminolevulinic acid (ALA) and porphobilinogen (PBG) has been established. The cancerogenic potential of ALA and findings of increased cancer risks in small cohort studies have led to an assumption that AHP is a risk factor for cancer in general. Risk estimates are however uncertain, and little is known about how biochemical activity affects the risk. Our aim was to assess the risks of non-hepatic cancers in correlation to biochemical activity in the largest AHP cohort assembled to date.
Method: All patients in the Swedish porphyria registry with verified AHP were included and matched 1:10 to reference individuals from the general population by age, sex and municipality. Data on incident cancers were collected from the national cancer and cause-of-death registries. Overall cancer incidence and incidence of a predetermined set of specific cancers were compared by incidence rate ratio. Data on biochemical disease activity based on maximal urinary PBG were used to assess the correlation between biochemical AHP activity and cancer risk.
Results: We identified 1, 245 patients with AHP between 1987 and 2015 with a median follow-up of 19 years. Health registries identified 150 AHP-subjects (12.2%) with non-hepatic cancer, similar to 1607 (13.3%) in the matched reference population (n = 12, 367). Preliminary results indicate that AHP patients have a higher risk of kidney cancer 0.8% (n = 10) vs. 0.2% (n = 27) in the matched reference population ($p < 0.001$), confirming findings in previous smaller cohorts. The risks of other common forms of cancer are however not significantly different in patients with AHP compared to the reference population. More detailed risk estimates regarding each cancer type, combined with subgroup analysis based on biochemical AHP-activity will be presented at the conference.
Conclusion: In addition to the increased risk of hepatocellular carcinoma, patients with AHP have an increased risk of kidney cancer. Preliminary results have not identified increased risks for other non-hepatic cancers.

FRI276

Innovative approach using clinical metagenomics for the diagnosis of non-elucidated liver disease

Anna Sessa[1,2], Christophe Rodriguez[3], Julien Calderaro[1], Slim Fourati[1], Giuliana Amaddeo[3], Jean-Michel Pawlotsky[1], Vincent Leroy[3]. *[1]APHP, Hopital Henri Mondor, Hepatology, Créteil, France; [2]Henri Mondor Hospital, Hepatology, Créteil, France; [3]APHP, Hopital Henri Mondor, Hepatology, Créteil, France*
Email: asessa1990@gmail.com

Background and aims: Diagnostic of acute and chronic liver diseases (CLD) may be challenging when main etiologies are absent. Liver histology usually provides hints but often fails to accurately identify the etiologic factor that can be toxic, genetic, auto-immune or infectious. Clinical metagenomics (CMg) is a new technique based on sequencing of nucleid acids allowing the identification of micro-organisms in an exhaustive manner. Our aim was to evaluate the performance of CMg for the diagnosis of non-elucidated liver diseases.
Method: All patients seen between 2019 and 2021 in a single tertiary centre for a non-elucidated liver disease were included. Inclusion criteria were elevated biochemical liver tests with no definite diagnosis after a comprehensive work-up including a liver biopsy. Patients with known CLD could be included if their features were not consistent with the etiology. The cut-off of 6 months discriminated acute and chronic profiles. Shotgun metagenomics was performed on each liver biopsy specimen with the aim to detect unexpected microorganisms.
Results: 48 patients (median age: 49, male: 58%) were included. Their clinical presentations consisted of acute cytolysis with or without jaundice (n = 9, 19 %, median ALT: 284 IU/l), acute cholestatis or mixed pattern (n = 19, 40 %, median ALP: 225 IU/L), chronic cytolysis (n = 8 , 16.7 %, median ALT 166 IU/L) and chronic cholestasis (n = 12, 25%, median ALP: 146 IU/L). 20 patients (42%) had immuno-suppression due to solid organ transplantation (n = 9, 19%), HIV infection (n = 6, 13%) and hematopoietic cancer (n = 5, 10%). Results of CMg were negative in 36 (75%), false positive due to contamination in 3 (6%), and positive in 9 (19%) patients. In 7 patients, CMg results allowed an etiologic diagnosis that changed the clinical management. Pathogens identified were adenovirus in one patient presenting with acute hepatitis, HCV in one seronegative liver-transplant recipient with recently acquired infection, HBV in one patient with unexplained cytolysis and low HBV DNA, HDV in 2 seronegative HBsAg (+) patients, Mycobacterium spp in an HIV-infected patient with unexplained granulomatosis, and Shingobium spp in a cirrhotic patient presenting with uncommon ACLF. Additionally, 2 patients had positive results that were considered as putative cofactors. Pathogens were EBV in one HIV-infected patient with tuberculosis, and TTV in one patient on immunotherapy for hematopoietic cancer. Taking the whole population, a definite diagnosis was eventually made after a comprehensive work-up combined to follow-up in 35 patients including 7 infectious diseases diagnosed by CMg (20%), and 13 patients remained with no definite diagnosis.
Conclusion: CMg performed on liver tissue is technically feasible and may bring etiologic diagnostic in patients with non-elucidated acute or chronic liver disease.

FRI277

Accumulation of molybdenum in major organs following chronic oral administration of bis-choline tetrathiomolybdate in Sprague Dawley rats

Kharmen Billimoria[1], Timothy Morley[2], Maria Estela del Castillo[3], Stanislav Stekopytov[3], Heidi Goenaga-Infante[1], John Foster[4]. *[1]LGC, National Measurement Laboratory, Teddington, United Kingdom; [2]Advotox, Harrogate, United Kingdom; [3]LGC, National Screening Laboratory, Teddington, United Kingdom; [4]ToxPath Sciences Ltd, Congleton*
Email: kharmen.billimoria@LGCGroup.com

Background and aims: Molybdenum (Mo) is an essential dietary element, functioning as a cofactor to activate essential enzymes including sulphite, aldehyde and xanthine oxidases. Bis-choline tetrathiomolybdate (BC-TTM) is under development as a therapeutic copper chelating agent for Wilson Disease with doses administered ranging from 15 to 60 mg/day (equivalent to 0.2 to 0.9 mg/kg/day in a 70 kg man). In a rat preclinical model (average bodyweight of 250 g), this would equate to a range of 0.8 to 3.6 mg/kg. The aim of this study was to determine if chronic administration of BC-TTM is associated with accumulation of molybdenum in major organs of a non-WD animal model and if tissue deposits of this metal are associated with haematological and biochemical abnormalities.

Method: Sprague Dawley (SD) rats were randomised to 3 groups of 12 [control, 15 mg/kg (low), 60 mg/kg (high)] and the BC-TTM was dosed by single oral gavage each day at volume of 5 ml/kg for 3 months. This drug exposure was equivalent to 3.75 to 15 mg/day in humans for nine years. Blood samples for clinical monitoring were taken at baseline, monthly and prior to euthanasia. Laser ablation inductively coupled plasma time-of-flight mass spectrometry (LA-ICP-ToF-MS) is an imaging technique used to confirm and spatially resolve the elemental distribution within a tissue. Tissue samples from major organs were prepared for conventional histopathology and LA-ICP-ToF-MS, to produce maps of Mo accumulation, quantified using a novel calibration strategy.

Results: Animals tolerated medication and no adverse clinical observations were made during the study. Dose dependent changes included increasing pigmentation of phagocytic and epithelial cells within each organ using conventional histopathological techniques were observed. However, data from LA-ICP-ToF-MS (Figure shown is from liver and brain) shows scaled spatial distribution of molybdenum deposits by concentration, increasing from blue to red. This accumulation was not associated with either biochemical or haematological abnormalities.

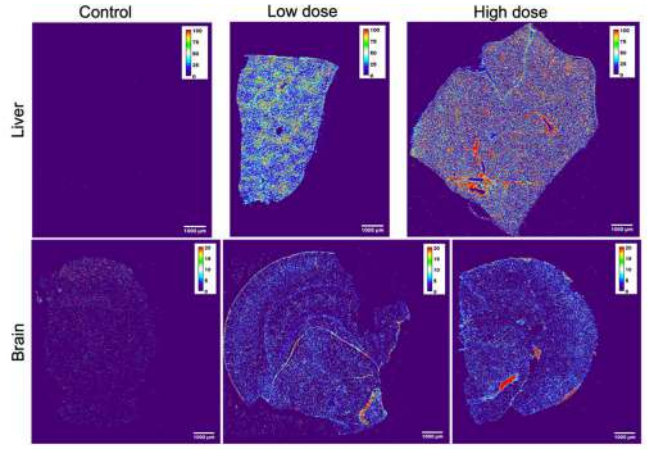

Figure1: LA-ICP-ToF-MS images showing molybdenum (Mo^{98}) in liver and brain tissue sections from the control (vehicle only), low drug dose (15 mg/kg/day) and high drug dose (60 mg/kg/day) groups. The colour scale bar indicates Mo^{98} concentration in femtograms molybdenum per pixel. The increase in colour intensity shows a dose dependence on the amount of molybdenum accumulation detected. Spatial resolution = 18 x 20 µm and the scale bar = 1000 µm.

Conclusion: LA-ICP-ToF-MS demonstrated dose dependent Mo accumulation in major organs and our findings show the limitations of conventional histopathology to characterise these deposits. SD rats exposed to BC-TTM for 3 months did not exhibit blood or biochemical abnormalities; this may provide false reassurance of molybdenum accumulation following chronic exposure.

FRI279

Liver fibrosis and fat by transient elastography in patients with Alpha-1 antitrypsin deficiency

Hassaan Yousuf[1,2], Tobias Maharaj[1,2], Daniel Fraughen[2,3], Noel G. McElvaney[2,3], John Ryan[1,2]. [1]*Beaumont Hospital, Hepatology, Dublin, Ireland;* [2]*Royal College of Surgeons in Ireland, Ireland;* [3]*Beaumont Hospital, Respiratory Medicine, Dublin, Ireland*
Email: Hassaanmyousuf@hotmail.com

Background and aims: Alpha-1 Antitrypsin Deficiency (AATD) is a common, inherited disorder which can lead to significant morbidity and mortality. The most severe form is seen in individuals with the homozygous PiZZ variant, with almost no circulating levels of AAT, while heterozygous (PiMZ; PiSZ) variants are associated with milder disease. While AATD effects on the lung have been extensively studied, its effects on the liver are poorly understood. Transient Elastography is widely used to stage liver disease by liver stiffness measurement (LSM), and provides a measure of hepatic steatosis, the Controlled Attenuation Parameter (CAP).

Our aim is to assess the prevalence of liver fibrosis and steatosis in AATD patients, using transient elastography.

Method: Clinical data along with TE measurement was obtained on adult patients attending a dedicated AATD at our centre over a 4-month period (July–October 2021). LSM cutoffs used were >7.1 kPa for fibrosis, and >10 kPa for advanced fibrosis/cirrhosis

Results: 80 patients were recruited; TE failed on 4 patients; 48 (60%) were female.

39/80 (48%) were homozygous PiZZ, 24/80 PiMZ (30%), 12 PiSZ and 4 were PiSS.

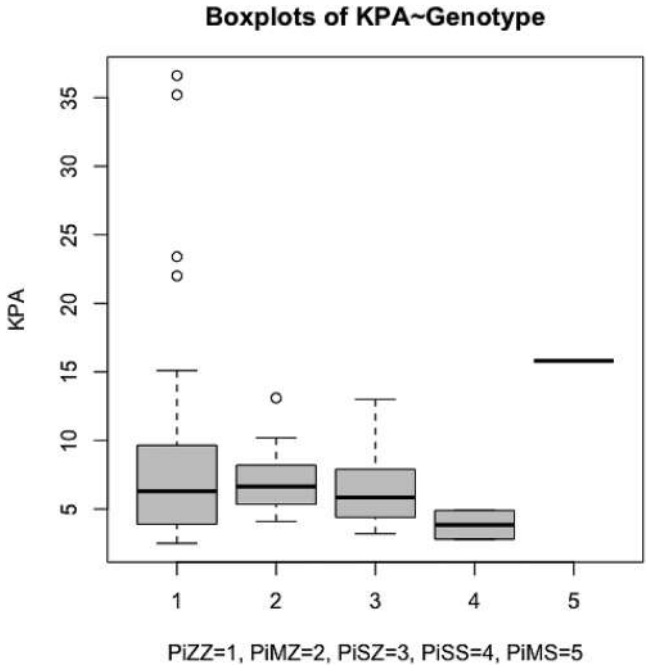
29/76 (38%) had LSM >7.1 KPa; of these 12 (16%) had LSM>10 KPa. Of the patients with advanced fibrosis, 8 were PiZZ, 2 were PiMZ and 1 each of PiSZ and PiMS. 16/39 (41%) PiZZ had evidence of fibrosis; 9 PiMZ (37.5%) had evidence of fibrosis, but only 2 had advanced fibrosis.

For PiZZ homozygotes, the median LSM was 6.3 kPa, and 6.25 kPa for heterozygotes (PiMZ/PiSZ); there was no significant difference in LSM between heterozygotes and homozygotes (Mann-Whitney U test, p = 0.84).

The median CAP for homozygotes PiZZ was 252 dB/m, and for heterozygotes (PiMZ/PiSZ) was 282.5 dB/m; there was no statistical significance between the 2 groups (Mann-Whitney U test p = 0.128)

6/12 (50%) individuals with advanced fibrosis were obese (BMI >30 kg/m^2). In total 17 out of 29 (59%) patients with evidence of fibrosis were either overweight or obese. Of the 29 individuals found to have liver fibrosis by TE, only 6 were known to have chronic liver disease, the rest (79%) were all new diagnoses.

Among the patients with PFTs available, fibrosis was evident on TE in 3/14 (21.4%) patients with GOLD stage IV COPD, 4/14 (28.5%) with GOLD stage II/III COPD, and 10/34 (29.4%) with GOLD stage 0.



Conclusion: In this study, a high rate of undiagnosed advanced liver fibrosis in AATD individuals was evident on routine screening using transient elastography. No association between lung and liver disease severity was noted, nor were there significant differences in liver stiffness or steatosis between AATD genotypes. Of note, a high prevalence of overweight/obesity was seen in those with liver fibrosis.

This study highlights the importance of screening AATD patients for liver fibrosis, and the potential clinical utility of transient elastography for these patients.

FRI280

Novel imaging feature in patients with porto-sinusoidal vascular disorder (PSVD)-radiological evaluation guiding diagnosis

Email: georg.semmler@meduniwien.ac.at

Background and aims: Porto-sinusoidal vascular disorder (PSVD) is a recently defined vascular liver disease often complicated by pre-sinusoidal portal hypertension (PH). Diagnosis is challenging and requires liver biopsy, and thus, PSVD is often misdiagnosed as cirrhosis. We investigated radiological features that are distinct between PSVD and cirrhosis.

Method: Demographic, clinical and laboratory parameters of patients with histologically-confirmed PSVD vs. cirrhosis vs. non-cirrhotic liver disease *and* available CT/MRI scans were retrospectively evaluated. The following imaging features were analyzed: Portosystemic collaterals, ascites, splanchnic vein thrombosis, spleen size, portal tract abnormalities, perfusion disorders, FNH-like lesions, changes in liver morphology and liver surface nodularity.

Results: 54 PSVD, 156 cirrhosis, and 41 non-cirrhotic patients were included. PSVD patients were younger (45.6 ± 16.3 vs. 56.4 ± 12.8, $p < 0.001$) and had lower HVPG (8 [IQR: 5–12]mmHg vs. 15 [IQR: 10–21] mmHg, $p < 0.001$), liver stiffness (8.4 [IQR: 6.8–12.2]kPa vs. 29.2 [IQR: 16.0–65.1]kPa, $p < 0.001$), and MELD (9 ± 3 vs. 13 ± 6points, $p < 0.001$). Specific clinical signs of PH according to PSVD-definition were similarly common in both groups. Intrahepatic portal tract abnormalities (52% vs. 15%; $p < 0.001$), splanchnic vein thrombosis (24% vs. 12%; $p = 0.025$) and FNH-like lesions (33% vs. 1%; $p < 0.001$) were significantly more common in PSVD patients. Hypertrophy of segment I (43% vs. 69%; $p < 0.001$), atrophy of segment IV (24% vs. 46%; $p = 0.004$) and nodular liver surface (19% vs. 87%; $p < 0.001$) were more common in patients with cirrhosis. In patients with adequate gadoxetic acid-enhanced MRI (PSVD: n = 25, cirrhosis: n = 95, non-cirrhotic controls: n = 41), we identified the imaging feature of 'periportal hyperintensity' in the hepatobiliary phase (HBP) as very specific for patients with PSVD: 52% in patients with PSVD vs. 1% in cirrhosis vs. 0% in non-cirrhotic controls; $p < 0.001$).

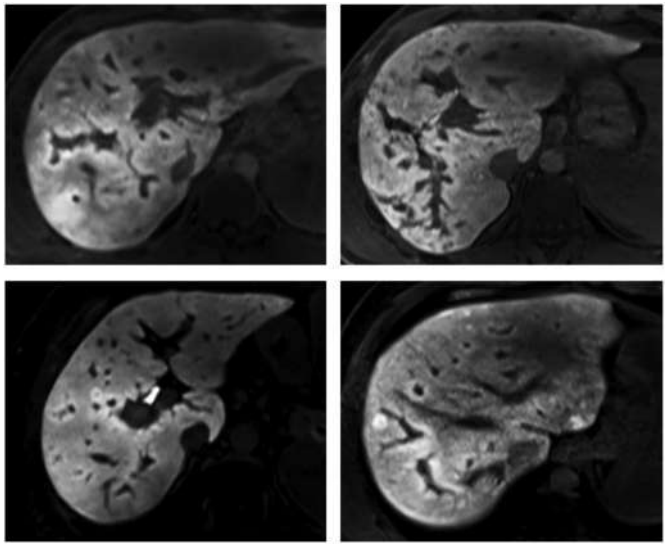

Figure: Periportal hyperintensity on the HBP in patients with PSVD.

Conclusion: Diagnosis of PSVD must be considered in younger patients presenting with clinical features of PH, portal tract abnormalities, splanchnic vein thrombosis, and FNH-like lesions on CT/MRI. 'Periportal hyperintensity' on HBP-MRI was identified as a very specific radiological feature of PSVD patients.

FRI281

Liver involvement in systemic light chain amyloidosis: is the heart guilty?

Margaux Charles[1], Amira Zaroui[2], Sebastien Mulé[2], Francoise Roudot Thoraval[3], Christophe Duvoux[1], Damy Thibaud[2], Edouard Reizine[3], Vincent Leroy[4]. *[1]Hôpital Henri Mondor, Hepatology, Créteil, France; [2]Hôpital Henri Mondor, Cardiology, Créteil, France; [3]Hôpital Henri Mondor, Radiology, Créteil, France; [4]Hôpital Henri Mondor, Hepatology, Créteil, France*
Email: vleroy.home@wanadoo.fr

Background and aims: Systemic light-chain (AL) amyloidosis is a systemic disease caused by the deposition in organs of unstable monoclonal light chains secreted by clonal plasma cells. Prognosis is mainly related to the degree of cardiac involvement. Elevated liver enzymes and/or hepatomegaly are frequently observed and may be related to deposition of amyloid fibrils in the liver, congestive hepatopathy or confounding factors such as DILI. Diagnostic approach for hepatologists can be extremely challenging, with certain reluctance to perform liver biopsies. The aim of our study was to describe in a large cohort of patients with cardiac AL amyloidosis the characteristics of liver abnormalities, their relationships with cardiac status and their potential prognostic value.

Method: All patients seen from 2008 and 2021 in a single national reference centre for new diagnosis of histologically proven AL amyloidosis with cardiac involvement and available longitudinal liver features were included. Clinical, biological and echocardiographic data were collected. Liver imaging mainly consisted of MRI, or when not available CT-scan. All images were read by a single expert radiologist with specific attention to liver morphometry and signs of congestion.

Results: 200 patients (median age: 66 years, male: 61%) were included. The majority of them had severe heart failure (stage III of Mayo Clinic). Chemotherapy was given in 90% of patients. At baseline, 98 (49%) patients had elevated liver enzymes greater than 1.5 fold the upper limit of normal. Liver abnormalities were associated to higher Pro-BNP and Troponin serum levels. Enzyme patterns were cholestatis, cytolysis and mixed in 81%, 4% and 15%, respectively. Liver abnormalities were significantly associated with higher concentrations of troponin and Pro-BNP. Liver imaging showed hepatomegaly

in 31% of cases, sinusoidal dilation in 43% and hepatic vein dilation in 26%. Compared to patients with normal liver tests, the cholestatic pattern group had more often hepatic vein dilation (40% vs 12%, $p < 0.006$) and sinusoidal dilation (57% vs 30%, $p < 0.04$), these features being significantly associated with lower cardiac flow and echocardiographic features of right ventricular dysfunction. There was no association between liver abnormalities and left ventricular ejection fraction. A liver biopsy was performed in 11 patients and showed amyloid deposits in 9 and features of congestion in 5 patients. During the follow-up, a significant increase of liver tests was observed after 3 months. A cytolysis pattern was associated with a peak of Pro-BNP and short-term mortality.
Conclusion: Liver involvement is frequent in patients with cardiac AL amyloidosis and seems mainly related to right cardiac dysfunction. The potential role of hepatic amyloid deposits is under investigation by scintigraphy and final results will be presented.

FRI282
The role of the mechanistic target of rapamycin (mTOR) in Alpha-1 Antitrypsin Deficiency
Lisa Bewersdorf[1], Pavel Strnad[1], Annika Gross[1], Yizhao Luo[1], Thorsten Cramer[2]. [1]*University Hospital RWTH Aachen, Medical Clinic III, Aachen, Germany;* [2]*University Hospital RWTH Aachen, Clinic for General, Visceral and Transplant Surgery, Aachen, Germany*
Email: lbewersdorf@ukaachen.de

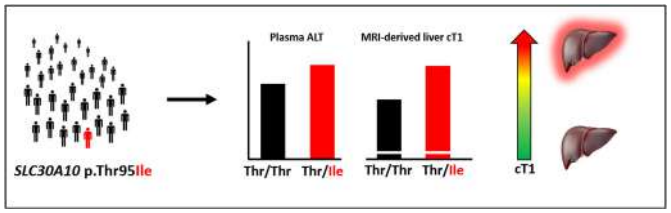
Background and aims: Alpha1-antitrypsin (AAT) mutations lead to the retention of the otherwise secreted hepatocellular protein in the endoplasmic reticulum (ER) thereby giving rise to AAT deficiency (AATD). Liver disease arising due to the proteotoxic stress is the second leading cause of mortality in AATD. mTOR signalling acts as the central proteostatic regulator. Our aim was to study the importance of mTOR signalling in AATD.
Method: Animals overexpressing the characteristic AAT mutation (PiZ mice) were cross-bred with rodents harboring a hepatocyte specific-ablation of the interaction partners RAPTOR/RICTOR corresponding to mTOR complexes 1/2 (mTORC1/2) or with mice lacking hepatocellular mTOR.
Results: At two month of age, PiZ-mTOR$^{\Delta hep}$ and PiZ-RAPTOR$^{\Delta hep}$ but not PiZ-RICTOR$^{\Delta hep}$ mice showed elevated liver enzyme levels, signs of increased liver injury and apoptosis despite diminished AAT accumulation. While PiZ-RAPTOR$^{\Delta hep}$ animals displayed increased levels of the pro-apoptotic protein CHOP, CHOP ablation did not rescue the phenotype. As a potential underlying mechanism, we observed reduced levels of several chaperones, i.e., Hsp90 or Grp94.
Conclusion: mTORC1 but not mTORC2 plays an important role in PiZ induced liver injury.

FRI283
Cerebrotendinous xanthomatosis: long-term course in 5 patients and first description of a successful pregnancy management during therapy with chenodesoxycholic acid (CDCA)
Jan Köhler[1], David Schoeler[1], Petra May[1], Linus Mrozek[1], Renate Kimmerle[2], Tom Lüdde[1], Stephan vom Dahl[1]. [1]*University Hospital Duesseldorf, Heinrich-Heine-University, Department of Gastroenterology, Hepatology and Infectious Diseases, Duesseldorf, Germany;* [2]*Endokrinologische Schwerpunktpraxis, Düsseldorf, Germany*
Email: JanPhilipp.Koehler@med.uni-duesseldorf.de

Background and aims: Cerebrotendinous xanthomatosis (OMIM #231700) is a rare autosomal-recessive bile acid synthesis defect due to defective mitochondrial sterol 27-hydroxylase CYP27A1, leading to tendon xanthomas, bilateral cataracts, diarrhea and progressive neurologic manifestations. Patients are usually diagnosed during adulthood. Oral therapy with CDCA, a bile acid, reverses the potentially debilitating symptoms and prolongs life span. To our knowledge, this is the first description of a successful pregnancy with CTX.
Method: After biochemical diagnosis, CTX patients were monitored in 6-month intervals with abdominal ultrasound, cMR imaging, ophthalmologic examinations and determination of cholestanol blood levels. Therapy with CDCA (10–15 mg/kg body wt.) was initiated along with lipid-lowering combination therapy and in one female patient, after positive pregnancy testing in 2019, CDCA was continued and monitoring intervals were shortened.
Results: Three siblings, their mother and aunt from a consanginous family were diagnosed with CTX at ages of 38, 27, 18, 14, and 9 respectively. The aunt was diagnosed in 1997, the mother in 2003 and the siblings in 2005. Mean follow-up in this cohort was 18 ± 2 years. At baseline, tendinous xanthomas were present in 4/5, diarrhea and ataxia in 1/5, hypercholesterolemia and hypertriglyceridemia in all patients. 3/5 patients suffered from cataracts and required surgical therapy. Slight cognitive impairment occurred in 4/5 patients. Ataxia and diarrhea subsided. Total cholesterol (TC), LDL-C and HDL-C at baseline were 217 ± 16 mg/dl, 108 ± 15 mg/dl and 77 ± 5 mg/dl and were reduced to 195 ± 7 mg/dl, 115 ± 12 mg/dl and 53 mg/dl ± 6 mg/dl at last visit. Pretherapeutic cholestanol levels and 7alpha—hydroxycholesterol were 3.1 ± 0.2 mg/dl (ref. range 0.21 to 0.67 mg/dl) and 3857 ± 802 ng/ml (ref. range <0, 5 ng/ml) decreased to 0.3 ± 0.02 mg/dl and 76 ± 10 ng/dl. In a pregnant patient, blood cholestenol and cholesterol levels were stable, and after an uncomplicated pregnancy, she gave birth to a healthy baby boy in term on 08/2020, who was age appropriate and reached normal developmental milestones up to now.
Conclusion: Oral CDCA therapy can help stabilize/reverts the control clinical symptoms of CTX and can successfully be continued during pregnancy. CTX is underdiagnosed and should be suspected in any adult dyslipidemic patients with heterogeneous neurologic manifestations and cataracts.

FRI284
A rare genetic variant in the manganese transporter SLC30A10 and elevated liver enzymes in the general population
Anne-Sofie Seidelin[1], Børge Nordestgaard[2], Anne Tybjaerg Hansen[1], Hanieh Yaghootkar[3], Stefan Stender[1]. [1]*Rigshospitalet, Clinical Biochemistry, København, Denmark;* [2]*Herlev Hospital, Clinical Biochemistry, Herlev, Denmark;* [3]*University of Exeter, United Kingdom*
Email: stefan.stender@regionh.dk

Background and aim: A rare genetic variant in the manganese transporter *SLC30A10* (rs188273166, p.Thr95Ile) was associated with increased plasma alanine transaminase (ALT) in a recent genome-wide association study in the UK Biobank (UKB). The aims of the present study were to validate the association of rs188273166 with ALT in an independent cohort, and to begin to test the clinical, hepatic and biochemical phenotypes associated with the variant.
Method: We included n = 334, 886 white participants from UKB, including 14, 462 with hepatic magnetic resonance imaging (MRI), and n = 113, 612 individuals from two Danish general population cohorts, the Copenhagen City Heart Study and the Copenhagen General Population Study combined.
Results: Genotyping *SLC30A10* p.Thr95Ile identified 816 heterozygotes in the UKB and 111 heterozygotes in the Copenhagen cohort. Compared to non-carriers, heterozygotes had 4 U/L and 5 U/L higher levels of plasma ALT in the UKB and Copenhagen cohort, respectively, and 3 U/L higher plasma aspartate transaminase and gamma glutamyl-transferase in the UKB. Heterozygotes also had higher corrected T1 on liver MRI, a marker of hepatic inflammation ($p = 4 \times 10^{-7}$), but no change in MRI-quantified steatosis ($p = 0.57$). *SLC30A10* p.Thr95Ile heterozygotes had an eight-fold increased risk of biliary tract cancer in UKB ($p = 5 \times 10^{-7}$), but this association was not replicated in the Copenhagen cohort.



Conclusion: *SLC30A10* p.Thr95Ile was associated with elevated liver enzymes in two large general population cohorts, and with MRI-quantified hepatic inflammation. We hypothesize that Thr95Ile heterozygosity associates with a mild form of hepatic manganese accumulation leading to liver damage.

FRI285

A small molecule chaperone for alpha-1 antitrypsin deficiency-associated liver disease reduces liver polymer burden in the PiZ mouse model

Britta Handyside[1], Lening Zhang[1], Katina Ngo[1], Ryan Murphy[1], Joseph Chen[1], Nicole Galicia[1], Olivia Gorostiza[1], Glenn Pacheco[1], Lin Xie[1], Donald Mackenzie[1], Heidi Jones[1], Brian Heglar[1], Bing Wang[1], Shripad Bhagwat[1], David Lomas[2], James Irving[2], Riccardo Ronzoni[2], Sherry Bullens[1], Sylvia Fong[1], Stuart Bunting[1]. [1]*BioMarin Pharmaceutical Inc., Novato, United States;* [2]*University College London, London, United Kingdom*
Email: britta.handyside@bmrn.com

Background and aims: Alpha-1 antitrypsin deficiency (AATD) is caused by mutations in the *SERPINA1* gene encoding alpha-1 antitrypsin (AAT). AAT is primarily produced by hepatocytes and is secreted into the blood stream where it functions as a neutrophil elastase inhibitor.
The most clinically severe form of AATD is caused by the Z mutation (Glu342Lys) resulting in expression of the mutant protein Z-AAT. Pathogenic Z-AAT protein can misfold, polymerize and accumulate in the endoplasmic reticulum (ER) of hepatocytes leading to progressive liver fibrosis and low levels of circulating AAT. There is currently no effective treatment for AATD-associated liver disease. Here we tested BMN 349, a molecular chaperone, for its ability to prevent Z-AAT polymerization in hepatocytes while increasing circulating Z-AAT in the PiZ mouse, a model for AATD-associated liver disease.
Method: Young (5 week) and adult (12 week) female heterozygous PiZ mice expressing human Z-AAT were treated twice daily for 30 days with 50 or 100 mg/kg of BMN 349 via oral gavage (10–13 mice per group). Plasma and liver Z-AAT levels were analyzed by ELISA. Z-AAT polymer globules in hepatocytes were evaluated using Periodic Acid-Schiff with Diastase (PAS-D) stains. Liver and plasma pharmacodynamic biomarkers were assessed using mass spectrometry-based proteomics.
Results: Treatment with BMN 349 increased levels of circulating Z-AAT and reduced liver polymer levels in both age groups. In adult mice a dose-response was observed with a liver polymer reduction of 33% with 50 mg/kg ($p = 0.00098$) and 49% with 100 mg/kg ($p < 0.0001$) of BMN 349 compared to vehicle as determined by ELISA. Histological analysis using the PAS-D stain confirmed a significant reduction in liver Z-AAT polymer globules by 25% ($p = 0.0008$) and by 34% ($p = 0.0232$) with 50 or 100 mg/kg of BMN 349, respectively. In young mice, a greater than 80% reduction in liver polymers was detected by ELISA ($p < 0.0001$) and a >85% reduction of Z-AAT polymer globules ($p < 0.0001$) was observed with either dose of BMN 349 compared to vehicle. Together, the data from both age groups showed that a greater effect on liver polymer burden was achieved when treatment was initiated early. Proteomics analysis revealed an increase in ER stress markers including GRP78 in PiZ mouse liver and plasma and reduced levels of circulating liver-derived clotting factor VII in PiZ mouse plasma compared to wildtype mice, suggesting impaired liver function. Treatment with BMN 349 resulted in a significant decrease of GRP78 and increase of FVII towards wildtype levels, demonstrating BMN 349 helped reduce cellular stress and restore normal biosynthetic function of the liver in PiZ mice in addition to reducing liver polymer burden.
Conclusion: Taken together, these data indicate that BMN 349 is effective in reducing Z-AAT polymer burden, reversing liver damage, and restoring liver function in the PiZ mouse model.

FRI286

A 'melting pot' of genetic variability in Wilson's disease-real world study from London, UK

James Liu Yin[1], Aftab Ala[1]. [1]*King's College Hospital, Institute of Liver Studies, London, United Kingdom*
Email: aftab.ala1@nhs.net

Background and aims: Wilson's disease (WD) has been shown to have more than 600 different variants causing abnormal function of the ATP7B peptide. There is wide global diversity in these variants with different variants appearing to be more prominent in certain geographical areas and populations than others. London, UK is one of the largest, ethnically diverse cities in Western Europe with a growing population of over 9 million. It receives over 100, 000 international migrants a year, with the largest proportions from the European Union and Indian Subcontinent. We aimed to review the genetic results at Kings College Hospital, London from patients with abnormal WD genetics and compare this to known global distribution.
Method: We retrospectively collected data on all WD genetic testing done at KCH since becoming one of the national testing centres (2015-present). We further extracted information on specific cDNA, protein change and zygosity status. We subsequently used *WilsonGen,* (Comprehensive genomic variant resource) which has compiled the largest database of variants, (2267 entries currently) to compare whether our variants were unique or previously documented.
Results: We identified 207 WD patients, 30 homozygous, 91 compound heterozygotes and 86 heterozygotes (Mean 28.9 years, range 4–70). Within this, there were 113 different variants identified. The most common was His1069Gln (11%), followed by Cys271Ter (3.6%), Met769Val (3.6%) and Ser1365fs (3.2%). On comparison with the *WilsonGen* database we found that 44 variants were not listed on their records (38.9%). We had ethnicity data accessible for 137 patients, 49% were documented as unspecified and the remaining were; Caucasian (35%), Indian Subcontinent (7%), Middle Eastern (4%), Black/Caribbean (3%), Chinese (1%) and other (<1%).
Conclusion: Our results demonstrate significant genetic variation in London with the most common mutation only accounting for 11% of the overall total. As genetic testing becomes a more utilized tool in furthering diagnostic pathways we need to understand that this variation may have significance. A recently suggested ATP7B-mutation specific diagnostic test would be less effective in a population like London and other Metropolitan cities. This needs to be taken into account in further studies to ensure that genetic variation will not delay or prevent diagnosis of new cases.
The importance of ATP7B genetic variation is yet to be fully understood and characterised with respect to the pathogenesis of WD. Within our cohort, the presence of novel variants was 39% which is a significant portion and higher than previously reported UK data (27% Coffey et al). Considering the wide spread of variation including novel variants, specific mutations have not been shown to confer benefit thus far and therefore further understanding of its significance is needed.

FRI287

The alpha-1 antitrypsin Pi*Z allele is an independent risk factor for liver transplantation/death in patients with advanced chronic liver disease

Lorenz Balcar[1,2], Bernhard Scheiner[1,2], Markus Urheu[1], Patrick Weinberger[1], Rafael Paternostro[1,2], Benedikt Simbrunner[1,2], Lukas Hartl[1,2], Mathias Jachs[1,2], David Jm Bauer[1,2], Georg Semmler[1,2], Claudia Willheim[1], Matthias Pinter[1], Peter Ferenci[1], Michael Trauner[1], Thomas Reiberger[1,2], Albert Stättermayer[1,2], Mattias Mandorfer[1,2].
[1]*Medical University of Vienna, Division of Gastroenterology and Hepatology, Department of Internal Medicine III, Vienna, Austria;* [2]*Medical University of Vienna, Vienna Hepatic Hemodynamic Lab, Vienna, Austria*
Email: mattias.mandorfer@meduniwien.ac.at

Background and aims: Alpha-1 antitrypsin (AAT) deficiency causes/predisposes for advanced chronic liver disease (ACLD). However, the role of the *SERPINA1* Pi*Z allele in patients who have already progressed to ACLD is unclear. Thus, we aimed to evaluate the impact of the Pi*Z allele on the requirement of liver transplantation/liver-related death in ACLD, while adjusting for the severity of liver disease at inclusion.

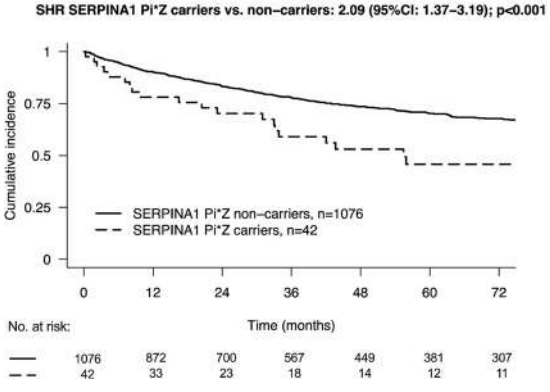
Method: 1118 ACLD patients who underwent HVPG-measurement and genotyping for the Pi*Z/Pi*S allele at the Vienna Hepatic Hemodynamic Lab were included in this retrospective analysis. Requirement of liver transplantation/liver-related death was the outcome of interest, while non-liver-related death and removal of the primary etiological factor were considered as competing risks.

Results: Viral hepatitis was the most common etiology (44%), followed by alcoholic (31%) and non-alcoholic fatty liver disease (11%). Forty-two (4%) and forty-six (4%) patients harboured the Pi*Z and Pi*S variants, respectively.

Pi*Z carriers had more severe portal hypertension (HVPG: 19 ± 6 vs. 15 ± 7 mmHg; $p < 0.001$) and hepatic dysfunction (Child-Turcotte-Pugh: 7.1 ± 1.9 vs. 6.5 ± 1.9 points; $p = 0.050$) at inclusion, as compared to non-carriers. Contrarily, the Pi*S allele was unrelated to liver disease severity.

In competing risk regression analysis, harbouring the Pi*Z allele was significantly associated with an increased probability of liver transplantation/liver-related death (Figure), even after adjusting for liver disease severity at inclusion. The detrimental impact of the common Pi*MZ genotype (vs. Pi*MM) was confirmed in a fully adjusted subgroup analysis. In contrast, Pi*S carriers had no increased risk for events.

Figure. Cumulative incidences of liver transplantation/liver-related death in Serpin Family A Member 1 (*SERPINA1*) Pi*Z carriers vs. non-carriers with etiological cure and non-liver-related death as competing risks.



Conclusion: Genotyping for the Pi*Z allele identifies ACLD patients at increased risk for adverse liver-related outcomes, thereby improving prognostication. Therapies targeting accumulated abnormal AAT should be evaluated as disease-modifying treatments in Pi*Z allele carriers with ACLD.

FRI288

Fontan associated liver disease: a cohort review into the prevalence of portal hypertension

Hannah Donnelly[1], James Orr[2]. [1]*Bristol Royal Infirmary, Bristol, United Kingdom;* [2]*Bristol Royal Infirmary, United Kingdom*
Email: donnellyhannah@hotmail.com

Background and aims: The Fontan procedure is a palliative operation for patients with functional univentricular congenital heart disease. It directs the systemic venous return directly into the pulmonary circulation without ventricular propulsion preventing mixing of blood. Up to 70 000 Fontan patients are alive worldwide today, and this is expected to double in the next 20 years. Fontan-associated liver disease (FALD) is emerging as a common complication and consensus recommends evaluation for FALD but specific guidelines on screening are not established. The Bristol Liver Unit and Heart Institute are collaborating to review their cohort of patients, particularly looking into the prevalence of portal hypertension.

Method: A database of Fontan patients was gathered, and demographics, bloods, imaging, and endoscopy results were collected from the electronic patient record.

Results: From the 101 Fontan patients on the database 11 had had gastroscopies. 10 patients had gastroscopies to look for signs of portal hypertension, and one due to a hereditary condition. One patient had presented with bleeding, with coffee-ground vomiting, all others were elective. 6/11 had signs of portal hypertension, details in table 1. 5/6 (83%) of those with endoscopic evidence of portal hypertension had either splenomegaly (>13 cm), Fibroscan >20 kpa or thrombocytopenia (platelet count <150). These are all established markers of possible portal hypertension. The patient that did not have any of these had varices shown on a USS and this was confirmed on endoscopy. In the cohort 37% (38/101) met one or more of these criteria.

Table 1: Findings of portal hypertension on endoscopy

Portal hypertensive gastropathy	5/6
(With GOV	4/6)
Oesophageal varices	4/6
Grade 1	
Gastric varix	1/6

Conclusion: Non-invasive markers of portal hypertension seem to predict the presence of portal hypertension detected on endoscopy. Our Fontan patients have a high prevalence of these non-invasive markers and this is with missing data. We plan to explore the prevalence further by establishing a joint clinic with Cardiology to assess the patients and perform gastroscopies if non-invasive markers indicate possible portal hypertension. We will also be looking at the relevance of portal hypertension in this patient group, considering the bleeding risk and impact on transplantation assessment.

FRI289

Senolytic therapies have a place in pediatric biliary cirrhosis

Giulia Jannone[1], Eliano Bonaccorsi[2], Catherine de Magnée[3], Roberto Tambucci[3], Jonathan Evraerts[1], Joachim Ravau[1], Mustapha Najimi[1], Etienne Sokal[1]. [1]*Université catholique de Louvain, IREC Institute, Laboratory of Pediatric Hepatology and Cell Therapy, Brussels, Belgium;* [2]*Université catholique de Louvain, IREC Institute, Laboratory of Experimental Surgery and Transplantation, Brussels, Belgium;* [3]*Cliniques Universitaires Saint-Luc, Pediatric Surgery and Transplantation Unit, Brussels, Belgium*
Email: giulia.jannone@student.uclouvain.be

Background and aims: Premature senescence has been extensively characterized in adult chronic hepatobiliary diseases and can worsen liver function and fibrosis evolution. Since new therapeutic options

are needed in pediatric biliary cirrhosis to delay liver transplantation, our aim was to investigate the presence of premature senescence in biliary atresia (BA) and to test the senolytic properties of Medicinal Signaling Cells in a preclinical model of biliary cirrhosis.
Method: Senescence was investigated through senescence-associated β-galactosidase activity assay (SA-beta-gal) as well as p16 and p21 gene/protein expression in BA livers at the time of hepatoportoenterostomy (n = 5) or liver transplantation (n = 30) as compared to control livers (n = 10). Co-localized expression of senescence (gammaH2AX or p21) with CK19, HNF4alpha, alphaSMA and Ki67 was also assessed. Bile duct ligation (BDL) was performed on 2-months old rats and senescence was characterized in the model through above-mentioned techniques. Human allogeneic liver-derived progenitor cells (HALPC) were injected in BDL rats 48 hours after the surgery at high (12.5×10^6 cells/kg, n = 6) versus low dose (1.25×10^6 cells/kg, n = 6) and compared to the vehicle (n = 6).
Results: Senescence was similarly increased in both BA stages as compared to control livers (SA-beta-gal: 5.9 ± 1.4 and 5.4 ± 1 vs 0.6 ± 0.1 %stained area/total, $p < 0.01$) and was also confirmed in BDL livers one and two weeks after the surgery (SA-beta-gal: 1.6 ± 0.6 and 6.6 ± 2.4 vs 0.2 ± 0.1 %stained area/total, $p < 0.05$). The pattern of senescence in BA and BDL was similar as senescence first appeared in cholangiocytes of the ductular reaction and subsequently developed in hepatocytes. HALPC transplantation at both doses decreased senescence in BDL rats (p21 gene expression: 0.4 ± 0.04 and 0.5 ± 0.1 vs 1 ± 0.2 fold change; $p < 0.05$).
Conclusion: Premature senescence occurs in BA livers and HALPC display senolytic properties in a preclinical model of biliary cirrhosis.

FRI290
PNPLA3 rs738409 G allele increases the risk of liver cirrhosis in SERPINA1 MZ heterogygotes
Sona Frankova[1], Zuzana Rabekova[2], Magdalena Neroldova[3], Ondrej Fabian[4], Martin Kveton[4], Jaroslav A. Hubacek[5], Julius Spicak[1], Vera Adamkova[6], Milan Jirsa[3], Jan Sperl[1]. *[1]Institute for Clinical and Experimental Medicine, Department of Hepatogastroenterology, Praha, Czech Republic; [2]Institute for Clinical and Experimental Medicine, Department of Hepatogastroenterology, Prague, Czech Republic; [3]Institute for Clinical and Experimental Medicine, Laboratory of Experimental Hepatology, Praha, Czech Republic; [4]Institute for Clinical and Experimental Medicine, Department of Clinical and Transplant Pathology, Praha; [5]Institute for Clinical and Experimental Medicine, Atherosclerosis Research Laboratory, Praha; [6]Institute for Clinical and Experimental Medicine, Preventive Cardiology Centre, Praha, Czech Republic*
Email: sona.frankova@ikem.cz

Background and aims: Homozygous carriage of mutated Z allele in rs28929474 locus of *SERPINA1* encoding alpha-1-antitrypsin (A1AT) leads to lung emphysema and liver cirrhosis. Recent data show that the *SERPINA1* MZ genotype increases the risk of liver cirrhosis in patients with various liver diseases. The mechanism behind this finding has not been elucidated so far. Our study aimed to demonstrate the synergy between the *SERPINA1* Z allele and unfavourable alleles in other liver disease-modifying genes.
Method: The study group consisted of 1079 liver transplant candidates with liver cirrhosis of various aetiology (642 males, 437 females, average age of 54 years). The aetiology of cirrhosis was as follows: 352 alcoholic, 309 cholestatic, 217 viral, 142 NASH, 59 metabolic. Patients with A1AT deficiency were excluded. The control group consisted of 3329 healthy individuals from the MONICA study (WHO Multinational Monitoring of Trends and Determinants in Cardiovascular Disease Project).
Genomic DNA was isolated from peripheral blood by Qiagen QIAamp kit (Qiagen, Hilden, Germany). *SERPINA1* rs28929474, *PNPLA3* rs738409, *TM6SF9* rs rs58542926 and *GCKR* rs1260326 loci were genotyped by TaqMan RT-PCR SNP assays (Thermo Fisher Scientific, Waltham, MA). Aggregates of A1AT in hepatocytes in liver explants were stained by PAS-D and immunostained with an anti-A1AT polyclonal rabbit antibody (Cell Marque, Inc., Rocklin, CA, USA).
Results: The frequency of *SERPINA1* MZ heterozygotes was significantly higher in the group with liver cirrhosis in comparison with the control group, 56/1079 (5.2%) vs. 89/3329 (2.7%), $p < 0.0001$, MZ heterozygotes thus have an increased risk of liver cirrhosis (OR 2.0, CI 95% 1.4–2.8).
Re-evaluation of 1009 histopathological reports of the explanted liver specimens revealed that PAS-D positive aggregates were detected in 52/56 (93%) MZ heterozygotes and 18/953 (1.9%) MM homozygotes ($p < 0.0001$). Forty-six out of 56 available specimens of MZ heterozygotes were assessed by immunohistochemistry; A1AT aggregates were confirmed in all cases.
PNPLA3 rs738409 genotype frequencies were 21 CC (37.5%), 24 CG (42.9%), and 11 GG (19.6 %) in 56 *SERPINA1* MZ heterozygotes with cirrhosis and 59 CC (66.3%), 26 CG (29.2%) and 4 GG (4.5%) in 59 MZ heterozygotes in the control group. The frequency of the unfavourable *PNPLA3* G allele was significantly higher in *SERPINA1* MZ carriers with cirrhosis than in healthy heterozygotes, and the carriage of the *PNPLA3* G allele increased the risk of liver cirrhosis ($p = 0.001$; OR = 3.278, CI 95% 1.633–6.581). Contrarily, the frequencies of the *TM6SF2* and *GCKR* genotypes in *SERPINA1* MZ heterozygotes did not differ significantly between the patients with cirrhosis and controls.
Conclusion: Our results suggest that the risk genotypes of *PNPLA3* accelerate the progression of fibrosis in *SERPINA1* MZ heterozygotes with chronic liver disease.

FRI291
Patient experience of their Primary Biliary Cholangitis (PBC) management compared to clinical practice guidelines
Chris Mitchell[1], Angela Eddy[2], James Neuberger[3]. *[1]PBC Foundation, Edinburgh, United Kingdom; [2]PBC Foundation, Edinburgh, United Kingdom; [3]NHS, Birmingham Queen Elizabeth Medical Centre, Birmingham, United Kingdom*
Email: chris@pbcfoundation.org.uk

Background and aims: Primary Biliary Cholangitis (PBC) is a chronic, cholestatic, autoimmune liver disease, which can have a profound impact on patients' quality of life and a significant demand for healthcare services. PBC management guidelines were published in 2017 by European Association for the Study of the Liver (EASL), which include recommendations for daily dosage (13–15 mg/kg) of licensed first-line therapy (ursodeoxycholic acid (UDCA)) and referrals for alternative treatment if UDCA response is inadequate, of which obeticholic acid (OCA) is the only licensed treatment alongside other re-purposed agents.
This study explored the efficacy of patient-clinician collaborations to manage PBC in accordance with EASL guidelines from a patient perspective.
Method: A closed question questionnaire was designed focussing on the application of treatments and the inclusion of patients in the management of their PBC. The questionnaire was piloted with PBC Foundation service users during a focus group testing its reliability and face validity. A convenience sample was used and participants recruited via the PBC Foundation's app during March 2022. Intercept Pharmaceuticals provided financial support and input into the questionnaire, however the PBC Foundation has retained editorial discretion over survey outputs.
Results: 172 patients completed the survey.
154 respondents (90%) take UDCA and 132 respondents (77%) received a timely UDCA prescription (0–3 months after diagnosis). 91% of UDCA patients believe they are taking the recommended dosage however only 54% of UDCA patients report taking dosage within guidelines.
Of those patients who are unresponsive or intolerant to UDCA, 68% were offered alternative treatment and 57% were included in discussions about the most suitable option.

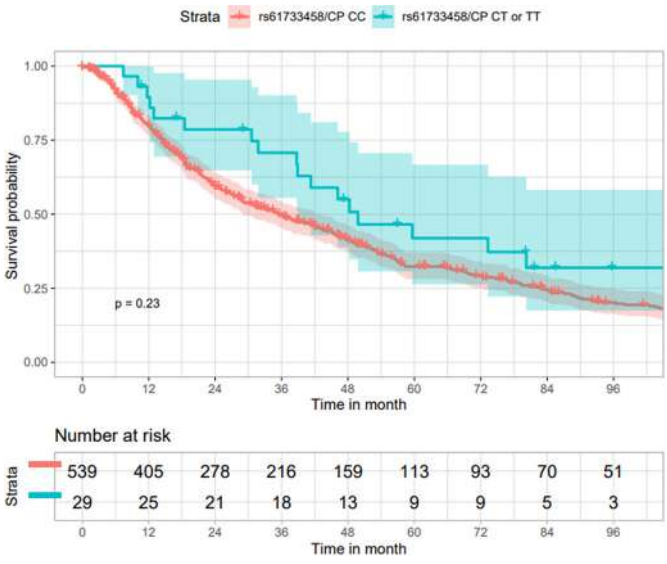
22% of all patients take 2nd line treatment (5% OCA and 17% unlicensed). 8% of all patients take no treatment for PBC management.
54% of patients had no access to face-to-face clinical appointments and 39% had appointments delayed or cancelled during the COVID pandemic. Patient comfort in raising PBC related queries ranges from 86% in face-to-face meetings, 46% on the telephone and 31% on screen-calls.
Latest blood test results were discussed with 73% of patients. 50% of patients believe they understand their test results and 40% say their test results help them manage their PBC.
Conclusion: Unmet PBC patient needs are evident in numerous stages of the life-long clinical journey. Data indicates substantial disparity between published PBC treatment guidelines and actual care delivered to patients, particularly relating to optimal application of PBC management therapies and patient inclusion in important discussions (test results and further treatment referrals). Unmet needs have been exacerbated during the COVID pandemic when timely appointments in patients' preferred formats were adversely affected.

FRI292

Evaluation of the clinical impact of the Ceruloplasmin variant p. Thr551Ile in liver cirrhosis

Marlene Panzer[1,2], Benedikt Schaefer[1], André Viveiros[1], Herbert Tilg[1], Heinz Zoller[1,3]. [1]*Medical University of Innsbruck, Department of Medicine I, Innsbruck, Austria;* [2]*VASCage Reserch Center of Vasuclar Ageing and Stroke, Innsbruck, Austria;* [3]*Christian Doppler Laboratory on Iron and Phosphate Biology, Innsbruck, Austria*
Email: heinz.zoller@i-med.ac.at

Background and aims: Ceruloplasmin is a multicopper oxidase and is involved in cellular iron efflux. Aceruloplasminemia (ACP) is a recessive disease, caused by pathogenic variants in the gene encoding ceruloplasmin (*CP*). The disease is characterized by iron accumulation in liver, pancreas and brain. Patients typically present in their 5th decade of life with the triad of retinal degeneration, diabetes mellitus and neurodegeneration. Early biochemical signs of ACP include hyperferritinemia and low transferrin saturation. Recent reports suggest that heterozygous variants in *CP* can also cause hyperferritinemia and hepatic siderosis in patients with non-alcoholic fatty liver. The aim of the present study was to investigate the allele frequency and the clinical impact of the common ceruloplasmin variant p.Thr551Ile in an unselected cohort of patients with liver cirrhosis.
Method: A cohort of patients referred to the Hepatology Laboratory at the Medical University of Innsbruck for *PNPLA3* genotyping was retrospectively assessed. Patients diagnosed with liver cirrhosis and available serum CP concentrations were included in this study (n = 568). Demographic, biochemical and clinical parameters were collected by review of patient records. Genotyping for the *CP* variant p.Thr551Ile (rs61733458) was performed by allelic discrimination PCR.
Results: Genotyping results revealed 2 homozygous and 27 heterozygous patients for p.Thr551Ile. This corresponds to an allele frequency of 2.73% (31 of 1136) in the liver cirrhosis cohort which is not different from the general population as reported in gnomAD (7795 of 282414; 2.76%). Biochemical surrogates of liver disease severity and serum iron parameters did not show significant differences when patients were stratified according to *CP* genotype. Reduced CP concentrations (≤20 mg/dL) were detected in 17.2% of patients carrying the variant p.Thr551Ile and in 11.7% in the normal group, which is not significantly different. Median CP concentrations were also numerically lower in patients heterozygous or homozygous for p.Thr551Ile, but this difference did not reach statistical significance (27.7 mg/dl vs 27.8 mg/dl; p = 0.368). Median time of transplant-free survival was significantly reduced in the group with decreased CP concentration (p = 0.004), but no significant difference in survival probability was observed when patients were stratified according to *CP* genotype. Cox regression analysis including age and NaMELD showed that CP serum concentration but not p.Thr551Ile genotype was an independent predictor of transplant-free survival.



Conclusion: Reduced serum ceruloplasmin is common in patients with liver cirrhosis and is independently associated with reduced transplant-free survival in unselected patients with cirrhosis. The *CP* variant p.Thr551Ile shows no association with serum iron parameters or transplant-free survival.

FRI293

Circulating miR-21 parallels the incidence of IBD in PSC patients

André A. Santos[1], Joana Torres[2], Susana Saraiva[2], Catarina Ferreira Gouveia[2], Catarina Bravo[2], Marília Cravo[2], Cecília M. P. Rodrigues[1]. [1]*Research Institute for Medicines (iMed. ULisboa), Faculty of Pharmacy, Universidade de Lisboa, Lisbon, Portugal;* [2]*Hospital Beatriz Angelo, Loures, Portugal*
Email: afasantos@ff.ulisboa.pt

Background and aims: Primary sclerosing cholangitis (PSC) is a chronic and progressive cholestatic liver disease. The major risk factor for developing PSC is having a concomitant diagnosis of inflammatory bowel disease (IBD). Around 71% of PSC patients have IBD. Conversely, PSC is present in only 3–8% of patients with established IBD. Although both diseases run distinct courses, patients with PSC-IBD present a characteristic phenotype, contributing to a high risk of colitis-associated neoplasia. Recently, small non-coding RNAs such as microRNAs (miRNAs) have been correlated with disease onset and progression. miR-21, one of the most studied oncogenic miRNAs, is known to be overexpressed in IBD. Here we aim to further explore miR-21 in patients in a systematic manner and determine its contribution to the typical PSC-IBD phenotype.
Method: In this case-control study we included 12 patients in the PSC—IBD group, 30 patients in the IBD-alone group, and 19 patients in the control group. Serum samples were collected for fasting serum miR-21 expression. Stool samples were used for calprotectin analysis and miR-21 expression. Gut microbiome was investigated using next generation sequencing analysis. During colonoscopy, two biopsies in the right and left colon were performed and expression analysis of miR-21 and inflammation, tight junction and oncogene analysed. In statistical data analysis, outliers were removed (ROUT Q = 1%) and Kruskal-Wallis test or ANOVA Tukey's multiple comparisons test were performed on non-parametric or parametric data, respectively.

Results: Serum and fecal miR-21 expression were significantly increased in PSC-IBD patients compared to IBD alone. miR-21 expression in the right colon was similar in both PSC-IBD and IBD alone but increased when compared to controls. The inflammatory marker IL-8 was more elevated in both left and right colon of PSC-IBD patients than in IBD alone. Moreover, macrophage recruitment markers TWIST1, COX2, and CCL2 were also significantly increased in both left and right colon tissue of PSC-IBD patients compared to IBD alone or in control groups. Finally, the genus *Intestinibacter*, often associated with IBD, was elevated in PSC-IBD patients compared to IBD alone.
Conclusion: Our data show that miR-21 in circulation, but not in colon tissue, together with macrophage recruitment and distinct microbiota profiles parallel the incidence of IBD in PSC patients. Given the proinflammatory and oncogenic activities of miR-21, its role in PSC-IBD disease pathogenesis and phenotype merits further evaluation. Supported by FCT CEECIND/04663/2017, GEDII Project Award 2019, and EASL Daniel Alagille Award 2019.

FRI294

Hepatocellular carcinoma in fontan associated liver disease: uncharted territory-are we doing enough?

Michael Christmas[1], Anthony Bergin[1], Wei Lian Tan[1], Myat Khaing[1], Lei Lin[1], Yuming Ding[1], Tony Rahman[1], Ryan Maxwell[2], Vishva Wijesekera[2]. *[1]The Prince Charles Hospital, Gastroenterology, Chermside, Australia; [2]The Prince Charles Hospital, Cardiology, Chermside, Australia*
Email: michael.christmas@health.qld.gov.au

Background and aims: Fontan associated liver disease (FALD) is a well-recognised consequence of the congestion and hypoxia created from the Fontan palliative procedure. Improved clinical management has led to significantly improved life expectancy and thus the paradigm of increased risk of developing FALD and HCC. There are no FALD specific surveillance guidelines for HCC. AASLD and EASL suggest biannual monitoring of serum alpha fetoprotein and ultrasound imaging as the gold standard for HCC screening in the cirrhotic population. This clinical audit seeks identify and audit compliance to the gold standard being offered in our Hepatology clinics.
Method: Retrospective analysis of Fontan patients and clinical, biochemical, radiological and endoscopic databases correlation was undertaken at the Hepatology clinic serving the quaternary regional referral centre for adult congenital heart diseases in Queensland (The Prince Charles Hospital, TPCH). Cirrhosis was identified in patients who had features identified on their liver ultrasound. The current conventional HCC screening requirements were then applied to identified patients.
Results: In the data set of 72 Fontan patients, 49% (35) were female and an average age of 30.3 years. Features of cirrhosis were identified in 44% (32). Of these 32, 90% (29) patients were linked in with an outpatient liver clinic. Only 66% (19) liver clinic patients had standard HCC surveillance. In our data set one patient has had treatment for HCC. Four patients had died due to causes unrelated to HCC.
Conclusion: The majority of cirrhotic patients in this cohort are linked in with a liver clinic. Sub-optimal HCC screening is taking place in this very vulnerable cohort with one third of patients not receiving minimum surveillance potentially leading to missed detection of curable HCC. The young age of this cohort should not disguise or detract from the risk of cirrhosis and HCC. This has identified an opportunity for education to improve the awareness and importance of HCC and screening in this unique population, for staff, patients and carers. International guidelines would be very valuable in this new cohort of cirrhotic patients.

FRI295

Are patients with Fontan-associated liver disease (FALD) appropriately screened for oesophageal varices? Queensland quaternary adult congenital heart disease referral centre experience

Anthony Bergin[1], Yuming Ding[1], Michael Christmas[1], Wei Lian Tan[1], Lei Lin[1], Myat Khaing[1], Alexandra Schlimmer[1], Ann Vandeleur[1], Hayley Thompson[1], Ryan Maxwell[1], Vishva Wijesekera[1], Tony Rahman[1]. *[1]The Prince Charles Hospital, Gastroenterology, Chermside, Australia*
Email: anthony.bergin@health.qld.gov.au

Background and aims: The Fontan procedure is palliative management of univentricular congenital heart disease. An extracardiac complication of haemodynamic changes from Fontan circulation is Fontan-associated liver disease (FALD). Variceal bleeding is the most severe and life-threatening complication of chronic liver disease and portal hypertension (1). Studies suggest that 15 years post-Fontan procedure greater than 27% of patients had oesophageal varices on oesophago-gastroduodenoscopy (OGD) (2). An ageing Fontan population is a new clinical phenotype due to advances in healthcare. It is thus imperative that cirrhotic Fontan patients are screened for oesophageal varices, however, no formal guidelines currently exist.
Method: Retrospective analysis of Fontan patients and clinical, biochemical, radiological and endoscopic databases correlation was undertaken at the Hepatology clinic serving the quaternary regional referral centre for adult congenital heart diseases in Queensland (The Prince Charles Hospital, TPCH). Cirrhosis was identified in patients who had features identified on their liver ultrasound. The current conventional HCC screening requirements were then applied to identified patients. For each OGD, procedure indication, endoscopic findings and therapeutic interventions were noted.
Results: Seventy-two post-Fontan patients were identified from our database. Of which 49% (n = 35) were female with a mean age of 30.3 years. Only 44% (n = 32) had an OGD, the indications included variceal surveillance, iron deficiency and dyspepsia. Among the cirrhotic FALD patients (n = 32), only 43.7% (n = 14) had an OGD. Of this subgroup 22.8% (n = 7) had grade I oesophageal varices, none of which required treatment. None were taking primary prophylaxis.
Conclusion: FALD patients with cirrhosis should at least have one screening OGD. While 25% of our screened cirrhotic patients had varices, concerningly only 43.7% had underwent an OGD. Future multi-centre collaborative research is needed to facilitate the development of guidelines on variceal surveillance for this growing cohort of FALD patients. The majority of cirrhotic patients in this cohort are linked in with a liver clinic. The young age of this cohort should not disguise or detract from the risk of cirrhosis and life threatening variceal bleeding. This study has identified an opportunity for education to improve the awareness and importance of variceal screening and this unique evolving population, for staff, patients and carers.

FRI296

Primary liver malignancies in patients with Wilson's disease

Rodolphe Sobesky[1,2], Olivier Guillaud[2,3], Aurelia Poujois[2,4], Audrey Coilly[1,2], Eric Vibert[1,2], René Adam[1,2], Daniel Cherqui[1,2], Cyrille Feray[1,2], Didier Samuel[1,2], Jean-Charles Duclos-Vallée[1,2]. *[1]CHB-Centre Hépato-Biliaire, Villejuif, France; [2]Centre référent Maladie de Wilson, France; [3]CHU Lyon, Gastro-entérologie, Hépatologie, Lyon, France; [4]Hôpital Fondation Rothschild, Neurologie, Paris, France*
Email: rodolphe.sobesky@aphp.fr

Background and aims: Wilson's disease (WD) can induce chronic liver disease, cirrhosis and its complications. Primary liver cancer in WD patients is currently believed to be rare. Reports of primary hepatobiliary malignancies in these cases are sparse. Our aim was to assess the frequency and characteristics of primary liver cancer in WD patients on long-term follow-up.

Method: We retrospectively analysis a monocentric cohort of WD patients with liver damage from a referral center for rare diseases. Patients of the cohort were regularly assessed with a maximal interval of 6 months. Patients with a history of cirrhosis had a biannual ultrasound examination. Occurrence, treatment and outcome of primary liver tumors were analyzed.
Results: We analyzed 149 WD patients of the cohort, with a mean follow up of 15 years. The mean age at diagnosis of WD was 20.1 years. Sixteen patients were diagnosed with a primary liver tumor during follow up. The mean age at onset of a liver tumor was 52.5 years, with a mean interval between diagnosis of WD and occurrence of tumor of 19.2 years. We diagnosed a hepatocellular carcinoma (HCC) for 10 patients and a cholangiocarcinoma (CCK) for 6 patients. Histological proof could be obtained for 7/10 patients with HCC and for all patients (6/6) with CCK. For the 3 other patient, diagnosis of HCC was based on the morphological aspect (hyper vascular tumor with washout) and elevated AFP markers. All patients who developed a liver tumor had evidence of cirrhosis at the diagnosis of WD. At the diagnostic of tumor, there was no cirrhosis on the pathological examination of the non-tumoral liver for 6 patients (2/10 patients with histological proof of HCC and 4/6 patients with CCK). For all patients with primary liver tumor, a treatment could be proposed. Resection was possible for 8 patients and liver transplantation for 5 patients. During follow up, six patients died from complications of tumor extension (3 from HCC and 3 from CCK).
Conclusion: WD patients with history of cirrhosis are at risk of developing primary liver tumor and require morphological screening, even if there is a regression of fibrosis. The proportion of CCK (37.5%) among these tumors suggests an interest of the biopsy for diagnosis of liver cancer in WD patients.

FRI297

Defining the boundaries for "stability" in Wilson disease patients on maintenance chelation therapy: lessons from the CHELATE trial

C. Omar Kamlin[1], Michael Schilsky[2], Peter Ott[3], Karl Heinz Weiss[4], Massimo Giovanni Zuin[5], Aurelia Poujois[6], Aftab Ala[7], Koenraad D'Hollander[8]. *[1]Orphalan SA France, Medical Affairs, London, United Kingdom; [2]Yale University, Division of Internal Medicine and Liver Unit, United States; [3]Aarhus University Hospital, Aarhus, Denmark; [4]Salem Medical Center, Heidelberg, Germany; [5]University of Milan, Milan, Italy; [6]Fondation Hopital Rothschild, Department of Neurology, Paris; [7]Kings College University Hospital, London, United Kingdom; [8]International Drug Development Institute (IDDI), Belgium*
Email: omarkamlin@doctors.org.uk

Background and aims: "Clinical stability" of patients with Wilson disease (WD) is a treatment goal for long-term maintenance therapy and a desired entry point for interventional therapeutic trials in this patient population. Stability evaluation relies on laboratory parameters and clinical assessment. Published guidance and practice guidelines are not aligned, leading to variations in assessments and therapeutic targets. We performed a descriptive secondary analysis of "clinically stable" patients enrolled into the Chelate trial to define the boundaries of biochemical stability (clinicaltrials.gov; NCT03539952).
Method: Clinically stable patients on D-penicillamine (DPA) >1 y were randomised to DPA or trientine tetrahydrochloride if 24-h urinary copper excretion [UCE] was 200–500 mcg/L (amended 100–900), alanine aminotransferase[ALT] <2× ULN IU/L, serum non-caeruloplasmin bound copper[NCC] 50–150 mcg/L, (amended 25–50) determined initially by EDTA method (NCC-Ex). NCC by speciation coupled with ICP-mass spectroscopy (NCC-Sp) was performed retrospectively. Amendments to these ranges and opportunities for biochemical screen failures to re-enter trial were made to improve trial feasibility. We reviewed day 1 data for all screened patients.
Results: Twenty-five of 76 (33%) screened patients had NCC-Sp <50 mcg/L at first sampling, majority (20/25) between 25 and 50 mcg/L. The mean (SD) age was 40.4 (14.3) years; 13 were female. Serum NCC-Sp, UCE, ALT and dose of DPA in mg/kg are shown in the Table. For comparison, graphs of NCC-Sp and NCC-Ex versus UCE at screening are shown in the figure. Though a wide range of UCE was observed, UCE and NCC had a positive correlation. Two subjects with ALT >ULN of 54 (73 and 61) U/L, had corresponding NCC-Sp of 41 and 44.8 mcg/L respectively. UCE ranged widely, however mean UCE was within 200–500. Dose of DPA was 13.2 ± 3.5 mg/kg (7.4–19), within the recommended guidance of 10–15. Sixteen (64%) with NCC -Sp <50, including 3/4 who underwent re-screening, were randomized.

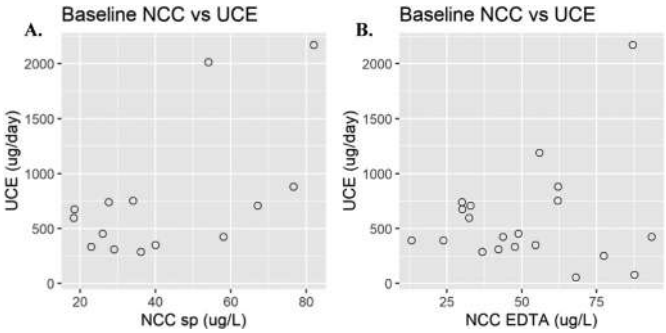


Figure: UCE- NCC scatter plots (A-NCC Sp and B-NCC Ex).

Table: Patients with Serum NCC-Sp <50 mcg/L at trial screening

	Mean	Max	Min	SD
NCC-Sp (mcg/L)	32.4	46.9	17.0	8.9
NCC-Ex	36.5	48.8	13.1	8.5
UCE (mcg/24 hr)	475	798	47	221
ALT (U/L)	26	73	6	16.3
DPA dose (mg/kg)	13.2	19.0	7.4	3.5

Conclusion: Re-screening of patients in clinical trials of rare disease facilitates recruitment. Single and multiple biochemical parameter analyses are helpful in defining the boundaries for "stability" of WD patients and lower values of NCC are common with the optimal lower limit requiring further study. Dosing in patients with very low NCC (<25 mcg/L) should be re-evaluated to avoid overtreatment. NCC may be a useful parameter for response guided dosing of therapy for chelation in WD.

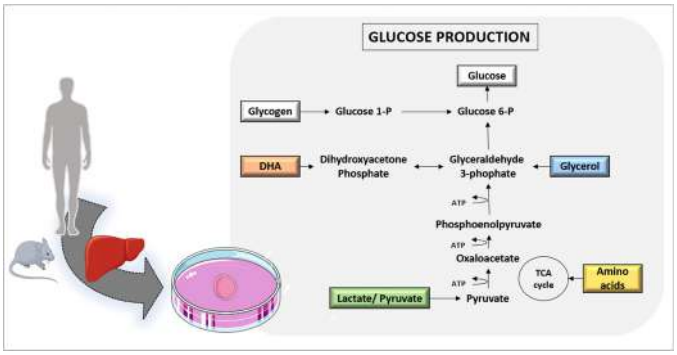
FRI298

Precision-cut liver slices as an ex vivo model to assess impaired hepatic glucose production

Kishore Alagere Krishnamurthy[1], Ligia Akemi Kiyuna[1], Miriam Langelaar[1], Albert Gerding[1], Trijnie Bos[1], Dorenda Oosterhuis[2], Peter Olinga[2], Karen Van Eunen[1], Barbara Bakker[1], Maaike Oosterveer[1]. *[1]University Medical Center Groningen, Groningen, Netherlands; [2]University of Groningen, Groningen, Netherlands*
Email: a.k.kishore@umcg.nl

Background and aims: Disturbed glucose metabolism is a common feature of metabolic diseases. For example, fasting hypoglycemia is a severe symptom of various inborn errors of metabolism, among which glycogen storage disease type 1 (GSD I). Due to the liver's central role in endogenous glucose production, the availability of a liver-specific *ex vivo* model will enable unravelling the mechanisms underlying perturbed glucose homeostasis. Given the limitations of *in vitro* hepatocyte cultures (e.g. reduced Glucose-6-phosphatase activity, proliferative nature), this study aims to optimize and characterize precision-cut liver slices (PCLS), both from the human and murine liver, as a model to study hepatic glucose production *ex vivo*.

Method: PCLS were prepared from fed and 12h-fasted male C57BL/6 mice and incubated in Williams E glucose-free medium supplemented with gluconeogenic precursors: (1) 10 mM glycerol, (2) 20 mM lactate plus 2 mM pyruvate, or (3) 10 mM dihydroxyacetone (DHA). Net cumulative glucose production was assessed at different time intervals (2 h–24 h). The amino acids in the medium and slice glycogen content were quantified at different time points to assess the source of glucose. Additionally, the efficacy of glucose production in response to fatty acid supplementation (500 µM palmitate), hormonal (0.1–1 µM glucagon or insulin), and pharmacological (10–20 µM forskolin or 50–100 µM dibutyryl-cAMP) stimulation were evaluated. Finally, to study GSD type 1 *ex vivo*, we used either PCLS derived from GSD Ia/Ib mouse models (*L*-G6PC$^{-/-}$ and *L*-SLC37A4$^{-/-}$) or subjected wildtype PCLS to pharmacological inhibition of G6P exchanger SLC37A4 (S4048).
Results: PCLS derived from fed and fasted mice produced glucose, both in the presence and absence of gluconeogenic precursors. The glycogen content in the PCLS was substantially and equally reduced in all conditions after 5 h in culture. No substantial changes were observed in the amino acid concentrations in any condition. Both forskolin and dibutyryl-cAMP increased net cumulative glucose production, while palmitate, glucagon or insulin did not alter glucose production. Lastly, PLCS from both pharmacological and genetic models of GSD type 1 showed markedly reduced glucose production and elevated lactate production, in line with the clinical disease phenotype.



Conclusion: PCLS can be used to study glucose production *ex vivo* up to 24 h in culture and DHA seems to result in the higher net glucose production. In ongoing follow-up experiments, ^{13}C-labelled DHA and/or glycerol are used to test their role as a gluconeogenic precursor or a gluconeogenic regulator. Finally, PCLS offer the possibility to use patient liver biopsy, murine genetic models and pharmacological intervention. Hence, they are an excellent and promising ex vivo platform to study endogenous glucose production in GSD type 1 and other inborn errors of metabolism.

FRI299

Interim 52-week analysis of immunogenicity to the vector capsid and transgene-expressed human FVIII in GENEr8-1, a phase 3 clinical study of valoctocogene roxaparvovec, an AAV5-mediated gene therapy for hemophilia A

Brian Long[1], Sylvia Fong[1], Britta Handyside[1], Tara Robinson[1], Jonathan Day[1], Hua Yu[1], Kelly Lau[1], Kathryn Patton[1], Greg de Hart[1], Josh Henshaw[1], Suresh Agarwal[1], Christian Vettermann[1], Soumi Gupta[1]. [1]*BioMarin Pharmaceutical Inc. San Rafael, CA. USA 94901*
Email: brian.long@bmrn.com

Background and aims: Valoctocogene roxaparvovec is an AAV5-mediated gene therapy under investigation for the treatment of hemophilia A and encodes a codon-optimized B-domain deleted human FVIII protein (hFVIII-SQ) under control of a liver-selective promoter. This report describes clinical immunogenicity monitoring data from up to 1 year of follow-up from GENEr8-1, an ongoing, fully enrolled, Phase 3, single-arm, open-label study in 134 male participants with severe hemophilia A.
Method: Participants were required to test negative for anti-AAV5 total antibody (AAV5 TAb) utilizing a bridging electrochemiluminescent (ECLA) screening assay being developed as a companion diagnostic by ARUP Laboratories (Salt Lake City, USA). Additionally, all participants were required to be on FVIII prophylaxis and have had at least 150 exposure days to FVIII replacement products without previous clinically detectable FVIII inhibitor development. Following dose administration, plasma was analyzed for AAV5 TAb, and a cell-based AAV5 transduction inhibition (TI) assay was used to further characterize the capsid-neutralizing potential of the anti-AAV5 antibodies. Development of FVIII inhibitors was monitored using the Nijmegen-modified Bethesda assay, and FVIII-specific TAb were assessed by bridging ECLA. Additionally, peripheral blood mononuclear cells were collected for analysis in a validated IFN-γ ELISpot assay for detection of capsid-specific and hFVIII-SQ-specific cellular immune responses.
Results: All participants developed a humoral antibody response to valoctocogene roxaparvovec following dose administration. Transient, low level AAV5 capsid-specific cellular immune responses were detected in the majority of subjects where incidence peaked at Week 2 following dose administration and often declined or reverted to negative over the first 52 weeks. Similarly, sporadic positive FVIII cellular immune responses were detected in a limited number of subjects. No subjects developed FVIII inhibitors following administration of BMN 270.
Conclusion: Immune responses to valoctocogene roxaparvovec were predominantly directed toward the AAV5 capsid, characterized by the production of anti-AAV5 binding and neutralizing antibodies as well as transient AAV5 capsid-specific cellular immune responses. Capsid-specific cellular immune responses showed a moderately positive correlation with plasma levels of the liver enzyme ALT suggesting these responses may be a contributing factor to transient elevations in ALT in some participants. There was no clinical evidence of inhibitor formation in subjects dosed with valoctocogene roxaparvovec.

Viral hepatitis C: Clinical aspects except therapy

FRI301

Sex effect on key intrahepatic gene networks in hepatitis C virus infection

Emanuele Marchi[1], Paul Klenerman[1], Narayan Ramamurthy[1], Azim Ansari[1], Eleanor Barnes[1], Caroline Harrer[1]. [1]*University of Oxford, NDM-Nuffield Department of Medicine, Oxford, United Kingdom*
Email: emanuele.marchi@ndm.ox.ac.uk

Background and aims: Spontaneous HCV clearance and successful antiviral therapy rates are largely in favour of women and/or in subjects with a specific IFNL4 genotype. The unfavourable IFNL4 genotype leads to an exaggerated interferon response eventually detrimental for the patient. However, women tend to have a more robust and prompt interferon activity. Beyond this, the causes of sex differences in infections are insufficiently understood. The transcriptional response in the liver during hepatitis C virus (HCV) infection is critical for determining clinical outcomes. This issue remains relatively unexplored as tissue access to address this at scale is usually limited. We aimed to profile the transcriptomics of HCV infected livers to describe the expression networks involved and assess the effect on them of major predictors of clinical outcome such as IFNL4 host genotype and sex.
Method: We took advantage of a large clinical study of hepatitis C therapy accompanied by baseline liver biopsy to examine the drivers of transcription in tissue samples in 195 patients also genotyped genome-wide for host and viral SNPs. We addressed the role of host factors (disease status, sex, genotype, age) and viral factors (load, mutation) on transcriptional responses.
Results: We observe key modules of transcription which can be impacted differentially by host and viral factors. Underlying cirrhotic state had the most substantial impact, even in a stable, compensated population. Notably, sex had a major impact on antiviral responses in concert with IL28B (interferon lambda) genotype, with stronger interferon and humoral responses in females. Males tended towards a dominant cellular immune response. In both sexes there was a strong influence of the underlying host disease status and of specific viral mutations, and sex-specific eQTLs were also observed.
Conclusion: These features help define the major influences on tissue responses in HCV infection, impacting on the response to treatment and with broader implications for responses in other sex-biased infections.

FRI302

Active case management to connect hepatitis C notifications to care and treatment in Australia (CONNECT study), a randomised controlled trial

Tafireyi Marukutira[1,2], Karen Moore[3], Margaret Hellard[1], Jacqui Richmond[1], Kate Turner[3], Alisa Pedrana[1], Shannon M. Melody[3], Louise Owen[3], Wijnand Van Den Boom[1], Nick Scott[1], Alexander Thompson[4], David Iser[4], Tim Spelman[1], Mark Veitch[3], Mark Stoove[1], Joseph Doyle[1]. [1]*Burnet Institute, Melbourne, Australia;* [2]*Monash University, Melbourne, Australia;* [3]*Tasmanian Department of Health, South Launceston, Australia;* [4]*St. Vincent's Hospital Melbourne, Fitzroy, Australia*
Email: tafireyi.marukutira@burnet.edu.au

Background and aims: Despite the simplicity, tolerability and subsidised access of directly acting antivirals (DAAs), hepatitis C (HCV) treatment uptake in Australia is declining. Initiatives are needed to actively engage people living with HCV to link them to care and treatment. In this study, we measured the impact of using

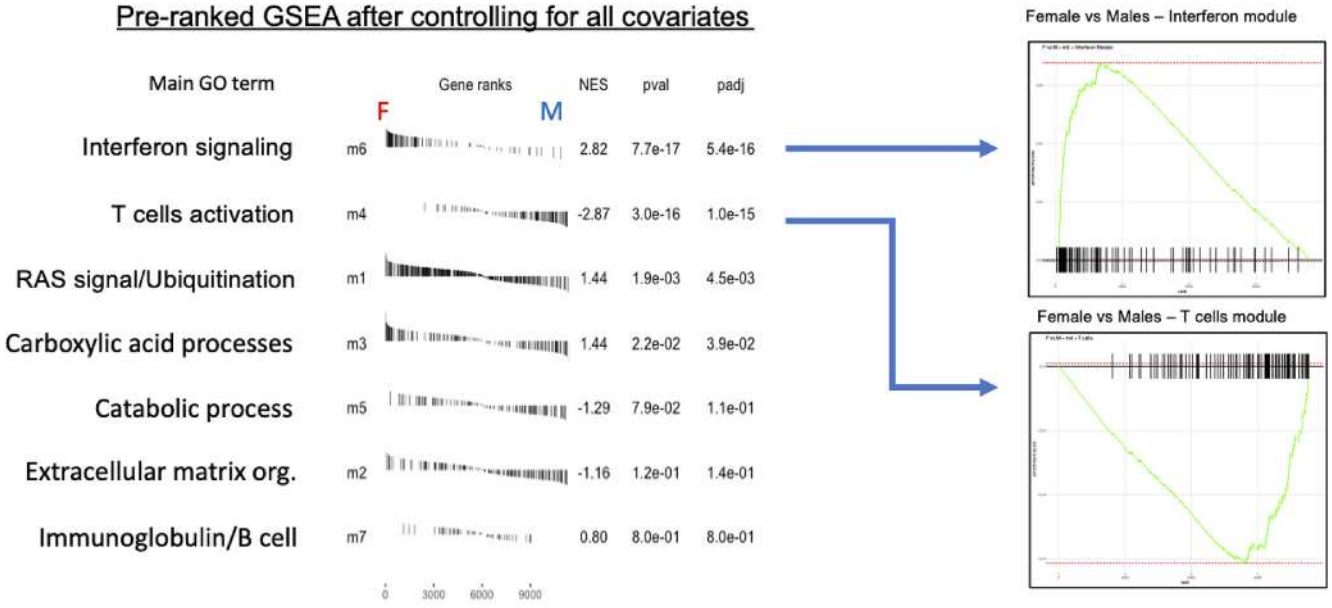

Figure: (abstract: FRI301)

hepatitis C notifications systems to engage diagnosing general practitioners (GPs) and improve patient access to treatment.
Method: The CONNECT study was a randomised controlled trial that compared enhanced case management delivered to clinicians notifying new/repeat HCV diagnoses to standard of care in Tasmania, Australia over 12 months in 2020–2021. GPs were randomised based on their first HCV notification during the study period. The intervention involved a health department nurse specialist contacting notifying GPs directly and providing stepwise support by telephone, and direct patient contact if required. The primary outcome was the proportion of individuals with HCV who initiated DAAs within 12 weeks of HCV antibody notification. Secondary outcomes compared proportion completing pre-treatment HCV RNA testing and blood work-up.
Results: A total of 171 GPs were enrolled and randomised to the intervention (n = 85) or the standard of care (n = 86) arms. Over the observation period, GPs in the intervention notified 111 HCV antibody positive cases compared to 115 in standard of care. A higher proportion of HCV notifications in the intervention compared to standard of care completed HCV RNA testing (96% vs. 86%; p = 0.03) and 33% compared to 30% were HCV RNA+ve (p = 0.19) respectively. Pre-treatment workup among those eligible for treatment (RNA+ve) was similar between intervention and standard of care arms (62% vs. 65%; p = 0.82). The proportion of all HCV notifications that initiated treatment was similar between intervention and standard of care arms (20% vs. 14%; p = 0.24). The proportion of treatment eligible cases initiating treatment within 12 weeks of notification was also similar between study arms (38% vs 32%; p = 0.63) (Figure 1). Most cases who did not initiate were lost to follow up or were referred to a specialist.

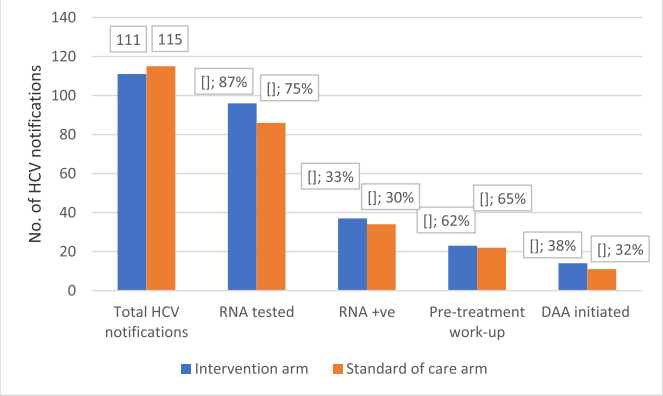

Figure: HCV Testing and Treatment Cascade.

Conclusion: This is the first prospectively randomised study that explored the utilisation of HCV surveillance data to enhance linkage to HCV treatment. While there was no difference in treatment initiation, the intervention encouraged more GPs to complete RNA testing as the initial stage of assessing DAA eligibility. Health Department follow up could potentially augment HCV antibody testing to ensure DAA eligibility is assessed early.

FRI303

Find out HCV patients: systematic study of 2013–2020 HCV files of a MDT viral hepatitis expert unit on the future of patients has made it possible to find out the lost ones and put them into treatment

André-Jean Remy[1], Sonia Djazouli[1], Hakim Bouchkira[1], Jeremy Hervet[1], Berengere Roy[1]. [1]*Perpignan Hospital, Mobile Hepatitis Team, Perpignan, France*
Email: andre.remy@ch-perpignan.fr

Background and aims: Access to direct antiviral agents (DAA) has been progressively needed since 2013. But what happened to the patients, treated or not, seen since that date? Several studies have been conducted to find patients seen in consultation or hospitalization but without assessing the fate of the entire active queue. Our objectives were to evaluate follow-up of patients spent in multidisciplinary team meeting (MDT) within our hospital viral hepatitis expert unit, even when it was no longer mandatory for an DAA, treatment decision in the absence of current healing, to offer them DAA treatment.
Method: All MDT sheets from September 2013 to December 2020 have been reviewed. We contacted GP, patient or private hepatologist by email or telephone for an estimated 5 hours of work per week. Follow-up data were collected via our hospital's computerized file. In the absence of direct contact; national death database was consulted.
Results: As of 31th August 2021, 1158 MDT files were initially studied corresponding to 1032 different patients; there were 683 men and 349 women of average age 37 years and 41% of F3F4 fibrosis; 97 patients were known to have died (69% of non-hepatic cause), 413 cured without liver complications; 153 followed for their cirrhosis and 41 for hepatocellular carcinoma; 328 were lost of sight of 68 previously followed by our team and 146 by liberal hepatologists. As of 31th October 2021, the contact information for 54patients was missing or incorrect; no information had yet been obtained for 126 patients followed in liberal; 37 additional patients were found within one month of which 8 were already cured and 15 died; 14 were eligible for immediate treatment due to an available positive viral load; 11 patients accepted an appointment for a referral of which 9 had already started the treatment and 2 patients refused the care; there were 90 patients followed by our team to contact or relaunch, which should be achieved within 3 months.
Conclusion: Maintaining MDT transition of all patients with chronic hepatitis C allows for an efficient database and to find untreated and/or untreated patients and offer them treatment. Number of refusals to care remains low, less than 10%. Our study, initially planned as a cohort retrospective analysis, found patients with chronic hepatitis C with RNA positive and untreated and immediately treated. This work shows that there are still patients who know they are infected with HCV but have not yet been treated. The research and treatment of these patients is essential to the elimination of hepatitis C.

FRI304

Effectiveness of a central monitoring system for the continuum of care of hepatitis C in Brazil during COVID-19 pandemic

Paulo Bittencourt[1], Liana Codes[1], Maria Lucia Ferraz[1]. [1]*Brazilian Liver Institute*
Email: plbbr@uol.com.br

Background and aims: Several healthcare facilities dedicated to hepatitis C testing and linkage and retention to care were closed in Brazil due to the COVID-19 pandemic, leading to a 40%-50% reduction in the distribution of HCV rapid tests as well as new treatments for HCV in 2020. To mitigate the adverse impact of the pandemic on the hepatitis C elimination plan, the Brazilian Liver Institute (Ibrafig) sponsored a remote patient support program (PSP) to monitor all aspects of the HCV care continuum (HCV CC) in the public health system. The aims of the present study were to assess the results of this strategy in different steps of the HCV CC in Brazil.

Method: After mapping of the active healthcare facilities offering HCV rapid tests to the general population as well as diagnosis and treatment for HCV, Ibrafig launched a remote PSP to follow-up subjects in all steps of HCV CC from testing of hepatitis C until HCV cure. The remote PSP wascomprised by trained healthcare personnel and contacts were made through phone calls, SMS, email or whatsapp according to users preferences. Awareness campaigns concerning hepatitis C elimination were coupled with nationwide advertising of the remore CMS on social media, TV and radio.
Results: From August 2020 to July 2021, 11.049 interactions were recorded between usersand CMS, most of them by Whatsapp (91%). Most of them became aware of the PSP by radio and/or TV (41%) and social media (31%). After informed consent, 601 subjects were registered in the PSP including 74 patients already diagnosed with HCV who were lost in the public healthcare system due to the COVID-19 pandemic. Overall, 501 subjects were referred for HCV testing. Fifteen (9%) out of the 115 subjects who reported their test results were positive for HCV. Up to now, 53 (60%) out of 89 HCV positive patients have scheduled their 1rst consultation, 12 (13%) are enrolled in care and 14 (16%) are under antiviral treatment. Seven (8%) who achieved end of treatment response are waiting HCV sustained virological response.
Conclusion: Our preliminary data showed that a remote PSP was an effective strategy to monitor the HCV CC. It was capable to refer at risk subjects for HCV testing and to provide linkage and retention to care of those HCV positive subjects in the Brazilian public health system during the COVID-19 pandemic.

FRI305

Retrieval of HCV patients lost to follow-up as a strategy as a strategy for hepatitis C microelimination: results of a brazilian multicentric study

Paulo Bittencourt[1], Maria Lucia Ferraz[1], Gustavo Henrique Santos Pereira[2], Liana Codes[1], Antonio Andrade[2], Carlos Brandão-Mello[2]. *[1]Brazilian Liver Institute; [2]Brazilian Society of Hepatology*
Email: plbbr@uol.com.br

Background and aims: Several HCV positive patients in Brazil were lost to follow-up in the last two decades before achievement of sustained virological response (SVR) due to either non-response to interferon-based therapy or lack of treatment due to comorbidity or mild fibrosis. The purpose of the present study was to identify and retrieve those lost patients to offer treatment with the current highly effective direct acting antivirals (DAAs).
Method: All medical charts from three major reference centers for treatment of hepatitis C were retrospectively reviewed by trained healthcare personel to identify all HCV positive subjects, their treatment status and, in those HCV RNA positive patients, the main reasons for non-achievement of SVR or lack of treatement. After review of a local senior hepatologist, all patients who were not treated or cured were contacted in order to offer therapy with DAAs.
Results: 7.498 medical charts were reviewed, 5549 (74%) from HCV positive patients (50, 1% males, mean age 51±12years). Advanced fibrosis or cirrhosis and hepatocellular carcinoma were observed in 1929 and 95 subjects, respectively. Only 3272 (59%) were submitted to treatment. SVR, non-response to IFN-based and IFN-free regimens was observed in 2348 (72%), 658 (20%) and 266 (8%) subjects, respectively. Lack of treatment due to loss of FU (29%) or other reasons (12%) such as comorbidity, mild fibrosis or treatment refusal were reported in the remaining patients. Until October 2021, 2745 patients were considered eligible to be retrieved by local investigators and 1593 phone calls were made with a callback success rate of 15%. 43 (2%)patients were retrieved for treatment. Most of the remaining patients have been treated elsewhere (n = 61) or have died or underwent liver transplantation (n = 69).
Conclusion: Our preliminary data showed that identification and retrieval for treatment of HCV patients lost to FU is an effective microelimination strategy despite the low callback success rate.

FRI306

Reorganizing and simplifying HCV diagnosis and treatment in special populations during COVID pandemic and beyond

Paolo Scivetti[1], Elisa Perfetti[1], Lorenzo Somaini[2], Sarah Vecchio[2], Antonio Panero[1], Paola Zaldera[3]. *[1]ASLBI Ospedale degli Infermi, SOC Internal Medicine-Hepatology Centre, Ponderano, Italy; [2]Aslbi, Addiction Treatment Centre, Biella, Italy; [3]Aslbi, Casa Circondariale-Health Section, Biella, Italy*
Email: paolo.scivetti@aslbi.piemonte.it

Background and aims: Hepatitis C infection has a high prevalence among prisoners and in people who use drugs (PWUDs) and his identification and treatment are a pivotal factor to achieve HCV elimination by 2030. However, PWUDs and prisoners often face multiple barriers during the treatment cascade. In our Local Health Unit of Biella we have already developed a shared model of care between Addiction Treatment Centre (SerD), prison and hospital hepatology centre, to gather clinical evaluations within a single visit in order to ameliorate the HCV treatment rate. Subsequently, the treatment journey has been complicated by Covid pandemic. The aim of this study is to describe the new model of care we have developed to overcome old and new barriers to HCV treatment in these special populations.
Method: Since march 2020 a new model of care has been developed and centered on three crucial elements: a collaboration between SerD, prison and hospital hepatology centre; the introduction by AIFA (Italian Agency of Drugs) of the "criterion 12" that allows treatment after ruling out liver fibrosis by APRI and FIB-4 without elastography; the evidence that these scores allow us to exclude severe fibrosis, the risk of a hepatocarcinoma and the need of an ultrasound test. Patients attending SerD performed HCV viral load by mean of on-site fingerstick assay and inmates by mean of salivary test for antiHCV. HCVrna positive patient's data were recorded into a database shared between the three services. After ruling out severe fibrosis by APRI and FIB-4, hepatologist prescribed the DAAs (direct-acting antiviral agent) with virtual "computer-generated" evaluation of the patients. DAAs were delivered by the SerD's or prison's health professionals. The patients were directly visited by the hepatologist only in the case of severe fibrosis at the scores.
Results: HCVrna was detected in out of 33/250 SerD patients' and in out of 4/44 inmates, respectively. Linkage to care was possible for a total of 34 patients (30 SerD and 4 Prison). The patients were mostly male, and heroin addicted. Sixteen of them had only a virtual evaluation, conversely 18 patients underwent to direct examination. Overall, 34 patients completed the treatment, and all of them achieved Sustained Virologic Response.
Conclusion: Our new model of care highlights the feasibility of the on-site HCV testing and the efficacy of this simplified virtual "computer-generated" procedure for the treatment of HCV in special populations. This new model of care has allowed us to continue the diagnosis, the linkage to care and the treatment of patients even during COVID-19 pandemic and hopefully beyond.

FRI307

The health economic outcomes of trial ACTG5360/MINMON

Benjamin Linas[1,2], Michelle Weitz[1], Tannishtha Pramanick[3], Mark Sulkowski[4], Irena Brates[5], Laura Smeaton[6], Sandra Cardoso[7], Sunil Suhas Solomon[4]. *[1]Boston Medical Center, Section of Infectious Diseases, Boston, United States; [2]Boston University School of Medicine, Medicine, Infectious Diseases, Boston, United States; [3]Boston Medical Center, Section of Infectious Diseases, Boston, United States; [4]Johns Hopkins University School of Medicine, Division of Infectious Diseases, Baltimore, United States; [5]Harvard T.H. Chan School of Public Health, Center for Biostatistics in AIDS Research (CBAR), Boston, United States; [6]Harvard T.H. Chan School of Public Health, Center for AIDS Research (CFAR), Boston, United States; [7]Instituto Nacional de Infectologia Evandro Chagas, Rio de Janeiro, Brazil*
Email: tannishtha.pramanick@bmc.org

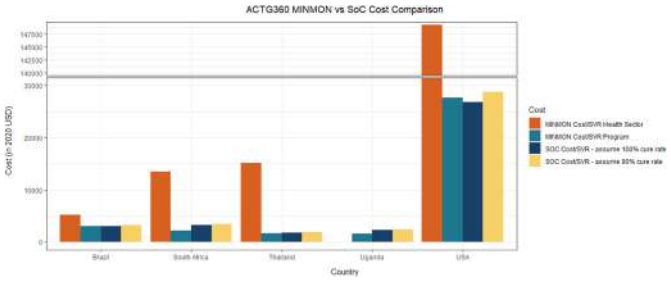
Background and aims: The ACTG MINMON trial demonstrated that HCV treatment with no planned in-person monitoring is safe and efficacious. We report resource utilization and cost in the MINMON trial.

Method: ACTG A5360 (MINMON) was a 5 country, single arm study providing 12 weeks of sofosbuvir/velpatasvir to people with HCV infection with no planned visits prior to SVR evaluation (Week 24). Trial records included planned/unplanned lab tests and visits. Participants completed a 4-week recall questionnaire at weeks 0, 24, and 48 reporting hospital nights, emergency department visits, and ambulatory visits. To cost MINMON, we tabulated consumption and multiplied units of consumption by country-specific cost. We report cost of MINMON per SVR attained (2020 US$) from the program perspective (includes costs of medications and monitoring from study entry to Week 24), and the health sector perspective (program perspective plus healthcare utilization outside the study prior to cure, plus the additional (or reduced) healthcare utilization observed after HCV treatment).

Sensitivity analyses explored potential cost savings of MINMON compared to the standard of care (SoC). We consulted in-country experts to develop country-specific SoC treatment protocols and employed standard micro costing to estimate cost. We present cost/SVR in MINMON along with that of the simulated SoC, ranging the expected SVR with the SoC.

Results: MINMON cost/SVR (healthcare sector perspective) varied by country from $5, 256/SVR in Brazil, to $149, 257/SVR in the U.S. (Graph). The program perspective ranged from $1, 637/SVR in Uganda to $27, 641/SVR in the U.S. The cost of pharmaceuticals was the largest component of treatment cost, ranging between 76%–96% of cost from the program perspective.

MINMON had a lower cost/SVR (program perspective) than the SoC across broad assumptions about cure rates. Outside of the U.S., the cost/SVR of MINMON was lower than that of the SoC even when the SoC achieved higher cure than MINMON. In the U.S., the MINMON cost/SVR was lower than the SoC unless the SoC would be expected to achieve at least a 4-percentage point higher cure rate.



Conclusion: MINMON is likely a cost saving strategy compared to the SoC for HCV treatment.

FRI308

Hepatitis C treatment during the COVID-19 pandemic has similar efficacy with less resource utilization: analysis from the British Columbia HCV network

Shirley Jiang[1], Jeanette Feizi[1], Julia MacIsaac[1], Edward Tam[2], Hin HIn Ko[1], Alnoor Ramji[1]. *[1]The University of British Columbia, Vancouver, Canada; [2]Pacific Gastroenterology Associates, Vancouver, Canada*
Email: sjiangx@gmail.com

Background and aims: During the COVID-19 pandemic, a 49% decrease in dispensation of direct-acting anti-virals (DAAs) for hepatitis C (HCV) infection has been observed in Canada. We sought to characterize HCV patients, treatments, and outcomes during the pandemic.

Method: Single-centre retrospective chart review at a site of the British Columbia HCV Network. Patients initiated on DAAs from 17/12/2018–16/3/2020 were included as the pre-pandemic group (pre-PG), and compared to those treated from 17/3/2020–16/6/2021, who were included as the comparison pandemic group (PG).

Results: Over a 15-month period, 139 HCV patients were initiated on treatment as part of the PG compared to 179 patients in the pre-PG, representing a 22% decline. Pandemic patients were significantly younger (mean age 56.1 vs 59.5 years, $p = 0.01$) and a greater proportion were on opioid agonist therapy (27% vs 12%, $p < 0.01$). Patients had similar HCV genotypes and FIB-4 score. Significantly fewer PG patients had transient elastography (TE) within 6 months of initiating DAAs (52% vs 91%, $p < 0.01$). Of patients with TE scores, cirrhosis was found in 12 (8.6%) PG patients compared to 29 (16.2%) pre-PG. Patients treated during the pandemic also had fewer total appointments (median 2 per patient vs 4 per patient pre-PG, $p < 0.01$), with fewer office appointments (median 1 per patient vs 2 per patient pre-PG, $p < 0.01$) but a similar number of telehealth appointments (median 2 per patient for each group). Treatment patterns were similar with predominant use of glecaprevir/pibrentasvir and sofosbuvir/velpatasvir. Treatment completion rate was higher for the PG vs pre-PG (96% vs 86%, $p < 0.01$). Fewer patients obtained lab work for sustained virologic response (SVR) in the PG compared to pre-PG (74% vs 86%, $p < 0.01$). SVR rate was similar in both groups at 96% in the PG compared to 99% pre-PG ($p = NS$).

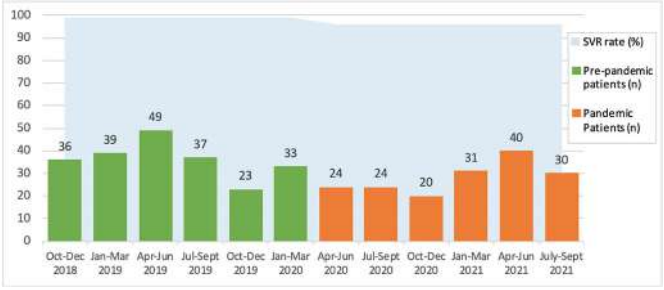


Figure: Patients started on HCV treatment and corresponding SVR rate

Conclusion: Patients with HCV infection treated during the COVID-19 pandemic utilized significantly less resources, had a higher rate of treatment completion, and similar rate of SVR. Treatment simplification through the use of telemedicine, minimizing investigations, and leveraging fewer healthcare resources can maintain high treatment completion and SVR rates.

FRI309

ELIMINATE-interim results of an Austrian HCV macro-elimination project

Email: thomas.reiberger@meduniwien.ac.at

Background and aims: The WHO has declared the elimination of HCV until 2030 a global public health goal. We present the preliminary results of an Austrian macro-elimination approach aiming to provide linkage to care and treatment initiation for persons who are recalled based on a "last-positive" HCV-RNA PCR result. Importantly, many of these lost-to-follow-up patients do not belong to known HCV risk groups and are, thus, often not recognized by targeted HCV screening/elimination projects.

Method: First, we identified patients with a "last-positive" HCV-RNA PCR result between 2010 and 2020 in laboratories of Eastern Austria (Burgenland, Lower Austria, Vienna) and (i) described their demographic characteristics. Subsequently, (ii) a systematic recall of these patients to the respective HCV treatment centers was performed, and (iii) HCV-DAA was initiated and SVR was monitored. Here we report the interim results of this ELIMINATE project including data/results from eight centers.

Results: Overall, 22692 patients underwent HCV-RNA PCR testing, 11216 (49.4%) ever showed a positive HCV-RNA result, and in 6223 (27.4%) patients the last available HCV-RNA result was positive (suggesting persisting HCV-viremia).

For this interim report, 1795/6223 HCV-RNA PCR (+) patients were evaluated: 305 (17.0%) were linked to HCV-care. 82 (4.6%) underwent liver disease evaluation and in 64 (3.6%) DAA treatment was initiated. In 10 (0.6%) sustained virologic response was documented.

Main reasons for the suboptimal cascade of care included invalid contact data (663; 36.9%) or patients' unavailability at the time of recall (172; 9.6%) and death (289; 16.1%). Successful DAA therapy at other centers had already been conducted in 366 patients (20.4%).

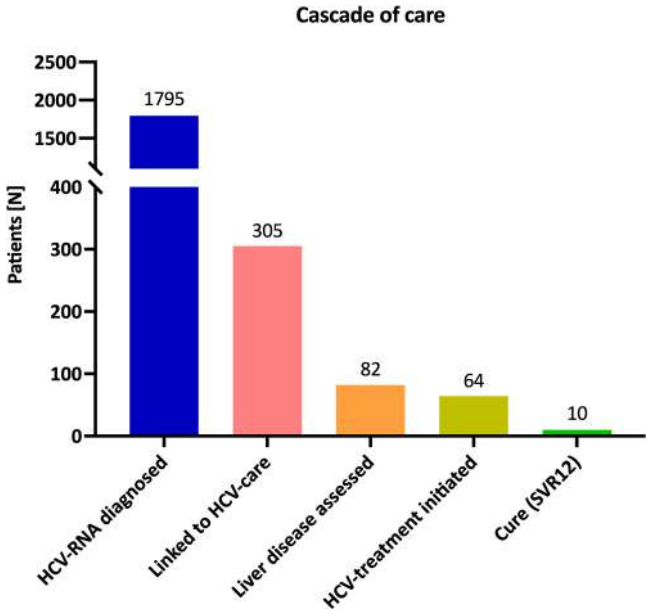

Figure 1: Cascade of care for the ELIMINATE project.

Conclusion: This lab record-based ELIMINATION project identified a considerable number of 6223 HCV patients with potential persisting viremia. Invalid contact data (36.9%) and pre-treatment death (16.1%) represent major problems/barriers. Importantly, at this interim stage 305 (17.0%) patients were successfully linked to care and 64 (3.6%) patients started DAA therapy.

FRI310

The korean hepatitis C virus care cascade in a tertiary institution: current status and changes in testing, link to care, and treatment

Jonggi Choi[1], Jina Park[1], Danbi Lee[1], Ju Hyun Shim[1], Kang Mo Kim[1], Young-Suk Lim[1], Han Chu Lee[1]. *[1]Asan Medical Center, University of Ulsan College of Medicine, Department of Gastroenterology, Seoul, Korea, Rep. of South*
Email: jkchoi0803@gmail.com

Background and aims: The care cascade for hepatitis C virus (HCV) infection is impeded by multiple barriers, including suboptimal HCV Ab testing, link to care, and diagnosis. We explored the changes in the care cascade of HCV for the past 20 years and its current status in a large cohort from a tertiary referral center.

Method: We analyzed 1, 144, 468 patients who had HCV Ab testing between January 2001 and June 2020. Metrics related to the care cascade of HCV infection and the long-term prognosis of patients were explored.

Results: The seroprevalence of HCV Ab was 1.8%, with a recent decreasing trend. In all, 69.9% of HCV Ab-positive patients performed HCV RNA testing, with a 65.7% positivity. Patients who did not have HCV RNA testing were older and more likely to have a non-hepatocellular carcinoma (HCC) malignancy, normal ALT level, and good liver function. Linkage times for HCV RNA testing from the HCV Ab positivity and for antiviral treatment from HCV diagnosis decreased, notably after 2015, when highly efficacious oral antiviral treatment was introduced to Korea. The average treatment uptake rate was 35.4%, which increased to 38.9% after 2015. Of the 5, 302 patients analyzed regarding long-term prognosis, the annual incidences of HCC were 1.02 and 2.14 per 100 person-years in patients with and without a sustained virological response, respectively.

Cascade steps	Metric	Results
HCV Ab testing	HCV Ab positivity, mean, (range)	1.8% (0.9–2.2)
	Performed HCV RNA testing, mean, (range)	69.6% (65.4–72.4)
	HCV RNA positivity, mean (range)	65.7% (55.7–83.2)
	Distribution of HCV genotypes	
	1b	48.4%
	2	45.3%
Link to care for HCV	Linkage time for HCV RNA from the detection of HCV Ab positivity, median	
	Before 2010	7.5 days
	2010–2014	3 days
	After 2015	1 day
	Linkage time for antiviral treatment from confirmed HCV infection, median	
	Before 2010	226 days
	2010–2014	192 days
	After 2015	84 days
HCV treatment	Liver disease status at the time of HCV diagnosis	
	Chronic hepatitis, mean proportion	63.1%
	Liver cirrhosis, mean proportion	14.3%
	HCC, mean proportion	22.6%
	Rate of antiviral treatment (without HCC)	35.4%
	Before DAA-era	33.9%
	DAA-era	38.9%
	SVR rate	
	Interferon-based regimen	71.2%
	DAA-based regimen	93.1%
Long-term outcome of HCV	Annual incidence of HCC	
	With SVR (per 100 person-years)	1.02
	Without SVR (per 100 person-years)	2.14
	Annual incidence of death or transplantation	
	With SVR (per 100 person-years)	0.55
	Without SVR (per 100 person-years)	4.34

Abbreviations: DAA, direct antiviral agents; HCC, hepatocellular carcinoma; HCV, hepatitis C virus; SVR, sustained virological response

Conclusion: The care cascade of HCV infection has been suboptimal for the past 20 years, despite the recent changes. More effort should be made to increase HCV RNA testing and treatment uptake.

FRI311

Macroeconomic assessment of overall and per-patient healthcare costs of Hepatitis C-infected patients in an integrated health system in the era of direct-acting antiviral therapy

David Kaplan[1,2], Claire Durkin[1], Marina Serper[1]. [1]*University of Pennsylvania, Medicine/Gastroenterology and Hepatology, Philadelphia, United States;* [2]*Corporal Michael J. Crescenz VA Medical Center, Medicine/Gastroenterology and Hepatology, Philadelphia, United States*
Email: dakaplan@pennmedicine.upenn.edu

Background and aims: Treatment of acute and chronic hepatitis C infection on a national or system-wide scale requires significant investment to acquire, dispense and monitor antiviral therapy with the intent to reduce downstream costs related to reduced liver-related complications. The US Veterans Administration (VA) initiated universal access to HCV direct acting antiviral (DAA) therapy in 2015. The Aim of this study was to quantify the total healthcare costs expended on prior and current hepatitis C-infected individuals before, during after the universal introduction of DAA therapy.

Method: All patients in the VA healthcare system with a positive HCV RNA by a qualitative or quantitative PCR tests at any time between 1999 and 2020 were identified. Exposure to antiviral therapy was identified by prescription fills for interferons and DAA medications. Treatment completion was assigned as 28 days after the final release for a specific regimen and the first date for possible assessment of SVR12 assigned to 84 days after treatment completion. Each course of therapy was characterized based on post-SVR12 date PCR results as cured, relapsed or untested if no PCR test was available. Health Economics Research Center (HERC) average cost estimates and Fee-Basis costs were utilized for outpatient and inpatient care within the VA and external costs, respectively. Cost of outpatient pharmacy were obtained from Managerial Cost Accounting data. For this analysis, total, outpatient, inpatient and pharmacy were aggregated by fiscal year (years 2010–2020) and presented as aggregate or per-patient costs. All costs were inflation-adjusted to year 2021 dollars using the consumer price index and post-treatment costs were discounted by 3% per year.

Results: During fiscal year 2010, 214, 531 unique infected individuals were under care. By 2020, only 68, 086 HCV-infected patients did not have documentation of SVR12 (Figure 1A). Total cost expenditures prior to DAA availability ranged between $5.3–5.8B then peaked at $9.0B in FY2015 due to massive increases in pharmacy-related costs (Figure 1B) then declined to pre-DAA levels by FY2020. Modest increases of outpatient and inpatient costs were observed from FY2010 to FY2018 at which point a significant decline occurred. However, the cost per-patient under care never declined to pre-DAA levels and only a modest decline in outpatient and inpatient expenditures was observed FY2019–2020 (Figure 1C).

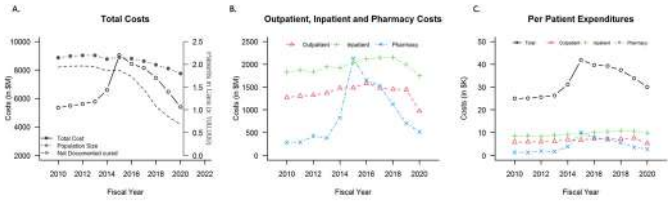

Figure 1. A. Total costs expended on hepatitis C-infected veterans by fiscal year. The number of infected veterans in care (filled circles) and those still viremic (dashed). B. Breakdown of overall costs to outpatient (triangle), inpatient (+) and pharmacy (X). C. Total, outpatient, inpatient and pharmacy costs divided per patient remaining in care.

Conclusion: These data suggest that reductions in overall healthcare costs for a hepatitis C-infected population cannot be observed within the first several years after implementation of universal treatment. Reductions in total cost to pre-DAA levels appear more related to patient attrition than to reduction of average patient treatment costs.

FRI312

Awareness of chronic hepatitis B and C among men who have sex with men (MSM): epidemiological survey and on-site screening

Marie Coessens[1,2,3], Tom Holvoet[4], Jeoffrey Schouten[4,5], Wim Verlinden[2,5]. [1]*VITAZ, Gastroenterology and Hepatology, Sint-Niklaas, Belgium;* [2]*University of Antwerp, Department of Medicine and Health Sciences, Antwerp, Belgium;* [3]*Laboratory of Experimental Medicine and Pediatrics (LEMP), University of Antwerp, Antwerpen, Belgium;* [4]*UZ Gent, Gastroenterology and Hepatology, Gent, Belgium;* [5]*AZ Nikolaas, Gastroenterology and Hepatology, Sint-Niklaas, Belgium*
Email: marie.coessens@student.uantwerpen.be

Background and aims: In order to eradicate Hepatitis B (HBV) and Hepatitis C (HCV) by 2030, the WHO focuses on screening in targeted high-risk populations, including men who have sex with men (MSM). The objectives of this study are to assess awareness and knowledge (1) and prevalence (2) of HBV and HCV infections in the MSM population in Flanders and Brussels.

Method: An online questionnaire in Dutch of 5 to 10 minutes was used, as well as face-to-face questionnaire using a tablet at the Belgian and Antwerp Pride (1). In 2018–2020 we joined Sensoa (a Flemish expertise center for sexual health) during outreach projects and tested visitors voluntarily at 14 gay bars, parties and saunas in Flanders by means of an oral quick test for HCV (e.g. OraSure Intercept 2). In addition, HCV test results collected by Ex Aequo (an MSM organization in Brussels that provides sexually transmitted diseases (STD) screening at offices and during on-site actions) in 2019 were analyzed (2).

Results: 300 MSM participated in the online Dutch questionnaire with a median age of 36 years old. HIV status was known to be positive in 7.7%. Knowledge of HBV and HCV infections was poor. Of all participants, 40.5% and 47, 6% thought HBV and HCV patients would always have symptoms; 52.9% thought there was an HCV vaccine; 37.1% thought there was no medication against HCV and of those who knew there was medication, 75% thought that treatment was long and hard. Only 15% and 1%, respectively, knew which sexual practices were with or without risk for HBV and HCV infection.

The knowledge of HBV was significantly correlated to the knowledge of HCV ($p < 0.0001$, r_s 0.324) and the degree of education ($p < 0.001$, r_s 0.209). The knowledge of HCV was significantly correlated to the number of sexual partners in the last six months ($p = 0.024$, r_s 0.131), the number of risky sexual practices ($p < 0.0001$, r_s 0.205).

In Sensoa's HCV prevalence study, only 1 of 260 test results was positive (0.38%) and this was an HIV co-infected patient. The Ex Aequo's HCV prevalence study yielded no positive test results. The HIV prevalences were 1, 15% (Sensoa) and 1, 3% (Ex Aequo) and the syphilis prevalence was 2, 5% (Ex Aequo).

Conclusion: There is a big knowledge gap of HBV and HCV infections in the MSM community in Flanders. More awareness campaigns that focus on transmission, disease process, treatment and vaccination need to be created that also target people with a low educational level.

The prevalence of hepatitis C infection and other STD's was low in the MSM population studied of 500 participants. Presumably a young MSM population that voluntarily has themself tested represents a rather low risk profile for HCV infection. HCV prevalence may be higher in an older population and/or in an illegal environment where more risk factors for HCV infection co-exist and that is more difficult to reach. However, given the high workload and low case finding, an on-site screening approach cannot be recommended.

FRI313

Predictive factors for lost to follow-up pre and post-hepatitis C treatment: Data from the British Columbia hepatitis C virus network

Alnoor Ramji[1], Edward Tam[2], Julia MacIsaac[3], Jean-Philippe Wallach[3], Jeanette Feizi[2], Hin Hin Ko[1]. [1]*University of British Columbia, Gastroenterology, Vancouver, Canada;* [2]*Pacific Gastroenterology Associates, Vancouver, Canada;* [3]*University of British Columbia, Vancouver, Canada*
Email: ramji_a@hotmail.com

Background and aims: In British Columbia (BC) 60% of identified HCV RNA (+) individuals remain untreated. A major challenge is the durable linkage to care of persons who are HCV RNA (+), many are lost to follow-up (LFU) prior to therapy (pre-LFU), or post therapy (post-LFU). Understanding patient profiles will inform resources for HCV elimination. Our aim was to determine predictive factors of HCV patients who are LFU pre- and post-treatment.

Method: Retrospective review of HCV RNA (+) persons in the BC HCV Network to determine the predictive factors of pre-LFU and post-LFU compared to treated persons with SVR12. Chi-square and multivariable regression analysis were performed.

Results: A total of 4057 patients were included, 2823 (70%) completed HCV therapy, 111 (2.5%) awaiting therapy, and 1123 (27.5%) were pre-LFU. See table. Pre-LFU patients were more likely to be male (70%), have psychiatric disorder (30%), history of injection drug-use (IDU) (37%), and heavy alcohol use (38%) compared to treated patients (64%, 18%, 26%, and 27% respectively, $p < 0.001$). Fewer persons with advanced fibrosis (FIB4 > 3.25 or LSM > 12.5 kPa) were in the pre-LFU group (22%) compared to treated group (30%), $p < 0.001$.

2823 patients completed HCV therapy, 2410 (85.5%) had SVR bloodwork, and 413 (14.5%) did not (post-LFU). Male gender (69%), history of psychiatric disorder (24%), IDU (36%), and heavy alcohol use (35%) were more likely to be post-LFU compared to treated patients (63%, 16%, 26%, 27% respectively, $p < 0.001$). Persons age > 60 years (57%), with a co-morbidity (12%), or advanced fibrosis (20%) were more likely to have SVR12 results documented than the post-LFU group (65%, 17%, and 29% respectively), $p < 0.001$. Multivariable regression for pre and post LFU compared to treated or followed persons, determined that male gender (OR:2.12 and 2.70), psychiatry disease (OR:3.45 and 3.33), IDU (OR:4.25 and 3.05), or heavy alcohol use (OR:3.65 and 2.90) were associated with pre and post-LFU.

	Treated (2823)	Pre-LFU (1123)	p-value
Male	1807 (64%)	786 (70%)	<0.001
Age>60	1843 (65%)	651 (57%)	<0.001
Co-morbidities	484 (17%)	173 (15%)	>0.05
Psychiatry	513 (18%)	336 (30%)	<0.001
IDU	755 (26%)	415 (37%)	<0.001
Alcohol	770 (27%)	426 (38%)	<0.001
Extensive fibrosis	869 (30%)	247 (22%)	<0.001
	Treated and SVR tested (2410)	Post-LFU (413)	p-value
Male	1523 (63%)	284 (69%)	<0.001
Age>60	1608 (66%)	238 (57%)	<0.001
Co-morbidities	420 (17%)	53 (12%)	<0.001
Psychiatry	405 (16%)	102 (24%)	<0.001
IDU	637 (26%)	148 (36%)	<0.001
Alcohol	663 (27%)	144 (35%)	<0.001
Extensive fibrosis	628 (29%)	83 (20%)	<0.001

Figure: Co-morbidity: DM, cardiac, renal, NASH; *p-value based on Chi-square

Conclusion: Male gender, history of psychiatric disorder, IDU, or and heavy alcohol use are predictive of LFU both pre- and post-HCV therapy. Successful HCV elimination strategies will need to incorporate interventions to improve durable engagement of these populations.

FRI314

HCV screening in a tertiary french hospital: just do it !

Si Nafa Si Ahmed[1], Souad Benali[1], Magalie Madau[1], Rania Kibeche[1], Romain Albenois[2], Michaël Ghez[3], Ines Belasri[1], Christine Hernandez[1], Paola Ramirez[1], Julien Negre[1], Laurence Lecomte[1], Floriane Sellier[1], Olivia Pietri[1], Paul Castellani[1], Xavier Adhoute[1], Marc Bourliere[1]. [1]*Hopital Saint Joseph, Hepatology Unit, Marseille, France;* [2]*Hopital Saint Joseph, Laboratory Unit, Marseille, France;* [3]*Hopital Saint Joseph, DIM, Marseille, France*
Email: ssiahmed@hopital-saint-joseph.fr

Background and aims: Universal screening appears to be the most cost-effective strategy to reach the HCV elimination planned by WHO for 2030. All HCV patients have currently access to treatment. In France HCV screening is based on identification of Risk Factor. The aim of the present study was to test universal screening strategy in all hospitalized patients.

Method: From November 2019 to November 2021, we conduct a prospective, longitudinal monocentric study screening all consent patients for HCV regardless identification of Risk Factor. All HCV Ab positive was followed by HCV RNA screening. All replicating patients were proposed to be treated according to the other pathologies for which the patients were hospitalized. The study was authorized by CPP Toulouse.

Because of occurrence COVID 19 pandemics, conducting this study we identify several limitations leading to the prolongation of inclusion time and to develop adaptive measures such as oral consent.

Results: As of September 30, 2021 results are shown in this figure:

Patients	HCV Ab-	HCV Ab+	HCV RNA+
28 806 Hospitalized	**4560 included (15.8%)**		
N (%)	4436 (97.28)	124 (2.71)	18 (0.4)
Sex Ratio	1.16	2.02	3.5
Prevalence % [IC 95]		2.71 [2.25-3.19]	
			14.5 [8.32-20.7]
Age mean - (extreme)	66.60 (18-101)	68.21 (21-95)	72.16 (49-95)
Two-sided t test		p = 0.08	
			p = 0.25

HCV Ab + patients seemed older; however this difference is not statistically different. Large part of patients (2/3) were unware of the HCV status.

49 (39.5%) patients come from surgical departments, 38 (30.5%) from the medical department and 37 (30%) are followed in gastroenterology office.

All HCV RNA+ patients have been evaluated for treatment. 8 are eradicated, 2 DAA therapy are still on going, 1patient refuse treatment (89 years old), 5 patients suffer from HCC and treatment was delayed, 2 patients died during palliative management

Conclusion: HCV Ab prevalence recorded is significantly higher than that observed in the general population in France. However only 15.8% of hospitalized patients have been included. Motivation of all health care workers is essential. Final results of the study will be present at the meeting

FRI315

Hepatitis C screening rates by age cohort 1945–1965 in a large community health system before, during and after the COVID pandemic

David Bernstein[1], Nitzan Roth[1], Ben Da[1], Sanjaya Satapathy[1], Henry Bodenheimer[1], Christian Kuntzen[1], Tai PIng Lee[1]. [1]*Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Hempstead, United States*
Email: dav31475@gmail.com

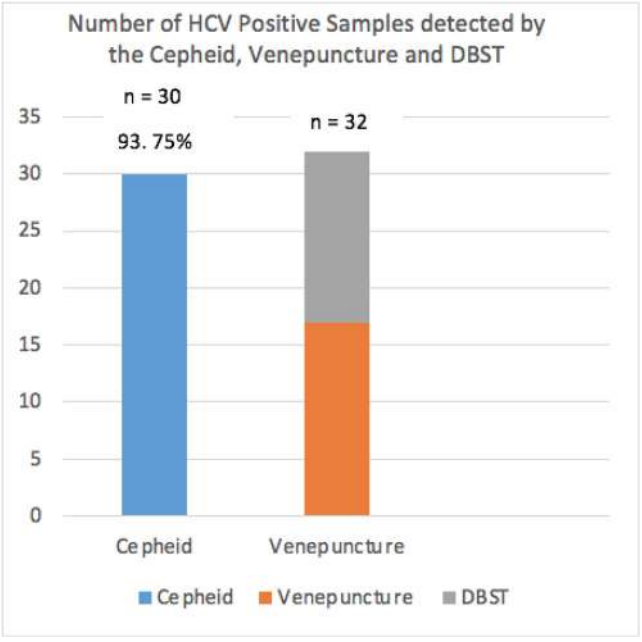
Background and aims: In the outpatient primary care setting, New York State mandates the offering of hepatitis C (HCV) testing for persons born between 1945 and 1965. Despite this mandate, <50% of HCV screening candidates are offered screening and among those found to be HCV Ab positive, not all patients undergo HCVRNA testing and even fewer are referred for treatment.
Method: We implemented a system where nurse educators personally visited 60 outpatient primary care offices to educate regarding HCV screening. Visits occurred for the first 2 years of the project and then were stopped due to the COVID pandemic. We evaluated our results by birth year, dividing patients into 4 groups, those born between 1945 and 1950, between 1951 and 1955, between 1956 and 1960 and between 1961 and 1965.
Results: From April 1, 2018–August 31, 2021, 50, 047 previously unscreened patients born between 1945 and 1965 were screened with an HCV AB with reflex testing to HCVRNA in all positive HCV ABs. 10819 were born between 1945 and 1950, 11573 were born between 1951 and 1955, 13586 were born between 1956 and 1960 and 14069 were born between 1961 and 1965. Screening decreased during the peak pandemic months of March-June 2020 but levels returned to baseline screening numbers by July 2020 and continued at a steady state for the duration of the study.
Subjects born 1945–1950, 234/10819 (2.2%) were HCV AB positive with 67/10819 HCVRNA positive (0.6%). Subjects born 1951–1955, 326/11573 (2.8%) were HCV AB positive with 76/11573 HCVRNA positive (0.7%). Subjects born 1951–1955, 303/13586 (2.2%) were HCV AB positive with 58/13586 (0.4%) HCVRNA positive. Subjects born 1961–1965, 230/14069 (1.6%) were HCV AB positive with 44/14069 (0.3%) HCVRNA positive.
All patients were referred to a hepatitis C treating practitioner. 101 patients completed therapy and 93 remain on treatment. There were no differences by age groups in those accepting DAA treatment, in declining DAA therapy or in the numbers of patients who died during the study.
Conclusion: This large community-based HCV screening program confirmed the NHANES study that approximately 2–2.5% of people born between the years 1945–1965 are HCV AB positive. There were no significant differences by age cohort in this group although there was a trend for patients born between 1956 and 1965 to spontaneously clear the HCV virus without treatment. The COVID pandemic temporarily led to decreased HCV screening but once the pandemic began to ease, screening rates rapidly returned to pre-COVID levels as did DAA treatment rates. The positive effects of in-person nurse educators on primary care providers and their staffs persisted even after these visits were stopped due to COVID.

FRI316

Maximizing the potential of Cepheid, GeneXpert PCR rapid testing for hepatitis C through use of finger prick blood samples collected into EDTA capillary tubes

Anam Choudhry[1], Louise Davies[2], Nicki Palmer[2], Jade Davies[3], Bazga Ali[4], Rhys Oakley[5], James Plant[6], Louise Evans[6], Chinlye Chng[6], Helen Thompson-Jones[6], Lorraine Wall[7], Sarah Nicholas[7], Brendan Healy[4,8]. [1]*Cardiff University School of Medicine, Cardiff, United Kingdom;* [2]*Public Health Wales Cardiff, Cardiff, United Kingdom;* [3]*Public Health Wales Swansea, Swansea, United Kingdom;* [4]*University Hospital Wales, Cardiff, United Kingdom;* [5]*Cardiff and Vale Pharmacy, United Kingdom;* [6]*Swansea Bay UHB BBV Team, Swansea, United Kingdom;* [7]*Cardiff and Vale UHB BBV Team, Cardiff, United Kingdom;* [8]*Public Health Wales, United Kingdom*
Email: choudhrya4@cardiff.ac.uk

Background and aims: The Cepheid, GeneXpert provides hepatitis C virus (HCV) PCR results <90 minutes. A major limitation is the need to load finger prick samples <15 minutes, as patients must be co-located with the machine. Venous blood collected into EDTA tubes can be stored for up to 72 hours at 2–8°C prior to processing. In this project finger-prick blood collected into EDTA capillary tubes and processed >15 minutes after collection was compared with venepuncture (gold standard) and dried-blood spot testing (DBST) to facilitate testing remote from the machine (e.g. prison clinics on different wings remote from a centrally located machine) but still delivering rapid turn-around times with testing in close proximity to the point of need.
Method: Capillary tubes (MiniCollect® Tube 0.25/0.5 ml K3E K3EDTA-450530) were spiked with venepuncture blood from 25 adult patients undergoing HCV testing, processed on the Cepheid and the results compared. HCV positive patients in the community undergoing testing (venepuncture or DBST) were then approached to provide an additional EDTA capillary tube finger-prick sample. Samples were left for >15minutes <72 hours prior to processing and results compared. As the lower limit of quantification on the Cepheid is 40 IU/ml, results below this level were analysed separately.
Results: Results from the first 36/50 patients are reported here. The time between sample collection and testing ranged from 44 minutes to 94 hours 34 minutes. Samples with longest delays tested positive (no suggestion of the results being affected). Two venepuncture results were detected, viral load <12 IU/ml. Corresponding Cepheid results were negative as expected (results are not included below). One sample registered as "error" (Cepheid) and was not detected by DBST. In one sample the Cepheid result was not detected and the DBST result detected in the "unreliable zone" –10 IU/ml. The LLD of DBST is 1000 IU/ml and this likely is a false positive DBST result. Of the remaining HCV positive samples (n = 32, log viral loads 0.19–2.05 IU/ml). The Cepheid successfully detected HCV in 30 (93.75%) (Figure 1). In the remaining two samples the Cepheid result was "invalid." This could be due to internal quality standards, probe check failures, system computer failures or PCR process inhibition.



Conclusion: The Cepheid successfully detected 93.75% of the HCV positive samples detected by venepuncture or DBST. The two samples that were not positive returned invalid results which would have prompted retesting. The one discordant result with a very low level DBST result is likely due to a false positive result on DBST. As such, none of the results from finger prick samples collected into EDTA capillary tubes and processed on the Cepheid returned false negative results. This method of sampling is now going to be adopted in Wales with ongoing monitoring of results over the next 12 months.

Email: ji.uriz.otano@navarra.es

Background and aims: Identifying factors that may influence healthcare resource utilization (HCRU) among patients with hepatitis C virus (HCV) infection is important to support the development of initiatives that reduce healthcare resource burden and allow for more patients to be treated. This study describes HCRU among treatment-naïve, compensated cirrhotic patients treated with 8-weeks' glecaprevir/pibrentasvir (G/P), according to their history of drug use (DU) and socioeconomic status.

Method: Here we present an interim subanalysis of the ongoing, noninterventional, multicenter CREST study which includes chart review data from France, Canada, Italy, and Spain. Demographic and baseline characteristics were reported overall and for patients with history of DU. HCRU was described by history of DU and occupational status. In the group of patients with DU, HCRU was described according to active vs former drug use, and route of drug administration.

Results: This analysis included 206 patients who received ≥1 dose of G/P; 139 (67.5%) were male, the median (range) age was 57 (31–88) years (assessed in 203 patients), 185 (89.8%) had stable housing, and 52 (25.2%) were employed full-time. Among 75 (36.4%) patients with history of DU, 52 (69.3%) were intravenous drug users (IVDUs), and 23 (30.7%) were active drug users. Other characteristics included: aged >50 years (n = 51; 68.0%), stable housing (n = 63; 84.0%), and employed full-time (n = 16; 21.3%). Full-time employed patients, compared with those not in full-time employment, had fewer visits to general physicians (0.9 vs 2.0), but more visits to hepatologists (2.0 vs 1.4) and gastroenterologists (0.2 vs 0.1), and a greater number of noninvasive procedures (1.9 vs 0.9). Patients with history of DU, especially IVDUs, had more general physician and nurse visits and fewer hepatologist and gastroenterologist visits than those with no history of DU. Additionally, active drug users had higher on-treatment laboratory test (3.7 vs 2.1) and noninvasive diagnostic procedures (1.7 vs 1.3) compared with former drug users. HCRU in IVDUs was mostly similar to those administering drugs through other routes (Figure).

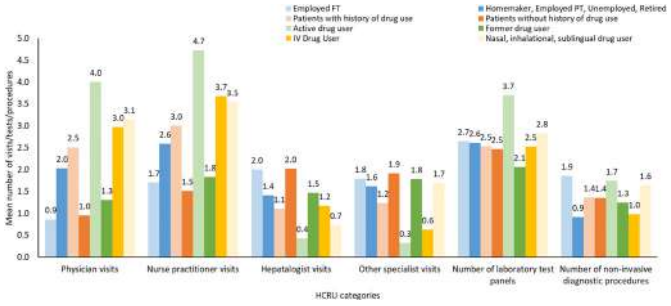

Figure: Healthcare resource utilization stratified by patients' occupational status, history of drug use, and current use of drugs. *Patients with history of illicit drug use included both active and former drug users administering drugs either IV, nasally, through inhalation, or sublingually. FT, full time; IV, intravenous; PT, part time; SD, standard deviation.

Conclusion: In this real-world cohort, HCRU was observed to vary by occupational status and history of DU among patients with HCV receiving G/P, with active drug users having the highest number of physician and nurse practitioner visits. Additional results will be presented at the congress.

Progress towards hepatitis C elimination: the feasibility and success of a nurse and harm reduction practitioner led model of care utilising rapid point of care HCV RNA testing at a medically supervised injecting room in Melbourne, Australia

Michael MacIsaac[1,2], Bradley Whitton[1], Jenine Anderson[3], Matthew Penn[3], Anthony Weeks[3], Shelley Cogger[3], Kasey Elmore[3], David Pemberton[3], Tim Papaluca[1,2], Margaret Hellard[4,5,6], Mark Stoove[4,6], David Wilson[4], Alisa Pedrana[4,6], Joseph Doyle[4,5], Nico Clark[3,7], Jacinta Holmes[1,2], Alexander Thompson[1,2]. *[1]St Vincent's Hospital Melbourne, Gastroenterology, Fitzroy, Australia; [2]University of Melbourne, Faculty of Medicine, Parkville, Australia; [3]North Richmond Community Health, Medically Supervised Injecting Room, Richmond, Australia; [4]Burnet Institute, Disease Elimination Program, Melbourne, Australia; [5]Alfred Hospital, Infectious Diseases, Melbourne, Australia; [6]Monash University, School of Public Health and Preventive Medicine, Melbourne, Australia; [7]The Royal Melbourne Hospital, Addiction Medicine, Parkville, Australia*
Email: michael.macisaac@svha.org.au

Background and aims: To achieve HCV elimination targets, efforts must focus on models of care engaging people who inject drugs (PWID). The XpertÒ HCV viral load fingerstick point of care (POC) test provides an HCV RNA level within 1 hour, allowing rapid diagnosis and treatment. We previously reported a successful nine-week pilot study incorporating HCV RNA POC testing at a medically supervised injecting room (MSIR) in Melbourne, Australia.[1] We now present the 12-month outcomes of this program.

Method: Prospective cohort study recruiting PWID attending a high-volume MSIR in Melbourne, Australia between 9/11/20 to 9/11/21. Clients were offered HCV screening using the XpertÒ HCV RNA POC test. Venepuncture for HBV/HIV screening and fibrosis assessment (APRI/FibroScan) were also offered to clients, regardless of HCV RNA status. HCV RNA results were returned same day if clients were still present, or via phone or at next MSIR visit if they had already departed. POC testing/treatment was led by a full-time hepatology fellow during the initial nine-week pilot program, and a nurse or harm reduction practitioner (HRP) for the remainder of the study period. DAA treatment was prescribed immediately upon return of a positive HCV test if the hepatology fellow was on-site, or by a GP/hepatologist after remote consultation for nurse/HRP assessments. Clients were invited to be followed 4-weekly during treatment and at SVR12. Primary endpoints were number of clients screened for HCV and number commencing DAAs. Testing rates were compared to a historical control period (9/11/18–9/11/19) of standard of care HCV venepuncture testing at the MSIR.

Results: 573 PWID consented to HCV RNA POC testing. By comparison, 180 clients underwent HCV testing during the control period, representing a 218% increase with POC testing. Median age was 42 yrs (IQR 37–49) and 75% male. 161 (28%) were HCV RNA+. An APRI score was calculated for 337 clients and 154 (16/32, 50% with APRI ≥1) had a FibroScan performed. Cirrhosis was uncommon (6% HCV RNA+, 5% overall), as was HBV (n = 3, 2%) and HIV co-infection (n = 0). 90% (n = 145/161) of HCV RNA+ clients were prescribed DAA therapy. Median time to treatment start was 8 days (IQR, 2–22); 13 clients (9%) initiated treatment same day as diagnosis. There was no difference in the number of clients linked to treatment with hepatology fellow led on-site prescribing compared to remote prescribing following nurse or HRP assessment (94% vs 88%, p = 0.204). Among those with complete follow up data (n = 43), SVR was 74%. Causes of non-SVR were re-infection (n = 3), relapse (n = 4), and non-response from medication non-adherence (n = 4).

Conclusion: Rapid HCV POC testing in a MSIR rapidly upscales testing and was associated with high rates of treatment initiation. Nurse or HRP led POC testing/treatment with remote prescribing is highly feasible, with similar rates of treatment initiation achieved.

Screening for hepatitis C in Denmark-the effect of a mobile outreach intervention

Sandra Droese[1,2,3], Lone Wulff Madsen[1,2], Gustav Bang Harvald[1], Søren Grinderslev[1], Karen Kofoed[1], Lene Kræmer[1], Anne Øvrehus[1,2], Peer Christensen[1,2,3]. *[1]Odense University Hospital, Department of Infectious Diseases, Odense, Denmark; [2]University of Southern Denmark, Clinical Institute, Odense, Denmark; [3]Odense University Hospital, Open Patient Data Explorative Network, Odense, Denmark*
Email: peer.christensen@dadlnet.dk

Background and aims: The prevalence of hepatitis C (HCV) in Denmark is low (0.21% of the adult population), 24% of HCV infected are undiagnosed (corresponding to 700 HCV patients in the Region of Southern Denmark (RSD)) and among diagnosed less than half have been cured. As part of the "C-Free-South" program we launched an outreach test and treat center on wheels in the Region of Southern Denmark in June 2020, targeting people with drug or alcohol use and/or psychiatric illnesses as well as festivals and open markets. The aim of this study is to describe the results of the intervention after the first 17 months.

Method: Low threshold non governmental organizations were approached by a mobile unit with medical personnel from the infectious disease department at Odense University Hospital. We used an HCV point of care rapid test for antiHCV, dried blood spot test for HCVRNA and a FibroScan™ Devise for diagnosis of liver fibrosis. Infected patients were offered treatment either by referral to the nearest clinic or in the mobile unit, as deemed feasible.

Results: 584 persons were tested in 37 different locations of whom 148 were in shelters or other residential institutions. Overall 7% (43) had a positive antiHCV by POC test and 2% (12) had current infection of whom at least 5 (42%) were reinfected after HCV cure. Men constituted 55% of all tested, and 70% of all antiHCV positives ($p < 0.05$). Median age at test was 50 years (IQR 40–60) with no relation to HCV status. Overall 95% of the 43 antiHCV positives had been tested before, 81% recalled being antiHCV positive at last test, 5% recalled being negative, (suggesting resent infection) and a total of 71% reported to have been cured for HCV (universal treatment for HCV became available Denmark in 2018). The prevalence of antiHCV was 16% (26/162) in facilities open to all (who accepted drug users) and 0% (0/187) in facilities restricted to psychiatric patients or alcohol users. Correspondingly, 91% of the 43 antiHCV positives had injected drugs compared to 8% of antiHCV negatives. We found no infections (0/71) when testing the general population (i.e. at markeds).

Conclusion: Our study suggests that most hepatitis C infected in Denmark have been identified and cured, and we found a very low proportion of undiagnosed (5%) compared to the previous national estimate of 24%. However our study is a selected sample of the population at risk for HCV and may not be representative for our region or Denmark. The low absolute number of current infection (2% of tested) suggest that our outreach campaign in its current form is unlikely to diagnose and treat the remaining patients with HCV in our region. An improved case finding strategy is needed to reach the WHO target of 90% diagnosed and 80% cured by 2030. This could be monetary incentives to be tested, and increased use of peer based testing ("snowballing"). A full update of treatment results and new screening methods will be presented at the meeting.

FRI320

Screening for HCV infection combined with SARS-CoV-2 vaccination in the Campania region

Pietro Torre[1], Mario Masarone[1], Roberta Sciorio[1], Monica Annunziata[1], Roberta Coppola[1], Laura Staiano[2], Carmine Coppola[2], Marcello Persico[1]. [1]*University of Salerno, Internal Medicine and Hepatology Unit, Department of Medicine, Surgery and Dentistry, "Scuola Medica Salernitana"; [2]OORR Area Stabiese, Plesso Nuovo Gragnano, Naples, Italy, Department of Internal Medicine-Unit of Hepatology and Interventional Ultrasonography*
Email: mpersico@unisa.it

Background and aims: The health emergency caused by the SARS-CoV-2 pandemic has negatively impacted the management of HCV infection, potentially jeopardizing the achievement of the goal of eliminate hepatitis C by 2030. To take advantage of the current sanitary situation, associated screening for HCV and SARS-CoV-2 infection have been carried out. We decided to propose HCV screening also to people who undergone SARS-CoV-2 vaccination.
Method: Screening for hepatitis C was carried out by finger-prick test to search for HCV antibodies. It took place in the minutes following the SARS-CoV-2 vaccination, in two different vaccination centers of the Campania region, and in two different time frames. In the period 1 May–20 July 2021, screening for hepatitis C was offered to the general population who got the vaccine at the Fisciano (province of Salerno) vaccination center. In the period 20 September–11 October 2021, screening for hepatitis C was offered to the general population who underwent vaccination at the San Leonardo Hospital (Castellammare di Stabia, metropolitan city of Naples). In both sites, Pfizer-BioNTech, Moderna, or Oxford-AstraZeneca vaccines were used.
Results: Out of 5095 people who underwent vaccination at the Fisciano vaccination center, 1952 (38, 3%, average age 41, 6 years) performed screening for hepatitis C. 5 of these (0, 25%, average age 54, 2 years) resulted HCV-Ab positive; all 5 were aware of their condition; 4 had previous treatment; 1 (0, 05%) was found to have active HCV infection. Out of 2202 people vaccinated at the San Leonardo Hospital, 1207 (54, 8%, average age 43, 1 years) underwent screening for hepatitis C. Among these, 9 (0, 7%, average age 54, 3) resulted positive. 5/9 tested negative on the confirmatory test; 2/9 were aware of their condition and had previous treatment; 1 subject (0, 08%) was found to have active HCV infection; 1 subject is awaiting the results at time of writing.
In both sites a consistent percentage of people refused the HCV-Ab test. Moreover, the prevalence of HCV-Ab positivity and HCV active infection was found to be lower than the national data. Frequent reasons for refusing the test were lack of knowledge of the disease, fear of a positive result, and distrust in the test's effectiveness. Someone refused the test because vaccination was considered a particularly stressful event. The low prevalence of HCV infection found in these projects could be at least partly attributable to the under-participation of the elderly, as at the time the screenings were carried out most of them had probably already received the expected doses of SARS-CoV-2 vaccine.
Conclusion: In conclusion, we believe that SARS-CoV-2 vaccination could be an opportunity to screen for HCV infection, but to maximize the benefits of this screening, the characteristics of the subjects to be tested should be reconsidered, by focusing particularly on the elderly population.

FRI321

Treating children with HCV close to home through a virtual national multidisciplinary network

Deirdre Kelly[1,2], Carla Lloyd[1], Maxine Brown[1], Kinza Ahmed[1], Ivana Carey[3], Sarah Tizzard[3], Joanne Crook[3], Penny North-Lewis[4], Palaniswamy Karthikeyan[4], Sanjay Bansal[3], Graham Foster[5]. [1]*Birmingham Children's Hospital, United Kingdom; [2]University of Birmingham, United Kingdom; [3]King's College Hospital, United Kingdom; [4]Leeds General Infirmary, United Kingdom; [5]Barts and The London School of Medicine and Dentistry, United Kingdom*
Email: carla.lloyd1@nhs.net

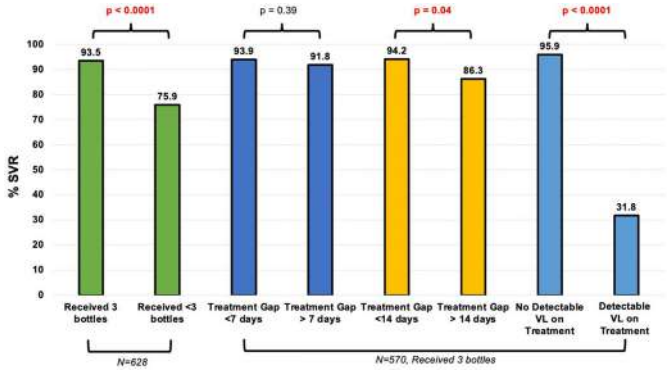
Background and aims: Hepatitis C virus (HCV) infection is a major global health problem in adults & children. The recent efficacy of Direct Acting Anti-viral therapy (DAA) has cure rates of 99% in adults and adolescents. These drugs were licensed for children 3–12 yrs during the recent coronavirus pandemic. To ensure equitable access, safe & convenient supply during lockdown, we established a virtual national treatment pathway for children with HCV in England & evaluated its feasibility, efficacy & treatment outcomes.
Method: A paediatric Multidisciplinary Team Operational Delivery Network (pMDT ODN), supported by NHS England (NHSE), was established with relevant paediatric specialists to provide a single point of contact for referrals & information. Referral & treatment protocols were agreed for HCV therapy approved by MHRA & EMA. On referral the pMDT ODN agreed the most appropriate DAA therapy based on clinical presentation & patient preferences, including ability to swallow tablets. Treatment was prescribed in association with the local paediatrician & pharmacist, without the need for children & families to travel to national centres. All children were eligible for NHS funded therapy; referral centres were approved by the pMDT ODN to dispense medication; funding was reimbursed via a national NHSE agreement. Demographic & clinical data, treatment outcomes & SVR 12 were collected. Feedback on feasibility & satisfaction on the pathway was sought from referrers.
Results: In the first 6 months, 34 children were referred; 30- England; 4-Wales; median (range) age 10 (3.9–14.5) yrs; 15M; 19F: Most were genotype type 1 (17) & 3 (12); 2 (1); 4 (4). Co-morbidities included: obesity (2); cardiac anomaly (1); Cystic Fibrosis (1); Juvenile Arthritis (1). No child had cirrhosis. DAA therapy prescribed: Harvoni (21); Epclusa (11); Maviret (2). 27/34 could swallow tablets; 3/7 received training to swallow tablets; 4/7 are awaiting release of granules.11/27 have completed treatment and cleared virus; of these 7/11 to date achieved SVR 12. 30 children requiring DAA granule formulation are awaiting referral and treatment.
Referrers found the virtual process easy to access, valuing opportunity to discuss their patient's therapy with the MDT & many found it educational. There were difficulties in providing the medication through the local pharmacy. However there are manufacturing delays in providing granule formulations because suppliers focused on treatments for COVID, leading to delays in referring and treating children unable to swallow tablets.
Conclusion: The National HCV pMDT ODN delivers high quality treatment & equity of access for children & young people, 3–18 yrs with HCV in England, ensuring they receive care close to home with 100% cure rates.

FRI322

Association of sustained virologic response with measures of direct-acting antiviral adherence in patients with Hepatitis C: data from the ASCEND and ANCHOR investigations

Sarah Kattakuzhy[1], Vivian Wang[2], Catherine Gannon[2], Sarah Mollenkopf[3], Charisse Ahmed[2], Sanjay Chainani[3], Junfeng Sun[2], Henry Masur[2], Shyamasundaran Kottilil[1], Elana Rosenthal[1]. *[1]Institute of Human Virology, University of Maryland School of Medicine, Baltimore, United States; [2]National Institutes of Health, Bethesda, United States; [3]University of Maryland School of Medicine, Baltimore, United States*
Email: skattakuzhy@ihv.umaryland.edu

Background and aims: While HCV treatment with direct-acting antivirals is highly efficacious in clinical trials, medication receipt and adherence is challenged by both policy and patient-specific barriers in real-world settings. Previous research suggests that sustained virologic response can be achieved with imperfect adherence[1], but current data is unclear on how the amount and timing of nonadherence impacts sustained virologic response (SVR).
Method: Data was pooled from two real-world investigations of HCV treatment using direct-acting antivirals from 2015 to 2020, ASCEND[2] and ANCHOR[3]. The analysis was limited to individuals with an anticipated duration of 12 weeks, who were dispensed at least one month of medication, on whom SVR was assessed. Measures of adherence were assessed in three ways: (1) medication receipt (MR), defined as the actual number of 28-pill bottles dispensed; (2) medication gap (MG), defined as the difference in days between expected medication receipt and actual medication receipt; and (3) on treatment detectable viral load (DVL), defined as viral load >1000 IU/ml at week 4 or >100 IU/ml at week 12.
Results: Of 628 individuals, 472 were treated with LDV/SOF (75%), 93 with SOF/VEL (15%), and 63 with ELB/GZV (10%). Overall the cohort was median age 59, majority (69%) male, with 94% Black race, 28% with current heroin use, 16% with current cocaine use, and 27% unstably housed.
Fifteen patients (2.3%) received 1 bottle, 43 (6.8%) received 2 bottles, and 570 (90.8%) received 3 bottles, and MR was significantly associated with SVR ($p < 0.00001$), but was not associated with gender, race, or substance use. Of the 570 who received all 3 bottles, 211 (37%) had a MG of at least 1 day (range 1–197, median 7). MG of 14 days or more was inversely associated with SVR ($p = 0.037$), however MG of 7 days or more was not associated with SVR. Of the 211 with MG, 89 individuals had a gap between months 1 and 2, 79 between months 2 and 3, and 43 between both. There was no association with timing of MG and SVR. Of 567 patients who received 3 bottles and who had on treatment VL assessment, 22 (3.9%) had DVL, which was inversely associated with SVR ($p < 0.0001$). Current cocaine ($p = 0.05$) and opioid use ($p < 0.0001$) were significantly associated with DVL, but race, gender, and housing status were not.



Conclusion: In this analysis of 628 individuals treated with DAA, 10% did not complete treatment, and more than a third had medication gaps, which were inversely associated with SVR. Despite this, patients with imperfect adherence still achieved rates of SVR greater than 75%. These data suggest that while nonadherence to DAA is common, patients should be continued on treatment regardless of imperfect adherence. Finally, these data support removal of polices which can delay medication receipt, such as mandatory on-treatment phone calls, visits, or lab checks.

FRI323

ATA haplotype of the interleukin-10 gene and low phase angle are associated with liver cirrhosis in chronic hepatitis C

Nataly Lopes Viana[1,2], Diego Alves Vieira[2,3], Thais Pontelo de Vries[1,2], Marta Paula Pereira Coelho[1,2], Pedro Alves de Castro[2,3], Tatiana Bering Bering[4], Maria Isabel Toulson Davidson Correia[5], Gifone Aguiar Rocha[6], Luciana Diniz Silva[1,2,7]. *[1]UFMG Faculty of Medicine, Sciences Applied to Adult Health Care Post-Graduate Programme, Belo Horizonte, Brazil; [2]UFMG Faculty of Medicine, Outpatient Clinic of Viral Hepatitis, Instituto Alfa de Gastroenterologia, Faculdade de Medicina, Brazil; [3]UFMG Faculty of Medicine, Medical Undergraduate Student, Brazil; [4]UFMT-Universidade Federal de Mato Grosso, Department of Food and Nutrition, Brazil; [5]UFMG Faculty of Medicine, Department of Surgery, Brazil; [6]UFMG Faculty of Medicine, Laboratory of Research in Bacteriology, Brazil; [7]UFMG Faculty of Medicine, Department of Internal Medicine, Brazil*
Email: lucianadinizsilva@gmail.com

Background and aims: Chronic infection caused by Hepatitis C virus (HCV) is a major public health problem. It is estimated that, globally, about 71 million people are infected. Approximately 55.0% to 85.0% of the infected individuals will develop chronic hepatitis C. Of those chronically infected by HCV, the risk of liver cirrhosis varies from 15.0% a 30.0% in 20 years. In this context, the progression of hepatic fibrosis may be influenced by host, viral and environmental factors. Among the host factors, the role played by the imbalance between pro- and anti-inflammatory cytokines and the development/progression of liver cirrhosis is highlighted. Interleukin-10 (IL-10) is considered a key cytokine in the control of the secretion of pro-inflammatory mediators. IL-10, single nucleotide polymorphisms (SNPs) in the positions –1082A/G (rs1800896), –819C/T (rs1800871) and –592C/A (rs1800872) in the promoter region of the gene encoding are associated with changing the transcription rates of this gene. Haplotypes GCC, ACC and ATA determine the production of high, intermediate and low levels of IL-10, respectively. Based on these findings, the objective of this present study was to evaluate whether SNPs in the promoter region of the IL-10 coding gene are associated with liver cirrhosis in patients chronically infected with HCV.
Method: We prospectively evaluated 155 patients [mean age, 51.3 ± 11.5 years; 94 (60.6%) men, 60 (38.7%) with cirrhosis]. Diagnosis of cirrhosis was performed based on clinical, laboratory, radiological and histological parameters. SNPs were genotyped by RT-PCR. Phase angle was obtained by electrical bioimpedance analysis. The data were analyzed by SPSS 21.0. The associations were analyzed by logistic regression models. Variables with $p \leq 0.25$ in the univariate analysis were selected for the multivariate model.
Results: Polymorphisms were in balance of Hardy-Weinberg. The ATA haplotype was observed in 43 (72.0%) and in 52 (55.0%) of the patients with and without liver cirrhosis, respectively ($p = 0.04$). In multivariate analysis, ATA haplotype (OR = 2.39; 95.0%CI = 1.10–5.19; $p = 0.03$), phase angle (OR = 0.58; 95.0%CI = 0.38–0.89; $p = 0.01$) and arterial hypertension (OR = 3.55; 95.0%.0CI = 1.72–7.33, $p = 0.001$) were independently associated with liver cirrhosis.

Conclusion: The ATA haplotype, which is related to lower IL-10 production, associated with liver cirrhosis in patients chronically infected with HCV. Also, phase angle, a nutritional marker that reflects the integrity of cell membranes, was inversely associated with cirrhosis in patients with chronic hepatitis C.

FRI324

Use of Glecaprevir/Pibrentasvir (G/P) for the treatment of HCV infection among fentanyl users: an interim analysis of the GRAND PLAN study

Brian Conway[1,2], David Truong[1], Leo Yamamoto[1], Rossitta Yung[1], Shawn Sharma[1]. [1]*Vancouver Infectious Diseases Centre, Vancouver, Canada;* [2]*Simon Fraser University, Burnaby, Canada*
Email: bconway5538@gmail.com

Background and aims: To achieve the World Health Organization mandate of eliminating Hepatitis C Virus (HCV) infection as a public health concern by the end of the decade, we must design and implement plans of intervention for all affected populations, including the most vulnerable and difficult to reach. We describe a community-based program targeting HCV-infected inner-city residents with active fentanyl use.
Method: Through weekly events held at single room occupancy dwellings in the inner city of Vancouver, Canada, we identified subjects with HCV infection and a history of ongoing fentanyl use. We engaged them in a multidisciplinary program of care to meet medical, psychological, social and addiction-related needs and provided HCV treatment with Glecaprevir/Pibrentasvir (G/P) within this context. HCV medications were administered in a way to maximize the likelihood of adherence and follow-up to the sustained virologic response (SVR) 12 time point. This included daily dispensing with opiate agonist therapy or weekly delivery of medications to the place of residence. If a subject was unavailable for weekly check-ins, interventions were immediately implemented to re-integrate into care. This analysis presents the rate of documented cure (achievement of SVR12) in the target population.
Results: We identified 118 eligible HCV-infected fentanyl users who were enrolled in the program. Key demographic characteristics include: 91 (77%) male, median age 47 (26–75) years, 102 (86%) on opiate agonist therapy, F0/1 (86, 73%), ≥F2 (32, 77%), known fentanyl use (74, 63%), other drug use (92, 78%). Of 107 who initiated treatment, 88 completed treatment to date and 82 achieved cure at the SVR12 and/or SVR24 time point. Those lost to follow-up included 2 overdose-related deaths prior to SVR12 time point and 4 disengaged from care. There were no cases of documented virologic failure.
Conclusion: To treat HCV infection among the most vulnerable inner-city populations, specific programs for integration and maintenance in care must be designed and evaluated. We have shown that this can be accomplished even among active fentanyl users who are precariously housed. This may provide the basis for successful interventions among similar populations in different settings.

FRI325

Indigenous methodologies in practice through community engagement and telehealth outreach increase hepatitis C access to care in Alberta, Canada

Kate Dunn[1], Samuel Lee[2]. [1]*Indigenous Wellness Core, Calgary, Canada;* [2]*University of Calgary Cumming School of Medicine, Medicine, Calgary, Canada*
Email: samlee@ucalgary.ca

Background and aims: Hepatitis C virus (HCV) is a major public health burden in Canada, with prevalence in Indigenous (First Nation, Metis and Inuit) communities 4–6 times higher than non-Indigenous population. Conventional care models have created barriers to curative DAA therapy in remote Indigenous communities. Innovative approaches are required to improve access to HCV services.
Method: The ECHO+ telehealth program in Alberta aims to increase access to HCV treatment through a hub-and-spoke model led by a hepatologist (hub) working with Indigenous communities (spokes) designing a model of care tailored to local needs. We incorporated Indigenous ways of knowingl (see figure), including building a predominantly Indigenous team, and embedding the 5 R's of Indigenous Research Methodology (Respect, Relationship, Relevance, Reciprocity, and Responsibility). ECHO+ builds relationships with Indigenous community healthcare teams while using a novel co-design approach to remove barriers while increasing awareness, screening for HCV, and providing telehealth access to specialist care.
Results: Collaborative methods included developing information resources translated into local languages; building infrastructure and supporting community-directed implementation to include other health topics. Due to the COVID-19 pandemic, virtual awareness presentations (HCV awareness topics, community interaction and knowledge sharing, opportunity to follow up with mailed resources packages, and sharing lived experience stories from Indigenous youth and Elders) have been shared with every Indigenous community in Alberta. Practitioners were interviewed to identify barriers to care. Biweekly Zoom meetings with community healthcare teams have expanded during the pandemic to include pandemic topics, and other liver diseases. Collaboration between ECHO+ and Indigenous community leadership and healthcare teams has improved HCV screening, de-stigmatization, increased treatment access, and supported local community healthcare providers to effectively access DAA therapy. Thus, currently 92% of the 53 Indigenous communities in Alberta have engaged with ECHO+, compared to 23% before this approach. This reflects success of the 5R method.

Figure: *Five R's as the foundational hub (inner circle) supporting Two-Eyed Seeing framework in community approaches surrounding hepatitis C care as illustrated in wording reflective funding requirement work streams (the outermost arrows) and Western written evidence alongside community directed priorities, oral knowledge and Indigenous perspective of wellness (segments or slices of the circle).*

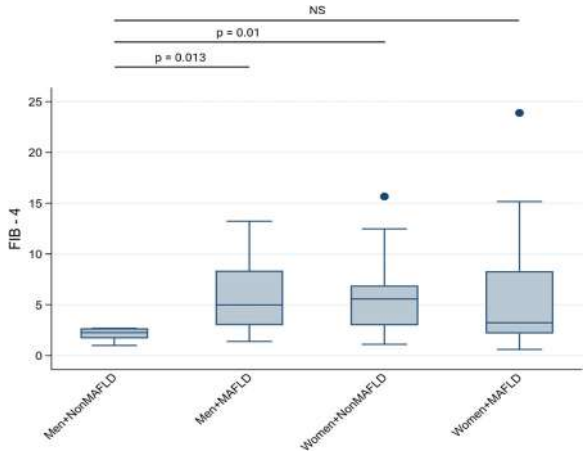
Conclusion: A culturally-sensitive framework combines Indigenous with western approaches to improve access to HCV awareness and care in remote Indigenous communities. This approach has increased community communication and involvement, facilitated engagement with every Indigenous community, and provided practical support throughout the pandemic.

FRI326

Implication of metabolic associated fatty liver disease and sex differences in the risk of developing liver fibrosis in patients with Hepatitis C

Martín Uriel Vázquez Medina[1], Eira Cerda Reyes[2], Cruz Vargas-De-León[1], Patty Marlen Ramírez Portillo[3], Alejandro Gutierrez Atemis[2], Juan Armendariz-Borunda[2]. [1]*ESM-Escuela Superior de Medicina-IPN, Laboratorio de modelación biomatemática y bioestadística para la salud, Ciudad de México, Mexico;* [2]*Hospital Central Militar Mexico, Ciudad de México, Mexico;* [3]*Benemérita Universidad Autónoma de Puebla, Heroica Puebla de Zaragoza, Mexico*
Email: arkiiman@hotmail.com

Background and aims: Hepatitis C (HCV) is a global health problem since it affects about 3% of the world's population. The major complications during the disease are related to the progression of liver fibrosis. Therefore, it is of great importance to study the sociodemographic factors that increase or decrease the risk of developing fibrosis. The aim of this work was to evaluate the involvement of Metabolic associated fatty liver disease (MAFLD) and sex of patients in the risk of developing liver fibrosis during hepatitis C infection.
Method: Cross-section study of Hepatitis C (HCV) newly diagnosed patients, information of age, sex, BMI, comorbidities, and laboratory results were obtained in the first medical consultation with a certified hepatologist, HCV was diagnosed by qualitative RT-PCR test COBAS AMPLICOR and MAFLD was diagnosed according to the international expert consensus statement Eslam (2020). Liver fibrosis was quantified using The Fibrosis-4 (FIB-4) Index. Four groups were formed: 1.- Men+NonMAFLD, 2.- Men+MAFLD, 3.- Women +NonMAFLD and 4. Women+MAFLD. Level of FIB-4 was obtained of each group and global statistical significancy (SSi) of the distribution of FIB-4 among groups was evaluated with the Kruskal Wallis test. Post Hoc analysis was performed using the Kruskal Wallis test, alpha was adjusted with the Bonferroni method to obtain the SSi of the FIB-4 distribution within the groups.
Results: A total of 84 patients (26.2% Male) were studied. The median age of the patients were 62 years (IQR 53–71), Distribution in the age and FIB-4 between men and women was not SSi. The prevalence of MAFLD was 73.75%. The difference of MAFLD between sexes was not SSi. The global difference among FIB-4 levels between the four groups was very close to SSi (p = 0.07). The Post Hoc analysis (Figure 1) found differences in the levels of FIB-4 between the groups Men +NonMAFLD with Men+MAFLD (2.25 (IQR 1.68–2.67) vs 4.98 (IQR 2.99–8.35), p = 0.01) and Men+NonMAFLD with Women+NonMAFLD (2.25 (IQR 1.68–2.67) vs 5.56 (IQR 2.98–6.89), p = 0.01). No SSi differences in FIB-4 levels were found between women with and without MAFLD.



Conclusion: In the studied population MAFLD is a risk factor for developing fibrosis in men. Men without MAFLD had lower risk of developing fibrosis than women without MAFLD. Although the literature mentions a lower risk in women of developing fibrosis in hepatitis C, our results could be explained by the age range of our patients in which most of the women were postmenopausal.

FRI327

Micro-eliminating hepatitis C in a network of 47 English Prisons through an industry, prison healthcare and patient organisation partnership

Andrew Jones[1], Nichola Royal[2], Arran Ludlow-Rhodes[2], Rob Cheetham[2], Emily Mongale[2], Julie Henderson[2], Katie Abraham[2], Hayley Cubbage[2], Samantha Allen[2], Lee Christensen[3], Kate Dorrington[1], Andrew Milner[1], Louise Missen[1], Phil Troke[1]. [1]*Gilead Sciences Ltd, Medical Affairs, London, United Kingdom;* [2]*Practice Plus Group Health and Rehabilitation, Reading, United Kingdom;* [3]*Hepatitis C Trust, United Kingdom*
Email: andy.jones@gilead.com

Background and aims: National Health Service England (NHSE) plans to eliminate Hepatitis C (HCV) in England by 2025, five years earlier than World Health Organisation goals. With a reported HCV prevalence of ~6% in male prisons, and ~12% in female prisons, secure environments are an essential component of this elimination plan. In 2020, NHSE defined HCV micro-elimination as ³95% of prison residents tested within the previous 12 months, ³90% of RNA positive patients treated or initiated on treatment and presence of a robust system to review ongoing testing and treatment performance to ensure these targets are maintained.
Method: To support NHSE in their HCV Elimination Program, a partnership between Gilead Sciences, Practice Plus Group (PPG) and the Hepatitis C Trust (HCT) was formed in 2019. PPG is the provider of healthcare to 47 English prisons with approximately 30, 000 residents. PPG Regional BBV Lead Nurses, and Gilead Medical Scientists worked with prison and HCV stakeholders to optimise test and treat pathways for new prison admissions. Whole prison HCV Intensive Test and Treat events (HITTs) were also run in targeted prisons to ensure testing of residents who were incarcerated before these optimisations were implemented.
Results: Following pathway optimisation across the PPG network of 47 prisons, the HCV screening within 7 days of prison entry increased from 41% in May 2019 to 84% in October 2021. This increase was achieved despite there being significant restrictions to reduce the transmission of COVID-19 being in place across all English prisons. HITTs have been performed in 15 PPG prisons to-date. 1, 909 new RNA+ diagnoses were made during this time with 1, 848 patients started on direct-acting antiviral treatments. By November 2021, 16 out of the 47 prisons have been given micro-elimination status by NHSE with 4 more having submitted data demonstrating achievement of this target and awaiting decision. A further 4 more prisons are on track to achieve micro-elimination by April 2022.
Conclusion: This partnership has demonstrated that, even during a global pandemic, it is possible to achieve the micro-elimination of HCV in a defined setting. Maintenance of micro-elimination status is essential if we are to achieve the WHO HCV targets, requiring robust pathways that are regularly adapted to the changing environment, and systems for tracking performance, both of which have been put in place by this partnership.

FRI328

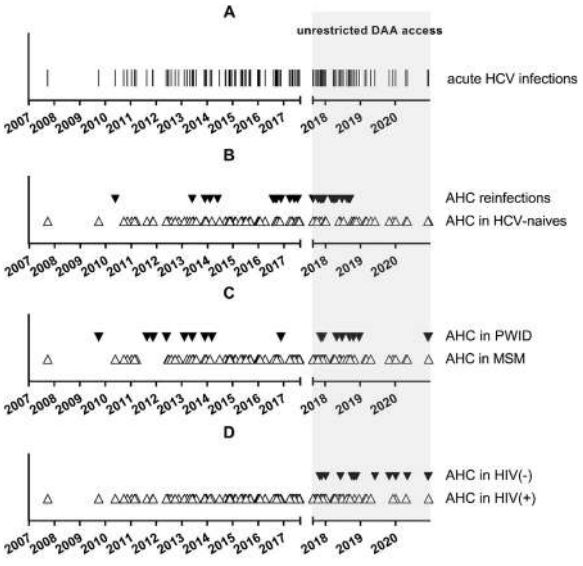
The 'Viennese epidemic' of acute HCV in the era of direct-acting antivirals

David Chromy[1,2,3], David Jm Bauer[1,2], Benedikt Simbrunner[1,2], Mathias Jachs[1,2], Lukas Hartl[1,2], Philipp Schwabl[1,2], Caroline Schwarz[1,2,4], Armin Rieger[2,3], Katharina Grabmeier-Pfistershammer[2,5], Mattias Mandorfer[1,2], Michael Trauner[1], Peter Ferenci[1], Michael Gschwantler[2,4], Thomas Reiberger[1,2]. [1]*Medical University of Vienna, Division of Gastroenterology and Hepatology, Department of Internal Medicine III, Vienna, Austria;* [2]*Vienna HIV & Liver Study Group;* [3]*Medical University of Vienna, Department of Dermatology, Vienna, Austria;* [4]*Wilhelminenspital, Wiener Gesundheitsverbund (WiGeV) der Stadt Wien, Department of Internal Medicine IV, Vienna, Austria;* [5]*Medical University of Vienna, Institute of Immunology, Center for Pathophysiology, Infectiology and Immunology, Vienna, Austria*
Email: thomas.reiberger@meduniwien.ac.at

Background and aims: An epidemic of acute hepatitis C virus (HCV) infections (AHC)-observed predominantly among men who have sex with men (MSM)-may now decline due to wide availability of direct-acting antivirals (DAAs). This study aimed to investigate changes in the epidemiology of AHC in a Viennese referral center over a 13-year period.

Method: Patients presenting with AHC between 01/2007–12/2020 at the Vienna General Hospital were retrospectively enrolled and followed after virologic clearance/eradication. AHC was defined by the European AIDS treatment network (NEAT) criteria. The introduction of unrestricted DAA-access after 09/17 defined the 'DAA-era', as compared to the 'pre-DAA-era' prior to 09/17.

Results: We identified 134 AHC cases in 119 patients with a mean age of 39 ± 9 years at inclusion. The majority of patients were male (92%), HIV-positive (88%), and MSM (85%). In the DAA-era, a history of prior chronic HCV infection at inclusion was found in 24% (11/46) compared to 7% (5/73) in the pre-DAA-era (p = 0.012). The annual rate of AHC cases increased in the DAA-era (17.11 per-year) compared to the pre-DAA-era (7.76 per-year). The DAA-era included an AHC-genotype-2 cluster and more HIV-negative AHC cases (0% (0/73) vs. 30% (14/46), p < 0.001). Patients were followed after spontaneous clearance or sustained virologic treatment response (SVR) for a total of 251.88 patient-years (median 1.39 years per patient). In the DAA-era, we recorded 15 AHC-reinfections-corresponding to an incidence rate of 5.96 (95%CI: 3.57–9.66) re-infections per 100-patient-years.



Overall incident acute HCV infections during the observational period (A) and incident acute HCV infections stratified by status of previous HCV infections (B), by mode of transmission (C) and by HIV status (D).

Conclusion: We observed a high incidence of AHC in Vienna in the DAA-era -primarily among HIV-positive MSM, but increasingly also in HIV-negative MSM. Sufficient screening and prevention strategies combined with fast treatment initiation are needed to confine further spread of HCV.

FRI329

Approaches for a hepatitis C-free city: preliminary results

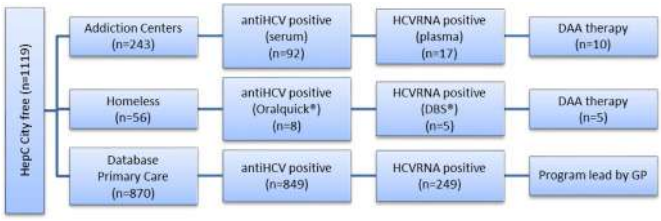
Email: mromerogomez@us.es

Background and aims: We aimed to develop a Hepatitis C elimination program to make Seville a Hepatitis C free city. The main concern was the capability to reach marginal and vulnerable populations. To overcome this drawback, a collaboration between different organizations is needed.

Method: Three groups were addressed: a) patients from primary care health centers database were classified according to anti-HCV status and viral load (HCVRNA); b) patients attended at addiction treatment centers; and c) homeless attended by non-profit organizations like *Médicos del Mundo* and *Fundación Atenea*, and social services from City Council in Seville.

Anti-VHC was offered by Oralquick® test in saliva or blood test and, if positive, by dry blood spot (DBS) tests or serum samples to detect HCVRNA. Positive patients got an appointment in clinical hepatology or if not possible, a phone visit can be arranged to allow patient evaluation and remote drug dispensation.

Results: Anti-HCV and HCVRNA tested positive in n = 92/243 (38%) and 17 (6.9%) [10 treated with AAD] from addiction centers and n = 8/56 (14%) and 5 (8.9%) [all 5 treated with AAD] in homeless population. In primary care centers n = 849/870 tested anti-HCV positive and 249 HCVRNA positive. We have identified 271 patients with a positive HCV viral load which may benefit from this Hepatitis C-free city program.



Conclusion: Collaborations between health, social and non-profit organizations is key for Hepatitis C elimination. In this sense, enabling HCV detection assays to be performed outside the hospital enhances the chances of identifying positive patients. Moreover, the short-cut for setting up the appointment allows faster access to treatment (presential or remote antiviral dispensation) at hepatology unit. At the same time, the possibility of doing phone visits and remote antiviral dispensation in patients refusing to be attended at the hospital increases treatment success rate. Coordinating these actions together can lead to a Hepatitis C-free city.

Success of a peer-led community based model of hepatitis C treatment support for marginalised populations

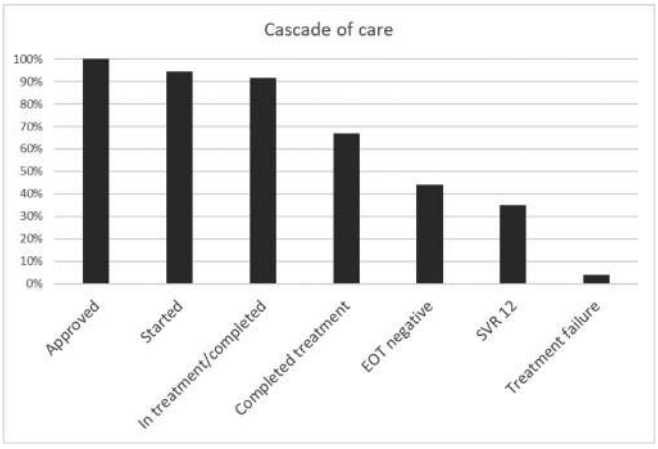
Binta Sultan[1,2], John Gibbons[1], Indrajit Ghosh[3], Julian Surey[1,2], Mark Leonard[4]. *[1]University College London Hospital, Find&Treat, United Kingdom; [2]University College London; [3]Mortimer Market Centre, United Kingdom; [4]Groundswell, United Kingdom*
Email: b.sultan@ucl.ac.uk

Background and aims: Community-based models of HCV care have been developed and shown to be an effective way of supporting marginalised people. Many outreach models of HCV care were scaled down during the pandemic. The Find&Treat team established a peer-led HCV outreach treatment service for vulnerable people in North London during the pandemic, to ensure continued access to care for these patients. We present a description and evaluation of this model of care, which was a multi-component intervention delivered by a highly trained peer.

Method: The model of care was peer-led with clinician support as needed and began in June 2020. Patients with confirmed current HCV infection were referred by drug services, Find&Treat service outreach HCV testing team and local clinics. All patients had a degree of social complexity, which included drug use and or experience of homelessness. The peer and clinician reviewed all patients who were referred. The whole HCV assessment and treatment cascade was managed in the community.

Interventions; Confirmatory bloods and liver fibroscan assessment was undertaken by the peer and a treatment referral was made to the local treatment approval centre. The peer took HCV medication to the patient at their place of residence, provided in monthly or weekly dosset boxes. The peer engaged the patient with appropriate treatment support which included daily text reminders, telephone calls, home visits, video supported care, blood tests for monitoring side effects and treatment response with capillary bloods, and support for hospital appointments. The clinician reviewed patients who had co-morbidities e.g. cirrhosis or other acute health needs and made referrals to secondary care as necessary. The peer supported people with engagement with drug and alcohol services and GP engagement. Routine clinical data was collected in electronic medical records. Data was captured about all interventions and healthcare interactions. This model of care is being evaluated using the integrated HCV candidacy framework developed by Hoj and colleagues (2019).

Results: As of October 2021, 72 patients were referred to the service, all with confirmed HCV infection. 2/72 had HIV co-infection, 2/72 had HBV co-infection, 57 were male, 42/72 had unstable housing, 72/72 had problematic drug or alcohol use. 72/72 had treatment approved, 68/72 have started treatment, 66/72 currently in or completed treatment, 48/72 completed treatment, 25/72 have SVR 12, 1/72 failed treatment.



Conclusion: A peer-led community-based HCV treatment model is effective at supporting people with social complexity to complete treatment. The components of the peer-led intervention addressed multiple domains in the candidacy framework for engagement of vulnerable populations. This model of care is essential to achieving HCV elimination targets and improved health outcomes, especially for vulnerable populations.

FRI331

Impact of hepatitis C virus point-of-care (PoC) viral load assay compared to laboratory-based assays on uptake of testing and treatment, and turnaround times: a systematic review and meta-analysis

Philippa Easterbrook[1], Adam Trickey[2], Emmanuel Fajardo[3], Daniel Alemu[3], Adelina Artenie[2]. *[1]World Health Organization, Global Hepatitis Programme, Geneva, Switzerland; [2]University of Bristol, Bristol, United Kingdom; [3]World Health Organization, Geneva, Switzerland*
Email: easterbrookp@who.int

Background and aims: The requirement for a confirmatory hepatitis C virus (HCV) viral load (VL) test for diagnosis of chronic HCV infection leads to significant loss to follow-up in the care cascade. Point of care (PoC) HCV VL assays are now being used as an alternate to laboratory-based HCV RNA NAT assays. We undertook a systematic review and meta-analysis to evaluate the impact of using PoC HCV VL compared to laboratory-based standard-of-care approaches on uptake of HCV RNA testing and treatment, and turnaround times (TAT) from HCV antibody (HCVAb) testing to treatment initiation.

Method: We searched PubMed, Embase, and Web of Science on 23/09/2020 for studies in English that used HCV PoC RNA assays and had data on key outcomes. We also searched relevant conference abstracts from 2016 to 2020 not picked up by the main search. We categorised study arms according to whether the PoC HCV VL assay was based on-site at the clinic (Model 1), in a mobile unit (Model 2), or in a laboratory (Model 3) versus a HCV lab-based high-throughput viral load assay (Model 4). For each model, studies were further stratified by whether testing and treatment were delivered at the same or different sites, and on the same day. For TATs we calculated the weighted median of medians. We analysed RNA testing and treatment uptake using random effects meta-analysis. Risk of bias was assessed using a tool adapted from Hoy et al and the ROBINS-I tool.

Results: We included 45 studies with 64 within-study arms: 28 studies among people who inject drugs (PWID)/homeless, 4 among prisoners, 9 among general populations, and 4 among persons with HIV. All were observational studies. The pooled median TAT between HCVAb test and treatment was shorter with PoC RNA assays on site (18.5 days [95% CI: 14–53]) than with use of either lab-based PoC RNA assays (64 [64–64]), or lab-based high-throughput RNA assays (67 [50–67]). Treatment uptake was higher with onsite PoC RNA assays

77% (95% CI: 72%-83%), and PoC assays in a mobile unit 81% (60%–97%) compared to lab-based high-throughput assays 53% (31%–75%), p value = 0.03 (models 1/2 vs 4). The effects were greatest among PWID. 4 studies had direct within-study comparisons between a PoC assay arm and a lab-based assay arm. The pooled relative risk for testing uptake was 1.11 (95% CI: 0.89–1.38) and 1.32 (1.06–1.64) for treatment uptake. Risk of bias was high for 36% of studies and moderate for 40%.
Conclusion: Access to PoC HCV VL was associated with reduced time to treatment initiation and increased treatment uptake, especially among PWID. It is now recommended by WHO guidelines as an additional strategy to promote access to VL testing, especially in marginalised populations with high rates of loss to follow-up.

FRI332
Diagnostic accuracy of point-of-care HCV viral load assays for HCV diagnosis: a systermatic review and meta-analysis
Weiming Tang[1], Yusha Tao[1], Emmanuel Fajardo[2], Elena Ivanova[2], Roger Chou[3], Jo Tucker[1], Philippa Easterbrook[2]. *[1]UNC Project-China; [2]WHO; [3]Oregon Health & Science University*
Email: chour@ohsu.edu

Background and aims: Despite the widespread availability of short-course curative HCV treatment, a significant proportion of HCV patients remain undiagnosed and untreated. The requirement for a confirmatory HCV viral load (HCV VL) test can result in substantial care cascade attrition. New point-of-care HCV RNA assays may enhance access to testing by decentralizing HCV RNA testing outside of laboratory settings. We undertook a systematic review and meta-analysis to compare the diagnostic performance of PoC HCV viral load assays to laboratory-based nucleic acid testing.
Method: We searched three databases, used Cochrane methods, and registered the protocol Studies were eligible if they utilized a laboratory reference standard to evaluate POC HCV RNA assays and if they reported or had raw data that could be extracted to calculate sensitivity, specificity, the limit of detection, and bias. Data were extracted by geographic region, collection year, risk group, and specimen type. Random effects bivariate models were used to summarize estimates and describe the variability in test performance across studies. We used the GRADE approach to assess the certainty of the evidence.
Results: A total of 25 studies including data from 8, 791 people were summarized. XX studies in high-income countries and XX in low and middle-income countries. Assays included the Xpert HCV Viral Load assay (Cepheid, USA) Xpert HCV VL Fingerprick (Cepheid, USA) Genedrive HCV ID Kit, Truenat HCV assay, and SAMBA II. Across all assays, the pooled sensitivity and specificity were 99% (95% CI: 98–99%) and 99% (95% CI: 99–100%), respectively, compared to a lab-based reference standard. High sensitivity and specificity were also observed across different study settings (including LMICs and HICs) and populations, using different assays. The evidence was moderate-high certainty. Specificity showed no difference among different specimen types.
Conclusion: POC HCV viral load assays have excellent sensitivity and specificity compared to gold standard laboratory-based nucleic acid testing methods across diverse settings and populations. WHO now recommends the use of POC HCV viral load assays as an additional strategy to promote access to treatment. The adoption of POC viral load assays will be facilitated through increasing availability of integrated molecular multiplex technologies that utilize the same technology for several assays and/or across diseases.
Disclosure: No significant relationships.

FRI333
Hepatitis-C virus viral load reflex testing following an innitial positive HCV antibody test: a global systematic review and meta-analysis
Yusha Tao[1], Weiming Tang[1], Mengyuan Cheng[1], Jennifer Bissram[2], Emmanuel Fajardo[3], Lindsey Hiebert[4], John Ward[4], Roger Chou[5], Philippa Easterbrook[3], Jo Tucker[1]. *[1]UNC Project-China; [2]UNC Chapel Hill; [3]WHO; [4]Task force/USCDC; [5]Oregon Health & Science University*
Email: weiming_tang@med.unc.edu

Background and aims: A significant proportion of persons who are HCV antibody positive do not in HCV viral load testing following a positive antibody test slow linkage to essential HCV services. HCV programmes have introduced reflex viral load testing (either lab-based reflex testing or clinic based reflex sample collection) as a strategy to reduce the steps in the HCV diagnostic pathway and improve linkage to care. A systematic review evaluated the effectiveness of reflex viral load testing in increasing uptake of HCV viral load testing and treatment, and in reducing turn-around time from HCV Ab screening to viral load testing, linkage to care, and treatment, compared to a standard multi-step viral load testing strategy.
Method: We searched three databases (Medline, EMBASE, and Google Scholar) for studies in English to used either reflex lab-based viral load testing or clinic-based reflex sample collection and had data on the key outcomes. Laboratory-based HCV reflex testing refers to a testing algorithm in which patients have only a single clinical encounter and only one blood draw or specimen taken and sent to the lab. If the sample for anti-HCV testing in the lab is positive, then the same existing or duplicate sample is used for a "reflex" lab-based HCV viral load test. No further visit or sample collection is required. Clinic-based reflex testing refers to a testing algorithm where there is only a single clinical encounter/visit for an initial rapid diagnostic HCV antibody test, but with two blood draws. A fingerstick sample is taken and tested using a rapid diagnostic HCV antibody test, which if positive is then immediately followed by a "reflex" blood draw (either venous blood sample or fingerstick) for HCV viral load confirmation of current infection. Data were extracted by geographic region, collection year, and risk group. Summary estimates (95% confidence intervals [CI]) were calculated using random-effects meta-analyses.
Results: 51 studies met the inclusion criteria reporting laboratory-based reflex testing (n = 32) and clinic-based reflex sample collection (n = 19). Forty-two were in high-income and nine were in low or middle-income countries. All studies were cross-sectional or cohort studies. Compared to laboratory non-reflex testing, laboratory reflex testing increased the likelihood of viral load testing among patients screened as HCV antibody positive (RR: 1.35 (1.16–1.58)), and may improve linkage to care among patients diagnosed with HCV infection with RNA testing (RR: 1.47 (0.81–2.67)).
Conclusion: HCV viral load reflex testing increased uptake and reduced time to HCV viral load testing and may enhance linkage to care. In addition, laboratory and clinic reflex testing were feasible in a diverse range of LMIC settings. WHO now recommends the adoption of reflex viral load testing as an additional strategy to promote linkage to care.
Disclosure: No significant relationships.

Finding cases of hepatitis C for treatment using automated screening in the emergency department is effective, but what is the cost?

David Prince[1,2], Julia Di Girolamo[1,3], Joseph Pipicella[1,3], Melissa Fraser[1], Tahrima Kayes[1], Frank Alvaro[4,5], Michael Maley[2,4,5], Hong Foo[4,5,6], Paul Middleton[2,3,7,8], Miriam Levy[1,2,3]. [1]*Liverpool Hospital, Gastroenterology and Liver, Liverpool, Australia;* [2]*UNSW Sydney, Medicine, Sydney, Australia;* [3]*Ingham Institute, Liverpool, Australia;* [4]*Liverpool Hospital, Pathology, Liverpool, Australia;* [5]*NSW Health Pathology, Liverpool, Australia;* [6]*Western Sydney University, Medicine, Parramatta, Australia;* [7]*Liverpool Hospital, Emergency Department, Liverpool, Australia;* [8]*The University of Sydney, Medicine, Camperdown, Australia*
Email: david.s.prince@gmail.com

Background and aims: Case detection remains a major challenge for hepatitis C virus (HCV) elimination. We have previously published results from a pilot of an emergency department (ED) semi-automated screening program, SEARCH; Screening Emergency Admissions at Risk of Chronic HCV. In this pilot, 5000 consecutive patients were screened including 4778 overseas born (targeted) from 14, 093 ED presentations. HCVAb was positive in 181 patients (3.6%); 51 (1.0%) were HCV RNA positive. This cost analysis aimed to accurately describe the overall costs of this pilot service. It also aimed to report on costs per patient tested, per HCV Ab positive patient detected and per RNA positive patient treated. We modelled the effect of proposed service refinements (SEARCH 2.0).

Method: All direct costs of HCV testing until direct acting anti-viral (DAA) therapy initiation were calculated. Cost was assessed in 2018 Australian Dollars. A cost analysis of the initial program and refinements are presented. Sensitivity analysis to understand impact of variation in staff time, laboratory test cost, changes in HCV antibody (Ab) prevalence, RNA positivity percentage and rate of linkage to care was conducted. Impact of refinements (SEARCH 2) to cost is presented.

Results: The total SEARCH pilot, testing 5000 patients was estimated to cost $110, 549.52 (range $92, 109.79–$129, 581.24) comprising of $68, 278.67 for HCV Ab testing, $21, 568.99 for follow up and linkage to care of positive patients and $20, 701.86 to prepare HCV RNA positive patients for treatment. Refinements resulted in a 32% cost reduction overall and reduced the cost of HCV antibody screening from $13.66 to $8.46 per test and the total cost per positive HCV Ab, positive HCV RNA and treated patient to $611.77, $2, 168.64 and $3, 566.11 respectively. Our sensitivity analysis indicates costs are modest so long as HCV Ab prevalence was 1% or greater.

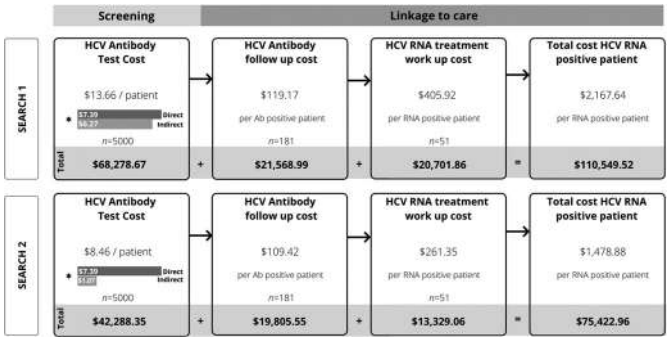

Figure: Costs of HCV screening in SEARCH 1 compared to costs modelled with SEARCH 2 program refinements

Conclusion: ED screening is an affordable strategy for HCV case detection and elimination.

FRI335

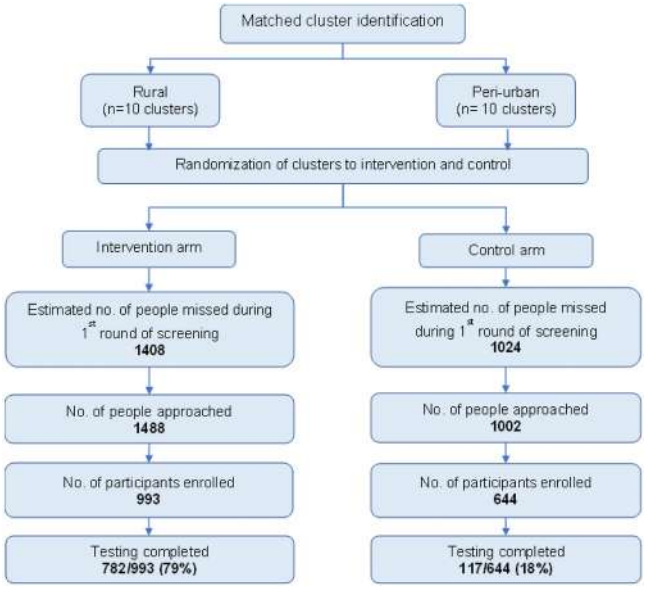
A cluster randomized controlled study of secondary distribution of HCV self-test to support micro-elimination in Karachi, Pakistan.

Aliya Hasnain[1], Sonjelle Shilton[2], Wasiuddin Shah[1], Jessica Markby[2], Niklas Luhmann[3], Muhammad Jamil[3], Elena Ivanova[2], Saeed Sadiq Hamid[4]. [1]*Aga Khan University, Karachi, Pakistan;* [2]*FIND, Geneva, Switzerland;* [3]*WHO, Switzerland;* [4]*Aga Khan University, Medicine, Karachi, Pakistan*
Email: saeed.hamid@aku.edu

Background and aims: Pakistan has a nationwide HCV prevalence of 6% with majority of cases undiagnosed due to lack of comprehensive screening programmes. Self-testing has shown to acceptable and increases testing uptake for HIV due to its convenience and privacy advantages. This study aims to evaluate the acceptability and effect of a program enabling home delivery of HCV self-testing using the oral-based OraQuick® HCV rapid antibody test. HCV self-testing study is nested within a community-based micro elimination project in an HCV endemic district of Karachi, Pakistan.

Method: This ongoing cluster randomized control study targets persons missed during house-to-house screening done as part of a micro-elimination study in two Union Councils in district Malir of Karachi. During house visits, individuals not found at home are eligible for participation. Target sample size is 1000 participants each in intervention and control group. In the intervention group, an HCV self-test is left with instructions for use explained to a senior household member. In the control group, a pamphlet is left with directions to visit the nearest clinic for HCV screening. Both groups are followed up within 4 weeks to inquire if testing was completed and a brief acceptability survey is conducted with the tester. Results report are incentivized and individuals with positive tests are linked for further management.

Results: 1637 participants were recruited between 29th Nov 2021 and 22nd March 2022, with 993 in the intervention group and 644 in the control group, from rural and peri-urban clusters of the district. Median (IQR) age across both groups is 30 (24–42) years with 82% (1337/1637) male participants. Half (51%) of the participants who completed self-testing had received no formal education. The proportion of participants who reported completing the HCV antibody test was 79% (782/993) in the intervention group compared to 18% (117/644) in the control group ($p < 0.05$). Nearly all (95%) participants who reported completing the test demonstrated willingness to perform HCV self-test in the future.



Conclusion: Preliminary results of this study demonstrate that HCV self-testing increases HCV screening rates in a peri-urban/rural setting consistent of a mostly illiterate population in a low-middle income country like Pakistan.

FRI336

HCV-viral load fingerstick assay to simplify screening and linkage to care of people who use drugs attending Italian addiction treatment centres

Sarah Vecchio[1], Lorenzo Somaini[2], Luigi Bartoletti[3], Daniela Mussi[3], Roberta Gaudenzi[4], Eugenia Vernole[5], Claudio Leonardi[6]. *[1]ASL Biella, Addiction Treatment Center, Biella, Italy; [2]ASL Biella, Addiction Treatment Center, Biella, Italy; [3]ASL Alessandria, Addiction Treatment Center, Alessandria, Italy; [4]ASL Umbria 1, Addiction Treatment Center, Perugia, Italy; [5]ASL Bari, Addiction Treatment Center, Bari, Italy; [6]ASL Roma 2, Addiction Treatment Center, Roma, Italy*
Email: lorenzo.somaini@aslbi.piemonte.it

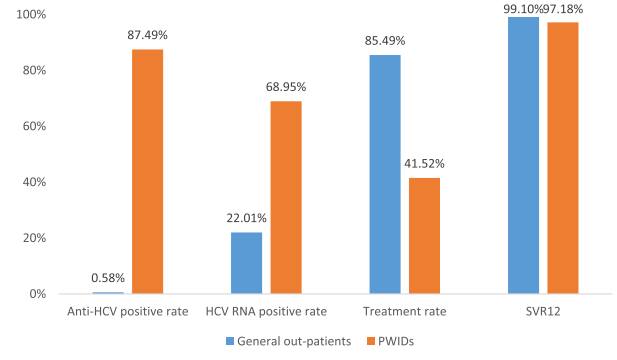
Background and aims: People who use drugs (PWUDs) are the major drivers of HCV transmission in the world, representing the target population for HCV screening and treatment. In Italy, the estimate prevalence of HCV infection in drug users exceeds the 80%, with 205.000 PWUDs not yet treated. Simplified strategies are required for the screening and diagnosis of hepatitis C infection among PWUDs, and HCV-RNA viral load fingerstick assay can help in overcoming existing challenges and barriers to HCV diagnosis and care. The aims of this prospective study were to evaluate the feasibility and the acceptability of HCV-RNA viral load fingerstick assay use to improve HCV screening and treatment among Italian PWUDs attending different Italian Addiction Treatment Centres (Ser.D) in an outpatient setting.
Method: Between October 2020 and December 2021, the HCV screening was offered to 1258 consecutive PWUDs from 5 Addiction Treatment Centres of 4 Regions of Northern, Central and Southern Italy. HCV analysis was carried out by means of a fingerstick capillary whole blood RNA test. Results were given in 60 minutes.
Results: 1221/1258 (97%) consecutive PWUDs were enrolled. Patients were mostly male (973/1221, 80%), with a mean age of 42.9 years ± 10.7 and a mean addiction treatment duration of 10.1 years ± 8.5. The main HCV risk factors identified were heroin addiction (935/1221, 76%), a history of injecting drug use (700/1221, 57%) and tattooing (794/1221, 65%). HCV RNA was identified in 240/1221 patients (20%) participants. The most common HCV genotypes, among available data, were 3 (40/240, 17%) and 1a (38/240, 16%). Among patients with detectable HCV RNA, 89% (214/240) were referred to specialists for HCV treatment and, at the time of writing, 53% (127/240) completed the treatment. All the treated patients achieved SVR (Sustained Virologic Response).
Conclusion: This is one of the largest HCV-RNA screening projects, highlighting the feasibility and the acceptability of onsite testing performed with HCV-RNA viral load fingerstick assay in PWUDs attending Ser.Ds. At present, HCV screening and linkage to care remain worldwide far from comprehensive. The described easy to use approach favours PWUDs engagement and increases HCV treatment and elimination, as evidenced by the high rate of completed treatments.

FRI337

From extensive to intensive screening, co-operations model of hepatitis C elimination in out-patients and people who inject drug population in southwest of China

Qing Lin[1], Youzhi He[2], Long Chen[3], Jingchun He[4], Xiaojian Yuan[5], Zhenglin Wang[1], Guohui Wu[6]. *[1]The People's Hospital of Jiulongpo District, Chongqing, China; [2]Methadone Maintenance Therapy Clinic of Jiulongpo District, Chongqing, China; [3]Chongqing Public Health Medical Center, Chongqing, China; [4]Jiulongpo District Center for Disease Control and Prevention, Chongqing, China; [5]Xiejiawan Street Community Health Service Center, Jiulongpo District, Chongqing, China; [6]Chongqing Center for Disease Control and Prevention, Chongqing, China*
Email: xiah302@126.com

Background and aims: The Southwest China has a relatively higher HCV prevalence rate among the whole country for large proportion of people who inject drugs (PWID) reside here. We established a co-operation model combined with intensive and extensive HCV screening, and this study aimed to determine its efficacy on the HCV elimination in PWIDs and general out-patients (GOP).
Method: The co-operation network consists of local Centers for Disease Control and Prevention (CDC) and the medical association including 39 community health centers, 15 district hospitals and 1 methadone clinic. The CDC was responsible for educational training, funding and patient-network management. The medical association was responsible for HCV antibody screening and linkage to care with the cascade referral system. Patients with positive HCV antibody were referred to the designated hospital for HCV RNA testing, in which positive patients will receive anti-HCV treatment of sofosbuvir/velpatasvir (SOF/VEL) for 12 weeks with or without RBV. The call-back system in methadone clinic requested the HCV RNA-positive PWID patients to return for further therapy. The patient-education and management were carried out in the district hospitals monthly. Reimbursement and free RNA testing were provided to enhance treatment affordability. The effect and safety of SOF/VEL were evaluated.
Results: From March 2021 to March 2022, 102873 residents and 1,199 PWIDs were screened. The seropositive rate of anti-HCV and HCV RNA were 0.58% (595/101674), 22.01% (131/595) in GOPs and 87.49% (1049/1199, 68.95% (171/248)) in PWIDs, respectively. 85.49% (112/131) GOPs patients and 41.52% (71/171) PWIDs initiated anti-HCV treatment, while only 8% before the model establishment. The genotype distribution is as follows: GT3a 22.13% (29/131), GT3b 20.61% (27/131), GT1b 18.32% (24/131) in GOPs, while GT3a 47.37% (81/171), GT3b 42.69% (73/171) and GT1b 9.94% (17/171) in PWIDs. The percentage of liver fibrosis, cirrhosis and hepatocellular carcinoma was 9.1% (12/131), 9.1% (12/131) and 0.7% (1/131) in GOPs, while 26.31% (45/171), 13.45% (23/171) and 1.75% (3/171) in PWIDs. The co-infection rate of HBV or HIV was 3.8% (5/131) or 1.5% (2/131) in GOPs and 7.6% (13/171) or 14.03% (24/171) in PWIDs. Both groups achieved high SVR12 as 99.10% (111/112) in GOPs and 97.18% (69/71) in PWIDs. None of patients discontinued anti-HCV treatment due to adverse events.



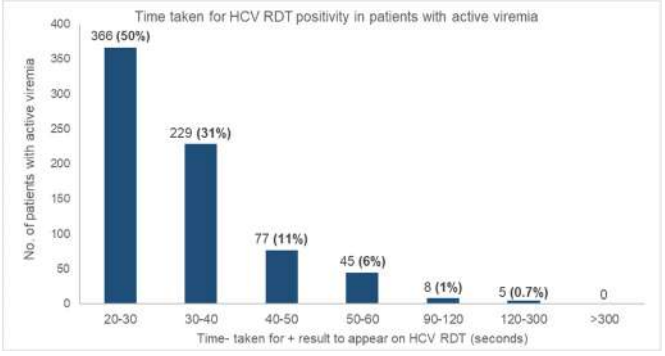
Conclusion: The co-operation model was effective in HCV elimination in both groups. The HCV prevalence of PWIDs was significantly higher than GOPs in the district scale. Although PWIDs had lower treatment adherence, the treatment rate in PWIDs were improved significantly by intensive follow-up. Both groups achieved high SVR with good safety profile by SOF/VEL treatment. The co-operations model with intensive and extensive screening was an optimal option for GOP and PWID to eliminate HCV.

FRI338

Using time to positivity of hepatitis rapid detection test results to determine active viremia

Saeed Sadiq Hamid[1], Sultan Salahuddin[2], Wasiuddin Shah[2], Aliya Hasnain[2], Muraduddin Gulab[2], Taj Muhammad[2], Sabiha Khan[2]. *[1]Aga Khan University, Karachi, Pakistan; [2]Aga Khan University, Medicine, Karachi, Pakistan*
Email: saeed.hamid@aku.edu

Background and aims: The recommended time taken to run the Rapid Diagnostic tests (RDTs) for HCV screening is 20 mins, which is followed by reflex PCR testing for confirmation of chronic HCV infection. Confirmatory viral load testing is a barrier in the HCV cascade of care as it is a cost and time-intensive step. This study hypothesises the correlation between shorter read time and active viremia in HCV infected patients, which can reduce the need for reflex RNA tests and help implement rapid-test-and-treat models for HCV.
Method: The findings from this study were obtained from a community-based micro-elimination study which targets a high burden HCV endemic area in Karachi, Pakistan. Door-to-door visits were performed to conduct rapid screening of individuals with unknown HCV status, using the finger-stick Abbott SD Bioline HCV diagnostic kits. The time taken for the RDT to display a positive result was measured using a stopwatch to record the duration from the point the blood sample was placed in the test kit till the point the test line appeared. Blood samples of individuals with a positive screening test were collected for Hepatitis C core antigen testing, on Abbott Architect *i*1000SR, to determine viremia.
Results: A total of 1327 participants, median age (IQR) 47 years (39–56), with 70% females, who screened positive on HCV RDT and had HCV core antigen testing done, were included. Overall, 730/1327 (55%) patients were viremic and in all cases, the HCV RDT test was positive within 5 minutes. 50% (366/730) of all viremic cases had a positive screening result within 20–30 seconds. No. of cases with active viremia decreased as the time taken for a positive result to appear on rapid screening increased (r = –0.63). Less than 1% of cases with active viremia were found amongst those who had a positive screening result from 120 seconds to 300 seconds.



Conclusion: The time to read SD Bioline HCV RDT can be reduced to 5 mins to identify patients with HCV infection. In patients displaying a positive result between 20 and 30 seconds HCV treatment using DAAs can be initiated using rapid test-and-treat models reducing loss to follow up and need for HCV RNA testing in resource limited settings.

FRI339

Liver-related mortality among people with hepatitis B and C: a validation study using linked healthcare administrative datasets

Syed Hassan Bin Usman Shah[1], Maryam Alavi[2], Behzad Hajarizadeh[2], Gail Matthews[2], Marianne Martinello[2], Mark Danta[3], Janaki Amin[4], Matthew Law[5], Jacob George[6], Hamish Innes[7], Gregory Dore[2]. *[1]The Kirby Institute, Viral Hepatitis Clinical Research Program, Kensington, Australia; [2]The Kirby Institute, Viral Hepatitis Clinical Research Program, UNSW, Kensington, Australia; [3]St Vincent's Hospital Sydney, Darlinghurst, Australia; [4]Macquarie University, Macquarie Park, Australia; [5]The Kirby Institute, Kensington, Australia; [6]Westmead Hospital, Westmead, Australia; [7]Glasgow Caledonian University, United Kingdom*
Email: hbinusman@kirby.unsw.edu.au

Background and aims: Routinely collected and linked healthcare administrative datasets could be used to monitor mortality among people with hepatitis B and C virus (HBV and HCV). This study aimed to validate a definition for liver-related mortality among people with an HBV or HCV notification, including any death (i.e. all-cause) following hospitalization for end-stage liver disease (ESLD), which included a first-time hospital admission due to decompensated cirrhosis (DC) or hepatocellular carcinoma (HCC).
Method: In New South Wales, Australia, HBV and HCV notifications (1993–2017) were linked to hospital admissions (2001–2018), all-cause mortality (1993–2018), and cause-specific mortality (1993–2016) databases. Hospitalization-defined ESLD-related mortality was validated in comparison with two death certificate-based definitions of liver deaths coded among primary and secondary cause-specific mortality data, including ESLD-related (deaths due to DC and HCC) and all-liver deaths (ESLD-related and other liver-related causes).
Results: Of 63, 292 and 107, 430 individuals with an HBV and HCV notification, there were 4, 478 (2.6%) post-ESLD hospitalization deaths, 5, 572 (3.3%) death certificate liver disease deaths, and 2, 910 (1.7%) death certificate ESLD deaths. Between 2001 and 2016, 63% (562/891) of HBV post-ESLD hospitalization deaths had death certificate ESLD deaths recorded, including 58% (390/676) of DC and 85% (431/510) of HCC deaths. Further, 83% (741/891) of HBV post-ESLD hospitalization deaths had death certificate liver disease deaths, including 81% (546/676) of DC and 95% (482/510) of HCC deaths. Similarly, 58% (2, 082/3, 587) of HCV post-ESLD hospitalization deaths had death certificate ESLD deaths recorded, including, 56% (1, 817/3, 236) of DC and 82% (1, 007/1, 224) of HCC deaths. Further, 87% (3, 135/3, 587) of HCV post-ESLD hospitalization deaths had death certificate liver disease deaths, including 87% (2, 812/3, 236) of DC and 96% (1, 171/1, 224) of HCC deaths.
Conclusion: Our findings support the use of healthcare administrative datasets as an efficient method and a reliable information source to represent liver-related mortality rates accurately; however, concordance between post-hospitalization and death certificate-based cause of death is clearly higher for HCC than DC.

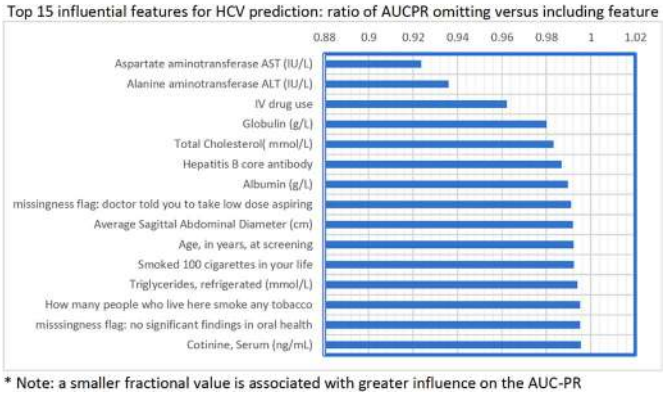
FRI340

Identifying risk factors associated with hepatitis C virus infection in participants in the national health and nutrition examination survey using Super Learner

Laura Telep[1,2], Rachael Phillips[3], Anand Chokkalingam[1,2]. *[1]Gilead Sciences, Inc., Foster City, United States; [2]University of California, Berkeley, Epidemiology, Berkeley, United States; [3]University of California, Berkeley, Biostatistics, Berkeley, United States*
Email: laura.telep@gilead.com

Background and aims: Under-diagnosis is a key impediment to eliminating hepatitis C virus (HCV) infection in the United States (US).

Machine learning methods offer an opportunity to support expanded HCV screening in a resource-optimized way by identifying the characteristics that are most influential in predicting HCV.
Method: The ensemble machine-learning method Super Learner (SL) was used with National Health and Nutrition Examination Survey (NHANES) data collected from 2013 to 2018 to build an HCV infection risk prediction algorithm. Because only 1% of survey participants tested positive for HCV RNA, case-control sampling was used to address class imbalance, with five HCV-uninfected individuals randomly selected for each HCV-infected individual (n = 1, 008). The SL was fit to the case-control data, its performance was evaluated with the area under the precision-recall curve (AUC-PR), and then it was used to predict HCV infection in the full NHANES dataset (n = 15, 237). We also identified the features that had the greatest impact on AUC-PR, and thus were most predictive of HCV infection.
Results: The SL's AUC-PR on the full NHANES dataset was 52%, a 47-fold improvement over baseline. At the probability threshold that optimized the F1 score, the SL achieved 55.4% precision and 61.3% recall; that is, if the goal was to identify at least 60% of those infected with HCV, then for every 100 individuals classified as HCV-infected, more than 50% would be true positives. Features that were most predictive of HCV infection included alanine aminotransferase (ALT), aspartate aminotransferase (AST), injection drug use, age, albumin, globulin, and HBV infection status. Additional influential predictors included smoking-related features, risk factors for heart disease or stroke (triglycerides, total cholesterol, recommendations by a doctor to take low dose aspirin), and features related to oral health.



* Note: a smaller fractional value is associated with greater influence on the AUC-PR

Conclusion: As outreach continues to identify the undiagnosed HCV-infected population in the US, knowledge of the characteristics most predictive of HCV infection should be utilized to guide screening and prevention efforts. Next steps include identifying HCV infection predictors from widely available data such as features collected in a single routine medical care visit and exploring variation in highly predictive features by age category. Algorithms such as the one demonstrated here can be useful tools to support these activities.

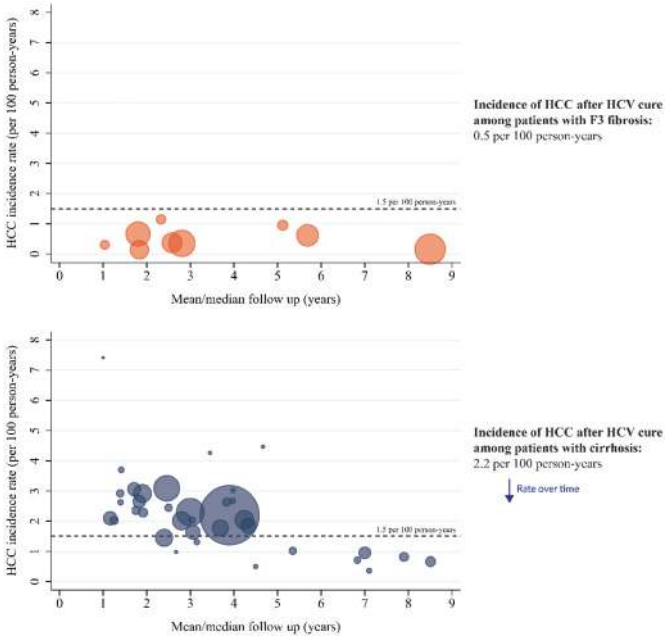
Viral Hepatitis C: Post SVR and long term follow up

FRI343

Hepatocellular carcinoma incidence after hepatitis C cure among patients with advanced fibrosis or cirrhosis: a meta-analysis

Ian Lockart[1,2], Malcolm Guan Hin Yeo[2], Behzad Hajarizadeh[3], Gregory Dore[1,3], Mark Danta[1,2]. [1]*St Vincent's Hospital, Sydney, Australia;* [2]*St Vincent's Clinical School, UNSW Sydney, Australia;* [3]*The Kirby Institute, UNSW Sydney, Australia*
Email: m.danta@unsw.edu.au

Background and aims: Hepatitis C virus (HCV) cure reduces but does not eliminate the risk of hepatocellular carcinoma (HCC). HCC surveillance is recommended in populations where the incidence exceeds 1.5% per year. In cirrhosis, HCC surveillance should continue after HCV cure, although it is uncertain if this should be indefinite. For patients with advanced fibrosis (F3), guidelines are inconsistent in their recommendations. This systematic review evaluated the incidence of HCC after HCV cure among patients with F3 fibrosis or cirrhosis.
Method: We searched bibliographic databases and conference abstracts for studies assessing the incidence of HCC after HCV cure among patients with F3 fibrosis or cirrhosis. Meta-analyses were used to cumulate HCC rates and meta-regression was used to explore heterogeneity across studies.
Results: Forty-four studies were included (36, 183 patients; 109, 385 person-years of follow up). The incidence of HCC was 2.2 per 100 person-years (95% CI 1.9–2.4) among patients with cirrhosis, and 0.5 per 100 person-years (95% CI 0.3–0.7) among patients with F3 fibrosis. In meta-regression analysis among patients with cirrhosis, older age (adjusted rate ratio [aRR] per 10-year increase in mean/median age: 1.34; 95% CI 1.04–1.74) and prior decompensation (aRR per 10% increase in the proportion of patients with prior decompensation: 1.05; 95% CI 1.00–1.11) were associated with an increased incidence of HCC. Longer follow-up after HCV cure was associated with a decreased incidence of HCC (aRR per year increase in mean/median follow-up: 0.87; 95% CI 0.80–0.96).



Conclusion: Among patients with cirrhosis, the incidence of HCC decreases over time after HCV cure and is lowest in patients with younger age and compensated cirrhosis. The substantially lower incidence in F3 fibrosis is below the recommended threshold for cost-effective screening.

FRI344

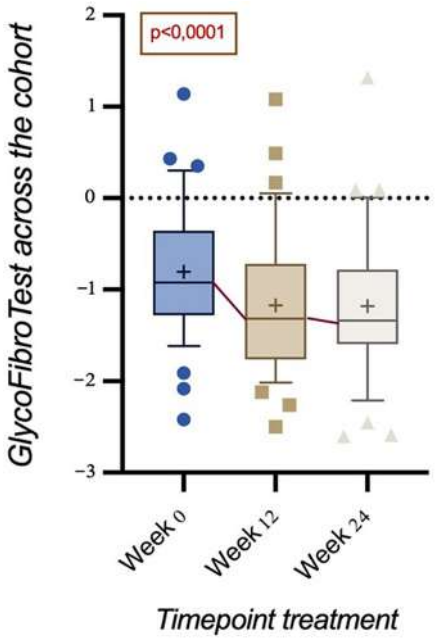
Glycomics-based serum marker as reliable tool for assessment of viral response after treatment with direct-acting antiviral drugs in hepatitis C virus infection

Nicky Somers[1], Elisabeth Vandekerckhove[1], Anja Geerts[1], Helena Degroote[1], Sander Lefere[1,2], Lindsey Devisscher[2], Leander Meuris[3,4], Nico Callewaert[3,4], Hans Van Vlierberghe[1], Xavier Verhelst[1]. *[1]Ghent University, Ghent University Hospital, Hepatology Research Unit, Department Internal Medicine and Paediatrics, Liver Research Center Ghent, Ghent University, Ghent University Hospital, Ghent, Belgium, Belgium; [2]Ghent University, Gut-Liver Immunopharmacology Unit, Department of Basic and Applied Medical Sciences;, Liver Research Center Ghent, Ghent University, Ghent, Belgium, Belgium; [3]Vlaams Instituut voor Biotechnologie, Center for Medical Biotechnology, VIB, Ghent, Belgium, Belgium; [4]Ghent University, Department of Biochemistry and Microbiology, Ghent University, Ghent, Belgium*
Email: nicky.somers@ugent.be

Background and aims: Patients with chronic hepatitis C virus (HCV) infection have a genuine risk of developing liver fibrosis and cirrhosis, potentially resulting in hepatocellular carcinoma (HCC), a risk that remains even after sustained viral response (SVR). It is of utmost importance to closely monitor these patients during and after antiviral treatment, which today consists of direct-acting antiviral drugs (DAAs). Glycomics-based biomarkers are an attractive tool to answer this medical need, as alterations in the abundance of N-glycans reflect an altered state of the liver. Progression of liver fibrosis has been linked to changes in serum glycosylation patterns before. Accordingly, our previously developed GlycoFibroTest measures the ratio of NGA2FB to NA3. The aim of this study was to assess the GlycoFibroTest for the evaluation of fibrosis regression during and after treatment of HCV with DAAs.

Method: N-glycosylation patterns were analyzed in sera from 36 HCV-infected patients, collected between January 2015 and June 2016. Patients showed liver biopsy-proven advanced fibrosis (F3, n = 12) or established cirrhosis (F4, n = 24) before therapy initiation, which consisted of a twelve-week oral administration of DAAs. The GlycoFibroTest was measured on serum samples at three timepoints: at the start (week 0), the end (week 12) and during follow up (week 24), by the use of an optimized glycomic technology on a DNA sequencer (DSA-FACE, Applied Biosystems).

Results: All patients achieved SVR after treatment and none of them developed HCC. Figure 1 demonstrates the significant decrease of the GlycoFibroTest ($p < 0.0001$) in all patients (F3 + F4)[12]. More specifically, this decrease was seen from week 0 to weeks 12 and 24, but no significant decline could be retained between weeks 12 and 24. Statistical analysis was performed using IBM SPSS Statistics version 28.0. Since measurements were repeated on the same subject and values were not normally distributed, the non-parametric Friedman's test was used. Statistical significance was set at the alpha level of 0.05.



Conclusion: In this study, we illustrated that changes in serum protein glycosylation that are observed with increasing levels of fibrosis decline after the decrease of viral load during treatment with DAAs of HCV-infected patients (all genotypes). The decrease started early after initiation of treatment and remained stable during post-treatment observation. The rapid decrease of glycomics-based fibrosis biomarkers probably reflects the amelioration of liver inflammation as underlying process rather than the improvement of liver fibrosis itself, which cannot occur in such a short timeframe. In conclusion, this study suggests that GlycoFibroTest shows an excellent correlation with viral response in HCV patients.

Post-treatment elevated gamma-glutamyl transferase is the best predictor for future outcomes in HCV patients achieving sustained virological response-data from the german hepatitis C-registry (DHC-R)

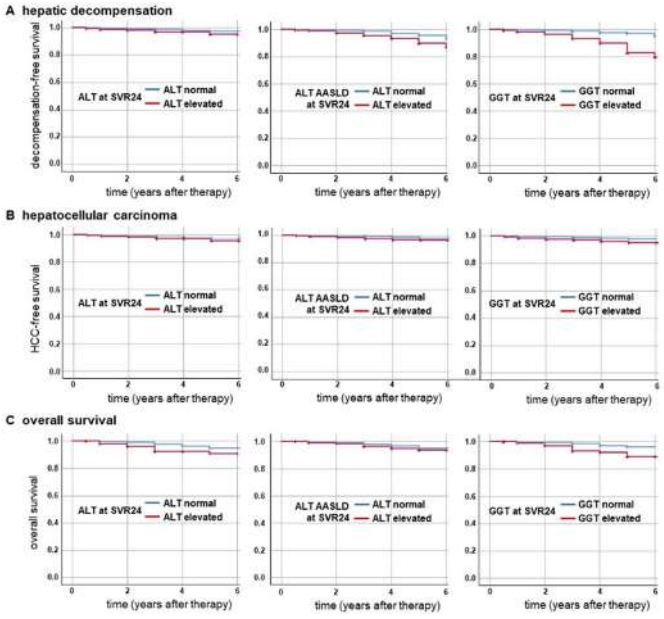
Stefan Mauss[1], Hartwig Klinker[2], Klaus Boeker[3], Uta Merle[4], Ralph Link[5], Peter Buggisch[6], Dietrich Hüppe[7], Markus Cornberg[8], Christoph Sarrazin[9,10], Heiner Wedemeyer[8,11], Thomas Berg[12], Frank Tacke[13], German Hepatitis C-Registry[11]. *[1]Center for HIV and Hepatogastroenterology, Düsseldorf, Germany; [2]University Hospital Würzburg, Würzburg, Germany; [3]Center of Hepatology, Hannover, Germany; [4]Heidelberg University Hospital, Heidelberg, Germany; [5]MVZ-Offenburg GmbH/St. Josefs-Klinik, Offenburg, Germany; [6]ifi-Institute for Interdisciplinary Medicine, Hamburg, Germany; [7]Gastroenterologische Gemeinschaftspraxis Herne, Herne, Germany; [8]Hannover Medical School, Hannover, Germany; [9]St. Josefs-Hospital, Wiesbaden, Germany; [10]Goethe University Hospital, Frankfurt, Germany; [11]Leberstiftungs-GmbH Deutschland, Hannover, Germany; [12]University Hospital Leipzig, Leipzig, Germany; [13]Charité-Universitätsmedizin Berlin, Department of Hepatology & Gastroenterology, Campus Virchow-Klinikum and Campus Charité Mitte, Berlin, Germany*
Email: stefan.mauss@center-duesseldorf.de

Background and aims: While direct acting antivirals (DAA) can cure chronic hepatitis C virus (HCV) infection in almost all patients, some patients remain at risk of liver disease despite HCV cure. We aimed at identifying predictors for liver-related morbidity and death after viral cure.

Method: The DHC-R (German Hepatitis C-Registry) is a national multicenter real-world registry. Patients are followed for up to 7 years after DAA therapy. Normal alanine transaminase (ALT; at 37°C) was

defined as (i) ≤35 U/l for females and ≤50 U/l for males and or (ii) according to AASLD as ≤19 U/l for females and ≤30 U/l for males. Normal gamma-glutamyl transferase (GGT) (at 37°C) was defined as ≤40 U/l (female) and ≤60 U/l (male). The present analysis is based on 6982 patients with available data as of January 1st, 2021.

Results: 97.4% of patients achieved sustained virological response (SVR). In patients achieving SVR, elevated ALT at SVR24 was documented in 657/6982 (9.4%), elevated ALT (AASLD) in 2609/6982 (37.4%) and elevated GGT in 1777/6982 (25.5%). At SVR24, elevated ALT was associated with categorized higher body mass index (BMI; $p < 0.05$), liver cirrhosis (OR 2.29, $p < 0.0001$), alcohol consumption (>30/40 g/day) (OR 2.93, $p < 0.001$), elevated ALT at baseline (OR 4.46, $p < 0.0001$) and no SVR (OR 43.49, $p < 0.0001$). The same variables were identified using AASLD criteria plus female sex (OR 2.39, $p < 0.001$). Increased GGT at SVR24 was associated with male sex (OR 2.12, $p < 0.001$), higher BMI (OR1.04, $p < 0.05$), age >50 years (OR 1.60, $p < 0.01$), liver cirrhosis (OR 3.97, $p < 0.0001$), alcohol consumption (OR 2, 99, $p < 0.001$), diabetes mellitus (OR 1.63, $p < 0.001$), non-SVR (OR 8.00, $p < 0.0001$) and elevated GGT at baseline (OR 17.12, $p < 0.001$). More importantly, we identified elevated GGT at SVR24 as the best predictor of overall survival, hepatic decompensation or HCC development over elevated ALT or ALT (AASLD; Figure). Combining ALT and GGT did not improve sensitivity substantially.



Conclusion: We here define risk factors for developing clinical complications after cure form HCV infection. In this context, elevated GGT may highlight the relevance of non-alcoholic fatty liver disease (NAFLD), diabetes mellitus, and alcohol consumption.

FRI346

The impact of liver function improvement after direct-acting antiviral therapy on the outcome in hepatitis C virus patients with decompensated cirrhosis

Email: yuki.tahata@gh.med.osaka-u.ac.jp

Background and aims: Direct-acting antiviral (DAA) therapy can improve liver function in the short term even in patients with hepatitis C virus (HCV)-related decompensated cirrhosis. However, the impact of DAA therapy on long-term outcome among patients with decompensated cirrhosis is unclear.

Method: This study enrolled 396 patients with HCV-related compensated or decompensated cirrhosis who started DAA therapy between February 2019 and December 2020 at 33 Japanese hospitals. Patients were excluded when sustained virologic response (SVR) could not be determined or died before SVR confirmation. SVR was defined as undetectable serum HCV-RNA for at least 12 weeks after the end of treatment (EOT). Our endpoints are the incidence of decompensated cirrhosis events with hospitalization and overall survival. Decompensated cirrhosis events were defined as aggravation of ascites or encephalopathy, rupture of varix, and the onset of spontaneous bacterial peritonitis, sepsis or acute kidney injury. We evaluated the impact of delta MELD score between at baseline and at 12 weeks after the EOT on these endpoints. Delta MELD score was classified into three groups: the MELD score decreased 2 points or more (MELD improved), the MELD score increased 2 points or more (MELD deterioration) and others (MELD stable).

Results: The median age was 70 years. The SVR rates of patients with CP class A, B and C were 100% (224/224), 96% (142/148) and 96% (22/23), respectively. Among 396 patients, delta MELD score were evaluated in 347 patients. The number of patients with MELD improved, MELD stable and MELD deterioration were 41, 275 and 31, respectively. During the median observation period of 20 months, 34 patients experienced decompensated cirrhosis events (the most

frequent event was ascites), 10 patients died, and two patients underwent liver transplantation. In patients with CP class A, five patients experienced decompensated cirrhosis events and two patients died. MELD changes at 12 weeks after the EOT were not associated with the incidence of decompensated cirrhosis events and overall survival. In patients with CP class B or C, the cumulative incidence rate of decompensated cirrhosis event at 2 years with MELD improved, MELD stable, MELD deterioration were 7%, 22% and 58%, respectively. Overall survival rates of patients at 2 years with MELD improved, MELD stable and MELD deterioration were 100%, 97% and 69%, respectively. Patients with MELD deterioration had a higher incidence of decompensated cirrhosis events and poorer overall survival than the other two groups.

Conclusion: In patients with decompensated cirrhosis who were treated with DAA, MELD score deterioration at 12 weeks after the EOT indicated an unfavorable outcome.

FRI347

De-novo occurrence of portal vein thrombosis in patients with HCV-related cirrhosis after sustained virological response: medium to long term observations from the ongoing PITER cohort

Email: loreta.kondili@iss.it

Background and aims: Achievement of sustained virological response (SVR) by direct-acting antiviral therapy (DAAs) ameliorates portal hypertension, improves hepatic function, and may reverse hyper-coagulability driven by cirrhosis. However, an unexpected finding of *de-novo* portal vein thrombosis (PVT) immediately after DAAs has been reported. Here, we analyzed the long-term impact of SVR on the development of PVT in patients with cirrhosis.

Method: Consecutive patients with liver cirrhosis, enrolled in the multicenter Italian PITER cohort and treated with DAAs were prospectively evaluated. Patients with history of PVT prior to start of DAAs, and those with no follow-up data after end of treatment (EOT) were excluded. Stepwise Cox regression analysis was used to evaluate factors independently associated with *de-novo* PVT. Kaplan Meier analysis and log rank test evaluated the PVT rates by DAA treatment response.

Results: Of 1632 patients evaluated, 40 (2.5%) developed *de-novo* PVT after DAA treatment. The two year PVT free survival was 99% for patients who achieved the SVR and 93% for those who didn't ($p = 0.002$). Of 1555 patients who achieved the SVR (median age 65 years, 55% males, 85% Child A and 15% Child B), 34 (2.2%) experienced *de-novo* PVT (median follow-up 36 months after EOT; IQR 24–44.7). Of them, 18 reported HCC development previous or after achieving the SVR; in 6 of whom (17.6%) PVT was of neoplastic nature. The PVT occurrence in patients who achieved the SVR, not related to HCC development, was 1.8% (28 patients); the median time to *de-novo* PVT occurrence was 33.8 months (IQR 17–45 months) after EOT. At pretreatment evaluation, patients who experienced *de-novo* non-neoplastic PVT were more likely Child B (39.3% vs. 14.2%, $p < 0.001$) and by Cox regression analysis, pre-treatment variables independently associated with *de- novo* PVT development were: platelet count ≤120.000/μL (HR: 3.56, CI 95%: 1.03–12.33), albumin level <3.5 g/dL (HR: 2.66, CI 95%: 1.15–6.15) and bilirubin level >1.1 mg/dL (HR: 2.70, CI 95%:1.10–6.65). Patients with *de-novo,* non-neoplastic PVT had higher risks of hepatic decompensation (39.3% vs. 4.9%; $p < 0.001$) and liver-related death (13% vs. 2%, $p < 0.001$) regardless the SVR achievement following the DAA treatment.

Conclusion: The risk of *de-novo* non-neoplastic PVT in patients with cirrhosis who achieved the SVR is low and mainly related to the severity of liver disease. Development of *de-novo*, non-neoplastic PVT following the SVR may identify patients with higher risks of hepatic decompensation and mortality despite viral eradication by DAA treatment.

FRI348

Suboptimal follow-up, high re-infection, and drug-related death, among HCV-treated people who inject drugs in Tayside, Scotland

Christopher Byrne[1,2], Lewis Beer[2], Sarah Inglis[2], Emma Robinson[1], Andrew Radley[3], Sharon Hutchinson[4,5], David Goldberg[4,5], Matthew Hickman[6], John Dillon[1,7]. *[1]University of Dundee, Molecular and Clinical Medicine, Dundee, United Kingdom; [2]University of Dundee, Tayside Clinical Trials Unit, Dundee, United Kingdom; [3]NHS Tayside, Public Health, Dundee, United Kingdom; [4]Glasgow Caledonian University, School of Health and Life Sciences, Glasgow, United Kingdom; [5]Health Protection Scotland, Glasgow, United Kingdom; [6]University of Bristol, Population Health Sciences, Bristol, United Kingdom; [7]NHS Tayside, Gastroenterology, Dundee, United Kingdom*
Email: c.x.byrne@dundee.ac.uk

Background and aims: In 2017, Tayside, in East Scotland, rapidly scaled-up Hepatitis C Virus (HCV) treatment among People Who Inject Drugs (PWID) using new care pathways. This study aimed to quantify HCV re-infection and routes of re-treatment; mortality; and efficacy of re-infection follow up.

Method: Annual follow-up RNA testing is offered. Re-infection follow-up was measured by calculating the proportion of cases with follow-up tests received in line with local policy. We estimated re-infection incidence, overall and by pathway, per 100 person-years (PY), assuming a Poisson distribution. Mortality was similarly calculated; time-at-risk was from primary HCV treatment to censor date or death.

Results: There were 713 treatments and 577 SVRs. 236 cases among 231 people were followed-up for re-infection. Of cured cases, 39% had ≥1 follow-up test. 87 (15%) cases had repeat testing in the first 12 months, in line with policy. Within 2 years, 110 (19%) had a follow-up test. Of those, 20 (18%) were continued follow-up. Within 3 or 4 years, 19 were tested.

Re-infection occurred 39 times over 256.57 PY, yielding a rate of 15.20 per 100 PY (95% CI 10.81–20.78). For recent injectors, there were 26 re-infections over 175.43 PY, yielding a rate of 14.82 per 100 PY (95% CI 9.68–21.72). Re-infection incidence was highest among needle exchanges (table 1), as was subsequent re-treatment.

Table 1: Clinical pathways of re-infected PWID, Tayside 2017–20.

Clinical pathway	n (%)	PY	Incidence per 100 PY*
Pathway prior to re-infection (n = 39)			
Community pharmacy	12 (30.8)	92.25	13.01 (6.72–22.73)
Needle exchange	19 (48.7)	64.08	29.65 (17.85–46.30)
Other‡	8 (20.5)	77.31	10.35 (4.47–20.39)
Pathway post re-infection (n = 25)			
Drug treatment centre	4 (16.0)		
Needle exchange	15 (60.0)		
Nurse-led community clinic	4 (16.0)		
Prison	2 (8.0)		

Abbreviations: HCV, hepatitis c virus; PWID, people who inject drugs; PY, person-years.
*95% CI in brackets.

Fifty-four patients died over 1, 553.04 PY, all-cause mortality was 3.48 per 100 PY (95% CI 2.61–4.54); 29 were drug related, drug-related mortality was 1.87 per 100 PY (95% CI 1.25–2.68).

Conclusion: Re-infection and drug-related mortality were high in this cohort of HCV-treated PWID, and follow-up was suboptimal. Harm reduction services in Tayside need strengthening alongside comprehensive follow-up RNA testing.

FRI349

Hepatitis C virus reinfection following direct acting antiviral treatment in the prison setting: the SToP-C study

Joanne Carson[1], Gregory Dore[1], Andrew Lloyd[1], Jason Grebely[1], Marianne Byrne[1], Evan B Cunningham[1], Janaki Amin[2], Peter Vickerman[3], Natasha Martin[4], Carla Treloar[5], Gail Matthews[1], Behzad Hajarizadeh[1]. *[1]The Kirby Institute, UNSW Sydney, Sydney, Australia; [2]Macquarie University, Sydney, Australia, Faculty of Medicine and Health Sciences, Sydney, Australia; [3]University of Bristol, Population Health Sciences, Bristol, United Kingdom; [4]University of California San Diego, Division of Infectious Diseases & Global Public Health, San Diego, United States; [5]Centre for Social Research in Health, UNSW Sydney, Sydney, Australia*
Email: jcarson@kirby.unsw.edu.au

Background and aims: Ongoing injecting drug use risk behaviours following successful treatment for hepatitis C virus (HCV) may lead to reinfection, reversing benefits of cure, particularly if harm reduction measures are not optimal. This study assessed HCV reinfection risk following direct-acting antiviral therapy in Australian prisons, where opioid agonist therapy is available, but not needle-syringe programs.
Method: The Surveillance and Treatment of Prisoners with hepatitis C (SToP-C) study enrolled people incarcerated in four prisons in Australia between 2014 and 2019. Participants successfully treated for HCV were followed every 3–6 months to assess for reinfection (identified by HCV sequencing). The incidence of HCV reinfection and associated factors were evaluated.
Results: Among 388 participants receiving treatment, 161 had available post-treatment follow up (92% male; median age 33 years; 67% injecting drug use in prison; median follow-up 9 months). During 145 person-years (py) of follow up, 18 cases of reinfection were identified. Reinfection incidence was 12.5 per 100 py (95%CI: 7.9–19.8) overall and 11.6 per 100 py (95%CI 6.6–20.4) among those continuously incarcerated. Incidence was highest among those injecting in the past month and sharing needles/syringes (28.7 per 100 py; 95%CI 16.3–50.6). In adjusted analysis, injecting drug use with sharing needles/syringes was associated with increased reinfection risk (adjusted hazard ratio 14.62; 95%CI 1.84–116.28; p = 0.011).

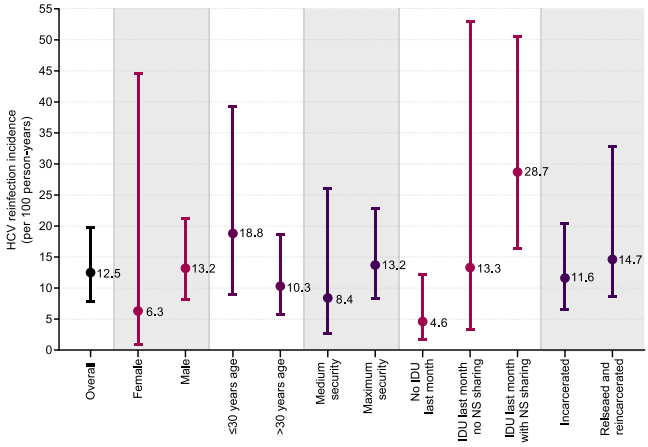

Figure 1. HCV reinfection incidence rates following DAA therapy treatment in the prison setting
Abbreviations: HCV, hepatitis C virus; IDU, injecting drug use; NS, needle or syringe

Conclusion: A high rate of HCV reinfection was observed within a four-prison network. Post-treatment surveillance and retreatment are essential to limit the impact of reinfection. Enhanced access to harm reduction services, including needle and syringe programs, should be considered within prisons.

Email: robert.flisiak1@gmail.com

Background and aims: Treatment of hepatitis C virus (HCV) infections with direct-acting antivirals (DAA) has demonstrated high efficacy even in patients with liver cirrhosis. The three-year stability of a sustained virological response (SVR) and an improvement in liver function with a persistent risk of hepatocellular carcinoma (HCC) has so far been confirmed in the literature. The purpose of the current study is to evaluate the virologic response, changes in liver function, stiffness and risk of HCC five years following the treatment.

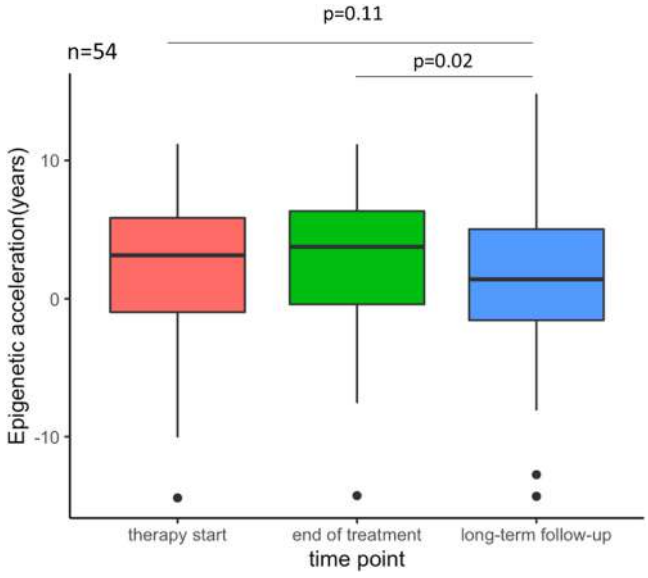
Method: A total of 192 patients originally infected with HCV genotype 1 or 4 were analyzed five years after treatment with ombitasvir/paritaprevir/ritonavir with or without dasabuvir and with or without ribavirin. Most of the patients were diagnosed with cirrhosis before treatment (57%) and did not respond to previous treatment attempts (69%).
Results: We confirmed that HCV clearance after DAA treatment is stable regardless of baseline advancement of the disease. We found that SVR is associated with a gradual but significant reduction in liver stiffness over 5 years. Liver function improved during the first 2 years of follow-up and remained stable thereafter. The risk of death due to HCC or any reason persists through 5 years after successful DAA treatment. However, in non-cirrhotic patients, it appears to clear up 3 years after treatment.
Conclusion: Despite the successful treatment of HCV infection 5 years after its completion, patients with cirrhosis are still at risk of developing liver cancer. This justifies screening for HCV, allowing therapy before the development of liver cirrhosis.

FRI351
Clearance of hepatitis C virus infection did not ameliorate the response to hepatitis B vaccine
Ebada Said[1], Tamer Al Eraki[2], Dalia Abdelhasseb[2], Shaimaa Ragab[2], Mona El Awady[2]. *[1]Benha University, Egypt; [2]*
Email: ebada.abdelhamid@fmed.bu.edu.eg

Background and aims: In Egypt, citizens older than 30 years did not get the compulsory vaccination against hepatitis B virus (HBV) infection during infancy. Patients with chronic hepatitis C (CHC) are advised to get vaccinated against HBV. The aim was to assess the response to HBV vaccine in CHC patients treated with direct acting antivirals (DDAs) in comparison to treatment-naive patients and healthy subjects and to identify predictors of weak response.
Method: This prospective study was carried out on 360 adult subjects subdivided into 3 groups. Group I (GI) included 150 consecutive CHC patients who initiated vaccination after getting sustained virologic response (SVR) following treatment with DAAs. Group II comprised 110 consecutive CHC treatment- naive patients while the control group (GIII) comprised 100 healthy subjects. The mean age of the 3 groups was 50, 45 and 39 year, respectively. Demographic and laboratory variables including HCV-viral load, FIB-4 score, Schistosomal antibody (Ab) titre, and Fibroscan® values were assessed. All the studied groups had received 3 intradeltoid, 20 µg, doses of HBV-vaccine (Euvax B, LG Life Sciences, Korea) given at 0, 1 & 6 months. Hepatitis B surface antibody (HBsAb) titres were tested 6–8 weeks after the 3rd dose.
Results: Patients of groups I & II showed a mean FIB4 score of 1.4 & 1.8 while a mean fibroscan value of 8.2 & 9.8 KPa, respectively.
CHC patients either treated (GI) or treatment-naïve (GII) had highly significant lower mean HBs Ab titre than controls ($p < 0.001$). Twelve patients (8%) in GI had negative response to the HBV-vaccine (HBsAb titres of <10 mIU/ml) compared to 5 patients (4.5%) in GII and only one subject (1%) in the control group. Those who got HBsAb titres of >100 mIU/ml were 125/150 (83.3%), 89/110 (85.5%) and 98/100 (98%) in group I, II and III respectively.
Regarding patients with SVR, univariate regression analysis showed that HBsAb titre was negatively associated with higher age ($p < 0.001$), FIB-4 score ($p < 0.001$), fibrosis stage ($p = 0.001$) and ALT levels ($p = 0.03$) while positively associated with platelet count ($p < 0.001$). Higher fibroscan values (KPa) were the most significant predictors of weak response to HBV vaccine. In treatment naïve CHC patients, HBsAb titre was negatively associated with ALT ($p = 0.001$), AST ($p = 0.03$), FIB-4 score ($p = 0.01$) and schistosomal Ab titre ($p < 0.001$) and positively associated with platelet count ($p = 0.001$). Vaccination response showed no association with gender, body mass index, viral load or other variables.
Conclusion: Patients with CHC demonstrate a significantly weak response to HBV-vaccine, particularly those with older age, fibrosis advancement and schistosomiasis. Treatment and SVR achievement did not ameliorate this response.

FRI352
Reverse Inflamaging: biological age is accelerated in chronic HCV patients and decelerates after HCV cure
Carlos Oltmanns[1,2], Zhaoli Liu[1], Jasmin Mischke[1,2], Jan Tauwaldt[1,2], Yonatan Mekonnen[1], Heiner Wedemeyer[2], Anke Kraft[1,2,3], Cheng-Jian Xu[1,2,4], Markus Cornberg[1,2,3,4]. *[1]TWINCORE a joint venture of Helmholtz Centre for Infection Research and Hannover Medical School Hannover Germany, Hannover, Germany; [2]Hannover Medical School, Department of Gastroenterology, Hepatology and Endocrinology, Hannover, Germany; [3]German Center for Infection Research, Partner-Site Hannover-Braunschweig, Hannover, Germany; [4]Centre for Individualised Infection Medicine (CiiM), Hannover, Germany*
Email: oltmanns.carlos@mh-hannover.de

Background and aims: Recently, HIV and HBV infections have been shown to cause significant biological age acceleration. Accelerated epigenetic or biological age may be a predictor of all-cause and cancer mortality. Thus, we analyzed if HCV is associated with biological age acceleration and if this is reversible after HCV cure.
Method: We included well-characterized 54 patients (mean age 56 years) with chronic hepatitis C at three time points (baseline, end of treatment and follow-up 24–240 (mean 96 weeks) weeks after the end of treatment). Genome-wide DNA methylation data were generated using the illuminaEpic array on PBMC and were used to calculate the epigenetic age acceleration (Horvath clock).
Results: Our results show that chronic HCV infection leads to a significant acceleration of epigenetic age ($p = 3.577e-05$). While chronic HCV patients without evidence of cirrhosis have a lower age acceleration, patients with cirrhosis have a higher biological age. Treatment of HCV patients with DAA results in reversal of age acceleration, but this effect is only detectable at long-term follow-up ($p = 0.02$). Epigenetic age acceleration does not correlate with estimated blood cell counts.
Interestingly, patients who developed HCC after SVR ($n = 8$) have the highest age acceleration and show no evidence of complete reversion after treatment.



Conclusion: Hepatitis C patients with cirrhosis show biological age acceleration that may be reversible after HCV cure. Lack of reversibility appears to be associated with HCC risk. Our findings underline the need for more individualized infectious disease medicine based on biological rather than chronologic age in the future.

Email: fabienne.marcellin@inserm.fr

Background and aims: The advent of direct acting antivirals has paved the way for a hepatitis C-free world. However, patients with hepatitis C virus (HCV) infection remain at high risk of morbidity and mortality, even after cure. We identify socio-behavioural factors associated with overall (i.e., all-cause) mortality in chronic HCV-infected patients.

Method: We used data collected from August 2012 to June 2018 in the French, multicentre, prospective cohort ANRS CO22 HEPATHER. The study sample comprised chronic HCV-infected patients who attended at least one annual follow-up visit. Analyses focused on the first five years of follow-up. Socio-behavioural data were collected at cohort enrolment (questionnaire administered by a physician). Living in poverty was defined as a standard of living below 1015€ (French poverty threshold in 2015), low educational level as level <high school diploma, unhealthy alcohol use as drinking >2 and >3 alcohol units/day for women and men, respectively, and elevated coffee intake as drinking ≥3 cups of coffee/day. Factors associated with overall mortality were identified using a Cox proportional hazards model. Adjusted population attributable fractions (PAF) were estimated for the modifiable factors of the multivariable analysis.

Results: Of the 10, 366 patients in the study sample, 697 died during follow-up. After multivariable adjustment (for sex, age, educational level, HCV genotype, HCV transmission category, and HCV cure), living in poverty (adjusted hazard ratio [aHR]: 1.34 [95% confidence interval, 1.13–1.60]), tobacco smoking (1.70 [1.35–2.14]), and a history of unhealthy alcohol use (1.48 [1.18–1.86]) were independently associated with increased overall mortality. By contrast, elevated coffee intake was associated with lower overall mortality (0.63 [0.52–0.77]). The risk factors accounting for the greatest mortality burden were tobacco smoking, low educational level, living in poverty, and a history of unhealthy alcohol use (PAF: 16.6%, 14.9%, 9.8%, and 7.4%, respectively), whilst HCV cure and elevated coffee intake averted a high proportion of deaths (86.0% and 13.4%, respectively).

Conclusion: In the era of HCV cure, tobacco cessation must be further encouraged in patients with chronic HCV infection, as a modifiable risk factor of mortality. Specific interventions should be developed to target socially vulnerable patients and those with a history of unhealthy alcohol use, who are at higher risk of mortality.

FRI354

Is routine Ribavirin mandatory for genotype 3 hepatitis C compensated cirrhosis patients receiving Sofosbuvir/Velpatasvir? A meta-analysis

Jing Hong Loo[1], Flora Xu[1], Gerald Low[1], Wei Xuan Tay[1], Le Shaun Ang[1], Steve Yew-chong Tam[2], Prem Harichander Thurairajah[3], Rahul Kumar[4], Yu Jun Wong[5]. [1]*Yong Loo Lin School of Medicine, National University of Singapore;* [2]*Education Resource Centre, Medical Board, Singapore General Hospital;* [3]*National University Hospital, Division of Gastroenterology & Hepatology, Singapore, Singapore;* [4]*Changi General Hospital, Department of Gastroenterology & Hepatology;* [5]*Department of Gastroenterology & Hepatology, Changi General Hospital, Singapore*
Email: loojinghong@gmail.com

Background and aims: Simplified treatment regimen is crucial for rapid treatment upscale to achieve hepatitis C virus (HCV) elimination. Addition of ribavirin (RBV) to Sofosbuvir/Velpatasvir (SOF/VEL) has been showed improved sustained virological response at 12 weeks (SVR12) in genotype 3 (GT3) decompensated cirrhosis patients. However, the benefits of RBV in GT3 compensated cirrhosis patients receiving SOF/VEL, remains unclear. We aim to systematically review the efficacy and safety of SOF/VEL, with or without RBV in GT3 compensated cirrhosis patients.

Method: With help of medical librarian, we systemically searched four electronic databases (PubMed/MEDLINE, EMBASE, Cochrane Library and Web of Science) from inception up to June 2021 using both free text and MeSH terms. There was no restriction on language, geography, publication dates and publication status. All GT3 compensated cirrhosis patients treated with 12 weeks of SOF/VEL, with or without RBV, were included, regardless of age, gender or prior treatment experience. The primary outcome was the SVR12. The secondary outcome was treatment-related adverse events, as defined by symptomatic anaemia requiring transfusion or a drop in haemoglobin beyond 2 g/dL. The pooled relative risk (RR), 95% confidence interval (CI) and heterogeneity (I^2) were estimated using Review Manager Version 5.3.

Results: From 1, 752 citations, a total of 7 studies (2 RCTs, 5 cohort studies) with 1, 088 subjects were identified. The SVR12 was similar in GT3 compensated cirrhosis patients, regardless of the use of RBV, for both the intention-to-treat (RR: 1.03, 95%CI: 0.99–1.07; $I^2 = 0\%$) and the per-protocol analysis (RR: 1.03, 95%CI: 0.99–1.07; $I^2 = 48\%$). The overall pooled rate of treatment-related adverse events was 7.2%. Addition of RBV was associated with 4-fold higher risk of treatment-related adverse events in GT3 compensated cirrhosis patients receiving SOF/VEL (RR: 4.20, 95%CI: 1.29–13.68; $I^2 = 0\%$). Subgroup analysis showed that RBV was associated with a numerically higher SVR12 (96% vs 87%, p = 0.12) in GT3 compensated cirrhosis patients with baseline resistance-associated substitutions (RAS). However, addition of RBV did not significantly increase the SVR12 among treatment-experienced GT3 compensated cirrhosis patients.

Conclusion: Ribavirin did not significantly increase the SVR12 in GT3 compensated cirrhosis patients receiving SOF/VEL. Our findings suggest limited role for RBV as routine add-on therapy to SOF/VEL in GT3 compensated cirrhosis patients.

FRI355

High frequency of hepatitis C virus reinfection following antiviral treatment in the North East of England

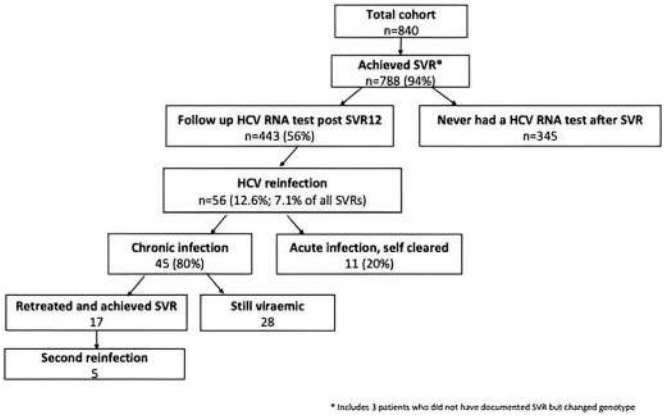
Sumar Askar[1], Ryan Jelley[1], Kate Mcque[1], Caroline Allsop[1], Francesca McCullough[1], Carolyn Miller[1], Yusri Taha[1], Steven Masson[1,2], Stuart Mcpherson[1,2]. [1]*Newcastle Freeman Hospital, Liver Unit, High Heaton, United Kingdom;* [2]*Translational and Clinical Research Institute, Newcastle University, Newcastle Upon Tyne, United Kingdom*
Email: sumar.askar@nhs.net

Background and aims: Hepatitis C virus infection (HCV) is common, and injecting drug use (IDU) is the major risk factor for acquisition in

Europe. Health services are working towards achieving the WHO target of HCV elimination by 2030. Reinfection following treatment is an important consideration for HCV elimination programmes because this has the potential to hamper elimination efforts. The aim of this work was to assess the rate of HCV reinfection in our region, where IDU is the predominant risk factor (>90%).

Method: All patients who completed treatment with direct acting antiviral (DAA) treatment for HCV in Tyne and Wear, North East England between Jan 2016 and May 2021 were included. Sustained virological response (SVR12) was defined as negative HCV RNA 12 weeks post treatment. Data was collected from our HCV database (HepCare), which automatically gathers laboratory data in real time from our hospital laboratory database. HCV reinfection was defined as a positive HCV RNA after achieving SVR12 or where a genotype has changed after completing DAA treatment when the SVR12 was not documented.

Results: 788 of the 840 patients (76% males; mean age 45.7 ± 11.4 years; 47% G1; 39% G3; 12% Cirrhosis) completing treatment achieved SVR (94%). 459 patients (58%) had a follow-up HCV RNA tested post SVR after a median 0.79 years (range 0.1–5.2 years). 56 reinfections (7.1% of all SVRs and 12.2% of those SVRs who had follow up blood testing) were diagnosed. The median time to reinfection was 1.37 years (range 0.1–5.2 years) and the rate of reinfection was 0.1 per person years. 45 of the 56 (80%) reinfections developed chronic infection, 17 of which were retreated and achieved SVR, while 28 remain viraemic. 5 patients developed a second reinfection. Individuals with reinfection were significantly younger than those maintaining SVR (38.9 ± 7.9 vs 46.2 ± 11.9 years, $p < 0.001$). Reinfection was more common in those with primary G3 infection compared with other genotypes (9.8% vs 5.7% $p = 0.049$). Reinfections were similar between males and females (4.4% females vs 7.4% males $p = 0.15$).



Conclusion: HCV reinfection is common in our cohort and may slow our HCV elimination efforts. In order to address our high reinfection rates we need to improve harm reduction and increase treatment of active IDUs. We aim to implement 'HCV track and trace' for recent infections and reinfections to try to reduce onward HCV transmission.

FRI356

Incidence and risk factors of hepatitis C liver morbidity and mortality in the era of direct-acting antiviral therapies: a population-based linkage study

Maryam Alavi[1], Heather Valerio[2], Matthew Law[1], Ian Lockart[3,4], Mark Danta[3,4], Jason Grebely[1], Janaki Amin[5], Behzad Hajarizadeh[1], Jacob George[6], Gregory Dore[1]. *[1]Kirby Institute, UNSW Sydney, Australia; [2]Kirby Institute, UNSW Sydney; [3]St Vincent's Clinical School, UNSW Sydney, Australia; [4]St Vincent's Hospital, Sydney, NSW, Australia; [5]Department of Health Systems and Populations, Macquarie University, Australia; [6]Storr Liver Centre, Westmead Millennium Institute, University of Sydney, Australia*

Email: msalehialavi@kirby.unsw.edu.au

Background and aims: Monitoring trends in hepatitis C virus (HCV) liver morbidity and mortality is increasingly crucial as direct-acting antiviral (DAA) therapy expands and we move towards World Health Organization HCV elimination targets. In New South Wales, Australia, we aimed to evaluate trends in decompensated cirrhosis (DC), hepatocellular carcinoma (HCC), and liver mortality in the pre-DAA (2001–2014) and DAA eras (2015–2020). Further, we assessed factors associated with each liver-related outcome in the DAA era.

Method: HCV notifications (1995-mid 2020) were linked to hospital admissions (2001–2020) and mortality (1995–2020). DC, HCC, and liver death numbers and age-standardised incidence rates [per 100 person-years (PY)] and corresponding 95% CIs were calculated assuming a Poisson distribution. We used Cox Proportional Hazards Regression analyses to evaluate factors associated with each liver-related outcome.

Results: Among 110, 022 people with an HCV notification, 5.2% and 2.1% had a DC and HCC diagnosis, respectively, and 4.2% died of liver-related causes. In the pre-DAA era, DC and HCC diagnoses, and liver-related mortality consistently increased, while age-standardised incidence rates were stable or increased: 0.39, 0.15 and 0.13 in 2001 to 0.40, 0.18, and 0.37 per 100 PY in 2014, respectively. Each liver-related outcome declined in the DAA era; in 2020, age-standardised incidence rates of DC, HCC, and liver-related mortality were 0.20 (95% CI 0.17, 0, 23), 0.12 (95% CI 0.10, 013), and 0.19 (95% CI 0.17, 0.22) per 100 PY, respectively (Figure 1). In the DAA era, a history of alcohol-use disorder was common among people with DC (64%) and HCC (48%). In the DAA era, following older age, a history of alcohol-use disorder was the strongest predictor of DC [adjusted hazard ratio (aHR) 6.70, 95% CI 6.08, 7.39] and HCC diagnoses (aHR 3.53, 95% CI 3.13, 3.99), and liver-related mortality (aHR 5.59, 95% CI 5.08, 6.16).

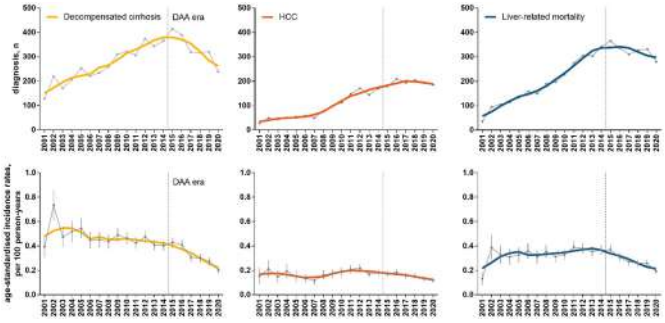


Figure: Trends in diagnoses and age-standardised rates of decompensated cirrhosis, HCC, and liver-related mortality among people with an HCV notification in New South Wales, 1995-mid 2020, n = 110, 022.

Conclusion: DAA scale-up in New South Wales, Australia, has reduced the HCV liver disease burden, most remarkably on DC diagnosis and liver-related mortality. However, alcohol-use disorder remains a significant cause of liver disease, both on its own and as a risk factor in the progression of chronic HCV. A broader focus on liver disease prevention is required, encompassing alcohol-use disorder

treatment, to facilitate enhanced declines in advanced liver disease complications in the DAA era.

FRI357

Direct acting antiviral agents improve survival in patients with hepatitis C virus related hepatocellular carcinoma

Hyun Young Woo[1], Won Lim[2], Jeong Heo[1], Young Joo Park[1]. [1]*Pusan National University Hospital, Internal Medicine, Busan, Korea, Rep. of South;* [2]*Good Samsun Hospital, Internal Medicine, Busan, Korea, Rep. of South*
Email: who54@hanmail.net

Background and aims: Survival data in patients with hepatitis C virus (HCV) associated hepatocellular carcinoma (HCC) treated with direct acting antivirals (DAAs) are limited. Survival rates were compared between patients with HCV-related HCC who were untreated for HCV and who treated with DAA.
Method: From 2010 to 2019, a total of 469 patients who were monoinfected with HCV-related HCC was categorized into patients untreated for HCV and patients treated with DAA. Multivariable Cox regression with HCV treatment status as a time-varying covariate was used to determine mortality risk.
Results: There were 95 untreated group and 94 DAA group. Of DAA group, 42 was active HCC state (patients without viable HCC). Baseline characteristics between untreated group and DAA with active HCC were balanced except genotype. Sustained virologic response rate was 88.2% by per protocol analysis in DAA treated patients. After time-varying adjustment for DAA treatment initiation compared with untreated patients, patients with DAA had significantly higher 5-year overall survival (76.7% vs. 22.4%, $p < 0.001$). Multivariate Cox regression showed that survival was significantly improved in patients with DAA treatment ($p < 0.001$), patients who were treated with curative treatment (0.034) and with history of interferon exposure ($p = 0.045$).
Conclusion: In this study, patients in HCV related HCV who treated DAA achieved 88.2% of SVR and showed significant improvement of survival compared with patients untreated with DAA.

FRI358

Lack of Alpha-fetoprotein reduction after successful Hepatitis C treatment in patients with cirrhosis predicts the development of hepatocellular carcinoma during surveillance-a single unit real-world experience

Aoife Alvain[1], Jack Lee[1], Eileen Shannon[1], Mary Kavanagh[1], Mary Bohan-Keane[1], Margaret Scarry[1], John Lee[1,2]. [1]*University Hospital Galway, Hepatology unit, Galway, Ireland;* [2]*National University of Ireland, Galway, Galway, Ireland*
Email: alvaina@tcd.ie

Background and aims: The value and limitation of alpha-fetoprotein (AFP) in hepatocellular carcinoma (HCC) screening is well established. In patients with chronic hepatitis C virus (HCV) infection and cirrhosis, AFP is often elevated in the absence of HCC. The aim of this study was to measure the impact of DAA treatment on AFP levels and correlate this with clinical outcomes. Correlation with changes in transient elastography (Fibroscan) scores were also evaluated.
Method: Patients with established cirrhosis prior to successful direct acting anti-viral (DAA) treatment were included. Patients with HCC were excluded. Laboratory values including AFP, transaminases, platelet count and Fibroscan scores were measured at baseline and post-treatment. Patients were followed-up for the development of HCC. Factors associated with improvement in AFP were investigated. Further analysis was carried out classifying patients based on a clinically relevant threshold.
Results: 77 patients (male n = 47, 61.0%) and median follow-up of 5.7 years. 11 (14.3%) have developed HCC during follow-up. Overall, the mean AFP significantly improved with treatment (Mean 17.69 ± SD 31.44 vs 7.27 ± 16.80, $p = 0.0015$). The mean Fibroscan score significantly improved with treatment (22.96 ± 14.07 vs 13.73 ± 9.05, $p < 0.001$). In linear regression analysis, reduction in AFP was found to positively correlate with reduction in Fibroscan scores (coefficient = 0.04, $p = 0.91$). We defined improvement in AFP levels as a pre-treatment value of >10 which reduced to ≤10 after treatment. 47 patients (61.0%) had a normal AFP at baseline, 24 patients (31.2%) improved and 6 (7.8%) remained high. The cumulative HCC risk was 50% for patient whose AFP remained high, 12.5% in those whose AFP improved, and 10.6% those whose AFP remained normal (chi-squared test $p = 0.068$).
Conclusion: The risk of HCC after successful HCV treatment in cirrhotic patients remains high. Overall, AFP levels improve with DAA treatment in patients with cirrhosis. Fibroscan scores improve with DAA treatment. Failure to see an improvement in AFP after treatment predicts the development of HCC. This should be considered in stratifying individual patient HCC risk during real-world follow-up surveillance protocols.

FRI359

Patients with chronic HCV and decompensated cirrhosis are at risk for MELD purgatory

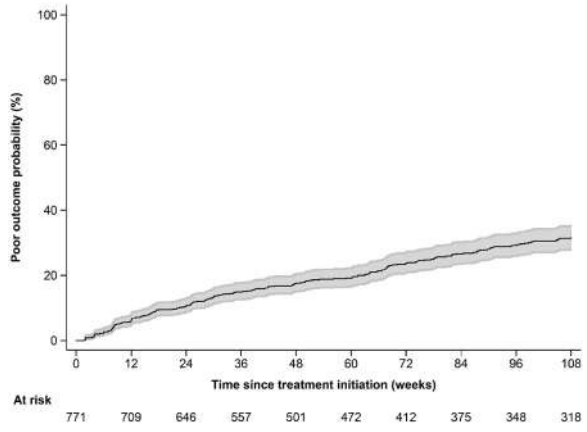
Background and aims: Treatment decisions are challenging in patients with decompensated cirrhosis due to chronic hepatitis C (HCV). Some patients might benefit from delaying HCV treatment until after liver transplantation, as a decrease in MELD-score without clinical benefit may limit transplant eligibility, also known as MELD purgatory. This study aims to predict the probability of a poor

outcome among patients who were eligible for a liver transplant at treatment initiation.
Method: Retrospective cohort study including HCV patients with a history of/current decompensated cirrhosis treated with DAAs in Europe and Canada. MELD purgatory was defined as presence of ascites or hepatic encephalopathy with sustained MELD-Na<15 after treatment initiation. The cumulative probability and factors associated with a poor outcome (sustained MELD purgatory, HCC or death) after treatment initiation were analyzed using Kaplan-Meier plots and multivariable (MV) Cox regression. The risk of death/HCC vs transplantation post-treatment was compared in those who were transplant ineligible at baseline.
Results: Among 877 patients: mean age 55 ± 9 years, 68% male, 86% Caucasian, median BMI 27 [24–30] kg/m^2, 24% diabetes and 44% history of alcohol abuse. At baseline, median INR was 1.3 (1.2–1.5), ALT was 54 (37–84) U/L, platelets were 77 (55–105) × 10^9/L, total bilirubin was 1.9 (1.2–2.8) mg/dL and mean albumin was 32 ± 5.8 g/L. Mean MELD-Na was 15 ± 5.5. The majority had MELD-Na ≥15 (62%), and 51% were decompensated at baseline. A total of 665 (80%) achieved SVR12. During a median follow-up of 35 (8–90) weeks after treatment initiation, 194 (22%) entered sustained MELD purgatory, 114 (13.0%) developed HCC, and 106 died (12.1%). Cumulative probabilities of a poor outcome at 36, 72, and 108 weeks were 15%, 24%, and 32%, respectively (Figure). On MV Cox regression, older age (aHR 1.02, p = 0.037), lower sodium (aHR 0.95, p = 0.014), and lower albumin (aHR 0.97, p = 0.032) at baseline were associated with higher rates of a poor outcome. Of those who met the definition of MELD-purgatory before treatment initiation (n = 195), cumulative probabilities of death/HCC were 5.1%, 8.1% and 9.0% at 36, 72, 108 weeks post-treatment start, whereas rates of liver transplant were 4.2%, 9.0% and 12.3% at the same time points.



Conclusion: Patients with chronic HCV and decompensated cirrhosis are at risk for MELD purgatory, HCC or death, even when SVR is achieved. Caution should be taken when treating these patients, especially transplant-eligible patients who may be better off with liver transplantation prior to HCV treatment. Decompensated patients who are not transplant-eligible at treatment start have a similar probability of HCC/death as of receiving a transplant post-treatment, making treatment decisions particularly challenging and highlighting the need for careful post-treatment follow-up.

FRI360

The long-term effect of Hepatitis C eradication by direct-acting antivirals on patient's mood and quality of life as determined by the Beck's Depression Inventory and EQ5D Quality of Life questionnaires-a single unit study

Aoife Alvain[1], Sarah Lanigan[1], Mary Bohan-Keane[1], Margaret Scarry[1], Lynda Jordan[1], Cynthia Garvey[1], Priyanka Jose[1], John Lee[1,2]. [1]*University Hospital Galway, Hepatology Unit, Galway, Ireland;* [2]*National University of Ireland, Galway, Galway, Ireland*
Email: alvaina@tcd.ie

Background and aims: Direct-acting antiviral (DAA) treatments are established to be well tolerated and achieve Hepatitis C virus (HCV) eradication in the quasi-totality of patients. This prevents progression to liver cirrhosis, reduces the risk of hepatocellular carcinoma, and improves overall prognosis. The aim of this study was to investigate the long-term effects of HCV eradication by DAA on patient's mood and quality of life.
Method: HCV patients completed a baseline Beck's Depression Inventory and Quality of Life Questionnaire (EQ5D) prior to DAA treatment and were prospectively evaluated. After anti-viral therapy, the questionnaires were repeated with a minimum of 12 months follow-up. A Beck's score of <10 is considered to be within the normal range of mood variation. An EQ5D of 5 represents optimal quality of life.
Results: A total of 54 patients with a mean age of 49.5 years were included (51.8% male). All patients had a sustained virological response to DAA treatment; the median follow-up was 4.1 years. Prior to treatment, 9 (16.7%) had established cirrhosis, and 14 (25.9%) had at least one psychiatric co-morbidity. The mean Beck's score pre-treatment (Mean 7.88 ± SD 7.88) and at long-term follow-up (7.31 ± 6.22) was not significantly different (p = 0.29). Median Beck's score pre-treatment (7) and at follow-up (6) were comparable, as were the number of patients with a Beck's score <10 pre-treatment (n = 37, 68.5%) and at follow-up (n = 37, 68.5%). In the sub-group analysis, no significant difference was found with sub-groups defined by patient's background psychiatric history, pre-treatment cirrhosis status or HCV mode of transmission (pre-treatment and follow-up median scores were comparable and so were the number of patients with a Beck's score <10). There was no significant difference in the EQ5D pre-treatment (6.88 ± 2.30) and at follow-up (6.74 ± 2.45) (p = 0.39). Median score pre-treatment (6) and at follow-up were comparable (6), as were the number of patients with EQ5D = 5 pre-treatment (n = 16) and at follow-up (n = 18).
Conclusion: In this prospective study of patients successfully treated for HCV with DAA treatment, the reported mood and quality of life at long-term follow-up did not significantly change from their pre-treatment baseline. It is expected that quality of life and mood would deteriorate in un-treated patients as they develop complications of chronic HCV and as such this study demonstrate the benefit of DAA treatment on mood and quality of life.

Background and aims: Dried blood spot (DBS) samples are a reliable tool to diagnose viremic HCV infection. However, there is scarce data on the usefulness of DBS to assess cure and reinfection after antiviral

therapy. Here, we aimed to evaluate the use of DBS for the assessment of sustained virological response (SVR) and reinfection 12 weeks after on-site treatment with direct-acting antivirals at a harm reduction service (HRS) in Catalonia.

Method: This evaluation was performed within the context of an ongoing micro-elimination study targeting people who inject drugs (PWID) in the largest HRS in Barcelona. At the time of SVR assessment (FU12), HCV-RNA was detected from DBS with an in-house real-time RT-PCR assay (lower limit of detection -LoD-, 541 IU/ml of blood) in comparison with the reference method (viral load in fingerstick capillary blood by GeneXpert®; LoD, 40 IU/ml). Additionally, DBS samples (baseline *vs.* FU12) were used to assess reinfection *vs.* treatment failure by an in-house method based on NS5B nested-PCR amplification followed by Sanger sequencing and phylogenetic analysis. When mixed or no signal was obtained, samples were genotyped by a commercial real-time PCR genotyping assay (Abbott).

Results: Among treated patients, 105 DBS samples corresponding to FU12 were tested (55 negative and 50 positive). The DBS-based HCV-RNA assay showed 100% specificity (55/55). Nine cases were not detected, with viral loads between 116 and 4660 IU/ml; sensitivity ranged from 82.0% to 95.0% according to different viral load cut-offs (Table 1). FU12 RNA positive samples ($n = 50$) were genotyped by sequencing ($n = 32$) or by the commercial genotyping assay ($n = 15$) in comparison with baseline DBS samples. Results evidenced the presence of reinfection in 29 cases and of treatment failure in seven cases with high viral loads. The rest of cases could not be classified by any of the two methods: three with low viral loads could not be amplified, one was indeterminate, and in seven cases the same genotype/subtype was detected at FU12 and baseline samples, with phylogenetic classification not assessable from the commercial genotyping assay.

	Detected by the DBS assay	
HCV viral load threshold by Xpert HCV	Proportion	%
Detectable	41/50	82.0
Quantifiable ≥100 IU/ml	41/49	83.7
Quantifiable ≥1000 IU/ml (EASL Guidelines)	41/46	89.1
Quantifiable ≥3000 IU/ml (WHO Testing Guidelines)	38/40	95.0

Conclusion: This study shows the usefulness of DBS samples for assessing cure and differentiating reinfection from relapse after HCV antiviral treatment in the real world, facilitating treatment decentralization in PWID attending HRS. However, some patients presented with low viral loads at FU12, limiting detection and genotyping. While the latter cases might reflect acute infections that may be spontaneously cleared, repeat testing over time would be required to identify all viremic cases.

Hepatitis C virus (HCV)-specific T cell confer resistance to HCV re-infection after sustained virologic response in a non-cytolytic fashion among people who inject drugs: results from ANCHOR study

Arshi Khanam[1], Alip Ghosh[2], Sarah Kattakuzhy[1], Shyamasundaran Kottilil[1], Elana Rosenthal[1]. [1]*Institute of Human Virology University of Maryland School of Medicine, Division of Clinical Care and Research, Baltimore, United States;* [2]*Institute of Human Virology, University of Maryland School of Medicine, Baltimore, United States*
Email: akhanam@ihv.umaryland.edu

Background and aims: People who inject drugs (PWID) remain a major reservoir of chronic hepatitis C virus (HCV) infection. Ongoing injecting drug use is associated with re-infection, however the role of HCV specific immune response in PWID is not understood. In this study, we evaluated the immune correlates that are associated with re-infection of HCV in PWID after achieving sustained virologic response (SVR).

Method: ANCHOR is a study of 198 people with opioid use disorder, ongoing opioid misuse and chronic HCV. All participants received DAAs, 157 achieved SVR, and 17 were reinfected. We studied 27 patients who achieved SVR without reinfection (Non-RI) and 13 patients who were reinfected (RI). Changes in the phenotypic profile of T cells were determined in the peripheral blood mononuclear cells (PBMCs) by flow cytometry. HCV specific T cell functions were investigated by stimulating the PBMCs with a pool of 21 overlapping peptides from envelop, core and NS3-NS5 regions of HCV. Immune profiles were evaluated at baseline (prior to HCV treatment) and after SVR (prior to reinfection) and compared between the two groups.

Results: At baseline, RI group displayed higher expression of inhibitory receptors including programmed death-1 (PD-1) (CD4 P = 0.002, CD8 P = 0.02) and 2B4 (CD4 P = ns, CD8 P = 0.01), and lower expression of activation markers CD38 (CD4 P = 0.02, CD8 P = ns) and HLA-DR (CD4 & CD8 T cells P = 0.02) on T cells than Non-RI group and continuously maintained exhaustive phenotype even after achieving SVR, suggesting persistent exhaustion of T cells in RI. At baseline, RI group constituted lower frequencies of naïve (14% vs. 29%) and terminally differentiated effector memory cells (3% vs. 10%) in CD4 T cell population that did not change upon SVR, while a marked reduction in effector memory cells were observed (48% vs. 31%) at SVR. Moreover, CD8 T cell population exhibited decreased percentage of naïve (17% vs. 35%) and central memory cells (3% vs. 8%) in RI group and similar profile was maintained upon SVR. However, the expression of the transcription factors Tbet and Eomes (CD4: 2% and 5%, CD8: 7% and 20%) was similar between both groups. Further, T cells from RI group persistently produced lower amounts of antiviral cytokines such as IFN-γ and TNF-α at baseline and after achieving SVR compared to the Non-RI (CD4 IFN-γ & TNF-α P = 0.04, P = 0.01) (CD8 IFN-γ & TNF-α P = 0.01, P = ns). In fact, polyfunctional T cell response determined by IFN-γ and TNF-α co-producing cells was also impaired in the RI compared to the Non-RI group (CD4 P = 0.03 and CD8 P = 0.04). However, cytotoxic potential of T cells evaluated by CD107a and perforin expression were maintained between both groups.

Conclusion: Peripheral T cells from PWID who were reinfected with HCV after achieving SVR displayed an exhaustive phenotype and had depressed anti-HCV response after SVR, suggesting a role for protection from re-infection by T cells in a non-cytolytic fashion.

FRI363

Lack of fibrosis remodelling in chronic hepatitis C post SVR, as demostrated by YKL-40, is predictive of hepatocellular carcinoma ocurrence

Maria Guerra Veloz[1], James Lok[1], Chiara Mazzarelli[2], Mary D Cannon[1], Ivana Carey[1], Kosh Agarwal[1]. [1]*King's College Hospital, Institute of Liver Studies, United Kingdom;* [2]*ASST Grande Ospedale Metropolitano Niguarda-Milano*
Email: maria.guerraveloz@nhs.net

Background and aims: The introduction of new direct-acting antivirals agents (DAA) have revolutionized the natural history of the chronic hepatitis C virus (HCV). However, the course of progressive liver damage, as well as the risk of developing HCC after achieving sustained virological response (SVR), is still uncertain. Our group´s preliminary data[1] showed that YKL-40 (acting as a growth factor for fibroblasts and being involved in matrix remodelling) and Hyaluronic acid (HA, acting as promoter of hepatic fibrogenesis) decreased in patients who achieved SVR. The aim of our study was to determine whether YKL-40 and/or HA could be a predictor of HCC occurrence in patients with cirrhosis who achieved SVR.

Method: In this retrospective study, we included patients with hepatitis C related cirrhosis, who achieved SVR after DAA therapy, in whom YKL-40 and HA were measured prior to treatment and at 36

weeks post SVR. Cirrhosis was defined based on FibroScan® >14.5 kPa and/or a combination of endoscopy and imaging criteria. Only those treated with DAA therapy between January 2015 and December 2016 were included. Patients were followed-up with until November 2021 or until HCC occurred.

Results: Our study included 71 patients of whom 64.8% were males with a mean age of 61 (±8) years. Of our total cohort, 62% had genotype 1, 55% were Child Pugh A (CPA), 24% were CPA with a previous decompensation, and 21% were CP B/C.

During a median follow up of 60 months (IQR 41–70), 25.4% (18) of patients had developed HCC. Patients who developed HCC had more advanced liver disease (CP B/C 53.3% vs 20.5% CPA vs 11.8% CPA previous decompensation; p = 0.031), a lower baseline albumin (34.7 vs 38.4; p = 0.004) and an elevated YKL-40 at 36 weeks after SVR (4789 vs 3333; p = 0.036) compared to those who had not developed HCC (table 1). Between start of treatment and 36 weeks post SVR, the mean decrease in YKL-40 was significantly greater in those who did not develop HCC (from 5098 to 3333, p < 0.001; vs 4752 to 4789 p = 0.987). There was no difference in the dynamics of HA between the two groups. In the multivariate analysis, YKL-40 at 36 weeks post SVR (HR 1; CI 95% 1–1) was an independent factor associated with HCC. Child Pugh status A (HR 0.36; IC 95% 0.142–0.937) was an independent factor associated with lower HCC.

Characteristics	Total cohort N = (71)	No HCC N =53	HCC N =18	P
Sex				
Male	46 (64.8)	34 (64.2)	12 (66.7)	0.926

CPT				
A previous decompensation	17 (24)	15 (88.2)	2 (11.8)	
A without decompensation	39 (55)	31 (79.5)	8 (20.5)	0.031
B/C	15 (21)	7 (46.7)	8 (53.3)	
MELD	8 (6-11)	8 (6-9)	9 (7-14)	0.137
Baseline AFP IU/L *median (IQR)*	9(5-23)	9(5-24)	8.5(5.3-15)	0.300
EOT AFP *median (IQR)*	6(3-9)	6(3-9)	5.5(3.3-8)	0.446
48EOT AFP *median (IQR)*	4(2-6)	4(2-6)	4(3-6)	0.749
Baseline albumin g/L *mean (SD)*	37.5 (±4.7)	38.4(±4.27)	34.7(±5.05)	0.004
Baseline Platelet (x10^9/L)	85(67-120)	89 (69-120)	77(58-114)	0.312
Baseline INR *mean (SD)*	1.2(±0.19)	1.22 (±0.19)	1.3(±0.17)	0.128
Baseline Bilirubin umol/L *mean (SD)*	19.5 (±12.3)	17 (±0.95)	24.2(±14.7)	0.057
Baseline YKL-40 pg/nl *mean (SD)*	5010 (±2933)	5098(±2967)	4752.9(±2908)	0.687
Baseline HA *mean (SD)*	919.8 (±556)	926.8 (±585)	896.9 (±467)	0.838
YKL-40 36weeks post SVR *mean (SD)*	3686(±2425)	3333(±2239)	4789(±2723)	0.036
HA 36weeks post SVR	836 (±507)	893.3 (±522)	638.9 (±404)	0.101

Conclusion: HCC occurrence was higher in patients with CP B/C and those who did not decrease YKL-40 after achieving SVR. YKL-40 could be a predictive factor of HCC occurrence however further studies with a larger sample are necessary to confirm these results.

HCV reinfection associated with IDU and cocaine use in a cohort of people with OUD: 4 Year follow-up data from the ANCHOR cohort

Elana Rosenthal[1], Junfeng Sun[2], Britt Gayle[1], Amelia Cover[1], Ashley Davis[1], Shivakumar Narayanan[1], Catherine Gannon[2], Grace Garrett[2], Vivian Wang[2], Meghan Derenoncourt[2], Henry Masur[2], Shyamasundaran Kottilil[1], Sarah Kattakuzhy[1]. *[1]Division of Clinical Care and Research, Institute of Human Virology, University of Maryland School of Medicine, United States; [2]National Institutes of Health/Critical Care Medicine Department, Bethesda, United States*
Email: erosenthal@ihv.umaryland.edu

Background and aims: People with HCV and opioid use disorder (OUD) who achieve sustained virologic response (SVR) may remain at risk of reinfection. Identification and retreatment of reinfected individuals is critical to HCV elimination. We sought to evaluate the rate of reinfection and factors associated with reinfection in a cohort of high-risk patients over a 4 year follow-up period.

Method: ANCHOR is a 96 week, prospective cohort study of people with OUD, opioid misuse within a year and chronic HCV. All participants received HCV treatment. Those who achieved SVR were followed for reinfection for 18 months, and subsequently had the option to enroll in LOOP, a 2 year long-term follow-up study. Reinfection was defined as a genotype switch or detectable viral load after SVR. Patients were administered surveys at each visit to assess for ongoing risk behaviors and medication for OUD (MOUD) status. A logistic regression model with GEE was created using covariates with p < 0.10 to model the probability of reinfection.

Results: 157 individuals achieved SVR and were followed for 273.2 person-years, median 86.2 weeks (range 12–210 weeks). Subjects were predominantly male (69%), black (84%), middle-aged (median 57 years), and 50.3% unstably housed. Seventeen individuals (10.8%) were reinfected a median of 76.1 weeks (range 21–175 weeks) after HCV treatment, a rate of 6.2/100 person-years. Reinfection was associated with past month IDU (p = 0.006), and cocaine positive UDS (p = 0.03), however was not associated with age, race, gender, education, or visit specific opioid positive UDS, housing stability, MOUD engagement, or HIV risk score (all p > 0.05). Of the 17 reinfected individuals, 12 (71%) initiated HCV re-treatment, with 10 achieving SVR and 2 deaths.

Conclusion: In this cohort of high-risk people with OUD, we found high rates of HCV reinfection which were associated with past-month IDU and cocaine positive UDS at the time of detection. Given the rate and timing of reinfection, these data reinforce the importance of long-term engagement, ongoing HCV testing, and low-barrier treatment of HCV reinfection. Further, in the era of rising stimulant use, these data highlight the importance of assessing for and reducing harms associated with polysubstance use and injection drug use in people with opioid use disorder.

Noninvasive prediction of hepatocellular carcinoma development after oral antiviral therapy in patients with chronic hepatitis C: a multicenter study

Yu Rim Lee[1], Jung Gil Park[2], Min Kyu Kang[2], Jung Eun Song[3], Byoung Kuk Jang[4], Young Oh Kweon[1], Won Young Tak[1], Se Young Jang[1], Changhyeong Lee[3], Byung Seok Kim[3], Jae-Seok Hwang[4], Woo Jin Chung[4], Soo Young Park[1], Nae-Yun Heo[5], Jeong Heo[6], Hyun Young Woo[6], Yanghyon Baek[7], Jun Sik Yoon[8], Joonho Jeong[9], Jae Young Jang[1]. *[1]Kyungpook National University, Kyungpook National University Hospital; [2]Yeungnam University College of Medicine; [3]Daegu Catholic University School of Medicine; [4]Keimyung University School of Medicine; [5]Inje University Haeundae Paik Hospital, Inje University College of Medicine; [6]Pusan National University; [7]Dong-A University Hospital; [8]Busan Paik Hospital, Inje University College of Medicine; [9]University of Ulsan College of Medicine, Ulsan University Hospital*
Email: psyoung0419@gmail.com

Background and aims: Hepatocellular carcinoma (HCC) can still occur after achieving a sustained virologic response (SVR) to direct-acting antiviral (DAA) therapy in patients with hepatitis C. We aimed to identify non-invasive parameters that predict the HCC development for patient with chronic hepatitis C after SVR.

Method: A total of 3, 489 HCV patients who treated with DAAs and had achieved SVR from nine hospitals in South Korea were included in this study. Predictors of HCC occurrence and HCC risk scores were assessed.

Results: During a median follow-up of 2.3 years, HCC occurred in 158 patients (4.5%). LSM gradually decreased from baseline to SVR and 1 year after treatment (p < 0.001). Platelet count, bilirubin, and albumin levels also improved from before treatment to 1 year after treatment (all *P* < 0.05). Multivariate analysis using the Cox regression test identified that age (HR 1.055, 95% CI 1.036–1.074, *P* < 0.001), sex

(HR 1.942, 95% CI 1.326–2.844, $P = 0.001$), platelet count (HR 0.987, 95% CI 0.984–0.991, $P < 0.001$), and albumin (HR 0.525, 95% CI 0.353–0.780, $P = 0.004$) at 1 year follow-up were independently associated with the risk of HCC. HCC risk scores including Modified PAGE-B scores (AUROC = 0.814) and aMAP risk score (AUROC = 0.826) at 1 year after SVR using age, gender, platelet counts, serum albumin levels can discriminate the risk of HCC.
Conclusion: In patients with chronic hepatitis C who have achieved SVR with DAAs, the use of HCC risk scores including Modified PAGE-B scores and aMAP risk score at 1 year after SVR accurately predicted the risk of HCC.

FRI366
Sustained low prevalence of HCV viremia among people who inject drugs following the treatment as prevention for hepatitis C (TraP HepC) nationwide elimination program in Iceland

Email: magnusgo@landspitali.is

Background and aims: Injection drug use (IDU) and sharing of injection equipment and paraphernalia is the main mode of transmission of Hepatitis C Virus (HCV) in most Western societies. People who inject drugs (PWID) therefore need to be diagnosed, treated and cured in order to curb transmission and achieve the WHO goal of eliminating HCV infection as a public health threat by 2030. Starting in 2016, the Treatment as Prevention for Hepatitis C (TraP HepC) program in Iceland has offered direct acting antiviral agents (DAA) to all HCV-infected patients with permanent residence in the country without restrictions. It has from its inception focused on PWID, with special emphasis on active IDU. Vogur addiction hospital screens all patients who report IDU activity upon admission for HCV and therefore is as an ideal sentinel site to monitor the prevalence of HCV viremia in this key population.
Method: We analysed the prevalence of HCV viremia by PCR among PWID who were admitted to Vogur for addiction treatment, 6 years before (2010–2015) and 5 years during the TraP HepC program (2016–2020).
Results: Prior to Trap HepC, 2010–2015 the prevalence of HCV viremia among admitted patients who gave history of ever injecting drugs was stable at 39.5–40.6%. Among those who were currently injecting at the time of admission (injecting within 6 months) the prevalence was stable at 53.2–57.7% during the same period. The prevalence of HCV viremia in the former group dropped to 32.9%, 12.0% and 8.6% during 2016, 2017 and 2018, respectively ($p < 0.001$) and subsequently has remained stable at 12.9% and 13.3% in 2019 and 2020.
Conclusion: In the absence of an effective vaccine, treatment with DAA remains the most efficient way to lower the prevalence of HCV. Efficacy among PWID is excellent and treatment has resulted in a sustained drop in HCV viremia in this population but continued monitoring of these patients is needed. Further studies and longer follow-up is needed to evaluate whether this drop eventually translates into a lower nationwide incidence of HCV in Iceland.

Direct-acting antiviral treatment in Albanian patients with chronic hepatitis C and advanced liver fibrosis
Liri Cuko[1], Eva Shagla[1], Adriana Babameto[1], Jovan Basho[1], Arlinda Hysenj[1], Stela Taci[1], Irgen Tafaj[1], Eno Pengili[1]. *[1]Mother Teresa Hospital, Department of Gastrohepatology, Tiranë, Albania*
Email: liricuko@yahoo.com

Background and aims: Treatment of chronic hepatitis C with direct-acting antiviral (DAA) is very effective at clearing the infection in more than 90% of people. In Albania treatment with DAA is limited to patients with liver stiffness F3-F4, and with other co-infections. The objective of this study was to evaluate the efficacy of DAA in Albanian patients with genotype 1–5, where most of patients are with advanced liver fibrosis.
Method: This was a retrospective study realized at University Hospital Center of Tirana during 2014–2019, including naïve and experienced patients with genotype 1–5. All patients are evaluated with elastography and most of them were F3-F4. The primary endpoint was SVR-12. In patients without genotype we have used pan genotypic regimen. All patients are treated with genotypic and pangenotypic DAA and are assessed for adverse event during the treatment.
Results: In this study are included 207 patients, main age 48.9 ± 13.1 years, 56% male and 44% female. 152 (73%) were genotype 1, 24 (11.5%) genotype 2, 9 (4.3%) genotype 3, 14 (6.7%) genotype 4, 1 (0.4%) genotype 5, and 7 (3.8%) anassigned genotype. SVR percentage according to genotype is shown in table. SVR to all patients was 93.2%. According to elastography 127 (66%) were F3-F4, 80 (44%) F1-F2. Two patients with decompesated cirrhosis discontinued treatment due to side effect.

Genotype (n, %)	SVR-12 (% n|n)
1 (152, 73%)	95% (145/152)
2 (24, 11.5%)	95.8% (23/24)
3 (9, 4.3%)	88.8% (8/9)
4 (14, 6.7%)	78.5% (11/14)
5 (1, 0.4%)	100% (1/1)
anassigned (4, 6.7%)	71.4% (5/7)

Conclusion: Treatment with DAA proved to be very effective in our patient, most of them with advanced liver fibrosis, compensated or decompesated liver cirrhosis. SVR in total patients was 93.2%. The results about genotype 3, 5, are not significant due to the small number of patients. In our country need to treat all patients with chronic hepatitis C without limitations to reach the objective of WHO.

FRI368
Improved recurrence-free survival rates in patients with HCV-related hepatocellular carcinoma and sustained virological response to direct-acting antivirals
Cristina-Maria Muzica[1], Anca Trifan[1], Laura Huiban[1], Oana Stoica[1], Irina Girleanu[1], Stefan Chiriac[1], Ana-Maria Singeap[1], Camelia Cojocariu[1], Tudor Cuciureanu[1], Sebastian Zenovia[1], Robert Nastasa[1], Carol Stanciu[1]. *[1]Grigore T. Popa University of Medicine and Pharmacy, Gastroenterology, Iasi, Romania*
Email: ancatrifan@yahoo.com

Background and aims: Despite the high efficacy of direct-acting antivirals (DAAs) in chronic HCV infection, a more aggressive pattern of hepatocellular carcinoma (HCC) in patients previously treated with DAAs, has been reported. Tumor aggression in HCV-related HCC after DAAs has been linked to impaired outcome. On this basis, we aimed to assess the pattern of HCC and survival rates in patients previously treated with DAAs therapy.
Method: This is a case-control study investigating the features of HCC and survival rates in patients with chronic HCV infection whom were previously treated with DAAs *versus* naïve patients. Patients were

matched for sex and age in a 1:3 fashion. HCC infiltrative pattern, portal vein thrombosis (PVT), metastases, Milan criteria, Barcelona Clinic Liver Cancer (BCLC) staging, tumor-node-metastasis (TNM) staging, Cancer of the Liver Italian Program (CLIP), as well as the recurrence and overall survival rate at 18 months of follow-up, were compared in the 2 groups. This research was carried out in the Institute of Gastroenterology Iasi, Romania, between January 1st, 2017 and December 31, 2019.

Results: The study included 124 patients that were divided into two groups according to DAAs status: 31 DAAs-treated HCC patients and 93 non-DAAs HCC patients. Overall, 65% were males, and the mean age was 58.9 ± 6.8 years. The mean values of APRI and Fib-4 scores were significantly higher in the DAAs-treated group than in naïve patients (p < 0, 001). The frequency of the infiltrative HCC pattern, PVT, and metastasis was higher in the non-DAAs group (p = 0, 002). According to BCLC, CLIP, and TNM, HCC patients in the non-DAAs group had more advanced stages and limited treatment options (p < 0, 001). Furthermore, HCC recurrence rate was higher in naïve patients than in those DAAs-treated (16, 2% versus 8, 6%, p = 0, 002). The 18-months overall survival rate was 73.3% in the DAAs-treated group and 43.7% in non-DAAs group (p = 0, 008).

Conclusion: Our study indicates a better recurrence-free overall survival rate in patients with HCV-related hepatocellular carcinoma with SVR to DAAs compared with naïve patients, demonstrating the beneficial impact on the outcome of these patients.

FRI369

Long-term outcomes associated with task-shifting of HCV treatment by non-specialist providers: five year follow-up from the ASCEND cohort

Sarah Mollenkopf[1], Elana Rosenthal[2], Gebeyehu Teferi[3], Rachel Silk[2], Nivya George[2], Henry Masur[4], Shyamasundaran Kottilil[2], Sarah Kattakuzhy[2]. *[1]University of Maryland School of Medicine, Baltimore, United States; [2]Institute of Human Virology, Division of Clinical Care and Research, Baltimore; [3]Unity Health Care, Washington, United States; [4]NIH, Critical Care Medicine Department, Bethesda, United States*

Email: skattakuzhy@ihv.umaryland.edu

Background and aims: Since 2015, an increasing body of evidence has supported task-shifting of Hepatitis C (HCV) treatment with direct-acting antivirals (DAA) to non-specialist providers, however, there are limited data on longitudinal outcomes associated with this treatment paradigm. We sought to assess outcomes of patients in the 5 years after initial DAA treatment by specialist and non-specialist providers, to evaluate the longitudinal evidence for task-shifting in the ASCEND cohort.

Method: This analysis included 525 patients treated for HCV with ledipasvir-sofosbuvir in the ASCEND investigation who had long term follow up data available. Chart review and abstraction of variables of interest from date of sustained virologic response (SVR) to June 2020 was completed. Baseline demographic and clinical characteristics were compared using t-tests, while change in outcomes was assessed using McNemar's or chi-squared tests. All analysis was conducted in R, version 4.1.0.

Results: Amongst 525 patients at ASCEND baseline, the mean age was 59.5 years, with majority male (69%), Black race (95%), and genotype 1a (71%), with 20% with HIV, 20% with cirrhosis and 18% IFN-treatment experienced.

In addition to 458 (87.2%) of patients with SVR at the end of the original investigation, 16 patients who were lost to follow up were found to have achieved SVR. Furthermore, of 32 patients with known NSVR, 23 were re-treated, 17 of whom achieved SVR. Therefore, 491 (93.5%) of ASCEND participants ultimately achieved HCV cure during the five-year follow up period.

Of the 458 patients who achieved SVR, 97% returned to clinic, of whom 70% were screened for HCV reinfection. Of 336 patients screened, only two (0.6%) were found to be reinfected.

Twenty-five patients died during the follow up period. There was a significant difference in morality rates based on SVR status, with 4.1% mortality in those with SVR, compared to 35.7% with NSVR (p < 0.5). Of 14 individuals with known cause of death, 5 patients died from HCV-related causes.

When comparing outcomes by original ASCEND treatment provider type, there were no significant differences in rates of loss to follow-up, SVR, HCV re-screening, HCV reinfection or mortality (p > 0.05) between nurse practitioners, primary care physicians, and specialist physicians.

Table 1. Five-Year Outcomes by Provider Type

		NP		PCP		Specialist		Comparison	
			95% CI		95% CI		95% CI	X^2	p
SVR	#	132		98		261			
	Prop	0.943	(0.891-0.975)	0.916	(0.846-0.961)	0.939	(0.904-0.964)	0.855	0.652
NSVR	#	3		4		7			
	Prop	0.021	(0.004-0.061)	0.037	(0.010-0.093)	0.025	(0.010-0.051)	0.645	0.724
Reinfection‡	#	0		0		2			
	Prop	0	(0.000-0.028)	0	(0.000-0.037)	0.008	(0.001-0.027)	1.770	0.413
HCV-Related Death¥	#	2		1		2			
	Prop	0.286	(0.037-0.710)	0.125	(0.003-0.527)	0.200	(0.025-0.556)	0.603	0.740

* Difference between baseline ASCEND and 5-year follow-up values is significant by 3-Sample Test Chi-Squared Test for Equality of Proportions (p<0.05)
‡ Denominator includes only those people who were tested for reinfection
¥ Denominator includes deaths of all causes

Conclusion: This five-year longitudinal follow-up of the ASCEND cohort identifies an even higher rate of SVR of 93.5% in an urban cohort, with limited reinfection. These data reinforce that task-shifting of HCV therapy to non-specialist providers results in both high rates of HCV cure, as well as favourable long-term outcomes. These data emphasize that restrictions on the basis of treating provider type stand as unnecessary hurdles in the HCV care continuum.

FRI370

Risk stratification of hepatocellular carcinoma in cirrhotic patients after hepatitis C virus eradication: russian single-center experience

Ekaterina Nabatchikova[1], Daria Zasorina[1], Teona Rozina[1,2], Elena Nikulkina[1], Elena Tanashchuk[1], Dzhamal Abdurakhmanov[1], Sergey Moiseev[1,2]. *[1]I.M. Sechenov First Moscow State Medical University (Sechenov University), Russian Federation; [2]M.V. Lomonosov Moscow State University, Russian Federation*

Email: e.nabat4ikova@gmail.com

Background and aims: The risk of hepatocellular carcinoma (HCC) in cirrhotic patients after HCV eradication with direct-acting antivirals (DAAs) is reduced, but not completely eliminated. The aim of our study was to assess incidence, risk factors of HCC and develop a scoring system to predict in patients with HCV-related cirrhosis treated by DAAs.

Method: The prospective single-center cohort study included patients with HCV-related cirrhosis treated by DAAs between July 2015 and May 2020. Exclusion criteria was previous and present HCC. Patients who achieved sustained virological response underwent clinical, laboratory and imaging assessment every 3–6 months after the end of therapy.

Results: : A total of 232 cirrhotic patients were enrolled. The median age was 54 (47; 60) years, 49.3% were males, diabetes was present in 19.8%, obesity-in 20.2%, HCV genotype 3-in 25.4% and 29.7% were treatment-experienced. Child-Pugh class B/C were found in 29.3%. Baseline median MELD score was 11 (9; 13), liver stiffness (n = 133)-23 (17.4; 30.6) kPa, platelet count $\leq 100 \times 10^3$/ml were in 54% of patients, albumin ≤35 g/l–35.3%, bilirubin ≥34 μmol/l–19.4%, prothrombin time ≤60%–19.4%, aspartate aminotransferase-platelet ratio index >2–56%, fibrosis-4 score (FIB-4) ≥3.25–67.7%. Esophageal varices 2/3 were in 60.3%, ascites-25.4%. The median follow-up time after EOT was 36 (24; 48) months. De novo HCC occurred in 19 (8.2%) patients. Median alpha-fetoprotein was 6.3 (2.8; 31) IU/ml. Sixteen patients (89%) were within the Milano criteria. The

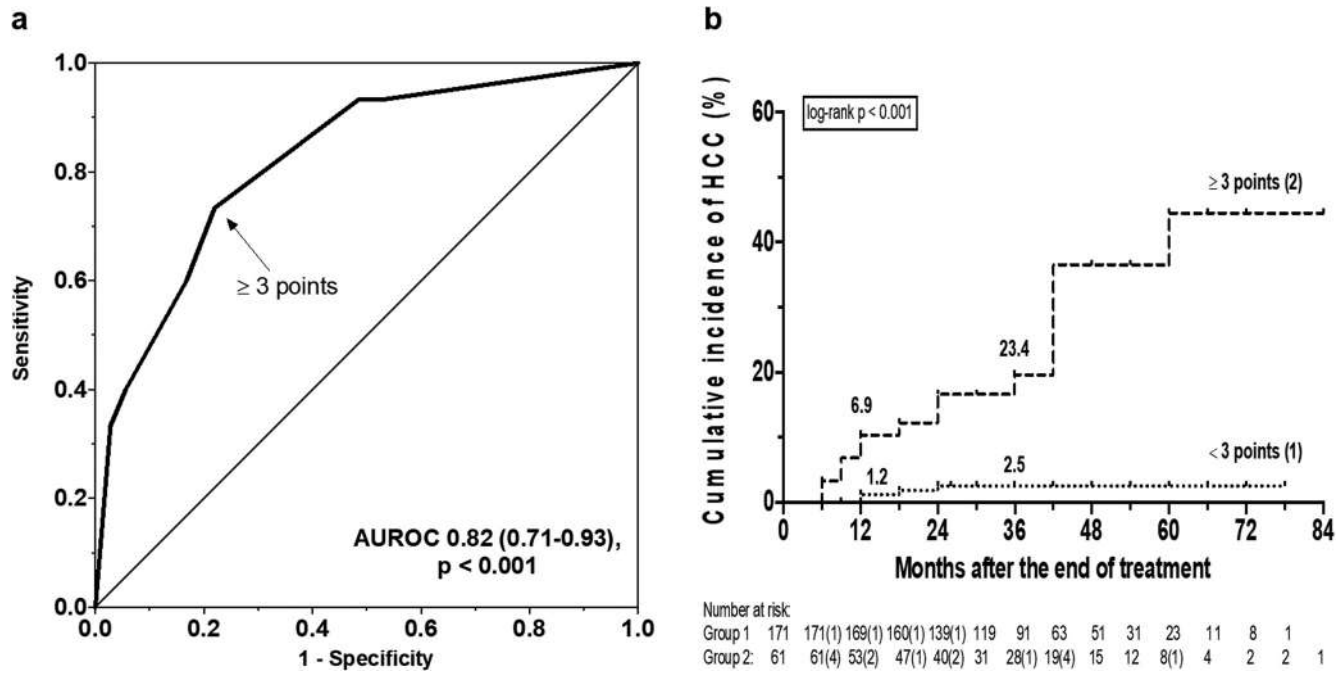

Figure: (abstract: FRI370)

median time from EOT to HCC diagnosis was 18 (12; 42) months. At the multivariate analysis, baseline bilirubin level ≥34 µmol/l (HR 4.19; p = 0.002), baseline ascites (HR 6.6; p < 0.001), MELD ≥15 (HR 3.82; p = 0.007) and FIB-4 >3.25 (HR 6.4; p = 0.015) at the SVR time were independent risk factors for HCC. We determined the weight of each factor equal to HR, and then converted it into an integer: baseline bilirubin level ≥34 µmol/l-1 point, baseline ascites-2 points, MELD ≥15 at the SVR time-1 point, FIB-4 >3.25 at the SVR time-2 points. The resulting scale allows to set from 0 to 6 points. Patients with HCC had a large sum of points compared to patients without HCC (4 (3; 6) points vs. 1 (0; 2) points, p < 0.001). The AUROC of the model was 0.82 (0.71–0.93, p < 0.001). The sum of points equal to ≥3 has the maximum values of sensitivity (73%) and specificity (78%) and can be used as a threshold value for determining the HCC risk (figure a). The cumulative risk of developing HCC in patients with ≥3 points is significantly higher (HR 12.03, log-rank p < 0.001) (figure b).
Conclusion: We developed a predictive score using four risk factors, which can help to customize HCC surveillance strategies in cirrhotic patients after HCV eradication.

FRI371
Distinct hepatocellular carcinoma risks in treated chronic hepatitis C patients with different definitions of advanced chronic liver disease

Yen-Chun Liu[1,2], Cheng Er Hsu[1,2], Ya-Ting Cheng[1,2], Chung-Wei Su[1,2], Chia-Hung Tai[1,2], Yi-Cheng Chen[1,2], Yi-Chung Hsieh[1,2], Wei Teng[1,2], Rachel Wen-Juei Jeng[1,2], Chun-yen Lin[1,2], Rong-Nan Chien[1,2], Tai Dar-In[1,2], I-Shyan Sheen[1,2]. [1]*Chang Gung Memorial Hospital, Linkou Branch, Taiwan;* [2]*College of Medicine, Chang Gung University, Taiwan*
Email: rachel.jeng@gmail.com

Background and aims: To identify target population for hepatocellular carcinoma (HCC) is an important issue in chronic hepatitis C (CHC) patients after antiviral treatment. Advanced chronic liver disease (ACLD) patients have been suggested by the guideline as the target surveillance group for their remnant HCC risk after sustained virological response (SVR). However, the definition of ACLD composed of different diagnostic tools including liver stiffness measurement (LSM), FIB-4 or both or by ultrasonography image. This study aims to compare the predictability of HCC among CHC patients with SVR who meet ACLD criteria by different diagnostic measurements.
Method: CHC achieved SVR by interferon-free direct acting anti-viral agents (DAA), whose LSM by transient elastography (TE, Fibroscan) and FIB-4 index were both available before DAA therapy were enrolled. The ACLD was defined as LSM >10 kPa and/or FIB-4 >3.25 and/or ultrasound signs of cirrhosis. Predictabilities for HCC and 3-year cumulative HCC incidences were compared among four groups of ACLD patients diagnosed by different non-invasive assessments (group A: FIB-4 > 3.25 but LSM ≦ 10; group B: FIB-4 ≦ 3.25 but LSM > 10; group C: FIB-4 > 3.25 + LSM > 10; group D: FIB-4 ≦ 3.25 and LSM ≦ 10 but ultrasonography showed cirrhosis.).
Results: Among 1600 enrolled patients, 922 (58%) patients met criteria of ACLD (group A, N = 128; group B, N = 369; group C, N = 406; group D, N = 19). The mean age was 62 years old, 41% was male and 63% was genotype 1. The annual incidence and 3-year cumulative HCC incidences showed 0.3% and 0.8%, 2.2% and 4.6%, 3.8% and 9.1% and 3.9% and 10.5% in patients with group A, group B, group C and group D (Log-rank p < 0.01), respectively (Figure). The negative predictive values (NPVs) for HCC were all the above 95% among these four groups with different ACLD definitions, while the sensitivity was much higher in group C of 62.5% compared to group A (1.4%), B (27.8%) and D (2.8%).

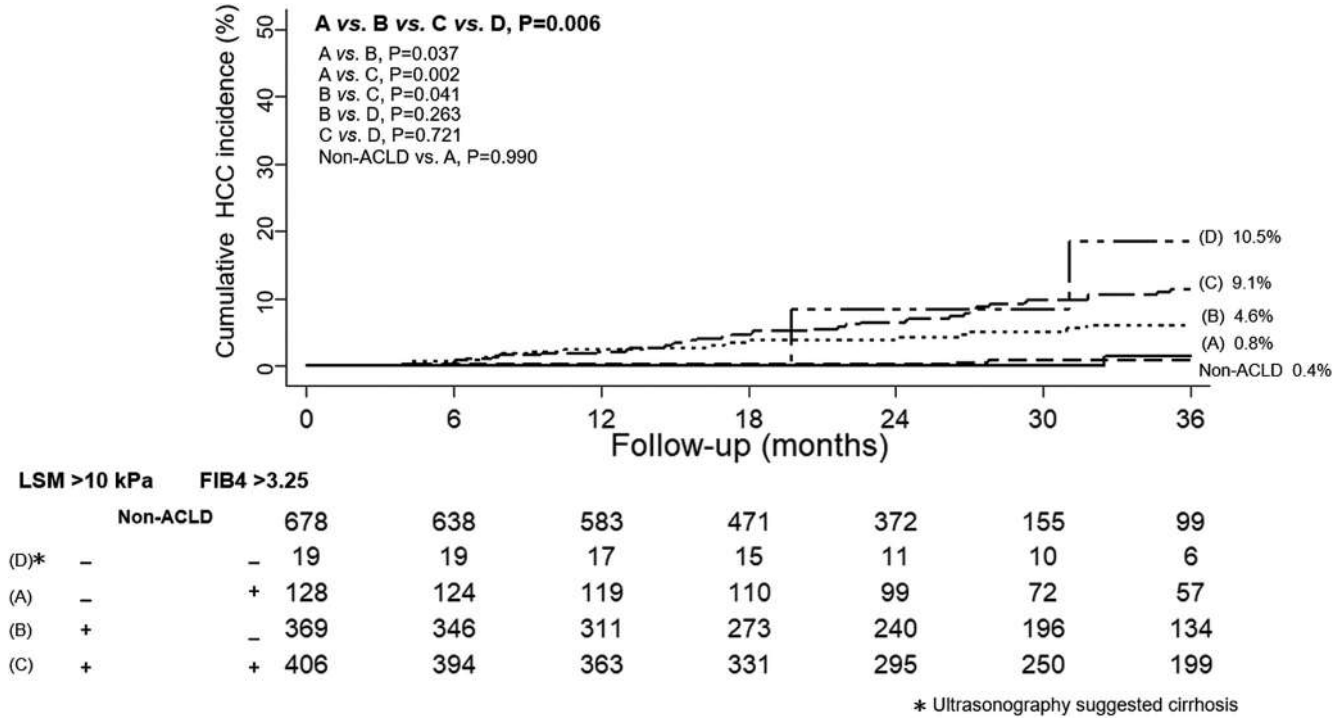

Figure: (abstract: FRI371)

Conclusion: LSM >10 kPa ± FIB-4 >3.25 are more appropriate criteria for ACLD than FIB-4 >3.25 alone which PPV is only 0.8% and its 3-year HCC cumulative incidence be approximate to that of the non-ACLD (0.4%). Those with echo appeared cirrhotic features but not fit the criteria of ACLD due to LSM<10 kPA and FIB-4 < 3.25 were still at high risk of HCC and also shall be under HCC surveillance program.

FRI372

Hepatocellular carcinoma risks of liver fibrosis changes after viral eradication in chronic hepatitis C patients

Yen-Chun Liu[1,2], Cheng Er Hsu[1,2], Ya-Ting Cheng[1,2], Chung-Wei Su[1,2], Chia-Hung Tai[1,2], Yi-Cheng Chen[1,2], Wei Teng[1,2], Rachel Wen-Juei Jeng[1,2], Chun-yen Lin[1,2], Rong-Nan Chien[1,2], Tai Dar-In[1,2], I-Shyan Sheen[1,2]. [1]*Chang Gung Memorial Hospital, Linkou*

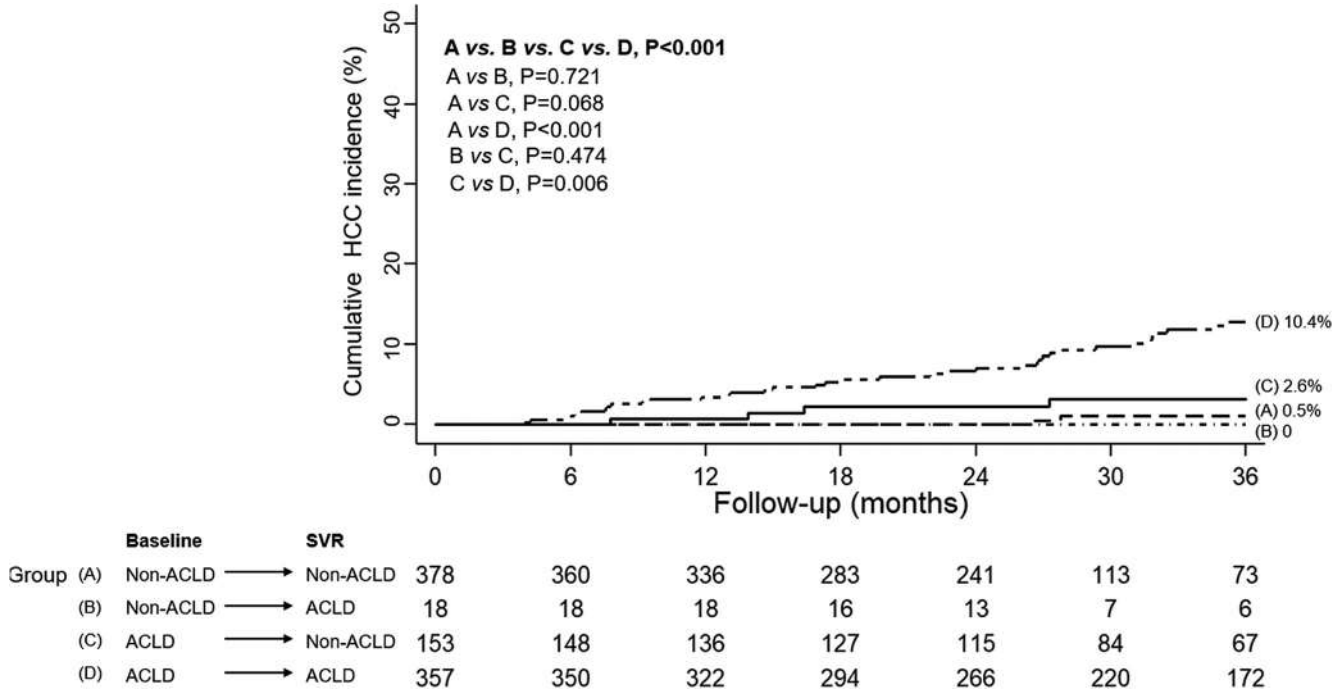

Figure: (abstract: FRI372)

Branch, Taiwan; [2]College of Medicine, Chang Gung University, Taiwan
Email: rachel.jeng@gmail.com

Background and aims: Hepatocellular carcinoma surveillance is suggested for chronic hepatitis C (CHC) patients with advanced chronic liver disease (ACLD) by the guideline. It is reported liver fibrosis in patients with advanced fibrosis or cirrhosis can be reversed after viral eradication by direct acting antivirals (DAA). The study aims to investigate the HCC risks among CHC sustained virological response (SVR) patients with fibrosis regression, stationary or progression after SVR, and predictors for ACLD regression.
Method: CHC achieved SVR by interferon-free DAA, whose LSM by transient elastography (TE, Fibroscan) and FIB-4 index were both available before DAA therapy and after SVR were enrolled. The ACLD was defined as LSM >10 kPa and/or FIB-4 >3.25 and/or ultrasound signs of cirrhosis. The 3-year cumulative HCC incidences were compared among four groups of dynamic fibrotic changes (group A: both pre-DAA and post-SVR timepoints: non-ACLD; group B: pre-DAA non-ACLD progressed to post-SVR ACLD; group C: pre-DAA ACLD regressed to post-SVR non-ACLD; group D: both pre-DAA and post-SVR: ACLD). Logistic regression was applied to find predictors for ACLD regression.
Results: There were 906 patients (group A: 378 (42%), group B: 18 (2%), group C: 153 (17%), group D: 357 (39%)) enrolling into the study with mean age of 62 years old, 38% of male and 92% of genotype 1. The 3-year cumulative HCC incidences showed 0.5%, 0%, 2.6% and 10.4% in patients with group A, group B, group C and group D (Log-rank $p < 0.01$), respectively (Figure). Logistic model showed that higher baseline ALT [adjusted OR (aOR): 1.006 (95% CI: 1.002–1.010), $p = 0.007$] was a predictor for ACLD regression, while higher baseline LSM [aOR:0.870 (0.825–0.917), $p < 0.001$] and FIB-4 [aOR:0.655 (0.496–0.864), $p = 0.003$] were unfavorable factors for post-SVR ACLD regression.
Conclusion: Patients with persistent ACLD after SVR posed the highest HCC risks, followed by those with ACLD regression. Those progressed from pre-therapy non-ACLD to post SVR ACLD occurred in 2% of all population with minimal HCC risk as that in the persistent non-ACLD group.

FRI373
Change in fibrosis and clinical progression three years after sustained virological response induced by direct antiviral agents in HIV/HCV subjects

Maria Carnevali Frias[1], Lourdes Dominguez[2], David Rial Crestelo[1], Otilia Bisbal[1], Rafael Rubio Garcia[1], Federico Pulido Ortega[1]. *[1]Hospital 12 de Octubre, Medicina Interna, Madrid, Spain; [2]King's College Hospital, HIV/Sexual Health, London, United Kingdom*
Email: macarfri@gmail.com

Background and aims: Sustained virological response (SVR) achieved after treatment of HCV infection with direct-antiviral agents (DAA) is associated with long-term clinical benefits. We evaluate changes in the estimated fibrosis on SVR confirmation and 3 years after SVR, and if changes on SVR confirmation are related to a decrease in the risk of liver events in people living with HIV (PLWH).
Method: A prospective observational cohort of PLWH with HCV infection and SVR after DAA therapy (January 2015–August 2016) was followed up until December 2020. Liver fibrosis was estimated by non-invasive methods: liver stiffness (LS), APRI and FIB4. Measures were done prior to treatment (baseline), 12 weeks post treatment (SVR12) and 3 years after SVR12 (3 y). Cut-off values for cirrhosis were ≥14.6 kPa (LS), ≥1 point (APRI), ≥3.25 points (FIB4). Cirrhosis regression or non-progression from non-cirrhosis was considered as fibrosis improvement. Clinical outcomes considered were liver-related complications occurred after SVR: death, portal hypertension decompensation (PHD), hepatocarcinoma (HCC) and a composite endpoint of these three.
Results: 393 people were followed-up for a median of 3.8 years (3.5–4.0). There was a significant improvement in LS, APRI and FIB4 from baseline to 3y [−3.0 kPa (−7.6 to 1.2); −0.4 points (−0.9 to 0.2); −0, 5 points (−1.3 to −0.1)] and major changes were observed from baseline to SVR12. Before the HCV treatment 30.0%, 35.1% and 26.5% subjects were considered as having cirrhosis according to LSM, APRI or FIB4. More than half of them (58.8%, 87.2% and 70.7% respectively) did not remain in that cathegory at the end of the study. Four HCC were detected [3y risk: 0.8% (0.3–2.4)]. At least one episode of PHD was reported in 13 patients [3y risk: 2.6% (1.4–4.8)]. 23 patients died [3 y overall mortality: 3.9% (2.4–6.4)] but only 3 of them due to liver-related causes [3 y related mortality: 0.3% (0.0–1.8)]. 15 patients developed the composite endpoint [3 y risk of any of the covered outcomes: 3.1% (1.8–5.4)]. Estimated liver fibrosis improvement from baseline to SVR12 was associated to lower risk of presenting any of these clinical outcomes, both in the global cohort and in the subgroup of patients with cirrhosis or advanced fibrosis.

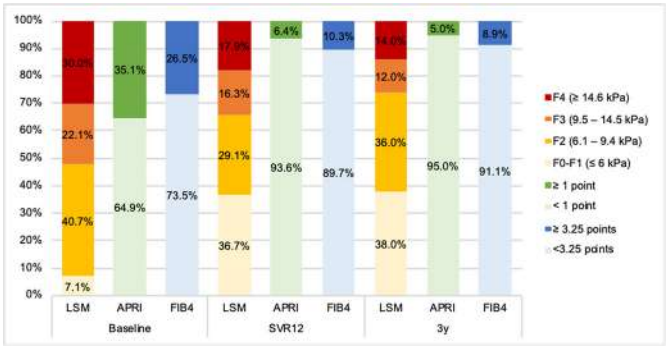

Figure: Patients distribution according to estimated liver fibrosis stage

Conclusion: There is a clinically relevant improvement in non-invasive liver fibrosis markers after 3 years of DAA-induced SVR in PLWH with HCV infection. Estimated fibrosis regression from baseline to SVR12 is associated with a reduction in liver-related complications.

FRI374
FOCUS Project: preliminary results toward hepatitis C Virus screening and elimination in Almería, Spain

Anny Camelo Castillo[1], Marta Casado[1], Teresa Cabezas Fernandez[1], Pedro Amado Villanueva[1], Alba Carrodeguas[2], Diogo Medina[2], José Luis Vega Sáenz[1], Manuel Rodriguez Maresca[1]. *[1]Torrecárdenas University Hospital, Almería, Spain; [2]GILEAD SCIENCES INC, Madrid, Spain*
Email: anjo134@gmail.com

Background and aims: Hepatitis C virus (HCV) elimination is a global challenge, and Spain may be one of the first countries to achieve the World Health Organization's goal of eliminating viral hepatitis by 2030. A 2017–2018 Ministry of Health serosurvey estimated 0.22% active HCV infection among the general Spanish population, 29.4% without prior infection records.
Increasing HCV screening is key, particularly among vulnerable populations with high prevalence. Emergency departments (ED) often act as safety nets due to health equity issues for key populations affected by viral hepatitis, as they often lack optimal links with their primary care providers.
Therefore, we aimed to evaluate HCV screening efficacy in the ED of Torrecárdenas University Hospital, in Almería, Andalusia, Spain.
Method: We implemented opportunistic HCV screening in the ED, using existing infrastructure and staff, aided by electronic health record system modifications to identify eligibility for the test and request serologies automatically. Patients were eligible for testing upon verbal consent if they were between 18 and 69, and had no known diagnosis or test performed in the previous year, and required blood tests in the current visit to the ED.

We used the LIAISON®X- Diasorin assay for HCV antibodies (anti-HCV) and the Roche Cobas® 6800 for viral RNA (HCV RNA) in the same specimen (i.e., reflex or single-step testing). Appropriate follow-up or discharge was given, regardless of test results. We contacted positive patients to ensure and monitor linkage to specialist medical care.

Results: We screened 1,131 patients for HCV from August to October 2021, finding 28 (2.47%) anti-HCV positive patients (with an average age of 55, 71% males), and 5 (0.44%) HCV RNA positive patients (80% males), 80% of whom had no prior records or knowledge of their infection.

Conclusion: Undocumented HCV infection among our ED population is higher than estimated in the general population, with twice the active infection rate and nearly two times undiagnosed infection. Thus, opportunistic HCV screening in EDs is feasible, non-disruptive, and effective in increasing diagnosis.

Email: angelo.sangiovanni@policlinico.mi.it

Background and aims: The usefulness of serum alfafetoprotein (AFP) assessment after sustained virologic response (SVR) in HCV cirrhotic patients treated with direct antiviral agents (DAA) in surveillance programs for the early diagnosis of hepatocellular carcinoma (HCC) is debated. Aim of this study was to evaluate the time course of AFP and its performance in predicting HCC development in this setting. Secondary aim was to define the AFP value predicting HCC development with at least 99% specificity.

Method: In a post-hoc analysis of consecutive cirrhotic patients treated with DAA in a multicenter national study, we enrolled all HCC-free patients with at least one AFP value available at or after SVR and extended the follow-up until 30 September 2020. HCC surveillance program was based on abdominal ultrasound (US) every 6 months. AFP was tested during follow-up on clinical basis depending on the policy of each centre. Joint modelling of

longitudinal data of log AFP and time-to-event endpoint (HCC) were applied for analysis, combining the linear mixed effects model and the Weibull model for survival.
Results: 870 SVR patients, median age 65 (IQR 55–73, 58% males), 92% Child-Pugh A were enrolled. During a median 34 (IQR 14–43) months of post SVR follow-up, 71 patients developed HCC, corresponding to a cumulative incidence at 1, 2 and 3 years of 3.3% (95% CI 2.3–4.8), 5.4% (95% CI 4.0–7.4), 8.3% (95% CI 6.4–10.7), respectively. The joint model considering log AFP values in a time dependent way achieved the best performance to predict the risk of developing HCC, HR 2.44 (95% CI 2.10–2.82, $p < 0.001$). The log-AFP value progressively increased in patients who developed HCC as compared to those who did not ($p < 0.001$). A log AFP increase was associated to increased risk of developing HCC with HR 21.9 (95% CI 4.6–103, $p < 0.001$). By Youden's index an AFP value above 8 ng/ml detected at any time defines the most accurate threshold to predict HCC, corresponding to a 59.6% sensitivity and 96.5% specificity. A 99% specificity was achieved for AFP value >21 ng/ml corresponding to a sensitivity of 23.9%. By Kaplan-Meier curve in a time-dependent association structure, HCC incidence was 10.8 per 100 patient-year (95% CI 7.2–16.1) in patients with AFp >21 ng/ml as compared to 2.2 (95% CI 1.7–3.0) in patients with AFP value ≤21 ng/ml ($p < 0.001$).
Conclusion: In cured HCV cirrhotic patients the AFP value over time is associated to HCC development and may help to refine the HCC surveillance strategies. The increase of AFP levels above 21 ng/ml at any time after SVR is associated with a specificity of 99% for the prediction of HCC development, albeit with low sensitivity.

FRI377
A 4 year multi-centre study of persons who inject drugs in Luxembourg, looking at hepatitis C virus seroprevalence, treatment uptake and reinfection rates

Madiha Sharaf[1], Vic Arendt[2], Thérése Staub[3], Carole Devaux[4], Emily Montosa Nunes[4]. [1]*Centre Hospitalier Luxembourg, Emergency Department, Luxembourg, Luxembourg;* [2]*Centre Hospitalier Luxembourg, National Service of Infectious Diseases, Luxembourg, Luxembourg;* [3]*Centre Hospitalier Luxembourg, National Service of Infectious Diseases, Luxembourg, Luxembourg;* [4]*Luxembourg Institute of Health, Department of Infection and Immunity, Esch-sur-Alzette, Luxembourg*
Email: madiha.sharaf@gmail.com

Background and aims: The global figure of persons who inject drugs (PWID) stands at 15.6 million persons. 50% of PWID have been estimated to be exposed to the Hepatitis C virus (HCV), and 39% are said to suffer from chronic HCV, in comparison to 1% of the general population. Chronic HCV can result in liver cirrhosis, hepatocellular carcinoma and premature death over 20 to 40 years. The "Hepatitis C among Drug Users"-"HCV-UD" study is the largest multi-centre study in Luxembourg looking at patterns of HCV prevalence amongst PWID, including uptake of treatment and reinfection.
Method: 480 participants were recruited at harm reduction sites throughout the country from November 2015 to December 2019. Participants were offered HCV screening, direct acting anti-viral (DAA) treatment and follow-up with an infectious disease specialist, without cost.
Results: 356 participants (74%) were exposed to HCV versus 124 participants (26%) who had no evidence of exposure. 51% were cured of which 25% were cured through treatment, as evaluated with a sustained viral response at 12 weeks or more. Of these, 27% were reinfected again with HCV. 75% were cured during the course of the study, attributed to previous unrecorded treatment or spontaneous cure. 47% of participants continued to have ongoing infection, of which 7% had undergone treatment, and 93% had not taken any treatment. There was missing data for 6 participants. The results are summarised in the figure below.

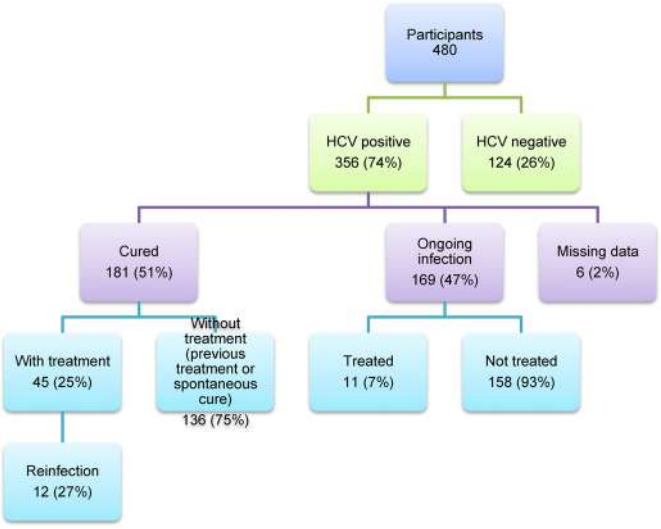

Figure: Patients distribution according to estimated liver fibrosis stage

Conclusion: The outreach set up of the study enabled insights in to the treatment and HCV status of PWID, which the authors feel is a closer representation of reality. HCV prevalence was comparable to other study estimates in the literature. Treatment uptake was low, despite the free DAA treatment offered, however within this subset only 27% went on to be reinfected. What is worrying, however, is that 47% of participants continued to be infected with HCV. This begs the question as to which barriers to care within a psychosocial framework need to be addressed to enable the World Health Organisation's (WHO) target of eradicating HCV as a public health risk by 2030.

Viral hepatitis C: Therapy and resistance

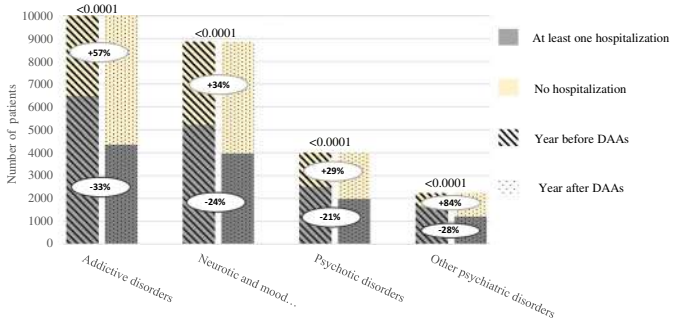
Benefits associated with HCV cure in people with mental disorders

Benjamin Rolland[1], Elias Benabadji[2], Olivier Lada[2], Pascaline Rabiega[3], Fayssoil Fouad[3], Nabil Hallouche[4], Stanislas Pol[5]. [1]*Université de Lyon-Sud et Service d'Addictologie de Lyon (HCL/CH Vinatier), Lyon, France;* [2]*Gilead Sciences, Boulogne-Billancourt, France;* [3]*IQVIA, France;* [4]*GHU Paris Psychiatrie et Neurosciences, Paris;* [5]*Université de Paris et Hépatologie de Cochin (AP-HP), Paris, France*
Email: stanislas.pol@aphp.fr

Background and aims: Retrospective and prospective studies have reported hepatic and extra-hepatic benefits after direct-acting antivirals (DAAs) treatment of hepatis C virus (HCV) chronic infection. However, the ability of virologic cure to improve the neuro-cognitive troubles is still questioned: HCV cure could improve neuro-cognitive troubles as the neurotropism of HCV has been suggested (in glial cells and astrocytes). Our main objective was to evaluate, in the subpopulation of patients with psychiatric disorders, the impact of DAAs (assimilated to HCV cure) on hospitalizations, both in general medicine and in psychiatric ward.
Method: All adult patients identified in the French administrative health care databases (SNDS) with DAAs treatment initiation between 2015 and 2018, and with at least one psychiatric disorder, were included. Individuals were assigned into one or several psychiatric disorder sub-groups based on algorithms: "addictive disorders," "neurotic and mood disorders," "psychotic disorders" and "other psychiatric disorders." A longitudinal approach was then used to compare the frequency and the duration of hospitalizations one

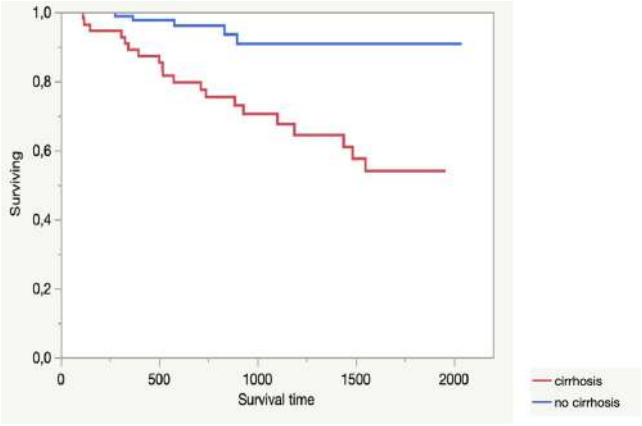
year before and one year after HCV treatment, both in general medicine (all-cause) and in psychiatric ward.
Results: Between 2015 and 2018, a total of 17, 203 HCV patients with at least one psychiatric disorder initiated a treatment in France. 57.4% of the subjects were hospitalized at least once the year before DAAs initiation, while only 41.6% were during the year following treatment ($p < 0.0001$). Put differently, the number of patients with at least one hospitalization decreased by 28% after HCV cure (9, 874 versus 7, 153 patients hospitalized respectively).
The mean number of hospitalizations per patient per year in general medicine department was 1.2 during the pre-DAAs year and decreased to 0.8 the post-treatment year ($p < 0.0001$). Similarly, this number decreased from 1.4 to 1.2 in psychiatric ward.
Among the patients hospitalized at least once in general medicine ($n = 2, 515$), both the year before and the year after treatment, the duration of hospital stays decreased significantly from 20.5 days to 16.7 days after HCV treatment ($p < 0.0001$). In psychiatric wards ($n = 589$) a decreasing trend was also observed from 73, 9 days to 68, 9 days but was not significant ($p = 0.2132$).
Interestingly, similar results were also observed in all four sub-groups and were statistically significant.



Conclusion: DAAs treatment in patients with psychiatric disorders results in a significant reduction in the frequency and the duration of hospitalizations the year following treatment, and even for the patients with severe psychiatric conditions. These results point out both the individual benefit-a better global and psychiatric prognostic-and the collective benefit-fewer resource utilization-of HCV cure in patients with psychiatric disorders.

FRI382
Dismal prognosis for cirrhotic HCV patients after initial DAA treatment failure, rescue therapy may be life-saving
Johan Westin[1], Rune Wejstål[1], Christian Kampmann[2], Magdalena Ydreborg[1], Ola Weiland[3]. *[1]University of Gothenburg and Sahlgrenska University Hospital, Department of Infectious diseases; [2]Skåne University Hospital, Department of Infectious Diseases, Lund, Sweden; [3]Karolinska Insititute and Karolinska University Hospital, Dept of Medicine, Division of Infectious Diseases, Stockholm, Sweden*
Email: johan.westin@gu.se

Background and aims: Effective direct-acting antiviral (DAA) treatment against hepatitis C virus (HCV) infection is universally available. A small portion of HCV patients does not respond, irrespective of treatment regimen. The aim was to study the long-term prognosis after initial DAA treatment failure in HCV infected patients, in a real-life setting.
Method: Data from all adult patients registered in the national Swedish HCV treatment register who did not achieve sustained virological response (SVR) after their initial DAA treatment course, were retrieved from 2014 through 2018.
Results: In total, 288 patients with primary DAA failure were included, of whom 236 underwent a second treatment course as rescue therapy after a median delay of 353 (IQR: 215–650) days. 15 patients received a third treatment course as second rescue treatment after a further median delay of 193 (IQR: 160–378) days. One-hundred-eleven out of 124 (90%) non-cirrhotic and 62/79 (78%) cirrhotic patients achieved SVR following the first rescue treatment. SVR was achieved by 108/112 (96%) patients after a triple DAA regimen. In total 69 (24%) patients were lost to follow-up or died waiting for rescue treatment. Baseline cirrhosis was associated with poor long-term survival. Overall survival 3 years after initial treatment failure was 70% for patients compared with over 90% for patients without baseline cirrhosis (Figure 1).



Conclusion: Our study indicates that rescue therapy in most patients with primary DAA failure have an excellent outcome, in particular when a triple DAA regimen was given. A significant number of patients were lost to follow-up or died waiting for rescue therapy, and the overall long-term prognosis for patients with baseline cirrhosis was poor. This indicates that patients with primary DAA failure should be offered rescue therapy, using a triple DAA regimen, without delay.

Requests for drug-drug interaction data on direct-acting antivirals and enzyme inducing anti-epileptic agents: an overview of the HEP Interaction checker database of the University of Liverpool
David Burger[1], David Back[2], Jasmine Martin[2], Daryl Hodge[2], Minou Van Seyen[3], Justin Chiong[2], Alison Boyle[2], Fiona Marra[2]. *[1]Radboud University Medical Center, Pharmacy, Nijmegen, Netherlands; [2]University of Liverpool, Liverpool, United Kingdom; [3]Jeroen Bosch Ziekenhuis, 's-Hertogenbosch, Netherlands*
Email: david.burger@radboudumc.nl

Background and aims: Drug-drug interactions (DDIs) between direct-acting antivirals (DAAs) for hepatitis C virus (HCV) infection and enzyme inducing anti-epileptic agents (eiAEs) are among the most difficult to manage, and form a potential barrier towards elimination of HCV. When patients are not able to switch the eiAE to a non-eiAE, DAA treatment is often deferred. With new data published recently on successful combined treatment of eiAEs and DAAs (Buti et al J Hepatol 2021; Natali et al J Pharm Practice 2021) we wondered how often people are looking for eiAE-DAA interactions at the University of Liverpool's HEP Interaction Checker (www.hep-druginteractions.org) to gauge some information about how widespread this problem may be.
Method: We extracted DDI queries submitted to the HEP Interaction Checker between July 1, 2017 and September 30, 2021. We removed queries on DAAs that are no longer in use (e.g. boceprevir, telaprevir). We only looked at eiAEs (including: carbamazepine, phenytoin, phenobarbital, primidone, oxcarbazepine and eslicarbazepine) as non-eiAEs (e.g. gabapentin, pregabalin) are less of interest from a DDI perspective, and are more often used for other indications such as

neuropathic pain, mood stabilization, etc. Queries to the database are anonymous, the key information that is recorded is the country of origin.

Results: During 51 months of follow-up, a total of 94, 695 queries from 98 countries were recorded by website users to check DDIs between eiAEs and DAAs. The most frequently requested DAAs were glecaprevir/pibrentasvir (GP; 23.3%) and sofosbuvir/velpatasvir (22.3%). Among the eiAEs, carbamazepine was the most frequently requested eiAE (37.9%) followed by phenytoin (19.9%) and oxcarbazepine (18.7%). Until recently, all of these combinations were contraindicated (red flag). On an individual level, the most frequently requested DDI between an eiAE and a DAA was carbamazepine & GP (n = 7, 773 queries).

Conclusion: During our observation period, we received an average number of 1, 857 requests per month for a potential DDI between an eiAE and a DAA, demonstrating a huge demand globally for advice on concomitant use of these drugs. Our recommendations have recently been updated to reflect recent real-life data. Given the high number of DDI requests involving an eiAE and DAAs, we believe physicians should be informed that treatment options have now been improved, and HCV treatment should no longer be deferred when an eiAE is on board.

Email: a.mangia@tin.it

Background and aims: The profile of HCV patients (pts) being started on direct-acting antivirals (DAAs) has shifted towards more vulnerable populations. This large real-world analysis describes the diverse profile of these populations according to age and sex.

Method: Adult HCV pts (aged 18+ years [y]) from 37 clinical cohorts across nine countries treated with SOF/VEL for 12 weeks without ribavirin were included. Those with a history of decompensation or prior NS5A-inhibitor exposure were excluded. This descriptive analysis evaluated pt characteristics, time to treatment (TT [time from HCV RNA diagnosis to DAA initiation]), and sustained virological response ≥12 weeks after end of treatment (SVR), stratified by age and sex.

Results: Among 6356 pts, 2274 were aged <50 y, 2568 50–65 y, and 1514 > 65 y. Within these age strata, 73%, 65%, and 45%, respectively, were male. Vulnerable populations were well represented, and ~20% of all pts had a history of IV drug use. Irrespective of age, male pts were more likely to have compensated cirrhosis and to be infected with HCV genotype (GT) 3 (Table). Within vulnerable populations, higher likelihood of incarceration among male pts was restricted to those aged ≤65 y. Significantly fewer mental health disorders were seen in male pts. However, use of antipsychotics appeared similar, irrespective of sex. Median TT was shorter in male pts across the age spectrum.

In 5845 pts with a valid result, SVR was high across age ranges, with no significant differences observed between male and female pts (<50 y: female 98.7%, male 99.2%; 50–65 y: female 98.7%, male 98.1%; >65 y: female 99.3%, male 98.3%). 475 pts did not achieve SVR for a non-virological reason; mostly loss to follow-up, with no differences between males and females across age strata.

Conclusion: SOF/VEL shows high cure rates across different age and sex groups. Antipsychotic drug use appeared similar in males and females, despite significantly fewer mental health disorders in male pts. TT varied from 1 day to >6 months and was shorter in males.

Email: cornberg.markus@mh-hannover.de

Background and aims: Sofosbuvir plus velpatasvir (SOF/VEL) is highly effective for the treatment of hepatitis C virus (HCV) infection, but it is only approved in chronic hepatitis C. The EASL recommendations suggest 8-weeks of SOF/VEL for the treatment of acute or recently acquired HCV infection. However, to date there are only data published for 6 and 12 weeks for recently acquired HCV infection. The objective of this study was to evaluate the safety and efficacy of 8 weeks of SOF/VEL treatment for acute HCV monoinfection.

Method: In this investigator-initiated, prospective, multicentre, single-arm study, we recruited a total of 20 adults (≥18 years) with acute HCV monoinfection (proven antibody or RNA seroconversion or ALT >10 ULN with known exposure within 4 month) from nine centers in Germany between March 2019 and June 2021. Patients received SOF/VEL (400/100 mg) as a fixed-dose combination tablet once daily for 8 weeks. The primary efficacy endpoint was the proportion of patients with sustained virological response (undetectable HCV RNA 12 weeks after the end of treatment, SVR12). Other endpoints included biochemical response and safety of SOF/VEL.

Results: The median HCV RNA viral load at baseline was 5.0 log10 IU/ml; the distribution of HCV genotypes was as follows: GT1a/1b/2/3/4: n = 12/1/1/3/3. Thirteen (65%) of the 20 patients were taking medication for HIV pre-exposure prophylaxis. Two patients were lost to follow-up. In the per protocol analysis, all patients achieved SVR12 (n = 18/18 [100%]). Median ALT levels were 249 U/L at baseline and 22 U/L 12 weeks after the end of treatment, with all but one patient (94%) achieving ALT normalization. Treatment was well tolerated; by 12 weeks post-treatment, there was one serious adverse event unrelated to study drug and 6 possible or probable drug-related adverse events with only mild symptoms.

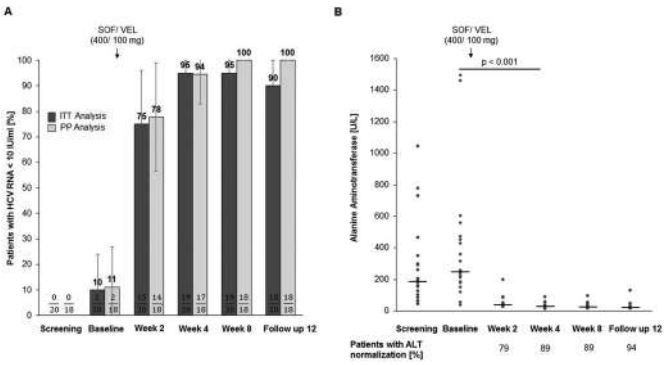

Figure: Response to 8 weeks sofosbuvir (SOF) plus velpatasvir (VEL) (A) Patients with serum HCV RNA levels below <10 IU/ml in the *intention-to-treat* (ITT) and *per protocol* (PP) analysis. percentage ± CI (B) Decline of ALT, median, Friedman test with post hoc analysis

Conclusion: The 8-week treatment with SOF/VEL was well tolerated and highly effective in patients with acute HCV monoinfection. Early treatment of hepatitis C might effectively prevent the spread of HCV in high-risk groups and should therefore be more targeted; ideally, approval for hepatitis C therapy should be pursued independently of chronic hepatitis C.

FRI386

Full-length genome characterization of inherently resistant african HCV genotype 1, subtype 1l in patients failing DAA-based therapy

Slim Fourati[1,2,3], Erwan Vo Quang[2,4], Christophe Rodriguez[1,2,3], Alexandre Soulier[1,2], Vanessa Demontant[1,2], Stéphane Chevaliez[1,2,3], Vincent Leroy[2,3,4], Jean-Michel Pawlotsky[1,2,3]. *[1]APHP-Henri Mondor Hospital, Virology, France; [2]INSERM U955, "Virus Hepatology, Cancer" Team, Créteil, France; [3]Paris-Est Créteil University, Créteil, France; [4]APHP-Henri Mondor Hospital, Hepatology, Créteil, France*
Email: slim.fourati@aphp.fr

Background and aims: Among the so-called "unusual" HCV genotypes, genotype 1, subtype 1l (GT-1l) is common in patients of African origin. GT-1l has recently been suggested to be less responsive to NS5A inhibitor-containing regimens than GT-1a or GT-1b. Here, we used shotgun metagenomics based on deep sequencing to generate full-length HCV genome sequences and characterize amino acid substitutions present at baseline and

selected by DAA therapy in regions targeted or not targeted by DAAs in GT-1l infected patients who failed to achieve SVR.

Method: Shotgun metagenomics were used to generate full-length HCV GT-1l genome sequences. Briefly, library preparation was performed using Total RNA and Nextera XT kit (Illumina). Deep sequencing was performed by means of NextSeq500 (Illumina). Full-length HCV sequences were analyzed using our original in-house MetaMIC® software (1% cutoff).

Results: Among 771 patients with HCV infection treated with DAAs who experienced a virological failure and were referred to our center between 2015 and 2019, 316 (41.0%) were infected with genotype 1, and 20 of them (6.3%) with GT-1l. All GT-1l-infected patients were of African origin. Deep sequencing of full-length HCV GT-1l genomes was performed in 10 patients at baseline and at time of relapse. Treatment regimens were SOF/LDV ± RBV (n = 8), SOF/VEL (n = 1) and SOF/SIM (n = 1).

At baseline, all of the 10 GT-1l patients had ≥3 dominant NS5A resistance-associated substitutions (RASs), including K24G/S (>99%), L31M (>99%) and H58P (>99%). Additionally, baseline NS5A-Q30R was present in 3 patients (>99% in 2 patients; 25% in 1 patient). Sequential analysis of full-length HCV genome sequences showed enrichment of NS5A-Q30R in one patient at failure (>99%) and the selection of NS5A RASs in other patients: baseline K24S (8% and 40%, respectively) replaced by K24G (>99%) in 2 patients; selection of Y93F and Y93H RASs at failure in 2 other patients (20% and 40% respectively).

No NS5B RASs were detected. NS3 R155 K was selected in one patient failing SOF/SIM (30%). No amino acid changes of interest were observed at treatment failure in genome regions other than those targeted by the HCV DAAs administered.

Data on retreatment by triple-combination regimens are ongoing and will be presented.

Conclusion: We report the largest cohort of GT-1l-infected African patients failing DAAs thus far. The large number of NS5A RASs present at baseline explains lower SVR rates with NS5A inhibitor-based therapies in these patients. Our results emphasize the need for identifying this subtype and other "unusual" subtypes (e.g. GT-4r) in Africa where they are common, and the urgent need to guarantee equal access to last-generation DAA therapies in Africa.

FRI387

Treating HCV in dual diagnosis acute psychiatric inpatients with substance use disorder

Vera Dreizin[1], Yael Delayahu[2], David Hovel[1], Gabriela Ilionsky[3], Neil Mfaria[4], Eran Israeli[1]. *[1]Wolfson Medical center, Institute of Gastroenterology, Holon, Israel; [2]Yehuda Abarbanel Mental Health Center, Dual Diagnosis (D) Ward, Bat Yam, Israel; [3]Yehuda Abarbanel Mental Health Center, Dual Diagnosis (D) Ward, Bat Yam, Israel; [4]Yehuda Abarbanel Mental Health Center, Bat Yam, Israel*

Email: verpav1@yandex.ru

Background and aims: People with severe mental illness (SMI) and substance use disorder (SUD) are at increased risk for hepatitis C (HCV). However, only 4.7% receive screening for HCV.

Psychiatric patients with dual diagnosis (DD) of SMI and SUD have multiple risk factors for HCV: homelessness, immigration, imprisonment, coinfections such as HIV or hepatitis B.

However, few treatment approaches have been studied in this patient group.

To describe an on-going project of accessing DD patients during their stay at a psychiatric facility for diagnostic work-up, treatment and follow-up.

Method: We initiated a collaboration between Hepatology clinic of a general hospital and Dual Diagnosis acute Ward (DDW) of a psychiatric hospital for treating HCV patients.

All patients admitted to the DDW are screened for HCV AB. Patients positive for HCV are examined at the facility by the project's expert hepatologist and undergo a full diagnostic workup. Treatment is administered during hospitalization; all patients undergo monthly clinical and laboratory assessment.

Patients discharged from the facility are referred for follow-up to the Hepatology Clinic. We keep close contact with family physicians, rehab centers, medical care providers and families.

Results: From January 2020 to November 2021 we allocated a cohort of 56 HCV patients at different stages of diagnosis and treatment (Table).

We were able to treat 22 patients. 7 have already achieved SVR, 5 have completed treatment and are waiting for SVR, 5 are now being treated and 5 are under investigation. 13 patients had negative HCV PCR due to spontaneous recovery. Two patients died during the follow-up period not due to liver disease. 7 patients were treated for HCV before the psychiatric hospitalization, 12 were not treated. FIB 4 was measured in 30 patients; 43% (13 patients) were with FIB-4 score greater than 1.45. Fibroscan/Fibrotest examination was performed in 26 patients, with evidence of advanced fibrosis in 19% (5 patients). 19 patients were treated by Sofosbuvir/Velpatasvir for 12 weeks and 3 patients were treated with Glecaprevir/Pibrentasvir for 8 weeks. There were no severe adverse events during treatment.

Patients M/F	56 (53/3)
Age	43.6 (24-62)
Multiple psychoactive drugs	56
Substitute treatment	16 (29%)
Active drug users	45 (80%)
Past imprisonment	45 (80%)
Alcohol abuse	43 (77%)
Homeless	36 (64%)
No family	44 (79%)
HIV coinfection	1
HBV coinfection	3
HDV coinfection	1
Liver or kidney transplantation	1
Psychiatric comorbidity	56
Schizophrenia	26 (46%)
Dissocial personality disorder	9 (16%)
Other nonorganic psychosis	21 (38%)
Non psychiatric comorbidity	20 (36%)

Conclusion: We present our ongoing experience of treating HCV in a population of drug dependent patients with SMI during their in-hospital stay. This model has proved efficiency in facilitating their access to care and achieving SVR where no other approach proved successful.

FRI388

Eight-weeks of glecaprevir/pibrentasvir is well tolerated and yields high sustained virological response in HCV-infected treatment-naive patients with compensated cirrhosis: the CREST study

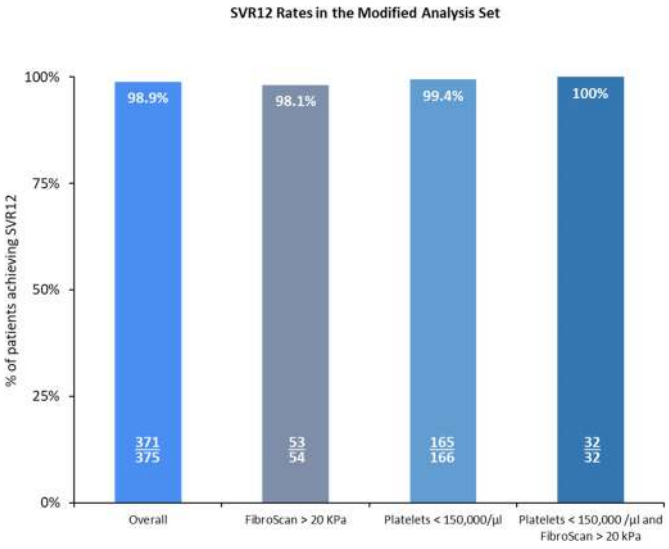
Background and aims: The direct-acting antiviral glecaprevir/pibrentasvir (G/P) is approved for 8-week treatment of chronic hepatitis C genotypes (GT) 1–6 in patients with or without compensated cirrhosis (CC). To support clinical trials findings, this study assessed real-world effectiveness and safety in treatment-naïve (TN) patients with CC treated with 8-weeks' G/P, with a focus on challenging-to-treat patients with advanced liver disease (platelets <150, 000/µl, elasticity >20 kPa [FibroScan®, Echosens, Paris, France], or both), and special populations such as drug users, human immunodeficiency virus coinfection, and psychiatric disorders.
Method: Here we present updated interim results from the CREST study, an ongoing, noninterventional, multicenter study including data from Canada, Germany, Israel, Italy, France, and Spain. The primary endpoint was sustained virologic response at posttreatment Week 12 (SVR12) based on the modified analysis set (MAS) which excluded patients who discontinued G/P for reasons other than nonvirologic failure or with missing SVR12. Safety and laboratory abnormalities were assessed on the full analysis set.
Results: Of 437 patients who received ≥1 dose of G/P, 24.5% (107/437) had GT3, 46.0% (189/411) had platelets <150, 000/µl, 16.4% (61/373) had elasticity >20 kPa, and 9.8% (36/366) had platelets <150, 000/µl and elasticity >20 kPa. Of 375 patients in the MAS with data available, SVR12 was reached by 371 (98.9%). SVR12 was 97.7% (84/86) in patients with GT3, 99.4% (165/166) in those with platelets <150, 000/µl, 98.1% (53/54) in those with elasticity >20 kPa, and 100% (32/32) in those with both elasticity >20 kPa and platelets <150, 000/µl (Figure). Of 117 (26.8%) patients with an adverse event (AE), 5 (1.1%) had a serious AE (SAE), with 1 (0.2%) discontinuing the study drug due to an AE. None of the SAEs were drug related. The most common AEs (>5%) were fatigue (9.6%; 42/437) and headache (6.4%; 28/437). Of 421 patients with laboratory data available, 9 (2.1%) and 10 (2.4%) had alanine or aspartate aminotransferase, respectively, >5x upper limit of normal.



Conclusion: In this real-world cohort, 8-week G/P therapy was well-tolerated, with SVR12 rates similar to those in clinical trials. These results support the use of G/P therapy in TN patients with CC, regardless of liver disease severity or GT, including GT3. Additional efficacy data in special populations will be presented at the congress.
Acknowledgements: The authors would like to express their gratitude to the patients who participated in this study and their families, as well as the study investigators and coordinators of the study. Glecaprevir was identified by AbbVie and Enanta. Medical writing support was provided by Marta Rossi, PhD, of Fishawack Communications Ltd, and funded by AbbVie.

Email: denis.ouzan@wanadoo.fr

Background and aims: Rational: The number of people who inject drugs (PWID) that are screened and treated for hepatitis C remains low. Many of them are lost to follow-up after serological testing. It is currently estimated that 20% of patients are treated in Harm reduction centers (CSAPAs) and in Needle exchange structures (CAARUDs). The measurement of the viral load by rapid RT-PCR from capillary blood (Xpert® HCV Viral Load Fingerstick) allows to obtain a result in <1 hour and thus to increase the percentage of HCV-seropositive patients who could benefit from treatment.
Aims: The aims of this prospective study were to evaluate the feasibility and the acceptability of HCV-RNA viral load fingerstick assay use to improve HCV screening and treatment among French PWIDs attending 3 Addiction Centers.

Method: From March 1, 2021, all HCV seropositive PWIDs (previously known positive for serology or determined using a rapid diagnostic test (RDT) simultaneous targeting HCV, HBV, and HIV) followed up in 3 Addiction Centers CAARUD/CSAPA (2 in Nice, 1 in Marseille) were offered a rapid RNA testing using a molecular point of care testing (POCT) (Xpert HCV Viral Load Fingerstick). If the RNA testing was positive, treatment was proposed.
Results: From March 1 to August 31, 2021, 119 PWID were included: 76.5% men with an average age of 45 years, 22 were without social rights, 26 with precarious housing and 22 homeless, 41 declared having injected: heroin, crack, other, 34 inhaled: cocaine, crack, other, 65 having multiple addictions of which cannabis 35 and drugs 11 and 67 excessive alcohol consumption. 46 were receiving substitution treatment. HCV serology was documented in 117 of the 119 DU and was positive in 43 (37%) of them. HBV surface antigen (HBsAg) was positive in 4 and HIV in 3 DU PWID (all previously known). Among 39/43 anti-HCV+ subjects agreed to perform a rapid RNA testing, HCV RNA was positive in 20, i.e. a prevalence of 16%. Antiviral treatment was initiated in 12. The rate of treatment success will be presented.
Conclusion: Despite the high rate of HCV infection among PWIDs, screening and linkage to care remain far from comprehensive. Our HCV-RNA screening project, highlights the feasibility and the acceptability of onsite testing performed with HCV-RNA viral load fingerstick assay in PWIDs. This easy to use approach increases the frequency of HCV RNA testing and the prescription of treatment.

Email: dorota1010@tlen.pl

Background and aims: The introduction of the direct-acting antivirals (DAA) has improved substantially the therapy effectiveness in patients with chronic hepatitis C and we aimed to compare the efficacy of pangenotypic and genotype-specific DAA in the cohort of genotype (GT) 4 patients with HCV monoinfection and HIV coinfection.
Method: The analysis included patients selected from the EpiTer-2 database, a large retrospective multicenter national real-world study evaluating DAA treatment in 13, 554 consecutive individuals with hepatitis C virus (HCV) infection.
Results: A total of 662 GT4-infected patients, of whom 168 (25.3%) were coinfected with HIV, treated in 2015–2020 were enrolled in the analysis. Significantly higher rate of males (67.9% vs. 57.7%), a lower proportion of liver cirrhosis (10.2% vs. 18.1%), and higher of treatment-naïve patients (87.5% vs. 76.7%) were documented in HIV coinfected individuals. The overall sustained virologic response after exclusion of non-virologic failures was achieved in 98% with no significant difference between HIV-positive and HIV-negative patients, 96.2% vs. 98.5%, respectively. While the genotype-specific regimens resulted in a similar cure rate regardless of the HIV status, the pangenotypic options were more efficacious in patients with HCV monoinfection as compared to HIV coinfected (99.3% vs. 94.4%, p = 0.05). No significant differences in demographic, clinical, and laboratory parameters were found between 13 virologic nonresponders and responders.
Conclusion: We demonstrated the high effectiveness and good safety profile of DAA regimens in GT4 infected patients with HIV coinfection. However, the current analysis demonstrated lower effectiveness of pangenotypic regimens in HIV/HCV GT4 coinfected patients compared to genotype-specific regimens.

Email: julia.dietz@em.uni-frankfurt.de

Background and aims: The approval of direct acting antivirals (DAA) for the treatment of chronic hepatitis C virus (HCV) infection resulted in high sustained virologic response (SVR) rates. Virologic failure is associated with the selection of resistance-associated substitutions (RASs). Long-term persisting RASs may have an impact on retreatment with first generation DAAs in resource-limited settings. This study evaluated the persistence of HCV RASs up to more than 24 months after end of DAA treatment (EOT).
Method: We included samples form n = 715 patients with a HCV GT1 and GT3 infection and virologic treatment failure which were collected in the European Resistance Database. HCV NS3, NS5A and NS5B genes were sequenced population-based and RASs conferring a >2-fold increased DAA susceptibility were analyzed and clinical parameters were evaluated retrospectively.
Results: A total of 253 patients with HCV genotype (GT)1a (35%), 250 with GT1b (35%) and 212 with GT3 (30%) were included and the mean sampling time point after EOT was 7.6 months (0.0–63.0). The majority of patients with GT1 had failed to LDV/SOF (53%) or PrOD (17%) and those with GT3 to DCV/SOF (46%) or VEL/SOF (35%). NS3 RASs reached frequencies of 70–90% after EOT in GT1 and 50% in GT3 after PI failure and disappeared rapidly in GT1b and GT3 after follow-up month 3 (FU3), while in GT1a RASs were stable (≥60%), due to Q80 K.
Within NS5B, SOF-resistant RAS S282 T was only found in individual patients with GT3a. Non-nucleoside NS5B RASs were frequent (60%–90%) in GT1 and declined to 27% in GT1a while remaining stable in

GT1b. NS5A RASs were very common (90%–95% after EOT) in all GT and even after FU24, RASs were detectable in more than 70% of the patients. RAS patterns in GT1b were dominated by L31M and Y93H and both variants showed a stable course over time (FU24: 95% patients with RASs). Several different RASs were detected in GT1a, most common were M28 T, Q30H/R, L31M and Y93H. However, NS5A RASs slightly decreased in GT1a and GT3a which was mainly caused by the decline of high-level resistant Y93H (FU24: GT1a, 71% and GT3, 73% of patients with RASs).
Conclusion: After DAA failure, NS3 and NS5B RASs disappeared quickly and NS5A RASs persisted beyond two years after EOT. While NS5A RASs remained stable in HCV GT1b, patients with GT1a and GT3 showed a decrease in particular of Y93H two years after EOT.

FRI392
Real-life effectiveness and safety of sofosbuvir/velpatasvir in difficult to treat hepatitis C patients
Hyun Young Woo[1], Jeong Heo[1], Young Joo Park[1]. [1]*Pusan National University Hospital, Internal Medicine, Busan, Korea, Rep. of South*
Email: who54@hanmail.net

Background and aims: In spite of recent advance in the treatment of hepatitis C virus (HCV), there are still difficult to treatment population such as prior direct antiviral agents (DAA) failure, decompensated cirrhosis or presence of hepatocellular carcinoma (HCC). Here we report our experience about these patients treated Sofosbuvir/Velpatasvir (SOF/VEL) in real world setting.
Method: All consecutive patients with HCV receiving SOF/VEL between August 2017–May 2021 in South Korea were enrolled. Sustained virological response (SVR) was defined as undetectable HCV-RNA 12 (SVR12) weeks after the end-of-treatment.
Results: A total of 37 patients were included: median age 65 (45–83) years, 59.5% males, median HCV-RNA 852, 500 (11, 100–10, 800, 000) IU/ml. HCV genotype was 1b in 67.6%, 2 in 29.7%, 1b &2b in 2.7%. 37.8% have concomitant HCC (BCLC stage A/B/C; 4/8/2). 56.8% have underlying cirrhosis and 7.5% was decompensated cirrhosis. 70.3% have failed prior DAA treatment (Daclatasvir + asunaprevir n = 16, sofosbuvir+ribavirin n = 3, sofosbuvir + ledipasvir n = 2, glencaprevir+ pibrentasvir n = 3, boceprevir n = 1) Naïve patients received SOF/VEL for 12 weeks and the patients with prior DAA failure received SOF/VEL for 24 weeks, ribavirin was added in 78.4% of treatment schedules. Undetectable HCV-RNA was achieved by 97.2% of patients at week 4 and end of treatment response was 97.2%. Overall, 36/37 (97.2%) patients by intention to treat analysis and 36/36 (100%) by per protocol analysis achieved SVR12, respectively; One patient was expired due to HCC progression during SOF/VEL treatment. Most patient well tolerated treatment without adverse events.
Conclusion: SOF/VEL is an effective and safe retreatment for difficult to treat HCV population in a real-life setting.

Email: a.mangia@tin.it

Background and aims: Current EASL, AASLD and APASL guidelines recommend a thorough drug–drug interaction (DDI) evaluation before starting pangenotypic direct-acting antiviral (pDAA) therapy. Previous studies have analyzed DDIs in HCV patients receiving pDAAs and comedications only by pairwise interactions. However, this does not reflect the polypharmaceutical reality of many HCV patients. The aim of this study was to evaluate the proportion of HCV patients with multiple comedications causing potential DDIs in three European countries.
Method: Comedication prescription data were collected from patients treated with pDAAs in Germany, Italy, and Spain. DDIs were identified using the Liverpool Hep Interaction checker. A multi-DDI profile was defined as the use of ≥2 comedications each predicted with a DDI with the administered pDAA. Potential DDI outcomes were summarized as an increase in comedication exposure (impact on safety) or a decrease in DAA exposure (impact on efficacy).
Results: A total of 10, 755 HCV patients (mean age: 53.6 years, 64.2% male) treated with either sofosbuvir/velpatasvir (n = 4583) or glecaprevir/pibrentasvir (n = 6172) were included in this multi-national analysis: 4950 from Germany, 4185 from Italy, and 1620 from Spain. Over one-half, 58.9% (6333/10, 755) received any comedication during their pDAA therapy, and 20.2% (2177/10, 755) were at risk of a DDI with their pDAA. In terms of multi-DDI risk, 566 patients were taking ≥2 comedications, each with a potential DDI with their pDAA. This represented 5.3% (566/10, 755) of the HCV patient population and 8.9% (566/6333) of patients receiving any comedication. Evaluation of predicted DDI impact revealed that approximately one-quarter (23.9%; 135/566) of patients taking ≥2 comedications had a risk of decreasing DAA plasma exposure, mainly caused by gastrointestinal drugs, such as proton-pump inhibitors, and analgesics, such as metamizole. This was observed mainly in Germany and Spain. A further one-quarter of patients (26.5%; 150/566) had a risk of increasing comedication, posing a potential safety risk, mainly in cardiovascular drugs, such as statins, and nervous system drugs, such as antipsychotics.
Conclusion: Across Germany, Italy, and Spain, 8.9% of HCV patients taking medications concomitantly during their pDAA therapy are at risk of multiple DDIs. Accurate prediction of the impact of multiple DDIs on pDAA efficacy and safety is difficult; this should prompt a thorough pDDI assessment before HCV therapy in comorbid patients.

FRI394

Use of comedication in patients with hepatitis C and addiction or drug abuse treated with direc-acting antivirals: implication in drug-drug interactions

Juan Turnes[1], Antonio Garcia Herola[2], Ramón Morillo Verdugo[3], Marinela Mendez Pertuz[4], Cristina De Alvaro[5], Candido Hernández[6], Antoni Sicras-Mainar[7]. *[1]CHU, Pontevedra, Gastroenterology and Hepatology Department, Pontevedra, Spain; [2]Hospital Marina Baixa de Villajoyosa, Digestive Medicine Department, Alicante, Spain; [3]Hospital de Valme, AGS Sur de Sevilla, Hospital Pharmacy, Sevilla, Spain; [4]Gilead Sciences S.L., Madrid, Spain, Medical Affairs, Madrid, Spain; [5]Gilead Sciences S.L., Madrid, Spain, Medical Affairs, Madrid, Spain; [6]Gilead Sciences Europe Ltd, Global Medical Affairs, United Kingdom; [7]Atrys Health, Health Economics and Outcomes Research, Barcelona, Spain*
Email: ansicras@atryshealth.com

Background and aims: In previous studies we have analysed drug-drug interactions (DDIs) in the general population. In this sub-analysis we focus on patients with addiction to substance or drug abuse. The objective is to describe the drug use, comedication and the associated risk of drug interactions.

Method: Retrospective observational study, obtained from the BIG-PAC database (Atrys Health), on HCV patients (pts) treated between 2017 and 2020. Possible DDIs with direct-acting antivirals (DAAs) (Sofosbuvir/Velpatasvir [SOF/VEL] and Glecaprevir/Pibrentasvir [GLE/PIB]) were evaluated using the University of Liverpool Interactions for Hepatitis database. The risk of DDIs was analyzed, as well as their potential outcome: increase (↑) in comedication concentration or ↑ DAA (possible impact on safety) and decrease in DAA, ↓DAA (possible impact on efficacy).

Results: 985 pts with history or current consumption of abuse and recreational substances were included, 450 for SOF/VEL (mean age: 53 years; men 65%; F3/4 42%) and 535 with GLE/PIB (mean age: 50 years; men 65% F3/4 30%). The most consumed substances are described in the table, highlighting the higher consumption of opioids in pts treated with SOF/VEL vs GLE/PIB (13% vs 9%, $p < 0.05$, respectively).

The mean number of medications prescribed was 3.9 for SOF/VEL and 2.1 for GLE/PIB ($p < 0.001$). The most prescribed drugs belonged to the nervous system (40%); anti-infectives for systemic use, (13%); cardiovascular (12%) and alimentary system (12%).

GLE/PIB presented a higher percentage of potential DDIs than SOF/VEL, with nervous system medication (8.5% vs 4.9%, $p < 0.01$) and cardiovascular (36.8% vs 13.7%, $p < 0.001$); and similar for alimentary system (45.4% vs 44.7%, ns) and anti-infectives (5.8% vs 6.9%, ns). The most prescribed nervous system drugs with potential DDIs were quetiapine and metamizole.

Table: Addiction to substances or drug abuse for HCV patients treated with AADs

Study groups Number of patients, %	SOF / VEL 450 (45,7%)	GLE / PIB 535 (54,3%)	Total 985 (100%)	p
Addictions				
Chronic alcoholism	110 (24%)	105 (20%)	215 (22%)	0.068
Opioids	60 (13%)	47 (9 %)	107 (11%)	0.022
Sedatives-anxiolytics	140 (31%)	136 (25%)	276 (28%)	0.048
Cannabis	198 (44%)	235 (44%)	433 (44%)	0.981
Cocaine	116 (26%)	142 (26%)	258 (26%)	0.786
Heroin	80 (18%)	77 (14%)	157 (16%)	0.148

Conclusion: In Spain, 9% of HCV patients with addictions to substance or drug abuse taking ≥2 comedications are at risk of multi-DDIs.

FRI395

Five years of progress towards achieving hepatitis C elimination in the country of Georgia, April 2015-October 2021

Tengiz Tsertsvadze[1,2], Amiran Gamkrelidze[3], Nikoloz Chkhartishvili[1], Akaki Abutidze[1,2], Lali Sharvadze[2,4], Vakhtang Kerashvili[1], Maia Butsashvili[5], David Metreveli[6], Lia Gvinjilia[7], Tinatin Kuchuloria[7], Shaun Shadaker[8], Tamar Gabunia[9], Ekaterine Adamia[10], Stefan Zeuzem[11], Nezam Afdhal[12], Sanjeev Arora[13], Karla Thornton[13], Paige A Armstrong[8]. *[1]Infectious Diseases, AIDS and Clinical Immunology Research Center, Tbilisi, Georgia; [2]Ivane Javakhishvili Tbilisi State University, Tbilisi, Georgia; [3]National Center for Disease Control and Public Health, Tbilisi, Georgia; [4]Clinic Hepa, Tbilisi, Georgia; [5]Health Research Union, Tbilisi; [6]Medical Center Mrcheveli; [7]The Task Force for Global Health; [8]Centers for Disease Control and Prevention, Division of Viral Hepatitis National Center for HIV, Hepatitis, STD&TB Prevention, Atlanta, USA; [9]Ministry of IDPs, Labour, Health and Social Affairs of Georgia, Tbilisi, Georgia; [10]Ministry of IDPs from the Occupied Territories, Labour, Health, and Social Affairs of Georgia; [11]University of Frankfurt; [12]Beth Israel Deaconess Medical Center Liver Center; [13]University of New Mexico*
Email: tt@aidscenter.ge

Background and aims: Georgia launched the world's first national hepatitis C elimination program in April 2015. Key strategies include nationwide screening, active case finding, linkage to care, decentralized care, and provision of treatment for all persons with hepatitis C virus (HCV) infection, along with effective prevention interventions. The elimination program aims to achieve the following targets: a) diagnose 90% of HCV-infected persons, b) treat 95% of those diagnosed, and c) cure 95% of those treated. We report progress towards elimination targets 5 years into the elimination program.

Method: The estimated number of persons living with HCV infection was based on a 2015 population-based national seroprevalence survey, which showed that 5.4% of the adult general population had chronic HCV infection (approximately 150, 000 persons). We analyzed data in the national HCV screening and treatment databases during April 2015–October 2021.

Results: As of October 31, 2021, 146, 533 persons screened positive for HCV antibodies, 145, 572 of whom were adults. Of the adults who screened positive, 119, 280 (81.9%) underwent HCV viremia testing. A total of 94, 891 (79.6%) persons tested had active HCV infection, and 76, 149 (80.2%) of them initiated treatment. Of 53, 806 patients who were evaluated for sustained virologic response (SVR), 53, 230 (98.9%) tested negative for HCV by PCR. Based on the 90-95-95 program goal, Georgia has diagnosed 63.3% of the estimated 150, 000 adults living with chronic HCV, treated 59.4% of the target 128, 250, and cured 43.7% of the target 121, 837.

High cure rates were achieved for all HCV genotypes: 98.9% in genotype 1, 98.9% in genotype 2 and 98.3% in genotype 3, typically the most challenging to treat. Treatment effectiveness was comparable among persons with advanced fibrosis (F3 and F4) with 98.2% achieving SVR, and among patients with mild or no liver fibrosis (≤F2), SVR = 99.1%.

Conclusion: Georgia has made substantial progress towards eliminating hepatitis C. Over 60% of persons with chronic HCV infection have been diagnosed, and most have initiated treatment with high cure rates regardless of fibrosis status. Challenges remain in identifying and linking to care persons living with HCV in Georgia. The Nationwide integrated, decentralized model of HCV treatment, which has already been implemented in many locations, will be critical to improve linkage to care and close gaps in the HCV cascade of care.

FRI396

Simplifying mathematical-based response guided therapy for reducing duration of direct acting antivirals in chronic hepatitis C infected patients

Ashish Goyal[1], Alex Churkin[2], Danny Barash[3], Scott Cotler[1], Amir Shlomai[4,5], Ohad Etzion[6], Harel Dahari[1]. [1]*Program for Experimental & Theoretical Modeling, Division of Hepatology, Department of Medicine, Stritch School of Medicine, Loyola University Chicago, Maywood, United States;* [2]*Department of Software Engineering, Sami Shamoon College of Engineering, Beer-Sheba, Israel;* [3]*Department of Computer Science, Ben-Gurion University, Beer-Sheba, Israel;* [4]*Department of Medicine D and The Liver Institute, Rabin Medical Center, Beilinson Hospital, Petah-Tikva;* [5]*Sackler Faculty of Medicine, Tel Aviv University, Tel Aviv;* [6]*Soroka University Medical Center, Beer-Sheba*
Email: harel.dahari@gmail.com

Background and aims: We recently reported the first proof-of-concept clinical trial assessing in real-time the utility of response-guided therapy (RGT) with direct-acting antivirals (DAA) in chronic hepatitis C virus (HCV) infected patients, based on a mathematical modeling approach (Etzion et al. *Scientific Reports*. 2020;10:17820). The RGT modeling approach relies on measuring HCV at baseline and days 2, 7, 14 and 28 after initiation of DAA therapy. A simplified on-treatment HCV monitoring procedure is highly warranted.

Method: The mathematical model used in the proof-of-concept study was re-fitted with the measured HCV kinetic data obtained from the 10 patients for whom the model was used to shorten the standard 12-week DAA therapy duration. The fitting procedure consisted of finding the best fits using corrected Akaike Information Criteria. The predicted time to cure (TTC) was defined as the time it takes during DAA therapy to reach less than 1 viral copy in the serum (i.e. 7×10^{-5} copies/ml). The first data point below detection or lower limit of quantification (LLOQ) was assigned a value ($\in[0.2, 15]$ IU/ml) as done in the proof-of-concept study. We next removed either day 2 or day 7 from the 10 patients and repeated the same procedure projecting TTC. Modeling calibration was done using MATLAB R2021a.

Results: We first verified that fitting the model to all the measured data points measured in the proof-of-concept study were in agreement with the current modeling approach (Table 1). Excluding day 2 did not affect maximum TTC projections (Table 1) and TTC were significantly correlated ($r = 0.91$, $p = 0.0007$) with the predicted TTC based on all measured data points. Notably, while excluding day 2 caused potential non-identifiability in estimating HCV viral clearance from circulation, the estimation of TTC remained unaffected. In contrast, excluding day 7 would lead to overestimation of the maximum TTC projections ($r = 0.29$, $p = 0.45$) (Table 1).

Patient	Etzion et al. *Scientific Reports*.2020;10:17820	Full observed data	Excluding day 2	Excluding day 7
P1	59	59 [59, 59]	59 [59, 59]	60 [52, 67]
P2	46	45 [45, 45]	44 [44, 44]	47 [45, 76]
P3	36	36 [36, 36]	27 [26, 32]	36 [36, 37]
P4	56	58 [58, 58]	58 [58, 58]	93 [93, 93]
P6	43	42 [42, 42]	40 [40, 40]	56 [56, 56]
P7	55	54 [54, 56]	47 [47, 47]	55 [54, 55]
P8	53	51 [50, 54]	54 [53, 54]	55 [55, 55]
P9	56	55 [55, 57]	57 [57, 57]	56 [56, 56]
P10	44	44 [44, 44]	44 [44, 44]	45 [45, 45]
P11	53	53 [53, 53]	53 [53, 53]	44 [42, 46]

Table 1: Modeling predicted time to cure (TTC) in 10 individuals from Etzion et al. The estimates are reported as median [minimum, maximum] in three scenarios, namely, (i) analyzing fully observed data, (ii) analyzing dataset while removing day 2, and (iii) analyzing dataset while removing day 7.

Conclusion: The current analysis indicates that on-treatment day 2 viral load measurement is not necessary to predict TTC. Measuring HCV at baseline and days 7 and 14 after initiation of DAA therapy provides a simplified on-treatment monitoring procedure during modeling-based RGT. Further validation in a large-scale clinical trial, will support the routine implementation of our individualized treatment approach in patients receiving DAA for HCV.

FRI397

Epidemiology of hepatitis B virus infection among hepatitis C (HCV) infected patients treated within HCV elimination program in Georgia

Senad Handanagic[1], Maia Butsashvili[2], Shaun Shadaker[1], Irina Tskhomelidze[3,3,3], Paige A Armstrong[1]. [1]*Centers for Disease Control and Prevention, Division of Viral Hepatitis, Atlanta, United States;* [2]*Health Research Union, Tbilisi, Georgia;* [3]*The Task Force for Global Health, Tbilisi, Georgia*
Email: ndv9@cdc.gov

Background and aims: Patients with hepatitis C virus (HCV) and hepatitis B virus (HBV) co-infection are at an increased risk of developing liver disease compared with mono-infected individuals. The Georgia Hepatitis C Elimination Program was established in 2015 and offers free treatment with direct-acting antivirals (DAA) to all persons with HCV infection. The program includes HBV screening for all HCV infected patients. We describe the epidemiology of HBV/HCV co-infection among patients treated within the HCV elimination program.

Method: Data for this analysis comes from the national electronic HCV elimination program treatment database. Persons aged ≥18 years with active HCV infection who initiated HCV treatment within the program during May 2015–September 2021 were included. Patients were grouped as HCV mono-infected, HCV/HBV coinfected (HBV surface antigen [HBsAg] positive), and HBV immune but not infected (HBV surface antibody or HBV core antibody positive, HBsAg negative). We present descriptive analysis and adjusted prevalence ratios (aPR) with 95% confidence intervals (CI) for HCV/HBV coinfection compared to HCV mono-infection for demographic, risk, clinical and treatment outcomes. aPRs were adjusted for age, sex, HCV genotype, and history of injection drug use in a multivariable model.

Results: As of September 2021, 71, 931 adult persons were treated for HCV and screened for HBV within the HCV elimination program in Georgia. The majority were 18–45 years old (48%; median age 46, interquartile range 39–55 years), male (78%), and did not report a history of injection drug use (57%).

Overall, 70% (n = 50, 103) had HCV mono-infection, 28% (n = 2, 202) had HCV mono-infection and were immune to HBV, and 2% (n = 1, 626) had HBV/HCV co-infection. HBV/HCV co-infection was more common among persons who were 18–45 compared to 46–60 years old (aPR: 1.7, 95% CI: 1.5–2.0), male (aPR: 1.3, 95% CI: 1.1–1.6), reported a history of injection drug use (aPR: 1.3, 95% CI: 1.1–1.5), had serum end of treatment (EOT) ALT >80 U/L compared to <40 U/L (aPR: 2.3, 95% CI: 1.6–3.4), and did not achieve sustained virologic response (aPR: 1.4, 95% CI:1.1–1.9).

Conclusion: HBV/HCV co-infection is associated with higher risk of liver disease, elevated EOT ALT, and DAA treatment failure. To improve outcomes for patients with HBV/HCV co-infection, it is essential to evaluate them for HBV treatment. Promoting preventative measures, such as HBV vaccination among patients with HCV infection, is also important to reduce mortality from hepatitis.

FRI398

Direct-acting antivirals and the risk of hepatitis B reactivation in hepatitis B and C coinfected patients: a systematic review and meta-analysis

Joo Hyun Oh[1], Sang Bong Ahn[1], Jeong-Ju Yoo[2], Dae Won Jun[3], Hyunwoo Oh[4], Huiyul Park[5], Joo Hyun Sohn[6], Hyo Young Lee[4], Bo-Kyeong Kang[7], Mi Mi Kim[7], Eileen Yoon[3], Chul-min Lee[7]. *[1]Nowon Eulji Medical Center, Eulji University School of Medicine, Department of Medicine, Seoul, Korea, Rep. of South; [2]Soonchunhyang University Bucheon Hospital, Department of Medicine, Gyeonggi-do, Korea, Rep. of South; [3]Department of Internal Medicine, Hanyang University College of Medicine, Seoul, Korea, Rep. of South; [4]Uijeongbu Eulji Medical Center, Department of Medicine, Gyeonggi-do, Korea, Rep. of South; [5]Uijeongbu Eulji Medical Center, Department of Family Medicine, Gyeonggi-do, Korea, Rep. of South; [6]Hanyang University College of Medicine, Department of Medicine, Gyeonggi-do, Korea, Rep. of South; [7]Hanyang University College of Medicine, Department of Radiology, Seoul, Korea, Rep. of South*
Email: dr486@eulji.ac.kr

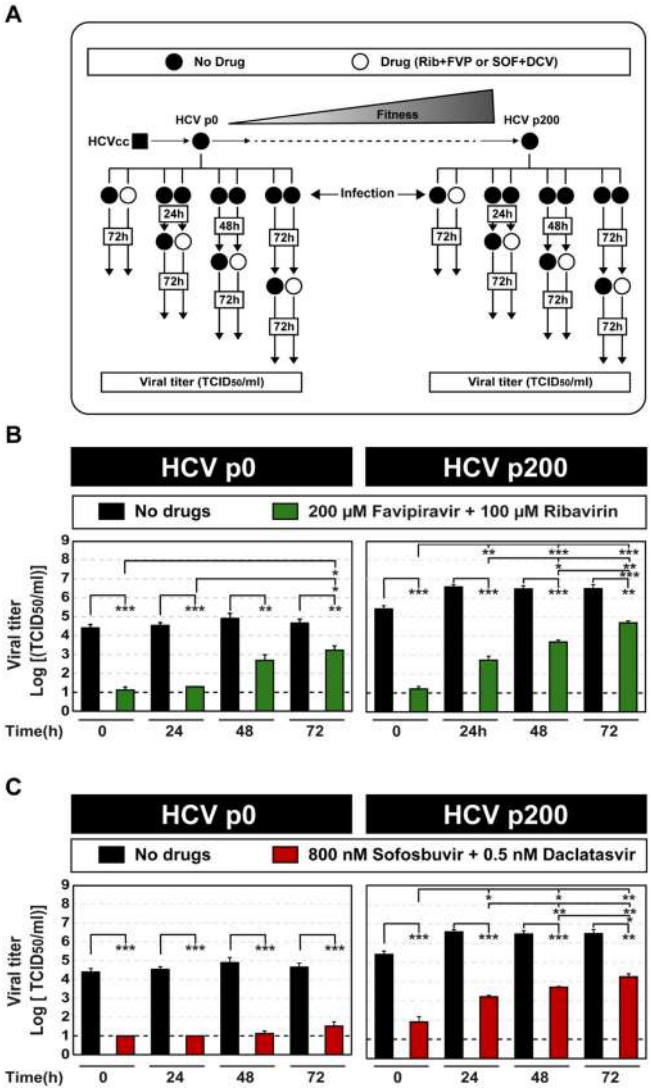
Background and aims: Hepatitis B virus (HBV) reactivation may occur in chronic hepatitis C (CHC) coinfected patients using direct-acting antivirals (DAAs). However, previous studies have reported inconsistent findings on this issue. We investigated the association between DAA and HBV reactivation by conducting a meta-analysis.
Method: Relevant studies were identified by searching Medline, EMBASE, Cochrane Central Register of Controlled Trials, KoreaMed, KMbase, and RISS to September 4th, 2020. The primary outcome was HBV reactivation. Random effect method was used for pooling the data.
Results: We identified 39 articles, comprising 119, 484 patients with chronic (n = 1, 673) or resolved (n = 13, 497) HBV infection who treated with DAA. When all studies were pooled, the rate of HBV reactivation was 12% (95% confidence interval (CI) 0.06–0.19). When stratified by baseline HBV DNA, undetectable HBV DNA (HBV DNA <20 IU/ml) group showed significantly lower risk of reactivation compared to detectable HBV DNA group (odds ratio (OR) 0.30, 95% CI 0.11–0.86). Although patients on prophylactic anti-HBV therapy showed a lower reactivation rate, there was no significant difference (OR 0.27, 95% CI 0.07–1.01). The rate of HBV reactivation was only 0.4% in patients with resolved HBV infection.
Conclusion: The risk of HBV reactivation was not negligible in HCV coinfected patients using DAAs, indicating watchful attention for HBV reactivation is still needed.
Key Words: Direct -acting antivirals, hepatitis B virus, hepatitis C virus, reactivation

FRI399

Inhibition of high fitness viruses by different antiviral strategies when the infection has started

Carlos García-Crespo[1], Lucía Vázquez-Sirvent[1], Maria Eugenia Soria[1], Isabel Gallego[1], Ana Isabel de Ávila[1], Brenda Martínez-González[1,2], Esteban Domingo[1,3], Celia Perales[1,2,3]. *[1]Centro de Biología Molecular Severo Ochoa, Department of Interactions with the environment, Madrid, Spain; [2]Hospital Universitario Fundación Jiménez Díaz, Department of Clinical Microbiology, Madrid, Spain; [3]Centro de Investigación Biomédica en Red de Enfermedades Hepáticas y Digestivas, Spain*
Email: cperales@cbm.csic.es

Background and aims: Previous results from our laboratory have documented that high fitness hepatitis C virus (HCV) can be a determinant of multidrug resistance, including nucleotide analogues, without the acquisition of specific resistance mutations. However, we recently demonstrated using favipiravir (T-705) and ribavirin that analogue concentrations that individually did not extinguish high fitness HCV in ten serial infections, when used in combination led to extinction in a few passages. With these two nucleotide analogues, we have described for the first time a new synergy mechanism in lethal mutagenesis against HCV. Here we have investigated the effectiveness of these strategies once the infection has been initiated, as a stringent tests of antiviral efficacy. Combinations of inhibitors and combinations of lethal mutagens were compared. Since new antiviral designs based on sequential inhibitor-mutagenic have proven effective for the extinction of RNA viruses, sequential versus combination therapies have been also examined for suppression of high fitness HCV infectivity once the infection was ongoing.
Method: Low and high fitness HCV populations were used to infect Huh-7.5 hepatoma cells in the absence and presence of mutagenic (ribavirin and favipiravir) and non-mutagenic (sofosbuvir and daclatasvir) antiviral agents. Treatment efficacy was analyzed by measuring virus progeny production when antivirals were administered at different times after infection. In addition, sequential and combination treatments were compared for the extinction these viruses.
Results: The results indicate that low and high fitness viruses were not extinguished by combinations of mutagenic antivirals once the infection is ongoing. Treatment efficacy was lower when time of infection increased. Sequential and combination therapies produced a similar inhibition, without achieving viral extinction.



Conclusion: The time at which antiviral agents were administered once the infection have been initiated influenced viral extinction independently of the mechanism of action of the antivirals (both

non-mutagenic and mutagenic agents). Also, the data reinforce that high viral fitness is a determinant of drug resistance independently of the type of therapy used (sequential and combination therapies). No significant differences were observed between both therapies for the extinction of high fitness HCV.

Treatment of hepatitis C in primary healthcare in the country of Georgia

Tengiz Tsertsvadze[1,2], Amiran Gamkrelidze[3], Nikoloz Chkhartishvili[1], Akaki Abutidze[1], Lali Sharvadze[2,4], Maia Butsashvili[5], David Metreveli[6], Lia Gvinjilia[7], Tinatin Kuchuloria[7], Shaun Shadaker[8], Tamar Gabunia[9], Ekaterine Adamia[9], Stefan Zeuzem[10], Nezam Afdhal[11], Sanjeev Arora[12], Karla Thornton[12], Paige A Armstrong[8]. *[1]Infectious Diseases, AIDS and Clinical Immunology Research Center; [2]Ivane Javakhishvili Tbilisi State University; [3]National Center for Disease Control and Public Health; [4]Clinic Hepa; [5]Health research union; [6]Medical Center Mrcheveli; [7]The Task Force for Global Health; [8]Centers for Disease Control and Prevention, Division of Viral Hepatitis National Center for HIV, Hepatitis, STD&TB Prevention, Atlanta, USA; [9]Ministry of IDPs, Labour, Health and Social Affairs of Georgia, Tbilisi, Georgia; [10]University of Frankfurt; [11]Goethe University Hospital; [12]University of New Mexico*
Email: tt@aidscenter.ge

Background and aims: With technical assistance from the U.S. CDC and support from Gilead Sciences, Georgia launched the world's first national hepatitis C elimination program in April 2015. By October 2021, more than 75 thousand persons initiated treatment, achieving >98% cure rates. Patient enrollment in hepatitis C virus (HCV) treatment sharply increased in 2016, but has since slowed due to challenges in HCV testing and linkage to care. To increase initiation of treatment, Georgia began service decentralization in 2018 by integrating HCV screening and treatment in primary healthcare centers (PHCs).

Method: By July 31 2021, a total of 10 PHCs were providing HCV care services throughout the country. The integrated model is based on "one stop shop" approach, where patients receive all HCV screening and care services in selected PHCs. Treatment naïve patients with no or mild fibrosis (FIB-4 score <1.45) receive care at PHCs and completed examinations according to a simplified diagnostic and treatment monitoring algorithm, and persons with FIB-4 score >1.45 were referred to specialized clinics. Patients received Sofosbuvir/Ledipasvir or Sofosbuvir/Velpatasvir for 12 weeks. Sustained virological response (SVR) was defined as undetectable HCV RNA 12–24 weeks after end of therapy. The Extension for Community Healthcare Outcomes (ECHO) telemedicine model was used to train and support primary healthcare providers. Regular teleECHO videoconferencing was conducted to provide primary care providers with advice and clinical mentoring.

Results: Among persons diagnosed with active HCV infection, 1, 454 were evaluated for FIB-4 score. A total of 954 patients initiated treatment, and of them 883 (92.6%) completed treatment. Of 864 patients eligible for SVR testing, 696 (80.6%) had been tested at the time of analysis, and 683 (98.1%) achieved SVR, yielding a >98% cure rate.

Conclusion: Our study reported the effectiveness of a simplified HCV treatment model in PHCs. Expanding this integrated decentralized model of HCV treatment nationwide would provide an opportunity to improve linkage to care and close gaps in the HCV cascade of care.

FRI401

Optimal screening and linkage to care model to achieve hepatitis C elimination targets in Georgia

Tengiz Tsertsvadze[1,2], Amiran Gamkrelidze[3], Nikoloz Chkhartishvili[1], Akaki Abutidze[1], Lali Sharvadze[2,4], Vakhtang Kerashvili[1], Manana Todua[2], Maia Butsashvili[5], David Metreveli[6], Lia Gvinjilia[7], Tinatin Kuchuloria[7], Shaun Shadaker[8], Tamar Gabunia[9], Ekaterine Adamia[9], Stefan Zeuzem[10], Nezam Afdhal[11], Sanjeev Arora[12], Karla Thornton[12], Paige A Armstrong[8]. *[1]Infectious Diseases, AIDS and Clinical Immunology Research Center; [2]Ivane Javakhishvili Tbilisi State University; [3]National Center for Disease Control and Public Health; [4]Clinic Hepa; [5]Health research union; [6]Medical Center Mrcheveli; [7]The Task Force for Global Health; [8]Centers for Disease Control and Prevention, Division of Viral Hepatitis National Center for HIV, Hepatitis, STD&TB Prevention, Atlanta, USA; [9]Ministry of IDPs, Labour, Health and Social Affairs of Georgia, Tbilisi, Georgia; [10]University of Frankfurt; [11]Beth Israel Deaconess Medical Center Liver Center; [12]University of New Mexico*
Email: tt@aidscenter.ge

Background and aims: Access to care and treatment is essential to achieving hepatitis elimination, however, ensuring all patients can navigate the care pathway is challenging and involves multiple steps. Despite marked success of Georgia's National Hepatitis C Elimination Program, with over 75, 000 persons initiating treatment April 2015–October 2021, since a peak in October 2016, patient enrollment in treatment has slowed. Developing an optimal model to ensure linkage-to-care at critical steps in the care cascade is paramount for the elimination program.

Method: We evaluated the effectiveness of various linkage-to-care modalities to assess diagnostic yield and engagement in hepatitis C virus (HCV) treatment. HCV care cascades for the period of March 2018–November 2020 were analysed and classified into 6 categories based on where the initial screening was performed: centralized and decentralized hospital sector, primary healthcare, harm reduction, specialized HCV provider sites and integrated HCV/HIV/TB screening locations. We defined linkage to care as: 1) completion of a viremia test after screening HCV antibody (anti-HCV) positive; and 2) establishment of a follow-up appointment for treatment with a hepatitis C specialist.

Results: Analysis included 24, 460 anti-HCV positive persons. Persons engaged through the HCV provider site model had the highest rates of both viremia testing and engagement in treatment (91.5% and 87.1%, respectively). These were significantly higher than all other models, including harm reduction (86.2% and 77.8%), decentralized hospital sector (79.5% and 61.6%), integrated HCV/HIV/TB (75.1% and 79.9%), centralized hospital sector (74.5% and 45.6%), and primary healthcare (63.6% and 69.1%) models; all $p < 0.0001$. The primary healthcare model had the lowest rate of viremia testing (63.6%), while the centralized hospital sector had the lowest engagement in treatment (45.6%).

Conclusion: Our data suggest the HCV provider site screening model has been most successful in linking persons to care, for both viremia testing and initiation of treatment. Universal inpatient screening has been effective at testing large numbers of people; among the hospital sector models, the decentralized approach to testing had higher rates of viremia testing and treatment. Decentralization of care is key to providing access to all, but the primary healthcare model showed the lowest rate of viremia testing in our study.

FRI402

Establishing a protocol for management and DAA treatment of HCV during pregnancy: adherence to a co-located care protocol

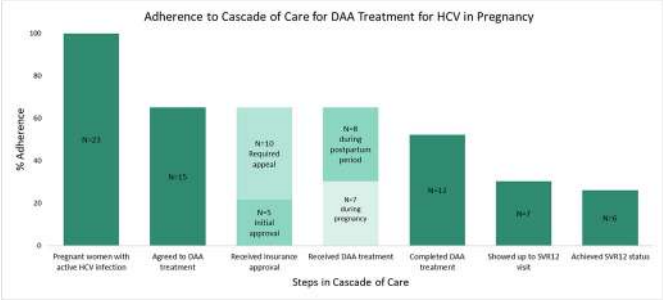
Tatyana Kushner[1], Marcia Lange[1], Rhoda Sperling[1], Douglas T Dieterich[1]. *[1]Icahn School of Medicine at Mount Sinai*
Email: tatyana.kushner@mssm.edu

Background and aims: There are currently no recommendations for directly acting antiviral (DAA) therapy during pregnancy. Emerging

data suggests that DAAs are safe and effective during pregnancy. We evaluated our center experience in implementing DAA treatment during pregnancy.

Method: After establishment of a sub-specialty Women's Liver Clinic (WLC) co-located in the ambulatory obsetrics practice and implementation of universal antepartum HCV screening, we offered DAA treatment during pregnancy to women with active HCV. We evaluated adherence to each step in the HCV treatment cascade of care.

Results: Twenty-three pregnant women with active HCV infection were referred to WLC for consideration for HCV treatment; they were of median age 31 (IQR 24, 36); predominantly white (39%) non-Hispanic (52%), and medicaid-insured (78%); 30% with injection drug use as a risk factor; 9% who acquired HCV through perinatal transmission; 26% with no known risk factors. Fifteen (65%) reported that HCV was initially diagnosed during pregnancy. Adherence to cacade of care is shown in the Figure. Initial DAA ordered was ledipasvir/sofosbuvir for 7 (42%), ledipasvir/velpatasvir for 7 (42%) and gleceprevir/pibrentasvir for 2 (12%). Among those with DAA approval, nine (45%) received their DAA during pregnancy and seven (35%) initiated DAA treatment during pregnancy; eight (40%) initiated postpartum. Twelve (70%) had documented completion of DAA treatment; only 7 (35%) showed up to their SVR12 check; 6/7 (86%) had documented SVR12; one patient required re-treatment. In regards to pregnancy outcomes, 35% had intrahepatic cholestasis of pregnancy; two (9%) had preterm birth; one patient had pregnancy loss prior to DAA treatment initiation. There was one documented mother-to-child transmission in a patient treated with DAA postpartum.



Conclusion: Pregnancy offers an important opportunity to link women with HCV to treatment-the majority were diagnosed initially during routine screening during pregnancy. Cholestasis of pregnancy was a prevalent complication. HCV treatment during pregnancy is feasible and will likely offer benefits to maternal and child health, however significant challenges remain to ensure adherence through the vulnerable postpartum period. Similar to the management of other chronic conditions in the postpartum period, linkage to care and case management programs designed specifically for post-partum women should be evaluated to improve DAA therapy completion and documentation of SVR12.

FRI403

Sofosbuvir/Velpatasvir (S/V) for the treatment of HCV infection among vulnerable inner-city residents: extending the results of clinical trial

Brian Conway[1,2], David Truong[1], Leo Yamamoto[1], Rossitta Yung[1], Shawn Sharma[1]. [1]*Vancouver Infectious Diseases Centre, Vancouver, Canada;* [2]*Simon Fraser University, Burnaby, Canada*
Email: bconway5538@gmail.com

Background and aims: The SIMPLIFY study demonstrated that sofosbuvir/velpatasvir (S/V) can be used to treat Hepatitis C Virus (HCV) infection among active drug users, achieving sustained virologic response (SVR) 12 rates comparable to those achieved in clinical trials enrolling other patient populations. There remains a need to replicate these results in more vulnerable populations, including those using fentanyl and not currently engaged in health care.

Method: Through dedicated outreach events, we identified HCV-infected patients who resided in single room occupancy dwellings who were not currently engaged in health care and who were eligible to receive government-funded antiviral treatment for HCV infection. We offered them the opportunity to enrol in a multidisciplinary program of care to address medical, psychological, social and addiction-related needs and provide S/V therapy in this context, with daily or weekly supervision of adherence, as appropriate. The endpoint of this preliminary analysis is the achievement of SVR12 in those who initiated therapy.

Results: We identified 172 eligible HCV-infected treatment-naïve subjects who were subsequently enrolled in the program. HCV diagnosis was documented 1–41 years before enrolment. Key demographic characteristics include: 126 (73%) male, median age 47 (23–75) years, F0/1 (120, 70%), ≥F2 (52, 30%), opiate/cocaine/amphetamine use (126/66/112, 73%/38%/65%). Once enrolled in care, 38 (22%) initiated addiction care with opiate agonist therapy. Of 142 who initiated treatment, 95 were available at the SVR12 time point to date. Of these, 88 achieved a cure. The main reasons an endpoint was not measured included 3 overdose-related deaths prior to SVR 12 time point and 4 disengaged from care. There were no cases of virologic failure or relapse.

Conclusion: Through dedicated initiatives, it is possible to identify vulnerable inner-city residents who were previously diagnosed with HCV infection and had never been offered treatment for it. These initiatives, combined with dedicated programs to provide HCV treatment in an optimized manner, must be considered to achieve HCV elimination in this unique population.

High efficacy and safety of pan-genotypic direct-acting antiviral regimens in adolescents and children: a global systematic review to inform new World Health Organization recommendations

Giuseppe Indolfi[1], Sabrina Giometto[2], Farihah Malik[3], Roger Chou[4], Philippa Easterbrook[5], Ersilia Lucenteforte[2]. [1]*Università di Firenze, Dipartimento Neurofarba, Firenze, Italy;* [2]*Università di Pisa;* [3]*UCL;* [4]*Oregon Health & Science University;* [5]*World Health Organization*
Email: giuseppe.indolfi@meyer.it

Background and aims: The global hepatitis C virus (HCV) response has to date largely focused on adults who bear the greatest burden of morbidity and mortality. There had been less attention to addressing case-finding and treatment of the estimated 3.26 million HCV infected children and adolescents. The recent regulatory approval of two pan-genotypic regimens down to 3 years provides opportunity to extend treatment opportunities down to all children above 3 years. To inform new World Health Organization (WHO) guidelines, we undertook a systematic review and meta-analysis of treatment outcomes in adolescents and children down to 3 years based on the key pan-genotypic direct-acting antiviral (DAA) regimens.

Method: We searched two databases and key conference abstracts for studies from inception to August 2021 that evaluated three pan-genotypic DAA regimens recommended by WHO for use in adults (sofosbuvir/daclatasvir, SOF/DCV, sofosbuvir/velpatasvir, SOF/VEL, glecaprevir/pibrentasvir, GLC/PIB) in HCV infected adolescents (12–18 years), older children (6–11 years) and young children (3–5 years). Randomised controlled trials (RCT), non-RCT, and prospective observational studies were eligible for inclusion. Key outcomes evaluated were attainment of sustained virological response (SVR12), any adverse events, and discontinuation. Estimates were pooled using random-effects models.

Results: 3 RCTS, 28 non-RCTs and 18 observational studies reported treatment experience in 167 young children (3–5 years), 472 older children (6–11 years), and 2228 adolescents (12–18 years). Across all

studies, there were 15 cirrhotic children, 304 treatment-experienced, and 157 with genotype 3 infection. SVR12 was high>95% for all three regimens and across age groups. There was a clear trend towards a higher rate of any adverse event with younger age groups (50% in adolescents, 53% in older children, and 72% in young children) but serious adverse events and treatment discontinuations were uncommon. There were 7 discontinuations of SOD/VEL in young children, because of palatability of the oral formulation.
Conclusion: SOF/DCV, SOF/VEL, and GLC/PIB regimens were highly effective and well tolerated in adolescents and older children, and SOF/VEL and GLC/PIB in young children and are now recommended by WHO. There is currently no direct evidence for SOF/DCV in young children, and studies are planned for 2022. SOF/DCV remains the most affordable and available DAA regimen for adults globally, and alignment of adult and paediatric procurement would simplify supply chain management.

Email: madisonccgunn@gmail.com

Background and aims: The advent of curative direct-acting antiviral (DAA) therapy for hepatitis C virus (HCV) has broadened the donor pool for solid organ transplants, allowing the use of organs from HCV + donors that were previously discarded. Although many centers have embraced this practice, the optimal timing of DAA initiation remains unclear. This study aims to summarize the virologic and clinical outcomes of DAA therapy in HCV donor+/recipient- solid organ transplants.
Method: Bibliographic databases were searched for studies published in English between Jan 2013 and Sept 2020. Using random effects models, meta-analysis was performed to pool estimates for sustained virologic response (SVR) and a composite adverse outcome of acute cellular rejection (ACR) and HCV-related complications (fibrosing cholestatic hepatitis and glomerulonephritis). Risk of bias was assessed using a modified Ottawa-Newcastle score.
Results: We included 25 non-randomized trials and observational studies with 635 participants, including 32 observations by organ type: 9 studies reported on heart transplantation (n = 185), 4 on lung (n = 93), 12 on kidney (n = 278) and 7 on liver (n = 79). 16 studies started DAAs <28 days after transplant (early) while 9 initiated DAAs >28 days post-transplant (late). The overall pooled SVR for all organ types was 0.96 (CI 0.95–0.98). SVR for non-liver organs was 0.97 (CI 0.94–0.98) and 0.96 (CI 0.91–1.0) for liver. For studies that had available data, the overall proportion of ACR was 0.10 (CI 0.06–0.15). In subgroup analyses, the SVR for early treatment was 0.97 (CI 0.96–0.99), while the SVR for late treatment was 0.95 (0.91–0.98). The proportion of the composite adverse outcome was 0.06 (CI 0.02–0.09) for early treatment and 0.18 (0.06–0.30) for late treatment. Proportion of ACR was 0.06 (CI 0.02–0.09) for early treatment compared to 0.17 (CI 0.01–0.28) for late treatment. Proportion of HCV-related complications for early treatment was 0.02 (0.01–0.04) and for late treatment was 0.02 (0.002–0.03). There were no cases of glomerulonephritis reported and only 5 cases of FCH. Of the FCH cases, 4/5 occurred in patients treated >28 after transplant. Early treatment was associated with 30% lower incidence of detectable viremia.
Conclusion: Overall, early DAA initiation (within 28 days) and late initiation (after 28 days) achieved similar SVR rates, although the early strategy reported 30% lower incidence of viremia. Early DAA initiation strategies reported a lower proportion of ACR than the delayed strategy, but this estimate was not statistically significant. On balance these results would support current guidelines recommending early treatment initiation, however randomized clinical trials may be required to more clearly define short-term responses and long-term clinical outcomes for these strategies.

FRI406
Effectiveness of pangenotypic retreatment of HCV infection after prior failure of pangenotypic therapies
Robert Flisiak[1], Justyna Janocha-Litwin[2], Anna Parfieniuk-Kowerda[1], Dorota Zarębska-Michaluk[3], Marek Sitko[4], Piekarska Anna[5], Jolanta Białkowska[5], Dorota Dybowska[6], Witold Dobracki[7], Simon Krzysztof[2], Aleksandra Murawska-Ochab[8], Małgorzata Pawłowska[6]. Email: robert.flisiak1@gmail.com

Background and aims: Pangenotypic therapies for HCV infections, although universal and highly effective, leave the risk of treatment failure. The aim of the analysis was to assess the effectiveness of pangenotypic re-treatment in patients with failure of previous treatment also with pangenotypic drugs; to our knowledge, the results of such real world experience studies have not been published so far.
Method: The analysis included patients selected from the EpiTer-2 database, a large retrospective, multicentre, national real-world study evaluating DAA treatment during 2015–2021 in 14, 450 consecutive subjects with hepatitis C virus (HCV) infection.
Results: A total of 3, 985 patients were treated with pangenotypic regimens, of which 37 (0.9%) received them as retreatment after failure of prior pangenotypic therapy. This group was significantly dominated by males (78%), cirrhotics (49%) and genotype 3 infection (67%) compared to the general population of patients treated with pangenotypic regimens (54%, 21%, 29%, respectively). As shown in figure 1 primary glecaprevir/pribrentasivir (GP) based therapy was changed to velpatasvir/sofosbuvir (VS) based in 18, and VS to GP in 13 patients. In 6 patients, the same regimen was used, extending the duration of therapy or supplementing it with an additional drug (ribavirin (R), sofosbuvir (S), voxilaprevir (V)). The response rate at the end of treatment was 95%, while the overall SVR was 89%. There was no significant difference in SVR between patients retreated with GP (93%) and VS based regimen (87%), which included also two patients on voxilaprevir/VS (VVS) regimen. All four non-responders were cirrhotic males infected with genotype 3 in age of 54–59 years.

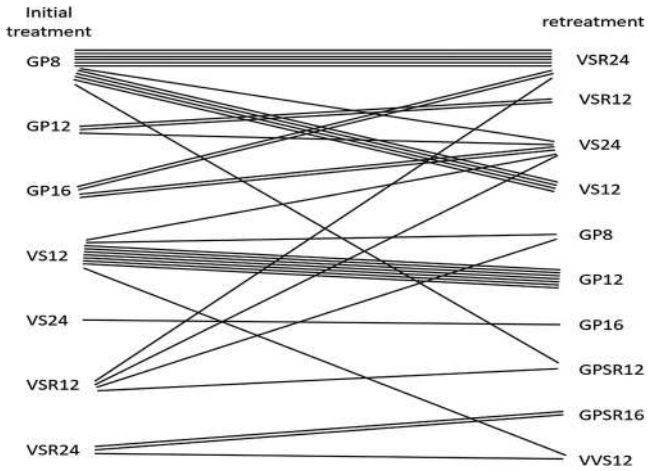

Figure: Change from primary to secondary pangenotypic regimens (letter abbreviations in abstract, numbers represent weeks of treatment).

Conclusion: We have demonstrated a high, almost 90% effectivenes of pangenotypic retreatment after failure of the primary pangenotypic therapy. Only men with cirrhosis, infected with genotype 3, did not eliminate HCV infection despite double pangenotypic treatment. We hope to provide data from more patients at the ILC.

FRI407

Infrequent hepatitis C genotypes/subtypes in patients treated with DAA-based regimens: successes and failures

Donald Murphy[1], Isaac Ruiz[2], Jean-Pierre Villeneuve[2], Catherine Vincent[2], Julian Hercun[2], Daphna Fenyves[2], Denis Marleau[2], Helene Castel[2], Julien Bissonnette[2], Genevieve Huard[2], Claire Fournier[2], Jeanne-Marie Giard[2], Daniel Corsilli[3], Ziad Hassoun[2], Philippe Willems[2], Iris Soto[2], Marc Bilodeau[2], Bernard Willems[2]. *[1]Institut national de santé publique du Québec, Laboratoire de santé publique du Québec (LSPQ), Montréal, Canada; [2]Centre hospitalier de l'Université de Montréal (CHUM), Liver Unit, Canada; [3]Centre hospitalier de l'Université de Montréal (CHUM), Intensive Care Unit, Canada*
Email: isaac.ruiz@me.com

Background and aims: Patients with infrequent Hepatitis C virus (HCV) genotypes/subtypes are characterized by resistance-associated substitution (RAS) profiles that have been associated with lower sustained virological responses (SVR). Real-world data regarding efficacy of direct-acting antiviral (DAA)-based regimens are needed in order to optimize HCV therapy and to further support expert recommendations.
The aim of this study was to evaluate the efficacy of DAA-based regimens in patients infected with infrequent HCV genotypes/subtypes in a real-world cohort at the Centre hospitalier de l'Université de Montréal (CHUM).
Method: A retrospective analysis of every patient referred to the CHUM was performed. Between 2014 and 2021, patients with an infrequent HCV genotype/subtype according to EASL guidelines definition were identified.
Patients treated with at least 1 DAA-based regimen were included. Patients enrolled in clinical trials were excluded. Liver fibrosis was assessed by means of liver elastography or by histological evaluation of liver biopsy. SVR was defined as an undetectable HCV RNA 12 weeks after the end of treatment (SVR12). The choice of the DAA combination was made at the physician's discretion.
Results: Among the 801 patients of the cohort, 106 (13.2%) had an infrequent genotype/subtype. Among them, median age was 64 (17–96), 54 (50.9%) were male, 54 (50.9%) had F3–F4 fibrosis.
The overall SVR12 rate following initial treatment with at least one DAA-based regimen was 87.7% (93/106). Twelve patients received a second-line DAA regimen. Before retreatment, 75.0% had F3-F4 fibrosis. SVR12 was 83.3% (10/12). One cirrhotic genotype 1d patient failed 2 one-DAA-based regimens (telaprevir (TPV)/pegylated interferon (pegIFN)/Ribavirin (RBV); sofosbuvir (SOF)/pegIFN/RBV) was successfully retreated with SOF/ledipasvir (LDV). One cirrhotic genotype 1 k patient failed 4 DAA-based regimens (SOF/simeprevir (SIM); SOF/LDV 24/48 weeks; SOF/LDV/RBV).
In a subgroup analysis of patients treated with a 2-last generation DAA (SOF/velpatasvir (VEL), SOF/VEL/RBV, glecaprevir (GLE)/pibrentasvir (PIB)), 50 patients were identified. SVR12 was 90.0% (45/50).
Among the 106 treated patients, 6 were treated after liver transplantation. One patient presented with fibrosing cholestatic hepatitis. The SVR12 was 83.3% (5/6). A genotype 3b patient failed SOF/VEL for 12 weeks and was successfully retreated with SOF/VEL/voxilaprevir (VOX) for 12 weeks.

Regimen	Genotypes/subtypes									
The successes (SVR12)[1]										
Last generation DAA										
SOF/VEL	2	2c	2i	4	4c	4h	4k	4l	4r	4s
	5a	6	6a	6e	6h	6l	6o	6xc	7	7a
SOF/VEL/RBV	1d	2i								
GLE/PIB	2c	4h	4k	6a	6f					
SOF/VEL/VOX	1	1l	3b	3i	4r					
Past generation DAA										
SOF/PegIFN/RBV	1e	2	4	5a						
SOF/RBV	2	2c	2i	2k	4c	4l	4r	4v	6a	
SOF/SIM	1d									
SOF/LDV	4	5a	6a	6e	6o					
SOF/LDV/RBV	1d	1g	4r	5a	6a	6e				
SOF/DCV/RBV	2									
EBR/GRZ	4c	4k	6o							
EBR/GRZ/RBV	4c	4k								
OBV/PTV/R/RBV	4k									
The failures[2]										
Last generation DAA										
SOF/VEL	3i	4b	4r	6p						
SOF/VEL/RBV	3b									
Past generation DAA										
TPV/PegIFN/RBV	1d									
SOF/PegIFN/RBV	1d									
SOF/RBV	2	2i								
SOF/SIM	1k									
SOF/LDV	1	1l	1k	4r	6a					
SOF/LDV/RBV	1k									
OBV/PTV/R/RBV	4k									

[1] n=1, except for 1d (n=3), 2 (n=9), 2c (n=7); 2i (n=6); 4 (n=5); 4c (n=5); 4h (n=2); 4k (n=9); 4l (n=2); 4r (n=8); 5a (n=12); 6 (n=2); 6a (n=11); 6e (n=3), 6h (n=2); 6o (n=3)
[2] n=1 for all genotypes/subtypes; 1d patient failed both treatments; 1k patient failed all 4 treatments including SOF/LDV 12/48w.

Conclusion: Our real-world data show that in patients with infrequent HCV genotypes/subtypes treated with 2 last-generation DAA the SVR rate is 90%. Although the data are limited, these results support the possibility of initially treating them with 2 last-generation DAA. More data are needed to determine optimal treatment regimen by genotype/subtype and the benefits of a rational approach based on RAS determination.

FRI408

Preemptive treatment with glecaprevir and pibrentasvir prevents HCV transmission from HCV viraemic donors to solid organ transplant recipients (single centre experience)

Sona Frankova[1], Ondrej Viklicky[2], Veronika Pitova[1], Janka Slatinska[2], Jan Sperl[1]. *[1]Institute for Clinical and Experimental Medicine, Department of hepatogastroenterology, Prague, Czech Republic; [2]Institute for Clinical and Experimental Medicine, Department of nephrology, Prague, Czech Republic*
Email: sona.frankova@ikem.cz

Background and aims: Organs from hepatitis C viraemic (HCV) donors were not used for transplantation in the past because the transmission of HCV infection to uninfected recipients used to be universal. Treatment of HCV infection in organ transplant recipients was complex and poorly effective before the introduction of direct-

acting antivirals (DAA) into clinical practice. Glecaprevir and pibrentasvir (GLE/PIB) represent a pangenotypic anti-HCV DAA combination also approved for patients with severe renal impairment or on maintenance haemodialysis. The study aims to analyze the efficacy and safety of GLE/PIB combination as preemptive therapy of HCV infection when using grafts from HCV viraemic donors.

Method: The solid organ transplant recipients, to whom an organ from HCV viraemic donor was allocated, were given a single dose of GLE/PIB (300 mg/120 mg) 2–6 hours before transplant, followed by a once-daily administration for 12 weeks after transplantation, as recommended for liver and kidney transplant recipients by the manufacturer. HCV RNA levels were assessed weekly in the first four weeks post-transplant, in the treatment weeks 8 and 12, and 12 weeks after the cessation of therapy. The endpoints were negative HCV RNA levels at the end of treatment and 12 weeks post-treatment.

Results: Twelve organs (two liver and ten kidney grafts) from 5 HCV viraemic cadaveric donors were allocated to 12 HCV uninfected recipients. All the recipients presented with an uncomplicated post-transplant course with the rapid development of graft function. None of the recipients presented with an acute rejection episode or severe graft dysfunction during the treatment and follow-up period. All the recipients completed the planned 12 weeks of preemptive antiviral treatment. None of them experienced an adverse event related to antiviral therapy or drug-drug interactions. HCV RNA was undetectable at all checked timepoints in all recipients. HCV infection was transmitted to none of the twelve recipients.

Conclusion: Preemptive treatment with GLE/PIB is safe and effective and allows the use of organs from HCV viraemic donors, so far considered marginal, to uninfected recipients. Organ procurement from HCV viraemic donors became a routine at our centre.

FRI409

Hepatitis C care cascade challenges in the homeless population. A case by case model of delivering care

Maria Guerra Veloz[1], Khin Aye Wint Han[1], Almuthana Mohamed[1], Kathryn Oakes[1], David Robertson[1], Mary D. Cannon[1], Ashley Barnabas[1], Sital Shah[1], Geoffrey Dusheiko[1], Kosh Agarwal[1].
[1]*Institute of Liver Studies. King's College Hospital, London, United Kingdom, London, United Kingdom*
Email: maria.guerraveloz@nhs.net

Background and aims: Given the significant Hepatitis C Virus (HCV) burden, despite curative treatments, efforts focusing on the scaling up of testing and treatment in the homeless population are still needed. The aim of this project was to implement education and flexible onsite HCV incentivised testing, treatment and follow up for the homeless population and evaluate their rates of engagement, therapy initiation and cure in the South London area.

Method: This project was conducted by a multidisciplinary team from Jan 2018 to Sept 2021. A mobile unit "van" for onsite HCV education, flexible screening (InTec HCV Rapid Antibody Test, Cepheid GeneXpert RNA test, DBS or classic venipuncture), treatment and follow up was placed on the street in well-known homeless population areas. Homeless was defined as living in temporary-*(hostel/hotel-based)* or as being on the street or visiting daily soup kitchens across the area *(street-based)*. Sociodemographic status, risk factors, comorbidities, concomitant medication, clinic data, the rates of treatment initiation and cure were recorded. Treatment adherence was defined as taking ≥75% of doses as self-reported by clients.

Results: 940 clients were identified as homeless and 933 (99.3%) participated. Of them 56.2% who were screened were street-based, 243 (26%) tested positive for HCV antibody and of these, 162 (67%) had detectable viremia. Clients with a positive HCV antibody had *significantly* higher rates of previous injection drug use (71.2 vs 8.6%), previous incarceration (12.3 vs 2.8%), previous HCV tests (28.8 vs 0.1%), as well as being active drug (36.2 vs 3.3%) and alcohol users (43.6 vs 5.2%) than those who were negative. HCV RNA positive clients had *significantly* more frequent psychiatric disorders, active drug use, active alcohol consumption, were on opioid substitution therapy, advanced fibrosis (23.5 vs 10%) and had lower rates of previous treatment in comparison with HCV RNA negatives (Figure 1c). The overall treatment initiation was 70.4% (114/162) and SVR 12 was 75.5% (83/110). In the multivariate analysis being screened in temporary housing (OR 2.755, 95%CI 1.356–5.600; p = 0.005) and having opioid substitution treatment (OR 2.288, 95%CI 1.041–5.026; p = 0.039) were positively associated with treatment initiation. HCV treatment adherence (OR 25.05, p < 0.001) was the only factor associated with achieving SVR.

	Total (n=933)	HCV antibody positive (243)	HCV antibody negative (690)	p	RNA positive 162	RNA negative 72	p

HIV coinfection							

Figure: a) Flow chart project b) Characteristics divided by HCV antibody and RNA status

Conclusion: Promoting education and having flexible onsite-testing and treatment for HCV in the homeless population improves their engagement with the healthcare system, leading to higher rates of treatment initiation and SVR. However, street based homeless people who are not linked with harm reduction services are less likely to initiate HCV treatment, highlighting that there is an urgent need for a broad health inclusion system.

FRI410

Effectiveness and safety of 8-week glecaprevir/pibrentasvir in HCV treatment naïve patients with compensated cirrhosis: real-world experience from Taiwan HCV registry

Chao-Hung Hung[1], Te-Sheng Chang[2], Chung-Feng Huang[3], Hsing-Tao Kuo[4], Ching-Chu Lo[5], Chien-Wei Huang[6], Lee-Won Chong[7,8], Pin-Nan Cheng[9], Ming-Lun Yeh[10,11], Cheng-Yuan Peng[12,13], Chien-Yu Cheng[14], Jee-Fu Huang[10,15], Ming-Jong Bair[16,17], Chih-Lang Lin[18], Chi-Chieh Yang[19], Sih-Ren Wang[20], Tsai-Yuan Hsieh[21], Tzong-Hsi Lee[22], Pei-Lun Lee[4], Wen-Chih Wu[23], Chih-Lin Lin[24], Wei-Wen Su[25], Shengshun Yang[26], Chia-Chi Wang[27,28], Jui-Ting Hu[29], Lien-Juei Mou[30], Chun-Ting Chen[31,32], Yi-Hsiang Huang[33,34], Chun-Chao Chang[35,36], Jia-Sheng Huang[37], Guei-Ying Chen[38], Jian-Neng Gao[39], Chi-Ming Tai[40,41], Chun-Jen Liu[42], Mei-Hsuan Lee[43], Pei-Chien Tsai[10], Chia-Yen Dai[10], Jia-Horng Kao[42], Han-Chieh Lin[33,34], Wan-Long Chuang[10], Chiyi Chen[44], Kuo-Chih Tseng[45,46], Ming-Lung Yu[47]. *[1]ChiaYi Chang Gung Memorial Hospital and College of Medicine, Chang Gung University, Division of Hepatogastroenterology, Department of Internal Medicine; Email: fish6069@gmail.com

Background and aims: The once-daily, oral, fixed-dose, direct-acting antiviral combination of glecaprevir/pibrentasvir (G/P) is indicated for chronic hepatitis C (CHC) infection with HCV genotypes 1–6 in patients with or without compensated cirrhosis (CC). Treatment duration of 8 weeks is recommended in most cases. Recent retrospective data from Taiwan revealed that G/P treatment resulted in high SVR12 rates according to label recommendations, comparable to those reported in the pivotal clinical trials. To further validate the data in the real-world setting, this study investigated effectiveness and safety of 8-week G/P therapy in treatment-naïve (TN), CC patients, with an emphasis on those with advanced liver disease in TASL HCV Registry (TACR).

Method: The TACR is an ongoing nationwide registry program organized and supervised by Taiwan Association for the Study of the Liver (TASL), which aims to setup a database and biobank of patients with CHC in Taiwan. Data were analyzed as of 31 October 2021 for patients treated with G/P for TN, CC patients. In this analysis, effectiveness reported as sustained virologic response at post-treatment week 12 (SVR12) was assessed by modified intent-to-treat (mITT) populations that excluded patients who lost to follow-up, underwent treatment and/or traced SVR12 data. Safety profile was assessed in the ITT population.

Results: Of 806 TN, CC patients treated with G/P, 301 patients received 8-week regimen (ITT), and 275 of which had SVR12 data available (mITT). Of the 301 ITT population, mean age was 63.0 years, 53.8% were male, 27.2% were with chronic kidney disease and 2.3% were coinfected with human immunodeficiency virus. The overall SVR12 rate was 98.2% (270/275) in the mITT population. For selected special patient groups including patients with HCV genotype 3 (GT3), platelets counts <150, 000/µl, FibroScan >20 kPa, or both platelet counts <150, 000/µl and FibroScan >20 kPa, the SVR12 rate was 100% (6/6), 98.0% (144/147), 100.0% (12/12) and 100.0% (7/7), respectively. Overall, 24.9% (75/301) of the patients experienced adverse events (AEs)in the ITT population. Seven patients (2.3%) experienced serious adverse events and two (0.7%) resulted in permanent drug discontinuation. None of them were considered as treatment drug related. The most frequent AEs (>5%) were fatigue (9.0%) and pruritus (7.0%). Laboratory data including international ratio of prothrombin time, total bilirubin, alanine aminotransferase, aspartate aminotransferase and albumin significantly improved after HCV eradication at SVR12.

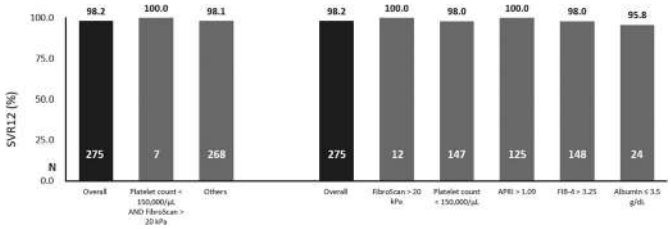

Figure: G/P-treated Patients with SVR12 data available as of Oct 2021 for analysis, n = 275 (mITT).

Conclusion: In this real-world Taiwanese cohort, 8-week G/P therapy was well-tolerated in TN, CC patients. SVR12 rates were similarly high as in the clinical trials, including those with characteristics of advanced liver disease.

FRI411

Reported safety of HCV direct-acting antivirals with opioids: 2017 to 2021

Anthony Martinez[1], Tipu Khan[2], Doug Dylla[3], John Marcinak[3], Michelle Collins[3], Brad Saget[3], Brian Conway[4]. [1]*State University of New York, Buffalo, New York, United States;* [2]*Ventura County Medical Center, Ventura, United States;* [3]*AbbVie Inc, United States;* [4]*Vancouver Infectious Diseases Centre, Canada*
Email: adm35@buffalo.edu

Background and aims: As a result of disengagement in addiction care during the COVID-19 pandemic, there has been a record increase in mortality associated with opioid overdoses (primarily fentanyl), particularly in North America. In the USA there were over 100, 000 overdose deaths in 2021, while over 2000 were recorded in the province of British Columbia. As we attempt to develop novel ways to increase HCV treatment following ≥30% declines during the pandemic, we evaluated publicly available adverse events (AEs) reports for opioids and DAAs to assess whether safety concerns from potential drug interactions are warranted, particularly amongst those using fentanyl.
Method: Data were downloaded from the US Food and Drug Administration (FDA) Adverse Event Reporting System (FAERS) Public Dashboard. AEs with the DAAs glecaprevir/pibrentasvir (G/P), sofosbuvir/velpatasvir (SOF/VEL), ledipasvir/sofosbuvir (LDV/SOF), sofosbuvir/velpatasvir/voxilaprevir (SOF/VEL/VOX), and elbasvir/grazoprevir (EBR/GZR) listed as the suspect product were analyzed with an initial received date from July 28, 2017-December 31, 2021, as were opioid-associated AEs for all 2017–2021. Subsequently, AEs were counted based on listed concomitant use of opioids (fentanyl, oxycodone, hydrocodone), or overdose outcomes irrespective of concomitant opioid use. Data are descriptive without any statistical analyses.
Results: In the reporting period, 40 total AEs were recorded with concomitant DAA and fentanyl use, 14 resulting in death (G/p = 3, SOF/VEL = 11; Table 1); 626 total AEs were recorded with concomitant DAA and oxycodone or hydrocodone use, 28 resulting in death. Separately, overdose events were reported 196 times, 32 resulting in death. The number of overdoses declined each year from 2018 (N = 56) to 2021 (N = 29). Fentanyl AEs showed no trend year to year.

Table 1: FAERs AEs and deaths with opioids and with concomitant HCV DAAs.

n	Fentanyl AEs (N = 58, 001)	Fentanyl deaths (N = 29, 850)	Oxycodone/ Hydrocodone AEs (N = 290, 224)	Oxycodone/ Hydrocodone deaths (N = 119, 013)	Overdose AEs* (N = 98, 037)	Overdose deaths* (N = 52, 318)
All DAAs	40	14	626	28	196	32
G/P	13	3	153	6	24	11
SOF/VEL	22	11	269	13	99	14
LDV/SOF	3	0	100	5	50	5
SOF/VEL/VOX	0	0	14	0	8	0
EBR/GZR	2	0	90	4	15	2

*N represents the sum of fentanyl, oxycodone, and hydrocodone overdose AEs and deaths, whereas n's for DAA overdose AEs and deaths are irrespective of concomitant opioids.

Conclusion: With the limitations of FAERS data (under or duplicate reporting, inability to establish causation or incidence), these data show that among ~58, 000 fentanyl, ~189, 000 oxycodone, and ~100, 000 hydrocodone AEs reported to FAERS since 2017, a small proportion (0.19%) have been reported in association with concomitant DAA therapy, with no association between recorded events and a specific DAA regimen. This should reassure HCV treaters on a lack of safety signal for concomitant opioid and DAA use.

FRI414

Impact of the presence of the infectious disease specialist in addiction services (SerDs) as a point-of-care to meet WHO goal of HCV eradication

Chiara Fanelli[1], Elija Princic[1], Andrea De Vito[1], Claudia Marcia[1], Giordano Madeddu[1], Sergio Babudieri[1], Ivana Rita Maida[1]. [1]*University of Sassari, Department of Medical, Surgical and Experimental Sciences, Sassari, Italy*
Email: chiarfan@hotmail.it

Background and aims: The World Health Organization (WHO) aim for Hepatitis C virus (HCV) elimination by 2030 appears to be threatened by most patients remaining undiagnosed, despite the availability of effective and safe antivirals. The main reservoir of HCV is represented by people who inject drugs (PWIDs). This study aimed to assess the crucial role of the infectologist at the Addiction Services (SerDs) and its potential as a linkage to care of PWID HCV carriers.
Method: This retrospective study compares the number of new diagnosis and treatments among PWIDs before and after the introduction of an infectologist at SerDs Point of Care of Sassari, Italy. Data were collected from February 2015 to August 2020. The watershed day was the 1st of May 2019, when the infectologist was integrated in the personnel of SerD. Logistic regression analysis was performed to assess the relationship between variables before and after the introduction of the infectologist.
Results: From February 2015 to August 2020, 901 users took advantage of at least one dose of under opiate substitution treatment (OST) at the SerDs of Sassari, Italy. In total, 419 users (46.5%) underwent HCV-screening test, of which 333 (79.47%) tested positive and 191 taken in charge by the infectologist. Of 157 patients with detectable HCV-RNA, 138 (87.89%) started HCV treatment. Comparing the group treated with Direct-acting Antiviral Agents (DAA) before and after May 2019, a statistical significance was found in age ($p = 0.0018$) and diagnose-to-treatment prescription time ($p < 0.001$). When comparing PWIDs taken in charge in the two periods, statistical significance emerged for median age ($p < 0.001$), alcohol dependence ($p = 0.005$), active PWID ($p = 0.01$), cirrhosis ($p = 0.006$) and DAA prescription ($p = 0.014$) (Table). The number of new diagnoses and treatments from May 2019 until August 2020 was higher than those between February 2015 and May 2019 (respectively, 72 in 15 months versus 66 in 50 months).

Variables	Total (N = 191)	Take-in-charge before May 2019 (N = 81)	Take-in-charge after May 2019 (N = 110)	p-value*
Age, n (IQR)	48, 9 (40, 1–53, 8)	50, 6 (43, 6–55, 4)	45, 7 (38, 6–52, 2)	<0, 001
Male sex, n (%)	177 (92, 7%)	78 (96, 3%)	99 (90%)	0, 099
Alcohol abuse, n (%)	10 (5, 2%)	0 (0%)	10 (9, 1%)	0, 005
Active PWID, n (%)	26 (13, 6%)	5 (6, 2%)	21 (19, 1%)	0, 01
Cirrhosis, n (%)	64 (33, 5%)	36 (44, 4%)	28 (25, 5%)	0, 006
Prescribed DAAs therapy, n (%)	138 (72, 3%)	66 (81, 5%)	72 (65, 5%)	0, 014

*Determined by chi-square test or wilcoxon test. IQR: range interquartile.

Conclusion: The improvement of the Meet-Test-Treat has been related to the introduction of the infectologist at SerDs. This work highlights the increase in patients' compliance to treatment and take-in-charge by a doctor in hard-to-reach population. Furthermore, it provides a higher chance of early diagnosis of patients with a still reversible degree of fibrosis and how to significantly reduce the management time.

FRI415

Eliminating hepatitis C virus infection in prisons: 7 years of experience

Frederico Duarte[1], Luís Manuel Moura[1], Clara Batista[1], Ricardo Correia de Abreu[1], Isabel Neves[1]. *[1]Unidade Local de Saúde de Matosinhos, Infectious Diseases, Matosinhos, Portugal*
Email: frederico.duarte1@gmail.com

Background and aims: Hepatitis C virus (HCV) infection is a major global health problem. The micro-elimination approach implies reaching specific populations, like people living in prisons. The introduction of direct-acting antiviral agents (DAAs) allowed a considerable change in public health.
Since 2015, the use of these drugs in HCV-infected inmates has allowed their cure, resulting from an ongoing optimized care partnership between two prisons and our healthcare unit in Matosinhos, bringing us closer to public health targets in eliminating the infection by 2030.
Method: The authors describe the epidemiological, clinical, analytical and imaging data of inmates with confirmed HCV infection undergoing treatment with DAAs since their availability in our healthcare unit.
Between 2015 and 2022 we identified 118 inmates with positive HCV antibody (65 men, 53 women), 16 have ongoing disease staging, 14 with spontaneous cure and 9 were released before complete staging. Twenty four HIV coinfected patients, all under treatment, 100% with viral suppression and 75% with $CD4^+$ count greater than 500/uL. Four patients were coinfected with HBV. Almost 55% of the patients were diagnosed with psychiatric illness and were under treatment.
Results: The 79 inmates with confirmed HCV infection (51 men, 28 women) showed an average of 42 years [24–72 years], 11 years of known infection [1–30 years] and 85% had intravenous drug use in the past. HCV genotypes distribution: 1–48%; 3–30%; 4–22%. Liver fibrosis stages ranged from 4 to 64 kPa (F0–F2 85%, F3–F4 15%).
All the 79 patients were initially treated with Sofosbuvir/Ledipasvir and Daclatasvir with or without ribavirin (according to criteria defined in initial protocols) and more recently, Grazoprevir/Elbasvir and pangenotypic drugs, namely Sofosbuvir/Velpatasvir, and Glecaprevir/Pibrentasvir. All were considered cured by achieving virological response 12 weeks post-treatment.
Conclusion: Our encouraging data is a result from an optimized partnership between the healthcare team in prisons and our hospital, allowing a fast diagnosis, an agile disease staging and adequate treatment, minimizing future risk of transmission and taking us closer to eliminating the infection by 2030.

FRI416

Real-world value and innovation of direct-acting antivirals for the treatment of chronic hepatitis C at Kaiser Permanente Southern California

Lisa Nyberg[1], Ankita Kaushik[2], Nate Smith[3], Fadoua El-Moustaid[3], Anders Nyberg[1], Su-Jau Yang[4], Kevin Chiang[5], Alon Yehoshua[2]. *[1]Kaiser Permanente Hepatology Research, San Diego, United States; [2]Gilead Sciences, Inc., Foster City, United States; [3]Maple Health Group, New York, United States; [4]Kaiser Permanente Research and Evaluation, Pasadena, United States; [5]Kaiser Permanente Pharmacy Analytical Services, Downey, United States*
Email: alon.yehoshua@gilead.com

Background and aims: Direct-acting antivirals (DAAs) have been a breakthrough therapeutic innovation in the treatment of chronic hepatitis C virus (HCV) with high efficacy rates and excellent safety and tolerability profiles. The objective of this study was to assess the long-term health and economic benefits associated with direct-acting antivirals (DAAs) vs. no treatment in the Kaiser Permanente Southern California (KPSC) healthcare delivery system.
Method: A hybrid decision-tree and Markov model was used to evaluate the long-term health and cost outcomes associated with treating HCV patients with DAAs (either sofosbuvir/velpatasvir [SOF/VEL] or ledipasvir/sofosbuvir [LDV/SOF]) vs. no treatment in the KPSC setting. A cohort of 7, 255 HCV patients, based on the total number of DAA-treated patients from 2014 to 2019, with an average age of 59 years was simulated over a lifetime (50 year) horizon. Demographic data included baseline distributions of genotype, cirrhosis, prior treatment/naïve, and mix of DAAs. Treatment efficacy by subpopulation was determined from a secondary, real-world, database analysis of HCV patients in the KPSC setting. Utility values, transition probabilities, and health state costs were sourced from published literature, prioritizing data from the KPSC setting where possible. Treatment costs based on wholesale acquisition costs were sourced from publicly available databases. The model considered only direct medical costs, presented in 2021 USD.
Results: Approximately 78% of patients were treated with LDV/SOF and 22% with SOF/VEL in the DAA scenario. DAAs use led to a reduction of 3, 179 cases of compensated cirrhosis (−98%), 3, 318 cases of decompensated cirrhosis (−96%), 646 cases of hepatocellular carcinoma (−80%), 447 cases of liver transplants (-86%), and 3, 078 events of liver-related mortality (−86%) as compared to no treatment. In the DAAs scenario, life-years, and quality-adjusted life-years (QALYs) improved by +25% (+3.21 LYs) and +36% (+3.53 QALYs) vs. the no-treatment scenario. DAAs use also resulted in a reduction of total costs of −72% (−$144, 592 per person) vs. no treatment. Furthermore, use of DAAs was found to lead to cost savings within 3 years.
Conclusion: Treating patients with DAAs resulted in a reduction in HCV-related morbidity and mortality and significant improvement in QALYs. Furthermore, use of DAAs was dominant (less costly and more effective) as compared to no treatment offering cost-savings within 3 years post-treatment. These findings highlight the substantial value of DAA treatment offered to HCV patients.

FRI418

Treatment options for hepatitis C in pregnancy: a systematic review of the evidence and future research needs

Neil Gupta[1], Lindsey Hiebert[1], Carolyn Wester[2], Paige A Armstrong[1,2].
[1]*Task Force for Global Health, Coalition for Global Hepatitis Elimination, United States;* [2]*US Centers for Disease Control and Prevention, Division of Viral Hepatitis, United States*
Email: ngupta-consultant@taskforce.org

Background and aims: Treatment for hepatitis C virus (HCV) infection during pregnancy has the potential to substantially increase HCV treatment coverage and prevent mother-to-child transmission. Although direct-acting antiviral (DAA) medications for the treatment of HCV infection have demonstrated excellent safety and efficacy in non-pregnant persons, HCV treatment is not recommended in pregnancy due to a lack of safety data. We assessed the published literature for information on treatment options for HCV infection in pregnancy, including linkage to care and treatment during pregnancy.
Method: We conducted a systematic literature review in PubMed for articles published in English from January 1, 2013–July 1, 2021. We searched using MESH and non-MESH equivalent search terms for "Hepatitis C virus" AND "pregnancy" AND "treatment" OR "direct-acting antivirals." All articles were reviewed and thematically coded by dual reviewers..
Results: Overall, 486 articles were identified, of which 219 were included as relevant with full-text available. Of these, 118 contained results of primary research and 101 were secondary research. Of the 118 primary research articles, most focused on outcomes of HCV vertical transmission in infants (n = 28, 23.7%), HCV screening results (n = 25, 21.2%), epidemiology of HCV (n = 19, 16.1%), and cost-effectiveness or policies for HCV testing (n = 19, 16.1%). Fourteen (11.9%) assessed linkage to care or follow-up for persons who tested HCV positive. Five (4.2%) studies described results of DAA exposure in pregnancy. This included one prospective trial that reported minor (grade I/II) adverse events in 4 out of 9 participants, one retrospective study that reported no adverse events among 100 participants, one case study with no reported adverse events, and 2 clinical trials that reported DAA discontinuation due to pregnancy in 6 enrolled participants (no clinical outcomes reported). Of the 101 studies without primary research, 13 explicitly included the possibility of HCV treatment during pregnancy.
Conclusion: Despite a substantial body of literature on HCV infection in pregnancy, there are very few reports on maternal linkage to HCV treatment and extremely limited data regarding the safety or effectiveness of DAA treatment in pregnancy. To improve the evidence base on HCV treatment in pregnancy, additional approaches are needed to collect and report relevant data. In response, the Coalition for Global Hepatitis Elimination, with support from the US Centers for Disease Control and Prevention, developed the first clinical case registry to record maternal and infant outcomes for persons exposed to DAAs during pregnancy ("TiP-HepC" Registry). The TiP-HepC registry, in complement to clinical studies and other real-world experiences, will provide urgently needed data to inform optimal treatment options for HCV in pregnancy.

Immune-mediated and cholestatic: Experimental and pathophysiology

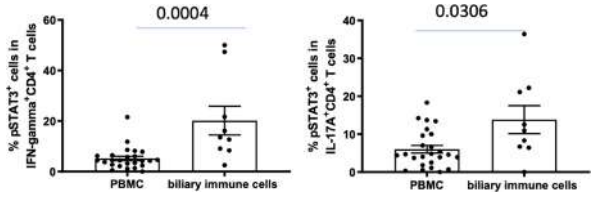
Over-responsiveness of the IL-6/STAT3 pathway in inflammatory CD4+ T cells of patients with primary sclerosing cholangitis

Leona Dold[1], Leonie Frank[1], Philipp Lutz[1], Tobias Weismüller[1], Dominik Kaczmarek[1], Vittorio Branchi[2], Marieta Toma[2], Christian Strassburg[1], Ulrich Spengler[1], Bettina Langhans[1]. [1]*University Hospital Bonn, Department of Internal Medicine I, Bonn, Germany;* [2]*University Hospital Bonn, Institute of Pathology, Bonn, Germany*
Email: Leona.Dold@ukbonn.de

Background and aims: Primary sclerosing cholangitis (PSC) is a chronic inflammatory disorder of the biliary ducts, which leads to fibrosis and predisposes to cholangiocellular carcinoma. Although the exact pathogenesis of PSC remains unclear, proinflammatory $CD4^+$ immune cells seem to play a pivotal role. Current treatment options are limited but over-activation of STATs (Signal Transducers and Activators of Transcription protein) was observed in $CD4^+$ immune cells and linked to disease activity in various autoimmune diseases. Thus far, activation of STATs has been poorly studied in PSC.
Method: Using multicolor flow cytometry we analyzed activation of STAT1 and STAT3 at baseline and after in vitro stimulation with recombinant IL-6 and IFN-gamma in immune cells from peripheral blood (PBMC) and from biliary tissue specimens collected by endoscopic retrograde cholangiopancreaticography (ERCP) from patients with PSC. In addition, we measured soluble factors in serum and bile via bead-based immunoassay and compared results to healthy controls.
Results: Serum levels of IL-6 (mean ± SEM; 62.1 ± 28.1 pg/ml, p = 0.0279), IFN-gamma (26.7 ± 11.7 pg/ml, p = 0.0082) and IL-17A (9.1 ± 3.0 pg/ml, p = 0.0356), were higher in PSC patients than in healthy controls (IL-6: 10.5 ± 3.6 pg/ml; IFN-gamma: 6.1 ± 2.9 pg/ml; IL-17A: 2.7 ± 1.1 pg/ml). Of note, in PSC patients, inflammatory cytokines were conspicuously higher in bile than in serum. Unlike phospho-STAT1, which was refractory to IFN-gamma and IL-6 stimulation, activation with recombinant IL-6 lead to higher frequencies of phospho-STAT3-positive cells in the IFN-gamma$^+$ (80.2 ± 2.3%, p = 0.0055) and IL-17A$^+$ $CD4^+$ T cell subsets (79.0 ± 2.4%; p = 0.0197) in patients with PSC than in healthy controls (66.1 ± 4.6% in IFN-gamma$^+$ and 68.4 ± 4.1% in IL-17A$^+$$CD4^+$ T cells). Frequencies of phospho-STAT3-positive cells in the IFN-gamma$^+$ and IL-17A$^+$ $CD4^+$ T-cell subsets were higher in bile duct tissue (from ERCP) when compared to peripheral blood (Fig. 1). Finally, the pan-Jak inhibitor baricitinib dose-dependently reduced IFN-gamma- and IL-17A-secretion of mitogen-stimulated PBMCs from PSC patients in vitro.



Conclusion: Patients with PSC exhibit increased phospho-STAT3 induction in pro-inflammatory $CD4^+$ T cells from blood and bile duct tissue, suggesting enhanced responsiveness of the STAT3 pathway in PSC. Although the cause of STAT3 over-responsiveness in PSC remains to be elucidated, targeted STAT3 inhibition may offer a novel approach to modify the course of PSC.

FRI452

Dosing ileal bile acid transporter inhibitors in the fasted state minimizes gastrointestinal adverse effects while maintaining pharmacodynamic effect

Cory Kostrub[1], Rakesh Raman[1], Douglas Mogul[1], Pamela Vig[1]. [1]*Mirum Pharmaceuticals Inc, Foster City, CA, United States*
Email: ckostrub@mirumpharma.com

Background and aims: Ileal bile acid transporter inhibitors (IBATi) interrupt enterohepatic circulation of bile acids (BAs) and increase fecal BA (fBA) excretion, thereby reducing serum BA (sBA). IBATi, including maralixibat (MRX; approved for the treatment of cholestatic pruritus in patients with Alagille syndrome [ALGS] ≥1 year of age) and volixibat (VLX), decrease the toxic accumulation of BAs in the liver and mitigate cholestasis. GI adverse events (AEs; diarrhea, abdominal pain) are side effects of IBATi due to increased excretion of fBA. The aim of this analysis was to assess the impact of timing of IBATi dosing, relative to food, on GI AEs and pharmacodynamic (PD) effects to inform the optimal dosing approach for IBATi.
Method: AE data from 3 phase 1 clinical studies on MRX and VLX in healthy participants were compiled to assess relative tolerability with different timing of IBATi dosing vs mealtime. In Study 1, 75 mg of VLX was dosed fasted (overnight fast and no food for 4 hrs post-dose) vs right after breakfast; in Study 2, 10 mg of MRX was dosed fasted vs immediately before breakfast, and in Study 3, 30 mg of MRX was dosed fasted vs right after breakfast. The PD of IBATi is challenging to directly measure in clinical trials, so the PD impact of IBATi dosing time relative to mealtime was investigated in healthy dogs by measuring fBA excretion over 7 days of dosing, comparing IBATi dosing 4 hr prior, 30 minutes prior, or 4 hours after the daily meal.
Results: Across the 3 phase 1 clinical studies there was a lower rate of GI AEs when dosing IBATi in the fasted state (0%, 0%, and 50% of participants reported a GI AE in Study 1, 2, and 3 respectively) compared to the fed state or at mealtime (75%, 33%, and 100% in Study 1, 2, 3 respectively). In healthy dogs, MRX significantly increased fBA excretion ($p < 0.01$ vs pretreatment baseline by paired t-test) regardless of dosing time relative to the daily meal, with maximal increases in fBA excretion when dosing 30 minutes prior (231% increase) or 4 hrs after (229% increase) the meal, indicating flexibility in the timing of IBATi dosing vs mealtime to maintain maximal PD effect.

Table: Comparison of the Incidence of GI TEAEs Following IBATi Administration in the Fasted State Versus in the Fed State or At Mealtime in Healthy Participants

	Study 1[1]		Study 2[2]		Study 3[3]	
	Fasted (n=8)	Fed (n=8)	Fasted (n=6)	At Mealtime (n=6)	Fasted (n=12)	Fed (n=12)
GI TEAE	**0 (0%)**	**6 (75%)**	**0 (0%)**	**2 (33%)**	**6 (50%)**	**12 (100%)**
Diarrhea	-	4 (50%)	-	1 (17%)	6 (50%)	11 (92%)
Loose stools	-	2 (25%)	-	-	-	-
Nausea	-	-	-	1 (17%)	-	3 (25%)
Abdominal pain	-	-	-	-	1 (8%)	5 (42%)
Anorectal discomfort	-	-	-	-	-	1 (8%)

[1] Study FED10634 (Volixibat 75 mg)
[2] Study NB4-02-06-002 (Maralixibat 10 mg)
[3] Study MRX-102 (Maralixibat 30 mg)

Conclusion: These data demonstrate that GI tolerability is improved when dosing an IBATi in the fasted state, versus dosing at mealtime or immediately after food intake. Animal data show that PD effect is maintained regardless of dosing time relative to mealtime, suggesting that efficacy can be maintained while minimizing GI events.

Email: jsimon.ciberehd@cicbiogune.es

Background and aims: Primary biliary cholangitis (PBC) and primary sclerosing cholangitis (PSC) are progressive diseases that eventually culminate in cirrhosis and related complications, as liver failure or portal hypertension among others. However, cholestasis is commonly present in these patients. Hepatocytes are adversely affected by the accumulation of bile acids and trigger inflammatory and cell death responses leading to development of fibrosis. Magnesium is known to play an important role in inflammatory and immune responses. Since magnesium distribution can be modulated by silencing Cyclin M4 (CNNM4), CNNM4 expression levels and the effectivity of a CNNM4-targeting therapy were evaluated in preclinical models for cholestasis.

Method: Hepatic CNNM4 expression was evaluated in PBC and PSC biopsies and in samples from rodent models by immunohistochemistry. An *in vitro* cholestasis model was set up by incubating primary hepatocytes with supraphysiological concentrations of glycodeoxicholic acid (GCDCA). Animal models of cholestasis were generated by bile-duct ligation (BDL) for 14 days and by the use of mice lacking *Mdr2* (*Mdr2-/-*) at 3, 5 and 8 months of age. The functional role of CNNM4 in disease progression was characterized in *in vitro* and *in vivo* models of cholestasis *via* GalNAc-siRNA mediated silencing approach.

Results: CNNM4 upregulation was detected in liver samples of patients with PBC and PSC. Furthermore, we found that CNNM4 expression was enhanced in mice that underwent BDL and in mice lacking *Mdr2*. GalNAc-siRNA mediated silencing of CNNM4 protected primary mouse hepatocytes from GCDCA-induced cell death, mitochondrial dysfunction, oxidative stress and endoplasmic reticulum stress. In rodent models for cholestasis, GalNAc CNNM4 siRNA treatment protected the liver from fibrotic development and inflammation. Silencing *Cnnm4* in hepatocytes induced intracellular magnesium accumulation, which may protect these cells by affecting the bile acid homeostasis.

Conclusion: CNNM4 has been identified as a potential novel therapeutic target for bile acid-induced liver damage. Herein, we show evidence that silencing *CNNM4* by a GalNAc siRNA-approach could also be a novel effective approach for treatment of cholestasis-associated liver fibrosis.

Association of bile acids composition and synthetic pathway with therapeutic effect of bezafibrate in chronic cholestatic liver disease

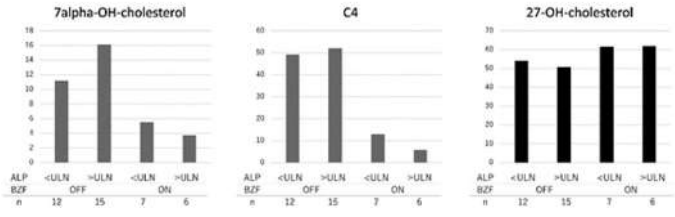
Manami Iida[1], Atsuko Higashide[2], Shuichi Ohtomo[1], Naoshi Horiba[1], Atsushi Tanaka[3]. *[1]Chugai Pharmaceutical Co., Ltd., Japan; [2]Chugai Research Institute for Medical Science, Inc., Japan; [3]Teikyo University School of Medicine, Medicine, Japan*
Email: iida.manami27@chugai-pharm.co.jp

Background and aims: While ursodeoxycholic acid (UDCA) and bezafibrate (BZF) are therapeutic options in primary biliary cholangitis (PBC) and primary sclerosing cholangitis (PSC), there are treatment resistance cases that do not respond to the combination. Here, we investigated the mechanism of UDCA + BZF treatment resistance in terms of the bile acid composition and synthesis pathway in patients with PBC and PSC.

Method: The subjects were PBC and PSC patients as well as control patients whose liver function test values were all within the normal limits. Fasting plasma was collected and the plasma levels of various bile acids, 7a-hydroxy cholesterol (7a-HC), 27-hydroxy cholesterol (27-HC), and C4 were measured by liquid chromatography-tandem mass spectrometry. In addition, various clinical test values tested on the same day and therapeutic agents were collected. The relationship between bile acid composition and synthetic pathway, UDCA and BZF treatment, and liver function tests was examined.

Results: Patients with PBC (n = 30, all females, mean age 67 yrs, UDCA/BZF administration: 26/8), PSC (n = 10, male/female = 7/3, mean age 44 yrs, UDCA/BZF administration: 10/5), and control patients (6 chronic hepatitis B, 23 chronic hepatitis C, 1 dyslipidemia, M/F = 16/14, mean age 66 yrs, UDCA/BZF administration: 3/0) were enrolled in the study. The plasma level of UDCA-related bile acids were high in PBC/PSC, reflecting UDCA administration. Furthermore, GCA, TCA, and TCDCA were higher in PBC/PSC than those in the controls, and the concentrations of these three types of bile acids were significantly correlated with the liver enzymes and bilirubin levels. In terms of the bile acid synthetic pathway, 27-HC was positively correlated with liver enzyme levels, and 27-HC was high in cases with elevated liver enzymes. In relation to BZF administration, BZF-administered PBC/PSC cases (PBC 8, PSC 5) had significantly lower values of 7a-HC and C4 and higher 27-HC than non-administered cases (PBC 22, PSC 5) (Figure).

Figure. Plasma levels of 7alpha-HC, C4, and 27-HC stratified by ALP levels and BZF administration



Conclusion: GCA, TCA, and TCDCA were higher in treatment-resistant PBC/PSC cases with elevated liver enzymes. In addition, 27-HC was elevated, suggesting that the alternative pathway was activated in these treatment resistant cases. In the BZF-administered cases, 7a-HC and C4 levels were low (Figure), indicating that Cyp7a1 was suppressed and the classical pathway was suppressed as previously reported. On the other hand, 27-HC was not decreased and the alternative pathway was not suppressed, irrespective of liver enzyme levels (Figure). Taken together, BZF treatment failed to inhibit the alternative pathway of bile acids which were activated in cases with elevated liver enzymes, possibly, in part, explaining the mechanism of treatment resistance.

FRI455

Reduced hepatic expression of PPAR alpha in primary biliary cirrhosis is modulated by miR-155

Monika Adamowicz[1], Agnieszka Kempinska-Podhorodecka[1], Joanna Abramczyk[1], Jesus Maria Banales[2], Piotr Milkiewicz[3], Małgorzata Milkiewicz[1]. [1]*Pomeranian Medical University, Department of Medical Biology, Szczecin, Poland;* [2]*Biodonostia Health Research Institute, Department of Liver and Gastrointestinal Diseases, Donostia University Hospital, Ikerbasque, CIBERehd, San Sebastian, Spain;* [3]*Medical University of Warsaw, Liver and Internal Medicine Unit, Warsaw, Poland*
Email: monika.adamowicz@pum.edu.pl

Background and aims: Peroxisome proliferator-activated receptor alpha (PPARa) regulates expression of multiple genes involving lipid metabolism, bile acids (BA) homeostasis, and shows protective effects against inflammation and apoptosis. Progressive diseases such as primary biliary cirrhosis (PBC) and primary sclerosing cholangitis (PSC) result in intrahepatic retention of toxic BA that may lead to liver dysfunction and failure. Small non-coding RNA molecules (miRNAs) regulate gene expression, and miR-155 was associated with silencing of PPARa. Since PPARa activation decreases inflammation and fibrosis we evaluated PPARa and miR-155 expressions in cholestatic livers. We have also analyzed the regulatory effect of miR-155 on PPARa expression *in vitro*.
Method: Liver samples were taken from biopsies at early stages (F1-F2) of PBC (n = 12) or from explanted livers in patients with cirrhotic PBC (n = 11) and PSC (n = 17). The functional role of miR-155 was characterized *in vitro* in hepatocytes (HepG2) and primary cholangiocytes (NHC) where overexpression of miR-155 was induced by mirVana miRNA Mimic. miR-155 expression levels were evaluated after treatment with lipopolysaccharide (LPS), glycodeoxycholic acid (GCDCA), lithocholic acid (LCA) or ursodeoxycholic acid (UDCA).
Results: When compared to controls hepatic PPARa mRNA and protein levels were reduced in cirrhotic PBC (both 50% reduction, P = 0.01), but not in PSC livers. In PBC livers this phenomenon was accompanied with induction of miR-155 (3.7-fold increase, P = 0.004 vs. control). Experimental overexpression of miR-155 in HepG2 led to the inhibition of PPARa (50% reduction, P = 0.02). LPS stimulated miR-155 expression in HepG2 (over 40-fold increase, p = 0.009), whereas the treatment with GCDCA or LCA enhanced the expression of miR-155 in NHC (2-fold $p < 0.05$, or 2.4 fold $p < 0.05$, respectively). UDCA suppressed the basal expression of miR-155 in NHC (20% reduction, p = 0.02 vs. control) as well as the LPS-induced miR-155 in HepG2 (p = 0.009 vs LPS).
Conclusion: We showed that PPARa is substantially reduced in PBC livers, and the observed concomitant overexpression of miR-155 induced either by inflammation or bile acids may be accountable for this suppression. Inhibition of miR-155 may be a potential novel therapeutic target in PBC.

Email: jiangcpu@163.com

Background and aims: Cholestasis is a pathophysiological process caused by disorders involving bile secretion and excretion. Chronic cholestasis can cause bile acids (BAs) to accumulate in the liver, induce liver injury, inflammation, and liver fibrosis. Sphingosine-1-phospholipid receptor 1 (S1PR1) is distributed in various organs, it is the receptor of endogenous substance sphingosine-1-phospholipid (S1P) and participates in a variety of physiological and pathological process. But its role in cholestatic liver disease has not yet been elucidated clearly.
Method: To study the cholangiocyte-specific role of S1PR1, we generated a novel knock-out mouse strains by breeding Krt19Cre mice with S1pr1 floxed mice. S1PR1 cell specific deletion was confirmed in primary isolated intrahepatic cholangiocytes by PCR, WB, and IF, and in liver frozen section by IF. Fibrosis was established by common bile duct ligand (BDL) (14 days) and CA (0.5%) chow diet (4 months). Liver damage was determined by serum ALT, AST, ALP, TBA, and H&E staining. Fibrosis was determined by hepatic hydroxyproline, Masson trichrome staining, Sirius staining, and IHC. Comprehensive serum and liver bile acids profiling were performed using HPLC-MS/MS. RNA-seq was performed in whole liver and primary cholangiocytes after BDL.
Results: First we observed that S1PR1 was more expressed on cholangiocytes after 14 days BDL and 4 months CA chow diet. Interestingly, $S1PR1^{Krt19CreERT+/+}$ mice displayed a trend towards attenuated liver injury and liver fibrosis compared to WT mice after BDL and CA chow diet, demonstrated by significantly decrease in serum ALT, AST, ALP, TBA, hepatic hydroxyproline, Masson Trichrome, H&E, and Sirius red staining as well as immunohistochemistry staining of α-SMA. BA profiling and PCA analysis indicated that $S1PR1^{Krt19CreERT+/+}$ mice alleviates the destruction of bile acid homeostasis induced by BDL and CA chow diet. RNA-seq analysis in BDL liver showed downregulation of ROS, ER stress, and CCR1 chemokine receptor binding signaling in $S1PR1^{Krt19CreERT+/+}$ mice compared to WT mice. WB analysis showed that cholangiocytes-specific deletion of S1PR1 attenuates CHOP induction, phosphorylation of JNK, eif2α, and PERK induced by BDL. Q-PCR analysis showed that cholangiocytes-specific deletion of S1PR1 attenuates the upregulation of *Ccl4*, *Ccl6*, and *Ccl7* induced by BDL.
Conclusion: Our results illustrate that the cholangiocytes-specific deletion of S1PR1 can alleviate liver fibrosis and injury caused by biliary obstruction or chronic cholestasis, which helps to develop S1PR1 as a target for the treatment of liver fibrosis and cholestasis.

Email: r.p.oude-elferink@amc.uva.nl

Background and aims: Pruritus can be a major and debilitating symptom in cholestasis. Treatment is difficult, as the pathophysiology of this symptom remains elusive. This study aims to identify circulating agonists for TRPA1 and other pruriceptors in the enterohepatic circulation, in bile and blood, as a possible cause for itching in cholestatic patients.
Method: Bile of 5 cholestatic patients with and without itch (various cholestatic liver diseases), was fractionated and assessed for in vitro pruriceptor activation ([Ca2+]I and luciferase assays) in HEK293T cells. Collected fractions were tested for activation of specific receptors (TRPA1, TRPV1, TRPV3, TRPV4, MRGPRX1, MRGPRX4, FXR) and active fractions were subfractionated and again tested. The content of positive fractions was identified by means of HPLC-MS/MS and, if possible, validated with commercially available standards.

Pruritogenic activity of these compounds was assessed by intradermal injection in wild type and TRPA1-deficient mice.
Results: Several fractions from bile activated the TRPA1 receptor (and several other receptors) in vitro. One of these fractions contained a compound with m/z 311.22 which could be identified as a hydrophilic isomer of hydroperoxylinoleic acid (HpODE). We could also show that in bile HpODE is rapidly converted into a hydrophilic isomer. Upon biliary diversion of a BRIC type 1 patient we could show that the initial excretion of HpODE and its metabolites is very high with gradual decrease concomitant with the disappearance of itch. In plasma of pruritic cholestatic patients HpODE concentrations were significantly increased compared to cholestatic patients without itch and healthy controls. Wild type mice exhibited scratching behavior upon intradermal injection of HpODE, whereas TRPA1 deficient mice did not.
Conclusion: HpODE, a pruritogen in vitro and in vivo is present in elevated levels in cholestatic patients who experience itch. This compound, and its metabolites is highly secreted into bile upon biliary diversion. Pruriceptor antagonists may be useful in the treatment of cholestatic pruritus.

FRI458
Characterising the early inflammatory landscape of primary sclerosing cholangitis

Calli Dendrou[1], Kate Lynch[2,3], Fabiola Curion[1,4], Charlotte Rich-Griffin[1], Hing-Yuen Yeung[1], Nicholas Provine[2], Nicholas Ilott[2], Helen Ferry[2], Eve Fryer[5], Holm Uhlig[2], Roger W.G. Chapman[2], Satish Keshav[2], Paul Klenerman[2]. *[1]Wellcome Centre for Human Genetics, University of Oxford, Oxford, United Kingdom; [2]Translational Gastroenterology Unit, University of Oxford, Oxford, United Kingdom; [3]Royal Adelaide Hospital, University of Adelaide, Adelaide, Australia; [4]Institute of Computational Biology, Helmholtz Munich, Neuherberg, Germany; [5]John Radcliffe Hospital, Nuffield Division of Clinical and Laboratory Sciences, Oxford, United Kingdom*
Email: cdendrou@well.ox.ac.uk

Background and aims: Primary sclerosing cholangitis (PSC) is a chronic inflammatory biliary disease characterised by progressive fibrosis that can lead to cirrhosis and liver failure. Over 70% of PSC patients also have gut co-morbidities, typically ulcerative colitis (UC), suggesting a link between liver pathology and gut microbial dysbiosis. Therapeutic options for PSC are limited, with liver transplantation being most effective, although disease may recur. Thus, there is a dire need to better understand and target the pathological mechanisms of PSC, particularly those acting early on.

A key challenge to characterising early pathology in PSC has been related to acquiring liver biopsies. However, fine needle aspiration (FNA) has emerged as a safe technique for obtaining liver infiltrating immune cells. We sought to assess the experimental efficacy of FNA to adequately sample liver immune cells, and to map the early inflammatory landscape in the liver relative to matched peripheral blood using single-cell profiling technologies. We also sought to assess how inflammation in the liver compares to pathology in the gut of PSC patients presenting with UC.
Method: We obtained liver-infiltrating mononuclear immune cells via FNA and peripheral blood mononuclear cells (PBMCs) from patients with PSC and with non-alcoholic fatty liver disease/steatohepatitis. Cells were analysed by polychromatic flow cytometry and by 10× Genomics single-cell RNA sequencing (scRNAseq). In addition, gut biopsies from PSC-UC patients were obtained and also analysed by scRNAseq.
Results: We obtained liver FNAs from 38 patients (21 PSC, 17 control patients). The median pain score was 0 and no serious adverse effects were reported. Flow cytometry analysis demonstrated a significant enrichment of natural killer (NK) cells, CD8+ T cells, and CD69+ T cells in the liver (all $p < 0.05$). High-resolution profiling of 38, 012 liver immune cells and 78, 751 PBMCs by scRNAseq in a patient subset specifically showed an enrichment of CXCR6+ NK cells, CD8+ central memory T cells, and mucosal-associated invariant T cells in the liver, and a relatively lower abundance of CD4+ regulatory T cells (all $p < 0.05$). Among other immune cell types captured, dendritic cells were enriched in the liver whilst FOShi classical monocytes were reduced ($p < 0.05$). Gene expression analyses also revealed PSC-specific inflammatory pathways, such as an increase in cytokine responsiveness, and analogous analyses were applied to the PSC gut samples.
Conclusion: FNA sampling is a safe approach for obtaining insights into the early inflammatory landscape of the liver in PSC and other diseases, with the application of single-cell methods across tissues revealing tissue-specific and shared inflammatory pathways that may provide a basis for further experimental medicine analyses.

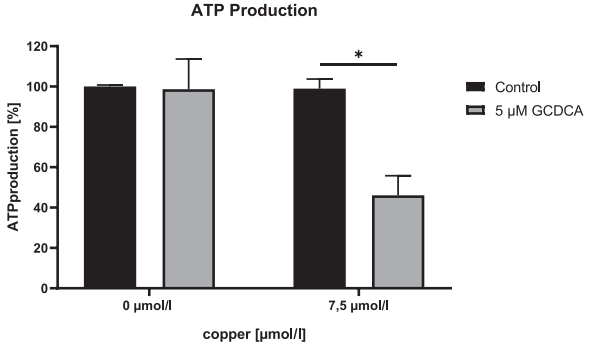
Hospital of Zunyi Medical University, Department of Gastroenterology, Zunyi, China; [5]Justus Liebig University, Gastroenterology, Center for Internal Medicine, Gießen, Germany
Email: dennis.koob@med.uni-muenchen.de

Background and aims: Derangement of copper homeostasis, as seen in Wilson's disease, causes liver damage. Copper accumulation also occurs in chronic cholestatic liver disease. In primary sclerosing cholangitis, copper accumulation, i.e. Orcein staining as a component of the Nakanuma score, even predicts reduced transplant-free survival. We hypothesize that copper accumulation might not only be a consequence of cholestasis, but modulate the course of disease. We aimed to investigate the role of copper accumulation in animal models of cholestasis and identify potential molecular targets of copper and bile salt co-toxicity.
Method: Hepatic copper content was determined in wild type and Mdr2$^{-/-}$ animals on both FVB and BALBc backgrounds. Liver damage and liver fibrosis were quantified. Mdr2/FVB animals were fed a copper-enriched diet (2 g/kg). The hepatocyte cell line HepG2 was stably transfected with Ntcp to allow for bile salt uptake and was stimulated with glycochenodeoxycholate (GCDC) and copper (5–10 µM, each). Cell survival, apoptosis, proliferation, and metabolic activity were assessed. In mitochondria from stimulated cells, oxygen consumption and ATP production were quantified.
Results: While hepatic copper content was not different from wildtype in Mdr2/FVB animals, it was increased 1.5 ± 0.2-fold in Mdr2/BALBc (wt/BALBc vs. Mdr2/BALBc, n = 5, $p < 0.05$). Overall, hepatic copper content correlated with liver fibrosis as determined by liver hydroxyproline ($r^2 = 0.8$, $p < 0.05$, n = 9). Copper feeding was well tolerated in wt animals and was associated with a slight but insignificant increase in serum ALT only in Mdr2/FVB animals. However, it led to an increase in hepatic copper content (13.5 ± 1.2 vs. 1898.3 ± 445.7 mg/kg, n = 6, $p < 0.01$) and liver fibrosis (Desment score, 0.4 ± 0.5 vs. 1.3 ± 0.5, $p < 0.05$) in Mdr2/FVB. In HepG2, doses applied of both GCDC and copper were non-toxic in WST assays. Combination of both stimuli, however, led to a marked impairment of metabolic activity to 65.9 ± 4.3% (n = 6, $p < 0.05$). While caspase-3/7 assays excluded apoptosis, reduced proliferative activity was found upon dual treatment. In isolated mitochondria from stimulated HepG2 cells, ATP production was unaffected by each stimulus alone. Combined treatment, however, led to a drop in ATP production from 100 ± 4.1% to 46.1 ± 9.7% (n = 3, $p < 0.05$) (Figure 1), accompanied by an increase in mitochondrial oxygen consumption.



Conclusion: Hepatic copper deposition in experimental cholestasis is associated with progression of liver fibrosis, mimicking the human phenotype. On a cellular level, bile salt and copper synergistically impair ATP production. Since the respiratory chain was unaffected (increase rather than drop in oxygen consumption), the adenine nucleotide translocator (ANT) is a likely molecular target. These results encourage testing of copper chelating strategies in cholestatic liver disease.

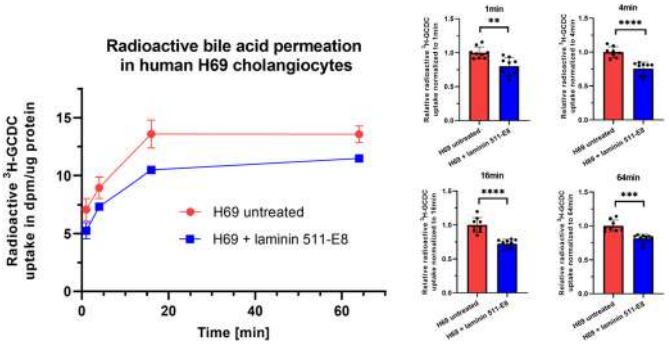
The IgG4-related cholangitis autoantigen laminin 511-E8 stabilizes the biliary bicarbonate umbrella in human cholangiocytes

David Trampert[1], Remco Kersten[1], Dagmar Tolenaars[1], Ronald Oude-Elferink[1], Stan van de Graaf[1], Ulrich Beuers[1]. [1]*Tytgat Institute for Liver and Intestinal Research, Amsterdam Gastroenterology Endocrinology Metabolism (AGEM), Amsterdam University Medical Centers, Department of Gastroenterology and Hepatology, Amsterdam, Netherlands*
Email: u.h.beuers@amsterdamumc.nl

Background and aims: IgG4-related cholangitis (IRC) is the hepatobiliary manifestation of IgG4-related disease (IgG4-RD), a systemic, B-cell driven, fibroinflammatory disorder. To date four autoantigens with pathogenetic relevance have been described by our group and others in IgG4-RD, namely annexin A11, laminin 511-E8, galectin 3 and prohibitin 1 (PMID 28765476, 30089633). We recently demonstrated that patient anti-annexin A11 autoantibodies destabilize the 'biliary bicarbonate umbrella' (PMID 34718050), a protective mechanism against toxic hydrophobic bile acids (PMID 20721884). Another autoantigen, laminin 511-E8, is an extracellular matrix protein that functions as a ligand of the integrin A6B1 (ITGA6B1) receptor (PMID 28879238). Laminin 511-E8 has been shown to upregulate critical components of the 'biliary bicarbonate umbrella' (PMID 27103433) and ITGB1 signaling is important for bile duct development (PMID 22761447). Therefore, we aimed to investigate the role of laminin 511-E8 in human cholangiocytes.
Method: Laminin 511-E8 expression was confirmed in RNA sequencing datasets of human cholangiocyte organoids. Human H69 cells were subjected to shRNA knockdown using lentiviral transduction. Individual knockdown cell lines were generated targeting the mRNA transcripts encoding laminin 511-E8 (LAMA5, LAMB1, LAMC1). Knockdown of LAMB1 and LAMC1 was verified on mRNA and protein level using qPCR and western blot. A parallel approach was taken subjecting H69 cells to recombinant laminin 511-E8 (0.25 ug/cm^2). The function of laminin 511-E8 in human cholangiocytes was assessed by three approaches: (i) intracellular pH (pHi) measurements microspectrofluorimetrically using BCECF-AM; (ii) rate of bile acid influx radiochemically by measuring 22, 23-^{3}H-glycochenodeoxycholic acid (^{3}H-GCDC) permeation over time; (iii) GCDC-induced apoptosis determined dynamically by real-time imaging of Caspase-3/7 Green signal and statically by conventional bulk Caspase-3/7 assays.
Results: Screening of the laminin 511-E8 constituent knockdown cell lines revealed that at least LAMB1 and LAMC1 could be of functional importance in cholangiocytes. ^{3}H-GCDC permeation was larger in LAMB1 and LAMC1 knockdown H69 cells compared to Sham controls. Treatment of human cholangiocytes with the recombinant 511-E8 fragment resulted in a decreased pHi and significantly reduced the rate of ^{3}H-GCDC permeation (Figure).



Conclusion: Collectively, our study indicates that the IgG4-RD autoantigen laminin 511-E8 has a protective role in human

cholangiocytes against toxic bile acids, similar as recently described for annexin A11. We speculate that autoantibodies against laminin 511-E8 may destabilize the biliary bicarbonate umbrella, thereby contributing to the pathogenesis of IRC.

FRI462

The risk-variant rs56258221 at the BACH2-locus associates with skewed polarization of naive CD4+ T cells towards pro-inflammatory phenotypes in primary sclerosing cholangitis

Background and aims: Primary sclerosing cholangitis (PSC) is an enigmatic disease of presumably multifactorial pathogenesis, including genetic predisposition and dysregulated immune responses as likely key contributors to the disease development. We have previously described an intrahepatic naive-like population of $CD4^+$ T cells in patients with PSC, prone to polarize towards a pro-inflammatory T_H17 phenotype. Genome-wide association studies (GWAS) have linked PSC to several polymorphisms in immune-related genes. We here hypothesized that genetic predisposition contributes to the observed T cell phenotype in patients with PSC.
Method: Patients with PSC (n = 270) were genotyped for the disease-associated risk variants *rs56258221* (*BACH2*), *rs80060485* (*FOXP1*), *rs4147359* (*IL2RA*) and *rs7426056* (*CD28*). To determine T cell function and phenotype, comprehensive immunophenotyping, *in vitro* experiments on polarization and proliferation, microRNA-assays, western blots and single-cell RNA sequencing from peripheral blood naive $CD4^+$ T cells was performed. The data generated was correlated to the underlying genotype of the patients.
Results: Functional *in vitro* experiments with naive $CD4^+$ T cells from patients with PSC and healthy donors (HD) showed an increased capacity of PSC-derived cells to convert into pro-inflammatory T Helper 1 (T_H1, 50.7% vs. 42.9%, p = 0.027) and T Helper 17 (T_H17, 5, 5% vs. 2, 2%, p = 0.042) subsets, which was accompanied by a lower conversion rate into induced regulatory T cells (iT_{REG}, 9.6% vs. 17.3%, p = 0.022). The observed effects were significantly increased in carriers of the PSC-associated risk variant *rs56258221* (*BACH2*), which was not seen for the other variants in immune-related genes assessed. Interestingly, single-cell RNA sequencing of the T cell compartment in homozygous SNP carriers vs. non-carriers identified a composition skewed towards activated phenotypes in *rs56258221*-carriers. Reduced expression of BACH2 itself was detected on protein but not mRNA level in naive $CD4^+$ T cells, which could be linked to a strongly increased expression of a microRNA located in close genomic proximity to the SNP and imputed to inhibit translation of BACH2.
Conclusion: We here present comprehensive data linking the risk variant *rs56258221* at the *BACH2*-locus to the recently described dysregulated T cell phenotype in patients with PSC. Decoding how genetic risk contributes to disease pathogenesis is the first step in understanding how the environment interacts with the immune system to fuel disease pathogenesis.

Email: b.k.chung@medisin.uio.no

Background and aims: Primary biliary cholangitis (PBC) and primary sclerosing cholangitis (PSC) are autoimmune hepatobiliary diseases with a high prevalence of autoantibodies. In PBC, anti-mitochondrial antibodies (AMA) serve as robust biomarkers whereas autoantibodies against relevant antigens in PSC remain undefined. Using anti-mitochondrial reactivity as a proxy of disease-relevance, we assessed if expanded B cell clonotypes in PBC livers recognize AMA targets and whether analogous B cells in PSC harbour unique gene expression and antigen specificities.
Method: Liver B cells from PBC (n = 3) and PSC explants (n = 3) were enriched by negative bead selection (Stemcell Technologies, Canada) and assessed for B cell receptor (BCR) and total gene expression by single-cell RNA sequencing (scRNAseq). B cell clonality and differential gene expression (DEG) was analyzed by Cell Ranger and Loupe Browser (10X Genomics, USA). Monoclonal antibodies (mAb) generated from BCR sequences of expanded B clonotypes (GenScript, USA) were pooled and screened against >20, 000 human proteins using HuProt v4 microarrays (Cambridge Protein Arrays, UK). A subselection of mAb microarray targets were verified by immunoblotting or enzyme-linked immunosorbent assays (ELISA).
Results: Cumulative frequencies of the five most-expanded B clonotypes as a percentage of total liver clonotypes were similar amongst PBC and PSC explants (mean: 16.8% vs 15.4%, range: 9.1–30.42% to 0.68–41.17%). In contrast, transcriptomes of expanded PBC clonotypes significantly differed from PSC clonotypes; plasma cell markers such as *CD38*, *JSRP1* and *MZB1* were significantly higher in PBC clonotypes while the naïve and memory B cell markers *MS4A1*, *CD79A*, *CD79B* and *HLA-DP, -DQ, -DR* were significantly enriched in PSC clonotypes (log2 fold-change >2.5, p < 0.05, Benjamini-Hochberg corrected). mAbs generated from the BCR sequences of expanded PBC clonotypes strongly recognized the AMA targets PDC-E2, PDHA1, PDHA2, PDHX whereas PSC mAbs did not recognize AMA targets but strongly bound ACTN4, SFMBT2 and RBP (p < 0.001). PBC mAbs (5 of 15) stained a pooled mixture of AMA antigens (PDC-E2, OGDC-E2, BCOADC-E2) by immunoblotting and ACTN4 binding was assigned to a single PSC mAb (1 of 14) by ELISA.

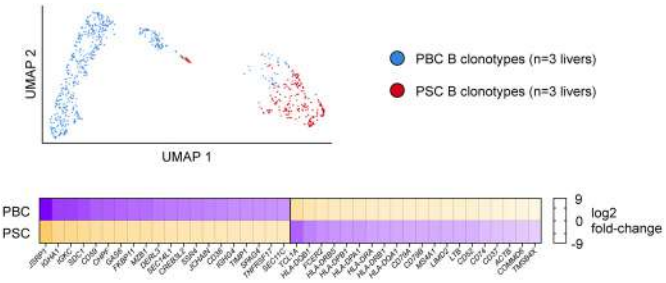

Figure: scRNAseq of expanded B clonotypes in PBC and PSC liver explants. UMAP shows cluster analysis of expanded clonotypes and heatmap indicates comparison of top 20 DEG amongst expanded PBC and PSC clonotypes.

Conclusion: Our results show that expanded B clonotypes in PBC livers resemble antibody-secreting plasma cells while expanded PSC clonotypes mirror naïve and memory B cell states. These findings may explain the lack of specific antibodies in PSC and underscore the utility of scRNAseq in generating mAbs for future antigen studies in PSC.

The rs429358 apolipoprotein E (APOE) polymorphism is associated with increased liver injury in patients with autoimmune hepatitis

Maciej K. Janik[1], Wiktor Smyk[2], Beata Kruk[3], Benedykt Szczepankiewicz[4], Barbara Górnicka[4], Susanne N Weber[5], Piotr Milkiewicz[1,6], Marcin Krawczyk[3,5]. *[1]Medical University of Warsaw, Liver and Internal Medicine Unit, Warsaw, Poland; [2]Medical University of Gdansk, Department of Gastroenterology and Hepatology, Gdansk, Poland; [3]Medical University of Warsaw, Laboratory of Metabolic Liver Diseases, Department of General, Transplant and Liver Surgery, Laboratory of Metabolic Liver Diseases, Centre for Preclinical Research, Warsaw, Poland; [4]Medical University of Warsaw, Department of Pathology, Warsaw, Poland; [5]Saarland University Medical Center, Saarland University, Department of Medicine II, Homburg, Germany; [6]Pomeranian Medical University, Translational Medicine Group*
Email: mjanik24@gmail.com

Background and aims: The natural course of autoimmune hepatitis (AIH) varies between patients; therefore, the potential role of genetic modifiers might be suspected. Recent analyses linked the variant rs429358 in apolipoprotein E (*APOE*) with steatosis and liver injury in fatty liver disease (*Jamialahmadi et al., Gastroenteorology 2021*). Here, we analyse this *APOE* variant in patients with AIH.
Method: The study cohort consisted of 312 non-transplanted (70% women, age 18–83 years) adults with AIH. Pure AIH and its cholestatic variants, namely AIH-primary sclerosing cholangitis (PSC) and AIH-primary biliary cholangitis (PBC), were diagnosed according to the EASL 2015 guidelines. The *APOE* rs429358 polymorphisms were genotyped using TaqMan assays. The liver fibrosis was assessed by liver biopsy, liver stiffness and serum indices (APRI, FIB-4), whereas liver steatosis was evaluated by controlled attenuation parameter (CAP). The effects of the *APOE* polymorphism were analysed in combination with the mitochondrial amidoxime-reducing component 1 (*MARC1*) p.A165T and adiponutrin (*PNPLA3*) p.I148M variants, which were previously shown to modulate liver injury in AIH.
Results: Among recruited patients, the median duration of the disease was 4 (range 0–33) years. Liver cirrhosis was present in 130 (42%) patients, and 70% of the entire cohort received steroid-based therapy. Sixty (19%) patients were therapy naïve at inclusion. In total, 26% of patients with AIH carry at least one copy of the *APOE* rs429358 minor allele. The *APOE* polymorphism was associated with more pronounced liver fibrosis according to APRI score ($p = 0.035$) and liver injury as reflected by increased AST ($p = 0.049$) and a trend for higher ALT ($p = 0.055$) activities in therapy-naïve patients with AIH. A trend between the genetic variant in *APOE* and higher ALT was also noticed in the entire cohort ($p = 0.054$). No link was found between the studied variant and results of liver biopsies, transient elastography or CAP (all $P > 0.05$). The protective effect of the *MARC1* polymorphism on serum ALT ($p = 0.045$) and AST ($p = 0.024$) activities were more pronounced in patients with *APOE* wild-type variant. The effect of the *PNPLA3* p.I148M polymorphism on liver phenotypes was not modulated by the APOE genotype.
Conclusions: Patients with AIH who carry the *APOE* polymorphism might manifest a more pronounced liver injury. Variant *APOE* (rs429358) together with previously detected *MARC1* p.A165T polymorphism might help to stratify patients with AIH concerning their risk of progressive liver injury.

Intrabiliary injection of MAIT antigens induces cholangitis in mice

Kathrine Sivertsen Nordhus[1,2,3], Freeman Zheng[1,2,3], Natalie Lie Berntsen[1,2,3], Laura Valestrand[1,2,3], Jonas Øgaard[1,2,3], Tom Hemming Karlsen[1,2,3,4], Xiaojun Jiang[1,2,3], Espen Melum[1,2,3,4,5]. *[1]Norwegian PSC Research Center, Division of Surgery, Inflammatory Diseases and Transplantation, Oslo University Hospital, Oslo, Norway; [2]Research Institute of Internal Medicine, Division of Surgery, Inflammatory Diseases and Transplantation, Oslo University Hospital, Oslo, Norway; [3]Institute of Clinical Medicine, University of Oslo, Olso, Norway; [4]Section of Gastroenterology, Division of Surgery, Inflammatory Diseases and Transplantation, Oslo University Hospital, Oslo, Norway; [5]Hybrid Technology Hub-Centre of Excellence, Institute of Basic Medical Sciences, Faculty of Medicine, University of Oslo, Oslo, Norway*
Email: espen.melum@medisin.uio.no

Background and aims: Mucosal-associated invariant T (MAIT) cells are a subset of unconventional T-cells that recognize microbial-derived vitamin B metabolites presented by MR1. Previously we have demonstrated that bile from patients with chronic biliary inflammation contains MAIT antigens. Therefore we now aimed to determine if MAIT cells could drive inflammation in the bile ducts by challenging mice with an increased frequency of MAIT cells (*Mr1*$^{+}$ B6-MAIT^{CAST} and i*Valpha*19 Tg C*alpha*$^{-/-}$ mice) with intrabiliary injection of MAIT cell activating antigens in terms of fixed E.coli and 5-OP-RU.
Method: *E.coli*, 5-OP-RU and PBS were injected into bile ducts of *Mr1*$^{+}$ B6-MAIT^{CAST} and i*Valpha*19 Tg C*alpha*$^{-/-}$ mice. Weight and general well-being were monitored daily. The mice were sacrificed after 2, 7 or 14 days. Isolated lymphocytes from liver and spleen were stained with monoclonal antibodies and an MR1 tetramer, then analyzed by flow cytometry. Serum was analyzed for alanine transaminase (ALT).
Results: Intrabiliary fixed *E.coli* injection in i*Valpha*19 Tg C*alpha*$^{-/-}$ mice caused a biliary immune response with increased histological cholangitis score (*E.coli*: 1.29 *vs.* PBS: 0.24, $p = 0.013$) after 2 days, but with similar weight loss and ALT levels compared to vehicle control. Importantly, a clear activation of hepatic MAIT cells were seen after injection of fixed *E.coli* (MFI CD69 *E.coli vs.* PBS: $p = 0.0015$) in contrast to a minor increase in CD69 MFI for non-MAIT T-cells. In *Mr1*$^{+}$ B6-MAIT^{CAST} mice, which has an increased frequency of MAIT cells independent of genetic manipulation, an increased cholangitis score ($p = 0.0485$) was also observed after injection of fixed *E. coli*.
In experiments with intrabiliary 5-OP-RU injection in i*Valpha*19 Tg C*alpha*$^{-/-}$ mice a clear increase in proportion of CD69^{+}CD25^{+} MAIT cells was observed in the liver (5-OP-RU: 18% *vs.* PBS: 7%, $p < 0.0001$) that translated into an increased histological cholangitis score (5-OP-RU: 1.78 *vs.* PBS: 0.47, $p = 0.021$). This suggests that direct activation of MAIT cells leads to cholangitis. A systemic effect, most likely mediated by the portal circulation, was also observed as the proportion of CD69^{+}CD25^{+} MAIT cells in the spleen was also increased (5-OP-RU: 6% *vs.* PBS: 3%, $p = 0.0386$).

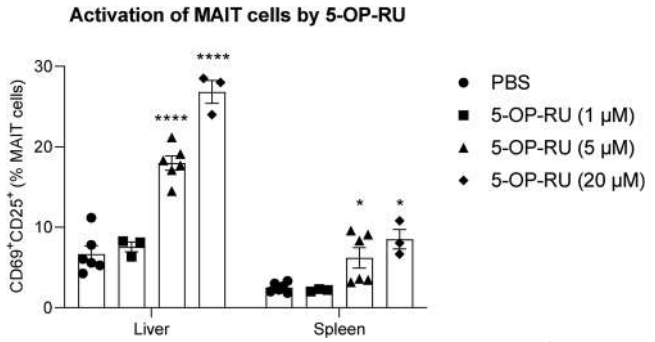

Figure: Intrabiliary 5-OP-RU injection in i*Valpha*19 Tg *Calpha*$^{-/-}$ mice activates MAIT cells.

Conclusion: We observed a clear activation of hepatic MAIT cells in a mouse model of bile duct inflammation that led to cholangitis. Biliary antigens potentially derived from gut microbiota present in the bile ducts could therefore be speculated to induce an immune response where MAIT cells play a role.

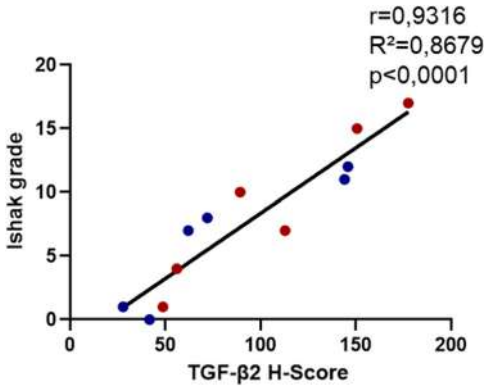
TGF beta 2 fuels inflammation and fibrosis in cholestatic liver disease through macrophage and myofibroblast recruitment and activation

Jan Albin[1], Nadja Meindl-Beinker[2], Matthias Ebert[2], Andreas Teufel[3], Steven Dooley[1], Anne Dropmann[1,3]. [1]*Medical Faculty Mannheim, Heidelberg University, Department of Medicine II, Molecular Hepatology, Mannheim, Germany;* [2]*Medical Faculty Mannheim, Heidelberg University, Department of Medicine II, Mannheim, Germany;* [3]*Medical Faculty Mannheim, Heidelberg University, Department of Medicine II, Clinical Bioinformatics, Mannheim, Germany*
Email: janeinar.albin@medma.uni-heidelberg.de

Background and aims: We have identified TGF-β2 as an important mediator and potential therapeutic target in cholestatic liver disease, in mouse and human. The aim of this study was (1) to correlate TGF-β2 expression with disease activity, fibrotic stage and degree of ductular reaction (DR), and (2) to identify the cell populations in the diseased liver that are source for and target of TGF-β2 and delineate their role in the disease course.
Method: Liver tissues from Abcb4*KO*, CDE & DDC diet, bile duct ligated and CCl_4 treated mice, as well as patient samples were stained for H&E and Sirius Red. Histologic evaluation of disease activity and stage of fibrosis were determined with the Ishak score and compared to age-matched wild type mice and healthy controls respectively. TGF-β2, pSmad3 and cell type markers were analysed by in-situ hybridisation and immunohistochemistry. TGF-β2 expression levels were evaluated with H-Score.
Results: TGF-β2 is produced by cholangiocytes during disease progression in ABCB4*KO* mice and primary sclerosing cholangitis patients, especially in regions of DR. This is also seen in BDL and DDC models, both displaying phenotypes of cholestatic liver disease and TGF-β2 expression levels that increase with severity of the injury. In contrast, CDE fed and CCl_4 treated mice show low TGF-β2 expression, even if DRs are present. In patients and mouse models of cholestatic liver disease mRNA expression levels of TGF-β2 highly correlate with disease activity-especially inflammation, stage of fibrosis and extent of DRs. The data suggest that TGF-β2 is a biomarker of cholestatic liver damage, but not of hepatocellular injury without cholestasis.
In line with high TGF-β2 levels, Abcb4*KO* livers show an increased Smad3 phosphorylation in Kupffer cells (KC) and other macrophages, as well as in hepatic stellate cells (HSC) or portal fibroblasts in the portal field area. In contrast Smad3 phosphorylation levels of hepatocytes and cholangiocytes did not change. KC/HSC also show upregulated TGF receptor expression and presence of activation markers (e.g. αSMA in HSC). The numbers of activated non parenchymal cells and the percentage of the pSmad3-positive fraction in the periportal area correlated with disease progression. Inhibiting TGF-β2 expression with antisense oligonucleotides leads to reduced pSmad3 positive cell numbers, suggesting that TGF-β2 is triggering Smad3 signaling.



Conclusion: TGF-β2 expression is upregulated in cholangiocytes in patients and mouse models with cholestatic liver disease. Neighboring inflammatory and fibrogenic cells display pSmad3 staining and increase in numbers. Next, we search for stress factors and upstream signals that induce TGF-β2 expression during cholestatic liver damage.

Email: anja.zeigerer@helmholtz-muenchen.de

Background and aims: The endosomal sorting complexes required for transport (ESCRT) play a key role in lysosomal degradation of membrane signaling receptors. The machinery consists four protein complexes (ESCRT –0 to –III), that are successively recruited to maturing endosomes, sorting ubiquitinated cargos into intraluminal vesicles destined for degradation. Recently, activation of the ESCRT-I has been reported to protect mice against non-alcoholic steatohepatitis (NASH) by targeting TLR4 for degradation, suggesting its potential role for treating non-alcoholic fatty liver disease (NAFLD) and NASH. Thus, the aim of this project is to identify the function of ESCRT-I in liver physiology by interfering with the major regulator of ESCRT-I stability and function, the tumor susceptibility gene 101 (Tsg101).
Method: Tsg101 was downregulated using lipid nanoparticle induced hepatocyte-specific *in vivo* and adenovirus based primary hepatocytes *in vitro* knockdown. The *in vivo* experiments were conducted in time course while serum and livers are collected for functional analysis.
Results: Consistent with previous data, we found Tsg101KD leads to ESCRT-I instability, supporting an essential role of Tsg101 on ESCRT-I function. Remarkably, loss of Tsg101 induces severe liver

inflammation and organ damage leading to animal lethality 8 days after injection. This is associated with a vast elevation of aspartate aminotransferase (AST), alanine aminotransferase (ALT) and bile acid levels in the serum accompanied by a decrease in blood glucose concentrations, indicating severe liver pathologies. Also, the size of the gallbladder is increased in Tsg101KD mice with disrupted bile canaliculi structure, pointing towards impairment of bile acid homeostasis. Initiation of the inflammatory response is dependent on the endosomal accumulation of tumor necrosis factor receptor (TNFR), which leads to the activation of canonical and non-canonical transcription factor nuclear factor kB (NF-kB) signaling and the upregulation of downstream cytokines. Moreover, we observe a time-dependent decrease in mitochondrial function, characterized by mitochondrial uncoupling and enhanced proton leak, which manifests into activation of caspase-3 cleavage and induction of apoptosis. The activation of inflammation upon Tsg101 KD is in line with data from NASH patients, where *TSG101* expression is decreased and negatively correlated with interleukin 6 (*IL6*) and 1 beta (*IL1b*) levels, highlighting a potential regulatory function of Tsg101 in liver inflammation.
