(alpha1-4), which heterodimerize with the Retinoid-X-Receptor (RXR) and activate transcription from a DNA motif (IR-1, inverted repeat-1). We recently showed that FXR isoforms alpha 2/4 bind to an additional DNA motif (ER-2, everted repeat-2), representing 90% of FXR binding events and regulating numerous genes of therapeutic interest. Here we investigated regulators of FXR activation from the IR-1 and ER-2 DNA binding motifs.

**Method:** Differential interactors of the ER-2 and IR-1 motifs were identified by DNA pull down followed by mass-spectrometry. The effect of candidate proteins on FXR-driven transactivation was tested on luciferase reporter assays. DNA binding was assessed by EMSA and ChIP in HepG2 cells. A novel mutation in the LBD of FXR was generated to abrogate its binding to RXR and further validate the role of this interaction in FXR target selectivity.

**Results:** RXR, the classical heterodimerization partner of FXR, is not required for FXR binding to ER-2 sites. Instead, RXR inhibits FXR-driven transactivation from these sites in reporter constructs and cell lines. Concomitantly, pharmacological and mutational abrogation of the FXR-RXR interaction selectively negates activation from IR-1 sites while retaining ER-2 activation capacities. Interestingly, transactivation by FXR $\alpha$ 2 from overlapping IR-1/ER-2 motifs is not affected by RXR availability.

**Conclusion:** Our results reveal a novel mechanism behind FXR alpha 2/4 target gene selectivity, and demonstrate the FXR-RXR interaction as a negative regulator of transcription from ER-2 sites upon FXR agonism. As the FXR alpha 2/4 selective binding to ER-2 sites induces a transcriptional profile predictive of enhanced handling of nutrient stress, promoting this FXR feature will likely increase therapeutic efficacy for metabolic disorders such as NAFLD/NASH.

#### cell cycle-regulatory genetic aberrations and their prognostic implications in early-stage hepatocellular carcinomas

Jihyun An<sup>1</sup>, Ji-hye Oh<sup>2</sup>, Wonkyung Kim<sup>2</sup>, Bora Oh<sup>2</sup>, Yoo-Jin Oh<sup>2</sup>, Chang Ohk Sung<sup>2</sup>, Ju Hyun Shim<sup>2</sup>. <sup>1</sup>Hanyang University, Korea, Rep. of South; <sup>2</sup>Asan Medical Center, Korea, Rep. of South  
Email: s5854@amc.seoul.kr.

**Background and aims:** Uncontrolled proliferation induced by cell cycle deregulation is a hallmark of cancer cells. This study aimed to explore fusional and non-fusional aberrations related to the cell cycle, and investigate their prognostic relevance in a surgical series of hepatocellular carcinomas (HCCs).

**Method:** Based on high-resolution transcriptomic data for 206 early-stage HCC samples obtained after curative hepatectomy at Asan Medical Center, South Korea, we fully characterized distinct patterns of fusion events using STAR-Fusion. The presence of the fusion transcripts was subsequently confirmed by Sanger sequencing. We also identified non-fusional genetic aberrations deregulating the cell cycle in the same cohort. Prognostic effects of genomic events were evaluated by competing risks regression analyses.

**Results:** We identified a total of 89 gene fusion events in 49 samples, including 77 novel and 7 recurrent fusion transcripts. The cell cycle-related gene fusions, *ERRF1-CCNE1*, *UPF3A-CDC16*, and *ITM2B-RB1*, were observed in different tumors (n = 4). Notably, the *UPF3A-CDC16* fusions recurrently detected in two samples harbored biallelic loss of function of *CDC16*, together with abnormally high levels of *cyclin B1* and *Ki-67*. We additionally found that a sub-category of 17 cell cycle gene aberrations other than gene fusions were present in 61 (29.6%) of the 206 patients. These fusional and non-fusional subgroups were enriched for gene sets related to cell proliferation, and were associated with poorer outcomes for cancer-specific death, when compared to non-affected individuals (adjusted hazard ratios [95% confidence intervals], 16.86 [5.37–52.88] and 2.58 [1.30–5.09], respectively).

**Conclusion:** We have provided a comprehensive overview of fused and mutated cell-cycle genes that confer a negative effect on tumor

behavior in early HCCs. Our clinical and biological insights may serve as the basis for better-tailored cares for patients with the disease.

### PO-1027

#### A low carbohydrate diet partially prevents the hepatic histological damage of hepatocyte OGT-deficient mice.

Lucia Parlati<sup>1</sup>, Paula Ortega Prieto<sup>1</sup>, Fadila Benhamed<sup>1</sup>, Melanie Montabond<sup>1</sup>, Tarik Issad<sup>1</sup>, Catherine Postic<sup>1</sup>. <sup>1</sup>Institut Cochin, U1016 INSERM, Université de Paris, PARIS 14E ARRONDISSEMENT, France  
Email: lucia.parlati85@gmail.com.

**Background and aims:** O-GlcNAcylation (O-GlcNAc) is a post-translational modification, controlled by two enzymes, OGT (O-GlcNAc transferase), which adds N-Acetylglucosamine on the serine or threonine residues and OGA (O-GlcNAcase) which eliminates it. O-GlcNAc is one of the main effectors of metabolism and contributes to gluco-lipototoxicity in the liver. A recent study reports that hepatocytes from liver OGT-deficient mice undergo massive necroptosis, elevated transaminases, inflammation and fibrosis (1). Our hypothesis is that since OGT is a glucose sensor, lowering glucose intake may protect OGT-deficient mice from liver damage.

**Method:** We analysed the hepatic phenotype and the clinical-biological parameters, the variation in the expression of the genes involved in proliferation, inflammation, fibrogenesis and metabolic pathways of control mice (OGT<sup>F</sup>) and mice with a selective deletion of hepatic *ogt* (OGT<sup>A</sup>) after weaning with a standard diet (SD: 72.4% of carbohydrates, 8.4% of fat, 19.3% of protein) and a low carbohydrate diet compensated by lipid enhancement (LCLE: 35% of carbohydrates, 45% of fat, 20% of protein). We used male and female mice.

**Results:** The OGT<sup>A</sup> mice did not exhibit any major disturbance in metabolic homeostasis, regardless of the diet used. We measured key genes involved in gluconeogenesis and lipogenesis and did not observe any significant difference in OGT<sup>A</sup> mice compared to controls, regardless of the diet used. The hepatic phenotype of OGT<sup>A</sup> mice, compared to OGT<sup>F</sup> mice, was characterized by: an increase in hepatocellular proliferation and inflammatory infiltrate, fibrosis and a tendency to increased hepatic triglycerides concentrations, regardless of the diet. Interestingly, OGT<sup>A</sup> mice under LCLE showed a decreased in serum alkaline phosphatase suggesting a less severe phenotype. Indeed, this was associated with a decreased in the expression of specific inflammatory, ER stress and DNA damage markers (TNF $\alpha$ , MCP1, CHOP, NQO1, pH2AX).

**Conclusion:** The loss of hepatic OGT leads to a severe hepatic phenotype with inflammation and fibrosis. While the LCLE regimen did not prevent the hepatic histological alterations of OGT<sup>A</sup> mice it partially reverted some aspects of the phenotype. Our data suggest that lowering glucose intake may prevent the deleterious effect of OGT silencing in liver.

### PO-1357

#### Role of ASCT2 and KGA for ammonia-induced astrocyte senescence

Olivia Knappe<sup>1</sup>, Alina Schrimpf<sup>1</sup>, Ayse Karababa<sup>1</sup>, Linda Czeszewski<sup>1</sup>, Hans Jürgen Bidmon<sup>2</sup>, Tom Luedde<sup>1</sup>, Dieter Häussinger<sup>1</sup>, Boris Görg<sup>1</sup>. <sup>1</sup>Clinic for Gastroenterology, Hepatology and Infectiology, Heinrich Heine University, Düsseldorf, Germany; <sup>2</sup>C. and O. Vogt Institute for Brain Research, Heinrich Heine University, Düsseldorf, Germany  
Email: boris.goerg@uni-duesseldorf.de.

**Background and aims:** Recent studies suggested a role of astrocyte senescence for permanent cognitive impairment in patients with liver cirrhosis and hepatic encephalopathy (HE) (Görg et al. 2019, *J Hepatol* 71: 930–941). In the present study, we examined a potential relevance of the mitochondrial glutamine importer ASCT2 and

A) Weaning and group composition, B) Diets' characteristics, C) RNA relative expression of ER stress (CHOP), oxidative stress (NQO1), and inflammation markers (MCP1 and TNFalpha), D) Western Blot of pH2AX (DNA damage markers), E) Western Blot of CHOP (ER stress markers)

Figure: (abstract: PO-1027)

kidney-type glutaminase (KGA) for the ammonia-induced and glutamine and glucosamine synthesis-dependent astrocyte senescence.

**Method:** KGA and ASCT2 protein and/or mRNA levels were investigated in ammonia-exposed rat astrocytes *in vitro* and in brain samples from ammonia acetate-treated rats and in *post mortem* samples from patients with liver cirrhosis with or without HE. mRNA levels were quantified by qPCR and protein levels were analysed by Western blot and immunofluorescence and confocal laserscanning and super-resolution microscopy. Senescence-associated beta-galactosidase (SA-beta-Gal) activity was measured using the SA-beta-Gal substrate C12FDG and fluorescence microscopy.

**Results:** Immunofluorescence analyses revealed that KGA and ASCT2 are both present in astrocytes *in vitro* and in rat brain *in situ*. KGA and ASCT2 were both localized in mitochondria and KGA mRNA and ASCT2 mRNA and protein levels were upregulated by NH<sub>4</sub>Cl (5 mM, 72 h) in astrocytes *in vitro*. Glutamine synthetase inhibition by methionine-sulfoximine (3 mM) or phosphinothricin (100 μM) prevented the NH<sub>4</sub>Cl-induced upregulation of KGA. siRNA-mediated knockdown of KGA or ASCT2 or ASCT2 inhibition by O-benzyl-L-serine (10 mM) inhibited the NH<sub>4</sub>Cl-induced upregulation of heme oxygenase 1, glucose regulated protein 78 and growth arrest and DNA damage inducible 45alpha. KGA knockdown also prevented the NH<sub>4</sub>Cl-induced upregulation of SA-beta-Gal activity and proliferation inhibition in astrocytes *in vitro*. KGA and ASCT2 protein levels were also elevated in cerebral cortex of ammonia acetate-treated rats

(4.5 mmol/kg, 24 h) and ASCT2 mRNA levels were increased in *post mortem* brain samples from patients with liver cirrhosis and HE.

**Conclusion:** Our findings suggest that ammonia triggers oxidative and ER stress and senescence in astrocytes by ASCT2-dependent mitochondrial glutamine import and subsequent KGA-mediated glutaminolysis. These findings may have important implications for senescence-induced persistent cognitive impairment in patients with liver cirrhosis and HE.

**FXR agonists increase liver-derived serum alkaline phosphatase by species-specific pharmacologic mechanisms independent of cholestasis**

Justin Schumacher<sup>1</sup>, Ting Su<sup>1</sup>, Anthony Azzara<sup>1</sup>, Vasanthi Bhaskaran<sup>1</sup>, Gary Cao<sup>1</sup>, Milinda Ziegler<sup>1</sup>, Lisa Burns<sup>1</sup>, Bo Kong<sup>2</sup>, Grace Guo<sup>2</sup>, Kristina Chadwick<sup>3</sup>, John Krupinski<sup>1</sup>, Evan Janovitz<sup>1</sup>. <sup>1</sup>Bristol Myers Squibb, Nonclinical Research and Development; <sup>2</sup>Rutgers University, Department of Pharmacology and Toxicology; <sup>3</sup>Bristol Myers Squibb, Global Regulatory Strategy and Policy  
Email: justin.schumacher@bms.com.

**Background and aims:** Serum alkaline phosphatase (ALP) activity is a commonly used biomarker to detect biliary injury. Targeting the farnesoid X receptor (FXR), a nuclear hormone receptor, has shown therapeutic potential in non-alcoholic steatohepatitis (NASH). Non-bile-acid based FXR agonists increase serum ALP without

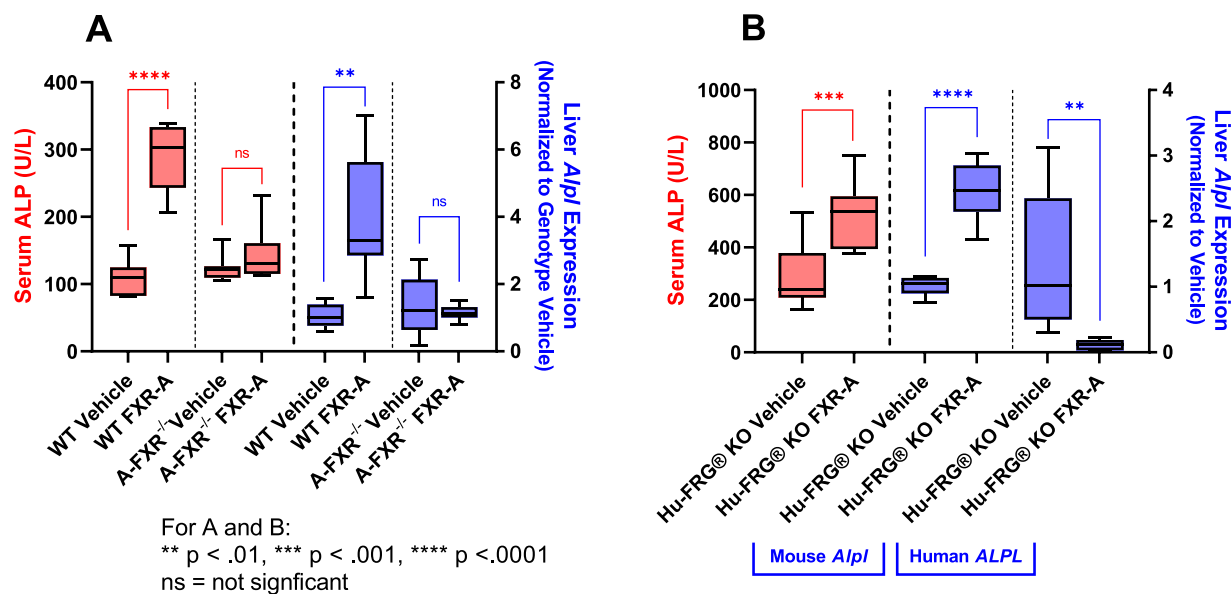

Figure: (abstract: PO-1606)

exacerbating underlying liver diseases. Increased serum ALP has been observed in mice, rats and monkeys treated with FXR agonists and it is hypothesized that the increase is based on de novo synthesis of ALP via transcriptional upregulation of genes encoding ALP.

**Method:** Wild-type mice (WT), hepatocyte specific FXR knockout mice (A-FXR<sup>-/-</sup>), human hepatocyte chimeric mice (Hu-FRG® KO), Sprague-Dawley (SD) rats and monkeys were treated orally with either of two structurally similar, non-bile acid derived FXR agonists (FXR-A or FXR-B). Serum ALP activity and expression of genes encoding ALP isoforms in the liver (*Alpl*) and ileum (*Alpi*) were determined. Putative FXR response elements in *Alpl* regulatory regions were identified using bioinformatics and confirmed to be functional using a luciferase assay.

**Results:** FXR-A and/or FXR-B increased serum ALP in WT mice, Hu-FRG® KO mice, SD rats and monkeys, but not in A-FXR<sup>-/-</sup> mice. These increases correlated with increased expression of liver *Alpl*, and were independent of bilirubinemia, cholestasis or biliary tract pathology. In the livers of A-FXR<sup>-/-</sup> mice, *Alpl* was unchanged by FXR-A (Figure A). In the ileum of both WT and A-FXR<sup>-/-</sup> mice, *Alpi* was unchanged by FXR-A. In the livers of Hu-FRG® KO mice, expression of murine *Alpl*, but not human, *ALPL* increased with FXR-A (Figure B). Correspondingly, functional FXR response elements in the rodent, but not human, regulatory regions of the *ALPL/Alpl* gene were identified. Response elements diverged between different species of non-human primates.

**Conclusion:** These studies indicate that FXR agonists increase serum ALP activity by FXR-dependent induction of hepatic *Alpl/ALPL* in mice, rats and monkeys, but suggest a different mechanism in humans.

**PO-1615**

**Role of cytosolic phospholipase A2 and 5-lipoxygenase for ammonia-induced astrocyte senescence**

Philipp Heimers<sup>1</sup>, Tom Luedde<sup>1</sup>, Dieter Häussinger<sup>1</sup>, Boris Görg<sup>1</sup>.  
<sup>1</sup>Heinrich Heine University Düsseldorf, Clinic for Gastroenterology, Hepatology and Infectiology, Düsseldorf, Germany  
 Email: Philipp.Heimers@uni-duesseldorf.de.

**Background and aims:** 5-lipoxygenase (5-LO) and cytosolic phospholipase A2 (cPLA2) have been suggested to play an important role for cerebral senescence during aging. Whether 5-LO and cPLA2 also contribute to astrocyte senescence and hepatic encephalopathy (HE) is currently unknown and was investigated in the present study.

**Method:** Effects of ammonia on protein levels and nuclear accumulation of cPLA2, 5-LO, coactosin-like protein 1 (COTL1), P53, P21 and growth arrest and DNA damage inducible protein 45alpha (GADD45alpha) were analyzed by immunofluorescence analyses and fluorescence microscopy in rat astrocytes *in vitro*. mRNA levels of surrogate markers for oxidative (heme oxygenase 1, HO1) and endoplasmic reticulum stress (78 kDa glucose-regulated protein, GRP78) and senescence (P21, GADD45alpha) were quantified by qPCR. The activity of the senescence-associated beta-galactosidase (SA-beta-gal) was measured using the fluorogenic SA-beta-gal substrate C12FDG and fluorescence microscopy.

**Results:** NH4Cl (5 mM) strongly increased cytosolic and nuclear cPLA2, nuclear P-Ser505-cPLA2, 5-LO and COTL1 immunoreactivities after 24 and 72 h in rat astrocytes *in vitro*. Nuclear levels of P-Ser392-P53 and mRNA levels of HO1, GRP78, P21 and GADD45alpha were increased in NH4Cl (5 mM)-exposed astrocytes. Inhibition of cPLA2 using CAY10650 (1 uM) and inhibition of 5-LO with Zileuton (10 uM) prevented the upregulation of HO1, GRP78, P21 and GADD45alpha mRNA at 24 h but not at 72 h after NH4Cl (5 mM)-exposure. Zileuton also prevented the NH4Cl (5 mM, 72 h)-induced nuclear accumulation of P21 and GADD45alpha and increase in C12FDG fluorescence. mRNA levels of 5-LO, 5-LO activating protein (FLAP) and COTL1 were upregulated in human *post mortem* brain tissue from patients with liver cirrhosis with HE but not in those without HE.

**Conclusion:** The findings of the present study suggest a role of cPLA2 activation and upregulation of 5-LO for ammonia-induced oxidative and ER stress and senescence in rat astrocytes *in vitro*. mRNA levels of 5-LO, FLAP and COTL1 were also elevated in *post mortem* brain samples from patients with liver cirrhosis with but not in those without HE. The data suggest that 5-LO dependent leukotriene synthesis may play a role for senescence in ammonia-exposed rat astrocytes and in the brain in HE. Supported by German Research Foundation (DFG) through Collaborative Research Center (CRC) 974.

**Signal regulatory protein alpha promotes immune escape of hepatocellular carcinoma through mediating T-cells apoptosis**

Dongbo Chen<sup>1</sup>, Pu Chen<sup>1</sup>, Kangjian Deng<sup>2</sup>, Liying Ren<sup>2</sup>, Xingwang Xie<sup>1</sup>, Weijia Liao<sup>2</sup>, Hongsong Chen<sup>1</sup>. <sup>1</sup>*Peking University People's Hospital, Peking University Hepatology Institute, Beijing Key Laboratory of Hepatitis C and Immunotherapy for liver Disease, Beijing, China;* <sup>2</sup>*Laboratory of Hepatobiliary and Pancreatic Surgery, Affiliated Hospital of Guilin Medical University, Guilin, China*  
Email: chen hongsong@pkuph.edu.cn.

**Background and aims:** Activation-induced cell death (AICD) in T lymphocytes helps maintain T cell homeostasis and peripheral immune tolerance. While tumor-mediated AICD of tumor-infiltrating T lymphocytes is more likely to be involved in tumor immune escape, detailed understanding of the mechanism is limited. In our study, we aimed to perform a genome-wide CRISPR/Cas9 knockout (GeCKO) library screening to identify key genes that, when lost, play an important role in tumor-mediated AICD of tumor-specific T cells.

**Method:** Firstly, the human leukemic T cell line Jurkat E6-1 cells were infected with the GeCKO lentiviral library in low multiplicity of infection (MOI), which consists 123, 411 single-guide RNAs (sgRNAs) targeting 19, 840 human genes. Then, the Jurkat E6-1-GeCKO library cells were stimulated with ConA, PMA + PHA and PMA + Ionomycin, respectively, which could lead to AICD in T-cells. Subsequently, the viable cells after culture and amplification were subjected to PCR and high-throughput sequencing to determine the corresponding genes of enriched sgRNAs that promote AICD. The candidate genes were verified in Jurkat cells with the corresponding sgRNAs, and the protein expression of these genes was detected in human HCC tissues using a novel multi-labelling immunohistochemical technique. Finally, the correlation between candidate genes and the frequency of tumor-infiltrated immune cells was determined by analyzing RNA-seq data of TCGA liver hepatocellular carcinoma (LIHC) dataset.

**Results:** By using GeCKO library screening, we identified 519 sgRNAs were enriched in ConA group, while 151 sgRNAs in PMA + PHA group and 449 sgRNAs in PMA + Ionomycin group. Interestingly, 121 sgRNAs were enriched in three groups. The gene ontology (GO) analysis showed that signal regulatory protein alpha (SIRPa) was involved in T cell-mediated cytotoxicity and other biological processes, suggesting that SIRPa might play an important role in promoting AICD in T-cells. In addition, we identified that the apoptosis level of Jurkat cells with SIRPa overexpression was significantly higher than that of the control group, while SIRPa depletion could significantly inhibit apoptosis. Importantly, compared to the adjacent normal tissues, SIRPa was overexpressed in tumor-infiltrating T lymphocytes of HCC tissues. Finally, the analysis of RNA-seq data of TCGA LIHC dataset revealed that the mRNA expression level of SIRPa in patients with advanced HCC was significantly higher than that in patients with early HCC, and was positively correlated with the frequency of tumor-infiltrated T cells, which suggested that SIRPa might mediate the immune escape of HCC through promoting AICD in tumor-infiltrated T cells.

**Conclusion:** SIRPa plays an important role in promoting AICD in T-cells and it may be as a potential therapeutic target in preventing tumor immune escape.

**PO-2627**

**Hepatocytes Caspase6 inhibition exacerbated inflammation and fibrosis in 3D liver spheroids, stellate cells, and the GAN mouse model of NASH**

Hani Jouihan<sup>1</sup>, Sheng-Ping Wang<sup>1</sup>, George Ho<sup>1</sup>, Stephen Beck<sup>1</sup>, Lifeng Wang<sup>1</sup>, Wensheng Lang<sup>1</sup>, Stephanie Rivera<sup>1</sup>, Carlos Rodriguez<sup>1</sup>, Krishna Yekkala<sup>1</sup>, Dozie Amuzie<sup>1</sup>, Fritz Kramer<sup>1</sup>, Andrea Nawrocki<sup>1</sup>, Alessandro Poca<sup>1</sup>. <sup>1</sup>*Janssen Research and Development Spring House, Spring House, United States*  
Email: hjouihan@its.jnj.com.

**Background and aims:** Non-alcoholic steatohepatitis (NASH) is a chronic liver disease that can result in cirrhosis and hepatocellular carcinoma (HCC). Cell death, including apoptosis is increased in human NASH and correlates with disease severity. Apoptosis is driven by the caspase cascade, which involves a series of protein cleavage and activation steps. Recent findings demonstrated that liver caspase 6 (Casp6) is increased in NASH patients and is a critical driver of hepatic cell death, however, the precise mechanism and cell type in which Casp6 is exerting its effects remains unclear.

**Method:** Here, we investigated the role of Casp6 across hepatic cellular populations. We leveraged siRNA to inhibit Casp6 in human 3D liver spheroids, primary human hepatic stellate cells (HSC) and the GAN diet-induced obese mouse model of NASH.

**Results:** Despite marked downregulation of Casp6 expression in primary HSC and 3D spheroids (−96% and −70%, respectively), no significant differences were observed in inflammatory (*IL1b*, *CCL2*, *CXCL1*) or fibrotic (*COL1a1*, *COL4a1*, *TIMP1*, *MMP-2*, *-9*) genes. We next utilized GalNAc-siRNA to specifically knockdown Casp6 in hepatocytes in the GAN mice. Hepatocyte Casp6 inhibition in GAN mice resulted in reduced Casp6 protein and mRNA (77% and 82% respectively) and a trend toward reduction of whole liver apoptosis (−20%, *p* < NS). Although no significant changes were observed in plasma ALT and AST levels, Casp6 KD resulted in reductions in liver fat mass (−12%, *p* < 0.01), and plasma cholesterol (−13%, *p* < 0.05) while expression of proinflammatory and pro-fibrotic genes such as *Tnfa*, *IL-6*, *Nlrp3*, *Col1a1*, and *Timp1* were increased. Consistent with these data, histological assessment of livers obtained from Casp6 KD mice exhibited significant increases in markers of inflammation (CD11b, +112%), fibrosis (*Col1a1* and *aSMA* +83% and +113%), newly synthesized collagen (+122%), plasma *TIMP1* (+27%), and worsening of parenchymal Fibrosis Score (+88%).

**Conclusion:** Our data suggest that hepatocyte casp6 does not play a major role in whole liver apoptosis and its inhibition in hepatocytes exacerbated inflammation and fibrosis, thereby increasing NASH severity in the GAN mouse model of NASH.

**PO-2793**

**Disrupted glucose-6-phosphate-ChREBP signalling aggravates hepatomegaly and accelerates liver disease progression in a mouse model for Glycogen Storage Disease type 1a**

Martijn Rutten<sup>1</sup>, Yu Lei<sup>2</sup>, Joanne Hoogerland<sup>1</sup>, Trijnie Bos<sup>1</sup>, Aycha Bleeker<sup>1</sup>, Rachel Thomas<sup>3</sup>, Gilles Mithieux<sup>4</sup>, Fabienne Rajas<sup>4</sup>, Alain de Bruin<sup>3</sup>, Bart van de Sluis<sup>2</sup>, Maaïke Oosterveer<sup>1</sup>. <sup>1</sup>*University Medical Center Groningen, Department of Pediatrics;* <sup>2</sup>*University Medical Center Groningen, Department of Pediatrics, Netherlands;* <sup>3</sup>*University of Utrecht, Dutch Molecular Pathology Center, Faculty of Veterinary Medicine, Netherlands;* <sup>4</sup>*INSERM U1213, Université de Lyon, Université Lyon 1, France*  
Email: m.h.oosterveer@umcg.nl.

**Background and aims:** Glycogen storage disease type 1a (GSD 1a) is an inborn error of metabolism caused by a defect in glucose-6-phosphatase (G6PC1) activity that is associated with hepatomegaly and hepatocellular tumour formation. Sustained intracellular glucose-6-phosphate (G6P) accumulation in GSD 1a results in constitutive activation of Carbohydrate Response Element Binding Protein (ChREBP), a glucose-sensitive transcription factor that has been proposed as a proliferative molecular switch. Here we assessed the consequence of disrupted G6P-ChREBP signalling on liver disease progression in a mouse model for GSD 1a.

**Method:** Male hepatocyte-specific *G6pc* knockout (*L-G6pc1<sup>-/-</sup>*) mice were treated with AAV-shChREBP to normalize hepatic ChREBP activity to levels observed in wildtype (*L-G6pc1<sup>+/+</sup>*) mice receiving AAV-shScramble. Animals were sacrificed three weeks after combined *G6pc1* knockout/ChREBP knockdown for organ and blood collection.

**Results:** Hepatic ChREBP knockdown severely aggravated hepatomegaly and hepatocyte size in *L-G6pc1<sup>-/-</sup>* mice. The livers of these

## POSTER PRESENTATIONS

animals showed increased nuclear expression and transcriptional activity of the oncogenic transcription factor Yes Associated Protein (YAP). This was paralleled by higher gamma-H2AX expression, mitotic induction, enhanced BrdU incorporation, and an enrichment of chromosomal instability, cGAS-STING cytosolic DNA sensing and hepatocyte dedifferentiation gene signatures.

**Conclusion:** Hepatic G6P-ChREBP signaling protects against liver disease progression in GSD Ia. These findings contribute to a better understanding of glucose imbalance-induced liver tumor development.

### NAFLD: Clinical aspects except therapy

#### PO-19

##### Modeling Disease Burden of Non-alcoholic Fatty Liver Disease (NAFLD) in Japan

Junko Tanaka<sup>1</sup>, Chris Estes<sup>2</sup>, Aya Sugiyama<sup>1</sup>, Akemi Kurisu<sup>1</sup>, Anvarjon Rakhimov<sup>1</sup>, Ko Ko<sup>1</sup>, Tomoyuki Akita<sup>1</sup>, Homie Razavi<sup>2</sup>.  
<sup>1</sup>Hiroshima University, Department of epidemiology, Infectious Disease Control and Prevention, Hiroshima, Japan; <sup>2</sup>Centers for Disease Analysis Foundation, California, United States  
 Email: jun-tanaka@hiroshima-u.ac.jp

**Background and aims:** NAFLD and resulting non-alcoholic steatohepatitis (NASH) is increasingly recognized as a growing cause of hepatocellular carcinoma (HCC) and indicator for liver transplantation globally. In Japan, a growing prevalence of obesity and metabolic syndrome, in combination with an aging population, will result in increasing rates of NAFLD-related liver disease.

**Method:** A dynamic disease progression model was used to track NAFLD incidence, prevalence, and related morbidity and mortality, by age- and gender-defined cohorts. New NAFLD cases were based upon trends for the increase in adult obesity (BMI  $\geq 25$  kg/m<sup>2</sup>) in Japan. The prevalence of NASH was based on the population-weighted distribution of NAFLD cases by fibrosis stage. Model assumptions were based on published literature and unpublished data. Changes in prevalence, advanced liver disease, and related mortality were examined.

**Results:** In 2020, there were an estimated 22.39 M NAFLD cases in Japan and 60% occurred among males (16.23 M cases). During 2020–2040, total NAFLD cases in Japan were estimated to decrease 7% to 20.90 M, due to decreasing total population. However, age-adjusted NAFLD prevalence (all ages) increased from 20.9% to 22.3% by 2040. The median age of the modeled NAFLD population increased from 57.6 years (2020) to 60.0 years (2040).  $\geq$ F2 NAFLD cases accounted for 7.2% of total cases, increasing to 8.9% of total cases in 2040, while the portion of  $\geq$ F3 NAFLD cases increased from 2.9% to 4.0% of total. Prevalent NASH cases were estimated to increase 2%, from 6.26 M

(2020), to 6.40 M (2040). Prevalent cases of advanced disease (cirrhosis, HCC, and liver transplant) increased by 30%, from 203,000 to 298,000 cases during 2020–2040. Incident HCC cases were projected at 1,600 cases in 2040, an increase of 20% from 2020 (1,200 cases). In 2020, there were an estimated 311,000 total deaths among the NAFLD population; 55% were among males (166,000 deaths) and 98% were classified as background mortality (306,000 deaths). Mortality attributable to NAFLD increased from 5,300 deaths in 2020 to 8,100 deaths in 2040 (35% increase).

**Conclusion:** The results demonstrate that growing prevalence of NAFLD will increasingly contribute to liver-related morbidity and mortality in Japan. Increasing case numbers of advanced liver disease will account for a growing portion of total liver transplants. Strategies to curb the growth of the NAFLD population, including interventions to prevent obesity and metabolic syndrome, are necessary to mitigate disease burden.

#### PO-33

##### Association between sarcopenic obesity and non-alcoholic fatty liver disease and fibrosis detected by fibroscan

Karn Wijarnpreecha<sup>1</sup>, Elizabeth Aby<sup>2</sup>, Aijaz Ahmed<sup>3</sup>, Donghee Kim<sup>3</sup>.  
<sup>1</sup>Mayo Clinic, Gastroenterology and Hepatology, Jacksonville, United States; <sup>2</sup>University of Minnesota; <sup>3</sup>Stanford University, United States  
 Email: dr.karn.wi@gmail.com

**Background and aims:** Non-alcoholic fatty liver disease (NAFLD) and sarcopenic obesity share several pathophysiologic backgrounds. No prior studies have determined a plausible association between sarcopenic obesity and NAFLD and NAFLD-associated fibrosis. We aim to investigate the association between sarcopenic obesity and NAFLD, and NAFLD-associated fibrosis detected by transient elastography.

**Method:** In a cross-sectional study from the 2017–2018 National Health and Nutrition Examination Survey, 1,925 participants were identified. NAFLD was defined by controlled attenuation parameter (CAP) scores and fibrosis/cirrhosis by liver stiffness measurements on transient elastography. Sarcopenic obesity was defined by appendicular lean mass and body fat.

**Results:** Individuals with sarcopenic obesity have a significantly higher odds of having NAFLD (CAP score  $\geq 263$  dB/m, odds ratio [OR]: 2.88, 95% confidence interval [CI] 1.82–4.57, and CAP score  $\geq 285$ , OR 3.71, 95% CI: 2.24–6.14) after adjusting for age, gender, and race/ethnicity. The association remains statistically significant after adjustment for socioeconomic status, lifestyle and behavioral risk factors, and metabolic conditions (CAP score  $\geq 263$ , OR 2.61, 95% CI: 1.51–4.50, and CAP score  $\geq 285$ , OR 3.31, 95% CI: 1.85–5.96). Sarcopenic obesity is also associated with higher odds of having NAFLD-associated fibrosis (OR 2.22, 95% CI 1.03–4.80) in the multivariate model.

**Conclusion:** Sarcopenic obesity is independently associated with an increased risk of NAFLD and NAFLD-associated fibrosis independent of well-defined risk factors. Targeted interventions to improve

Table:(abstract: PO-33): Univariate and Multivariate Odds Ratio of Risk Factors for NAFLD, NAFLD-associated Fibrosis and Cirrhosis based on the Prevalence of Sarcopenic Obesity

	Sarcopenic Obesity OR (95% CI)	P value	Sarcopenic Obesity OR (95% CI)	P value
	NAFLD (CAP $\geq 263$ dB/m)		NAFLD (CAP $\geq 285$ dB/m)

The multivariate model 1 included age, gender, race/ethnicity, education status, marital status, diabetes, smoking status, hypertension, and total cholesterol. The multivariate model 2 includes physical activity, total calorie intake, and alcohol consumption in addition to the variables in model 1.

sarcopenic obesity may reduce the risk of NAFLD and NAFLD-associated fibrosis.

**PO-381**

**Relevance of psychosocial biomarkers on therapeutic adherence in patients with non-alcoholic fatty liver disease**

Jesús Funuyet-Salas<sup>1</sup>, María Ángeles Pérez-san-Gregorio<sup>1</sup>, Agustín Martín-Rodríguez<sup>1</sup>, Manuel Romero Gomez<sup>2</sup>. <sup>1</sup>Faculty of Psychology, Department of Personality, Assessment, and psychological treatments, University of Seville, Seville, Spain; <sup>2</sup>Digestive Diseases Unit, Virgen del Rocío University Hospital, SeLiver group at Institute of Biomedicine of Seville (IBIS), University of Seville, Seville, Spain  
Email: jfunuyet1@us.es

**Background and aims:** The influence of psychosocial biomarkers on therapeutic adherence in patients with non-alcoholic fatty liver disease (NAFLD) is unknown. Therefore, we propose: (1) To find out whether depressive symptomatology mediates the relationship between social support and adherence to diet, as well as the relationship between physical quality of life (QoL) and adherence to physical activity, and (2) Test in both cases whether self-efficacy exerts a moderating effect on these relationships.

**Method:** Four hundred and thirteen biopsy-proven NAFLD patients (252 men and 161 women, mean age 55.51 ± 11.64) were evaluated using the SF-12, MSPSS, HADS, GSE, IPAQ and MEDAS instruments. For the first objective, Model 4 mediation was performed using the SPSS PROCESS v3.5 macro, while for the second objective, Model 7 for moderated mediation was used. In both models, 5000 bootstrap samples were employed to test the indirect effects estimated, which were considered significant when the confidence interval (CI) at 95% did not include 0.

**Results:** Depressive symptomatology mediated the association between social support and adherence to diet (effect = 0.148, CI = 0.035–0.275), as well as the relationship between physical QoL and adherence to physical activity (effect = 6.248, CI = 1.917–10.727). Self-efficacy moderated the effects that social support (beta = 0.026, p < 0.001) and physical QoL (beta = 0.004, p < 0.001) exerted through depressive symptomatology, on the adherence to diet and physical activity, respectively. In both cases, the higher self-efficacy was, the more the indirect conditional effects decreased: low self-efficacy (diet, effect = 0.095, CI = 0.025–0.181; physical activity, effect = 5.232, CI = 1.593–9.309), moderate (diet, effect = 0.050, CI = 0.011–0.103; physical activity, effect = 2.342, CI = 0.671–4.385) and high (diet, effect = 0.005, CI = -0.029–0.041; physical activity, effect = -0.549, CI = -2.557–0.817).

**Conclusion:** These results showed self-efficacy as a protective factor for therapeutic adherence in NAFLD patients with a psychosocial risk profile. The higher self-efficacy the lower the negative impact on the NAFLD patient's mental health. The probability of success of lifestyle intervention could be improved by self-efficacy, which could prevent a negative impact of low social support and poor physical QoL on adherence. Self-efficacy should be a psychological target in future multidisciplinary approaches for NAFLD.

**PO-441**

**Low alcohol consumption is associated with a decreased frequency of cirrhosis and hepatocellular carcinoma in a cohort of NAFLD outpatients**

Silvia Ferri<sup>1</sup>, Bernardo Stefanini<sup>1</sup>, Luca Muratori<sup>1</sup>, Lorenzo Mulazzani<sup>1</sup>, Margherita Alvisi<sup>1</sup>, Simona Leoni<sup>1</sup>, Francesco Tovoli<sup>1</sup>, Fabio Piscaglia<sup>1</sup>. <sup>1</sup>Division of Internal Medicine, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, Italy  
Email: silvia.ferri@aosp.bo.it

**Background and aims:** The role of moderate degrees of alcohol use in the evolution of Non-alcoholic Fatty Liver Disease (NAFLD) is still debated, as most studies evaluated ongoing drinking habits but did not consider lifetime drinking histories. The aim of this study is to evaluate the impact on natural history of liver disease of both current and lifelong alcohol consumption in a

cohort of outpatients with NAFLD. We created a new tool, called LACU (lifetime alcohol consuming unit) to estimate the amount of alcohol consumed in lifetime: 1 LACU was defined as 7 alcohol units per week for 1 drinking year.

**Method:** From 1 March 2015 to 01 February 2020, we enrolled 276 consecutive patients fulfilling criteria of NAFLD: fatty liver at ultrasound, HSI (hepatic steatosis index) >30 and exclusion of other well-known causes of fatty liver. A Physician performed an interview at baseline and after 2 years regarding alcohol consumption including questions about current and lifetime alcohol consumption.

According to their current alcohol intake per week, 276 patients were divided in: abstainers, current low consumers (C1, 1–70 g per week) and moderate consumers (C2, 71–140 g per week for women and 71–210 g for men). In a different analysis patients were divided according to lifetime exposure to alcohol in abstainers and consumers. The latter were furtherly divided into quartiles: Q1 (0.1–4.29 LACU), Q2 (4.30–12.85 LACU), Q3 (12.86–40.00 LACU), and Q4 (>40.01 LACU).

**Results:** Age, diabetes, hypertension and alcohol consumption were independent predictors of cirrhosis and hepatocellular carcinoma (HCC) in the multivariable models. Stratification according to alcohol intake showed that a lower current alcohol consumption (C1) was associated with a decreased risk of cirrhosis and HCC compared to abstinence (p < 0.001 and p = 0.009, respectively) and to moderate alcohol consumption (C2) (p < 0.009 and p = 0.001, respectively). Similarly, low alcohol consumers attested by LACU, specifically subgroup composed by patients in Q1, Q2 and Q3, had a decreased risk of cirrhosis and HCC compared to abstainers (p = 0.005 and p = 0.001, respectively) and moderate consumers (Q4) (p = 0.002 for cirrhosis and p < 0.001 for HCC).

Figure:

**Conclusion:** Low alcohol consumption, both evaluated as current and lifelong exposure, is associated with a decreased frequency of cirrhosis and HCC compared to both abstainers and moderate alcohol consumers in patients with NAFLD.

**association of maflD with mortality in patients with covid-19 in México**

Martín Uriel Vázquez Medina<sup>1</sup>, Cesar Montejo Velazquez<sup>2</sup>, Cruz Vargas-de León<sup>1</sup>, Arcelia Carolina Barrón Campos<sup>2</sup>, José Antonio Almeyda-Farfán<sup>2</sup>, Alejandro Gutierrez Atemis<sup>2</sup>, Julián-Gonzalo Gándara<sup>2</sup>, Claudia Pantaleón Martínez<sup>2</sup>, Nerina De Carmen Fernández-Martínez<sup>2</sup>, Maria Del Rosario Herrero Maceda<sup>2</sup>, EIRACERDA Reyes<sup>2</sup>. <sup>1</sup>ESM-Escuela Superior de Medicina-IPN, Ciudad de México, Mexico; <sup>2</sup>Hospital Central Militar Mexico, Gastroenterology, Ciudad de México, Mexico  
Email: arkiiman@hotmail.com

**Background and aims:** COVID-19 infection has generated a global crisis. To optimize public health measures, it is necessary to detect the population susceptible to presenting increased risk of death from

## POSTER PRESENTATIONS

Figure 1. (abstract: PO-445): Forest Plot of simple (A) and multiple (B) Logistic Regression Predictions for death in COVID-19.

COVID-19. There is evidence that more severe COVID-19 infections occur in pre-existing liver abnormalities; therefore, the aim of this study is to determine if MAFLD is associated with more mortality in COVID-19 patients of a Mexican population.

**Method:** All the patients admitted in a tertiary referral hospital located in México city with a positive SARS-Cov-2 PCR test from 4 April to 24 June 2020 were analyzed. Three groups were formed: 1.- Control group (n = 80), 2.- Isolated hypertransaminasemia (IH) group (n = 185) and 3.- MAFLD group (n = 83). Additionally, other variables associated with severity in COVID-19 were obtained, including gender, age, and comorbidities (T2D, Hypertension and obesity). A Binary Logistic Regression adjusted to the variables associated with severity in COVID-19 was made to obtain OR of death between the groups.

**Results:** We studied a total of 348 patients, the mean age was  $54.4 \pm 14.7$  years, 250 (71.8%) were male and 182 patients died (52%). The adjusted OR for death with respect to control group were 2.9 CI 95% (1.63–5.34) for the IH group and 5.1 CI 95% (2.68–9.89) for the MAFLD group; Figure 1.

**Conclusion:** In the studied population MAFLD and IH are associated with increased risk of death independently of age, gender, and comorbidities.

### PO-534

#### Pharmacokinetics of tropifexor, a potent farnesoid X receptor agonist, are similar in subjects with mild, moderate, and severe hepatic impairment: results from a multi-centre, open-label, single-dose study

Rowan Stringer<sup>1</sup>, Jin Chen<sup>2</sup>, Jessie Gu<sup>3</sup>, Melissa Hackling<sup>2</sup>, Bharti Shah<sup>2</sup>, Prasanna Kumar Nidamarthy<sup>4</sup>, William Prince<sup>3</sup>, Ralph Woessner<sup>1</sup>. <sup>1</sup>Novartis Institutes for BioMedical Research, Basel, Switzerland; <sup>2</sup>Novartis Pharmaceutical Corporation, East Hanover, New Jersey, United States; <sup>3</sup>Novartis Institutes for BioMedical Research, Cambridge, Massachusetts, United States; <sup>4</sup>Novartis Healthcare Pvt. Ltd., Hyderabad, India  
Email: rowan.stringer@novartis.com

**Background and aims:** Tropifexor is a potent farnesoid X receptor (FXR) agonist that is currently under development for the treatment of non-alcoholic steatohepatitis. As a non-bile acid FXR agonist, tropifexor has no obvious enterohepatic circulation and shows dose-proportional pharmacokinetics. This study evaluated safety and the effect of hepatic impairment (HI) on the systemic exposure of

tropifexor, to support treatment and dosing decisions for patients with varying degrees of HI.

**Method:** This open-label, single-dose, parallel-group study enrolled 42 subjects: 8 each with mild, moderate, and severe HI (Child-Pugh classification) and 18 matched healthy controls. Tropifexor 200 mcg was administered as a single oral dose under fasting conditions. Dosing in the severe HI group began after half of subjects in the mild and moderate HI groups completed the study. Serial blood samples for pharmacokinetic (PK) assessments (maximum drug concentration [C<sub>max</sub>], area under the concentration-time curve from time zero to (i) the time of last quantifiable concentration [AUC<sub>last</sub>], and (ii) infinite time [AUC<sub>inf</sub>]) were collected up to 168 h post-dose. Safety assessments included vital signs, electrocardiogram (ECG), and adverse event (AE) monitoring up until and including 30 days post-dose.

**Results:** Geometric mean treatment ratio and 90% confidence interval for tropifexor PK parameters are summarized below (Table). Exposure to total tropifexor was similar in the mild and severe HI and control groups. A geometric mean C<sub>max</sub> decrease of 10% in the mild HI group and of 36% in the severe HI group was noted, while AUC<sub>last</sub> and AUC<sub>inf</sub> were similar versus controls. In patients with moderate HI, AUC<sub>last</sub> and AUC<sub>inf</sub> increased by 28%. Plasma protein binding of tropifexor was ~99.8% in all groups. Exposure to unbound (u) tropifexor was similar in the mild HI and control groups. C<sub>max, u</sub> increased on average by 30% in the moderate HI group but was similar in the severe HI and control groups. AUC<sub>last, u</sub> and AUC<sub>inf, u</sub> increased on average by 64% in the moderate HI group and by 61% in the severe HI group versus controls. No drug-related AEs, serious AEs or deaths were reported. None of the vital signs or ECG abnormalities were reported as an AE for any subject.

**Conclusion:** A single oral dose of tropifexor 200 mcg was well tolerated in all subjects, with exposure of total tropifexor similar across groups. Although increased exposure to unbound tropifexor was seen in the moderate and severe HI groups, it was within the well-tolerated limit seen previously in healthy subjects. The safety and efficacy profile for doses planned in future studies will determine if dose adjustments in patients with moderate and/or severe HI will be warranted based on the observed increase in tropifexor unbound AUC.

Pharmacokinetic parameter	Comparison	Group comparison (total tropifexor)		Group comparison (unbound tropifexor)	
		Geo-mean ratio	90% CI	Geo-mean ratio	90% CI
C <sub>max</sub> (ng*h/mL)	Mild (n = 8) versus control (n = 6)	0.90	0.52, 1.55	0.95	0.52, 1.75
	Moderate (n = 8) versus control (n = 9)	1.03	0.74, 1.44	1.30	0.96, 1.76
	Severe (n = 8) versus control (n = 5)	0.64	0.38, 1.07	1.02	0.60, 1.72
AUC <sub>last</sub> (ng*h/mL)	Mild (n = 8) versus control (n = 6)	1.04	0.71, 1.53	1.11	0.70, 1.74
	Moderate (n = 8) versus control (n = 8)	1.28	1.02, 1.59	1.64	1.26, 2.15
	Severe (n = 8) versus control (n = 5)	1.01	0.66, 1.54	1.61	1.04, 2.50
AUC <sub>inf</sub> (ng*h/mL)	Mild (n = 8) versus control (n = 6)	1.05	0.71, 1.54	1.11	0.71, 1.75
	Moderate (n = 8) versus control (n = 8)	1.28	1.03, 1.58	1.64	1.25, 2.16
	Severe (n = 8) versus control (n = 5)	1.01	0.66, 1.54	1.61	1.04, 2.49

AUC<sub>inf</sub>, area under the concentration-time curve from time zero to infinite time; AUC<sub>last</sub>, area under the concentration-time curve from time zero to the time of the last quantifiable concentration; CI, confidence interval; geo, geometric; PK, pharmacokinetic

A separate linear mixed effects model, with group as a fixed effect and matched pair as random effect, was fitted to compare each hepatic impairment group with its matching control group for each log-transformed PK parameter. Results were back transformed to obtain geo-mean ratio and 90% CI on the original scale.

**Background and aims:** It is still controversial if increased hepatic fat independently contributes to cardiovascular risk. Although magnetic resonance imaging (MRI) has demonstrated its overall best

## POSTER PRESENTATIONS

performance in detecting subclinical changes in different organs, there is a paucity of studies utilizing MRI to examine the association between hepatic fat content and parameters of subclinical vascular disease. We aimed to assess the association between hepatic fat quantified by MRI and various subclinical vascular disease parameters.

**Method:** We included two cross-sectional investigations imbedded in two independent population-based studies (SHIP: n = 1341; KORA: n = 386). The participants underwent a whole-body MRI examination. Hepatic fat content was quantified by proton-density fat fraction (PDFF). Aortic diameters in both studies and carotid plaque-related parameters in KORA were measured with MRI. In SHIP, carotid intima-media thickness (cIMT) and plaque were assessed by ultrasound. We used (ordered) logistic or linear regression to assess associations between hepatic fat and subclinical vascular disease.

**Results:** The prevalence of fatty liver disease (FLD) (PDFF > 5.6%) was 35% in SHIP and 43% in KORA. In SHIP, hepatic fat was positively associated with ascending (beta, 95% confidence interval [CI]: 0.06 [0.04, 0.08]), descending (0.05 [0.04, 0.07]) and infrarenal (0.02 [0.01, 0.03]) aortic diameters, as well as with higher odds of plaque presence (odds ratio [OR], 95% CI: 1.22 [1.05, 1.42]) and greater cIMT (beta, 95% CI: 0.01 [0.004, 0.02]) in the age- and sex-adjusted model. However, further adjustment for additional cardiometabolic risk factors, particularly body mass index, attenuated these associations. In KORA, no significant associations were found.

**Conclusion:** The association between hepatic fat and subclinical vascular disease was not independent, but explained by overall adiposity. Given the close relation of FLD with cardiometabolic risk factors, in accordance with guidelines, people with FLD should still be prioritised for cardiovascular disease screening.

### PO-614

#### Additive Effects of Diabetes and NAFLD on Liver Disease Severity and Clinical Outcomes in the General Population (NASH-CO Study)

Oumarou Nabi<sup>1</sup>, Nathanaël Lapidus<sup>2</sup>, Jerome Boursier<sup>3,4</sup>, Victor de Lédinghen<sup>5</sup>, Philippe Mathurin<sup>6,7</sup>, Marcel Goldberg<sup>8</sup>, Marie Zins<sup>8,9</sup>, Karine Lacombe<sup>10,11</sup>, Lawrence Serfaty<sup>12</sup>. <sup>1</sup>Institute Pierre Louis Epidemiology And Public Health, Sorbonne Université, Paris, France; <sup>2</sup>Institute Pierre Louis Epidemiology and Public Health, Sorbonne Université, Paris, France; <sup>3</sup>Centre Hospitalier Universitaire d'Angers, Angers, France; <sup>4</sup>UPRES EA3859, Angers, France; <sup>5</sup>Hospital Center University De Bordeaux, Medecine, Bordeaux, France; <sup>6</sup>Chu De Lille, Lille, France; <sup>7</sup>Inserm U995, Lille, France; <sup>8</sup>Inserm UMS 11, Villejuif, France; <sup>9</sup>Hôpital Paul-Brousse Ap-Hp, Villejuif, France; <sup>10</sup>Hospital Saint-Antoine Ap-Hp, Paris, France; <sup>11</sup>Institute Pierre Louis Epidemiology And Public Health, Medecine, Paris, France; <sup>12</sup>Arlin Alsace Hospitals Academics De Strasbourg, Strasbourg, France  
Email: lawrence.serfaty@chru.strasbourg.fr

**Background and aims:** Relationships between diabetes and NAFLD have been mainly investigated at the hospital setting, with the risk of an overestimation of the true burden of liver disease. From a general population-based cohort, this study aimed to assess the severity of NAFLD and clinical outcomes among type 2 diabetic subjects in a community setting.

**Method:** The study population consisted of 199, 341 participants from the nationwide CONSTANCES cohort. After exclusion of subjects with excessive alcohol consumption, viral hepatitis or other causes of liver diseases, 164, 285 were analyzed. Among them, 8386 (5.3%) had type 2 diabetes. Non-invasive diagnosis of NAFLD and advanced fibrosis was performed using the combination of Fatty Liver Index and Forns Index. Outcomes analyzed were liver-related events, cardiovascular disease, extrahepatic cancer, chronic kidney disease, liver transplantation and overall mortality. Median follow-up was 2.5 years.

**Results:** The prevalence of NAFLD and NAFLD with advanced fibrosis among diabetic versus non-diabetic subjects was 61.1% (95% CI 60–62.2) vs 15.2% (95% CI 15–15.3) ( $p < 0.0001$ ) and 4.8% (95% CI 4.2–5.4)

vs 1.2% (95% CI 1–3) ( $p < 0.0001$ ), respectively. Rate of advanced fibrosis raised to 10% (95% CI 8–12) in case of additional metabolic disorders and to 13.9% (95% CI 7.2–20.6) in diabetic requiring insulin therapy. When adjusted for other risk factors, diabetes, diabetes remained associated with both NAFLD and advanced fibrosis (OR = 1.36, 95% CI 1.24–1.51 and OR = 1.95, 95% CI 1.36–2.8, respectively). When adjustment for usual risk factors, presence of diabetes in NAFLD subjects was associated with increased risk of liver-related events (aHR = 4.26, 95% CI 2.46–7.38), while presence of NAFLD in diabetic subjects was associated with increased risk of cardiovascular-related events or extra-hepatic malignancy (aHR = 1.99, 95% CI 1.16–4.22, and aHR = 4.63, 95% CI 1.18–15.1, respectively). Risk of death was significantly increased by both the presence of diabetes among NAFLD subjects (aHR = 1.32, 95% CI 1.02–2.31) and the presence of NAFLD among diabetic subjects (aHR = 1.25, 95% CI 1.03–2.51).

**Conclusion:** From a large community-based cohort with no excessive alcohol consumption, this study confirms the additive effect of diabetes and NAFLD on liver disease progression, diabetes-related complications and overall mortality, regardless of usual risk factors. Advanced fibrosis, which was less frequent in this unselected population than previously reported, should be screened in subjects with additional metabolic disorders or advanced diabetes.

### PO-630

#### Undiagnosed obstructive sleep apnoea is a major component in NAFLD quality of life impairment

Wenhao Li<sup>1</sup>, Benjamin Karl Kadler<sup>1</sup>, James Hallimond Brindley<sup>1</sup>, Victoria Berryman<sup>1</sup>, Johanna Preston<sup>1</sup>, Melanie Patrick<sup>1</sup>, Caroline Sutcliffe<sup>1</sup>, Gillian Hood<sup>1</sup>, Wing-kin Syn<sup>2</sup>, William Alazawi<sup>1</sup>. <sup>1</sup>Barts Liver Centre, Blizard Institute, Queen Mary University of London, London, United Kingdom; <sup>2</sup>Division of Gastroenterology and Hepatology, Department of Medicine, Medical University of South Carolina, Charleston, United States  
Email:

**Background and aims:** Quality of life (QOL) is lower in people with NAFLD compared to the general population. This particularly affects physical health-related domains and is associated with co-morbid obesity and type 2 diabetes (T2DM). Obstructive sleep apnoea (OSA) is a breathing disorder that can affect people with obesity and is also associated with reduced QOL. However the role of undiagnosed OSA on QOL in NAFLD is unclear. Epworth Sleepiness Scale (ESS) is a validated screening questionnaire that identifies individuals with symptoms of OSA. However, ESS is not routinely utilised in QOL assessments in NAFLD patients. We aim to assess whether ESS-determined symptoms of OSA are independently associated with reduced QOL in NAFLD patients.

**Method:** In a prospective study, we conducted QOL assessments in 192 individuals with NAFLD using Short Form-36 (SF-36) version 2 questionnaire and ESS questionnaire. SF-36 consists of 36 questions related to physical and mental wellbeing, resulting in physical component score (PCS) and mental component score (MCS). QOL data were analysed with using multivariate linear regression to identify factors independently affecting QOL scales.

**Results:** Individuals with NAFLD reported lower SF-36 scores compared to published data for the general UK population. Physical health in particular was significantly reduced (PCS: 35.33 vs 50.02,  $p < 0.0001$ ). 1 in 8 NAFLD patients had known OSA at enrolment, but a significantly higher proportion (1 in 4) recorded ESS score >10. Compared to NAFLD individuals with ESS score ≤10, those with ESS score >10 were more obese (36.7 kg/m<sup>2</sup> vs 31.3 kg/m<sup>2</sup>,  $p < 0.0001$ ), with higher prevalence of T2DM (58.9% vs 42.7%,  $p = 0.044$ ), and had lower PCS (26.9 vs 38.2,  $p < 0.0001$ ) and MCS (39.3 vs 51.5,  $p < 0.0001$ ). No differences in age or gender were observed. In multivariate linear regression, ESS score >10 was the most significant independent predictor of reduced PCS. Age, BMI and transient elastography score were also significantly associated (Table).

Predictors of physical health-related QOL	Multivariate analysis (whole cohort, n = 192)				Multivariate analysis (excluding pre-existing OSA, n = 166)			
	B Coefficient	(95% CI)		P value	B Coefficient	(95% CI)		P value
Age	<b>-0.254</b>	-0.401	-0.106	<b>0.001</b>	<b>-0.229</b>	-0.378	-0.080	<b>0.003</b>
Diabetes diagnosis	-1.364	-5.413	2.684	0.507	-1.531	-5.821	2.760	0.482
BMI	<b>-0.510</b>	-0.817	-0.203	<b>0.001</b>	<b>-0.565</b>	-0.888	-0.243	<b>0.001</b>
Transient elastography score	<b>-0.318</b>	-0.579	-0.057	<b>0.017</b>	<b>-0.302</b>	-0.586	-0.018	<b>0.037</b>
ESS score > 10	<b>-8.478</b>	-12.907	-4.049	<b>&lt;0.001</b>	<b>-7.498</b>	-12.445	-2.551	<b>0.003</b>

(Only variables with p < 0.05 in univariate analysis were included for multivariate analysis)

Table: (abstract: PO-630)

Sensitivity analysis showed that after excluding those with diagnosed OSA, ESS score >10 remained the strongest predictor of reduced PCS. **Conclusion:** Elevated ESS score >10, which is likely to represent undiagnosed OSA, is an independent predictor of reduced QOL in patients with NAFLD. Risk of OSA, as determined by elevated ESS scores, should be considered in clinical practice and when evaluating patient-related outcomes in clinical trials.

**PO-685**  
**The benefits of the novel nomenclature of metabolic fatty liver disease**

Álvaro Santos-Laso<sup>1</sup>, Paula Iruzubieta<sup>1,2</sup>, María Teresa Arias Loste<sup>1,2</sup>, Tatiana Fernandez<sup>1</sup>, Lorena Cayon<sup>1</sup>, Agustín García<sup>1</sup>, Laura Rasines<sup>1</sup>, Ana Álvarez-Cancelo<sup>1</sup>, José Luis Calleja Panero<sup>2,3</sup>, Javier Crespo<sup>1,2</sup>.

 Email: javier.crespo@scsalud.es

**Background and aims:** A consensus of international experts has recently proposed a new nomenclature and diagnostic criteria for fatty liver disease associated with metabolic dysfunction, opening a great debate. The impact of this new classification in clinical practice is not yet known. We aim to determine the prevalence of metabolic-associated fatty liver disease (MAFLD) and non-alcoholic fatty liver disease (NAFLD) in general population and to evaluate the clinical-related differences between both criteria.

**Method:** Observational, cross-sectional, population-based study from the ETHON Cantabrian cohort (n = 5, 989). This population cohort includes clinical data, laboratory test, transient elastography (TE) and controlled attenuation parameter (CAP) obtained the same day. Fatty liver was defined by CAP ≥ 248 dB/m or fatty liver index (FLI) ≥ 60, and significant fibrosis by TE ≥ 7.2 kPa.

**Results:** We excluded 48 subjects for lacking CAP and FLI. A total of 3, 167 subjects had fatty liver and, consequently, were amenable to meet the NAFLD and/or MAFLD diagnostic criteria. NAFLD and MAFLD were diagnosed in 2, 883 (48.5%) and 2, 809 (47.3%) subjects of general population, respectively. Compared with NAFLD, MAFLD patients were significant more likely to be male, older and with higher body mass index. Moreover, MAFLD patients showed higher levels of triglycerides, liver enzymes, FLI and CAP, as well as higher rate of significant fibrosis (8.8% vs 7.2%, p = 0.03), in comparison to NAFLD patients. Importantly, when we excluded MAFLD patients with other causes of liver injury (i.e., alcohol, viral hepatitis or cholestatic disorders) (n = 264), no significant difference was found in significant fibrosis between purely metabolic MAFLD and NAFLD patients (7.9% vs 7.2%, p = 0.3). In fact, in MAFLD patients, the presence of other concomitant factor of liver injury was identified as an independent risk factor for fibrosis (OR 2.583; 95% CI 1.374–4.855; p = 0.003). Diabetes was also associated with a risk for significant fibrosis in MAFLD patients (OR 6.029; 95% CI 3.519–10.328; p < 0.001).

**Conclusion:** The presence of MAFLD led to increased risk of significant fibrosis, being incremented when other causes of liver injury were identified.

**Binge Eating Disorder is associated with an unfavourable body mass composition in patients with Non-Alcoholic fatty liver disease**

Roberta Forlano<sup>1</sup>, Chris Harlow<sup>1</sup>, Benjamin H. Mullish<sup>1</sup>, Mark Thursz<sup>1</sup>, Pinelopi Manousou<sup>1</sup>, Michael Yee<sup>2</sup>. <sup>1</sup>Imperial College London, Department of Metabolism, Digestion and Reproduction, London, Northern Ireland; <sup>2</sup>Imperial college NHS Trust, Department of Endocrinology, London, Northern Ireland  
 Email: r.forlano@imperial.ac.uk

**Background:** The impact of eating disorder on NAFLD remains unexplored, especially with regards to eating disorders such as Binge Eating Disorder (BED). The aim of this study was to assess the risk factors for the presence of BED among patients with Non-Alcoholic Fatty liver disease and the impact of BED on body mass composition.

**Methods:** all consecutive referrals of NAFLD were prospectively assessed in a tertiary hepatology centre in London. Patients were asked to fill a BED screener-7 (BEDS-7), while clinical parameters, body mass composition on bioelectrical impedance analysis (BIA) and Fibroscan measurements were recorded at baseline and at 6 months follow-up.

**Results:** 81 patients were included, 23 (28.4%) of whom screened positive for BED. BED positive patients were younger (52 vs 59 years, p = 0.03), more frequently not committed in a stable relationship (61.5% vs 20.8%, p = 0.013) compared to BED negative (n = 58). On

## POSTER PRESENTATIONS

multivariate analysis, a previous diagnosis of depression (OR 3.8,  $p = 0.025$ ) and marital status (OR 6.08,  $p = 0.018$ ) were associated with a positive BEDS-7. Furthermore, BED positive patients were heavier (BMI 33.8 vs 29.6 kg/m<sup>2</sup>,  $p = 0.01$ ), presented with larger waist ( $p = 0.03$ ) and hip ( $p = 0.01$ ) circumferences, with further increase of waist circumference during follow-up (+0.04 vs -0.23 cm/month,  $p = 0.02$ ). Finally, those with BED presented with greater fat mass (37.1% vs 31.4%,  $p = 0.002$ ) and lower muscle mass (56.7% vs 65.1%,  $p = 0.001$ ) on BIA, when compared to the non-BED (Figure 1). There was no difference in terms of disease stage as assessed by liver stiffness, although CAP score was higher among those positive for BED (331 vs 299 dB/m,  $p = 0.041$ ).

**Figure 1:** Fat and muscle mass as percentage of total body weight in BED and non-BED patients on bioelectrical impedance analysis.

Blue: BED positive. Yellow: BED negative

Figure:

**Conclusion:** BED is highly frequent and associated with an unfavourable body mass composition in patients with NAFLD. Tackling obesity and metabolic diseases requires a holistic approach.

#### Carriage of CYP2E1rs2070673:A is associated with higher prevalence of non-alcoholic steatohepatitis in patients with biopsy-proven non-alcoholic fatty liver disease

Hong-Lei Ma<sup>1</sup>, Sui-Dan Chen<sup>2</sup>, Kenneth I. Zheng<sup>1</sup>, Yue Yu<sup>3</sup>, Xin-Xin Wang<sup>3</sup>, Liangjie Tang<sup>3</sup>, Gang Li<sup>3</sup>, Rafael Rios<sup>3</sup>, Ou-Yang Huang<sup>3</sup>, Xiao-Yong Zheng<sup>3</sup>, Ren-Ai Xu<sup>3</sup>, Giovanni Targher<sup>4</sup>, Chris Byrne<sup>5</sup>, Xiaodong Wang<sup>1</sup>, Yong-Ping Chen<sup>1</sup>, Ming-Hua Zheng<sup>1</sup>.

 Email: zhengmh@wmu.edu.cn

**Background and aims:** Cytochrome P450 2E1 (CYP2E1) plays a role in lipid metabolism, and by increasing hepatic oxidative stress and inflammation, up-regulation of CYP2E1 may be involved in development of non-alcoholic steatohepatitis (NASH). We aimed to explore the relationship of CYP2E1 genetic variants and histological severity of non-alcoholic fatty liver disease (NAFLD).

**Method:** We studied a cohort of 438 consecutive patients with biopsy-proven NAFLD. NASH was defined as NAFLD Activity Score  $\geq 5$  with existence of steatosis, ballooning and lobular inflammation. SNP rs2070672 and rs2070673 encoding CYP2E1 were genotyped by MALDI-TOF mass spectrometry. Serum cytokines related to inflammation were measured by the Bio-plex 200 system to investigate possible mediating factors involved in the process.

**Results:** Carriage of rs2070673:A in CYP2E1 was associated with a higher prevalence of severe lobular inflammation (26.1% vs. 13.3%,  $P < 0.01$ ) and NASH (52.9% vs. 40.5%,  $P = 0.01$ ). Multivariable regression modelling showed that this genetic variant was associated with severe lobular inflammation (adjusted-odds ratio: 2.79, 95% CI 1.57–4.93,  $P < 0.01$ ) or NASH (adjusted-odds ratio, 95% CI: 1.74, 1.13–2.67,  $P = 0.01$ ), independently of age, sex and common metabolic risk factors. Compared with no-NASH, patients with NASH had significantly higher levels of serum interleukin-1 receptor antagonist, interleukin-18 and interferon-inducible protein-10 (IP-10), whereas only IP-10 was increased with rs2070673:A ( $p < 0.01$ ). Mediation analysis showed that IP-10 was responsible for 66% of the association between the CYP2E1 rs2070673 variant and NASH.

**Conclusion:** rs2070673:A in the CYP2E1 gene is strongly associated with NASH and this effect is largely mediated by serum IP-10 levels.

#### Real-world assessment of NAFLD stages using FibroScan in the US population and diabetes subpopulation based on data from NHANES 2017–2018

Mazen Nouredin<sup>1</sup>, Fady Tanios<sup>2</sup>, Birol Emir<sup>2</sup>, Deepa Malhotra<sup>2</sup>, Euan McLeod<sup>3</sup>, Katherine Hoover<sup>2</sup>, Naim Alkhouri<sup>4</sup>.  
<sup>1</sup>Karsh Division of Gastroenterology and Hepatology, Comprehensive Transplant Center, Cedars-Sinai Medical Center, Los Angeles, United States; <sup>2</sup>Pfizer Inc, New York, United States; <sup>3</sup>Pfizer Ltd, Tadworth, Surrey, United Kingdom; <sup>4</sup>Arizona Liver Health, Chandler, United States  
 Email: mazen.nouredin@cshs.org

**Background and aims:** Non-alcoholic steatohepatitis (NASH) is a progressive subset of non-alcoholic fatty liver disease (NAFLD), and

can lead to hepatic fibrosis, cirrhosis and cardiovascular disease. This analysis aimed to determine the prevalence of NAFLD with fibrosis, as assessed by transient elastography (FibroScan®), in the National Health and Nutrition Examination Survey (NHANES) database (2017–2018), including a cohort with type 2 diabetes mellitus (T2DM).

**Methods:** Adult subjects with valid FibroScan® measurements were included (N = 4, 471) in this analysis. The age-adjusted prevalence of NAFLD was calculated for the overall population and a subpopulation with T2DM. Clinical characteristics, NAFLD, fibrosis stage and comorbidities were compared between groups. Controlled attenuation parameter cut-off of 302 dB/m determined NAFLD; liver stiffness cutoffs were ≤8.2, ≤9.7, ≤13.6 and >13.6 kPa for F0–F1, F2, F3 and F4, respectively.

**Results:** Dataset included 3, 831 eligible subjects (excluding subjects with heavy alcohol use, viral hepatitis and HIV), 821 (21.4%) of whom had T2DM. Of eligible subjects, 1, 226 (32.0%)/468 (57.0%) had NAFLD in the overall/T2DM cohorts. For the NAFLD cohorts (overall/T2DM), most subjects had F0–F1 fibrosis (71.4/66.2%), followed by F2 (6.4/8.5%), F3 (6.9/9.0%) and F4 (4.6/8.1%). Rates and means of clinical characteristics and comorbidities are in the Table.

Table: Age-adjusted characteristics and comorbidities of subjects

	Overall NAFLD/non- NAFLD	NAFLD F2– F3/F0–F1	T2DM NAFLD/non- NAFLD
% of subjects	31/69	12/75*	66/34
<b>Characteristics</b>			
Age, years, mean	48/47	48/48	49/50
Male, %	57/44	66/57	45/39
BMI ≥ 30 kg/m <sup>2</sup> , %	74/29	94/73	82/48
Alanine aminotransferase, U/L, mean	29/20	37/29	33/25
Aspartate aminotransferase, U/L, mean	24/20	27/22	25/21
<b>Comorbidities, %</b>			
Hypertension	45/24	43/44	51/47
Diabetes	30/8	44/24	100/100
Hypercholesterolaemia	43/33	50/43	53/45
Ischaemic heart disease	7/4	11/6	11/8

\*Remainder NASH F4 (5%), cryptogenic cirrhosis (2%), fibrosis and moderate steatosis (6%)

**Conclusion:** Results estimate NAFLD prevalence in the US population and in a subpopulation with T2DM. Results may inform disease diagnosis rates, health regulators and access to treatment as they provide real-world size estimates of the NAFLD population that needs therapeutic intervention. Results also highlight the clinical characteristics and higher prevalence of NAFLD with fibrosis in patients with T2DM.

**PO-825**

**Use of machine learning to develop a NAFLD screening tool using demographic, clinical and FibroScan data from the NHANES 2017–2018 database**

Birol Emir<sup>1</sup>, Mazen Noureddin<sup>2</sup>, Naim Alkhoury<sup>3</sup>, Deepa Malhotra<sup>1</sup>, Euan McLeod<sup>4</sup>, Katherine Hoover<sup>1</sup>, Darren Jeng<sup>5</sup>, Gordon Siu<sup>1</sup>, Fady Tanios<sup>1</sup>. <sup>1</sup>Pfizer Inc, New York, United States; <sup>2</sup>Karsh Division of Gastroenterology and Hepatology, Comprehensive Transplant Center, Cedars-Sinai Medical Center, Los Angeles, United States; <sup>3</sup>Arizona Liver Health, Chandler, United States; <sup>4</sup>Pfizer Ltd, Tadworth, Surrey, United Kingdom; <sup>5</sup>Pfizer Inc, Groton, United States  
Email: birol.emir@pfizer.com

**Background and aims:** Several scores have been developed to predict NAFLD based on liver ultrasound. However, liver ultrasound has known sensitivity and specificity limitations and may be difficult

to apply for screening in large health system populations. Machine learning (ML) techniques have been used clinically to predict outcomes based on subject-level data. The objective of this analysis was to explore a new screening tool to predict NAFLD, identified by the controlled attenuation parameter (CAP; FibroScan®) using demographic and clinical data from a large US cohort in the National Health and Nutrition Examination Survey (NHANES) database (2017–2018).

**Methods:** Adult subjects (>20 years of age) with valid FibroScan® measurements were included, and heavy drinkers were excluded. Overall, 3, 381 subjects were analysed. The population was split into training (N = 2, 874) and test/validation (N = 957) sets. NAFLD was defined as CAP > 302 dB/m; other causes of liver disease were excluded. Covariates for which less than 10% of data were missing were imputed using a random forest approach. Over 100 features were inputted to the models. Six different ML methods were fit to the training data: an elastic net (lasso), logistic regression, conditional single classification tree, random forest, support vector machine and neural network.

**Results:** The test/validation performances of the ML methods were very similar with respect to predictive ability (area under the receiver-operating characteristic curve [ROC] ranged between 0.79–0.84, sensitivity between 0.66–0.71 and specificity between 0.75–0.86) (Figure). The following variables were statistically significant predictors of NAFLD (p value <0.01): age, body mass index, waist, HbA1c, aspartate aminotransferase, alkaline phosphatase, diastolic blood pressure, high-density lipoprotein, triglycerides and gender. Logistic regression was selected as the most appropriate model due to its simplicity, ease of interpretation and similar performance, compared with the other models, to develop a new ML-based screening tool to predict NAFLD in the general population.

Figure: Validation/test performances of area under the ROC for the six different ML methods.

**Conclusion:** The newly developed ML models may be used to screen patients with NAFLD using standard demographic and clinical data and to potentially replace more costly, less accurate or invasive diagnostic tools.

## POSTER PRESENTATIONS

### PO-831

#### Liver related and extrahepatic events in patients with non-alcoholic fatty liver disease: a competing risk analysis

Email: graziapennisi901@gmail.com

**Background and aims:** Non-alcoholic fatty liver disease (NAFLD) is associated with a high risk of liver-related events (LRE) and also extrahepatic events (EHE). We evaluated the competitive risk occurrence of LRE and EHE in a large cohort of biopsy-proven NAFLD stratified according to baseline severity of fibrosis.

**Method:** Patients with a histological diagnosis of NAFLD were enrolled. During follow-up, LRE and EHE were recorded. Observed cumulative incidence functions (CIFs) were used to evaluate the risk of LRE and EHE occurrence; cause-specific Cox, subdistribution hazard models and predicted CIFs were fitted to identify predictors of LRE and EHE. Models were validated in a replication cohort of NAFLD with non-invasive assessment of liver fibrosis by liver stiffness.

**Results:** 2135 patients (F0–F1 = 1136; F2 = 362; F3–F4 = 637) with biopsy-proven NAFLD were enrolled. According to the observed CIFs the 60 month probability of LRE and EHE was 0.2% and 3% in F0–F1, 2% and 3.8% in F2, and 9.7% and 6.4% in F3–F4 patients, respectively. In the cause-specific Cox model, in F0–F1 and F2 patients, age >50 years (HR2.7, beta0.99, p = 0.001) was the only one predictor of LRE, while age >50 years (HR2.96, beta1.08, p < 0.001), previous cardiovascular events (CVE, HR2.07, beta0.73, p = 0.03) and previous extra hepatic cancer (EHC, HR2.36, beta0.86, p = 0.003) were independent risk factors for EHE. In F3–F4 patients, age >55 years (HR1.73, beta0.55, p = 0.03), obesity (HR1.52, beta0.42, p = 0.03), PLT < 150,000/mm<sup>3</sup> (HR3.66, beta1.30, p < 0.001) and GGT (HR1.77, beta0.57, p < 0.001) were associated with LRE, while age >55 years (HR1.74, beta0.55, p = 0.006) and previous CVE (HR2.51, beta0.92, p < 0.001) were independent predictors of EHE. Predicted CIFs for HE and EHE in F0–F1, F2 and F3–F4 patients well stratified the risk of events. The results were confirmed with the FineandGray model, and externally validated.

**Conclusion:** In NAFLD patients, by using competing risks models, the likelihood of EHE is relevant and raises according to the severity of liver fibrosis, while the risk of LRE is negligible in F0–F1, low but clinically relevant in F2 and high in F3–F4 patients. These data could help to personalize follow-up in NAFLD.

### PO-950

#### A serum metabolic fingerprint may predict advanced fibrosis due to NAFLD in a cohort of diabetic patients

Roberta Forlano<sup>1</sup>, Benjamin H. Mullish<sup>1</sup>, Jesus Miguens Blanco<sup>1</sup>, Nathan Danckert<sup>1</sup>, Mark Thursz<sup>1</sup>, Pinelopi Manousou<sup>1</sup>. <sup>1</sup>Imperial college London, Department of Metabolism, Digestion and Reproduction, London, United Kingdom  
Email: r.forlano@imperial.ac.uk

**Background and aims:** Several serum metabolites have been previously-associated with the onset and progression of non-alcoholic fatty liver disease (NAFLD) and type-2 diabetes mellitus (T2DM). However, only a relatively limited number of such metabolites are currently recognised, and study to design to date has made it difficult to delineate whether such metabolites represent NAFLD *per se* or if they are proxies of T2DM. The aim of this study was to identify serum metabolomic profiles in T2DM patients with and without NAFLD and with different disease stage.

**Method:** Fasting serum samples obtained from patients with T2DM who were screened for liver disease by blood tests, ultrasound (US), fasting liver stiffness measurement (LSM) and CAP score. Samples were analysed using a non-targeted approach with Proton-Nuclear Magnetic Resonance (<sup>1</sup>H-NMR)-based metabolomics. Results were explored by performing multivariate statistical analysis using SIMCA<sup>®</sup>.

**Results:** Of 300 patients enrolled, serum samples were collected from 254 subjects. Overall, 167 (65%) had NAFLD, 20 (7%) other causes of liver disease (BAFLD and HBV) and 67 (26%) no liver disease. Among those with NAFLD, 46 (18%) showed evidence of significant fibrosis (LSM > 8.1 kPa).

A range of serum metabolites-including amino acids, lipoproteins and other small molecules-were identified and quantified in all samples. A valid model separated the serum metabolite profile of NAFLD vs non-NAFLD patients, with NAFLD patients demonstrating higher serum glutamate and lower glycine and glutamine compared to those without NAFLD (cross-validated residuals (CV) ANOVA, p = 0.02) (Figure 1). Similarly, patients with NAFLD and increased LSM demonstrated higher serum glutamate and lower glycine and glutamine compared to those with NAFLD and normal LSM (CV-ANOVA, p = 6.5 × 10<sup>-6</sup>) and compared to those without NAFLD (CV-ANOVA, p = 1.1 × 10<sup>-5</sup>; R2X: 0.137; R2Y: 0.535; Q2: 0.228).

On linear regression, glycine correlated inversely with CAP score (R<sup>2</sup> = -0.18, p = 0.003) and with LSM (R<sup>2</sup> = -0.15, p = 0.014). Conversely, the glutamate to glutamine ratio (glutamate/glutamine) correlated positively with CAP score (R<sup>2</sup> = 0.26, p < 0.0001) and with LSM (R<sup>2</sup> = 0.41, p < 0.0001). Furthermore, the glutamate/glutamine ratio predicted the presence of significant fibrosis (LSM > 8.1 kPa) with AUROC 0.74 (p = 0.0001, 95% CI: 0.65–0.83) and advanced fibrosis (LSM > 12.1 kPa) with AUROC 0.809 (p = 0.001, 95% CI: 0.71–0.9) (Figure 1).

**Conclusion:** In T2DM patients, the glutamate to glutamine ratio may predict NAFLD with fibrosis accurately. Metabolomics in combination with clinical parameters holds promise for improving the non-invasive detection of NAFLD. New insights from metabolomics may also allow for discovering novel drug targets and precision treatment of patients with NAFLD.

### PO-969

#### Successful implementation of a weight loss intervention pathway for non-alcoholic fatty liver disease patients by advanced practice hepatology providers with obesity training

Vicki Shah<sup>1</sup>, Sarah Repking<sup>1</sup>, Colleen Folkers<sup>1</sup>, Sujit Janardhan<sup>1</sup>, Lelani Fetrow<sup>1</sup>, Nancy S. Reau<sup>1</sup>. <sup>1</sup>Rush University Medical Center, Chicago, United States  
Email: vickishah2@gmail.com

**Background and aims:** American Association for the Study of Liver Diseases (AASLD) practice guidelines state that 5–10% weight loss with lifestyle changes or bariatric surgery in obese patients are treatments of choice to prevent NAFLD progression. Weight loss

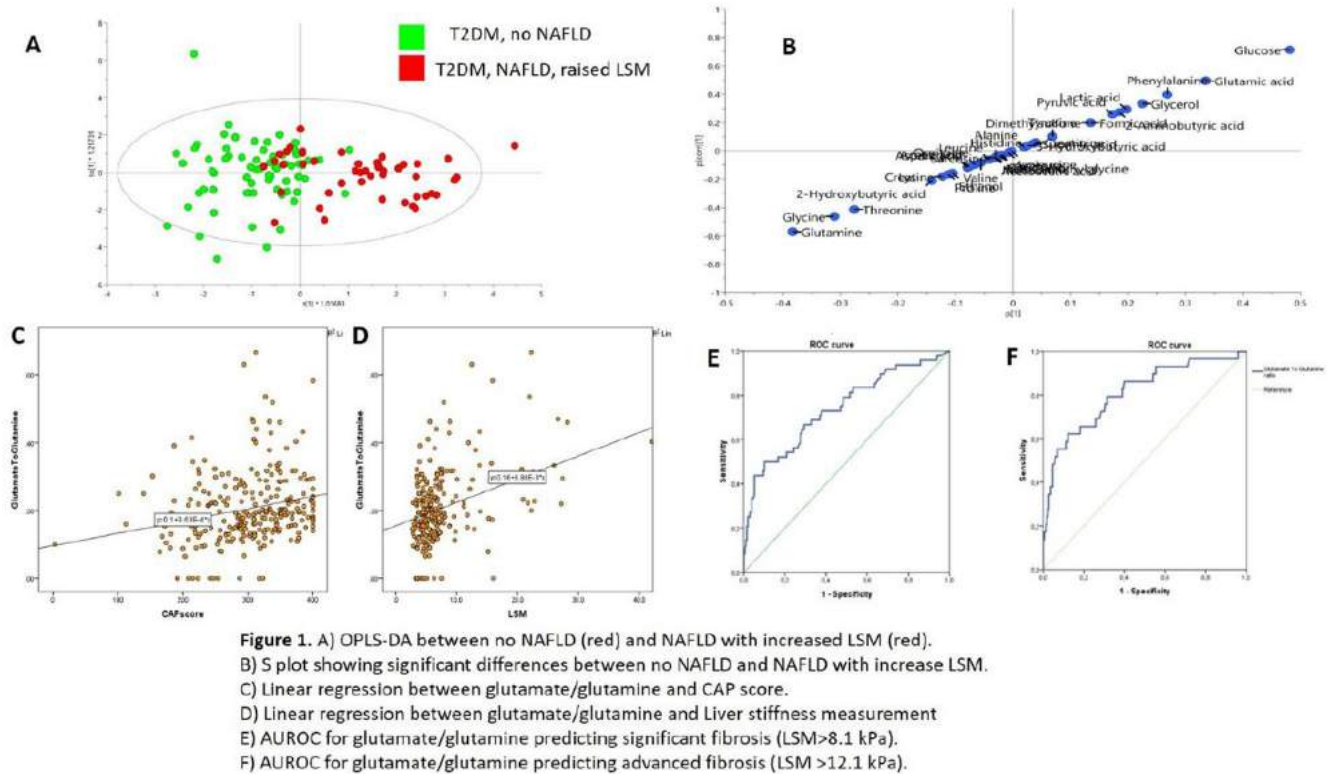

Figure 1: (abstract: PO-950)

interventions may include dietary changes, behavioral modifications, physical activity, and pharmacologic treatment. While clinical trials for weight loss in NASH have shown to achieve >5% total body weight loss (TBWL) in 30% of patients and >10% TBWL in 10% of patients, it is unclear if this can be recreated in the real-world clinical setting.

**Method:** In 2018, our department started an embedded Weight Loss Intervention in Liver Disease (WILD) pathway led by a hepatologist and advanced practice providers (APPs) all trained in obesity medicine. WILD provided intensive lifestyle strategies for those with liver disease and BMI > 25. Patients are followed monthly after initial consultation. A retrospective review was completed for retention rate and percent weight change for patients who attended at least one WILD appointment.

**Results:** Between November 2018 to December 2020, 77 patients attended at least one WILD appointment. Fifteen failed to return after the first visit with mean TBWL of 0.6%. Sixty-two patients attended >1 WILD visit indicating 80.6% retention rate. 45 (73%) achieved TBWL of 5.47%, 14 (22%) had weight gain of 1.22%, and three (5%) had no change. Of the 45 patients with TBWL, 15 patients achieved >5% weight loss and 7 achieved >10% weight loss.

**Conclusion:** Our study demonstrates that an APP run weight intervention was successful in achieving weight loss in engaged patients comparable to those achieved in clinical trials for weight loss in NASH patients. 73% WILD patients achieved weight loss and 33% of patients that remained in the pathway lost at least 5% of TBW which has been associated with improvement in NAFLD.

**PO-1030**

**Different associations of variants in hydroxysteroid 17-beta dehydrogenase 13 with liver histology in ethnic Chinese**

Wen-yue Liu<sup>1</sup>, Mohammed Eslam<sup>2</sup>, Kenneth I. Zheng<sup>3</sup>, Hong-Lei Ma<sup>3</sup>, Rafael Rios<sup>3</sup>, Min-Zhi Lv<sup>4</sup>, Gang Li<sup>3</sup>, Liangjie Tang<sup>3</sup>, Pei-Wu Zhu<sup>5</sup>, Xiao-Dong Wang<sup>3</sup>, Chris Byrne<sup>6</sup>, Giovanni Targher<sup>7</sup>, Jacob George<sup>2</sup>, Ming-Hua Zheng<sup>3,8,9</sup>. <sup>1</sup>Department of Endocrinology, the First Affiliated

Hospital of Wenzhou Medical University, Wenzhou, China; <sup>2</sup>Storr Liver Centre, Westmead Institute for Medical Research, Westmead Hospital and University of Sydney, Sydney, Australia; <sup>3</sup>MAFLD Research Center, Department of Hepatology, the First Affiliated Hospital of Wenzhou Medical University, Wenzhou, China; <sup>4</sup>Department of Biostatistics, Zhongshan Hospital, Fudan University, Shanghai, China; <sup>5</sup>Department of Laboratory Medicine, the First Affiliated Hospital of Wenzhou Medical University, Wenzhou, China; <sup>6</sup>Southampton National Institute for Health Research Biomedical Research Centre, University Hospital Southampton, Southampton General Hospital, Southampton, UK; <sup>7</sup>Section of Endocrinology, Diabetes and Metabolism, Department of Medicine, University and Azienda Ospedaliera Universitaria Integrata of Verona, Verona, Italy; <sup>8</sup>Institute of Hepatology, Wenzhou Medical University, Wenzhou, China; <sup>9</sup>Key Laboratory of Diagnosis and Treatment for The Development of Chronic Liver Disease in Zhejiang Province, Wenzhou, China  
Email: zhengmh@wmu.edu.cn

**Background and aims:** In Europeans, variants in the hydroxysteroid 17-beta dehydrogenase 13 (HSD17B13) gene impact the liver histology of metabolic associated fatty liver disease (MAFLD). The impact of these variants in ethnic Chinese is unknown. The aim of this study was to investigate the potential associations in Chinese patients

**Method:** 427 Han Chinese with biopsy-confirmed MAFLD were enrolled. Two single nucleotide polymorphisms in HSD17B13 were genotyped-rs72613567 and rs6531975. Logistic regression was used to test the association between the SNPs and liver histology.

**Results:** As shown in Table, the minor allele TA of the rs72613567 variant was related to an increased risk of fibrosis [OR = 2.93 (1.20–7.17), p = 0.019 for the additive model; OR = 3.32 (1.39–7.91), p = 0.007 for the recessive model], an inverse association as compared to the results from European cohorts. In contrast, we observed a protective effect on fibrosis for the minor A allele carriers of the HSD17B13

## POSTER PRESENTATIONS

Table. Association between *HSD17B13* variants and liver histology features in Chinese MAFLD patients

SNPs	Severe steatosis		Severe ballooning		Severe Inflammation		Presence of fibrosis

\*OR and 95% CI obtained by binary logistic regression analysis adjusted for age, sex, BMI, presence of diabetes, fasting glucose, triglycerides and HDL-cholesterol.

\*\*OR and 95% CI obtained by binary logistic regression analysis adjusted for age, sex, BMI, presence of diabetes.

Abbreviations: BMI, body mass index; HSD17B13, hydroxysteroid 17-beta dehydrogenase 13; ref., reference.

Table 1: (abstract: PO-1030)

rs6531975 variant [OR = 0.48 (0.24–0.98),  $p = 0.043$  for the additive model; OR = 0.62 (0.40–0.94),  $p = 0.025$  for the dominant model]. HSD17B13 variants were only associated with fibrosis but not other histological features. Furthermore, HSD17B13 rs6531975 modulated the effect of PNPLA3 rs738409 on hepatic steatosis.

**Conclusion:** The HSD17B13 rs72613567 variant is a risk variant for fibrosis in a Han Chinese MAFLD population but with a different direction for allelic association to that seen in Europeans. This data exemplifies the need for studying diverse populations in genetic studies in order to fine map GWAS signals.

### PO-1205

#### Prevalence of lean NAFLD vs lean MAFLD indicates a distinct risk of mortality

Georg Semmler<sup>1,2</sup>, Sarah Wernly<sup>1</sup>, Sebastian Bachmayer<sup>1</sup>, Isabella Leitner<sup>1</sup>, Matthias Egger<sup>1</sup>, Lorenz Balcar<sup>1,2</sup>, Marie Semmler<sup>1</sup>, David Niederseer<sup>3</sup>, Elmar Aigner<sup>4</sup>, Christian Datz<sup>1</sup>. <sup>1</sup>General Hospital Oberndorf, Teaching Hospital of the Paracelsus Medical University Salzburg, Department of Internal Medicine, Oberndorf, Austria; <sup>2</sup>Medical University of Vienna, Department of Internal Medicine III, Division of Gastroenterology and Hepatology, Vienna, Austria; <sup>3</sup>University Hospital

Zurich, Department of Cardiology, Zurich, Switzerland; <sup>4</sup>Paracelsus Medical University Salzburg, First Department of Medicine, Salzburg, Austria

Email: c.datz@kh-oberndorf.at

**Background and aims:** Recently, the novel “metabolic associated fatty liver disease” (MAFLD) definition has been introduced. However, lean patients with (non-alcoholic-) fatty liver disease (NAFLD) not meeting MAFLD-criteria are left without diagnosis, and management of these patients is unclear.

**Method:** 5372 patients without chronic liver disease other than NAFLD/MAFLD or significant alcohol consumption participating in a colorectal screening program were grouped according to their BMI and the presence or absence of NAFLD/MAFLD. Mortality was compared among these groups by performing a systematic read-out of the national health insurance system using Kaplan-Meier analyses with log-rank-test.

**Results:** Overall, 1574 (29.3%) subjects were lean and did not have NAFLD/MAFLD, 119 (2.2%) were lean and had NAFLD, but did not fulfil criteria for MAFLD, and 237 (4.4%) subjects were lean and fulfilled criteria for MAFLD. Additionally, 1093 (20.3%) and 976 (18.2%) were

Figure: (abstract: PO-1205): (A) Reasons for death, (B) overall survival among all patients, (C) excluding traumatic deaths, suicide, and unknown deaths, and (D) also excluding patients with newly diagnosed colorectal cancer and active malignancy at baseline.

overweight (BMI 25–30 kg/m<sup>2</sup>) and obese (BMI ≥ 30 kg/m<sup>2</sup>) and had MAFLD while 1134 (21.1%) and 239 (4.4%) were overweight and obese without MAFLD. During a median follow-up was 7.5 (IQR: 5.7) years, 320 deaths (6.0%) occurred. Of these, 112 (2.1%) were malignancy-associated and 78 (1.5%) were cardiovascular, among others (Figure 1A). Overall survival

(Figure 1B) was different among patient strata, attaining statistical significance for lean patients without NAFLD, lean NAFLD and lean MAFLD (after 5 years: 96.9% vs. 99.0% vs. 91.9%,  $p = 0.002$ ; lean NAFLD vs. lean MAFLD:  $p = 0.008$ ). Results were similar after excluding patients with trauma-associated death, suicide, and unknown reasons (Figure 1C) being significantly different for lean subjects ( $p$

## POSTER PRESENTATIONS

=0.002) and lean NAFLD vs. lean MAFLD (after 5 years: 99.0% vs. 92.3%,  $p=0.013$ ). However, results did not attain statistical significance when also excluding patients with newly diagnosed colorectal cancer at baseline and active malignancy (lean NAFLD vs. lean MAFLD: 99.0% vs. 95.3%,  $p=0.077$ ; Figure 1D).

**Conclusion:** Survival is different among lean patients according to the presence/absence of NAFLD and MAFLD. Specifically, lean NAFLD seems to follow a benign course.

### PO-1227

#### Poor Awareness of Non-alcoholic Fatty Liver Disease (NAFLD) Among Adults in the United States

James Paik<sup>1,2</sup>, Rakish Biswas<sup>3</sup>, Tamooore Arshad<sup>3</sup>, Saleh Alqahtani<sup>1,4</sup>, Alita Mishra<sup>1,2,5</sup>, Zobair Younossi<sup>1,2,5</sup>. <sup>1</sup>Inova Health System, Department of Medicine, Center for Liver Diseases, Falls Church, United States; <sup>2</sup>Inova Health System, Beatty Liver and Obesity Research Program, Falls Church, United States; <sup>3</sup>Center for Outcomes Research in Liver Disease, Washington DC, United States; <sup>4</sup>King Faisal Specialist Hospital, Riyadh, Saudi Arabia; <sup>5</sup>Inova Health System, Medicine Service Line, Falls Church, United States

Email: zobair.younossi@inova.org

**Background and aims:** Despite being the most common cause of liver disease, there is substantial lack of disease awareness about NAFLD. We aimed to estimate disease awareness about NAFLD in the US general population.

**Method:** We used data for adults ( $\geq 18$  years) collected as a part of National Health and Nutrition Examination Survey (NHANES) from 2007 to 2016. The U.S. Fatty Liver Index for the (US-FLI) was used to establish the diagnosis of NAFLD in the absence of secondary causes of liver disease. Advanced fibrosis was defined by Fibrosis-4 score of  $>2.67$ . Awareness was defined as a positive response to the question "Have you ever told by a doctor or health professional that you had any kind of liver condition?"

**Results:** Among 11,700 eligible participants [mean age 47.4 years; 48.8% male; 67.6% white, 10.2% black and 8.7% Mexican American], 34.19% (95% confidence interval [CI], 32.77%–35.62%) had NAFLD. This prevalence rate remained stable over time: 32.6% (2007–2008) to 36.6% (2015–2016) (trend  $P=0.286$ ). Awareness of having liver disease among NAFLD subjects increased from 4.27% (2.92%–5.63%) in 2007–2008 to 6.31% (4.76%–7.86%) in 2015–2016. When stratified by age, awareness of having liver disease among NAFLD subjects improved during the same period (from 1.18% to 3.68% for aged 30–44, from 5.45% to 8.28% for aged 45–64 and from 6.09% to 7.67% for aged  $\geq 65$ ), while the awareness decreased from 2.65% to 0% for aged 18 to 29. Awareness was higher in female subjects (8.23% vs. 4.83%). In multivariable analysis, presence of diabetes (adjusted odds ratio [aOR] = 2.44, 95% CI, 1.53–3.88), having advanced fibrosis (aOR = 2.17, 1.14–4.41) and higher numbers of health care visits (aOR = 1.31, 1.13–1.50) were independently associated with better awareness of having liver disease among subjects with NAFLD. In contrast, non-Hispanic Black race/ethnicity (aOR = 0.37, 0.18–0.77) was associated with lower awareness of having liver disease.

**Conclusion:** Nearly 95% of adults with NAFLD in the U.S. were unaware that they had liver disease. These data suggest that substantial efforts are needed to improve awareness of NAFLD among the general population, particularly among the young adults and the non-Hispanic Black Americans.

### PO-1296

#### Pruritus, anxiety, and depression in patients with non-alcoholic fatty liver disease

Albrecht Boehlig<sup>1</sup>, Florian Gerhardt<sup>1</sup>, David Petroff<sup>2,3</sup>, Florian van Bömmel<sup>1</sup>, Thomas Berg<sup>2</sup>, Valentin Blank<sup>3,4</sup>, Thomas Karlas<sup>4</sup>, Johannes Wiegand<sup>1</sup>. <sup>1</sup>Division of Hepatology, Department of Medicine II, Leipzig University Medical Center; <sup>2</sup>Clinical Trial Center Leipzig, University of Leipzig, Leipzig, Germany; <sup>3</sup>Integrated Research and Treatment Center AdiposityDiseases Leipzig, Faculty of

Medicine, University of Leipzig, Leipzig, Germany; <sup>4</sup>Division of Gastroenterology, Department of Medicine II, Leipzig University Medical Center, Leipzig, Germany

Email: Albrecht.Boehlig@medizin.uni-leipzig.de

**Background and aims:** Patient reported outcomes are gaining attention in non-alcoholic fatty liver disease (NAFLD). Interventional trials show increased prevalence of depression in NAFLD patients compared to the general population. Pruritus is of special interest for evolving therapies with farnesoid X receptor (FXR) agonists. Thus, we aimed to analyse the prevalence of pruritus, anxiety, and depression and possible associations.

**Method:** We offered a screening for patient reported outcomes to outpatients with NAFLD. Pruritus was assessed using a visual-analogue- (VAS) and 5-D itch-scale (5-D) and classified (VAS/5-D) as absent (0/5–8), mild (1–3/9–11), moderate (4–6/12–17), severe (7–8/18–21), or very severe (9–10/22–25). Anxiety and depression were evaluated by Beck's-Depression-Inventory (BDI, relevant score  $\geq 18$ ) and the Hospital Anxiety and Depression Scale (HADS-A and HADS-D, relevant score  $\geq 11$ ). Fibrosis and steatosis were assessed with vibration controlled transient elastography including liver stiffness measurement (LSM) and controlled attenuation parameter (CAP). An optimal logistic regression model was found with a step-wise procedure to investigate variables associated with pruritus. Contingency tables were analysed with Fisher's Exact Test.

**Results:** 123 NAFLD patients were prospectively recruited (mean age 56 years, 53% women, 12% cirrhosis, mean BMI  $29.8 \pm 5.1$  kg/m<sup>2</sup>; 33% diabetes mellitus). Mean VAS was  $1.7 \pm 2.2$  and was  $8.3 \pm 4.0$  for 5-D with a strong correlation between the two (Spearman 0.89). Moderate or severe pruritus was observed in 19% (VAS) and 21% (5-D) of patients. Clinically relevant anxiety was found in 12% of patients and depression in 4% (HADS-D) and 12% (BDI). There was a significant association between VAS and BDI ( $p=0.019$ ). The final multivariate model for VAS included CAP with odds ratios (OR) for moderate/severe itching per 10 dB/m of 1.06 (95% CI 0.97–1.17;  $p=0.17$ ) and relevant HADS-A (OR 2.78, 95% CI 0.75–9.53;  $p=0.12$ ). For 5-D, the model included diabetes mellitus (OR 4.51; 95% CI 1.43–15.3;  $p=0.01$ ), relevant BDI (OR 5.98; 95% CI 1.27–28.8;  $p=0.024$ ) and relevant HADS-A (OR 7.75; 95% CI 1.62–40.1;  $p=0.011$ ).

**Conclusion:** One fifth of NAFLD patients report moderate or severe pruritus. 5-D and VAS were highly correlated, however, only 5-D but not VAS was significantly associated with diabetes mellitus, depression (BDI) and anxiety. These findings should be tested in larger populations to further clarify comorbidities associated with pruritus and consider them in candidates for treatment with FXR agonists.

### PO-1334

#### Mild alcohol consumption and risk for cardiovascular disease in patients with non-alcoholic steatohepatitis: data from a multicenter observational study

Savvoula Savvidou<sup>1</sup>, Margarita Papatheodoridi<sup>2</sup>, Konstantinos Zisimopoulos<sup>3</sup>, Kanellos Koustenis<sup>4</sup>, Demetrios N. Samonakis<sup>5</sup>, Theodoros Voulgaris<sup>2</sup>, Spilios Manolakopoulos<sup>4</sup>, Christos Triantos<sup>3</sup>, Christos Tsoulas<sup>6</sup>, George Papatheodoridis<sup>2</sup>, Ioannis Goulis<sup>1</sup>. <sup>1</sup>Hippocraton University Hospital of Thessaloniki, Medical School of Aristotle University, Thessaloniki, 4th Department of Internal Medicine, Thessaloniki, Greece; <sup>2</sup>General Hospital of Athens "Laiko", Medical School of National and Kapodistrian University of Athens, Department of Gastroenterology, Athens, Greece; <sup>3</sup>Department of Internal Medicine, University Hospital of Patras, Medical School of Patras, Division of Gastroenterology, Patras, Greece; <sup>4</sup>Hippocraton University Hospital of Athens, Medical School of National and Kapodistrian University of Athens, Gastroenterology and Endoscopy Unit, 2nd Department of Internal Medicine, Athens, Greece; <sup>5</sup>University Hospital of Heraklion, Crete, Gastroenterology and Hepatology Department, Heraklion Crete, Greece; <sup>6</sup>Gilead Sciences Hellas, Medical Department, Athens, Greece

Email: ssavidou@med.auth.gr

**Background and aims:** The beneficial effects of light alcohol drinking on the cardiovascular system have never been investigated in patients with non-alcoholic fatty liver disease (NAFLD). Aim of this multicenter study was to investigate possible associations of mild/occasional alcohol consumption with the risk for cardiovascular disease (CVD) in patients with advanced NAFLD, namely non-alcoholic steatohepatitis (NASH).

**Method:** Consecutive NASH pts from five tertiary liver centers were assessed with the QRISK2 formula (incl. age, gender, ethnicity, smoking, diabetes, antihypertensive drugs, cholesterol to HDL ratio and BMI) that estimates the % risk of experiencing a major CVD incidence in the forthcoming decade. Mild/occasional drinking was defined as self-reported consumption of less than 1 standard drink per day, for less than 3 days per week, in the preceding 6-month period. Current or past use of alcohol exceeding this limit was within exclusion criteria.

**Results:** 804 NASH pts were included, of which 106 with NASH-related compensated cirrhosis: 428 (53.2%) males, mean age 58.3 ± 14.5 years, all of white Caucasian origin, mean BMI 30.3 ± 4.7 kg/m<sup>2</sup>, diabetes 239 (29.7%), dyslipidemia 404 (50.2%), hypertension 211 (26.2%), current smokers 38.6%-former 16.3%. Distribution of hepatic fibrosis to F0–F4 stages: 13.1%–28.8%–21.2%–15.3%–21.6%. Liver biochemistry: median ALT 66 IU/L (IQR 49–96), AST 42 IU/L (IQR 31–58),  $\gamma$ GT 63 IU/L (IQR 38–117). About 1/3 of pts (n = 256, 31.8%) reported mild/occasional alcohol consumption compared to none. QRISK2 was calculated in 776 (96.5%) NASH pts without previous history of CVD (median 5.2%, IQR 1.8–12.7%, 26.2% high-risk pts with QRISK2 ≥ 10%). Mild alcohol was associated with male gender (p <

0.001), younger age (p < 0.001), smoking (p < 0.001), absence of diabetes (p = 0.042) and higher cholesterol/HDL ratio (p = 0.017). QRISK2 ranged to lower values in pts consuming mild/occasional alcohol (3.8%, IQR 1.15–10.9 vs. 5.9%, IQR 2.15–13.55, Mann-Whitney test, p = 0.005), irrespective of age, gender, BMI or fibrosis stage. (GRAPH). Comparisons between groups revealed that mild alcohol was associated with statistically significant lower CVD risk independently in pts with normal BMI (p = 0.03) or with F2 fibrosis stage (p = 0.011).

**Conclusion:** The results of this study suggest that mild/occasional alcohol consumption compared to absolute abstinence may lower risk for CVD in NASH. Prospective studies are needed to confirm this effect.

**PO-1429**

**Clinical and prognostic differences between non-alcoholic fatty liver disease and mixed fatty liver disease**

Nicolau Vallejo-Senra<sup>1</sup>, Maria-Violeta Mauriz-Barreiro<sup>1</sup>, Esther Molina<sup>1,2</sup>. <sup>1</sup>Hospital Clínico Universitario de Santiago de Compostela, Gastroenterology and Hepatology, Santiago de Compostela, Spain; <sup>2</sup>Hospital Clínico Universitario de Santiago de Compostela, Liver Transplantation Unit, Spain  
Email: nicolau.vallejo@hotmail.com

**Background and aims:** Non-alcoholic fatty liver disease (NAFLD) is the most frequent liver disease in developed countries. Alcohol itself can cause liver steatosis and cell damage. However, there is little data about the differences between patients with low-risk alcohol intake

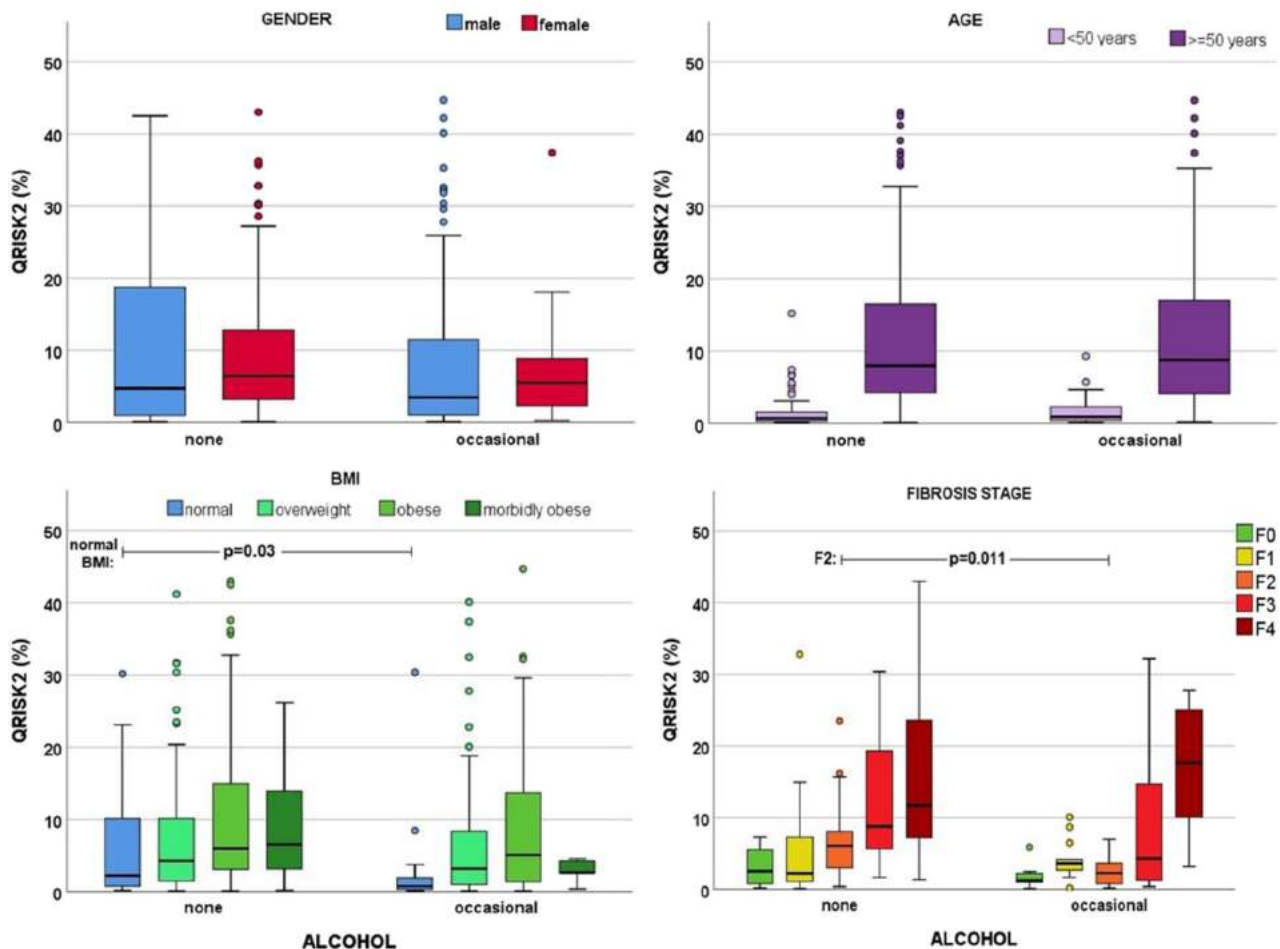

Figure: (abstract: PO-1334)

## POSTER PRESENTATIONS

and liver steatosis (mixed fatty liver disease [MiFLD]) and non-alcohol intake with liver steatosis ("pure" non-alcoholic fatty liver disease [NAFLD]). The aim of this study is to assess the characteristics of these 2 types of non-predominant-alcoholic liver steatosis diseases.

**Method:** A retrospective study of all patients visited at our unit during the year 2019 with the diagnosis of NAFLD was performed. Sex, age, date of diagnosis, obesity, arterial hypertension, diabetes, dyslipidemia were evaluated. Patients with high-risk alcohol intake ( $\geq 4$  units/day for men and  $\geq 3$  units/day for women) were excluded, as well as patients with other liver diseases. Patients with low-risk alcohol intake (1–3 units/day for men and 1–2 units/day for women) were defined as MiFLD. Patients without any intake of alcohol were defined as NAFLD. The diagnosis of F3 and cirrhosis was based on a combination of radiological studies, histology, transient elastography (considering F3  $> 10$  kPa and F4  $> 15$  kPa in two occasions, when histology was not available) and analysis parameters (platelets, liver function test). Results are shown as means and percentages and analyzed by chi-square test and Student-t test. P value  $< 0.05$  was considered significant.

**Results:** 495 patients were included (60.4% male), with median age of 58 years (range 19–86). 63.4% were considered NAFLD, and 36.6% were MiFLD. The global prevalence of obesity, diabetes, dyslipidemia and arterial hypertension were 57.7%, 33.3%, 60.6% and 54.5%, respectively. The prevalence of  $\geq F3$  was 23.6%, with cirrhosis in 15.7%. There were significant differences between NAFLD and MiFLD in age (57 vs 61,  $p = 0.001$ ), male sex (43.3% vs 90%,  $p < 0.001$ ), arterial hypertension (46.2% vs 69.1%,  $p < 0.001$ ),  $\geq F3$  (18.1% vs 33.1%,  $p < 0.001$ ) and cirrhosis (11.4% vs 23.2%,  $p = 0.001$ ). However, no significant differences in diabetes ( $p = 0.919$ ), obesity ( $p = 0.306$ ) and dyslipidemia ( $p = 0.083$ ) were found.

**Conclusion:** Patients with MiFLD have a higher risk of advanced fibrosis and cirrhosis than NAFLD, without more prevalence of metabolic factors except hypertension. This data supports that any amount of alcohol intake should be avoided in fatty liver disease.

### PO-1436

#### Ultra-processed food is associated with features of the metabolic syndrome and naflrd related liver damage

Dana Ivancovsky Wajcman<sup>1</sup>, Naomi Fliss Isakov<sup>2</sup>, Revital Kariv<sup>2,3</sup>, Muriel Webb<sup>2,3</sup>, Oren Shibolet<sup>2,3</sup>, Shira Zelber-Sagi<sup>1,2</sup>. <sup>1</sup>University of Haifa, School of Public Health, Haifa, Israel; <sup>2</sup>Tel Aviv Medical Clinic, Gastroenterology, Tel Aviv-Yafo, Israel; <sup>3</sup>Tel Aviv University, Sackler Faculty of Medicine, Tel Aviv-Yafo, Israel  
Email: danaivanc@gmail.com

**Background and aims:** Ultra processed foods (UPF) comprise up to 50% of the calories in a western diet and are characterized by low nutritional quality, high energy, sugar and fat density and additives. High consumption of UPF was recently found to be associated with all-cause mortality, cancer, cardiovascular disease, type-2 diabetes and metabolic syndrome, but has not been studied in relation to non-alcoholic fatty liver disease (NAFLD) or fibrosis. Therefore, we aimed to test the association of UPF consumption with the metabolic syndrome and its components and with NAFLD.

**Methods:** A cross-sectional study among subjects who underwent anthropometrics, blood pressure measurements and fasting blood tests including FibroMax for non-invasive assessment of NASH and borderline significant fibrosis (F1–F2 and above). Fatty liver was diagnosed by abdominal ultrasound (US). The metabolic syndrome was diagnosed according the acceptable criteria. Food-frequency questionnaire was used to evaluate UPF consumption using the NOVA classification. UPF Kcal/total Kcal intake above the sample median (corresponding to  $> 28\%$ ) was considered as high consumption. Smoking habits were evaluated by self-reported questionnaires.

**Results:** A total of 789 subjects were included in the total sample (mean age  $58.83 \pm 6.58$  years, 52.60% men), reliable FibroMax test was obtained from 714 subjects, 305 subjects were diagnosed with NAFLD by US. In multivariate analysis adjusting for age, gender, body mass index and other nutritional habits, high consumption of UPF was significantly associated with higher odds for metabolic syndrome (OR = 1.88, 95% CI 1.31–2.71,  $P = 0.001$ ) and its components hypertension, high triglycerides and low HDL (OR = 1.53, 95% CI 1.07–2.19;  $P = 0.020$ ; OR = 1.55, 1.05–2.29,  $P = 0.028$ ; OR = 1.51, 1.08–2.11,  $P = 0.017$ , respectively) among the entire sample and with higher

Figure: (abstract: PO-1436): Multivariate association between UPF consumption (by medians) and significant fibrosis stratified by smoking status among the entire sample (A) or subjects with NAFLD (B). The multivariate model is adjusted for: age, gender, BMI, saturated fat and protein intake (% of total Kcal), fibers intake (gr/d), physical activity (hours/week) and coffee (cups/d).

odds for NASH and hypertension (OR = 1.89, 95% CI 1.07–3.38, P = 0.030; OR = 2.26, 1.20–4.26, P = 0.012, respectively) among subjects with NAFLD. Stratification by smoking status (ever vs. never smokers) revealed an association between high UPF consumption and significant fibrosis among ever smokers in the entire sample and in a sub sample of subjects with NAFLD (OR = 1.89, 95% CI 1.03–3.45, P = 0.039; OR = 2.85, 1.14–7.14, P = 0.026, respectively).

**Conclusions:** High UPF consumption is associated with the metabolic syndrome and NASH marker. Among smokers, high UPF consumption is associated with significant fibrosis, suggesting a synergistic effect.

**PO-1526**

**The natural history of pediatric Non-alcoholic Fatty Liver Disease: interim analysis of a long term follow-up study**

Laura Draijer<sup>1</sup>, Maaïke Voorhoeve<sup>1</sup>, Marian Troelstra<sup>2</sup>, Meeike Kusters<sup>3</sup>, Eric de Groot<sup>4,5</sup>, Aart Nederveen<sup>2</sup>, Marc Benninga<sup>1</sup>, Bart Koot<sup>1</sup>. <sup>1</sup>Amsterdam UMC, location AMC, Pediatric Gastroenterology, Hepatology and Nutrition, Amsterdam, Netherlands; <sup>2</sup>Amsterdam UMC, location AMC, Radiology and Nuclear Medicine, Amsterdam, Netherlands; <sup>3</sup>Amsterdam UMC, location VUmc, Pediatrics, Amsterdam, Netherlands; <sup>4</sup>Imagelabonline and Cardiovascular, Erichem, Netherlands; <sup>5</sup>Amsterdam UMC, location AMC, Gastroenterology, Amsterdam, Netherlands  
Email: l.g.draijer@amsterdamumc.nl

**Background and aims:** The long term hepatic outcome of pediatric Non-alcoholic fatty liver disease (NAFLD) remains unclear due to the lack of robust longitudinal data. Between 2008–2012, an unselected cohort of 104 children with severe obesity was screened for NAFLD. Steatosis was detected in 50% of the children based on Proton Magnetic Resonance Spectroscopy (<sup>1</sup>H-MRS). None of them had significant fibrosis based on the Enhanced Liver Fibrosis Test (ELF test). Cardiovascular risk was assessed by measuring the carotid intima-media thickness (c-IMT) using ultrasound. The aim of this follow-up study is to determine the 10 year natural history of pediatric onset NAFLD.

**Method:** A prospective follow-up study was carried out in all 104 subjects that participated in the previous study of 2008–2012. All subjects underwent <sup>1</sup>H-MRS, ELF test and Liver Stiffness Measurement (LSM) by FibroScan<sup>®</sup> to detect fibrosis and all subjects underwent c-IMT. Significant fibrosis was defined as LSM > 8.2 kPa. The main study objectives were to evaluate the change in proportion of subjects with steatosis measured by <sup>1</sup>H-MRS; evaluate the change in proportion of subjects with fibrosis measured by ELF test and FibroScan<sup>®</sup>; determine risk factors for progression of NAFLD; evaluate the association between vascular changes (c-IMT) and progression of NAFLD.

**Results:** An interim analysis included 29 patients (7 males, 22 females) with a median age of 24 years, mean BMI of 41.1 kg/m<sup>2</sup>, median ALT of 24 IU/L (IQR 15–31) and median HOMA-IR of 2, 13 (IQR 1, 14–3, 21). Seven out of 22 subjects that underwent <sup>1</sup>H-MRS had steatosis at 10 years follow-up (32%), as compared to four subjects (18%) at baseline. Three out of seven subjects with steatosis at follow-up already had steatosis had baseline. Five out of 24 patients that underwent FibroScan<sup>®</sup> (21%) had developed significant fibrosis and had significantly higher HOMA-IR, BMI and waist circumference. Results of the ELF test and c-IMT will be available and analyzed in March 2021.

**Conclusion:** These preliminary results indicate that a substantial proportion of young adults who had childhood obesity develop steatosis or fibrosis in young adulthood. The severity of obesity and higher HOMA-IR at follow-up was associated with progression of NAFLD. This suggests that adequate follow-up in children and adolescents with NAFLD is necessary in order to monitor disease progression. However, a larger number of subjects is needed to validate this hypothesis.

**PO-1667**

**Elevated serum bile acids in NASH patients with fibrosis in the context of their cholestatic genetic predisposition**

Monika Rau<sup>1</sup>, Theresa Schmitt<sup>1</sup>, Marcin Krawczyk<sup>2</sup>, Lütjohann Dieter<sup>3</sup>, Jose Marin<sup>4</sup>, Andreas Geier<sup>1</sup>. <sup>1</sup>University Hospital Würzburg, Department of Internal Medicine II, Würzburg, Germany; <sup>2</sup>Saarland University Medical Center, Saarland University, Department of Medicine II; <sup>3</sup>University Hospital Bonn, Institute of Clinical Chemistry and Clinical Pharmacology; <sup>4</sup>University of Salamanca, Laboratory of Experimental Hepatology and Drug Targeting (HEVEPHARM), CIBERehd, IBSAL  
Email: rau\_m@ukw.de

**Background and aims:** Current drug development in NAFLD patients show promising results for FXR agonists, a bile acid (BA) receptor, which appears to be protective against NAFLD progression, but BA retention could also promote liver injury. Genetic variant p.V444A (c.1331T>C) of the bile-salt export pump (ABCB11) as the most frequent pro-cholestatic polymorphism represents a predisposition factor for bile salt retention under pathologic conditions and may render carriers more susceptible to cholestatic insults. To analyze whether the relationship between serum BAs and NAFLD patients depends on the p.V444A variant.

**Method:** In total, 70 NAFL, 124 NASH patients, and 165 clinically diagnosed NAFLD patients (Fibroscan, CAP) were included in this study. The c.1331T>C variant was genotyped using TaqMan assays. Serum BAs were analyzed by mass-spectrometry in 33 NAFL, 58 NASH, and 146 clinically diagnosed NAFLD patients.

**Results:** The pattern of serum biochemical markers in NAFLD patients was cholestatic with (ALT/ALTULN)/(AP/APULN) <2 in 69% of cases (26% of patients with mixed and 5% with cytolytic pattern). Total serum BAs were significantly higher in NASH patients compared to NAFL (2.64 ± 2.24 vs. 1.77 ± 1.63 μM, p = 0.02). Serum BA profiles showed higher levels of deoxycholic acid in NASH patients compared to NAFL. No significant association between overall BAs and histological signs of steatosis, inflammation, or ballooning was found. Histology proved NAFLD patients with advanced disease (F3/F4) had the highest BAs, and F1/F2 patients still had higher BAs compared to F0 (p = 0.02 F3/4 vs. F0–2). All NAFLD patients with cholestasis (BAs >10 μM) had significantly higher liver stiffness compared to non-cholestatic NAFLD patients (41.1 ± 28.6 vs. 8.4 ± 9.1 kPa, p < 0.001). A trend towards less steatosis was observed in cholestatic NAFLD patients measured by CAP. No significant elevation in serum BAs was observed in TT carriers compared to CT+CC (1.90 ± 1.02 vs. 2.36 ± 2.01). A significant correlation between liver stiffness and serum BA was observed for CT+CC patients (R = 0.261, p < 0.05), but not for TT patients (R = 0.104, p > 0.05).

**Conclusion:** Cholestatic serum biomarkers are frequently present in NAFLD patients. NASH patients are characterized by higher serum BAs, and BAs are associated with advanced fibrotic disease. The ABCB11 c.1331T>C variant might be a co-factor for cholestasis in NAFLD patients, but a significant impact was not found in the present study cohort. Whether the genetic susceptibility affects systemic and intrahepatic obeticholic acid levels under therapy—particularly in those with advanced fibrosis—remains to be determined.

**PO-1693**

**Frailty in non-alcoholic fatty liver cirrhosis in comparison to alcoholic cirrhosis, risk patterns and impact on prognosis**

Lubomir Skladany<sup>1</sup>, Janka Vnencakova<sup>1</sup>, Pavol Molcan<sup>1</sup>, Petra Vrbova<sup>2</sup>, Lukas Laffers<sup>3</sup>, Tomáš Koller<sup>2</sup>. <sup>1</sup>FD Roosevelt Faculty Hospital, Department of Hepatology, Gastroenterology and Transplantation (HEGITO), 2nd Department of Medicine, Slovak Medical University, Banska Bystrica, Slovakia; <sup>2</sup>Comenius University Faculty of Medicine, 5th Department of Internal Medicine, Subdiv. Gastroenterology and Hepatology, Bratislava, Slovakia; <sup>3</sup>Faculty of Natural Sciences Matej Bel University, Department of Mathematics, Banska Bystrica, Slovakia  
Email: koller.tomas@gmail.com

## POSTER PRESENTATIONS

**Background and aims:** Physical frailty increases the susceptibility to stressors and predicts a wide range of adverse outcomes in cirrhosis. Data on its impact on the disease course in NAFLD cirrhosis are scarce. We aimed to explore the differences in the prevalence of frailty, its associated factors and the impact on prognosis between alcoholic and non-alcoholic cirrhosis.

**Method:** Cirrhosis registry RH7 operates since 2014 and includes patients requiring hospitalization for decompensated cirrhosis, liver transplant evaluation, or curable hepatocellular carcinoma (HCC) from 2 centers. From the registry, we identified all ALD and NAFLD patients having complete data, nutritional (BMI, arm circumference (MAC), skinfold) and functional parameters (handgrip strength, chair stands, equilibrium, liver frailty index (LFI)) and at least 6 months of follow-up.

**Results:** 280 ALD and 105 NAFLD patients were included. NAFLD patients were significantly older (62 vs. 57 y), with a higher proportion of females (47 vs. 30.4%), higher BMI (28.6 vs. 26) and MAC (29 vs. 26 cm), lower MELD (15 vs. 19), CRP (11 vs. 16.2 mg/l), and a lower proportion of refractory ascites (22.3 vs. 33.1%, all  $p < 0.05$ ). NAFLD patients had a higher proportion of HCC (17.1 vs. 6.8%,  $p = 0.002$ ). Frailty (LFI > 4.5) did not differ between the groups (47.6 vs. 47.9%). Age, sex, albumin and CRP were independent predictors of frailty in both groups. In NAFLD, frailty was also driven by higher BMI and lower MAC, in ALD only by the MELD score. A transplant-free survival model adjusted for age, sex, MELD, CRP, HCC and LFI, showed that NAFLD patients had a higher risk of death or LT (HR = 1.9, 95% CI 1.32–2.67,  $p < 0.001$ , Figure). The HR for NAFLD was more sensitive to 1 unit increase in LFI compared with ALD (HR = 1.51, 1.05–2.2).

Adjusted Cox model for the probability of survival in NAFLD cirrhosis (dotted line) and ALD cirrhosis (solid line), NAFLD HR=1.9 (95% CI 1.31-2.7)

Figure:

**Conclusion:** Hospitalized patients with NAFLD compared with ALD cirrhosis had a lower liver disease burden and higher prevalence of HCC. However, all-cause mortality was higher in NAFLD and it was associated with an increased sensitivity to frailty which likely reflected a higher all-disease burden.

### PO-1747

#### Spleen size does not correlate with stage of liver disease in people with non-alcoholic fatty liver disease

Tessa Cacciottolo<sup>1,2,3</sup>, Anupa Kumar<sup>1</sup>, Susan E. Davies<sup>4</sup>, Michael Allison<sup>1,3</sup>. <sup>1</sup>Liver Unit, Cambridge University Hospitals NHS Foundation Trust, Cambridge NIHR Biomedical Research Centre, Cambridge, United Kingdom; <sup>2</sup>Department of Medicine, University of Cambridge, Cambridge, United Kingdom; <sup>3</sup>Metabolic Research Laboratories, Wellcome Trust-MRC Institute of Metabolic Science, Cambridge, United Kingdom; <sup>4</sup>Department of Histopathology, Cambridge University Hospitals NHS Foundation Trust, Cambridge, United Kingdom

Email: tc463@medschl.cam.ac.uk

**Background and aims:** Splenomegaly in the context of liver disease is classically driven by portal hypertension, and is a sign of advanced

liver disease. However, through clinical experience, we observed that this was often not the case in people with non-alcoholic fatty liver disease (NAFLD), and others have reported an increased incidence of splenomegaly in NAFLD compared to other disease groups. We hypothesised that specifically in NAFLD, splenomegaly is not representative of the degree of underlying liver fibrosis. In this study, we sought to test the correlation between histological stage of liver disease and longitudinal spleen size in a large group of subjects with biopsy-proven NAFLD.

**Method:** We undertook a retrospective analysis of all patients who had a liver biopsy for staging NAFLD between 2015 and 2018, and sonographic measurement of longitudinal spleen size within one year. Liver biopsies were scored using the SAF (Steatosis, Activity and Fibrosis) scoring system by an experienced pathologist. Body height and weight were measured during clinical review, and fasting blood tests were measured using standard methods. Data was analysed using simple linear regression or Fisher's exact test, using GraphPad Prism v8.

**Results:** We identified 226 patients who had both a liver biopsy and recorded spleen size at our centre between 2015 and 2018 (59% males, mean body mass index (BMI) =  $35.2 \pm 6.1$  kg/m<sup>2</sup>, mean Age =  $55.7 \pm 10.8$  years). There was good representation of the various stages of fibrosis (3.1% = F0, 26.1% = F1, 19.9% = F2, 39.8% = F3, 11.1% = F4). We found no correlation between spleen size and histological stage of hepatic steatosis ( $p = 0.39$ ), inflammation ( $p = 0.07$ ) or fibrosis ( $p = 0.68$ ). Spleen size was positively correlated with age ( $R^2 = 0.05$ ), height ( $R^2 = 0.05$ ), body mass index ( $R^2 = 0.05$ ) and the triglyceride to HLD-cholesterol ratio, a surrogate marker of insulin resistance ( $R^2 = 0.05$ ).

**Conclusion:** In this study, we found no correlation between splenomegaly and the degree of underlying liver disease in a large population of people with biopsy proven NAFLD. We found a strong correlation between spleen size, BMI and markers of insulin resistance, which may represent increased visceral deposition of adipose deposition in the spleen. This work indicates that splenomegaly is not a good indicator of advanced liver disease in people with NAFLD, and other methods for monitoring disease progression are required.

### PO-1772

#### Metabolic-associated fatty liver disease is associated with length of stay but not worse survival post COVID-19

Konstantinos-Cédric Perdakis<sup>1</sup>, Alexandre Balaphas<sup>2</sup>, Kyriaki Gkoufa<sup>3</sup>, Nicolas Colucci<sup>2,4</sup>, Sebastian Carballo<sup>1</sup>, Christophe Gaudet-Blavignac<sup>5,6</sup>, Christian Lovis<sup>5,6</sup>, Francesco Negro<sup>7,8</sup>, Christian Toso<sup>2</sup>, Nicolas Goossens<sup>6,7,9</sup>. <sup>1</sup>Hôpitaux Universitaires de Genève (HUG), Internal Medicine, Genève, Switzerland; <sup>2</sup>Hôpitaux Universitaires de Genève (HUG), Digestive Surgery, Genève, Switzerland; <sup>3</sup>Hôpitaux Universitaires de Genève (HUG), Endocrinology, Diabetology, Nutrition and Patients Education, Genève, Switzerland; <sup>4</sup>The University of Pavia, Department of Clinical-Surgery, Diagnostic and Pediatric Sciences, Pavia, Italy; <sup>5</sup>Hôpitaux Universitaires de Genève (HUG), Medical Information Sciences, Genève, Switzerland; <sup>6</sup>Faculty of Medicine, Genève, Switzerland; <sup>7</sup>Hôpitaux Universitaires de Genève (HUG), Gastroenterology and Hepatology, Genève, Switzerland; <sup>8</sup>Hôpitaux Universitaires de Genève (HUG), Clinical Pathology, Genève, Switzerland; <sup>9</sup>Hôpitaux Universitaires de Genève (HUG), Transplantation, Genève, Switzerland  
Email: nicolas.goossens@hcuge.ch

**Background and aims:** The prognostic role of advanced liver disease and metabolic-associated fatty liver disease (MAFLD) in patients with coronavirus disease 2019 (COVID-19) remains unclear. Previous studies have suggested that advanced liver disease and MAFLD are associated with increased severity of COVID-19. However, most studies relied on samples of convenience or case reports with non-systematic clinical characterization. We aimed to investigate the implication of advanced liver disease and MAFLD on the prognosis of

COVID-19 in a mono-centric cohort of consecutive hospitalized subjects.

**Method:** We collected data of all >16-year-old COVID-19 patients hospitalized at the Geneva University Hospital during the first wave of the COVID-19 pandemic (i.e. between February and June 2020). MAFLD was diagnosed in line with recent position statements with the presence of steatosis (imaging, biomarker or biopsy) and evidence of metabolic dysregulation. Advanced liver fibrosis was diagnosed based on biopsy, imaging (signs of portal hypertension) or a high FIB4 score in the 12 months before COVID-19 diagnosis. Outcomes were assessed over 90 days after adjusting for confounders.

**Results:** Among 1026 patients consecutively hospitalized with COVID-19, 73 (7.1%) had advanced fibrosis from any aetiology of liver disease, and 117 (11.4%) had MAFLD. Subjects with advanced liver fibrosis were older (79.7 vs 68.7 y,  $p < 0.001$ ) and, more often male (60.3 vs 53.9%,  $p = 0.330$ ) than those without advanced liver fibrosis. MAFLD subjects had similar age (72.8 vs 69.2 y,  $p = 0.594$ ) and proportions of male sex (60.3 vs 53.9%,  $p = 0.33$ ) than non-MAFLD subjects but higher proportions of T2D (42 vs 18%,  $p < 0.001$ ) and obesity (35 vs 4.0%,  $p < 0.001$ ). The presence of advanced liver fibrosis was associated with increased 90-day death (adjusted OR 2.8 [1.2–6.2],  $p = 0.010$ ) but lower admission to the ICU (adjusted OR 0.39 [0.13–0.94],  $p = 0.058$ ), whereas length of hospital stay was similar. MAFLD was associated with similar 90-day death (adjusted OR 0.9 [0.5–1.6],  $p = 0.761$ ) and ICU admissions (adjusted OR 1.1 [0.6–1.9],  $p = 0.702$ ) than non-MAFLD but increased length of hospital stay (adjusted beta 37.1 [1.9–753],  $p = 0.019$ ).

**Conclusion:** In a consecutive monocentric cohort of more than 1000 patients hospitalized with COVID-19, we found that patients with advanced liver fibrosis, but not MAFLD, had increased 90-day mortality but decreased ICU admission possibly in part related to the triage of these patients and less access to ICU. MAFLD patients had increased length of hospital stay.

#### PO-1823

##### Body weight variability and the risk of cardiovascular outcomes in patients with non-alcoholic fatty liver disease: a nationwide cohort study

Mi Na Kim<sup>1</sup>, Kyungdo Han<sup>2</sup>, Juhwan Yoo<sup>3</sup>, Yeonjung Ha<sup>1</sup>, Young Eun Chon<sup>1</sup>, Ju Ho Lee<sup>1</sup>, Seong Gyu Hwang<sup>1</sup>. <sup>1</sup>CHA University School of Medicine, Division of Gastroenterology, Department of Internal Medicine, Rep. of South, Seongnam, Korea; <sup>2</sup>Soongsil University, Department of Statistics and Actuarial Science; <sup>3</sup>the Catholic University of Korea, Department of Biomedicine and Health Science  
Email: mina2015@cha.ac.kr

**Background and aims:** Body weight variability is often hypothesized to be an indicator of poor health outcome, including cardiovascular diseases (CVDs) and mortality. In consideration of substantial non-alcoholic fatty liver disease (NAFLD) patients who try weight loss experiencing weight regain, the investigation of the influence of body weight variability on NAFLD outcome is crucial to prevent the deleterious consequences of NAFLD. We aimed to investigate the association between body weight variability and risk of CVD and mortality in patients with NAFLD using large-scale, nationwide cohort data.

**Method:** We included 726, 736 individuals with NAFLD who underwent health examinations provided by the Korean National Health Insurance System between 2009 and 2010 until the end of 2017. Body weight variability was assessed using four indices, including variability independent of the mean (VIM). A multivariate-adjusted Cox proportional hazards regression analysis was performed. NAFLD was defined as a fatty liver index  $\geq 60$ , after excluding excess alcohol intake and viral hepatitis.

**Results:** During the follow-up, 11, 358, 14, 714, and 22, 164 cases of myocardial infarction (MI), stroke, and all-cause mortality, respectively, were recorded. Body weight variability was associated with increased risks of major cardiovascular outcomes after adjusting for confounding variables. Compared with the hazard ratios (HRs) of the lowest quartile group, the HRs (95% CIs) of the highest quartile group of VIM for body weight were 1.15 (1.10–1.20), 1.22 (1.18–1.26), and 1.56 (1.53–1.62) for MI, stroke, and all-cause mortality, respectively.

**Conclusion:** Body weight variability was associated with increased risks of MI, stroke, and all-cause mortality in NAFLD patients and may be a predictor of cardiovascular outcomes in such patients. Appropriate interventions to maintain stable weight could positively influence health outcomes in NAFLD patients.

#### PO-1865

##### Association between non-alcoholic fatty liver disease and extrahepatic malignancy

Mesut Gumussoy<sup>1</sup>, Ramazan Idilman<sup>1</sup>, Hale Gokcan<sup>1</sup>, Dilara Turan Gokce<sup>2</sup>, Bahar Beliz Ulas<sup>2</sup>, Ozge Koc<sup>2</sup>, Gokturk Karatas<sup>2</sup>, Emin Bodakci<sup>1</sup>, Mubin Ozercan<sup>1</sup>, Fatih Karakaya<sup>1</sup>, Ramazan Erdem Er<sup>1</sup>, Zeynep Ellik Melekoglu<sup>1</sup>, Serkan Duman<sup>1</sup>. <sup>1</sup>Ankara Üniversitesi Tıp Fakültesi, Gastroenterology, Ankara, Turkey; <sup>2</sup>Ankara Üniversitesi Tıp Fakültesi, Internal Medicine, Turkey  
Email: mesutgumussoy1987@hotmail.com

**Background and aims:** Non-alcoholic fatty liver disease (NAFLD) is strongly associated with metabolic disorders and is associated with extrahepatic complications. The aim of the present study was to determine the development of extrahepatic malignancy in patients with NAFLD over a long-term period of follow-up.

**Method:** This was a single-center, retrospective cohort study. Between January 2001 and January 2020, a total of 1099 patients had been diagnosed with NAFLD, who were followed for at least six months were included into the study. The diagnosis of NAFLD was made based on biochemical, radiological and histological when available. The median follow-up period was 62.3 months (interquartile range: 23.3–128.0 months).

**Results:** The mean age was 51.1 ± 11.0 years. Female gender was predominant (57%). Of 1099 patients, 40.7% were obese, 19.7% had diabetes mellitus, 29.5% had hypertension. Ninety and three patients (8.5%) had cirrhosis. Extrahepatic malignancy was developed in 54 NAFLD patients during the follow-up period, whereas hepatocellular carcinoma developed in 10 patients. Of 54 patients, 48 patients had solid organ malignancies and 9 had hematological malignancies. Of note, two different malignancies were developed in three patients. Female breast cancer was more commonly developed (28%, 16/57), followed by thyroid cancer (19%), lymphoma (12%) and lung cancer (11%). Extrahepatic malignancy was more commonly developed in older patients (54.4 ± 8.4 years vs. 50.9 ± 11.1 years,  $p = 0.038$ ), in female patients ( $n = 40$  6.4% vs  $n = 14$ , 2.9%,  $p = 0.01$ ), in patients with baseline high GGT level (72.1 ± 68.0 U/L vs. 60.7 ± 80.2 U/L),  $p = 0.038$ ). There was no significant association in term of development of extrahepatic malignancy between obese and non-obese NAFLD patients ( $p = 0.71$ ). Obesity was not associated with female breast cancer ( $p = 1.0$ ). The severity of NAFLD did not effect on the development of extrahepatic malignancies. There was no association in term of development of extrahepatic malignancy between patients with a high FIB-4 score ( $\geq 1.45$ ) and patients with a low FIB-4 score ( $< 1.45$ ) ( $p = 0.97$ ). With logistic regression analysis, the development of extrahepatic malignancy was significantly associated with female gender (adjusted odds ratio (OR): 1.92,  $p = 0.05$ ).

**Conclusion:** NAFLD was associated with development of extrahepatic malignancies, especially breast cancer in female patients.

**PO-1880**

**Association between Non-alcoholic Fatty Liver Disease and the Risk of Dementia: A Nationwide Cohort Study**

Gi-Ae Kim<sup>1</sup>, Chi Hyuk Oh<sup>1</sup>, Jung Wook Kim<sup>1</sup>, Su Jin Jung<sup>2</sup>, In-Hwan Oh<sup>2</sup>, Jin San Lee<sup>3</sup>, Key-Chung Park<sup>3</sup>, Jae-Jun Shim<sup>1</sup>. <sup>1</sup>Kyung Hee University School of Medicine, Department of Internal Medicine, Rep. of South, Seoul, Korea; <sup>2</sup>Kyung Hee University School of Medicine, Department of Preventive Medicine, Rep. of South, Seoul, Korea; <sup>3</sup>Kyung Hee University School of Medicine, Department of Neurology, Rep. of South, Seoul, Korea  
Email: joyshim@khu.ac.kr

**Background and aims:** Little is known about the association between non-alcoholic fatty liver disease (NAFLD) and dementia. Given that hepatic steatosis is one of the abnormal fat metabolisms in the body and fat dysregulation in the brain is related to dementia, this study aimed to investigate whether NAFLD is associated with the risk of dementia.

**Method:** We conducted a nationwide population cohort study involving 4, 031, 948 subjects aged 40 to 69 years who had health checkups twice or more under the National Health Insurance Service in Korea between January 2004 and December 2007. Based on the hepatic steatosis index (HSI), the subjects were categorized into non-NAFLD (HSI < 30 at all health checkups) and NAFLD (HSI > 36 once or more). The development of dementia was assessed using the International Classification of Diseases Codes and the prescription of any anti-dementia drug until December 2017. Cox proportional hazards regression models analyzed the dementia risk of each group.

**Results:** During follow-up of 38, 302, 553 person-years, 414, 851 subjects developed dementia. Compared with the non-NAFLD group, the NAFLD group was associated with a higher risk of dementia on multivariable-adjusted analysis (HR, 1.05; p < 0.001), competing risk analysis (HR, 1.08; p < 0.001) and propensity-score matched analysis (HR, 1.09; p < 0.001). The association between NAFLD and dementia risk was more prominent among females (HR, 1.16; p < 0.001) than males (HR, 1.02; p = 0.001). The association between NAFLD and the risk of dementia was stronger among non-obese NAFLD (BMI < 25 kg/m<sup>2</sup>; HR, 1.09; p < 0.001).

**Conclusion:** This nationwide study found that NAFLD was associated with the increased risk of dementia. The association between NAFLD and dementia risk was stronger among females and non-obese NAFLD.

**PO-1904**

**Low skeletal muscle mass is a potential risk factor for lean non-alcoholic fatty liver disease in patients with non-alcoholic fatty liver disease**

Min Kyu Kang<sup>1</sup>, Jung Gil Park<sup>1</sup>. <sup>1</sup>Yeungnam University, College of Medicine, Internal Medicine, Rep. of South, Daegu, Korea  
Email: kmggood111@naver.com

**Background and aims:** Recently, low skeletal muscle mass (LSMM) has emerged as a potential risk factor for NAFLD. However, the association between LSMM and lean NAFLD are not well-known. We investigated the association between LSMM and lean NAFLD in patients with NAFLD.

**Method:** Lean-NAFLD was defined as a body mass Index (BMI) ≤ 23 kg/m<sup>2</sup> with NAFLD. Fatty liver was defined using ultrasound and appendicular skeletal muscle mass (ASM) was adjusted by the height<sup>2</sup> using bioelectrical impedance analysis. LSMM was based on 1SD below the sex-specific mean for Korean adults (cut-off values of 6.74 for men and 4.93 for women).

**Results:** Of 10, 711 NAFLD patients, 4300 (40.1%) were diagnosed with lean NAFLD. Lean NAFLD group were younger (45.0 vs 49.0 years, p < 0.001), more likely to be women (66.3 vs. 34.3%, p < 0.001), had a lower waist circumference (74.0 vs 85.0 cm, p < 0.001), had lower prevalence of diabetes (3.2 vs. 7.8%, p < 0.001), hypertension (4.4 vs. 16.5%, p < 0.001), metabolic syndrome (3.9 vs. 18.3%, p <

0.001), and higher proportion of low skeletal muscle mass (4.5% vs. 0.3%, p < 0.001) than non-lean NAFLD group.

The presence of LSMM was associated with lean NAFLD in patients with NAFLD (odd ratio [OR] = 11.34, p < 0.001) using stepwise adjusted models for age, sex, diabetes, hypertension, waist circumference, fasting glucose, triglyceride, and high sensitivity C-reactive protein (Table).

Table 1: Adjusted odds ratio of low skeletal muscle mass for lean non-alcoholic fatty liver disease in patients with non-alcoholic fatty liver disease

	Low skeletal muscle mass	
	OR (95% CI)	P value
Total NAFLD population (n = 10, 711), OR for lean NAFLD		
Unadjusted	14.45 (9.43–23.39)	<0.001
Multivariate model 1	33.93 (21.79–55.59)	<0.001
Multivariate model 2	11.42 (5.93–23.24)	<0.001
Multivariate model 3	11.34 (5.90–23.03)	<0.001

OR, odds ratio; CI, confidential interval; NAFLD, non-alcoholic fatty liver disease

Low skeletal muscle mass was defined as the appendicular skeletal muscle mass divided by the square of the height (mm<sup>2</sup>/m<sup>2</sup>) using bioelectrical impedance analysis, with sex-specific cut-off values of <6.74 mm<sup>2</sup>/m<sup>2</sup> for men and <4.93 mm<sup>2</sup>/m<sup>2</sup> for women.

Model 1 was adjusted for age and sex.

Model 2 was adjusted diabetes, hypertension, and waist circumference inclusive of model 1.

Model 3 was adjusted for serum fasting glucose, triglyceride, and C-reactive protein inclusive of model 2.

**Conclusion:** LSMM may be a potential risk factor for lean NAFLD patients compared with non-lean NAFLD patients independently of classic metabolic factors.

**PO-1951**

**Novel MAFLD criteria identifies additional individual at risk for FIBROSIS: in depth comparison of MAFLD and NAFLD criteria in the Rotterdam Study**

Laurens van Kleef<sup>1</sup>, Ibrahim Ayada<sup>1</sup>, Qiuwei Pan<sup>1</sup>, Robert De Knegt<sup>1</sup>. <sup>1</sup>Erasmus MC, University Medical Center, Gastroenterology and Hepatology, Rotterdam, Netherlands  
Email: laurensvkleef@gmail.com

**Background and aims:** Recently a transition from non-alcoholic fatty liver disease (NAFLD) to metabolic dysfunction associated fatty liver disease (MAFLD) has been proposed to shift the focus to metabolic health, one of the main drivers of fatty liver disease (FLD). We investigated the application of the MAFLD criteria compared to the conventional NAFLD criteria.

**Method:** We performed a cross-sectional study within The Rotterdam Study, a large ongoing prospective population-based cohort study. All participants between the years 2008 and 2013 who attended the abdominal ultrasound and FibroScan program were eligible for inclusion. Viral hepatitis and alcohol abuse were exclusion criteria. In addition, participants with insufficient metabolic or alcohol data were excluded for the MAFLD or NAFLD analysis, respectively. Both NAFLD and MAFLD criteria were applied and participants were subsequently allocated in overlap FLD, NAFLD only, MAFLD only and no FLD for further analysis. Multivariate analyses were adjusted for age, gender, alcohol, smoking and education level.

**Results:** Of the participants in both analysis (n = 5513), 34.2% had MAFLD and 29.7% had NAFLD. Exclusion criteria for NAFLD were present in 14.1% and among them 39.4% met the MAFLD criteria. Overall, this resulted in 306 (5.4%) participants with MAFLD only and 58 participants (1.1%) with NAFLD only (Figure). MAFLD only was strongly associated with fibrosis (aOR 4.02, p = 0.001) compared to no FLD. This is in contrast to NAFLD only, where no cases of fibrosis were identified. Moreover, NAFLD only was not associated with changes in

liver stiffness measurement (kPa) compared to no FLD (Beta = -0.15, p = 0.57). Furthermore, among participants with MAFLD, there was a significant association with fibrosis for meeting all MAFLD inclusion criteria (aOR 3.55, p < 0.001) or having the metabolic syndrome (aOR 1.87, p = 0.006).

Figure: NAFLD and MAFLD distribution in participants that were eligible for both analyses (n = 5513). The inner circle represents MAFLD and outer circle NAFLD diagnosis.

**Conclusion:** Applying the novel criteria, NAFLD only was uncommon (1.1%) and not associated with increased liver stiffness, whereas MAFLD only was present in 5.4% of the study population and was associated with fibrosis. Moreover, among participants with MAFLD, the presence of all MAFLD inclusion criteria or the presence of the metabolic syndrome was associated with fibrosis, underlining the importance of metabolic health. To identify the MAFLD only group and provide them with appropriate multidisciplinary treatment, we recommend to consider using the novel MAFLD criteria in addition to the conventional NAFLD criteria.

**PO-2002**

**MAFLD-related cirrhosis is the main contributor to admissions for decompensated cirrhosis in intensive care unit. A single-center, 18-month experience**

Marika Rudler<sup>1</sup>, Charlotte Bouzbib<sup>1</sup>, Christiane Stern<sup>1</sup>, Raluca Pais<sup>1</sup>, Filomena Conti<sup>1</sup>, Philippe Sultanik<sup>1</sup>, Sarah Mouri<sup>1</sup>, Vlad Ratziu<sup>1</sup>, Dominique Thabut<sup>1</sup>. <sup>1</sup>GH Pitié-Salpêtrière Charles Foix, Hepatology, Paris, France  
Email: marika\_rudler@yahoo.fr

**Background and aims:** The burden of NASH among patients (pts) hospitalized for decompensated cirrhosis, either alone or in combination with alcohol, is unknown. The concept of metabolic-associated fatty liver disease (MAFLD) allows to identify pts exposed to metabolic risk factors (MRF) either alone or in combination with alcohol. We estimated the prevalence, severity and prognosis of MAFLD and dual MAFLD-alcoholic cirrhosis in pts with cirrhotic decompensation.

**Method:** All consecutive cirrhotic pts hospitalized in intensive care were prospectively included between February 2019 and July 2020. MAFLD was diagnosed based on long-term exposure to diabetes or obesity/overweight, or the association of 2 other MRF (hypertension,

dyslipidemia). We analyzed 3 groups of pts: MAFLD alone (alcohol <30 g/d), mixed MAFLD (MAFLD + alcohol ≥40 g/d), and alcoholic cirrhosis alone. Six-month survival, readmission, and liver transplantation were compared.

**Results:** 231 pts were included (73% males, mean age 58 yrs, obesity 35%, diabetes 28%, alcohol ≥40 g/d 71%, MELD score 21, Child-Pugh class A/B/C 10/31/59%, previous episode of decompensation 68%). Causes of cirrhosis were: 14% MAFLD alone, 36% mixed MAFLD, 35% alcohol alone, 15% other. Overall, 39% of pts were admitted for gastrointestinal bleeding, 9% for neurological disorder, 7% for suspected acute alcoholic hepatitis, 22% for sepsis, 10% for renal failure, 11% for TIPS placement, and 2% for other causes. At admission, pts with MAFLD alone were significantly older (64 ± 1.9 vs 58 ± 1 and 55 ± 1 yrs, p = 0.001), had a lower Child-Pugh score (8.8 ± 0.4 vs 10.1 ± 0.3 and 10.4 ± 0.3, p = 0.02), and MELD score (18 ± 1.4 vs 21 ± 0.9 and 23 ± 0.9, p = 0.02) than pts of the 2 other groups. In-hospital mortality rates were 9.4%, 17.8% and 18.5%, respectively (p = 0.47). Readmission rate was higher in MAFLD alone (56.2% vs 34.5% vs 31.2%, p = 0.03). Six-month survival was 55% and 6-month transplant-free survival was 48%, similar between the 3 groups. Independent factors associated with 6-month transplant-free survival were: lower MELD score (HR = 1.06, CI 95%:10.4–1.09, p < 0.001), absence of HE at admission (HR = 2.3, CI 95%: 1.5–3.5, p < 0.001), and alcohol abstinence post discharge (HR = 1.7; CI: 1.1–2.7, p = 0.02).

**Conclusion:** In pts with decompensated cirrhosis MRF are second only to alcohol as an etiology of liver disease, with the dual MAFLD-alcohol currently a leading cause. Morbidity and mortality are as severe as those seen with other causes of cirrhosis.

**PO-2074**

**Systematic review with meta-analysis: Non-Alcoholic Fatty Liver Disease (NAFLD) in Pregnancy**

Hydar ElJamaly<sup>1,2</sup>, Martin Weltman<sup>1,2</sup>, GUY Eslick<sup>3</sup>. <sup>1</sup>Nepean Hospital, Department of Gastroenterology and Hepatology, Kingswood, Australia; <sup>2</sup>The University of Sydney, Nepean Clinical School, Kingswood, Australia; <sup>3</sup>The University of Sydney, The Whiteley-Martin Research Centre, PENRITH, Australia  
Email: h.eljamaly@gmail.com

**Background and aims:** Maternal and fetal outcomes in pregnant patients with NAFLD has been largely unexplored. To determine the level of evidence associated with both maternal and fetal outcomes in pregnant women with NAFLD.

**Method:** We conducted a comprehensive literature search. The studies included pregnant patients with a previous, current or subsequent diagnosis of NAFLD. We used a random-effects model using odds ratios (OR) with 95% confidence intervals (CI).

**Results:** Twenty-one studies, with 13, 461 NAFLD patients. NAFLD patients had a statistically significant increased likelihood of Baseline DM (OR = 5.79, 95% CI: 1.23–27.36, p = 0.027; I<sup>2</sup> = 84.85, p = 0.01), Baseline HTN (OR = 5.78, 95% CI: 5.38–6.21, p < 0.001; I<sup>2</sup> = 0.00, p = 0.41), GDM (OR = 3.06, 95% CI: 1.74–5.39, p < 0.001; I<sup>2</sup> = 83.50, p = 0.002), GHTN (OR = 1.83, 95% CI: 1.03–3.26, p = 0.041; I<sup>2</sup> = 43.81, p = 0.18), and Pre-eclampsia (OR = 2.43, 95% CI: 1.46–4.04; P = 0.001; I<sup>2</sup> = 0.00, p = 0.94). Analysis revealed that pregnant NAFLD patients were more likely to have a premature birth (OR = 1.87, 95% CI: 1.50–2.33; P < 0.001; I<sup>2</sup> = 21.03, p = 0.28) or large for gestational age (LGA) birth (OR = 2.06, 95% CI: 1.83–2.31; P < 0.001, I<sup>2</sup> = 0.00, p = 1.00). Egger's regression revealed no evidence of publication bias (p > 0.05).

**Conclusion:** This meta-analysis provides pooled evidence that NAFLD is associated with a substantial increase in maternal diabetic and hypertensive complications and that mothers with NAFLD are more likely to have premature births and a LGA birth compared to normal controls. This data is important for clinicians managing these patients before, during and after pregnancy.

## POSTER PRESENTATIONS

PO-2326

### Assessment of how modifiable and non-modifiable factors can impact fibrosis outcomes in non-alcoholic steatohepatitis patients: a 12-country real-world assessment

Kate Hallsworth<sup>1,2</sup>, James Pike<sup>3</sup>, James Carroll<sup>3</sup>, Jessica Jackson<sup>3</sup>, Victoria Higgins<sup>3</sup>. <sup>1</sup>The Newcastle upon Tyne Hospitals NHS Foundation Trust, United Kingdom; <sup>2</sup>Newcastle University, Newcastle upon Tyne, United Kingdom; <sup>3</sup>Adelphi Real World, Bollington, United Kingdom  
Email: victoria.higgins@adelphigroup.com

**Background and aims:** It is well recognised that the rising prevalence of obesity and non-alcoholic steatohepatitis (NASH) are closely associated, with NASH estimated to increase 63% by 2030. Guidelines recommend weight loss as a key strategy for NASH management. This analysis examines how modifiable (diet, exercise levels, weight concerns, patient knowledge/engagement with NASH management) and non-modifiable (age, comorbidities including type 2 diabetes (T2DM), socio-economic status (SES) factors impact patient outcomes as measured by a change in fibrosis stage.

**Method:** Data were derived from the 2018/19 Adelphi NASH Disease Specific Programme, a real-world, point-in-time chart review across 12 countries across Europe, North America, Middle East and Australasia. Physicians completed questionnaires describing up to 8 NASH patients capturing fibrosis score, age and comorbidities, including T2DM status. Patients completed a voluntary questionnaire measuring diet, exercise, weight concerns, SES and degree of knowledge/engagement with NASH management. Generalized structural equation modelling was used to explore associated relationships of modifiable/non-modifiable factors and their impact on outcomes as measured by a change in fibrosis stage and patient-reported overall health.

**Results:** 654 physicians (29% Hepatologist, 48% Gastroenterologist, 21% Diabetologist, 2% PCP) provided data on 3434 patients. Of these, 1880 NASH patients qualified for the analysis. Of non-modifiable factors, high SES correlated with good knowledge/engagement with NASH management, and overall improved fibrosis score but does not influence diet, exercise or weight concern levels; T2DM presence was negatively associated with diet, exercise and weight concern levels, but not associated with NASH knowledge/engagement level. Of modifiable factors, higher diet, exercise and weight concern levels are likely to be present in younger patients with fewer comorbidities, patients who are more informed/engaged about NASH management, and patients that present with an improvement to fibrosis score/overall health. High patient NASH knowledge/engagement is negatively associated with improved fibrosis stage/overall health.

Figure:

**Conclusion:** Non-modifiable factors such as age, SES and T2DM status present as potential barriers to achieving fibrosis improvement. This analysis suggests, however, that fibrosis outcomes could be improved if modifiable factors, such as patient awareness of importance of diet, exercise and weight status, are targeted.

PO-2328

### NAFLD and colorectal adenoma-rather an association than causality

Lorenz Balcar<sup>1,2</sup>, Georg Semmler<sup>1,2</sup>, Sarah Wernly<sup>1</sup>, Sebastian Bachmayer<sup>1</sup>, Matthias Egger<sup>1</sup>, Marie Semmler<sup>1</sup>, David Niederseer<sup>3</sup>, Elmar Aigner<sup>4</sup>, Christian Datz<sup>1</sup>. <sup>1</sup>General Hospital Oberndorf, Teaching Hospital of the Paracelsus Medical University Salzburg, Department of Internal Medicine, Oberndorf, Austria; <sup>2</sup>Medical University of Vienna, Department of Internal Medicine III, Division of Gastroenterology and Hepatology, Vienna, Austria; <sup>3</sup>University Heart Center Zurich, University Hospital Zurich, Department of Cardiology, Zurich, Switzerland; <sup>4</sup>Paracelsus Medical University Salzburg, First Department of Medicine, Salzburg, Austria  
Email: c.datz@kh-oberndorf.at

**Background and aims:** Since NAFLD and hepatic fibrosis have been associated with an increased risk for colorectal adenoma and/or colorectal cancer (CRC) in selected cohorts, we tested this hypotheses in asymptomatic subjects participating in a program for colorectal cancer screening (SAKKOPI).

**Method:** 5311 subjects were included if none of the exclusion criteria were fulfilled: (I) significant alcohol consumption ( $\varnothing \geq 20$  g/d,  $\sigma \geq 30$  g/d), (II) established autoimmune, cholestatic, viral or hereditary liver disease, (III) missing data on the prevalence and severity of NAFLD, and (IV) insufficient colonoscopy. Diagnosis of NAFLD was established using ultrasound (Cohort I, n = 3945) and liver stiffness measurement (LSM) using transient elastography with controlled attenuation parameter (CAP; Cohort II, n = 1366). Colorectal neoplasia were classified macroscopically and histologically as hyperplastic polyps (HP), adenomas, advanced adenomas (AA) and CRC.

**Results:** Cohort I: Mean age  $58.7 \pm 10.0$  years, mean BMI  $26.6 \pm 4.7$  kg/m<sup>2</sup>. Prevalence was 29.9% for adenoma, 7.2% for AA, 46.2% for NAFLD and 3.1% for advanced fibrosis (Fib-4 > 2.67). Adenoma were more prevalent in patients with NAFLD (38.9% vs. 33.3%, p = 0.033), severe NAFLD (41.1% vs. 33.6%, p = 0.005) and advanced fibrosis (45.5% vs. 35.9%, p = 0.072) with no differences for HP or AA. HP (30.8% vs. 24.4%, p < 0.001), adenoma (34.9% vs. 25.6%, p < 0.001) and AA (8.7% vs. 6.0%, p = 0.001) were more prevalent in subjects with NAFLD, adenoma (43.5% vs. 26.4%, p < 0.001) and CRC (3.2% vs. 0.7%, p = 0.015) were more prevalent in subjects with Fib-4 > 2.67 vs. < 1.45. After correcting for age and gender, NAFLD was associated with adenoma (aHR: 1.253 [95% CI: 1.084–1.447], p = 0.002) and HP, but not AA. Although Fib-4 strata (< 1.45 vs. 1.45–2.67 vs. 2.67) were associated with adenoma and AA, these associations were driven by age.

Cohort II: Mean age  $58.9 \pm 8.8$  years, mean BMI  $26.8 \pm 4.6$  kg/m<sup>2</sup>. Prevalence was 36.5% for adenoma and 7.3% for AA. Mean CAP was  $262 \pm 62$  dB/m with 57.8% having NAFLD ( $\geq 248$  dB/m) and 39.4% having severe steatosis ( $\geq 280$  dB/m), mean LSM was  $5.0 \pm 2.9$  kPa with 6.4% suspected advanced fibrosis ( $\geq 8$  kPa). Adenoma were more prevalent in patients with NAFLD (38.9% vs. 33.3%, p = 0.033), severe NAFLD (41.1% vs. 33.6%, p = 0.005) and advanced fibrosis (45.5% vs. 35.9%, p = 0.072) with no differences for HP or AA. While LSM was not associated with adenoma after correcting for age and gender, CAP (aHR per 10 points: 1.025 [95% CI: 1.001–1.049], p = 0.038) and severe NAFLD (aHR: 1.339 [95% CI: 1.021–1.756], p = 0.035) were associated only if stringent quality criteria were applied.

Associations of NAFLD and adenoma were attenuated when correcting for BMI or metabolic syndrome in both cohorts.

**Conclusion:** NAFLD indicates a metabolic situation promoting colorectal adenoma while advanced fibrosis assessed non-invasively is not associated with colorectal lesions.

PO-2343

**Does fibrosis severity or diabetes status influence patient-reported lifestyle changes and degree of success among non-alcoholic steatohepatitis patients?**

Victoria Higgins<sup>1</sup>, James Carroll<sup>1</sup>, Jessica Jackson<sup>1</sup>, Liane Gillespie-Akar<sup>1</sup>. <sup>1</sup>Adelphi Real World  
 Email: victoria.higgins@adelphigroup.com

**Background and aims:** Non-alcoholic steatohepatitis (NASH) often presents asymptotically and is highly associated with metabolic comorbidities such as type 2 diabetes mellitus (T2DM). While EASL-EASD-EASO clinical guidelines advocate first addressing diet and lifestyle factors in T2DM and NASH, evidence suggests patients struggle to change their lifestyle, especially those with milder disease. This analysis aimed to evaluate if the degree of patient

weight and lifestyle change adopted is associated with fibrosis stage and/or T2DM status.

**Method:** Data were derived from the 2018/19 Adelphi NASH Disease Specific Programme, a real-world, cross-sectional chart review in Europe, North America, Middle East and Australasia. Physician-completed forms described up to 8 consecutive NASH patients including assessment of T2DM status, clinical test values and weight assessment. Patients completed a voluntary form measuring weight concerns and lifestyle changes. Retrospective assessment of fibrosis staging applied a hierarchical approach from most recent liver biopsy (EF F0–2; AF F3–4); vibration-controlled transient elastography (EF < 6.5 kPa; AF ≥ 12.1 kPa) or FIB-4 results (EF < 1.30; AF ≥ 2.67). Patients were categorized into 4 sub-groups, EF-T2DM, EF+T2DM, AF-T2DM, AF+T2DM. All results p > 0.05 unless stated.

	EF-T2DM (n=264)	EF+T2DM (n=399)	AF-T2DM (n=209)	AF+T2DM (n=440)

## POSTER PRESENTATIONS

**Results:** 654 physicians recruited 4656 patients of which 1312 qualified for the analysis; 56% male, mean age 56 years. T2DM presence increases BMI, low socio-economic status and physician-recommended weight loss, regardless of NASH fibrosis. Physician weight loss concern increases as fibrosis worsens and with T2DM presence. Physicians report high dissatisfaction on weight-loss achievements with opportunity for improvement, which becomes increasingly difficult by AF+T2DM status; patients in contrast report greater satisfaction and acceptance with current weight loss status. Patient-reported physician-recommended lifestyle changes are more likely among AF+T2DM patients. Though success varies across the 4 patient groups, AF-T2DM patients are least likely to succeed. Patients report controlling blood sugar and losing weight as key lifestyle changes helping with health.

**Conclusion:** Fibrosis severity and T2DM status seem to influence patients to implement lifestyle changes. NASH+T2DM patients, irrespective of fibrosis stage, appear to understand the importance of weight loss to help manage their condition vs. non-diabetic patients. This highlights the need to make patients more aware of how implementing preventative lifestyle changes in early disease whilst still asymptomatic is important.

### PO-2583

#### Indirect healthcare costs in biopsy-proven NAFLD is higher than in matched controls and independent of comorbidities

Lina Gruneau<sup>1</sup>, Linnea Widman<sup>2</sup>, Martin Henriksson<sup>1</sup>, Hannes Hagström<sup>2</sup>. <sup>1</sup>Linköping University, Sweden; <sup>2</sup>Karolinska Institutet, Sweden  
Email: lina.gruneau@liu.se

**Background and aims:** Patients with NAFLD have high direct healthcare costs, but studies analysing the costs outside the healthcare sector are limited. The aim of this study was to investigate non-healthcare costs of NAFLD.

**Method:** We analysed data from a cohort of 646 biopsy-proven Swedish NAFLD patients diagnosed between 1974 through 2009. Reference individuals from the general population were matched on age, sex, and municipality. The number of days with sickness leave covered by sickness benefits from the Swedish Social Insurance Agency and the incidence of permanent long-term benefit due to the inability to ever work again (long-term sickness benefit) were quantified using data from national register data and compared between NAFLD-patients and reference individuals. Linear and Cox regression was used to investigate the association between NAFLD and these outcomes. Confounders in the models included age, sex, several somatic and psychiatric comorbidities, and socio-economic parameters such as income levels and education.

**Results:** Full data was available from 400 patients. Patients with NAFLD had a mean annual number of sick-leave benefit days of 23.9 (95% CI: 21.7–26.0), the corresponding figure for controls was 11.5 (95% CI: 11.1–12.0). The mean annual number of sick-leave benefit days was higher for NAFLD patients with fibrosis stage 3–4 (40.0, 95% CI = 28.5–51.5) compared to patients with stage 0–2 (22.7, 95% CI = 20.0–25.3). Patients with NAFLD also had a higher rate of permanent long-term benefit (aHR 1.68, 95% CI = 1.40–2.03). Results were stable across a range of sensitivity analyses.

**Conclusion:** Patients with biopsy-proven NAFLD have a higher risk for needing long-term sickness benefit, and higher annual days of sickness leave, independent of several confounders. The highest risk was found in patients with advanced fibrosis. These data suggests that the indirect costs due to NAFLD will further contribute to a high total cost on society.

Figure: Kaplan-Meier risk estimate of sickness pension requirement in patients with NAFLD and matched reference individuals.

### PO-2673

#### Colonic permeability is increased in non-cirrhotic non-alcoholic fatty liver disease

Toon De Munck<sup>1</sup>, Pauline Verhaegh<sup>1</sup>, Corinne Spooen<sup>1</sup>, Tobias Wienhold<sup>1</sup>, Zlatan Mujagic<sup>1</sup>, Daisy Jonkers<sup>1</sup>, Ad Masclee<sup>1</sup>, Ger Koek<sup>1</sup>, Jef Verbeek<sup>2</sup>. <sup>1</sup>Academic Hospital Maastricht, Maastricht, Netherlands; <sup>2</sup>University Hospital KU Leuven, Gastroenterology and Hepatology, Leuven, Belgium  
Email: jef.verbeek@uzleuven.be

**Background and aims:** Increased intestinal permeability (IP) plays an important role in the pathophysiology of non-alcoholic fatty liver disease (NAFLD). However, colonic permeability has not been assessed in human non-cirrhotic NAFLD to date. We assessed site-specific (gastroduodenum, small intestine, colon and whole gut) IP in NAFLD patients and healthy controls (HC) and its association with the degree of hepatic steatosis, hepatic fibrosis and dietary composition in NAFLD patients.

**Method:** *In vivo* site-specific IP was analysed with a validated multi-sugar test in non-cirrhotic NAFLD patients and HC. Furthermore, in NAFLD patients, hepatic steatosis (chemical shift MRI), hepatic fibrosis (transient elastography) and dietary composition (253-item food frequency questionnaire on food intake in prior year) were assessed. Clinically significant fibrosis was defined as liver stiffness  $\geq 7$  kPa (F2–3).

**Results:** Fifty-two NAFLD patients (median age 54 (IQR 47–61), 25 (48%) female, median BMI 33 (IQR 29–39)) and forty-six non-obese HC (23 (50%) female;  $p = 1.000$ ) were included in this study. Small intestinal ( $p < 0.001$ ), colonic ( $p = 0.004$ ) and whole gut ( $p < 0.001$ ) permeability were increased in NAFLD patients compared to HC (Figure). Furthermore, colonic ( $p = 0.024$ ) and whole gut ( $p = 0.042$ ) permeability were significantly higher in NAFLD patients with clinically significant fibrosis ( $n = 16$ ) compared to those without ( $n = 32$ ). Colonic permeability, but not whole gut permeability, remained positively associated with the presence of clinically significant fibrosis ( $p = 0.047$ ) after adjustment for age, sex and BMI in a multivariable linear regression analysis. Furthermore, no association between IP and the degree of hepatic steatosis or dietary composition was observed.

**Conclusion:** Colonic, small intestinal and whole gut permeability are increased in at least a subset of non-cirrhotic NAFLD patients compared to HC. Colonic permeability is independently associated with clinically significant NAFLD fibrosis.

**Liver test-derived R factor is associated with portal hypertension in patients with non-alcoholic fatty liver disease**

Dor Shirin<sup>1</sup>, Ana Tobar<sup>2</sup>, Ahinoam Glusman Bendersky<sup>1</sup>, Rabab Naamneh<sup>2</sup>, Amir Shlomai<sup>3,4</sup>. <sup>1</sup>Beilinson, Internal ward D, Petah Tikva, Israel; <sup>2</sup>Beilinson, Pathology, Petah Tikva, Israel; <sup>3</sup>Beilinson, Internal Medicine D, Petah Tikva, Israel; <sup>4</sup>Beilinson, Liver institute, Petah Tikva, Israel  
Email: dorshirin@yahoo.com

**Background and aims:** Early development of portal hypertension (PHT) is a well described phenomenon in some patients with non-alcoholic fatty liver disease (NAFLD), but the underlying mechanism is still elusive. Several studies suggest that isolated elevated alkaline phosphatase (ALP), or alternatively, a “cholestatic pattern” of liver enzymes, reflected by R factor (calculated as alanine transaminase (ALT)/upper limit of normal (ULN) divided by alkaline phosphatase (ALP)/ULN at presentation) <2, are associated with a more progressive form of NAFLD. Compared to patients with liver tests abnormalities of hepatocellular pattern. We therefore hypothesized that patients with established NAFLD and a “cholestatic” pattern of liver injury are more likely to develop PHT compared to non-cholestatic NAFLD patients.

**Method:** We collected data of 80 constitutive patients with a diagnosis of NAFLD, who underwent trans jugular liver biopsy and hepatic venous pressure gradient (HVPG) measurement in our institute during the years 2008–2020. Patients were divided into cholestatic (R < 2) vs. non-cholestatic (R ≥ 2) liver injury groups, and further divided into advanced (F3–4) vs. non-advanced (F0–2) liver fibrosis, based on liver histology results.

**Results:** Patients with R < 2 were significantly older, had a lower platelet count and a significantly higher HVPG (12.68 ± 6.09 vs. 7.60 ± 4.13, p = 0.001), although the percentage of patients with advanced fibrosis was not significantly different between the groups. We next focused only on patients with no significant fibrosis (F0–F2). Interestingly, in contrast to the R ≥ 2 group who had a normal mean HVPG, the R < 2 group had an abnormally high mean HVPG (5.00 ± 2.86 vs. 10.61 ± 5.92, p < 0.001). We next incorporated the R factor in a multivariate analysis, including age, sex, platelet count and METAVIR score, known predictors for advanced liver disease. Both, higher METAVIR score (beta = 0.319, p = 0.004) and a lower R factor (beta = -0.298, p = 0.007) were significantly associated with HVPG.

Fig 1

Figure: XY Graphs with the HVPG values as a function of the R factor values at the time of trans jugular HVPG measurement and liver biopsy in all patients with NAFLD.

**Conclusion:** Among patients with NAFLD, those with the lower R factor are at increased risk for PHT.

**NAFLD: Diagnostics and non-invasive assessment**

PO-167

**Derivation and validation of the NAFLD cirrhosis score (NCS) to distinguish bridging fibrosis from cirrhosis and to predict liver-related outcomes**

Christian Labenz<sup>1</sup>, Gerrit Toenges<sup>2</sup>, Peter Galle<sup>1</sup>, Ming-Hua Zheng<sup>3</sup>, Dora Ding<sup>4</sup>, Robert Myers<sup>5</sup>, Angelo Armandi<sup>6</sup>, Javier Ampuero<sup>7</sup>, Manuel Romero Gomez<sup>7</sup>, Elisabetta Bugianesi<sup>6</sup>, Jörn M. Email: christian.labenz@unimedizin-mainz.de

**Background and aims:** The distinction of bridging fibrosis from cirrhosis in non-alcoholic fatty liver disease (NAFLD) is critical to guide the clinical management. It was the aim of this study to develop an easy-to-perform score predicting the presence of cirrhosis in the subgroup of patients with advanced fibrosis.

**Method:** A derivation cohort comprising 251 NAFLD patients from Germany, Italy and Spain with biopsy-proven bridging fibrosis (F3) or cirrhosis (F4) was used to develop the NAFLD cirrhosis score (NCS). The NCS was externally validated in two cohorts consisting of 1,666 patients recruited in the STELLAR trials and 47 patients from China. Patients of the STELLAR trials were also followed-up for the progression to cirrhosis (in the F3 cohort) or time to first hepatic decompensation/qualification for transplantation (MELD ≥ 15)/all-cause mortality/liver transplantation.

**Results:** A model including INR, gGT, ALT, platelets and age discriminated between patients with bridging fibrosis and cirrhosis with an area under the curve (AUC) of 0.733 (95% CI 0.671–0.795). Diagnostic performance of the NCS was similar in the large external validation cohort from the STELLAR studies (AUC 0.700; 95% CI 0.680–0.730) and the smaller cohort from China (AUC 0.727; 95% CI 0.533–0.921). We derived two NCS cut-off values (<64.5 points and >79.17 points) to classify patients at low, intermediate, or high risk for the presence of cirrhosis. Using the above-mentioned cutoffs and considering that patients in the intermediate-risk group subsequently receive additional diagnostic workup, the sensitivity, specificity, PPV and NPV of the resulting diagnosis algorithm were high and are displayed in Table 1. By using NCS, further diagnostic workup could be avoided by ruling in or ruling out cirrhosis in approximately one half of the patients. Furthermore, NCS identified patients at risk for progression to cirrhosis in the F3 cohort and liver-related clinical events in the F4 cohort.

Table 1: Diagnostic performance of the NAFLD cirrhosis score (NCS)

	Derivation cohort.	Validation cohort. (STELLAR)	Validation cohort. (China)
Sensitivity	91% (83–96)	88% (86–90)	70% (35–92)
Specificity	90% (84–94)	92% (90–94)	97% (84–100)
PPV	85% (76–92)	93% (90–94)	88% (47–99)
NPV	94% (89–97)	88% (85–90)	92% (78–98)
LR+	5.80 (3.61–9.32)	12.34 (9.70–15.69)	7.00 (1.10–44.61)
LR–	0.06 (0.03–0.12)	0.14 (0.12–0.17)	0.08 (0.03–0.25)
Intermediate-risk group	50.4%	61.6%	34.0%

Diagnostic performance of the NAFLD cirrhosis score for the detection of liver cirrhosis in the derivation and validation cohorts considering cutoff values of <64.5 and >79.17 points with subsequent specialized testing in the intermediate group.

**Conclusion:** The NCS is a simple tool able to identify patients with compensated cirrhosis in the larger group of advanced disease stage. In addition, NCS is prognostic for liver-related outcomes.

**PO-313**

**The prognosis is impaired in NAFLD patients with diabetes despite negative FIB4 <1.30**

Jerome Boursier<sup>1</sup>, Mattias Ekstedt<sup>2</sup>, Manuel Romero Gomez<sup>3</sup>, Clemence Moreau<sup>4</sup>, Martin Bonacci<sup>5</sup>, Sandrine Cure<sup>5</sup>, Aldo Trylesinski<sup>5</sup>, Hannes Hagström<sup>6</sup>. <sup>1</sup>Angers University Hospital, Angers, France; <sup>2</sup>Linköping University, Linköping, Sweden; <sup>3</sup>University of Seville, Seville, Spain; <sup>4</sup>Angers University, Angers, France; <sup>5</sup>Intercept, London, Northern Ireland; <sup>6</sup>Karolinska Institutet, Stockholm, Sweden  
Email: jeboursier@chu-angers.fr

**Background and aims:** Non-invasive liver fibrosis tests play a key role in identifying NAFLD patients at greatest risk of developing liver-related events (LRE). Diabetes (T2D) is strongly associated with NAFLD severity and progression. We evaluated the ability of the blood test FIB4 and vibration controlled transient elastography (VCTE) by FibroScan to correctly identify NAFLD patients with impaired prognosis, with comparison between T2D and non-T2D patients.

**Method:** NAFLD patients with data on FIB4 and/or VCTE from 4 European academic centers were included. The main study outcome was LRE, a composite end point combining cirrhosis complication or hepatocellular carcinoma. Incident LRE were ascertained by chart review. T2D was defined as the use of antidiabetic treatment. FIB4 and VCTE results were stratified in 3 groups according to published cut-offs (FIB4: 1.30 and 3.25, VCTE: 8.0 and 15.7 kPa). Multivariate Cox regression models were performed including each time one fibrosis test together with age, sex, antidiabetic treatment, anti-hypertensive treatment, and lipid-lowering treatment.

**Results:** Data were available at baseline in 984 patients for FIB4 (35% T2D) and 835 patients for VCTE (38% T2D). Baseline characteristics were similar across these 2 groups. After a median follow-up of 3.8 and 2.9 years, respectively, LRE occurred in 53 (5.3%) and 51 (6.1%) patients from FIB4 and VCTE groups. Multivariate Cox models identified T2D and the fibrosis test evaluated (FIB4 or VCTE) as independent predictors of LRE. Of note, in patients with baseline FIB4 < 1.30, Kaplan-Meier curves showed a significantly impaired prognosis in T2D compared to non-T2D patients (p < 0.001). Ten patients from the FIB4 group had LRE during their follow-up despite baseline FIB4 < 1.30, 7 of them having T2D. These patients could be identified by following the evolution of FIB4 which became >1.30 several years before LRE occurrence, or by using VCTE (available in 7 patients and always >8.0 kPa before FIB4 > 1.30). Liver biopsy was available at baseline in respectively 557 and 428 patients from the FIB4 and VCTE groups. Among patients with baseline FIB4 < 1.30, advanced fibrosis F3-4 was present in 37% of T2D versus 8% in non-T2D patients (p <

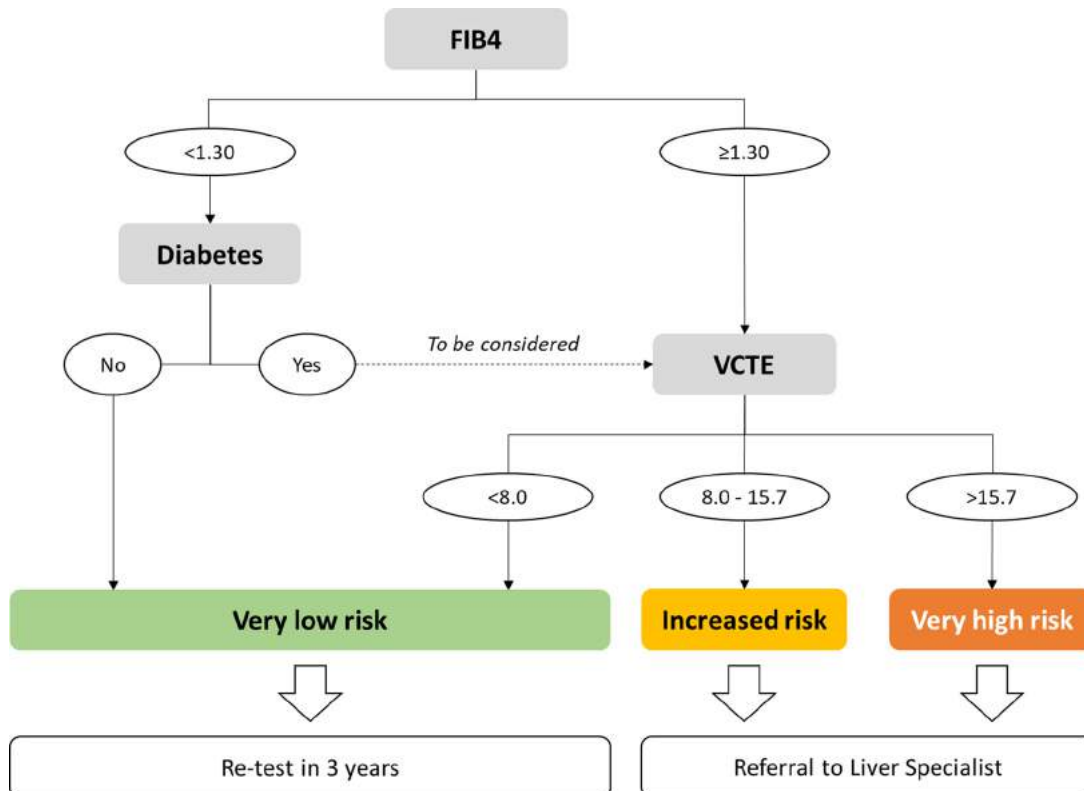

Figure: (abstract: PO-313)

## POSTER PRESENTATIONS

0.001). VCTE result was >8.0 kPa in 83% of the T2D patients having false negative result with FIB4 (advanced fibrosis despite FIB4 < 1.30). Based on these results and our previous report (increased LRE risk from FIB4 ≥ 1.30 with VCTE ≥ 8.0 kPa; AASLD Liver Meeting 2020), an adapted FIB4-VCTE algorithm is proposed by considering VCTE examination in T2D patients despite FIB4 < 1.30 (Figure).

**Conclusion:** Diabetes is associated with an impaired prognosis in NAFLD, and an increased advanced fibrosis rate despite FIB4 < 1.30. To decide referral to the liver specialist, NAFLD patients with diabetes and FIB4 < 1.30 should undergo a close follow-up or be considered for VCTE.

### PO-454

#### The use of age-specific cutoffs for FIB4 and NAFLD Fibrosis Score in a primary care setting finds over one-third of older diabetic patients are at high risk for NAFLD with advanced fibrosis

Kendall Islam<sup>1</sup>, Danielle Brandman<sup>1</sup>, Janet Chu<sup>1</sup>, Rena Fox<sup>1</sup>. <sup>1</sup>University of California, San Francisco, San Francisco, United States  
Email: rena.fox@ucsf.edu

**Background and aims:** There is a need for tools to assist primary care (PC) in identifying and risk stratifying patients with NAFLD. The FIB4 and NAFLD Fibrosis Score (NFS) accurately characterize the risk of advanced fibrosis, but since specificity decreases with advancing age, age-specific score cutoffs have been proposed. No studies have examined age-specific cutoffs in PC. We aimed to examine a cohort of older PC patients with diabetes mellitus (DM) categorized by FIB4 and NFS with age specific cutoffs.

**Method:** We created a cohort of all adult DM patients from a large academic PC practice using the electronic medical record (EMR). Patients with HBV, HCV or alcohol disorder were excluded. For the study period 2015–2020, we computed a FIB4 and NFS per patient per year. Those ≥65 yo were categorized as low- (FIB4 < 2.0, NFS < 0.12), indeterminate- (FIB4 2.0–2.67, NFS 0.12–0.676), and high-risk (FIB4 > 2.67, NFS > 0.676).

**Results:** From a total clinic population of 26, 602, 3, 040 patients met criteria for the cohort and 1, 821 were ≥65 yo. Mean age was 77 (SD 7.6) and 74% (n = 1, 354) had data in the EMR to calculate at least one FIB4 or NFS. Of these, 498 (37%) were low risk, 346 (25%) indeterminate risk, and 510 (38%) high risk. Characteristics of the risk groups are shown in Table 1. In univariate analyses, age, gender, BMI, AST, ALT, platelet and albumin were significantly associated with high-risk classification, though average laboratory values were all in the normal range.

**Conclusion:** Using age-specific cutoffs for FIB4 and NFS, we found that over 1/3 of DM patients ≥65 yo met criteria for high risk of advanced fibrosis but only 13% were already diagnosed with NAFLD. Since ¾ had available data, these scores could be a practical first step for DM patients in PC.

### PO-565

#### A prospective cohort study for the prevalence and screening policy of NAFLD in patients with T2DM in primary care

Roberta Forlano<sup>1</sup>, Benjamin H. Mullish<sup>1</sup>, Michael Yee<sup>2</sup>, Robert D. Goldin<sup>3</sup>, Mark Thursz<sup>1</sup>, Pinelopi Manousou<sup>1</sup>. <sup>1</sup>Imperial College London, Department of Metabolism, Digestion and Reproduction, Northern Ireland; <sup>2</sup>Imperial college NHS Trust, Department of Endocrinology, London; <sup>3</sup>Imperial College London, Department of Cellular Pathology, London, Northern Ireland  
Email: r.forlano@imperial.ac.uk

**Background and aims:** Non-alcoholic fatty liver disease (NAFLD) is associated with Type-2 diabetes mellitus (T2DM), with diabetics being at higher risk for adverse outcomes. The aim of this study was to establish prevalence and develop a screening pathway for NAFLD referral/management.

**Method:** Consecutive patients with T2DM, between 18 and 69 years, were enrolled from North-West London Community Care. Patients were screened for liver disease by bloods (including NAFLD fibrosis score and FIB-4), ultrasound (US) and fasting liver stiffness measurement (LSM) and CAP.

**Results:** Of 300 patients enrolled, 287 were included; 13 withdrew. Overall, 184 (73%) had NAFLD, 28 (10%) other causes of liver disease (BAFLD and HBV) and 75 (26%) no liver disease. Those with NAFLD had larger waist (p = 0.0001) and hip (p = 0.0001) circumferences and higher BMI (p = 0.0001) compared to those without NAFLD. They also had higher ALT (p = 0.0001), AST (p = 0.0001), GGT (p = 0.0001) and HbA1c (p = 0.0001).

Among those with NAFLD, 50/183 (28%) and 50/287 (17%) of total had increased LSM (>8.1 kPa). Those with increased LSM had larger waist (p = 0.0001) and hip (p = 0.0001) circumferences and higher BMI (p = 0.0001) compared to those with normal LSM (n = 134). Those with increased LSM also presented higher ALT (p = 0.001), AST (p = 0.0001), GGT (p = 0.0001) and HbA1c (p = 0.0001). Multivariately, waist circumference (OR 1.089, p = 0.006), BMI (OR 1.24, p = 0.005) and AST (OR 1.092, p = 0.0001) were independent predictors of increased LSM. A variable was derived by logistic regression: 0.086\*

Table 1: (abstract: PO-454): Characteristics of primary care diabetes patients by risk of advanced fibrosis

	Low risk n = 498	Intermediate risk n = 346	High risk n = 510	p value
Age [mean (SD)]	75 (6.3)	75 (7.9)	79 (8)	<0.001
Gender (% female)	60.4%	52.9%	48.2%	<0.001
Race/Ethnicity				0.83
White or Caucasian	136 (28.0%)	98 (29.1%)	139 (27.5%)	
Black or African American	54 (11.1%)	44 (13.1%)	60 (11.9%)	
Hispanic or Latino	67 (13.8%)	40 (11.9%)	59 (11.7%)	
Asian	184 (37.9%)	126 (37.4%)	211 (41.7%)	
BMI categories				0.046
Normal	100 (20.1%)	60 (17.3%)	106 (20.8%)	
Overweight	132 (26.5%)	84 (24.3%)	151 (29.6%)	
Obese	261 (52.4%)	192 (55.5%)	249 (48.8%)	
HbA1C % [mean (SD)]	7.11 (1.3)	7.13 (1.5)	7.0 (1.3)	0.50
NASH/NAFLD ICD coding	53 (10.6%)	41 (11.8%)	67 (13.1%)	0.47
AST U/L [mean (SD)]	22 (6)	24 (7)	28 (10)	<0.001
ALT U/L [mean (SD)]	22 (7)	23 (8)	27 (10)	<0.001
Platelet x10 <sup>9</sup> /L [mean (SD)]	278 (61)	227 (44)	185 (44)	<0.001
Albumin g/dL [mean (SD)]	4.02 (0.3)	3.95 (0.4)	3.87 (0.3)	<0.001
Liver biopsy (ever)	1 (0.2%)	2 (0.6%)	5 (1.0%)	0.27
FIB-4 [mean (SD)]	1.37 (0.3)	1.86 (0.4)	3.25 (2.0)	<0.001
NFS [mean (SD)]	-0.47 (0.9)	0.62 (0.8)	1.68 (0.8)	<0.001

(Waist circumference, cm) + 0,08\* (BMI, kg/m2) + 0,025\* (AST, IU/L) - 14,607.

In the whole population, the derived variable predicted the presence of increased LSM with an AUROC of 0.868 (p = 0.0001, cut-off 0.19, PPV 90%, NPV 96%). AUROCs for predicting the presence of increased LSM were 0.81 (p = 0.0001, cut-off 0.057, PPV 79%, NPV 97%) for US plus LFTs (AST, ALT plus GGT), 0.75 (p = 0.0001, cut-off 1.07, PPV 56%, NPV 98%) for LFTs alone, 0.73 (p = 0.0001, cut-off 1, PPV 45%, NPV 90%) for US alone, 0.72 (p = 0.0001, cut-off -1.4, PPV 46%, NPV 85%) for NFS and 0.61 (p = 0.013, cut-off 1.00, NPV 32%, PPV 84%) for FIB-4 (Figure 1).

Figure:

**Conclusion:** In patients with diabetes in the community, 73% had NAFLD and 17% significant fibrosis. BMI, AST and waist circumference combined, could identify those at higher risk for significant fibrosis better than current non-invasive markers. This model may be used to shape a referral management pathway in this population.

**PO-569**

**Long term prognosis of patients with alcoholic disease or nafld according to metabolic syndrome or alcohol use**

Marie Decraecker<sup>1</sup>, Dan Dutartre<sup>2</sup>, HIRIART Jean-Baptiste<sup>1</sup>, Marie Irlès-Depe<sup>1</sup>, Marraud Des Grottes<sup>1</sup>, Faiza Chermak<sup>1</sup>, Juliette Foucher<sup>1</sup>, Adele Delamarre<sup>3</sup>, Victor de Lédinghen<sup>1,4</sup>. <sup>1</sup>Chu Haut Leveque, Pessac, France; <sup>2</sup>University of Bordeaux-Talence Campus, Talence, France; <sup>3</sup>Avenue du Haut Lévêque, Pessac, France; <sup>4</sup>CHU Bordeaux, Service d'Hépatologie, Bordeaux, France  
Email: marie.decraecker@gmail.com

**Background and aims:** The boundary between non-alcoholic (NAFLD) and alcoholic fatty liver disease (AFLD) is based on alcohol consumption. However, metabolic syndrome and alcohol use frequently co-exist. The aim of this study was to determine prognostic factors of long-term mortality and morbidity in patients with chronic alcoholic and/or metabolic fatty liver disease.

**Method:** From 2003 to 2016, all consecutive NAFLD or AFLD patients with valid liver stiffness measurement (FibroScan®) were prospectively included in a cohort study and followed until December 2017. We evaluated overall survival, specific cause of mortality (hepatic, cardiovascular or neoplastic) and occurrence of any complication (hepatic, cardiovascular or cancer). The occurrence of mortality was analysed by the Kaplan-Meier method. The risk of morbidity was estimated by logistic regression. Factors independently associated with mortality and morbidity were identified by a multivariate Cox model. The prognostic performance of liver stiffness for mortality prediction was evaluated by Harrell's C-index; and morbidity prediction by AUC.

**Results:** A total of 3,365 patients (1,667 AFLD and 1,698 NAFLD) were included: median age 56 years, men 63%, BMI 28 kg/m2, metabolic syndrome 43%, abdominal obesity 61%, type II diabetes 30%, HBP 45%. Median follow-up was 54 months [30 – 86] and 563 subjects died.

*In overall population*, overall and cause-specific mortality were higher in patients with AFLD (p < 0.0001) and with weekly alcohol consumption >7 units (p < 0.0001). Liver stiffness was an independent predictor of morbimortality (global and specific, p < 0.001). A model combining liver stiffness and clinical parameters had the best performance in predicting overall mortality (C-index 0.81).

*In NAFLD group*, weekly alcohol consumption >1 unit was associated with higher overall (p = 0.025) and cardiovascular (p = 0.028) mortality and weekly alcohol consumption >7 units was associated with higher overall (p < 0.001) and cardiovascular (p = 0.021) morbidity.

*In AFLD group*, the presence of metabolic syndrome was associated with higher overall (p = 0.029), liver (p < 0.001) and cardiovascular (p = 0.033) mortality and overall (p < 0.001), hepatic (p = 0.031), cardiovascular (p = 0.028) morbidity.

**Conclusion:** In NAFLD, light alcohol consumption is associated with mortality and morbidity and abstinence should be recommended. In AFLD, metabolic syndrome is associated with mortality and morbidity and should be managed.

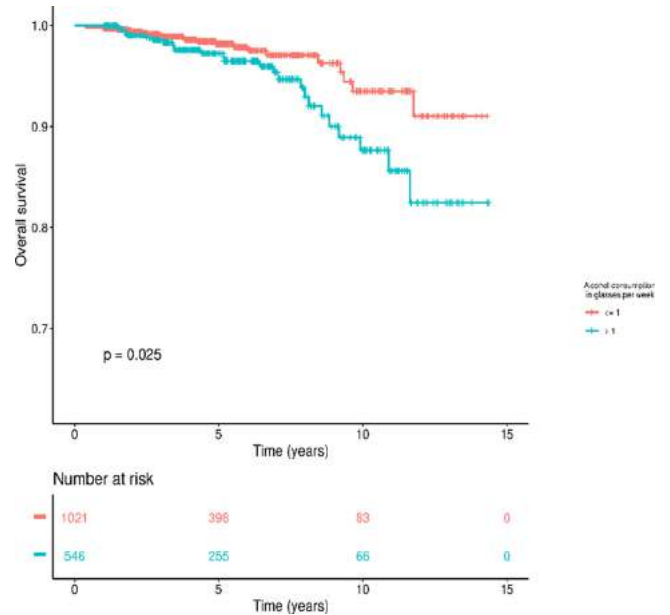

Figure: Mortality in non-alcoholic fatty liver disease patients according to alcohol use.

Overall survival with a threshold of 1 unit/week.

**PO-580**

**Modeling regional variation in the return on investment of VCTE for fatty liver disease (FLD) in the U.S.**

Mazen Nouredin<sup>1</sup>, Andrew Mackenzie<sup>2</sup>, Elaine Zhao<sup>2</sup>, Scott Howell<sup>3</sup>, Michael Tunkelrott<sup>4</sup>, Ian Duncan<sup>2</sup>. <sup>1</sup>Cedars-Sinai Medical Center, Fatty Liver Program, Los Angeles; <sup>2</sup>Santa Barbara Actuaries, Santa Barbara; <sup>3</sup>AIDS Healthcare Foundation, Los Angeles; <sup>4</sup>Echosens North America, Waltham, United States  
Email: mazen.nouredin@cshs.org

**Background and aims:** FLD is the most common cause of chronic liver disease. Despite high prevalence, FLD remains underdiagnosed, with complex and wasteful diagnostic pathways. This study explores U.S. regional variations for potential cost savings of deploying VCTE in a general population.

## POSTER PRESENTATIONS

**Method:** Our model leveraged administrative claims data of 5 million commercial members in 2015–2017 from IBM's MarketScan dataset and 3 million Medicare members in CMS' Limited Data Set from 2012 to 2016, informing baseline statistics on disease prevalence, healthcare cost and utilization associated with each stage of liver disease (i.e., simple fatty liver, steatohepatitis, fibrosis, cirrhosis, end stage liver disease and liver cancer). All statistics and calculations were performed by U.S. census regions. A multi-state model was developed to represent disease transition probabilities. With limited U.S. deployment of VCTE by 2016, we consulted expert clinical opinion and literature to inform other assumptions. Longitudinal results were modelled for up to 5 years.

**Results:** In one scenario, a Medicare payer with 100,000 members deploying VCTE devices to primary care may expect 4-year discounted cumulative net savings (subtracting device rental at \$2,800/month) as follows: \$11.8 million in the Midwest; \$10.2 million in the South; \$7.5 million in the West; and \$7.4 million in the Northeast region. These correspond to a Return on Investment (ROI) ranging from 2.0:1 to 3.2:1 over 4 years. Repeating in a commercial population resulted in the following: \$9.3 million in the South; \$7.2 million in the Midwest; \$6.6 million in the West region; and \$4.0 million in the Northeast. These correspond to ROIs ranging from 1.1:1 to 2.6:1 over 4 years.

Savings are created in two ways: (1) VCTE tests result in early identification of patients with FLD (as majority are currently undiagnosed) allowing for proactive intervention and behavior change to slow disease progression. (2) VCTE tests can reduce the aggregate volume of some current diagnosis methods such as liver biopsy or advanced imaging.

**Conclusion:** Scenario testing demonstrated net savings within 2 years across most scenarios and regions. We conclude that broad deployment of VCTE devices is a financially advantageous solution to address the FLD epidemic, with the South and Midwest regions standing to benefit the most, likely due to a combination of the higher prevalence rates of FLD and relevant comorbidities as well as medical utilization and costs.

### PO-632

#### Prevalence of hepatic steatosis and advanced fibrosis in patients living with HIV in Germany

Maurice Michel<sup>1</sup>, Alica Wahl<sup>1</sup>, Malena Andres<sup>1</sup>, Peter Galle<sup>1</sup>, Marcus-Alexander Wörns<sup>1</sup>, Martin Sprinzl<sup>1</sup>, Jörn M. Schattenberg<sup>1</sup>.

<sup>1</sup>Metabolic Liver Disease Research Programm, I. Department of Medicine, University Medical Centre Mainz, Mainz, Germany

Email: schatten@uni-mainz.de

**Background and aims:** The prevalence of advanced liver disease and hepatic steatosis in patients living with HIV is poorly defined. An independent risk of HIV infection or antiretroviral therapy (ART) has been proposed. The current analysis explored hepatic steatosis and fibrosis stages defined by transient elastography in patients living with HIV.

**Method:** In this cross-sectional study, 280 patients with an HIV mono-infection were prospectively enrolled and liver steatosis as well as liver fibrosis were measured with transient elastography (TE). Based on controlled attenuation parameter (CAP; db/m) and liver stiffness measurement (LSM; kPa), patients were analyzed according to the presence of steatosis (>280 db/m) or relevant fibrosis (>8.2 kPa). Independent predictors of liver steatosis and fibrosis were identified using linear regression models. To identify patients with NASH and at least F2 fibrosis, the FAST-score was calculated.

**Results:** In this cohort of 280 patients with HIV mono-infection on ART, the prevalence of liver steatosis was 34.3% (n = 96) and the prevalence of relevant liver fibrosis was 7.1% (n = 20). Among these patients, 28 (10%) exhibited severe steatosis (CAP > 337 db/m) and 13 (4.6%) had advanced fibrosis (E > 9.7 kPa). The FAST-score (cutoff > 0.35) identified 32 (12, 4%) patients. Multivariable regression analysis revealed ALT and waist-circumference (cm) as independent risk

factors for higher degree steatosis and fibrosis, respectively. In general, factors associated with the metabolic syndrome were more common in patients with relevant steatosis and fibrosis. Patients with liver fibrosis showed a longer disease duration in comparison to those with no fibrosis (22 years vs 10 years, p < 0.05).

**Conclusion:** Hepatic steatosis is highly prevalent among patients living with HIV and compared to epidemiological studies patients with steatosis and relevant fibrosis were younger. This study identified modifiable and preventable risk factors. Addressing these factors by education may support metabolic health in patients living with HIV.

**Funding:** This analysis was in parts supported by a research grant from Gilead Sciences.

**Background and aims:** Non-invasive assessment of fibrosis and steatosis is used to rule in/out advanced liver disease. Vibration controlled transient elastography (VCTE) with liver stiffness measurement (LSM) and controlled attenuation parameter (CAP) has become a reference standard. A VCTE-based score (FAST-score) was recently introduced to identify patients with non-alcoholic fatty liver disease (NAFLD) at risk for steatohepatitis (NASH). VCTE probe choice (M or XL) can be made either by the user's own measure of skin-to-liver-capsule distance (SCD) or based on an automated probe selection tool (auto-PS). Consider three scenarios: (i) The "M-first clinic" always uses the auto-PS from the M probe to choose either to retain the M probe or switch to the XL probe. (ii) The "XL-first clinic" always uses auto-PS from the XL probe. (iii) A "reference clinic" uses SCD for probe selection. This study aimed to compare the results from these three scenarios.

**Method:** VCTE (FibroScan 530) was performed prospectively in patients with chronic liver disease with the M and XL probes. The SCD at the measurement site was determined using a linear ultrasound probe. SCD ≥ 25 mm defined the need for the XL probe. Auto-PS from the M and XL probes was compared with Fleiss' kappa and discrepancies in LSM and CAP (>5% difference to the reference) using McNemar's test. FAST-score categories in NAFLD patients were compared between the three clinics.

**Results:** 200 patients with NAFLD (42%) and other liver diseases were included (58% female, 56 years old, BMI 28.1 kg/m<sup>2</sup>). Fleiss' kappa for agreement in auto-PS between the M and XL probes was 0.11 (95% CI -0.09 to 0.31), but accuracy was 0.855 (95% CI 0.800 to 0.897) for the M probe and 0.825 (95% CI 0.766 to 0.871) for the XL probe. Probe failure occurred for 16 (M-first clinic), 4 (XL-first clinic) and 3 patients (reference clinic). Use of XL probe in case of M probe failure improved performance of the M-first approach. The odds ratio for a discrepancy in the XL-first vs the M-first clinic is 2.4 (95% CI 1.2 to 5.2, p = 0.012) for LSM and 4.8 (95% CI 1.8 to 16.1, p < 0.001) for CAP. FAST-score was misclassified in one (1%) NAFLD patient in the M-first clinic and there were seven probe failures (8%) compared to four (5%) misclassifications in the XL-first clinic with no probe failures.

**Conclusion:** Agreement in automated probe selection between the M and XL probes is poor although each has fairly good accuracy. The M-first approach leads to fewer discrepancies than the XL-first strategy. Initial probe choice is crucial to obtain reliable and comparable VCTE results using auto-PS although it had little impact on FAST-score

Figure: (abstract: PO-751): Discrepancies for CAP and LSM according to probe choice strategy. Dashed line indicates upper limit of normal values.

categories in our data. The M-first approach should be adopted as standard, especially for multicenter studies where data comparability is an important prerequisite.

**Combination treatments including semaglutide, cilofexor, and/or firsocostat lead to greater improvements in the FibroScan-AST (FAST) score compared to semaglutide alone in patients with non-alcoholic steatohepatitis**

Naim Alkhour<sup>1</sup>, Robert Herring, Jr.<sup>2</sup>, Zeid Kayali<sup>3</sup>, Tarek Hassanein<sup>4</sup>, Anita Kohli<sup>1</sup>, Lars Damgaard<sup>5</sup>, Kristine Buchholtz<sup>5</sup>, Mette Kjaer<sup>5</sup>, Clare Balendran<sup>5</sup>, Yanni Zhu<sup>6</sup>, Andrew Billin<sup>6</sup>, Ryan Huss<sup>6</sup>, Robert Myers<sup>6</sup>, Rohit Loomba<sup>7</sup>, Mazen Noureddin<sup>8</sup>. <sup>1</sup>Arizona Liver Health, Chandler, AZ, United States; <sup>2</sup>Quality Medical Research, Nashville, TN, United States; <sup>3</sup>Jubilee Clinical Research, Las Vegas, NV, United States; <sup>4</sup>Southern California Research Center, Coronado, CA, United States; <sup>5</sup>Novo Nordisk A/S, Bagsvaerd, Denmark; <sup>6</sup>Gilead Sciences, Inc., Foster City, CA, United States; <sup>7</sup>University of California at San Diego, La Jolla, CA, United States; <sup>8</sup>Cedars-Sinai Medical Center, Los Angeles, CA, United States  
Email: ryan.huss@gilead.com

**Background and aims:** The FAST score is a non-invasive tool that includes liver stiffness (LS) and controlled attenuation parameter (CAP) by transient elastography (TE; FibroScan) and serum AST. FAST can identify non-alcoholic steatohepatitis (NASH) patients at risk of progressive disease, and changes in FAST are associated with histologic response. Our aims were to evaluate the effects of the glucagon-like peptide-1 receptor agonist semaglutide (sema), alone or in combination with the farnesoid X receptor agonist cilofexor (CILO) and/or the acetyl-CoA carboxylase inhibitor firsocostat (FIR) on FAST, and to evaluate associations between changes in FAST with other parameters.

**Method:** NASH patients (n = 108) with mild to moderate fibrosis (F2-F3 on biopsy, or MRI-PDFF ≥ 10% and LS by TE ≥ 7 kPa) were randomized to sema (n = 21), sema+CILO 30 mg (n = 22), sema+CILO 100 mg (n = 22), sema+FIR 20 mg (n = 22), or sema+CILO 30 mg+FIR 20 mg (n = 21) for 24 weeks (W24). Semaglutide was dose escalated to 2.4 mg weekly in all groups. Exploratory end points included changes in liver biochemistry, LS by TE and MRE, and hepatic steatosis by CAP and MRI-PDFF, and Enhanced Liver Fibrosis score (ELF). Patients were categorized according to FAST at baseline (BL) and W24 (rule-out zone: ≤0.35; grey zone: >0.35- <0.67; rule-in zone: ≥0.67).

In patients with BL and W24 FAST, changes in FAST were compared between groups (analysis of covariance, Wilcoxon rank sum and Fisher's exact tests) and Spearman correlations with other parameters were calculated.

**Results:** At BL, median (Q1, Q3) LS by TE, CAP and AST were 9.25 kPa (7.70, 12.00), 344 dB/m (319, 375), and 40 U/L (26, 57), respectively. Median BL FAST was 0.56 (0.40, 0.70) and similar across groups; 31% and 45% of patients were in the rule-in and grey zones, respectively. Compared to sema alone (LSmean change in FAST from BL to W24: -0.19), treatment with sema+CILO 30 mg (-0.32), sema+FIR (-0.37) and sema+CILO+FIR (-0.39) led to significant improvements in FAST (all p < 0.05). At W24, the proportion of patients with ≥1-zone improvement in FAST was greater with combinations (90-100%) vs sema alone (58%). Treatment with sema+CILO+FIR led to the highest proportion of subjects in the rule-out zone at W24 (94% vs 42% with sema; Figure). Across groups, changes from BL to W24 in FAST were correlated with changes in alanine aminotransferase (ρ = 0.67), gamma-glutamyl transpeptidase (ρ = 0.33), ELF (ρ = 0.30), CK18-M30 (ρ = 0.44), and glucose (ρ = 0.24; all p < 0.05), but not body weight, MRI-PDFF, LS by MRE, HbA1c, insulin, or HOMA-IR.

\*Patients with Baseline and Week 24 FAST included in analysis. BL, baseline; CILO, cilofexor; FAST, FibroScan-aspartate aminotransferase; FIR, firsocostat; SEMA, semaglutide; W24, week 24.

Figure: FAST by Zone at Baseline and Week 24

**Conclusion:** In patients with mild to moderate fibrosis due to NASH, treatment with CILO and/or FIR in addition to sema, leads to greater improvements in FAST score. Changes in FAST are correlated with

## POSTER PRESENTATIONS

changes in other biomarkers, suggesting potential utility as an end point in NASH clinical trials.

Zheng<sup>4</sup>, Yi Jin<sup>5</sup>, Giovanni Targher<sup>6</sup>, Chris Byrne<sup>7</sup>, Zhihan Yan<sup>3</sup>, Xiaoling Chi<sup>2</sup>, Ming-Hua Zheng<sup>4,8,9</sup>. <sup>1</sup>the First Affiliated Hospital of Wenzhou Medical University, Department of Radiology, Wenzhou, China; <sup>2</sup>Guangdong Provincial Hospital of Chinese Medicine, the Second Affiliated Hospital of Guangzhou University of Chinese Medicine, Department of Hepatology, Guangzhou, China; <sup>3</sup>the Second Affiliated Hospital and Yuying Children's Hospital of Wenzhou Medical University, Department of Radiology, Wenzhou, China; <sup>4</sup>the First Affiliated Hospital of Wenzhou Medical University, NAFLD Research Center, Department of Hepatology, Wenzhou, China; <sup>5</sup>the First Affiliated Hospital of Wenzhou Medical University, Department of Pathology, Wenzhou, China; <sup>6</sup>University and Azienda Ospedaliera Universitaria Integrata of Verona, Section of Endocrinology, Diabetes and Metabolism, Department of Medicine, Verona, Italy; <sup>7</sup>Southampton National Institute for Health Research Biomedical Research Centre, University Hospital Southampton, Southampton General Hospital, Southampton, United Kingdom; <sup>8</sup>Wenzhou Medical University, Institute of Hepatology, Wenzhou, China; <sup>9</sup>Key Laboratory of Diagnosis and Treatment for The Development of Chronic Liver Disease in Zhejiang Province, Wenzhou, China

Email: zhengmh@wmu.edu.cn

**Background and aims:** Currently, there is no effective method for assessing hepatic inflammation without resorting to histological examination of liver tissue obtained by biopsy. T2 weighted images (T2WI) are routinely obtained from liver magnetic resonance imaging (MRI) scan sequences. We aimed at establishing a radiomics signature based on T2WI for assessment of hepatic inflammation in people with non-alcoholic fatty liver disease (NAFLD).

**Method:** A total of 203 individuals with biopsy-confirmed NAFLD from two independent Chinese cohorts with liver MRI examination were enrolled in this study. The hepatic inflammatory activity score was calculated by the unweighted sum of the histologic scores for lobular inflammation and ballooning. 1032 radiomics features were extracted from the localized region of interest on the right liver lobe of T2WI and, subsequently, selected by minimum redundancy maximum relevance and least absolute shrinkage and selection operator (LASSO) methods. The T2-radiomics signature (T2-RS) was calculated by summing the selected features weighted by their coefficients.

**Results:** 18 radiomics features from Laplacian of Gaussian, wavelet, and original images were selected for establishing T2-RS. The T2-RS value differed significantly between groups with increasing degrees of hepatic inflammation ( $p < 0.01$ ). The T2-RS yielded an area under the ROC curve (AUROC) of 0.80 (95% confidence intervals 0.71–0.89) for predicting hepatic inflammation in the training cohort with excellent calibration. The AUROCs of T2-RS in the internal cohort and external validation cohorts were 0.77 (0.61–0.93) and 0.75 (0.63–0.84), respectively (Table 1).

Table 1: Operating characteristics of T2-RS for discriminating hepatic inflammatory activity in NAFLD

	Training Set (n = 91)	Internal Validation Set (n = 38)	External Validation Set (n = 74)
AUC (95% CI)	0.80 (0.71–0.89)	0.77 (0.61–0.93)	0.75 (0.63–0.84)
Sensitivity, % (n/N)	76.19 (32/42)	70.59 (12/17)	71.43 (40/56)
Specificity, % (n/N)	73.47 (36/49)	76.19 (16/21)	72.22 (13/18)
Accuracy, % (n/N)	74.73 (68/91)	73.68 (28/38)	71.62 (53/74)
PPV, % (n/N)	71.11 (32/45)	70.59 (12/17)	88.89 (40/45)
NPV, % (n/N)	78.26 (36/46)	76.19 (16/21)	44.83 (13/29)
LR+	2.87	2.96	2.57
LR-	0.32	0.38	0.40
Diagnostic odds ratio	8.97	7.79	6.43

Note: T2-RS, radiomics signature based on T2WI.

Abbreviations: NAFLD, non-alcoholic fatty liver disease; AUC, area under the receiver operating characteristic curve; CI, confidence interval; PPV, positive predictive value; NPV, negative predict value; LR+, positive likelihood ratio; LR-, negative likelihood ratio.

**Conclusion:** T2-RS derived from radiomics analysis of T2WI shows promising utility for predicting hepatic inflammation in people with NAFLD.

### PO-775

#### The effectiveness of a community based two-tier risk stratification pathway for non-alcoholic fatty liver disease

Rebecca Harris<sup>1,2</sup>, David Harman<sup>3</sup>, Timothy Card<sup>1,4</sup>, Guruprasad Aithal<sup>1,2</sup>, Neil Guha<sup>1,2</sup>, Joanne Morling<sup>1,4</sup>. <sup>1</sup>NIHR Nottingham Biomedical Research Centre (BRC), Nottingham University Hospitals NHS Trust and the University of Nottingham, Nottingham, United Kingdom; <sup>2</sup>Nottingham Digestive Diseases centre, School of Medicine, University of Nottingham, Nottingham, United Kingdom; <sup>3</sup>Royal Berkshire NHS Foundation Trust, Reading, United Kingdom; <sup>4</sup>Division of Epidemiology and Public Health, School of Medicine, University of Nottingham, Nottingham, United Kingdom

Email: rebecca.harris@nottingham.ac.uk

**Background and aims:** Developing community-based strategies which identify patients at risk of cirrhosis secondary to non-alcoholic fatty liver disease (NAFLD) is imperative to reduce associated complications. Yet, this poses a significant challenge due to the large number of people exposed to the risk within the general population. A two-tier risk stratification pathway using inexpensive clinical algorithms initially, could be a valuable strategy to reduce the referral rate for more specialist tests of liver fibrosis. We aimed to determine the effectiveness of this strategy.

**Method:** A two-tier risk stratification pathway was applied to a prospective community cohort who had risk factors for NAFLD and stratified using transient elastography (TE) and the Enhanced liver fibrosis test (ELF). Validated cut offs from the literature, specific to TE and ELF, were used to define patients with significant liver fibrosis. Five clinical algorithms including Fibrosis-4 (Fib4), BARD score (BARD), NAFLD fibrosis score (NFS), AST:ALT ratio and AST to platelet ratio index (APRI) were applied as first line tests to evaluate the reduction in referral rate along with the misclassification rate.

**Results:** Of the 887 patients within the cohort, 21.2% had a reliable TE reading  $\geq 8$  kPa and 45.7% had an ELF score  $\geq 9.5$ , consistent with a classification of significant liver fibrosis. Application of the simple non-invasive tests would have resulted in a decrease in referrals (Fib4: 57.0–58.6%; BARD: 11.1–12.4%; NFS: 23.9–26.4%; AST:ALT ratio: 27.9–28.1%; APRI: 98.6–98.7%). However, a large proportion of patients with significant fibrosis would have been misclassified (Fib4: 42.1–51.8%; BARD: 7.2–9.2%; NFS: 13.9–15.0%; AST:ALT ratio: 22.2–34.7%; APRI: 95.7–97.3%). Increasing the sensitivity of these

clinical algorithms reduced the misclassification rate but resulted in the majority still requiring a second test.

Figure:

**Conclusion:** A two-tier risk stratification pathway utilising widely accessible clinical algorithms in the first instance would reduce the referral rate, but leads to a large proportion of patients with significant liver fibrosis being missed and inappropriately reassured.

**PO-836**

**Patients with elevated Fibrosis-4 Index or NAFLD Fibrosis Score have higher rates of cardiovascular events: a post-hoc analysis from two large, randomised statin clinical trials in 18 814 patients**

Frank Tacke<sup>1</sup>, Naim Alkhoury<sup>2</sup>, Mazen Nouredin<sup>3</sup>, David DeMicco<sup>4</sup>, Rana Fayyad<sup>4</sup>, Fady Taniou<sup>4</sup>. <sup>1</sup>Charité University Medicine Berlin, Department of Hepatology and Gastroenterology, Berlin, Germany; <sup>2</sup>Arizona Liver Health, Chandler, United States; <sup>3</sup>Karsh Division of Gastroenterology and Hepatology, Comprehensive Transplant Center, Cedars-Sinai Medical Center, Los Angeles, United States; <sup>4</sup>Pfizer Inc, New York, United States  
Email: fady.ntaniou@pfizer.com

**Background and aims:** Patients with non-alcoholic fatty liver disease (NAFLD) and non-alcoholic steatohepatitis (NASH) are at increased risk for cardiovascular (CV) diseases. Non-invasive scoring tools, Fibrosis-4 Index (FIB-4) and NAFLD Fibrosis Score (NFS), correlate with an elevated risk of NASH with fibrosis. This post-hoc analysis aimed to identify correlations between CV events and elevated FIB-4 or NFS.

**Method:** Baseline data were pooled from two large, prospective Phase 4 trials comparing high-dose with usual-dose statins for secondary prevention of CV events (IDEAL, NCT00159835 and TNT, NCT00327691). Patients with established coronary heart disease were enrolled. FIB-4 and NFS were calculated from baseline assessments. Associations between baseline FIB-4 and NFS were modelled using a Cox proportional hazards model with adjustments.

**Results:** Patient characteristics are shown in the Table. Those in FIB-4 high and intermediate score categories experienced more CV and mortality events vs the low score category for all events except any coronary event (Table). Results from NFS categories were consistent with those for FIB-4. Age increased with FIB-4 score and was a significant predictor of incidence of any major coronary, CV, myocardial infarction, and stroke event and death ( $p < 0.02$  for all).

Table: Characteristics and CV event risk by FIB-4 score category in pooled IDEAL and TNT population

	FIB-4 score		
	LOW <1.30 <b>n = 11659</b>	INTERMEDIATE 1.30–2.67 <b>n = 6800</b>	HIGH >2.67 <b>n = 355</b>
Baseline characteristics <sup>a</sup>			
Age (years), mean (SD)	58.2 (9)	66.3 (7)	69.1 (7)
Diabetes	1589 (14)	921 (14)	47 (13)
Hypertension	3009 (26)	2290 (34)	108 (30)
AST (IU/L), mean (SD)	18.3 (7)	21.3 (8)	31.2 (22)
ALT (IU/L), mean (SD)	24.2 (14)	21.2 (13)	23.4 (17)
CV event <sup>a,b</sup>			
Any CV event	3309 (28)	2154 (32)*	131 (37) <sup>†</sup>
Hazard ratio (95% confidence limit)	-	1.16 (1.10, 1.23)	1.40 (1.18, 1.67)
Any coronary event	2643 (23)	1606 (24) <sup>‡</sup>	92 (26)
Major coronary event	934 (8)	641 (9)*	39 (11) <sup>‡</sup>
Myocardial infarction	701 (6)	425 (6) <sup>‡</sup>	31 (9) <sup>‡</sup>
Stroke	314 (3)	260 (4)*	19 (5) <sup>‡</sup>
All-cause mortality	630 (5)	624 (9)*	43 (12)*

\* $p < 0.0001$ ; <sup>†</sup> $p < 0.001$ ; <sup>‡</sup> $p < 0.01$ ; <sup>§</sup> $p < 0.05$

<sup>a</sup>n (%) unless otherwise noted; <sup>b</sup>Reference group is FIB-4 < 1.30

ALT, alanine aminotransferase; AST, aspartate aminotransferase; CV, cardiovascular; FIB-4, Fibrosis-4 index; SD, standard deviation

**Conclusion:** Baseline high and intermediate score groups (defined by FIB-4 and NFS) had higher CV event rates vs the low score group. However, this association was not independent of the association with age.

**PO-866**

**Comparing traditional machine learning and deep learning models to Fibrosis-4 index in the prediction of non-alcoholic fatty liver disease-associated liver fibrosis**

Devon Y. Chang<sup>1,2</sup>, Naim Alkhoury<sup>3</sup>, Mazen Nouredin<sup>2</sup>. <sup>1</sup>Arnold O. Beckman High School, Irvine, United States; <sup>2</sup>Cedars Sinai Medical Center, Division of Gastroenterology and Hepatology, Comprehensive Transplant Center, Los Angeles, United States; <sup>3</sup>Arizona Liver Health, Chandler, United States  
Email: devonychang@gmail.com

**Background and aims:** Patients with non-alcoholic fatty liver disease (NAFLD) who develop liver fibrosis (LF) are at increased risk of liver-related complications and death. Identifying NAFLD patients with LF to allow early intervention is crucial. Even though machine learning (ML) has touched many aspects of human life, its application in diagnostic prediction of NAFLD is only in its infancy. We demonstrate that ML can be used as an effective tool to help predict clinically significant NAFLD-associated LF.

**Method:** We trained and tested ML models, including logistic regression (LR), random forests (RF), and artificial neural networks (ANN), to predict NAFLD-associated LF using data from the 2017–2018 National Health and Nutrition Examination Survey. A cohort of 2099 subjects without significant alcohol intake and with CAP (controlled attenuation parameter) scores  $\geq 274$  dB/m on Fibroscan<sup>®</sup> were selected. Clinically significant LF ( $\geq F2$ ) was defined as LSM (liver stiffness measurement)  $\geq 8.2$  kPa on Fibroscan. Ten variables with the highest absolute Pearson correlation coefficients to LSM were chosen to train the models. 80% of the cohort was used to train the models, and 20% was used for testing. The sensitivity (Sn), specificity (Sp), positive predictive value (PPV), negative predictive value (NPV), accuracy (Ac), and area under receiving operator characteristic curve (AUC) of the ML models for predicting LF in our cohort were compared to those of Fibrosis-4 index (FIB-4) using a threshold of  $\geq 1.45$  ( $\geq F2$ ).

**Results:** The performances of the models are shown in Table 1. LR and ANN had higher Sn than RF ( $p < 0.5$ ). Sp and Ac of RF were higher than

## POSTER PRESENTATIONS

LR and ANN ( $p < 0.5$ ). All ML models had higher Sn and AUC than FIB-4 ( $p < 0.5$ ). FIB-4 had higher Sp than all ML models ( $p < 0.5$ ).

Table 1:

	Sn (95% CI)	Sp (95% CI)	PPV (95% CI)	NPV (95% CI)	Ac (95% CI)	AUC (95% CI)
LR	0.61 (0.57–0.66)	0.70 (0.69–0.71)	0.28 (0.26–0.30)	0.90 (0.88–0.92)	0.69 (0.66–0.72)	0.69 (0.67–0.72)
RF	0.29 (0.25–0.33)	0.90 (0.89–0.91)	0.35 (0.30–0.40)	0.87 (0.85–0.89)	0.80 (0.78–0.82)	0.67 (0.64–0.69)
ANN	0.60 (0.51–0.69)	0.67 (0.64–0.70)	0.26 (0.23–0.29)	0.90 (0.87–0.93)	0.66 (0.64–0.68)	0.68 (0.66–0.71)
FIB-4	0.15	0.93	0.31	0.85	0.81	0.54

**Conclusion:** All ML models performed better than FIB-4 at predicting LF in our cohort. Among the ML models, LR and ANN were better than RF at identifying patients with LF. If trained on a larger cohort with more balanced datasets, ML could serve as an effective screening tool to help identify NAFLD patients with LF for population health management.

Email: director@cicbiogune.es

**Background and aims:** Non-alcoholic fatty liver disease (NAFLD) is a complex heterogeneous disease with impaired hepatic lipid metabolism reflecting nutritional and environmental factors acting on a susceptible genetic background. Here we examine CVD risk in an international cohort of 1099 individuals with biopsy-proven NAFLD. **Method:** We used LC-MS serum metabolomic subtyping and NMR lipoprotein profiling in 5 mouse models of NASH and fibrosis: (1) germline methionine adenosyltransferase 1a knockout (Mat1a-KO);

(2) C57BL/6 mice fed 0.1% methionine and choline deficient (0.1MCD) diet; (3) liver-specific microsomal triglyceride transfer protein KO (Mttp-LKO); (4) liver-specific transmembrane 6 superfamily member 2 KO (Tm6sf2-LKO); and (5) germline Ldlr-deficient (Ldlr-/-).Leiden) KO mice fed high fat diet (HFD). Murine serum metabolomes were compared to serum metabolomes of 1099 patients with biopsy-proven NAFLD. Lipoprotein profiles were determined in a subgroup of 233 NAFLD patients. VLDL-triglyceride (TG) secretion rate (SR) was measured in 20 obese individuals with high intrahepatic TG (IHTG), and in 10 lean subjects with normal IHTG and VLDL-TG SR.

**Results:** NAFLD patients were classified into three major subtypes (A, B, and C). Subtype A phenocopies the serum metabolome of four mice with impaired VLDL-TG secretion (Mat1a-KO, 0.1MCD, Mttp-LKO, Tm6sf2-LKO), while subtype C phenocopies the metabolome of Ldlr-/-Leiden/HFD mice. VLDL-TG secretion rate was lower in obese individuals with high IHTG and subtype A vs subjects with increased IHTG and subtypes B and C. Grades of steatosis/NASH or fibrosis were comparable among subtypes. The frequency of NAFLD subtypes was 44%, 25%, and 31% for A, B, and C, respectively. Serum VLDL-TG was independent of steatosis grade (S1-3) in subtype A, whereas subtypes B and C showed a curvilinear relationship in VLDL-TG and steatosis with a peak at grade S2. The same pattern was observed for each of the VLDL subclasses (VLDL<sub>1-5</sub>). Hepatic biosynthetic capacity (serum albumin) was similar for all three subtypes. Total serum TG, VLDL, small dense LDL<sub>5,6</sub> and remnant lipoprotein cholesterol, were lower among subtype A vs subtypes B and C, while the typical LDL-cholesterol-to-HDL-cholesterol ratio was similar.

**Conclusion:** Metabolomic signatures identify 3 NAFLD subgroups, independent of histological disease severity. These signatures align with known CVD risk factors that may account for the variation in hepatic vs cardiovascular outcomes and, if validated, offers novel, clinically relevant, risk stratification.

### PO-919

#### Comparative diagnostic accuracy of blood-based biomarkers for diagnosing NASH: phase 1 results of the LITMUS project

Email: y.vali@amc.uva.nl

**Background and aims:** The presence of active steatohepatitis (NASH) is a regulatory requirement for NAFLD trial recruitment and an important severity indicator in clinical care. There is a pressing need for robust, non-invasive tests (NITs) to discriminate simple steatosis from NASH, but most evaluations have been non-comparative and performed in small groups. The LITMUS project independently assessed NITs that, singly or in combination, would enable detection of NASH.

**Method:** Thirteen NITs, including single markers and combination panels, were evaluated against histology to identify NASH (NAS ≥ 4 with ≥1 point in each component). The area under the receiver operating curve (AUC) ± 95% confidence interval (95% CI) were calculated for each NIT. Due to the absence of any existing validated NIT for NASH and the high collinearity between NASH and fibrosis stage, performance of FIB-4, a widely used simple fibrosis test, was adopted as a comparator in the same subgroup of patients for whom biomarker results were available to aid interpretation.

**Results:** Data from 686 participants from nine European centers were included. Mean age 50 years; 57% male; 36% type2 diabetics; mean BMI 35. Histological evidence of NASH was present in 54%. AUCs ranged from 0.51 to 0.76, with some marker combinations showing higher AUCs than single markers (Table 1). The SomaScan™ algorithm showed the highest AUC (0.76) followed by MACK-3 (0.69).

Table 1: Diagnostic accuracy of markers in detecting active NASH vs. FIB-4

NIT	n	AUC (95% CI)	
		NIT	FIB-4
CK-18 (M30)	588	0.67 (0.62–0.71)	0.64 (0.59–0.68)
CK-18 (M65)	608	0.65 (0.60–0.69)	0.63 (0.59–0.68)
PRO-C3	431	0.64 (0.59–0.69)	0.64 (0.59–0.69)
P4NP7S	229	0.63 (0.56–0.70)	0.63 (0.55–0.70)
ADAPT	417	0.68 (0.63–0.73)	0.63 (0.58–0.69)
FIBC3	413	0.64 (0.59–0.69)	0.63 (0.58–0.69)
ABC3D	413	0.64 (0.58–0.69)	0.63 (0.58–0.69)
DIAFIR	242	0.67 (0.60–0.74)	0.63 (0.56–0.70)
MACK-3	391	0.69 (0.63–0.74)	0.61 (0.56–0.67)
GLP (fibrosis)	324	0.51 (0.45–0.57)	0.63 (0.57–0.69)
SomaScan	278	0.76 (0.71–0.82)	0.62 (0.55–0.69)
ELF	673	0.62 (0.58–0.66)	0.61 (0.57–0.66)
NFS	668	0.60 (0.56–0.64)	0.62 (0.58–0.66)

**Conclusion:** Fibrosis targeted biomarkers and single biomarkers (eg CK18) showed limited performance in detecting NASH. However, novel combinations produced more promising results. Among these, panels specifically developed to detect NASH, such as the SomaScan algorithm and MACK-3, significantly outperformed FIB-4 (P value <0.05). Validation in an expanded cohort is underway.

**PO-941**

**Independent validation of Agile 4: novel FibroScan based score for the diagnosis of cirrhosis in patients with non-alcoholic fatty liver disease**

Jerome Boursier<sup>1,2</sup>, Marine Roux<sup>2</sup>, Charlotte Costentin<sup>3</sup>, Adele Delamarre<sup>4</sup>, Clémence M. Canivet<sup>1,2</sup>, Nathalie Sturm<sup>5</sup>, Victor de Lédinghen<sup>4</sup>. <sup>1</sup>Angers University Hospital, Hepato-gastroenterology and Digestive Oncology Department, Angers, France; <sup>2</sup>Angers University, HIFIH UPRES EA3859 Laboratory, Angers, France; <sup>3</sup>Grenoble Alpes University Hospital, Hepatology, Gastroenterology and Digestive Oncology, Grenoble, France; <sup>4</sup>Haut Leveque Hospital,

Hepatology, Gastroenterology and Digestive Oncology, Pessac, France; <sup>5</sup>Grenoble Alpes University Hospital, Pathology Department, Grenoble, France  
Email: jeboursier@chu-angers.fr

**Background and aims:** Currently available non-invasive tests, including FIB-4 and liver stiffness measurement (LSM) by vibration-controlled transient elastography (VCTE-FibroScan), are highly effective in excluding cirrhosis yet their ability to rule in cirrhosis is moderate. Recently, Agile 4, a score combining LSM with routine clinical parameters (AST/ALT ratio, platelets count, age, sex, diabetes status) was proposed to identify cirrhosis in NAFLD patients with the aim to optimize positive predictive value (PPV) and reduce the number of cases with indeterminate results (1). The objective of the present work was to independently validate this score.

**Method:** This retrospective study included adults with NAFLD from three French tertiary care centers who underwent liver biopsy, LSM by VCTE, and blood sampling as part of routine clinical practice. Calibration was assessed with goodness of fit (calibration plot), and discrimination with the area under the receiver operating characteristic curve (AUROC) with comparison to LSM alone and FIB-4. Cut-off values for high sensitivity (Se) and high specificity (Sp) previously determined (1) were applied to this cohort in order to define rule-out, indeterminate and rule-in zones.

**Results:** The cohort comprised 1042 patients of which 13% had cirrhosis. Calibration plot for Agile 4 was close to the ideal calibration, which conveyed a satisfactory goodness of fit. The AUROC of Agile 4 was 0.89 and significantly different from that of FIB-4 (Table). 88% of the patients without cirrhosis had Agile 4 result below the rule out cut-off, which was higher compared to LSM and FIB-4 (respectively 54% and 79%). Using the high cut-off, Agile 4 provided better PPV (68%) compared to FIB4 and LSM (respectively 55% and 62%). Finally, using Agile 4, the number of patients in the indeterminate zone was respectively 4 and almost 2 times lower than with FIB-4 and LSM (Table).

	FIB-4	LSM	Agile 4
AUROC [95% CI]	0.81 [0.77;0.85]	0.88 [0.85;0.91]	0.89 [0.86;0.92]
Delong test p (vs Agile)	<0.0001	0.2363	NA
Rule out cut-off (≥85% Se)	<1.39	<12.1	<0.251
% patients	49%	72%	81%
Se/Sp	0.85/0.54	0.76/0.79	0.71/0.88
NPV	0.96	0.96	0.96
Indeterminate zone			
% patients	43%	19%	11%
Rule in cut-off (≥95% Sp)	≥3.25	≥23.2	≥0.565
% patients	8%	9%	8%
Se/Sp	0.35/0.96	0.44/0.96	0.44/0.97
PPV	0.55	0.62	0.68

**Conclusion:** This study externally and independently validates Agile 4 confirming previous results (1). It indeed improves the identification of cirrhotic patients and may reduce the need for liver biopsy for this diagnostic target. It also demonstrates its interest in the identification of patients to start hepatocellular carcinoma and esophageal varices screening.

## POSTER PRESENTATIONS

### PO-944

#### Prognostic value of FibroScan based Agile 3+ and Agile 4 scores in patients with non-alcoholic fatty liver disease

Jerome Boursier<sup>1,2</sup>, Clémence M. Canivet<sup>1,2</sup>, Marine Roux<sup>2</sup>, Lannes Adrien<sup>1,2</sup>, Isabelle Fouchar<sup>1,2</sup>, Frédéric Oberti<sup>1,2</sup>. <sup>1</sup>Angers University Hospital, Hepato-gastroenterology and Digestive Oncology Department, Angers, France; <sup>2</sup>Angers University, HIFIH UPRES EA3859 Laboratory, Angers, France  
Email: jeboursier@chu-angers.fr

**Background and aims:** Recently, Agile 4 and Agile 3+, two scores combining liver stiffness measurement (LSM) by vibration-controlled transient elastography (VCTE) with routine clinical parameters were proposed to diagnose cirrhosis and advanced fibrosis in NAFLD patients, respectively (1). The objective of the present work was to assess the prognostic accuracy of Agile 4 and Agile 3+ for the prediction of liver-related events (LRE) and to compare them to LSM alone.

**Method:** This retrospective study included adults with NAFLD from a French tertiary care center who underwent LSM and blood sampling as part of routine clinical practice. The main study outcome was LRE, a composite end point combining cirrhosis complication or hepatocellular carcinoma. LRE were ascertained by chart review. Cut-off values of Agile 4 and Agile 3+ previously determined (1) and Baveno cut-off values for LSM (10 kPa–15 kPa) were used to define the rule-out, indeterminate and rule-in zones at baseline. Kaplan-Meier curves were compared using the Log-rank test.

**Results:** 341 NAFLD patients were included in the study (median age: 58 years, male sex: 65%, diabetes: 36%). LRE occurred in 27 (7.9%) patients after a median follow-up of 5.2 years (1<sup>st</sup> and 3<sup>rd</sup> quartiles: 2.9–7.2). The rate of patients included in the rule-out/indeterminate/rule-in zones of the Agile 3+ and Agile 4 were respectively 56%/15%/29% and 83%/9%/8%. Kaplan-Meier curves (Figure) for Agile 4 and Agile 3+ showed significant differences between the rule-out and the rule-in zones ( $p < 0.001$  for both) and between indeterminate and rule-in zones ( $p \leq 0.002$  for both), while the difference between indeterminate and rule-out zones was not significant. By comparison, the rates of patients included in the rule-out/indeterminate/rule-in zones with LSM were 57%/23%/20%. Using LSM, patients experiencing a LRE were initially either in the indeterminate or the rule-in zones and consequently, a significant difference ( $p < 0.001$ ) between the rule-out and the indeterminate zone was observed while the difference between the indeterminate and rule-in was less significant ( $p = 0.03$ ).

**Conclusion:** Agile 4 and Agile 3+ well predict the occurrence of liver-related events in patients with NAFLD. Particularly, rule-in cut-offs of both scores better identify at-risk patients than LSM alone. These results demonstrate the interest of those scores in the identification of patients requiring hepatocellular carcinoma and esophageal varices screening. 1. Younossi, ZM et al. AASLD 2020 LP12.

#### Incidence rates of hepatobiliary outcomes among patients with non-alcoholic steatohepatitis based on fibrosis-4 score severity at baseline

Lina Titievsky<sup>1</sup>, Aziza Jamal-Allial<sup>2</sup>, Kerrin Gallagher<sup>2</sup>, Thomas Capozza<sup>1</sup>, Stephen Dodge<sup>1</sup>, Simo Du<sup>2</sup>, Amy Law<sup>1</sup>, Macky Natha<sup>1</sup>, Erik Ness<sup>1</sup>, Mindie Nguyen<sup>3</sup>, Yuval Patel<sup>4</sup>, Amarita Randhawa<sup>1</sup>, Daina Esposito<sup>2,5,6</sup>. <sup>1</sup>Intercept Pharmaceuticals, Inc., New York, United States; <sup>2</sup>HealthCore, Inc., Watertown, United States; <sup>3</sup>Stanford University, Redwood City, United States; <sup>4</sup>Duke University, Durham, United States; <sup>5</sup>Boston University School of Public Health, Boston, United States; <sup>6</sup>Ciconia, Inc., United States  
Email: lina.titievsky@interceptpharma.com

**Background and aims:** Non-alcoholic steatohepatitis (NASH) is a chronic inflammatory condition that can generate fibrosis over time, resulting in liver dysfunction and poor outcomes. The fibrosis-4 (FIB-4) index score is a simple, accessible non-invasive test of liver fibrosis

based on laboratory data that is used as an alternative to biopsy to categorize degree of fibrosis and associated risk. This study estimated incidence rates of hepatobiliary outcomes among NASH patients stratified by FIB-4 defined fibrosis severity.

**Method:** The HealthCore Integrated Research Database was used to identify NASH patients from October 01, 2015, to March 31, 2020. The NASH algorithm required either (1) NASH as the principal discharge diagnosis on an inpatient claim, (2) liver biopsy followed by NASH diagnosis, or (3) liver imaging followed by NASH diagnosis, liver function procedure, and  $\geq 1$  risk factor (obesity, type 2 diabetes, pre-diabetes, or dyslipidemia). Patients with concurrent liver disease or a history of liver transplant were excluded. All patients had  $\geq 12$  months of baseline continuous health plan enrolment. All patients with sufficient lab data to determine the FIB-4 score were categorized as no/early fibrosis (NF), indeterminate (INF), or advanced fibrosis (AF), using published thresholds. Incidence rates (IR) and 95% confidence intervals were calculated as the number of outcomes of interest in the follow-up period divided by the total person-time at risk and expressed per 1,000 Person Years (PY).

**Results:** Baseline FIB-4 was estimated for a total of 7,937 NASH patients (~40% of the final NASH cohort): 55.6% NF, 28.2% INF, and 16.2% AF. The presence of hepatic comorbidities at baseline was greatest among AF, followed by INF and NF (e.g., baseline cirrhosis was 63.1%, 17.1%, and 4.6%, respectively). AF patients were older (28%  $\geq 65$  years vs. 18% and 8%) and more likely to have type 2 diabetes (69% vs. 54% and 38%) and hypertension (89% vs. 82% and 67%) than INF and NF, respectively. The IR (Figure) of new events followed an expected pattern with increasing fibrosis severity where the lowest rates were seen among the NF followed by INF and AF (e.g., the cholelithiasis IR increased from 9.4 to 13.0 and 45.8).

Figure:

**Conclusion:** AF per FIB-4 assessment corresponds to a higher burden of hepatic comorbidities at baseline and a higher IR of new outcomes during the follow-up period. These findings further support to the utility of FIB-4 as a prognostic indicator in NASH patients.

**PO-1001**

**External Validation of the FAST Score as a Predictor of Fibrotic NASH in a Large Cohort of U.S. Adults with Biopsy-Proven NAFLD**

Prido Polanco<sup>1,2</sup>, Phuc Le<sup>3</sup>, Rashmee Patil<sup>4</sup>, Mario Dgyves<sup>1</sup>, Nikhil Kahlon<sup>1</sup>, Pranay Garg<sup>1</sup>, Sahil Choudhri<sup>1</sup>, Shrika Kantala<sup>1</sup>, Vinyas Bhat<sup>1</sup>, Yash Chatha<sup>1</sup>, Anita Kohli<sup>1</sup>, Mazen Noureddin<sup>5</sup>, Naim Alkhouri<sup>1</sup>. <sup>1</sup>Arizona Liver Health; <sup>2</sup>Arizona Liver Health, Chandler, United States; <sup>3</sup>Cleveland Clinic, Department of Internal Medicine; <sup>4</sup>South Texas Research Institute, Edinburg, TX; <sup>5</sup>Cedars-Sinai Medical Center, Department of Gastroenterology and Hepatology, Los Angeles, California  
Email: naim.alkhouri@gmail.com

**Background and aims:** The FAST score was recently developed to predict the presence of fibrotic NASH defined as having NAFLD activity score (NAS)  $\geq 4$  and Fibrosis  $\geq 2$  using the following variables: liver stiffness measurement (LSM) by transient elastography (TE) for fibrosis, controlled attenuated parameter (CAP) for steatosis, and AST for inflammation. The FAST score was initially developed in a UK cohort and externally validated in several other international cohorts but limited data exist on multiethnic U.S. patients who tend to have higher BMI. We aimed to evaluate the performance of the FAST score in a large U.S. cohort using liver histology as the gold standard.

**Method:** Consecutive patients seen at 4 tertiary care centers were included. NAFLD was diagnosed based on society guideline recommendations. NASH, NAS, and fibrosis stage were assessed using the Kleiner's histology score. M and XL probes were chosen based on the automated machine recommendation. Liver biopsy was done within 6 months from VCTE and patients were excluded if they had  $>5\%$  change in body weight. C statistics were used to assess FAST accuracy and sensitivity, specificity, NPV, and PPV were calculated.

**Results:** 733 patients were included with mean age of 56.5 years ( $\pm 3.7$ ), 246 (33.6%) were from Hispanic ethnicity, 39.7% had type 2 diabetes, and a mean BMI of 36.4 ( $\pm 4.1$ ) kg/m<sup>2</sup>. The prevalence of fibrotic NASH was 24% and that of significant fibrosis (F2-F4) was 31.7%. The FAST score had good overall accuracy in predicting fibrotic NASH with AUC of 0.76 (95% CI: 0.72–0.79). At the low cutoff value ( $<0.35$ ) that corresponds to 90% sensitivity (rule out zone), the FAST had an excellent NPV of 91.1%. However, at the high cutoff value ( $>0.67$ ) that corresponds to 90% specificity (rule in zone), the FAST score had low PPV of 46.2%. 350 patients were in the rule out zone, 186 were in the rule in zone, and 197 were classified as indeterminate.

**Conclusion:** The FAST score is an accurate score in ruling out the presence of fibrotic NASH in U.S. adults. However, the score has low PPV indicating lower accuracy in making a definitive diagnosis of fibrotic NASH.

**PO-1020**

**Individualized polygenic risk score identifies NASH in the eastern Asia region: a derivation and validation study**

## POSTER PRESENTATIONS

Hospital Southampton, Southampton National Institute for Health Research Biomedical Research Centre, Southampton, United Kingdom; <sup>7</sup>Wenzhou Medical University, Institute of Hepatology, Wenzhou, China; <sup>8</sup>Key Laboratory of Diagnosis and Treatment for The Development of Chronic Liver Disease in Zhejiang Province, Wenzhou, China  
Email: zhengmh@wmu.edu.cn

**Background and aims:** The correct identification of patients at increased risk of non-alcoholic steatohepatitis (NASH) is a critical step in the assessment of non-alcoholic fatty liver disease (NAFLD). Genome-wide association studies have showed that some genetic variants play an important role in the development and progression of NAFLD. On this background of evidence, the aim of our study was to develop and validate a polygenic risk score for identifying NASH in a large multi-national cohort of Asian patients with biopsy-proven NAFLD.

**Method:** The primary cohort comprised 538 patients with biopsy-proven NAFLD at a tertiary hospital in China. Another independent validation cohort of 532 patients with NAFLD from a tertiary medical centre in South Korea was also included. NASH was diagnosed based on an overall pattern of histological hepatic injury consisting of steatosis, inflammation, and hepatocellular ballooning.

**Results:** In the primary Chinese cohort, patients were randomly assembled into a "training set" (n = 402) and a "validation set" (n = 136). Patients had a median age of 42 years in the training set, and a median age of 43 in the validation set. The prevalence of NASH was 42.5% in the training set and 36.8% in the validation set, respectively. In the external validation cohort (South Korean), the median age was 54 years and the prevalence of NASH was 33.5%. An individualized risk score was developed based on the multivariable regression coefficients. The formula for the score was as follows:  $0.548 \times \text{sex}$  (female = 1; male = 0) +  $0.467 \times \text{MetS}$  (yes = 1; no = 0) +  $1.909 \times$

elevated AST levels (AST  $\geq 40 = 1$ ; AST < 40 U/L = 0) +  $1.074 \times$  insulin resistance (HOMA-IR > 2.5 = 1; HOMA-IR  $\leq 2.5 = 0$ ) +  $0.581 \times$  PNPLA3 (rs738409) genotype (GC = 1; CC or GG = 0) +  $1.228 \times$  PNPLA3 (rs738409) genotype (GG = 1; CC or GC = 0) +  $0.607 \times$  HSD17B13 (rs72613567) genotype (AA or -/A = 1; -/- = 0). As shown in Figure, the score had a good discriminatory capacity (assessed by the area under the receiver operating characteristic curve [AUROC]) and calibration (assessed by the calibration curve and the Hosmer-Lemeshow goodness of fit test) in both the training and validation cohorts.

**Conclusion:** We have developed and validated a novel score incorporating both genetic and clinical risk factors that accurately identifies NASH in a large cohort of Asian patients with biopsy-proven NAFLD. These results may translate into clinical practice to guide the risk stratification of NAFLD and also stimulate further research into the pathogenic role of our risk score in NASH.

### PO-1056

#### Biomarker screening strategies to identify fibrosing steatohepatitis cases for clinical trial recruitment in NAFLD

 Email: y.vali@amc.uva.nl

**Background and aims:** A widely adopted recruitment target for NAFLD clinical trials is "fibrotic NASH," identified through liver biopsy (NAS  $\geq 4$  with  $\geq 1$  point in each component, plus fibrosis  $\geq F2$ ). The ability to accurately pre-select cases for biopsy using non-invasive tests (NITs) could increase the efficiency of recruitment and accelerate drug development. In this respect, blood-based NITs are particularly tractable as no specialist equipment is required at recruitment sites. The LITMUS consortium evaluated blood-based NITs as tools to reduce histological screen failure rates in future trials.

**Method:** Following a survey among clinicians and leading drug developers, we determined that a screen failure rate of 37% was acceptable for efficient trial enrolment. For 10 NITs, we then identified thresholds that yield the corresponding failure rate and selected the threshold with the highest sensitivity.

**Results:** Data from 686 participants from nine centers were included. Table 1 shows the biomarker thresholds that achieved a screen failure rate  $<37\%$  when biopsy is selectively performed in participants with a positive biomarker result, as well as the number of eligible patients found among those undergoing liver biopsy. We identified several NITs that would substantially reduce histological screen failure rates when biopsy was reserved for only biomarker positive patients.

**Conclusion:** Non-invasive pre-screening strategies for potential trial participants based on MACK-3, CK-18 M65 or the SomaScan proteomic algorithm could lead to substantial efficiencies in recruitment of trials targeting fibrotic NASH: reducing the number of cases biopsied to identify each eligible patient. Given the high screen failure rate in current trials, such preselection could facilitate trial recruitment and accelerate drug development. These results also have implications to guide risk-stratification in routine clinical practice.

Table 1: NIT to increase the efficiency in identifying patients with fibrotic NASH for trial recruitment

Biomarker	N	Threshold	Number of patients undergoing biopsy (per 100)	Screen failure rate	Number of eligible patients found (per 100)	Number needed to test
No screening	686	-	100	59%	41	-
MACK-3	391	0.30	60	37%	38	3
SomaScan	278	0.03	50	36%	32	3

Email: zhengmh@wmu.edu.cn

**Background and aims:** Recently, Papatheodoridi *et al.* proposed refined Baveno VI elastography dual cutoffs (8 and 12 kPa) for detecting compensated advanced chronic liver disease (cACLD) in patients with liver diseases of various etiologies including non-alcoholic fatty liver disease (NAFLD). They also proposed an algorithm for unclassified patients whose liver stiffness (LS) were between 8 and 12 kPa. We aimed to validate the performance of this 'two-step' method in three Asian NAFLD cohorts.

**Method:** We included 830 biopsy-proven NAFLD from three Asian cohorts. Clinical and pathological information, and LS measured by FibroScan were documented.

**Results:** The prevalence of cACLD was 6.9%, 35.6%, and 20.7% in the three cohorts. Compared with the original Baveno VI elastography criteria (10 and 15 kPa), the new cutoffs showed a comparable specificity (about 90%) and a higher sensitivity for identifying cACLD (Figure A). In this study, 44, 87, and 94 patients in Wenzhou, Hong Kong, and Malaysia fell in the grey zone. However, the risk model for unclassified patients proposed by Papatheodoridi *et al.* was not better

## POSTER PRESENTATIONS

than LS value alone identified by ROC curves in the Asian population (all  $p > 0.1$ ). Thus, we attempted to construct a simplified risk model for Asian patients with intermediate results. We merged unclassified patients within two Chinese cohorts with available laboratory data ( $n=101$  in total) as the training set. Based on the adjusted multivariate logistic regression with bootstrap resampling, we proposed a simplified risk model: Risk of cACLD =  $e^a / (1 + e^a)$ , with  $a = -5.421 + 0.868 \times \text{age (per quintile)} + 0.469 \times \text{LS} - 0.526 \times \text{platelet count (10}^9/\text{mm}^3 \text{ per quintile)}$ . The simplified risk model outperformed the LS alone in two Chinese cohorts ( $p = 0.001$ ), and was further validated in 94 Malaysia NAFLD patients with intermediate results by LS alone ( $p = 0.04$ ; Figure B). Overall, the 'two-step' screening of cACLD improved correct classification rates from 73.5% by original dual cutoffs to 86.7% in the whole cohort; both refined screening approach by Papatheodoridi *et al.* and our simplified risk model yielded a classification rate of about 85%. Notably, the simplified risk model missed less cACLD cases in all three cohorts.

**Conclusion:** The dual cutoffs of 8 and 12 kPa are more reasonable to identify cACLD in patients with NAFLD. For Asian patients with intermediate results, a simplified risk model for cACLD prediction in unclassified patients can be used.

### PO-1195

#### PNPLA3 and SERPINA1 are associated with liver disease severity in an unselected fatty liver disease cohort

Lorenz Balcar<sup>1,2</sup>, Georg Semmler<sup>1,2</sup>, Hannes Oberkofler<sup>2</sup>, Stephan Zandanel<sup>2</sup>, Michael Strasser<sup>2</sup>, David Niederseer<sup>3</sup>, Alexandra Feldman<sup>2</sup>, Felix Sticker<sup>4</sup>, Pavel Strnad<sup>5</sup>, Christian Datz<sup>6</sup>, Bernhard Paulweber<sup>2</sup>, Elmar Aigner<sup>2</sup>. <sup>1</sup>Medical University of Vienna, Department of Internal Medicine III, Division of Gastroenterology and Hepatology, Wien, Austria; <sup>2</sup>Paracelsus Medical University, First Department of Medicine, Salzburg, Austria; <sup>3</sup>University Hospital Zurich, Department of Cardiology, Zürich, Switzerland; <sup>4</sup>University Hospital Zurich, Department of Gastroenterology and Hepatology, Zürich, Switzerland; <sup>5</sup>Universitätsklinikum Aachen, Medical Clinic III, Aachen, Germany; <sup>6</sup>General Hospital Oberndorf, Internal Medicine, Oberndorf, Austria

Email: e.aigner@salk.at

**Background and aims:** Single nucleotide polymorphisms (SNPs) including PNPLA3 (rs738409 G-allele) and Serpin Family A Member 1 (SERPINA1 rs17580, Pi\**MZ*, Pi\**Z*, Pi\**ZZ*) have been identified as risk modifiers of progression in alcoholic (ALD) and non-alcoholic fatty liver disease (NAFLD). While PNPLA3 has been studied in various settings, the value of both SNPs has so far not been addressed in a

Figure: (abstract: PO-1106)

real-world cohort of subjects referred for diagnostic work-up of liver disease.

**Method:** Liver disease severity was assessed by liver stiffness measurement (LSM) and clinical manifestations of advanced chronic liver disease (ACLD) in 1257 consecutive patients with suspected fatty liver disease (ALD and NAFLD) at the time of first referral to a tertiary center. ACLD and clinically significant portal hypertension (CSPH) were defined as LSM  $\geq$  20/10 kPa or unequivocal clinical signs of cirrhosis. The associations of risk variants with disease severity were calculated.

**Results:** The majority of patients were male (n = 759, 60%) with a mean age of 53  $\pm$  15 years. 1048 (83%) were diagnosed with NAFLD and 209 (17%) with ALD. ACLD was present in 309 (25%) and CSPH in 185 (15%) patients. The PNPLA3 G-allele was independently associated with higher LSM (adjusted B: 2.707 [1.435–3.979], P < 0.001), higher odds of ACLD (aOR: 1.971 [1.448–2.681], P < 0.001) and CSPH (aOR: 1.685 [1.180–2.406], P = 0.004) and there was a numeric trend towards more frequent hepatocellular carcinomas (HCC, GC/GG: 2.1% vs. CC: 0.8%, P = 0.063). While SERPINA1 Z-allele was not associated with higher LSM (adjusted B: 2.581 [-0.244–5.406], P = 0.073) or the presence of ACLD (aOR: 1.748 [0.925–3.307], P = 0.086), it was independently associated with higher odds of CSPH (aOR: 2.122 [1.067–4.218], P = 0.032). Associations of PNPLA3 G-allele and SERPINA1 Z-allele with CSPH were maintained independently of each other and results of the overall cohort were similar in patients with either NAFLD or ALD. The presence of both risk variants further increased the likelihood of ACLD (aOR: 3.892 [1.561–9.706], P = 0.004) and CSPH (aOR: 4.282 [1.667–10.996], P = 0.003).

**Conclusion:** PNPLA3 G-allele is independently associated with liver disease severity in an unselected patient cohort while SERPINA1 was only associated with end-stage liver disease, suggesting a dominant influence of PNPLA3 over SERPINA1 as a genetic risk modifier in fatty liver disease on a population level.

**PO-1202**

**Curriculum-based education in NAFLD/NASH improves knowledge, competence, and confidence among gastroenterologists**

Shari Dermer<sup>1,1</sup>, Susan Smith<sup>1</sup>, Briana Betz<sup>1</sup>, John Maeglin<sup>1</sup>. <sup>1</sup>*Medscape Education, Education, New York, United States*  
Email: SDERMER@MEDSCAPE.NET

**Background and aims:** Non-alcoholic fatty liver disease (NAFLD) and non-alcoholic steatohepatitis (NASH) are the most common causes of chronic liver disease worldwide, affecting an estimated 25% of the world's population. The aim of this study was to assess the educational impact of a series of continuing medical education (CME) activities on the knowledge, competence, and confidence of gastroenterologists on the diagnosis and management of NAFLD/NASH.

**Method:** The educational series consisted of 6 online, CME-certified activities in multiple delivery formats, including a baseline practice assessment. For each activity, educational effect was assessed with a repeated pairs pre-/post-assessment study including a 3-item, multiple choice, knowledge/competence questionnaire and one confidence assessment question, with each participant serving as his/her own control. To assess changes in knowledge, competence, and confidence data from all clinicians who completed both pre- and post-questions were aggregated across activities and stratified by learning theme. McNemar's test or paired samples t-test (p < 0.05) assessed educational effect. The first activity launched August 2019 and the last launched October 2020; data were collected until December 2020.

**Results:** Overall gastroenterologists had significant improvements in knowledge (N = 733, p < 0.001) and competence (N = 831, p < 0.001) after education. Improvement in knowledge and competence measured as relative % change in correct responses pre/post education across the learning themes are reported:  
Diagnostic Tools: 24% increase, 66% pre/82% post (n = 312; p < 0.001)  
Risk Stratification: 38% increase, 32%pre/44% post (n = 614; p < 0.001)  
Current Management of NAFLD/NASH: 69% increase, 42% pre/71% post (n = 312; p < 0.001)  
New and Emerging Therapies: 21% increase, 57% pre/69% post (n = 733; p < 0.001)

	LSM	ACLD	CSPH
Age, yr	0.113 (0.070-0.156) P<0.001	1.055 (1.042-1.067) P<0.001	1.042 (1.028-1.056) P<0.001
BMI, kg/m <sup>2</sup>	0.332 (0.205-0.459) P<0.001	1.125 (1.090-1.161) P<0.001	1.054 (1.018-1.092) P=0.003
Alcohol consumption, y/n	13.302 (11.658-14.947) P<0.001	7.896 (5.573-11.188) P<0.001	7.553 (5.252-10.862) P<0.001
PNPLA3 (G=1)	2.715 (1.444-3.986) P<0.001	1.989 (1.461-2.709) P<0.001	1.707 (1.194-2.441) P=0.003
SERPINA1 (Z=1)	2.624 (-0.182-5.430) P=0.067	1.832 (0.963-3.483) P=0.065	2.196 (1.103-4.371) P=0.025

Linear and logistic regression analyses investigating the association of individual risk alleles with liver stiffness measurement (LSM), presence of advanced chronic liver disease (ACLD) and clinically significant portal hypertension (CSPH) in a combined regression model for both PNPLA3 and SERPINA1. Covariables were: Age (yr), BMI (kg/m<sup>2</sup>), active or past alcohol abuse (women  $\geq$  2 drinks per day, men  $\geq$  3 drinks per day).

Figure: (abstract: PO-1195)

## POSTER PRESENTATIONS

Across the educational activities, 27% (n = 1045; p < 0.001) of learners had a measurable increase in confidence following education. Comparison of baseline knowledge from the Clinical Practice Assessment with pre-/post-education assessment is shown in Figure 1.

Figure:

**Conclusion:** This series of online, CME-certified educational activities delivered in multiple formats resulted in significant improvements in knowledge, competence, and confidence regarding the diagnosis and management of patients with NAFLD/NASH. These results demonstrate the effectiveness of curriculum-based education for gastroenterologists designed to address specific gaps in care.

### PO-1217

#### Hepatocellular carcinoma in patients with NASH is associated with a specific pattern of muscle fat infiltration: a first-order radiomics study based on MRI-PDFF

Maxime Nachit<sup>1,2</sup>, Marco Dioguardi Burgio<sup>3,4</sup>, Anton Abyzov<sup>3</sup>, Philippe Garteiser<sup>3</sup>, Valérie Paradis<sup>5,6</sup>, Valerie Vilgrain<sup>3,4</sup>, Isabelle Leclercq<sup>1</sup>, Bernard E. Van Beers<sup>3,4</sup>. <sup>1</sup>UCLouvain, Laboratory of Hepato-Gastroenterology, Institut de Recherche Expérimentale et Clinique, Belgium; <sup>2</sup>KULeuven, Department of Imaging and Pathology, Belgium; <sup>3</sup>Université de Paris, Laboratory of Imaging Biomarkers, Center of Research on Inflammation, UMR 1149, Inserm, France; <sup>4</sup>AP-HP Beaujon University Hospital Paris Nord, Department of Radiology, France; <sup>5</sup>Université de Paris, Center of Research on Inflammation, UMR 1149, Inserm, F-75018, France; <sup>6</sup>AP-HP Beaujon University Hospital Paris Nord, Department of Pathology, France  
Email: maxime.nachit@gmail.com

**Background and aims:** The prevalence of NAFLD-associated hepatocellular carcinoma (HCC) is alarmingly increasing. Tools evaluating the risk of HCC development are needed to optimize surveillance in the still growing NAFLD population. Muscle fat infiltration has been associated with increased HCC incidence in patients with chronic liver disease. The aim of this study was to evaluate the association between muscle fat infiltration and HCC in patients with NAFLD.

**Method:** In a cohort of 72 histologically-proven NAFLD patients in which a subset had histological-diagnosed HCC, we used proton density fat fraction (PDFF) at MRI to evaluate fat infiltration in muscles (mean fat concentration and 1<sup>st</sup> order radiomic-based pattern) at the third lumbar level (L3): erector spinae, quadratus lumborum, psoas, oblique and rectus muscles.

**Results:** In patients with NASH and HCC, mean muscle PDFF was twice as high compared to patients with NASH but without HCC (quadratus lumborum:  $5.7 \pm 3.9\%$  versus  $3.2 \pm 2.4\%$ , erector spinae  $11.0 \pm 5.0\%$  versus  $5.4 \pm 3.1\%$  and oblique:  $12.6 \pm 6.9\%$  versus  $8.1 \pm 4.9\%$ , all p < 0.05) (Fig. 1a). HCC presence was a significant predictor of the mean PDFF of erector spinae ( $ES_{PDFF}$ ) in patients with NAFLD even when multiple confounding factors (age, sex, activity and fibrosis score, visceral fat area) were taken into account (p = 0.014). Further,  $ES_{PDFF}$  was an independent and significant predictor of HCC presence in patients with NASH when adjusted for similar confounders (associated AUROC = 0.79–0.94, all p < 0.05). Energy [a radiomics feature for homogeneity] in erector spinae ( $ES_{Energy}$ ) was a strong and independent predictor of HCC in patients with NASH (AUROC 0.87, 95% CI 0.73–1.00, p < 0.001) (Fig. 1b).

**Conclusion:** In patients with NASH, the presence of HCC is associated with a heterogenous increase of fat infiltration in skeletal muscles. Whether the pattern and magnitude of fat infiltration in skeletal muscles could be an indirect sign of and/or a risk factor for HCC development in patients with NASH needs to be investigated.

Figure: (abstract: PO-1217)

**PO-1220**

**PNPLA3 and TM6SF2 are neither associated with decreased cardiovascular nor increased liver-related mortality in the general population**

Lorenz Balcar<sup>1,2</sup>, Georg Semmler<sup>1,2</sup>, Sarah Wernly<sup>1</sup>, Sebastian Bachmayer<sup>1</sup>, Matthias Egger<sup>1</sup>, Marie Semmler<sup>1</sup>, Elmar Aigner<sup>3</sup>, David Niederseer<sup>4</sup>, Christian Datz<sup>1</sup>. <sup>1</sup>General Hospital Oberndorf, Department of Internal Medicine, Oberndorf, Austria; <sup>2</sup>Medical University of Vienna, Department of Internal Medicine III, Division of Gastroenterology and Hepatology, Vienna, Austria; <sup>3</sup>Paracelsus Medical University Salzburg, First Department of Medicine, Salzburg, Austria; <sup>4</sup>University Hospital Zurich, Department of Cardiology, Zürich, Switzerland  
Email: c.datz@kh-oberndorf.at

**Background and aims:** Single nucleotide polymorphisms in PNPLA3 and TM6SF2 genes have been associated with increased risk and severity of liver disease. At the same time, they have been discussed as being potentially protective from cardiovascular diseases due to their implications on serum lipid levels. Thus, the aim of this study was to evaluate whether PNPLA3 and/or TM6SF2 are associated with cardiovascular or liver-related mortality in a cohort of asymptomatic patients.

**Method:** The study cohort comprised 1762 Caucasians undergoing routine screening colonoscopy at a single center in Austria between 2010 and 2014 with information on PNPLA3 and TM6SF2 genotype variants. All patients with established liver diseases, colorectal cancers and significant alcohol consumption were excluded. Survival analyses were performed using Kaplan Meier analyses.

**Results:** Half of included patients were male (n = 903 [51%], mean age 60 ± 10 years) with a mean BMI of 27 ± 5 kg/m<sup>2</sup>. Among cardiovascular comorbidities, arterial hypertension and hypercholesterolemia were most frequent (n = 1008 [57%] and n = 1383 [79%]). Overall, hepatic steatosis was present in 792 patients (45%). NAFLD (PNPLA3-G: 41% vs. 38%, p = 0.055, TM6SF2-K: 51% vs. 37%, p < 0.001) and MAFLD (PNPLA3-G: 40% vs. 37%, p = 0.054, TM6SF2-K: 49% vs. 36%, p < 0.001) were more frequently diagnosed in patients carrying PNPLA3-G or TM6SF2-K alleles. Framingham risk score was lower for PNPLA3-G alleles (median 8 vs. 10, p = 0.011). Atrial fibrillation (n = 72 [4%]), coronary heart disease (n = 130 [7%]) and history of strokes (n = 53 [3%]) were equally distributed in each group.

During a median follow-up of 7.5 years, 132 patients died (7.5%), mainly due to cardiovascular- (n = 42) or tumor-related deaths (n = 40). PNPLA3 G-allele was neither associated with overall mortality (Log-rank-test: p = 0.100), nor with cardiovascular (Log-rank-test: p = 0.720) or liver-related mortality (Log-rank-test: p = 0.325). Similarly, TM6SF2 risk allele was also not associated with overall mortality (Log-rank-test: p = 0.539), cardiovascular (Log-rank-test: p = 0.993) or liver-related mortality (Log-rank-test: p = 0.179). Combining those two risk alleles did not increase granularity.

**Conclusion:** Whereas genotyping for symptomatic patients with liver disease seems useful, it does not provide prognostic information in asymptomatic patients. Therefore, genotyping for PNPLA3 and TM6SF2 should not be routinely performed in the absence of risk behavior.

**PO-1336**

**The liver fibrosis marker PRO-C3 increases with fibrosis stage and is neither elevated in diabetics without liver disease nor in healthy obese subjects**

Elisabeth Erhardt<sup>1</sup>, Daniel Guldager Kring Rasmussen<sup>1</sup>, Tina Manon-Jensen<sup>1</sup>, Peder Frederiksen<sup>1</sup>, Diana Leeming<sup>1</sup>, Diane Shevell<sup>2</sup>, Morten Karsdal<sup>1</sup>, Guruprasad Aithal<sup>3</sup>, Jörn Schattenberg<sup>4</sup>. <sup>1</sup>Nordic Bioscience A/S, Fibrosis Biology, Herlev,

Denmark; <sup>2</sup>Bristol-Meyers Squibb, Clinical Biomarkers, New Jersey, United States; <sup>3</sup>University of Nottingham, Faculty of Medicine and Health Sciences, Nottingham, United Kingdom; <sup>4</sup>Medical Centre of the Johannes Gutenberg-University, Mainz, Germany  
Email: dgr@nordicbio.com

**Background and aims:** Progressive fibrosis has been identified as predictor of mortality in patients with non-alcoholic fatty liver disease (NAFLD) and non-alcoholic steatohepatitis (NASH). Biomarkers are currently being evaluated for their ability to substitute the liver biopsy as the reference standard for staging the disease. Recent clinical studies in NAFLD/NASH patients support the utility of PRO-C3 as a marker for the degree of fibrosis, and effect of treatment. NAFLD patients suffer from several comorbidities, such as type 2 diabetes (T2D) and obesity. Even in type 1 diabetes, progressive liver injury can occur. It is therefore critical that biomarkers for determination of fibrosis in non-alcoholic liver injury are not influenced by comorbidities. In this study we define levels of PRO-C3 in type 1 and type 2 diabetics, non-diabetic obese, and non-obese otherwise healthy subjects. These are compared to PRO-C3 levels measured in NAFLD/NASH patients.

**Method:** We analyzed samples from 326 healthy subjects with no signs of liver disease obtained from Discovery Life Science. 97 patients were obese and 54 were nonobese type 1 and type 2 diabetics (subjects with abnormal levels of ALT, AST, ALP, or bilirubin were excluded from the study). PRO-C3 levels were compared across gender, age, ethnicity, BMI, and diabetes and reference ranges were estimated. Levels of PRO-C3 was measured in 222 NAFLD/NASH patients diagnosed and staged based on histology of a liver biopsy.

**Results:** In the 326 healthy subjects assessed PRO-C3 median levels were not influenced by gender, age, ethnicity, BMI, or diabetes (all p > 0.05). Median levels in all healthy groups were below the median levels measured in patients diagnosed with NAFLD/NASH. As expected for a biomarker reflecting fibrosis, PRO-C3 levels in the NAFLD/NASH population gradually increased with fibrosis stage (Table 1). Levels of PRO-C3 were able to identify patients with both significant (AUC = 0.83, sensitivity 63.0%, specificity 91.2%, p < 0.0001) and advanced fibrosis (AUC = 0.79, sensitivity 73.6%, specificity 75.0%, p < 0.0001).

	N	Lower limit (ng/ml) [90% CI]	Upper limit (ng/ml) [90% CI]	Median [90% CI]
<b>All</b> (healthy + Diabetes +obese)	326	6.1 [6.1–6.1]	16.3 [15.0–17.7]	8.9 [8.6–9.2]
<b>Healthy</b>	175	6.1 [6.1–6.1]	16.2 [14.4–18.2]	8.8 [8.5–9.4]
<b>Diabetes</b>	54	6.1 [6.1–6.1]	18.0 [14.9–21.8]	8.8 [8.0–9.6]
<b>Obese (BMI &gt; 30)</b>	97	6.1 [6.1–6.1]	16.1 [14.0–19.0]	9.0 [8.4–9.4]
<b>Total NAFLD/ NASH Patients</b>	222			
<b>Stage F0/F1</b>	57	6.1 [6.1–6.3]	15.5 [14.1–17.0]	9.5 [8.6–10.2]
<b>Stage F2</b>	59	6.1 [6.1–6.5]	25.4 [21.2–29.5]	11.5 [10.7–13.1]
<b>Stage F3</b>	66	6.5 [6.1–7.7]	34.2 [29.1–40.2]	14.8 [13.7–16.6]
<b>Stage F4</b>	40	6.1 [6.1–7.3]	54.2 [39.1–69.8]	16.3 [15.0–20.5]

**Conclusion:** We show PRO-C3 to be a robust marker that is not affected by age, gender, ethnicity, obesity, or diabetes and that it increased with fibrosis stage in patients with NAFLD/NASH.

#### Screening for non-alcoholic fatty liver disease (NAFLD)-related advanced fibrosis, real life data and comparison of two endocrinology-hepatology referral strategies

Cyrielle Caussy<sup>1,2,3</sup>, Charlène Telliam<sup>1</sup>, Bader Alnuaimi<sup>1</sup>, Massimo Levrero<sup>2,4,5</sup>, Marie Louyot<sup>4,5</sup>, Marianne Maynard<sup>4,5</sup>, Jérôme Dumortier<sup>2,6</sup>, Fabien Zoulim<sup>2,4,5</sup>, Emmanuel Disse<sup>1,2,3</sup>, Cyrille Colin<sup>2,7</sup>, Philippe Moulin<sup>2,3,8</sup>. <sup>1</sup>Hospices Civils de Lyon, Endocrinologie, Diabète et Nutrition, Hôpital Lyon Sud, Pierre Bénite, France; <sup>2</sup>Université de Lyon, Université Claude Bernard Lyon 1, Lyon, France; <sup>3</sup>INSERM, CarMen Laboratory, Unité 1060, LYON, France; <sup>4</sup>Hospices Civils de Lyon, Service d'Hépatologie, Hôpital Croix-Rousse, Lyon, France; <sup>5</sup>INSERM, Centre de Recherche sur le Cancer de Lyon, Unité 1052, Lyon, France; <sup>6</sup>Hospices Civils de Lyon, Fédération des Spécialités Digestives, Hôpital Edouard Herriot, Lyon; <sup>7</sup>Hospices Civils de Lyon, Service d'Evaluation Economique en Santé, Pôle de Santé Publique, Lyon; <sup>8</sup>Hospices Civils de Lyon, Département Endocrinologie, Diabète et Nutrition, Hôpital Cardiologique, Bron  
Email: cyrielle.caussy@chu-lyon.fr

**Background and aims:** Patients with type 2 diabetes (T2D) or obesity are at high risk of non-alcoholic fatty liver disease (NAFLD)-related advanced fibrosis (AF). Strategies for endocrinology-hepatology referral are needed to improve the clinical care of these patients but real-life data remain scarce. We compared the capacity of two different referral strategies for the screening of AF in patients with T2D or obesity and NAFLD.

**Method:** This is a retrospective comparative study from two endocrinology clinics at the Lyon University Hospital with distinct screening strategies for NAFLD-related AF. Data from adult patients included in the referral pathways from November 2018 to December 2019 were extracted from electronic charts. Other causes of chronic liver diseases were excluded. The proportion of patients with histological or high suspicion of AF (F3-F4), as defined by transient elastography (TE)  $\geq 9.7$  kPa, among the patients referred to hepatologists were compared.

**Results:** Center 1 included 285 patients requiring a hepatology assessment based upon a standardized and systematic screening using the EASL-EASD-EASO algorithm. The mean (SD) age was 53.9

(13.6) years, BMI: 39.1 (8.0) kg/m<sup>2</sup> and 62.8% had T2D. Only 44.2% (n = 126) had a hepatology consultation due to the saturation of the referral pathway and a minority 3.2% (n=4) had a liver biopsy including 2 with AF (Figure 1A). Center 2 included 225 patients with a suspicion of AF based upon a non-standardized screening strategy using NAFLD fibrosis score, abnormal liver enzymes and TE assessment. The mean (SD) age was 57.1 (10.8) years, BMI: 33.5 (6.0) kg/m<sup>2</sup> and 84.4% had T2D. Of them 27.9% (n = 63) were referred in hepatology and a minority 6.3% (n = 4) had a liver biopsy, including none with AF (Figure 1B). The proportion of patients with a strong suspicion of AF among those referred in hepatology was significantly higher in Center 2 compared to Center 1: 66.1% (n = 41) versus 17.4% (n = 22), OR: 9.5, 95% CI [4.6–19.6], p < 0, 0001. However, 18.4% (n = 30) patients from Center 2 had TE  $\geq 9.7$  kPa and were not referred in hepatology.

**Conclusion:** A referral strategy using TE in the endocrinology clinic significantly improves the screening capacity for NAFLD-related AF and reduces the risk of over-referral. However, a lack of standardized referral criteria may lead to an under-referral of AF patients. Collaboration between endocrinologists and hepatologists is key to optimize the referral strategy for patients with T2D or obesity.

### PO-1518

#### Serum metabolomics-based steatohepatitis score for the non-invasive identification of patients with non-alcoholic steatohepatitis (NASH) in multiethnic, including type 2 diabetes mellitus population

**Background and aims:** The prevalence of non-alcoholic fatty liver disease (NAFLD) is high in the western world and it is often comorbid with type 2 diabetes mellitus (T2DM). We aimed to develop an accurate, serum-based, easy to use test independent of glycated hemoglobin (HbA1c) for the diagnosis of non-alcoholic steatohepatitis (NASH) regardless of the presence of T2DM.

**Method:** Serum metabolomic testing was performed in an original cohort of 682 patients that was subsequently blind validated in two separate international cohorts of 202 patients (100 from Chile and 102 from USA). The derivation cohort was a cross-sectional, multi-center study of patients aged 18 years or older, who underwent liver biopsy for suspicion of NAFLD. To classify those patients with NASH, a NAFLD Activity Score (NAS)  $\geq 3$  (with at least one point on each of steatosis, lobular inflammation and ballooning) was considered. The best fitting multivariable logistic regression model was identified and internally validated using a K-fold Cross-Validation process. Score calibration and discrimination performance were determined in both the derivation and validation datasets.

**Results:** We performed serum metabolomic testing in a multiethnic, multicenter derivation cohort of 682 subjects with biopsy proven NAFLD (312 Steatosis, 370 NASH). The characteristics of this cohort were 51% Male, BMI  $35.5 \pm 7.3$ ; alanine aminotransferase, ALT  $51.4 \pm 37.6$ ; aspartate aminotransferase, AST  $37.2 \pm 24.3$  and HbA1c  $6.5 \pm 1.2$ . The final score (OWLiverDM2) includes 16 lipids, BMI, AST and ALT. Using logistic regression analysis, we could discriminate between patients with NASH and steatosis. The diagnostic performance of the OWLiverDM2 showed an area under the receiver operating characteristic curve (AUC) of  $0.80 \pm 0.03$ , while a model generated with only clinical variables, could only reach to an AUC of  $0.71 \pm 0.04$ , this difference being statistically significant (DeLong Test z-score = 5.239, p value =  $1.62 \times 10^{-7}$ ). Sensitivity, specificity, PPV and NPV of both models were 0.74, 0.73, 0.71 and 0.77 for OWLiverDM2 and 0.61, 0.69, 0.60 and 0.70 for the clinical variables algorithm.

Furthermore, the new test maintained a better performance and the statistical significance versus the clinical algorithm in a subgroup of 406 subjects with T2DM or HbA1c  $\geq 6$ , AUC = 0.78 versus AUC = 0.71 (DeLong test, z-score = 3.064, p value = 0.00218).

Finally, we validated OWLiverDM2 performance in an independent cohort of 202 patients of similar characteristics with the following values of AUC, sensitivity, specificity, PPV and NPV:  $0.81 \pm 0.02$ , 0.78, 0.76, 0.66 and 0.85, respectively.

**Conclusion:** The new serum-based OWLiverDM2 score accurately discriminates between steatosis and NASH in a more general, multiethnic, including controlled and non-controlled T2DM population without using HbA1c.

**Background and aims:** Non-invasive tests of fibrosis (NITs), including the ELF score, FIB-4, and liver stiffness by transient elastography (LS by TE), have utility as diagnostic/prognostic biomarkers, and are increasingly used to monitor treatment response. We evaluated longitudinal variation of these NITs using the placebo groups from the STELLAR trials in NASH patients with stable, advanced fibrosis.

**Method:** Patients with advanced fibrosis due to NASH (NAS  $\geq 3$ , NASH CRN F3-F4) were enrolled in two randomized, placebo-controlled trials of selonsertib (STELLAR-3/-4). FIB-4 and ELF (Siemens) were collected at baseline (BL) and weeks 12 (W12), 24 (W24), and 48 (W48), and LS by TE (FibroScan; Echosens) was measured by trained operators at BL, W24, and W48. Intra- and inter-subject variability of these NITs was assessed in placebo-treated patients between BL and W48 by within- and between-subject coefficients of variation (CVs) using mixed-effect models with visit as a fixed effect and subject as a random effect. The impact of BL covariates and on-treatment weight loss (<vs  $\geq 5\%$ ) on these CVs was assessed using linear models.

**Results:** 251 placebo-treated patients with stable fibrosis were included in this analysis. 57% had cirrhosis and median LS by TE

## POSTER PRESENTATIONS

Figure: (abstract: PO-1568): CVs of NITs According to Baseline Covariates and On-Treatment Weight Loss

	FIB-4		LS by TE		ELF	
	Intra-individual CV (%)	Inter-individual CV (%)	Intra-individual CV (%)	Inter-individual CV (%)	Intra-individual CV (%)	Inter-individual CV (%)

F4	19.1	48.1	32.3	48.1	3.6	6.8

\*≥5% reduction between BL and W48.

†≤33 U/L for males and ≤25 U/L for females..

was 16.2 kPa (IQR 11.8, 24.7). Over 48 weeks, intra- and inter-individual CVs of FIB-4 and LS by TE were 20.1% and 46.9%, and 33.0% and 55.6%, respectively. ELF had the lowest variability (intra- and inter-individual CVs of 3.8% and 7.8%). Only BL BMI and weight loss were associated with variability of FIB-4; greater within-subject CVs were observed in patients with BL BMI ≥ 30 (21.1% vs 15.8% with BMI < 25;  $p = 0.02$ ) and those with ≥5% weight loss (31.6% vs. 19.4% with <5%;  $p = 0.001$ ) (Figure).

**Conclusion:** In NASH patients with advanced fibrosis, FIB-4 and LS by TE have high variability compared to ELF, suggesting that ELF may have greater precision for disease monitoring in NASH.

Email: quentin.anstee@newcastle.ac.uk

**Background and aims:** Assessment of liver fibrosis in clinical trials relies primarily on histology, and there is a need for non-invasive methods. Fibrosis response in patients with non-alcoholic steatohepatitis (NASH) treated with subcutaneous semaglutide was compared

using enhanced liver fibrosis (ELF) score, FibroScan® liver stiffness measurement (LSM) and histology assessment.

**Method:** This was a post-hoc analysis of the 72-week phase 2 trial (NCT02970942) of once-daily subcutaneous semaglutide (0.1, 0.2 or 0.4 mg) vs placebo on NASH resolution in 320 patients with NASH and fibrosis stage F1-F3, which showed significant NASH resolution and a non-significant trend for fibrosis improvement with semaglutide 0.4 mg vs placebo. Fibrosis improvement or progression was categorised using ELF (decrease or increase of ≥0.5 units), LSM (decrease or increase of ≥25%) and liver histology (decrease or increase of ≥1 stage) at baseline and at week 72. For ELF and LSM response, the proportion of subjects were compared using a logistic regression model.

**Results:** Baseline median (min-max) ELF score was 10.3 (0.8–54.7) and LSM was 9.7 (7.4–12.8). At baseline, a weak correlation was found between ELF and LSM ( $r$  [95% confidence interval] = 0.22 [0.13–0.31]), and fibrosis stage assessed by histology was associated with ELF ( $p < 0.001$ ) and LSM ( $p = 0.016$ ). At week 72, mean change from baseline in ELF score with semaglutide 0.4 mg was –0.7 (vs 0 with placebo) and mean ratio to baseline in LSM was 0.79 with semaglutide 0.4 mg (vs 1.66 with placebo). Although the percentage of patients with histological improvement in fibrosis was not significantly different between groups, the proportion of ELF and LSM responders was higher with semaglutide vs placebo (Figure). At week 72, fewer patients in the semaglutide 0.4 mg arm had fibrosis progression, as assessed by histology (5.8% vs 21.4%;  $p = 0.009$ ), ELF (6.7% vs 23.0%;  $p = 0.01$ ) and LSM (10.9% vs 34.8%;  $p = 0.002$ ). For both the placebo and semaglutide 0.4 mg treatment groups, change from baseline to week 72 in ELF and LSM correlated with biomarkers of NASH activity (aspartate aminotransferase, alanine aminotransferase, cytokeratin 18 M65 and M30), fibrosis (Fibrosis-4, AST to platelet ratio index, Forns index) and body weight.

**Conclusion:** Treatment with semaglutide for 72 weeks reduced fibrosis progression measured by histology as well as ELF and LSM. The changes were suggestive of fibrosis response related to semaglutide treatment.

Data are from all randomized patients during the on-treatment period. \*p < 0.05; \*\*p < 0.01; \*\*\*p < 0.001 vs placebo; †Fibrosis improvement was defined as decrease of ≥ 1 fibrosis stage without worsening of NASH (increase of ≥ 1 point in either the lobular inflammation score or the hepatocyte ballooning score, according to the NASH Clinical Research Network criteria). ELF, enhanced liver fibrosis; LSM, liver stiffness measurement; NASH, non-alcoholic steatohepatitis.

 Email: lina.titievsky@interceptpharma.com

**Background and aims:** Non-alcoholic steatohepatitis (NASH) is a chronic, progressive condition that can lead to cirrhosis. The fibrosis-4 (FIB-4) score is a non-invasive test of liver fibrosis based on laboratory data. This study characterized the comorbidity burden and healthcare resource utilization (HCRU) among NASH patients stratified by FIB-4 defined fibrosis severity.

**Method:** An algorithm to identify NASH patients was applied to a large US administrative claims database (01 October 2015 and 31 March 2020). The algorithm required either (1) NASH as the principal discharge diagnosis from an inpatient claim, (2) liver biopsy followed by NASH diagnosis, or (3) liver imaging followed by NASH diagnosis, procedure codes for liver function testing, and ≥1 risk factor (obesity, type 2 diabetes, pre-diabetes, or dyslipidemia). Patients with concurrent liver diseases or history of liver transplantation were excluded. Continuous health plan enrolment was required for ≥12 months prior to index date (i.e., baseline period). All patients with sufficient lab data to determine their FIB-4 scores were categorized as no/early fibrosis (NF), indeterminate (INF), and advanced fibrosis (AF) using published thresholds. Descriptive statistics were used to summarize baseline patient characteristics and HCRU.

**Results:** Of 20,198 qualifying NASH patients, baseline FIB-4 were available for 7,937 (39%): 4,415 (56%) had NF, 2,239 (28%) INF, and 1,283 (16%) AF. AF patients were older, with higher rates of type 2 diabetes (69% vs. 54% and 38%) and hypertension (83% vs 77% and 61%) than patients with INF or NF, respectively. Similar proportions of patients had liver biopsies (13% for AF vs. 13% INF and 11% NF). A larger proportion of patients with INF had undergone liver elastography than NF or AF (13% vs. 10% and 8%), and a greater proportion of patients with AF was seen by a gastroenterologist (GI) than patients with INF or NF (49% vs. 38% and 33%). Inpatient stays were also more common for those with AF (mean ± SD: 0.85 ± 1.55) than those with INF or NF (0.42 ± 1.12 and 0.35 ± 1.07).

**Conclusion:** Patients across all FIB-4 levels of fibrosis severity have appreciable burden of metabolic comorbidities. However, diagnosis by GI specialty, comorbidity burden and HCRU, including inpatient stays, increased with worsening FIB-4. FIB-4 offers a simple, accessible, non-invasive tool that has the ability to risk stratify NASH patients for liver-related morbidity and mortality.

**PO-1648**  
**Clinical utility of 30% relative decline in MRI-PDFF in predicting fibrosis regression in non-alcoholic fatty liver disease**

## POSTER PRESENTATIONS

**Background and aims:** Liver fibrosis is most important factor associated with the prognosis and liver-related complications in non-alcoholic fatty liver disease (NAFLD) and improvement in liver fibrosis is an important end point in non-alcoholic steatohepatitis (NASH) clinical trials. Emerging data suggest that  $\geq 30\%$  relative decline in magnetic resonance imaging-proton density fat fraction (MRI-PDFF) is correlated with NAFLD Activity Score response ( $\geq 2$  points improvement, with no worsening in fibrosis), but the association between decline in MRI-PDFF and fibrosis regression is still unclear. Therefore, we investigated the association between  $\geq 30\%$  relative decline in MRI-PDFF and fibrosis regression in NAFLD.

**Method:** This is a prospective study including 100 well-characterized NAFLD patients who received paired biopsy with contemporaneous MRI-PDFF assessment. The primary outcome was  $\geq 1$  stage fibrosis regression using the NASH CRN Histologic Scoring System. MRI-PDFF response was defined as  $\geq 30\%$  relative decline in MRI-PDFF.

**Results:** The median (interquartile range) age was 54 (43–62) years, and body mass index was 31.9 (29–36) kg/m<sup>2</sup>. Twenty patients had fibrosis regression at the follow-up biopsy, and 25 patients had MRI-PDFF response. In univariable analysis, gamma-glutamyl transferase (GGT) level at baseline, MRI-PDFF response, and an increase in platelet count were significantly associated with fibrosis regression. In multivariable-adjusted logistic regression analysis (adjusted for age, gender, diabetes status, race/ethnicity, GGT, and change in platelet counts), MRI-PDFF response was an independent predictor of fibrosis regression with adjusted-odds ratio (OR) of 5.16 (95% confidence interval [CI]: 1.1–24.9,  $p = 0.04$ ). The proportion of patients with MRI-PDFF response with fibrosis regression, fibrosis no change, and fibrosis progression were 40.0%, 24.6%, and 13.0%, respectively, and the proportion of patients with MRI-PDFF response increased with fibrosis regression ( $p = 0.03$ ). In sensitivity analysis for histological outcome, MRI-PDFF response was associated with an interval decrease in steatosis grade (OR: 3.78, 95% CI: 1.5–9.8), NAS response (OR: 4.75, 95% CI: 1.8–12), and fibrosis regression (OR: 3.75, 95% CI: 1.2–12).

**Conclusion:** MRI-PDFF response defined as a  $\geq 30\%$  relative decline in MRI-PDFF is associated with fibrosis regression and may be used as a potential surrogate marker for evaluating therapeutic effect in a NASH trial.

### PO-1689

#### Combination treatment with cilofexor and firsocostat leads to improvements in the FibroScan-AST (FAST) score which are associated with treatment response in patients with advanced fibrosis due to NASH

Email: ryan.huss@gilead.com

**Background and aims:** The FAST score is a non-invasive tool that includes liver stiffness (LS) and controlled attenuation parameter (CAP) by transient elastography (TE; FibroScan) and AST, for the identification of patients at risk of progressive NASH. Our aims were to evaluate the effects of cilofexor (CILO) and firsocostat (FIR) on FAST and to explore associations between treatment-induced changes in FAST with histologic and non-invasive test (NIT) responses.

**Method:** NASH patients with histologically-confirmed, advanced fibrosis (NASH CRN F3–F4) in the phase 2b ATLAS trial were treated with regimens including CILO 30 mg ( $n = 40$ ), FIR 20 mg ( $n = 40$ ), CILO +FIR ( $n = 78$ ), or placebo ( $n = 39$ ), once daily for 48 weeks (W48). Liver histology was evaluated by a central reader and a machine learning (ML) approach (PathAI; Boston, MA). End points included a  $\geq 1$ -stage improvement in fibrosis without worsening of NASH (primary end point [PE]),  $\geq 2$ -pt reduction in NAFLD Activity Score (NAS response [NAS-R]), and ELF response (ELF-R), defined as a  $\geq 0.5$ -unit reduction from baseline to W48. Patients were categorized according to FAST at baseline (BL) and W48 (rule-out zone:  $< 0.35$ ; grey zone:  $0.35$  to  $< 0.67$ ; rule-in zone:  $\geq 0.67$ ) and changes in FAST were evaluated using ANCOVA and Wilcoxon rank sum and Fisher's exact tests.

**Results:** At BL, 56% of patients had cirrhosis (F4). Median BL FAST was 0.69 (IQR 0.51, 0.81); 53% and 33% of patients were in the rule-in and grey zones, respectively. FAST was similar between cirrhotic and non-cirrhotic patients (0.71 vs 0.67;  $p = 0.081$ ). Compared with placebo (LSmean change in FAST from BL to W48:  $-0.04$ ), treatment with CILO ( $-0.18$ ), FIR ( $-0.22$ ), and CILO+FIR ( $-0.22$ ) led to significant improvements in FAST (all  $p < 0.05$ ). Improvements in FAST category were observed in 16% of placebo-treated patients compared with 53% to 65% treated with CILO, FIR, or CILO+FIR (all  $p < 0.05$ ; Figure). Across study groups, changes in FAST were correlated with changes in ELF score ( $\rho = 0.28$ ), LS by TE ( $\rho = 0.61$ ), ALT ( $\rho = 0.57$ ), CK18-M30 ( $\rho = 0.45$ ), CK18-M65 ( $\rho = 0.49$ ), ML NASH CRN fibrosis score ( $\rho = 0.28$ ), and proportionate areas by ML of steatosis ( $\rho = 0.40$ ) and hepatocellular ballooning ( $\rho = 0.22$ ; all  $p < 0.05$ ), but not portal or lobular inflammation. Greater reductions in FAST were observed in responders vs non-responders for all W48 end points: PE ( $-0.27$  vs  $-0.10$ ,  $p = 0.0013$ ), NAS-R ( $-0.24$  vs  $-0.10$ ,  $p = 0.0069$ ), and ELF-R ( $-0.25$  vs  $-0.09$ ;  $p < 0.001$ ).

**Conclusion:** In patients with advanced fibrosis due to NASH, treatment with CILO and/or FIR leads to significant improvements in FAST score. Changes in FAST are greatest in histologic and ELF responders, suggesting that FAST is a useful marker of treatment response in NASH patients with advanced fibrosis.

Figure includes only subjects with baseline and week 48 FAST data.

**Background and aims:** Liver stiffness (LS) measured by vibration-controlled transient elastography (VCTE) is associated with fibrosis stage and risk of decompensation in patients with NAFLD. However, prospective data describing associations between LS and disease progression in well-characterized NASH cohorts with biopsy-confirmed advanced fibrosis are limited. The aim of this study was to establish thresholds of LS by VCTE that predict clinical outcomes in patients with bridging fibrosis and cirrhosis due to NASH.

**Method:** Patients with advanced fibrosis (NASH CRN F3-F4) due to NASH were enrolled in four placebo-controlled trials of simtuzumab and selonsertib. The trials were discontinued due to lack of efficacy; hence treatment groups were combined for this analysis. Liver fibrosis (baseline [BL] and W48) was staged centrally according to the NASH CRN classification, and LS was measured by VCTE (FibroScan; Echoscans, Paris, France) by trained operators. Cox regression determined associations between LS at BL with disease progression (i.e. progression to cirrhosis in patients with bridging fibrosis and adjudicated clinical events [e.g. decompensation, transplantation, death] in those with cirrhosis), and discrimination was assessed using c-statistics. Optimal LS thresholds were determined based on Youden's index.

**Results:** 1, 398 patients with bridging fibrosis (n = 664) or cirrhosis (n = 734) were included in this analysis (median age 59 years, 60% female, 73% with diabetes). Median (IQR) LS at BL was 12.7 kPa (9.7, 17.3) in those with bridging fibrosis and 21.1 kPa (14.2, 29.3) in those with cirrhosis. During a median follow-up (FU) of 17 mos (range 1, 40), 16% of patients with bridging fibrosis (96/103 with post-baseline biopsies) progressed to cirrhosis. The risk of histological progression was greater with higher LS at BL (hazard ratio [HR] per 3-kPa: 1.16; 95% CI 1.12, 1.20). The c-statistic of BL LS to predict progression to cirrhosis was 0.72 (95% CI 0.66, 0.77) and the optimal threshold was 16.6 kPa (sensitivity 58%, specificity 76%, PPV 31%, NPV 91%). During a median FU of 16 mos (range 0, 39), 27 cirrhotic patients (4%) had liver-related events. The risk of events was greater with higher BL LS (HR per 5-kPa: 1.29; 95% CI 1.18, 1.41). The c-statistic of BL LS to predict clinical events was 0.77 (95% CI 0.67, 0.87) and the optimal threshold was 30.7 kPa (sensitivity 70%, specificity 79%, PPV 11%, NPV 99%).

Figure: Clinical Disease Progression According to LS by VCTE at BL

**Conclusion:** Clinical disease progression in patients with advanced fibrosis due to NASH is associated with higher LS by VCTE. The LS thresholds identified in this study may be useful for risk stratification of NASH patients in clinical trials and clinical practice.

 Email: aidan.mcglinchey@oru.se

**Background and aims:** Non-alcoholic fatty liver disease (NAFLD), the leading cause of chronic liver disease, affects 25%+ of people worldwide. Detailed understanding of the metabolomics of NAFLD, and non-invasive diagnostic techniques for the stages of NAFLD are unavailable. We identify specific serum molecular lipid signatures to these ends.

First, we leverage lipidomic and polar metabolomic data (n = 643) subjects, to produce a clear, meaningful interaction map, linking lipids, metabolites, clinical factors and disease outcomes. We find non-spurious associations therein, as features of interest, and for downstream analysis.

Third, NAFLD fibrosis biomarker identification was performed using machine learning, with our candidate lipids/metabolites to be forwarded to a successor project; the LITMUS project, towards clinically-applicable, non-invasive, sensitive and specific classification of NAFLD patients.

**Method:** Serum lipids and polar metabolites were measured by mass spectrometry in the EPoS cohort of patients (n = 176 lipids and n = 36 polar metabolites), combined with clinical data from (n = 643 subjects), followed by model-based clustering, giving 10 lipid clusters (LCs).

Correlations were calculated pairwise between (1) all LCs, (2) "input" clinical data (height, weight, BMI, blood platelet count) and (3) outcomes (fibrosis, steatosis, NAS score, etc.). Non-rejection rates (NRRs) were calculated for relationships, remove spurious associations (NRR > 0.4). We project the remaining associations as a network; a novel metabolomic overview NAFLD.

ANOVA and Tukey's Honest Significant Differences (Tukey HSDs) revealed detailed metabolic signatures across NAFLD, fibrosis and steatosis stages.

Random forest machine learning was used to classify NAFLD patients: LOW (0-1 fibrosis grade) or HIGH (2-4 fibrosis grade), using individual lipids and metabolites, identifying putative biomarkers.

**Results:** In line with our previous findings, many lipids associate with steatosis and fibrosis in NAFLD. Our novel overview network reveals associations between specific LCs and clinical variables, such as TGs (LC3), and a subgroup of TGs of lowest and highest carbon numbers

# POSTER PRESENTATIONS

(LC9) along with PC (O)s (LC7) positively associating with NAFLD score and fibrosis. Conversely, LPCs (LC4), particularly sphingomyelins (SMs, LC6), negatively associated with these variables. Many other metabolites changing across NAFLD stages beg further discussion.

**Conclusion:** In addition to generation of a novel metabolomic network of NAFLD, we demonstrate feasibility of lipidomic and

metabolomic data to classify NAFLD patients' fibrosis grades (median AUC: 0.765), competitive with gold-standard clinical variables (age, BMI, sex, diabetes, liver AST/ALT, platelet count) (median AUC: 0.778). These biomarkers are being taken forward (LITMUS project) to develop clinical testing.

**Clinical care pathways for non-alcoholic fatty liver disease (NAFLD) in U.S. Veterans will improve resource utilization and linkage to specialty care**

Puneet Puri<sup>1,2</sup>, Joseph Spataro<sup>2</sup>, April Morris<sup>1</sup>, Shuchi Jain<sup>3</sup>, Michael Fuchs<sup>1,2</sup>. <sup>1</sup>Central Virginia VA Healthcare System, Department of Medicine, Richmond, United States; <sup>2</sup>Virginia Commonwealth University, Department of Medicine, Richmond, United States; <sup>3</sup>Virginia Commonwealth University, Department of Statistical Sciences and Operations Research, Richmond, United States  
Email: laura1fuchs@icloud.com

**Background and aims:** The Veterans Health Administration is the largest single healthcare system in the U.S. providing care for 6 Million Veterans. Accurate disease assessment and staging of NAFLD still heavily relies on liver biopsies because non-invasive tests (NITs) such as FIB-4 and transient elastography (TE) have suboptimal discrimination for early (F0-2) vs. advanced (F3-4) liver fibrosis. We aimed to develop clinical care pathways to better discriminate F0-2 vs. F3-4 and address the resource limitations of a single healthcare system operating throughout the entire U.S.

**Method:** A prospective cohort of Veterans referred for NAFLD evaluation and undergoing a liver biopsy was studied. Fibrosis staging was based on NASH Clinical Research Network criteria. Machine learning with decision tree analysis (DTA) incorporating comorbidities, medications, demographics, biochemical, ultrasound (US) and TE parameters was performed.

**Results:** Of 201 Veterans, 154 (72%) were stage F0-2 and 56 (28%) had advanced fibrosis (F3-4). DTA generated good discrimination for F0-2 vs. F3-4. Clinical Care Pathway-A (without using TE and US): Using DTA, providers can avoid specialist referral in 93/201 (46%) patients as it correctly predicted stage F0-2 in 94% (87/93). The model generated first split at FIB-4 < 1.34, then absence of gastroesophageal reflux disease (GERD) to diagnose F0-2 with 97% probability. In patients with FIB-4 < 1.34 and GERD (+), gamma-glutamyl transferase of <70 U/L had 88% probability of F0-2. When FIB-4 was ≥1.34, after excluding diabetes patients with obesity, neutrophil lymphocyte ratio of <1.5 had 94% probability of F0-2. Clinical Care Pathway-B: When TE was used with variables in CCP-A, specialist referral can be avoided in 96/201 (48%) patients with stage F0-2 correctly predicted in 90% (89/96). The model generated first split at liver stiffness (kPa) <9.7 to diagnose F0-2 with 91% probability. When kPa ≥9.7, a FIB-4 < 1.53 and absence of GERD had 96% probability of diagnosing F0-2. Clinical Care Pathway-C: Use of US and TE with all other variables in CCP-A can decrease referral to specialists in 85/201 (42%) patients correctly predicting stage F0-2 in 94%. The model generated first split with spleen size <12.5, then AST < 27 to diagnose F0-2 with 95.5% probability. When AST was ≥27, then kPa <12.4 on TE and patients not on aspirin had 91% probability of F0-2.

**Conclusion:** Using machine learning decision tree analysis models we demonstrate that nearly 50% of U.S. Veterans with NAFLD can be managed by primary care with a small risk (<10%) of missing patients with advanced fibrosis. This resource based diagnostic heuristic for NAFLD merits further evaluation and validation in larger cohorts. If confirmed, this approach may be a major step forward towards identification of U.S. Veterans with NAFLD and advanced liver fibrosis and their linkage to specialty care.

**Agreement in non-invasive fibrosis risk assessments in a primary care NAFLD cohort**

Andrew Schreiner<sup>1</sup>, Sherry Livingston<sup>2</sup>, Justin Marsden<sup>1</sup>, Jingwen Zhang<sup>1</sup>. <sup>1</sup>Medical University of South Carolina, Medicine, Charleston, United States; <sup>2</sup>Medical University of South Carolina, Biostatistics  
Email: schrein@muscc.edu

**Background and aims:** Using natural language processing (NLP) to create a primary care non-alcoholic fatty liver disease (NAFLD)

cohort, we assessed advanced fibrosis risk with the Fibrosis-4 Index (FIB-4) and NAFLD Fibrosis Score (NFS) and evaluated risk score agreement.

**Method:** In this retrospective cohort study of adults with radiographic evidence of hepatic steatosis, we calculated patient-level FIB-4 and NFS scores and categorized them by fibrosis risk. Risk category and risk score agreement was analyzed using weighted kappa, Pearson correlation, and Bland-Altman analyses. A multinomial logistic regression model evaluated the associations between clinical variables and discrepant FIB-4 and NFS results.

**Results:** Of the 767-patient cohort, 71% had either a FIB-4 or NFS score in the indeterminate or high-risk category for fibrosis. Risk categories disagreed in 43% and FIB-4 and NFS scores would have resulted in different clinical decisions in 30% of the sample. The weighted kappa statistic for FIB-4 and NFS category agreement was 0.41 (95% CI: 0.36–0.46) and the Pearson correlation coefficient for log FIB-4 and NFS was 0.66 (95% CI: 0.62, 0.70). The multinomial logistic regression analysis identified Black race (OR 2.64, 95% CI 1.84–3.78) and A1c (OR 1.37, 95% CI 1.23–1.52) with higher odds of having a higher NFS risk category than FIB-4.

**Conclusion:** In a primary care NAFLD cohort, many patients had high FIB-4 and NFS risk scores and these risk categories were often in disagreement. The choice between FIB-4 and NFS for fibrosis risk assessment can impact clinical decision making and may contribute to gaps in quality of care.

Figure: Patient FIB-4 and NFS scores, categorized by advanced fibrosis risk.

		NAFLD Fibrosis Score			Total (%)
		Low NFS ≤ -1.455	Indeterminate -1.455 < NFS ≤ 0.676	High NFS > 0.676	
Fibrosis-4 Index					
Low	FIB-4 ≤ 1.3	222	177	20	419 (55%)
Indeterminate	1.3 < FIB-4 ≤ 2.67	30	152	65	247 (32%)
High	FIB-4 > 2.67	4	37	60	101 (13%)
Total (%)		256 (33%)	366 (48%)	145 (19%)	767

**Background and aims:** Non-alcoholic fatty liver disease (NAFLD) has become the most frequent cause of chronic liver disease. Moreover, fibrosis stage has been identified as the most important predictor of prognosis. The majority of fibrotic NAFLD patients are currently undetected. The general practitioner's (GP) outpatient clinic is usually their first contact in the health care system. The Fibrosis-4 (FIB-4) is a non-invasive score to predict fibrosis based on routine blood parameters and is therefore easy to use in primary care. We aimed to determine whether the FIB-4 is a valuable tool for identifying NAFLD patients with fibrosis for referral to secondary or tertiary care.

**Method:** In a prospective pilot study in the Belgian regions of Limburg, East-Flanders, and Antwerp, patients were invited for screening in five GP practices. The fibrosis stage was determined using Vibration Controlled Transient Elastography (VCTE) by FibroScan<sup>®</sup> (Echosens, France) as a reference method. Based on the most recent laboratory data from the electronic patient file, the FIB-4 was calculated. Cut-off values stated in the guidelines of the Belgian Association for the Study of the Liver were used to grade the FibroScan<sup>®</sup> measurements. To determine the intermediate and high risk of significant liver fibrosis with the FIB-4 score, a cut-off value of 1.3 was used for patients younger than 65 years and 2.0 for patients older than 65 years.

**Results:** Of the 292 patients who signed up for the screening, 151 (51.7%) were male, mean age was 65 ± 12 years, BMI was 28.9 ± 5.6 kg/m<sup>2</sup>, and waist circumference was 107.8 ± 84.5 cm. For 248 (84.9%) patients, both the FIB-4 and VCTE were available. FIB-4 values ≥ 1.3 or 2.0 were present in 64 (26.8%) patients. Of these, 11 (16.4%) had a fibrosis grade F4, four (6.0%) were staged F2-F3 and 52 (77.6%) F0-F1. FIB-4 values ≤ 1.3 or 2.0 were present in 181 (72.9%) patients. Of these, 19 (10.5%) patients had F4, 14 (7.7%) had F2-3 and 148 (81.8%) had a fibrosis grade of F0-F1. This results in a positive predictive value of 22.4%, a negative predictive value of 81.8%, and an overall accuracy of 65.7% for screening of ≥ F2 fibrosis in primary care. Of the 48 ≥ F2 patients diagnosed according to VCTE, only 15 (31.3%) were correctly identified as having fibrosis.

**Conclusion:** The parameters for calculating the FIB-4 score were available in more than 80% of patients in primary care in Belgium. However, the use of the FIB-4 score has only moderate accuracy to correctly identify patients with significant fibrosis for referral: missing 69% of cases, and the false-positive rate is high. Therefore, we suggest evaluating other test strategies in primary care for referral of fibrotic NAFLD patients to secondary and tertiary care centres.

### PO-1927

#### In vivo SPECT imaging of steatohepatitis in NAFLD preclinical models using VCAM-1 nanobody: a proof-of-concept study

Email: maxime.nachit@gmail.com

**Background and aims:** We lack non-invasive tools to detect the presence of liver inflammation (i.e. steatohepatitis) in patients with non-alcoholic fatty liver disease (NAFLD). Vascular cell adhesion molecule-1 (VCAM-1) is a vascular protein that contributes to *in situ* recruitment of inflammatory cells. Here, we evaluated the hepatic expression of VCAM-1 in relation to liver inflammation severity in preclinical NAFLD models. Next, we performed *in vivo* imaging of VCAM-1 as to detect liver inflammation using <sup>99m</sup>Tc-cAbVCAM1-5.

**Method:** C57BL6/J mice fed a choline deficient (MCD) or a normal diet (ND) were injected either with <sup>99m</sup>Tc-cAbVCAM1-5 (V-MCD) or an irrelevant control (C-MCD) to evaluate the specificity of VCAM-1 imaging in a fast model of liver inflammation. Wild-type (WT) and FOZ mice fed a high fat diet (WT HF and FOZ HF) or control WT mice fed a normal diet (WT ND), and C57BL6/J fed a choline- deficient (CDH) or supplemented (CSH) fat rich diet, were employed as murine models of NAFLD. Liver histology was evaluated with NAS score and digital automated analysis. We measured liver VCAM-1 and proinflammatory markers expression using RT-qPCR and VCAM-1 protein content with ELISA. Liver inflammation was monitored by single-photon emission computed tomography (SPECT) following mice injection of a <sup>99m</sup>Tc-cAbVCAM1-5. <sup>99m</sup>Tc-cAbVCAM1-5 liver uptake was measured *in vivo* and expressed either as a concentration (SUV: standard uptake value) or as a total uptake (%ID Liver<sub>in-vivo</sub>: % of injected dose).

Figure: (abstract: PO-1927)

**Results:** Proinflammatory marker MCP1 was markedly elevated in V-MCD and C-MCD when compared to Ctl (up to 15-fold,  $p < 0.0001$ ). V-MCD, but not C-MCD, had up to 2-fold increase of SUV Liver when compared to Ctl ( $0.48 \pm 0.11$  vs  $0.28 \pm 0.04$  and  $0.26 \pm 0.03$ , respectively,  $p < 0.001$ ) thus confirming the high specificity of  $^{99m}\text{Tc}$ -cAbVCAM1-5. NAFLD was found in WT HF, FOZ HF, CDH and CSH (steatosis score:  $1.2 \pm 0.7$ ,  $3.0 \pm 0.0$ ,  $3.0 \pm 0.0$  and  $0.8 \pm 0.4$ , respectively) with severe or mild steatohepatitis in FOZ HF and CDH or in WT HF and CSH, respectively (inflammation score:  $2.7 \pm 0.5$  and  $3.0 \pm 0.0$  vs  $1.0 \pm 0.6$  and  $0.7 \pm 0.5$ ). VCAM-1 expression was higher in mice with NAFLD when compared to Ctl (FOZ HF:  $7.61 \pm 2.28$ , CDH:  $8.29 \pm 4.52$ , WT HF:  $1.40 \pm 0.70$  and CSH:  $2.74 \pm 0.38$  fold) and was highly correlated with the expression of proinflammatory marker F4/80 and MCP1 ( $r = 0.97$  and  $r = 0.77$ , respectively,  $n = 30$ ,  $p < 0.0001$ ). The % ID Liver<sub>in-vivo</sub> of VCAM-1 was respectively 6-fold and 3-fold higher in FOZ HF and CDH liver than in controls and was strongly correlated with histological inflammatory score ( $r = 0.86$ ,  $p < 0.0001$ ,  $n = 31$ ) (Fig. 1). %ID Liver<sub>in-vivo</sub> of VCAM-1 robustly distinguishes steatohepatitis from simple steatosis in mice with NAFLD (AUROC = 0.89, 95% CI 0.72–1.00,  $p = 0.035$ ).

**Conclusion:**  $^{99m}\text{Tc}$ -cAbVCAM1-5 is suitable to detect liver inflammation and distinguish steatohepatitis from steatosis *in vivo* in NAFLD preclinical models.

**PO-1981**

**Non-invasive LIVERFAST transition rate to liver fibrosis is similar to that estimated with liver biopsy in NAFLD patients**

Email: mona\_munteanu@hotmail.com

**Background and aims:** Due to the high prevalence of NAFLD and the drawbacks of liver biopsy (LB) including the poor acceptance, its routine use is limited. There is an urgent need for reliable non-invasive tools (NITs) of differentiating NAFL from NASH and disease staging. Moreover, screening non-invasively for NASH fibrosis in Type 2 diabetes (T2D) patients (pts) is mandatory, as liver enzymes are often normal despite advanced fibrosis. LIVERFAST (LF) is a serum NIT with CPT code for assessing liver fibrosis (LF-Fib) along with activity and steatosis and with prognostic value to predict mortality and morbidity (overall and liver-related). (submitted). The aim was to demonstrate that LF-Fib is an alternative to LB for the estimation of the transition rate to fibrosis [transition to stage F1 or more (TRF)] in T2D and noT2D, comparatively to other NITs [FIB-4, liver stiffness measurement (LSM) by Fibroscan].

**Method:** TRF was evaluated using Cox-Mantel Hazard Ratio [HR (95% CI) and logrank comparison,  $p$  value  $< 0, 05$ ] with a modeling of hazard from birth to age of LB or NIT in a prospectively collected NAFLD population evaluated for fibrosis with LB, and 3 concomitant NITs (LF-Fib, LSM, FIB4). NITs cut-offs with highest sensitivity for minimal fibrosis were used (0.28, 1.45 and 5.6 kPa, respectively).

**Results:** N = 583 pts were included, 52% T2D, 56% males, median (range) age 59.5 (18–85), HbA1c 6.6% (4.7–12), BMI 31.5 (20–54) kg/m<sup>2</sup> (obesity 59%), mean (SE) time lapse between LB and NITs 1.7 (0.4) months. The estimation of TRF [HR (95% CI)] using LF-Fib was similar to that using LB in both T2D [0.67 (0.56–0.80) vs. 0.65 (0.54–0.79)], and noT2D [1.50 (1.26–1.78) vs. 1.54 (1.27–1.86)], respectively, with earlier TRF in noT2D compared to T2D (logrank  $p < 0.0001$ ). The TRF of TE and FIB4 were also similar to LB however, less fit in both T2D and noT2D groups for both TE [0.75 (0.63–0.89) vs 1.34 (1.12–1.60),  $p < 0.001$ ] and FIB4 [0.79 (0.63–0.99) vs 1.26 (1.01–1.59),  $p < 0.05$ ], respectively. In pts having ALT > 30 IU compared to those with ALT ≤ 30 IU, the TRF was faster in noT2D [2.13 (1.55–2.95) vs 0.47 (0.34–0.65), logrank  $p < 0.001$ ] and not significantly different in T2D [1.28 (0.93–1.75) vs 0.78 (0.57–1.07),  $p = \text{ns}$ ]. In multivariate analysis, including NITs, arterial hypertension (AHT), HbA1c and BMI, only AHT, BMI ≥ 35, male gender, FIB-4 and LF (Ste, Act and Fib) were significantly associated to TRF in T2D (all  $p < 0.001$ ) and the same with the exception of BMI and FIB-4 in noT2D ( $p < 0.0001$  for AHT and LF,  $p < 0.05$  for male gender).

**Hazard Rate Plot HR (95%CI, logrank) for the transition to fibrosis according to:**

## POSTER PRESENTATIONS

**Conclusion:** Validated biomarkers such as LIVERFAST should allow a powerful analysis of fibrosis progression in NAFLD, similar to LB and better screening strategies for stratifying patients.

### PO-2030

#### Screening of advanced liver fibrosis in patients with coronary arterial disease, the CORONASH Study

Thierry Thévenot<sup>1</sup>, Sophie Vendeville<sup>1</sup>, Linda Akkouche<sup>2</sup>, Delphine Weil-Verhoeven<sup>1</sup>, Claire Vanlemmens<sup>1</sup>, Carine Richou<sup>1</sup>, Jean Paul Cervoni<sup>1</sup>, Marie-France Seronde<sup>2</sup>, Jerome Boursier<sup>3</sup>, Vincent Di Martino<sup>1</sup>. <sup>1</sup>CHU Besançon, Hepatology, Besançon, France; <sup>2</sup>CHU Besançon, Cardiology, Besançon, France; <sup>3</sup>CHU Angers, Hepatology, Angers, France  
Email: tthevenot@chu-besancon.fr

**Background and aims:** It has been previously suggested an association between coronary arterial disease (CAD) and advanced liver fibrosis (ALFib) in patients with non-alcoholic fatty liver disease (NAFLD) selected by liver biopsy. However, the “real-life” prevalence of ALFib and the results of non-invasive fibrosis tests (NITs) in patients with CAD have never been evaluated so far. This study reports a systematic screening of ALFib in patients with proved CAD.

**Method:** Consecutive patients aged  $\leq 70$  yrs with significant stenosis at coronarography were prospectively included. ALFib was suspected on biochemical NIT using the following cutoffs: APRI  $\geq 1.5$ , Forns  $\geq 6.9$ , NAFLD fibrosis score (NFS)  $\geq 0.676$ , Fib4  $\geq 2.67$  and eLIFT  $\geq 8$ . All patients underwent Fibroscan examination (FS), and liver biopsy was proposed in case of suspected ALFib (FS  $\geq 8$  kPa). Results were given in intent-to-screen FS  $\geq 8$  kPa.

**Results:** 199 patients (males 81%; age  $60 \pm 7$  yrs; BMI  $28 \pm 4$  kg/m<sup>2</sup>; metabolic syndrome 57%; diabetes 30%; normal serum ALT 92%) were included in the study. Liver stiffness was  $\geq 8$  kPa in 10 patients (5%) and 5 of them underwent liver biopsy (F3/F4: n = 3; no fibrosis: n = 2). According to NITs, ALFib was suspected in 32% of the patients using eLIFT (specificity for FS  $\geq 8$  kPa, Sp 69%), 14% with Forns (Sp 19%), 6% with NFS (Sp 62%), 3% with Fib4 (Sp 75%), and 1% with APRI (Sp 91%). In selected “high-risk NAFLD subgroup” (111 patients with  $\geq 1$  of the following conditions: elevated ALT, diabetes, hypertriglyceridemia or BMI  $\geq 30$  kg/m<sup>2</sup>), the proportion of patients with ALFib using the combined intermediate and high-risk zones of NITs ranged between 14% (APRI) to 86% (Forns). In this “high-risk subgroup,” the best strategy to minimize the number of patients referred for FS examination because of positive NIT (Sp) and to maximize sensitivity (Se) was to use eLIFT (Se 63%, Sp 67%) or NFS (Se 63%, Sp 67%). Using eLIFT, 39 “high-risk” patients (20% of the study population) were considered at risk of ALFib, 5 of them had FS  $\geq 8$  kPa among whom 3 were biopsied and were F3/F4. Using NFS, 58 “high-risk” patients had ALFib, 5 of them had FS  $\geq 8$  kPa among whom 2 were biopsied and were F3/F4.

**Conclusion:** Screening of ALFib in CAD patients could be implemented by cardiologists using a simple two-step procedure: the first step identifies “high-risk NAFLD patients” using common risk factors, and the second step calculates the user-friendly eLIFT to determine which patients need to be referred for a Fibroscan.

### PO-2369

#### Current non-invasive tests have suboptimal performance for the identification of candidates for pharmacological therapy for pre-cirrhotic non-alcoholic steatohepatitis.

Jesús Rivera<sup>1</sup>, Jose Luis Calleja<sup>2</sup>, Rocio Aller<sup>3</sup>, Hugo Gonzalo-Benito<sup>3</sup>, María Teresa Arias Loste<sup>4</sup>, Paula Ireuzubieta<sup>4</sup>, Javier Ampuero<sup>5</sup>, Ana Lucena<sup>5</sup>, Yolanda Sanchez<sup>5</sup>, Manuel Romero-Gomez<sup>5</sup>, Salvador Augustin<sup>1</sup>, Javier Crespo<sup>4</sup>. <sup>1</sup>Vall d'Hebron Hospital

Email: jesusriveraest@gmail.com

**Background and aims:** The clinical burden of non-alcoholic steatohepatitis (NASH) is growing rapidly, but still there are no approved therapies. Under the current regulatory framework, upcoming therapies are being targeted to patients with biopsy-proven NASH with fibrosis stage 2–3 and NAFLD Activity Score (NAS)  $\geq 4$ . Non-invasive identification of these pre-cirrhotic pharmacological-therapy candidate patients (PTCP) is challenging. The aim of this study was to evaluate different diagnostic strategies based on non-invasive tests (NITs) to identify pre-cirrhotic PTCP.

**Method:** This was an observational, multi-centric, retrospective, cross-sectional study in 501 consecutive patients with biopsy-proven NASH with paired clinical and elastography data from 5 tertiary centers in Spain between 2015–2020. Patients with liver stiffness (LS)  $< 7$  kPa were excluded, under the assumption that in practice these patients will not be followed-up in specialized clinics. We also excluded patients with LS  $> 25$  kPa due to the low prevalence of PTCP above that value ( $< 15\%$ ), in line with usual clinical practice. In the targeted LS 7–25 kPa NASH population, diagnostic accuracy for PCTP histological criteria was analyzed for the most commonly recommended NITs in NASH (FIB4, NFS, LS, FAST), using the usual cutoffs for maximizing sensitivity (Se) or specificity (Sp) for each NIT.

**Results:** Among the 501 patients, 77 (15%) had LS  $< 7$  kPa and 39 (8%) had LS  $> 25$  kPa and were excluded for analysis. Among the remaining 385 patients with LS 7–25 kPa, 109 (28%) fulfilled histological PCTP criteria. Diagnostic accuracy for ruling in/out PCTP criteria was poor for the usual cutoffs for FIB-4 and NFS (negative predictive values, NPV,  $< 80\%$  and positive predictive values, PPV,  $< 35\%$ ). In this population, the strategy of performing a biopsy only in all patients with LS  $> 10$  kPa did not increase the detection yield (PPV 29%). Of all NITs tested, only FAST had a potentially useful diagnostic accuracy: Se and NPV for 0.35 cutoff were 0.92 and 90%, respectively, and Sp and PPV for 0.67 cutoff 0.74 and 49%, respectively. Only 32% of patients had FAST  $> 0.67$ . Thus, among the LS 7–25 population, only 16% [ $(0.32 \times 0.49) \times 100$ ] fulfilled PCTP criteria.

**Conclusion:** Pre-cirrhotic PTCP represent a small proportion of all the patients currently seen in specialized NASH clinics. Use of some NITs (such as the FAST score) improve the ability to identify these patients as compared to use of TE alone, but still half of the patients selected for biopsy with FAST will not fulfill PCTP histological criteria. Better NIT-based strategies are urgently needed to identify candidates for inclusion in trials and for implementation of effective therapies.

Figure:

	Cutoff	Sn (%)	Sp (%)	PPV (%)	NPV (%)
FIB-4	1.30	70.6	45.2	34.8	78.8
	2.67	15.5	87.4	34.0	71.4
NFS	-1.45	70.3	29.8	29.3	70.9
	0.67	13.8	85.8	28.8	70.6
LS	10 kPa	64.2	37.2	29.5	71.7
FAST	0.35	91.6	30.8	36.2	89.6
	0.67	55.2	75.5	49.0	79.8

**Background and aims:** Multiparametric MRI is a promising technique to assess hepatic steatosis as well as inflammation and fibrosis, potentially enabling non-invasive identification of individuals with active and advanced stages of NAFLD. We aimed to examine the diagnostic performance of multiparametric MRI for assessment of disease severity along the NAFLD disease spectrum compared to histology.

**Method:** Histological steatosis grades were compared to proton density fat fraction measured by MR spectroscopy (PDFF<sub>MRS</sub>), magnitude-based MRI (PDFF<sub>MRI-M</sub>) and 3-point-Dixon (PDFF<sub>Dixon</sub>), as well as FibroScan<sup>®</sup> controlled attenuation parameter (CAP). Fibrosis and disease activity were compared to intravoxel incoherent motion (IVIM) MRI and MR elastography (MRE). FibroScan<sup>®</sup> liver stiffness measurements (LSM) were compared to fibrosis levels. Diagnostic performance of all imaging parameters was determined for distinction between simple steatosis and NASH.

**Results:** 37 patients with NAFLD were included. Histological steatosis grade correlated significantly with PDFF<sub>MRS</sub> ( $r_s = 0.66$ ,  $p < 0.001$ ), PDFF<sub>MRI-M</sub> ( $r_s = 0.68$ ,  $p < 0.001$ ) and PDFF<sub>Dixon</sub> ( $r_s = 0.67$ ,  $p < 0.001$ ), whereas no correlation was found with CAP. MRE and IVIM diffusion and perfusion significantly correlated with both disease activity ( $r_s = 0.55$ ,  $p < 0.001$ ;  $r_s = -0.40$ ,  $p = 0.016$ ;  $r_s = -0.37$ ,  $p = 0.027$  resp.) and fibrosis ( $r_s = 0.55$ ,  $p < 0.001$ ;  $r_s = -0.46$ ,  $p = 0.0051$ ;  $r_s = -0.53$ ,  $p < 0.001$  resp.). Of the MRI parameters, MRE and IVIM diffusion had the highest area-under-the-curve for distinction between simple steatosis and NASH (0.79 and 0.73 resp.). Specificity was highest for MRE (86.7%) and sensitivity for IVIM diffusion (85.7%).

Figure:

	AUROC	CUT-OFF VALUES	SENSITIVITY (%)	SPECIFICITY (%)
MRE	0.79	2.27 kPa	70	86.7
FIBROSCAN <sup>®</sup>	0.73	9.9 kPa	63.6	86.7
LSM				
IVIM D	0.73	0.0012 mm <sup>2</sup> /s	85.7	53.3
IVIM F	0.68	22.90%	81	53.3
FIBROSCAN <sup>®</sup>	0.65	336 m/s	77.3	53.3
CAP				
IVIM D*	0.58	0.10 mm <sup>2</sup> /s	47.6	80
PDFF <sub>MRI-M</sub>	0.57	23.72%	40.9	86.7
PDFF <sub>MRS</sub>	0.56	21.19%	45.5	73.3
PDFF <sub>DIXON</sub>	0.52	21.84%	33.3	86.7

**Conclusion:** Multiparametric MRI is a promising method for non-invasive, accurate and sensitive distinction between simple hepatic steatosis and NASH, as well as for the assessment of steatosis and fibrosis severity.

**PO-2710**

**Gamma-Glutamyl Transpeptidase Dynamics as a Biomarker for Advanced Fibrosis in Non-Alcoholic Fatty Liver Disease**

Yeonjung Ha<sup>1</sup>, Joo Ho Lee<sup>1</sup>, Seong Gyu Hwang<sup>1</sup>. <sup>1</sup>CHA Bundang Medical Center, CHA University, Gastroenterology, Seongnam-si, Korea, Rep. of South Korea  
 Email: yeonjung.ha@gmail.com

**Background and aims:** Abnormal lipid profiles and liver biochemistry are common in non-alcoholic fatty liver disease (NAFLD). However, it is unclear whether changes in blood tests are associated with advanced fibrosis.

**Method:** Patients diagnosed with NAFLD between 2009 and 2017 at a health check-up were included. The changes in blood tests were calculated using the following formula: [(value at 6-month-value at baseline)/value at baseline] × 100. The end point was advanced fibrosis determined by the NAFLD fibrosis score, calculated every year from the index date until 2019. Cox proportional hazards models were used to identify factors predicting advanced fibrosis.

**Results:** After a median follow-up of 31.7 (19.4–50.8) months, advanced fibrosis occurred in 64 (6.3%) of 1021 patients. The advanced fibrosis group was older and had a higher prevalence of obesity, hypertension, or diabetes ( $P_s < 0.05$ ). Gamma-glutamyl transpeptidase (GGT) levels (72.9 vs. 51.1 IU/L;  $P = 0.23$ ) and  $\Delta$ GGT (+6.0% vs. -6.9%;  $P = 0.06$ ) were higher in the advanced fibrosis group. After multivariate adjustment,  $\Delta$ GGT (hazard ratio [HR] 1.03;  $P < 0.001$ ), age, and platelet counts were significantly associated with advanced fibrosis. The positive  $\Delta$ GGT group showed a higher incidence of advanced fibrosis than the negative group ( $p = 0.01$ ). The 1-standard deviation increment in  $\Delta$ GGT showed a significant association with advanced fibrosis both in statin users (HR, 1.35) and in non-users (HR, 1.31;  $P_s < 0.001$ ). The restricted cubic spline model identified a positive correlation between  $\Delta$ GGT and the NAFLD fibrosis scores ( $p < 0.001$ ). The sensitivity analysis showed consistent results.

**Conclusion:**  $\Delta$ GGT calculated at 6 months following NAFLD diagnosis is associated with advanced fibrosis.

PO-2739

## In type-2 diabetic patients, the identification of at-risk NASH is impacted by age: a comparison of serum-based NITs including NIS4

Vlad Ratziu<sup>1</sup>, Jeremy Magnanensi<sup>2</sup>, Sylvie Deledicque<sup>2</sup>, Elodie Delecroix<sup>2</sup>, Yacine Hajji<sup>2</sup>, Christian Rosenquist<sup>2</sup>, Suneil Hosmane<sup>2</sup>, Arun Sanyal<sup>3</sup>. <sup>1</sup>Sorbonne Université, Institute for Cardiometabolism and Nutrition, Hôpital Pitié-Salpêtrière, Paris, France; <sup>2</sup>Genfit, Loos, France; <sup>3</sup>VCU School of Medicine, Department of Internal Medicine, Richmond, United States  
Email: arun.sanyal@vcuhealth.org

**Background and aims:** At-risk NASH, defined as NASH with a NAFLD Activity Score  $\geq 4$  and fibrosis stage  $\geq 2$ , is associated with high risk of disease progression. The risk is substantially modulated by age and type-2 diabetes (T2D). EASL guidelines recommend screening patients (pts) with T2D for at-risk NASH using a NIT-based algorithm, which implies robust NIT performance across all pts ages. This work investigated the effect of age on NITs performance for the identification of at-risk NASH, particularly among pts with T2D.

**Method:** 1129 pts with T2D screened for a phase 3 NASH trial (NCT02704403) with available data for NIS4<sup>TM</sup>, FIB-4, NFS, and ELF were analysed. Pts were stratified by age into 4 groups ( $\leq 45$  yo, N = 146; 46–55 yo, N = 306; 56–64 yo, N = 394;  $\geq 65$  yo, N = 283). Sensitivity (Se), specificity (Sp), positive predictive value (PPV), negative predictive value (NPV) and percentage of pts in the moderate risk zone were computed for each NIT within the specified age group, using either published low (Lc) and high (Hc) cut-offs and new optimized ones. Area under the curve (AUC) was used for comparison within each age group, independent of cut-offs values.

**Results:** Prevalence of at-risk NASH, defined histologically, ranged from 60 to 66% across age groups. In both not-at-risk and at-risk NASH pts, NIS4<sup>TM</sup>, FIB-4, NFS and ELF mean values increased with age. Published cut-offs were not optimal across age groups for any NIT (FIB-4: 3–24% Se at Hc, NFS: 6–25% Se at Hc, ELF: 0–7% Sp at Lc, NIS4<sup>TM</sup>: 30–44% Sp at Lc). We computed new Lc and Hc to respectively achieve 80% Se and 90% Sp in each age group. Even with optimized cut-offs, NFS had the lowest performance (18–31% Sp at Lc, 8–18% Se at Hc, 0.5–0.63 AUC) and the largest proportion of pts in the moderate risk zone (61–71%). FIB-4 and ELF achieved reasonable performance for 46–55 and  $\leq 45$  yo age groups, respectively (0.74 AUC). NIS4<sup>TM</sup>

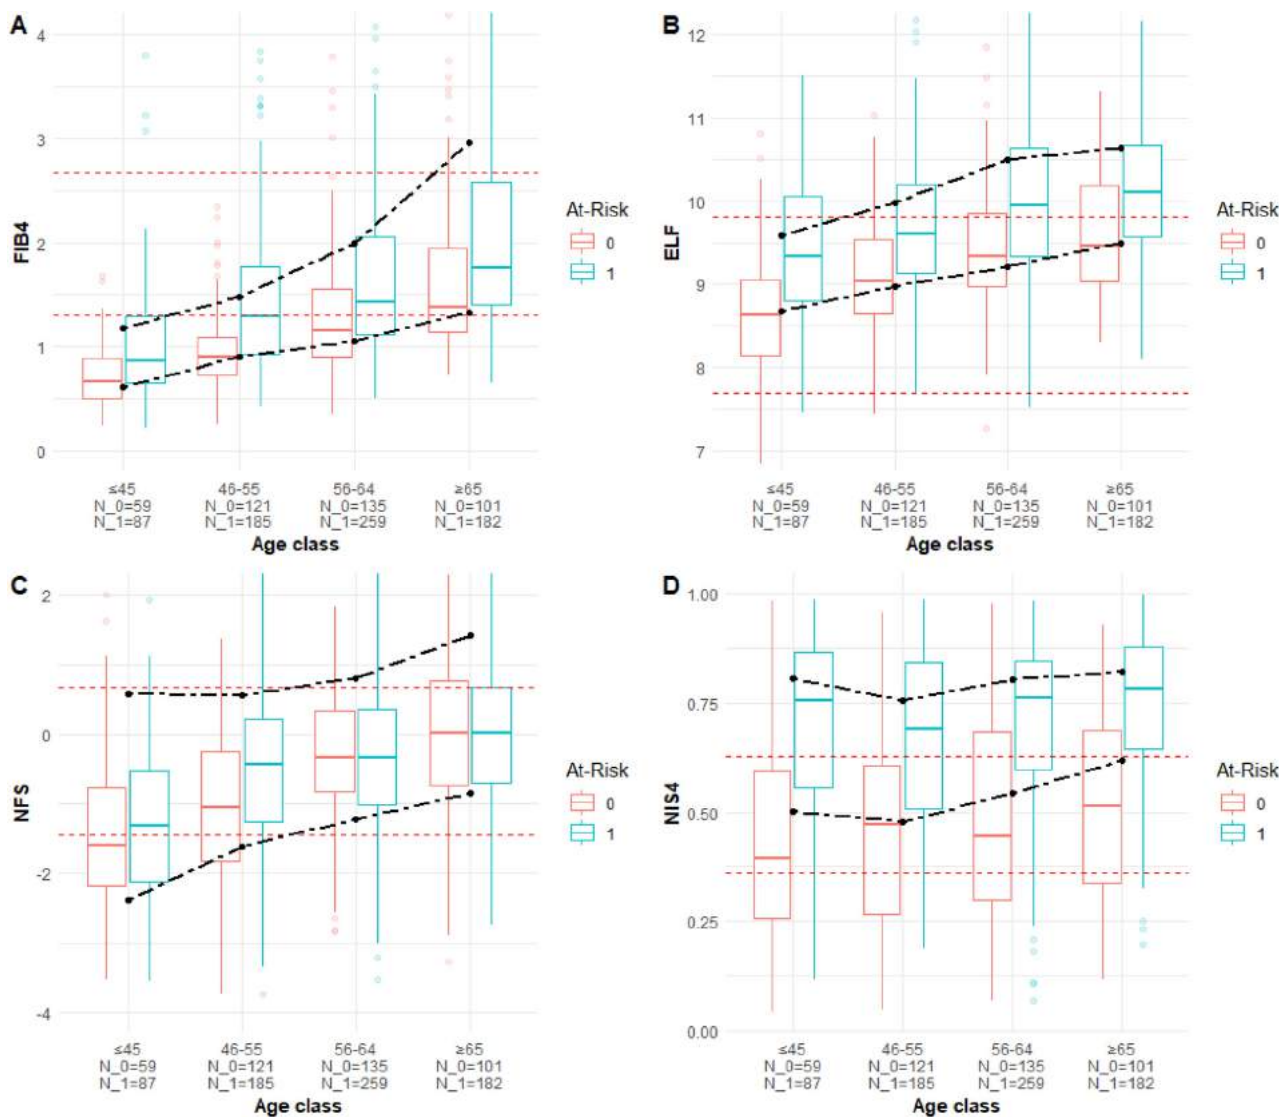

Figure: (abstract: PO-2739): Red dashed lines stand for published cut-offs, black two-dashed lines for “optimized” cut-offs.

globally outperformed all other NITs: 51–63% Sp at Lc, 37–43% Se at Hc, 62–69% NPV, 85–89% PPV, AUC of 0.76–0.79 and a proportion of pts in the moderate risk zone of only 33–41%.

**Conclusion:** Age significantly impacts the performance of NITs for the diagnosis of at-risk NASH and therefore age-adapted cut-offs should be factored in the interpretation of the results. NFS is not performant for the identification of at-risk NASH in pts with T2D. NIS4™ was the most robust NIT across all age groups. It outperformed all other NITs in diagnosing at-risk NASH among pts with T2D, in particular in those aged ≥55 yo which are at highest risk of disease progression.

## NAFLD: Experimental and pathophysiology

### PO-195

#### Role of Mcpip1 in obesity-induced hepatic steatosis as determined by myeloid and liver-specific conditional knockouts

Natalia Pydyn<sup>1</sup>, Dariusz Zurawek<sup>1</sup>, Joanna Koziel<sup>2</sup>, Edyta Kus<sup>3</sup>, Kamila Wojnar-Lason<sup>3</sup>, Agnieszka Jaształ<sup>3</sup>, Mingui Fu<sup>4</sup>, Jolanta Jura<sup>1</sup>, Jerzy Kotlinowski<sup>1</sup>. <sup>1</sup>Faculty of Biochemistry, Biophysics and Biotechnology, Jagiellonian University, Department of General Biochemistry, Kraków, Poland; <sup>2</sup>Faculty of Biochemistry, Biophysics and Biotechnology, Jagiellonian University, Department of Microbiology, Kraków, Poland; <sup>3</sup>Jagiellonian Centre for Experimental Therapeutics, Jagiellonian University, Kraków, Poland; <sup>4</sup>School of Medicine, University of Missouri, Department of Biomedical Science and Shock/Trauma Research Center, Kansas City, United States  
Email: j.kotlinowski@uj.edu.pl

**Background and aims:** Monocyte chemoattractant protein-induced protein 1 (MCP1P1) is a negative regulator of inflammation, acting through cleavage of transcripts coding for proinflammatory cytokines and by inhibition of NFκB activity. Moreover, it was demonstrated, that MCP1P1 regulates lipid metabolism both in adipose tissue and hepatocytes. In this study, we investigated the effects of tissue-specific Mcpip1 deletion on the regulation of hepatic metabolism and development of non-alcoholic fatty liver disease (NAFLD).

**Method:** We used control Mcpip1<sup>fl/fl</sup> mice and animals with deletion of Mcpip1 in myeloid leukocytes (Mcpip1<sup>fl/fl</sup>LysM<sup>Cre</sup>) and in liver cells (Mcpip1<sup>fl/fl</sup>Alb<sup>Cre</sup>), which were fed chow or a high-fat diet (HFD) for 12 weeks.

**Results:** Mcpip1<sup>fl/fl</sup>LysM<sup>Cre</sup> mice fed a chow diet were characterized by reduced hepatic expression of genes regulating lipid and glucose metabolism, which resulted in decreased glucose concentration and dyslipidemia. These animals displayed also systemic inflammation manifested by increased serum levels of Il-6, Il-12, Il-16, Tnf-alpha, Mcp-2, Mip-1 alpha and hepatic leukocyte infiltration. Although we detected a reduced hepatic expression of genes regulating glucose metabolism and β-oxidation in the Mcpip1<sup>fl/fl</sup>Alb<sup>Cre</sup> mice, they did not develop any abnormalities related to lipid metabolism. Despite feeding with HFD for 12 weeks, Mcpip1<sup>fl/fl</sup>LysM<sup>Cre</sup> mice did not develop obesity, glucose intolerance, nor hepatic steatosis. Mcpip1<sup>fl/fl</sup>Alb<sup>Cre</sup> animals, following a HFD, became hypercholesterolemic, but accumulated lipids in the liver at the same level as Mcpip1<sup>fl/fl</sup> mice.

**Conclusion:** In conclusion, we demonstrated that Mcpip1 protein plays an important role in the liver homeostasis. Depletion of Mcpip1 in myeloid leukocytes, followed by systemic inflammation, has a more pronounced effect on controlling liver metabolism and homeostasis than its deletion in liver cells.

**Acknowledgments:** This study was supported by National Science Centre, grant number 2015/19/D/NZ5/00254.

#### Transcriptomics identifies longitudinal biomarker gene signatures of NASH fibrosis regressors

Christina Ebert<sup>1</sup>, Narayanan Raghupathy<sup>1</sup>, Elizabeth Brown<sup>1</sup>, Alice Walsh<sup>1</sup>, Edgar Charles<sup>1</sup>, Yi Luo<sup>1</sup>, Peter Schafer<sup>1</sup>, Leon Carayannopoulos<sup>1</sup>, Lei Zhao<sup>1</sup>, Francisco Ramirez-Valle<sup>1</sup>, David Gordon<sup>1</sup>, Raymond Chung<sup>2</sup>, Kathleen Corey<sup>2</sup>. <sup>1</sup>Bristol Myers Squibb, Lawrence Township, United States; <sup>2</sup>Massachusetts General Hospital/Harvard Medical School, Boston, United States  
Email: kathleen.corey@mgh.harvard.edu

**Background and aims:** Non-alcoholic steatohepatitis (NASH) prevalence is estimated at 1.5–6.5% globally and can progress to cirrhosis, liver failure and hepatocellular cancer. NASH, a complex and heterogeneous disease associated with both environmental and genetic risk factors, has no effective treatment other than lifestyle intervention. Developing an understanding of NASH at the molecular level could lead to potential prognostic and patient stratification biomarkers, and novel therapeutic hypotheses. In this study, we used longitudinal RNA-seq data to identify hepatic genes/gene signatures associated with NASH fibrosis regression to understand NASH pathophysiology, which may provide a basis for exploration of non-invasive biomarkers of disease regression.

**Method:** High quality RNA from FFPE liver tissues from 47 biopsy-proven NASH patients, collected at Massachusetts General Hospital Fatty Liver Clinic at baseline (METAVIR F0-F3) and follow-up (METAVIR F0-F4) within 8 years, were sequenced by Illumina RNA-seq. To perform longitudinal analysis, individuals were grouped based on change in disease stage from baseline to follow-up. NASH fibrosis regressors (13 out of 47 patients) were defined as individuals whose fibrosis stage improved by ≥1 stage from baseline to follow-up. Principal Component (PC) analysis was used after adjusting for covariates such as age and RNA quality to identify genes/gene signatures associated with biological signals in regressors.

**Results:** Transcriptomic analysis of regressors identified over 490 genes highly correlated with the first PC that captured the effect of time points under stringent 0.9 Spearman rank correlation. Analysis of these genes revealed significant gene signatures reflecting several mechanistic pathways associated with NASH including ECM remodeling, immune response, lipid metabolism, and cell death. These genes include some previously identified, such as C7 and CD24, and novel biomarkers of steatosis, fibrosis and NASH.

**Conclusion:** We have identified gene signature changes associated with a favorable prognostic outcome in NASH patients who are likely to regress in fibrosis stage. These findings provide a framework for the development of potential prognostic models of fibrosis regression using composite panels of biomarkers, which enable patient stratification.

Email: justine.gillard@uclouvain.be

**Background and aims:** We previously reported that *foz/foz* mice with NASH (NAFLD Activity Score (NAS)  $\geq 7$ ) have a markedly altered bile acid pool with low concentration in secondary deoxycholic acid (DCA) in bile and portal blood compared to WT mice (NAS  $\leq 1$ ). Perturbed bile acid pool results in reduced activation of the Takeda G-protein coupled receptor 5 (TGR5), a receptor mainly activated by secondary bile acids and that regulates lipid and glucose homeostasis, energy expenditure, inflammation and fibrosis. Low TGR5 agonism and resulting low TGR5 signaling could thereby contribute to NASH pathogenesis in this experimental model. We thus sought whether a modulation of the bile acid pool could prevent NASH.

**Method:** *Foz/foz* mice received a high fat diet (HFD) enriched or not with 0.03% or 0.1% of DCA for 12 weeks. They were compared to 12 weeks HFD-fed WT mice (n = 7 per group). Portal blood and tissues were sampled after 12 hours of fasting and 4 hours of refeeding. Bile acid profile was established by LC-MS/MS. We used a cell reporter assay, HEK293T cells overexpressing TGR5 and a CRE luciferase reporter, to quantify TGR5 ligand activity.

**Results:** A HFD supplemented with 0.1% DCA, but not 0.03%, increased total bile acids as well as cholic and deoxycholic acids concentrations in portal blood of *foz/foz* mice, to values seen in WT mice. While very low in HFD-fed *foz/foz* mice, the activation of TGR5 as measured in a reporter assay was higher when mice were supplemented by DCA 0.1%. While 0.03% DCA did not improve metabolic features in HFD-fed *foz/foz* mice, 0.1% DCA significantly reduced body weight gain and fat mass, despite an increased food intake. Glucose intolerance, fasting glycemia and insulinemia were also lowered by 0.1% DCA. As shown in the figure, 0.03% DCA did not

significantly change liver weight, hepatic steatosis or inflammation and slightly decreased the histological NAS compared to HFD-fed *foz/foz* mice. By contrast, 0.1% DCA reduced liver weight, hepatic steatosis and ballooning. Although inflammation continued, 0.1% DCA treatment significantly decreased NAS such as six out of the seven *foz/foz* mice treated with 0.1% DCA did not have NASH.

**Conclusion:** Supplementation of the HFD with a secondary bile acid restored bile acid pool and TGR5 agonism and in consequence, prevented the development of NASH and associated metabolic features in this mouse model.

PO-475

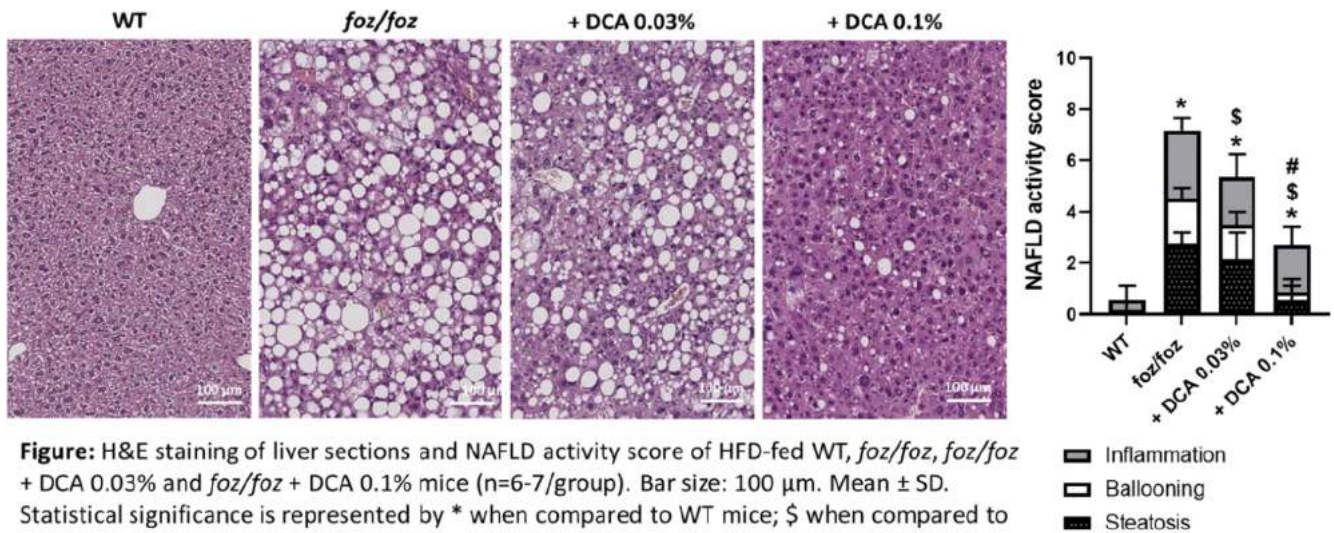

### Inactivation of ACSL5, an interacting protein of TM6SF2, results in decreased plasma TG and cholesterol without affecting hepatic lipids

Fei Luo<sup>1,2,3</sup>, Eriks Smagris<sup>2</sup>, Jonathan Cohen<sup>4</sup>, Helen Hobbs<sup>2,4,5</sup>. <sup>1</sup>The Second Xiangya Hospital of Central South University, Department of Cardiovascular Medicine, Changsha, China; <sup>2</sup>University of Texas Southwestern Medical Center at Dallas, Molecular Genetics; <sup>3</sup>The Second Xiangya Hospital of Central South University, Department of Cardiovascular Medicine; <sup>4</sup>University of Texas Southwestern Medical Center at Dallas, Internal Medicine; <sup>5</sup>Howard Hughes Medical Institute  
Email: Helen.Hobbs@utsouthwestern.edu

**Background and aims:** Transmembrane 6 Superfamily Member 2 (TM6SF2) is a polytopic protein that is expressed predominantly in liver and small intestines. A missense variant in *TM6SF2* (E167K) is strongly associated with alcoholic and non-alcoholic fatty liver disease (FLD) as well as hypocholesterolemia. Mice expressing no *TM6SF2* (*Tm6sf2*<sup>-/-</sup>) also have FLD and reduced plasma lipid levels. *TM6SF2* is required for normal lipidation of ApoB-containing apolipoprotein; *Tm6sf2*<sup>-/-</sup> have a reduced rate of secretion of VLDL-TG but not of ApoB secretion. To glean possible insights into how *TM6SF2* promotes lipidation of VLDL, we identified proteins that interact physically with *TM6SF2*.

**Method:** Proteins that co-immunoprecipitated (Co-IP) with *TM6SF2* were identified using mass spectrometry. Mouse embryonic stem cells with an inactivated *Acs15* allele were used for generation of *Acs15*<sup>-/-</sup> mice. The animals were fed a chow diet and fasted for 4 hours before sacrifice.

**Results:** We identified Apolipoproteins B (APOB) and Long chain Fatty Acid-CoA Ligase 5 (ACSL5) as interacting partners of *TM6SF2*. To determine if *TM6SF2* is required for *ACSL5* action in the ER, we

**Figure:** H&E staining of liver sections and NAFLD activity score of HFD-fed WT, *foz/foz*, *foz/foz* + DCA 0.03% and *foz/foz* + DCA 0.1% mice (n=6-7/group). Bar size: 100  $\mu$ m. Mean  $\pm$  SD. Statistical significance is represented by \* when compared to WT mice; \$ when compared to *foz/foz* and # when compared to *foz/foz* + DCA 0.03%.

Figure: (abstract: PO-470)

generated *Acs15*<sup>-/-</sup> mouse. The body weight of the male *Acs15*<sup>-/-</sup> mice and wild-type (WT) littermate controls did not differ significantly but the knockout (KO) mice had reduced fat mass and increased lean body mass when compared to the WT animals. The mean levels of plasma triglycerides (122.2 mg/dl vs 85.0 mg/dl, *p* < 0.05) and cholesterol (111.0 mg/dl vs 72.1 mg/dl, *p* < 0.01) were lower in the *Acs15*<sup>-/-</sup> mice. Although the rate of secretion of VLDL-TG was decreased in the male KO mice, these mice did not have any increase in hepatic triglyceride or cholesterol content. The levels of alanine transaminase (ALT) and aspartate transaminase (AST) were both higher in the KO mice.

**Conclusion:** TM6SF2 interacts with ApoB and ACSL5. Inactivation of *Acs15* results in a reduction in plasma TG and cholesterol and secretion of VLDL-TG without any increase in hepatic TG or cholesterol.

 Email: qianlinglin0703@163.com

**Background and aims:** Non-alcoholic steatohepatitis (NASH) is a severe form of non-alcoholic fatty liver disease characterized by fat accumulation and inflammation in liver. However, the underlying molecular basis remains elusive. Serpina3c is a serine protease inhibitor (serpin) that plays a key role in metabolic diseases in previous studies. This study aimed to investigate the role of serpin3c in NAFLD and regulation of hepatocyte necroptosis and possible mechanisms.

**Method:** Male *Apoe*<sup>-/-</sup>/*serpina3c*<sup>-/-</sup>-double-knockout (DKO) and *Apoe*<sup>-/-</sup> mice were fed with a high-fat diet (HFD) for 12 weeks to induce non-alcoholic steatohepatitis. Several markers of steatosis, inflammation and fibrosis were evaluated. Activation of necroptosis in alpha mouse liver 12 (AML-12) cells by palmitic acid (PA) were evaluated by Western Blot after overexpression and knockdown serpin3c.

**Results:** In vivo, serpin3c deficiency in DKO mice evidently increase the levels of alanine transaminase (ALT), aspartate transaminase (AST) in plasma. DKO mice exhibited significantly aggravated hepatic steatosis, liver damage, hepatic triglyceride content, fibrosis as well as increase hepatic cell death, liver inflammatory cell infiltration and gene expression of inflammatory factors, compared to *Apoe*<sup>-/-</sup> mice. In vitro saturated palmitic acid (PA) treatment aggravated hepatic cell death, lipid droplet formation, the expression of inflammatory factors, however, these phenomena were reversed by overexpression serpin3c. The results also indicated that both lipotoxicity with HFD in vivo and saturated PA treatment in vitro were able to increase markers of necrosis, liver receptor-interacting protein 1/3 (RIP1/3) and phosphorylated mixed lineage kinase domain-like (MLKL). Mechanistically, downregulation serpin3c promoted beta-catenin signaling resulting in beta-catenin nuclear transfer. Meanwhile, downregulation serpin3c increased expression of the transcription factor FOXO1 and decrease phosphorylated FOXO1, and FOXO1 and beta -catenin colocalized in the nucleus, whereby the Foxo1 interaction with beta -catenin under lipotoxicity conditions, and consequent upregulation of and toll-like receptor 4 (TLR4), a death receptor at the plasma membrane. Additionally, disruption of the FOXO1- beta -catenin axis by Foxo1 inhibitor ameliorated hepatic cell death, lipid droplet formation, and decreased expression of TLR4, leading to decrease of necrosis markers, RIP3 and phosphorylation of MLKL.

**Conclusion:** Serpina3c plays an important role in protection of HFD-induced steatohepatitis through regulation necroptosis via beta-catenin-FOXO1 axis inhibiting TLR4 expression.

**Distinctive alterations of the hepatic unfolded protein response in models of diabetes and non-alcoholic fatty liver disease**

Bedair Dewidar<sup>1,2,3</sup>, Lucia Mastrototaro<sup>1,2</sup>, Cornelia Englisch<sup>1,2</sup>, Michelle Reina Do Fundo<sup>1,2</sup>, Fariba Zivehe<sup>1,2</sup>, Dominik Pesta<sup>1,2</sup>, Claudia Röss<sup>4</sup>, Irene Esposito<sup>5</sup>, Michael Roden<sup>1,2,6</sup>. <sup>1</sup>German Diabetes Center, Institute of Clinical Diabetology, Düsseldorf, Germany; <sup>2</sup>German Center for Diabetes Research, München-Neuherberg, Germany; <sup>3</sup>Faculty of Pharmacy, Tanta University, Department of Pharmacology and Toxicology, Tanta, Egypt; <sup>4</sup>Medical University Innsbruck, Department of Internal Medicine I, Innsbruck, Austria; <sup>5</sup>Medical Faculty, Heinrich-Heine University Düsseldorf, Institute of Pathology, Düsseldorf, Germany; <sup>6</sup>Medical Faculty, Heinrich-Heine University, Division of Endocrinology and Diabetology, Düsseldorf, Germany  
 Email: michael.roden@ddz.de

**Background and aims:** Diabetes mellitus (DM) worsens prognosis of non-alcoholic fatty liver disease (NAFLD) likely by accelerating its progression to steatohepatitis (NASH) and fibrosis. For both diseases, endoplasmic reticulum (ER) stress-mediated cellular dysfunction has been described. As adaptive response to ER stress, unfolded protein response (UPR) activates three signaling branches i.e. PKR-like endoplasmic reticulum kinase (PERK), inositol requiring enzyme 1 (IRE1), and activating transcription factor (ATF) 6, which cooperatively interact to restore ER homeostasis. Here, we examined these pathways in experimental models of DM, obesity, and NASH.

**Method:** Two-days old male C57BL/6j mice received streptozotocin (STZ) or vehicle (placebo, PLC). From week 4 on, they were kept either on high-fat diet (HFD) or continued standard chow diet (SCD), thus yielding 4 groups (n = 8 each) as models of obesity [PLC+HFD], DM [STZ+SCD], NASH [STZ+HFD] and control [PLC+SCD]. NASH development was confirmed by histology, immunohistochemistry, and ELISA, whereas alterations in UPR were assessed using immunoblotting and qPCR. Body composition analysis was performed using nuclear magnetic resonance.

**Results:** Fasting blood glucose was about 180% higher in NASH and DM than in controls (both *p* < 0.0001). Obesity and NASH models had 3.9fold (*p* < 0.0001) and 1.8fold (*p* = 0.014) greater relative fat mass than the controls. In NASH, hepatic steatosis and fibrosis were 23.5-

## POSTER PRESENTATIONS

Figure: (abstract: PO-716)

and 2.9-fold increased, respectively ( $p < 0.0001$  and  $p = 0.013$  vs control). Elevation of hepatic MCP-1 in DM and NASH ( $p = 0.02$  and  $p < 0.0001$ ) and TNF- $\alpha$  in DM, obesity and NASH ( $p = 0.013$ ,  $p = 0.002$ , and  $p < 0.0001$  all vs control) indicated inflammation. The downstream target of the PERK branch, ATF4, was markedly decreased by 53%, 70%, and 73% in DM, obesity, and NASH ( $p = 0.012$ ,  $p = 0.0007$ ,  $p = 0.0004$  vs control) and negatively correlated with liver TNF- $\alpha$  expression in NASH (Pearson  $r = -0.72$ ,  $p = 0.046$ ). Spliced X box binding protein 1 (XBPs) was increased by 58% and 50% in DM and NASH, suggesting activation of IRE1 axis ( $p = 0.0001$ ,  $p = 0.0009$  vs control). Cleaved ATF6 was not different between all groups. Interestingly, ER resident chaperone, BiP, was decreased by 43–73% in all groups as compared to control (obesity  $p = 0.044$ , DM  $p = 0.014$ , and NASH  $p = 0.0003$ ).

**Conclusion:** This study shows differential changes in the UPR signaling axes in metabolically driven liver diseases and suggests that they may independently associate with NAFLD progression (Figure).

### PO-725

#### Effects of empagliflozin and L-ornithine L-aspartate on behaviour, cognitive function, and physical performance in mice with non-alcoholic steatohepatitis

Veronika Prikhodko<sup>1</sup>, Yuriy Sysoev<sup>1,2</sup>, Sergey Okovityi<sup>1</sup>. <sup>1</sup>Saint Petersburg state chemical pharmaceutical university, Department of pharmacology and clinical pharmacology, Saint Petersburg, Russian Federation; <sup>2</sup>Saint Petersburg state university, Institute of translational biomedicine, Saint Petersburg, Russian Federation  
Email: veronika.prihodko@pharminnotech.com

**Background and aims:** Non-alcoholic fatty liver disease (NAFLD) has a number of extrahepatic complications, which include cerebrovascular disease, cognitive and behavioural alterations, and accelerated

brain aging. Patients with NAFLD are at a 4 times higher risk to develop cognitive impairment, and tend to have decreased physical performance. As current treatment options for these complications are often insufficient, our aim was to evaluate the effects of empagliflozin (EMPA) and L-ornithine L-aspartate (LOLA) in a mouse model of non-alcoholic steatohepatitis (NASH).

**Method:** A total of 52 male C57BL/6 mice were randomized into four groups: Intact (0.9% NaCl;  $n = 10$ ), Control (NASH + 0.9% NaCl;  $n = 14$ ), EMPA (NASH + 2 mg/kg b.w. EMPA;  $n = 14$ ), and LOLA (NASH + 1.5 g/kg b.w. LOLA;  $n = 14$ ). To model NASH, the mice were fed a high-fat, high-calorie “western” diet for 6 months, given 42 g/L fructose solution to drink, and injected with carbon tetrachloride (0.32 mg/kg) once a week. Intact mice were offered standard chow and tap water. All drugs were administered orally once a day as freshly prepared solutions. Behaviour and cognitive function were assessed in the open field, elevated plus maze (EPM), light/dark box (LDB), and Barnes maze (BM) tests. Physical performance was assessed using the weight-loaded (7.5% of b.w.) forced swim (FS) and triple weight-loaded exhaustive swim (TES) tests.

**Results:** In all NASH groups, the mortality rate equalled about 40% and was not affected by either of the drugs. Movement speed was decreased ( $p < 0.01$ ), while total freezing time ( $p < 0.01$ ) and the number of head dips ( $p < 0.05$ ) and rearing episodes ( $p < 0.05$ ) were increased in the Control group. Control mice had higher error rate ( $p < 0.05$ ) and latency to reach the target hole ( $p < 0.05$ ) when tested for long-time memory in the BM, and exhibited poorer physical performance ( $p < 0.05$ ) in both swimming tests. EMPA increased the number of grooming bouts ( $p < 0.01$ ) and time spent in the light chamber of the LDB ( $p < 0.05$ ), and LOLA increased the time spent in the open arms of the EPM ( $p < 0.05$ ). LOLA also restored maximal swimming time in FS ( $p < 0.05$ ) and swimming time in the third trial of TES ( $p < 0.01$ ) to intact levels.

**Conclusion:** Experimentally induced NASH causes anxiety-like behaviour, impairs long-time memory, and reduces physical performance in C57BL/6 mice. Chronic administration of EMPA or LOLA ameliorates NAFLD-related cognitive deficit, while LOLA also improves physical performance and post-exercise recovery.

**PO-1037 inhibition of atg3 ameliorates liver steatosis by increasing sirt1 in an autophagic-independent action**

**Background and aims:** Non-alcoholic fatty liver disease (NAFLD) is a major health threat in both developed and developing countries and is a precursor of the more advanced liver diseases including non-alcoholic steatohepatitis (NASH), liver cirrhosis and liver cancer. One of the numerous molecules participating in the development of liver steatosis is p63. Although p63 is mainly known for its roles as a tumor suppressor and cell maintenance and renewal, we have recently reported that it is also relevant in the control of lipid metabolism. More specifically, TAp63 $\alpha$  isoform is elevated in the liver of animal models of NAFLD as well as in liver biopsies from obese NAFLD patients. Furthermore, downregulation of p63 $\alpha$  in the liver attenuates liver steatosis in diet-induced obese (DIO) mice. Autophagy is a critical intracellular pathway that targets cytoplasmic components

to the lysosome for degradation. A specialized form of autophagy that degrades lipid droplets, is known to be a major pathway of lipid mobilization in hepatocytes. Its impairment has been associated with the development of fatty liver and insulin resistance. Thus, it is established that autophagy acts as a protective mechanism in the pathogenesis of NAFLD. Autophagy-related gene 3 (ATG3) is an enzyme mainly known for its actions in the LC3 lipidation process, which is essential for autophagy. Despite it is implicated in different biological functions, its role in lipid metabolism and its contribution to NAFLD remains unknown.

**Method:** We performed proteomics in the liver of mice with genetic knockdown or overexpression of TAp63 $\alpha$  to get insights into novel proteins modulating lipid metabolism in a global and unbiased manner. Since ATG3 was increased in NAFLD and NASH preclinical models, we next evaluated its expression in liver biopsies of patients. HEPG2 cells treated with oleic acid (OA), and TAp63 $\alpha$  and ATG3 were up and downregulated with plasmids and siRNAs. *In vivo*, hepatic ATG3 and SIRT1 were specifically downregulated in the liver of mice through the tail vein injection of lentivirus encoding shRNA for ATG3. Over-expression of hepatic p63 was achieved by tail vein injection of the adenoviral vector encoding p63.

**Results:** We found that autophagy-related gene 3 (ATG3) was modified by TAp63 $\alpha$  activation and downregulated after p63 $\alpha$  inhibition. Further *in vitro* and *in vivo* experiments demonstrated that ATG3 is elevated in several animal models of NAFLD and in the liver of patients with NAFLD, who also show a positive correlation between ATG3 and steatosis grade and NAS score. Genetic over-expression of ATG3 increased the lipid load in hepatocytes, while its repression alleviated TAp63 $\alpha$ - and diet-induced steatosis. Unexpectedly, ATG3 exerted its role in lipid metabolism by regulating SIRT1 independent of an autophagic action.

**Conclusion:** Our findings indicate that ATG3 is a novel gene implicated in the development of NAFLD.

**PO-1150 The hepatic IKK-NFkB axis induces liver steatosis by increasing de novo lipogenesis and cholesterol synthesis**

**Background and aims:** Obesity-related chronic inflammation plays an important role in the development of Metabolic Associated Fatty

Figure: (abstract: PO-1037)

## POSTER PRESENTATIONS

Liver disease (MAFLD). Although the contribution of the pro-inflammatory NF $\kappa$ B signaling pathway to the progression from simple steatosis to non-alcoholic steatohepatitis (NASH) is well established, its role as a driver of steatosis remains unclear.

**Method:** To study the impact of hepatic NF $\kappa$ B activation on MAFLD development we used a hepatocyte-specific constitutively active IKK $\beta$  mouse model (Ik $\kappa$ bc $\alpha$ <sup>Hep</sup>) and Ik $\kappa$ bc $\alpha$ <sup>Hep</sup> mice in a hepatocyte A20-deficient background (Ik $\kappa$ bc $\alpha$ <sup>Hep</sup>A20KO). Both models were fed on a carbohydrate-rich diet. These mice were histologically characterized and metabolic fluxes were determined using C<sup>13</sup>-labelled acetate water. Gene and protein expression were determined using qPCR analysis and RNA-sequencing, and immunoblotting, respectively.

**Results:** Hepatic NF $\kappa$ B activation by a constitutively active form of *Ikk2* resulted in steatosis but not liver inflammation in mice (Hep-IKK $\beta$  $\alpha$ ). The upstream inhibitor of the IKK-NF $\kappa$ B axis, *A20*, was highly upregulated in Hep-IKK $\beta$  $\alpha$  livers. Ablation of hepatocyte *A20* in Hep-IKK $\beta$  $\alpha$  mice (IKK $\beta$  $\alpha$ ;A20<sup>LKO</sup> mice) did not lead to liver inflammation but exacerbated steatosis, characterized by hepatic accumulation of triglycerides and cholesterol, accompanied by high plasma cholesterol levels. *De novo* lipogenesis (DNL) and cholesterol synthesis were both elevated in IKK $\beta$  $\alpha$ ;A20<sup>LKO</sup> mice. Phosphorylation of AMPK-a central regulator in lipogenesis and cholesterol synthesis-was decreased in IKK $\beta$  $\alpha$ ;A20<sup>LKO</sup> mice. This was paralleled by elevated protein levels of hydroxymethylglutaryl-CoA synthase (HMGCS1) and reduced phosphorylation of HMG-CoA reductase (HMGCR), both key enzymes in the cholesterol synthesis pathway. Whereas inflammation was not observed in young IKK $\beta$  $\alpha$ ;A20<sup>LKO</sup> mice, sustained hepatic NF $\kappa$ B activation resulted in liver inflammation, together with elevated hepatic and plasma cholesterol levels in middle-aged mice.

**Conclusion:** Our data reveals a hepatocyte-specific role for the NF $\kappa$ B signaling pathway in MAFLD, which is distinct from its central role in inflammation. The IKK-NF $\kappa$ B axis controls DNL and cholesterol synthesis by regulating the phosphorylation levels of AMPK and HMGCR and the protein levels of HMGCS1 and, thereby, acts as a driver of steatosis and may also contribute to cardiovascular disease risk in MAFL patients.

### PO-1235

#### Proteomics Signature of Advanced Fibrosis in Non-alcoholic Steatohepatitis (NASH) using Data-independent Acquisition (DIA) Mass Spectrometry

Estep<sup>1,2</sup>, Brian Lam<sup>1,2</sup>, Bijal Rajout<sup>1,2</sup>, Pegah Golabi<sup>1,2</sup>, Arathi Krishnakumar<sup>3</sup>, Elizabeth Brown<sup>3</sup>, Qing Xiao<sup>3</sup>, Samuel Hellings<sup>3</sup>, Ashok Dongre<sup>3</sup>, John Thompson<sup>3</sup>, Yi Luo<sup>3</sup>, Edgar Charles<sup>3</sup>, Lei Zhao<sup>3</sup>, David Gordon<sup>3</sup>, Azza Karrar<sup>1,2</sup>, Fatema Nader<sup>4</sup>, Zachary Goodman<sup>1,2</sup>, Maria Stepanova<sup>4</sup>, Zobair Younossi<sup>1,5</sup>. <sup>1</sup>Inova Health System, Department of Medicine, Center for Liver Diseases, Falls Church, United States; <sup>2</sup>Inova Health System, Beatty Liver and Obesity Research Program, Falls Church, United States; <sup>3</sup>Bristol Myers Squibb, Princeton, United States; <sup>4</sup>Center for Outcomes Research in Liver Disease, Washington DC, United States; <sup>5</sup>Inova Health System, Medicine Service Line, Falls Church, United States

Email: zobair.younossi@inova.org

**Background and aims:** NASH is the most common liver disease with potential for progression. Histologic stage of fibrosis is the most important predictor of liver-related mortality. Our aim is to use Data-independent Acquisition (DIA) Mass Spectrometry to evaluate the serum proteome signature associated with advanced fibrosis in NASH.

**Method:** Sera samples were obtained from patients with biopsy-proven NASH and non-NASH NAFLD who are enrolled in our center. All liver biopsies were read by a single hepatopathologist. Proteomics analysis was performed using high-performance LCMS, peptides missing in >50% samples were filtered out, leaving 372 proteins

assessed. Proteome signatures associated with NASH and advanced fibrosis were determined using Limma regression modeling after adjusting for age, sex, and type 2 diabetes (T2DM), applying Benjamini-Hochberg correction for multiple testing. Multivariate analysis adopting a stricter cut off ( $p < 0.01$ ) and a lasso selection algorithm were performed to detect peptides independently associated with NASH and advanced fibrosis.

**Results:** We included 150 patients with NAFLD [100 with histologic NASH, 33% male, 71% white, 44% T2DM 34% advanced fibrosis ( $\geq F3$ )]. Patients with advanced fibrosis had higher levels of AST, ALT, and lower platelet count and had higher rate of T2DM than patients with early fibrosis or non-NASH NAFLD (all  $p < 0.02$ ). Limma modeling revealed that a signature of 22 proteins was differentially expressed between NASH and non-NASH patients (adjusted  $p \leq 0.05$ ) (Figure 1a). Furthermore, 29 proteins were differentially expressed between advanced fibrosis and non-advanced fibrosis (Figure 1b). Multivariate modeling revealed that Insulin-like growth factor binding protein, and acid labile subunit (IGFALS), were independently associated with lower risk of advanced fibrosis (OR = 0.963 (CI: 0.989–0.996),  $p < 0.0001$ ) while C7 was associated with higher risk of advanced fibrosis (OR = 1.009 (CI: 1.006–1.012),  $p < .0001$ ).

Figure:

**Conclusion:** This serum proteome signature suggests that NASH-related advanced fibrosis is associated with protein profile involved in insulin-like growth factor pathway, including IGFALS, IGFBP7 and IGFBP3, which regulate, metabolic and liver regenerative functions and C7 which has immune activation functions.

### PO-1369

#### Non-alcoholic fatty liver disease in a rodent model of bariatric surgery with different bypass lengths

Paula Richwien<sup>1</sup>, Magdalena Eilenberg<sup>1</sup>, Jakob Eichelter<sup>1</sup>, Carolin Lackner<sup>2</sup>, Sarocchi Francesca<sup>2</sup>, Gerhard Prager<sup>1</sup>, Katharina Stauer<sup>3</sup>. <sup>1</sup>Department of General Surgery, Medical University of Vienna, Vienna, Austria; <sup>2</sup>Institute of Pathology, Medical University Graz; <sup>3</sup>Department of Visceral Surgery and Medicine, Inselspital, University Hospital Bern

Email: paula.richwien@meduniwien.ac.at

**Background and aims:** Non-alcoholic fatty liver disease (NAFLD) usually improves after bariatric-metabolic surgery. However, in some cases clinical and histological liver deterioration was described. We established a rodent model to investigate if one-anastomosis gastric bypasses (OAGB) with extended limb lengths, are more likely to lead to a histological worsening compared to moderate bypass lengths.

**Method:** Thirty-two male Sprague-Dawley rats received high-fat high-fructose diet (HFHFD) for a total of 16 weeks. Glucose tolerance, and body weight were assessed. After the first 8 weeks, either moderate OAGB (35 cm bypass length, n = 9), extended OAGB (55 cm bypass length, n = 9), or sham surgery (n = 7) was performed. Liver

tissue was gained during surgery, as well as 8 weeks thereafter, and was analyzed according to the clinical research network's scoring system.

**Results:** Body weight increased after 8 weeks of HFHFD (median: 561.5 g, Q1;Q3: 535.3;612.8,  $p < 0.001$ ). At week 16 median weight was 719.0 g in sham, 644.5 g in moderate and 532.0 g in extended bypass, and significantly reduced after OAGB in comparison to sham operated animals (sham vs. moderate bypass:  $p = 0.042$ , sham vs. extended bypass:  $p < 0.001$ ). Glucose tolerance was impaired after 8 weeks of HFHFD compared to baseline ( $p < 0.001$ ). Surgery induced a significant improvement of glucose tolerance after moderate ( $p = 0.021$ ) and extended bypass ( $p = 0.038$ ) in contrast to sham operated animals ( $p = 0.859$ ). Eight weeks of HFHFD led to liver fibrosis, inflammation and macrosteatosis in 15.6%, 84.4% and 56% respectively. After 16 weeks of HFHFD, liver fibrosis was present in 42.9%, 33.3%, and 11.1% in sham, moderate and extended OAGB, respectively, but advanced fibrosis (F3) was substantially more frequent after OAGB than in sham operated animals (0% vs. 16.7%,  $n = 3/18$ ,  $p = 0.074$ ). Inflammation was present in 100%, 66.7%, and 55.6%, respectively (sham vs moderate  $p = 0.003$ ; sham vs extended  $p = 0.001$ ). Macrosteatosis was present in 71.4%, 55.6%, and 44.4%, with no significant differences over the course of time nor in between the groups.

**Conclusion:** OAGB animals showed a significant improvement in body weight, allover presence of liver fibrosis, inflammation and steatosis. However, advanced fibrosis was substantially more frequent after OAGB. There was no significant difference in body weight, glucose tolerance or liver pathology between moderate and extended OAGB.

**Background and aims:** Surveillance for hepatotoxicity relies on clinical status and liver tests as signs and symptoms suggestive of DILI. Liver biopsy (Bx) is reserved for confirmation or exclusion of indefinite cases. This approach is useful for acute toxicity, but drugs (e.g., methotrexate, amiodarone) can cause chronic toxicity leading to cirrhosis without clinical or laboratory signs. NASH trials with baseline (BL) and end-of-treatment (ET) Bxs might detect such cases. In a seladelpar NASH study, a study pathologist (SP) read BL Bx for study eligibility. ET Bxs were read by 2 SPs without rescored BL Bxs. Atypical histology for NASH was noted in 42/152 ET Bxs (**1A**): Portal inflammation (PI) and Interface Hepatitis (IH) with plasma cells, bile duct injury/cholangitis (BDI), vascular changes (VC), and other misc. findings. We describe the adjudication of suspected chronic hepatotoxicity of seladelpar identified in ET Bxs.

**Method:** The SHRC comprised of 3 pathologists and 5 hepatologists experienced in DILI and NASH reviewed clinical, biochemical and histological data for all patients with paired Bxs. Two blinded randomized Bx reviews were conducted: 1) 302 BL and ET Bxs using the Ishak Histologic Activity Index and, 2) 151 BL and ET paired comparisons classified as "Better, Same or Worse." Reviews scored BL and ET Bxs for IH, PI, BDI, and VC. The SHRC reviewed the 42 cases for BL characteristics, NASH diagnosis, medical history, medications, labs, adverse events, immune biomarkers and BL and ET Bx histology.

Cases were assessed for evidence of DILI using clinical and laboratory results and for new or progressive unexpected liver pathology. The SHRC was unblinded to the treatment groups only after adjudication of cases.

**Results:** BL Bxs commonly showed IH (61–73%), PI (88–92%) and BDI (22%) with various grades. SHRC adjudication identified no cases of DILI. New or progressing unexpected histology (**1B**) was noted in 13 cases, but none were scored as "probable" or "highly likely" related to drug.

**Conclusion:** The SHRC determined that the ET Bx features identified by the 2 SPs were confirmed and were qualitatively similar in both BL and ET Bxs. They found no clinical, biochemical or histologic evidence that seladelpar was hepatotoxic. These results suggest the necessity of concurrent review of both BL and ET Bxs in NASH studies. The association of NASH with uncommonly reported histological features of IH and PI with plasma cells and BDI should be further investigated.

### PO-1547

#### Steatosis, inflammasome upregulation and fibrosis are attenuated in microRNA-155 deficient mice in a diet-induced model of NASH

Mrigya Babuta<sup>1</sup>, Shashi Bala<sup>1</sup>, Michal Ganz<sup>2</sup>, Yuan Zhuang<sup>1</sup>, Timea Csak<sup>2</sup>, Charles D. Calenda<sup>1</sup>, Gyongyi Szabo<sup>1</sup>. <sup>1</sup>Beth Israel Deaconess Medical Center (BIDMC), Department of Medicine, Boston, United States; <sup>2</sup>University of Massachusetts Medical School, Department of Medicine, Worcester, United States Email: gszabo1@bidmc.harvard.edu

**Background and aims:** Non-alcoholic fatty liver disease (NAFLD) is the most common cause of chronic liver disease globally. miRNAs (miRs) regulate various cellular events that lead to NAFLD. In this

study we tested the hypothesis that miR-155 is an important regulator of steatohepatitis and fibrosis pathways in diet induced NASH.

**Method:** C57BL/6 wild type (WT) and miR-155 deficient (KO) mice received a high fat-high cholesterol-high sugar-diet (HF-HC-HS) for 34 weeks. Human liver samples were from controls and patients with NASH. Samples were analyzed by western blotting and qPCR.

**Results:** In patients with NASH and in the mouse model of HF-HC-HS diet we found increased miR-155 levels in the liver compared to normal livers. Upon HF-HC-HS diet feeding for 34 weeks, miR-155 KO mice displayed less liver injury, decreased steatosis, and attenuation of fibrosis compared to WT mice. Furthermore, we observed a decrease in the ALT levels, triglyceride levels in miR-155 KO mice suggesting a decrease in liver injury. In HF-HC-HS diet-fed WT mice, we found increased expression of genes involved in fatty acid metabolic pathway (Cpt1 $\alpha$ , FAB4, ACC2, FAS) mice which were attenuated in miR-155 KO mice. HF-HC-HS diet induced a significant increase in the expression of NLRP3 inflammasome components (NLRP3, ASC, Caspase-1) in the livers of WT mice compared to chow fed diet. Compared to WT mice, miR-155 KO showed attenuated induction in the NLRP3, ASC and caspase1 inflammasome expression on HF-HC-HS diet. Fibrosis markers such as collagen content and deposition,  $\alpha$ SMA and Zeb2, were all increased in WT mice while miR-155 KO mice showed attenuated fibrosis marker expression.

Figure:

**Conclusion:** Our study indicates that miR-155 KO mice display attenuated liver damage, steatosis, NLRP3 inflammasome complex upregulation and fibrosis compared to WT mice after 34 weeks of HF-HC-HSD feeding suggesting that miR-155 plays a role in steatosis, inflammation and fibrosis in NASH.

**PO-1626**

**Rilpivirine-induced anti-inflammatory effects in non-alcoholic fatty liver disease involve the inhibition of CCL2/CCR2 axis**

Ángela B. Moragrega<sup>1,2</sup>, Aleksandra Gruevska<sup>1,2</sup>, Isabel Fuster-Martínez<sup>1,2</sup>, Ana Benedicto<sup>1,2</sup>, Federico Lucantoni<sup>1,2</sup>, Juan V. Esplugues<sup>1,2,3</sup>, Nadezda Apostolova<sup>1,2,3</sup>, Ana Blas-García<sup>2,3,4</sup>.  
<sup>1</sup>Universitat de València, Farmacologia, Valencia, Spain; <sup>2</sup>FISABIO (Fundación para el Fomento de la Investigación Sanitaria y Biomédica de la Comunidad Valenciana), Valencia, Spain; <sup>3</sup>CIBERehd (Centro de Investigación Biomédica en Red de Enfermedades Hepáticas y Digestivas), Valencia, Spain; <sup>4</sup>Universitat de València, Fisiología, Valencia, Spain  
 Email: angela.moragrega@uv.es

**Background and aims:** Non-alcoholic fatty liver disease (NAFLD) has become the most common cause of chronic liver disease worldwide. Both liver resident macrophages and monocyte-derived macrophages (MDMs) are key regulators of inflammation and hepatic injury. Recruitment of monocytes into the liver is mainly regulated by the chemokine receptor CCR2 and its ligand CCL2, which is synthesized and released by Kupffer cells (KC), hepatic stellate cells (HSC), liver sinusoidal endothelial cells (LSEC) and hepatocytes. In addition, evidence supports a central role of NLRP3-mediated pathways in the development of hepatic inflammation and fibrosis. As our group has previously described that treatment with RPV induces clear anti-inflammatory and anti-fibrotic effects in murine models of chronic liver diseases, the aim of this study is to determine the molecular mechanisms by which RPV exerts its anti-inflammatory properties.

**Method:** *In vivo*, a nutritional model of NAFLD in C57BL/6 mice (12 weeks) was used; RPV was daily administered at clinical doses. *In vitro*, MDMs obtained from human peripheral blood mononuclear cells isolated from healthy donors, LX-2 (as HSC model) and human umbilical vein endothelial cells (HUVEC) were treated with RPV for 48 h. The molecular routes involved were studied using transcriptomic analysis, immunohistochemistry and standard molecular biology techniques (RT-PCR, Western Blot and ELISA).

**Results:** Transcriptomic analysis performed with liver samples from NAFLD mice showed RPV down-regulated biological processes associated with the inflammatory response and leukocyte chemotaxis and migration. In-depth study of these functions revealed a decrease in *Adgre1* and *Ccr2* expression and in the number of CCR2+ cells in the periportal areas of RPV-treated NAFLD mice. This RPV-induced effect on the CCL2/CCR2 axis was confirmed *in vitro* by a decrease of CCL2 expression in HUVEC, and a significant reduction of the synthesis and release of CCL2 by MDMs and LX-2. In addition, RPV inhibited the NLRP3 inflammasome pathway *in vivo* and *in vitro* (MDMs and LX-2), decreasing NLRP3 protein expression, Caspase-1 activation and *IL-1 $\beta$*  gene expression.

**Conclusion:** Beyond its well-described role in antiretroviral therapy, RPV has a clear anti-inflammatory effect which involves the inhibition of CCL2/CCR2 axis. Although further studies are needed to clarify the mechanisms involved, this effect could be of great relevance in the treatment of chronic liver diseases.

**PO-1727**

**Combination therapy of lanifibranor and firsocostat further improves steatohepatitis and fibrosis compared to monotherapy in a diet-induced murine model of NASH**

Guillaume Wettstein<sup>1</sup>, Francois Briand<sup>2</sup>, Thierry Sulpice<sup>2</sup>, Jean-Louis Junien<sup>1</sup>, Pierre Broqua<sup>1</sup>. <sup>1</sup>Inventiva, Daix, France; <sup>2</sup>Physiogenex, Escalquens, France  
 Email: guillaume.wettstein@inventivapharma.com

**Background and aims:** lanifibranor, a panPPAR agonist with moderate and well-balanced activity on the three PPAR isoforms ( $\alpha$ ,  $\delta$  and  $\gamma$ ) showed clinical efficacy on both resolution of NASH and fibrosis improvement in NASH patients. Firsocostat, an ACC1/2 inhibitor, reduced liver fat and markers of fibrosis in patients with advanced fibrosis due to NASH. ACC inhibitors inhibit de novo lipogenesis and reactivate beta oxidation, whilst PPARs stimulate lipid catabolism and redirect hepatic lipids to adipocytes. The potential complementary mode of action of both compounds provides a rationale to investigate whether their combination has additive effects in a nonclinical model of NASH and fibrosis.

**Method:** Mice were fed a 60% high fat/1.25% cholesterol/0.5% cholic acid diet with 2% 2-hydroxypropyl beta-cyclodextrin in drinking water for 3 weeks. After 1 week of diet, mice were randomized according to their ALT, AST plasma levels and body weight and were orally treated (QD) for 2 weeks either with vehicle, lanifibranor (10 mg/kg), firsocostat (15 mg/kg) or the combination lanifibranor

## POSTER PRESENTATIONS

Table: (abstract: PO-1727)

	Vehicle Mean (SD)	Lanifibranor 10 mg/kg		Firsocostat 15 mg/kg		Combination lanifibranor/ firsocostat
		Mean (SD)	Stats	Mean (SD)	Stats	Mean (SD)
FA (nmol/mg liver)	41.6 (7.7)	45.4 (12.3)	andandandand	35.1 (6.3)	and	22.5 (5.1)
TG (µg/mg liver)	80.9 (12.7)	74.8 (12.0)	andandandand	69.4 (13.7)	andandandand	41.9 (5.7)
TC (µg/mg liver)	62.0 (12.0)	51.0 (5.7)	andand	56.5 (2.9)	andandandand	35.5 (5.5)
total score (steatosis + inflammation + fibrosis)	6.9 (0.3)	4.7 (0.7)	andandandand	5.1 (0.3)	andandandand	2.9 (0.7)

and vs combination lanifibranor/firsocostat (and  $p < 0.05$ ; andand  $p < 0.01$ ; andandand  $p < 0.001$ ; andandandand  $p < 0.0001$ ).

and firsocostat. Biochemistry, liver histology and gene expression were analyzed.

**Results:** Combination treatment of a suboptimal dose of lanifibranor with firsocostat showed a stronger decrease in hepatic free fatty acid (FA), total cholesterol (TC) and triglycerides (TG) and further improved histological parameters such as Steatosis, inflammation and fibrosis as well as the global NASH/fibrosis scores compared to each single treatments (Table 1).

**Conclusion:** Lanifibranor and firsocostat combination reach greater efficacy than monotherapy at the selected doses for each parameters evaluated. These data emphasize the complementary effect of these two compounds on lipids metabolic leading to further improvement of NASH and fibrosis. These data support the clinical investigation of a combination of lanifibranor and firsocostat in NASH patients.

### PO-1753

#### Implication of the Patatin-like phospholipase domain-containing 3 I148M mutation on hepatic stellate cells mitochondrial dysfunction and profibrogenic potential

Elisabetta Caon<sup>1</sup>, Maria Martins<sup>1</sup>, Ana Levi<sup>1</sup>, Dong Xia<sup>2</sup>, Leo Ghemtio<sup>3</sup>, Kessarar Thanapirom<sup>1</sup>, Walid Al-Akkad Abu Zeina<sup>1</sup>, Jan-Willem Taanman<sup>4</sup>, Michele Vacca<sup>5,6</sup>, Giuseppe Mazza<sup>1</sup>, Massimo Pinzani<sup>1</sup>, Krista Rombouts<sup>1</sup>. <sup>1</sup>University College of London, Royal Free Campus, Regenerative Medicine and Fibrosis Group, Institute for Liver and Digestive Health, London, United Kingdom; <sup>2</sup>University College of London, Royal veterinary College, Comparative Biomedical Sciences, London, United Kingdom; <sup>3</sup>University of Helsinki, Faculty of Pharmacy, Division of Pharmaceutical Biosciences, Drug Research Program, Helsinki, Finland; <sup>4</sup>University College of London, Queen Square Institute of Neurology, Department of Clinical and Movement Neurosciences, London, United Kingdom; <sup>5</sup>University of Cambridge, Metabolic Research Laboratories, Institute of Metabolic Science, Cambridge, United Kingdom; <sup>6</sup>University of Bari "Aldo Moro", Clinica Medica "Frugoni", Interdisciplinary Department of Medicine, Bari, Italy  
Email: elisabetta.caon@gmail.com

**Background and aims:** The I148M variant of the Patatin-like phospholipase domain-containing 3 (PNPLA3) protein is a well validated risk locus for the hHSC-driven fibrogenic progression of chronic liver diseases, particularly in NAFLD. Mitochondrial dysfunction has also been associated with NAFLD development. In this study we investigated the impact of PNPLA3 I148M mutation on mitochondrial dysfunction in hHSCs in 2D and 3D culture models.

**Method:** Primary hHSC were isolated (n = 23 donors) and cultured in 2D, then genotyped for PNPLA3 (I148M) variants CG/GG. RNAseq data was analysed on 3 donors/genotype with Ingenuity pathway analysis (IPA). Cell behaviour of PNPLA3 (WT) hHSC and PNPLA3 (I148M) hHSC was evaluated in 3D decellularized scaffolds from human

healthy and cirrhotic liver. Cells were cultured for 13 days and stimulated 3 × 48 h with TGFβ1. QRT-PCR, western blot and cytochrome-c-oxidase activity assay was performed.

**Results:** IPA associated the PNPLA3 (I148M) hHSC variant to the "NRF2 mediated oxidative stress response" and "Oxidative phosphorylation" signalling pathways. A possible derangement of intracellular anti-oxidant response was also suggested by qPCR on 3D cultured hHSC, with a significant decreased expression in VARS2, a mitochondrial enzyme, and GSTT1, a Glutathione-S-Transferase in PNPLA3 (I148M) hHSC compared to PNPLA3 (WT) hHSC with/without TGFβ1 treatment ( $p < 0.05$ ). This was further confirmed by protein expression of VARS2 and cytochrome-c-oxidase subunit MTCO1, which was significantly downregulated in PNPLA3 (I148M) hHSC compared to PNPLA3 (WT) hHSC ( $p < 0.05$ ) and in PNPLA3 (WT/I148M) hHSC when cultured in healthy scaffolds compared to cirrhotic scaffolds ( $p < 0.05$ ). The lower expression of MTCO1 protein also determined a significant reduction in enzymatic activity of the cytochrome-c-oxidase in PNPLA3 (I148M) hHSC compared to PNPLA3 (WT) hHSC when measured in 2D and healthy scaffolds ( $p < 0.005$  and  $p < 0.05$ ).

**Conclusion:** In this study, following IPA analysis on the genetic background of hHSC carrying different variants of the PNPLA3 I148M mutation, mitochondrial function of hHSC was investigated in a 3D model recapitulating the ECM microenvironment of normal and cirrhotic human liver. Results indicate that the PNPLA3 (I148M) variant is linked to a disrupted expression and activity of different mitochondrial proteins, including a key enzyme of the respiratory chain. This leads to a dysfunctional hHSC mitochondrial phenotype which is worsened by the fibrotic ECM.

### PO-1797

#### Effect of seladelpar and CB-0406 combination therapy on obesity, liver fibrosis and steatosis in a diet-induced obese (DIO) mouse model of biopsy-confirmed non-alcoholic steatohepatitis (NASH) with fibrosis

Yun-Jung Choi<sup>1</sup>, Jeffrey Stebbins<sup>1</sup>, Ed Cable<sup>1</sup>, Jianga Song<sup>1</sup>, Jeff Johnson<sup>1</sup>, Charles McWherter<sup>1</sup>. <sup>1</sup>CymaBay Therapeutics, Newark, United States  
Email: ychoi@cymabay.com

**Background and aims:** The rising prevalence of NASH, for which there are no approved therapies, has fueled a search for combinations of drugs to address its multifactorial nature. Seladelpar, a potent transcription factor PPAR delta agonist, regulates pathways involved in metabolism, inflammation, and fibrosis. Our aim is to evaluate the combination of seladelpar with CB-0406, a non-agonist ligand of PPAR gamma with anti-inflammatory activity, in a DIO mouse model of NASH.

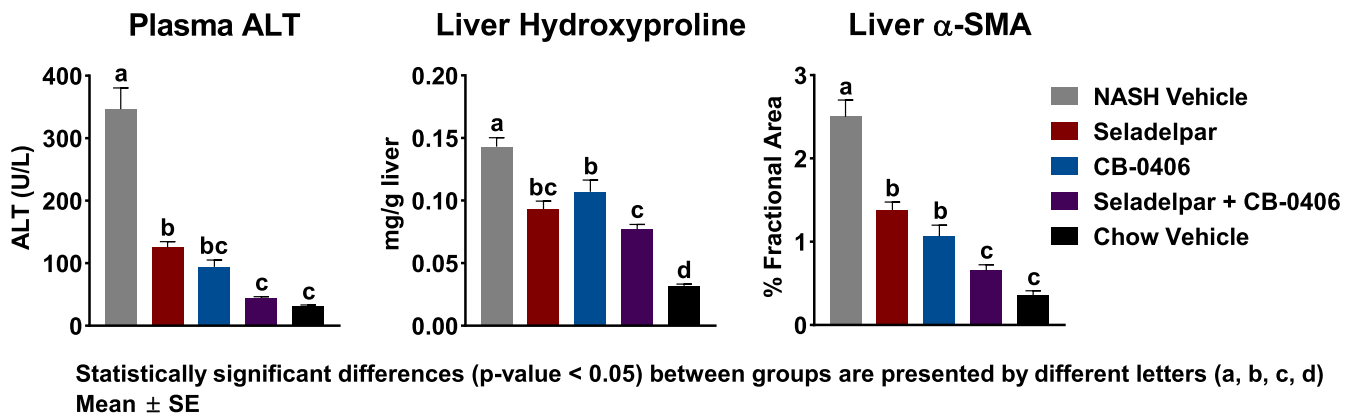

Figure: (abstract: PO-1797)

**Method:** NASH with advanced fibrosis was induced in male C57BL/6J mice by feeding a diet high in fat, fructose, and cholesterol for 56 weeks. Mice with biopsy-confirmed steatosis and fibrosis were randomized to receive daily vehicle, seladelpar (10 mg/kg), CB-0406 (100 mg/kg) alone or in combination for the last 12 weeks. Body composition, blood and liver biochemistry and histological parameters were assessed.

**Results:** Seladelpar and CB-0406 each resulted in significant decreases in body weight compared to vehicle. The combination led to greater weight loss than the monotherapies: -19% (combination), -11% (seladelpar), -3% (CB-0406), and +6% (vehicle). Weight loss in the seladelpar groups was associated with decreased fat mass without changes in food consumption or lean mass. Elevated liver enzymes (ALT/AST) were dramatically improved (all  $p < 0.0001$ ) in the combination (-84%/-71%) followed by CB-0406 (-65%/-54%), seladelpar (-51%/-41%) vs. vehicle (+23%/+22%). A  $\geq 2$ -point improvement in the NAFLD Activity Score (NAS) was seen in 81%, 30%, 93% and 6% of mice for the seladelpar, CB-0406, combination and vehicle groups, respectively. Only the combination group (43%) showed a 4-point reduction in NAS. A  $>1$ -point reduction in steatosis score was seen in 81% and 93% of mice for the seladelpar and combination groups, but in only 6% and 30% for the vehicle and CB-0406 groups. Significant reductions in liver fibrosis measured by hydroxyproline content were observed with seladelpar, its combination group ( $p < 0.0001$ ) or CB-0406 ( $p = 0.0003$ ) compared to the vehicle group. Morphometric measures of picro sirius red, collagen 1a1,  $\alpha$ -SMA and galectin-3 staining demonstrated that the combination was more efficacious in reversing fibrosis than either monotherapy.

**Conclusion:** The combination of seladelpar and CB-0406 in a mouse model of NASH led to substantially greater reductions in fibrosis and NASH than either monotherapy. This combination may offer a novel treatment option for patients with NASH.

**PO-1839**

**The Association of Dietary Factors and Physical Activity with Sarcopenia in Non-Alcoholic Fatty Liver Disease (NAFLD)**

James Paik<sup>1,2</sup>, Khalid W. Kabbara<sup>1</sup>, Katherine Eberly<sup>1</sup>, Michael Harring<sup>1</sup>, Janus Ong<sup>3</sup>, Zobair Younossi<sup>1,2,4</sup>. <sup>1</sup>Inova Health System, Department of Medicine, Center for Liver Disease, Falls Church, United States; <sup>2</sup>Inova Health System, Beatty Obesity and Liver Research Program, Falls Church, United States; <sup>3</sup>Univeristy of the Phillipines, College of Medicine, Manila, Philippines; <sup>4</sup>Inova Health System, Medicine Service Line, Falls Church, United States  
 Email: zobair.younossi@inova.org

**Background and aims:** The modern diet and physical inactivity have contributed to the epidemic of obesity, NAFLD and sarcopenia. We aimed to determine the association of dietary habits and physical activity with an increased risk of sarcopenia among adults with NAFLD.

**Method:** Self-reported diet and physical activity data and imputed dual-energy x-ray absorptiometry data for adults (aged 20–75 years) were obtained from the National Health and Nutrition Examination Surveys (NHANES 1999–2004). NAFLD was determined by US Fatty Liver Index (US-FLI) in the absence of other liver disease. Sarcopenia was defined using appendicular lean mass divided by BMI as defined the FNIIH criteria. Ideal diet level was defined as Healthy Eating Index (HEI) score  $\geq 69.3$ ; intermediate diet score of 56.9–69.3 and poor diet score  $< 56.9$ . Physical activity (PA) level was determined as inactive (sedentary), intermediate, ideal (based on CDC definition of 150 minutes of moderate activity/week). Multiple imputation methods on publicly available imputed dual-energy x-ray absorptiometry (DXA) datasets were performed for all data analyses.

**Results:** Of 4, 435 adult NHANES participants [mean age 44.1 years; 48.6% male; 71.2% white, 10.6% black and 13.7% Hispanic], NAFLD prevalence was 29.6%; 15.7% of those with NAFLD had sarcopenia; only 6.3% met ideal diet with 18.4% reaching ideal PA. Among those without NAFLD (N = 2, 991), 4.9% had sarcopenia; 7.7% met ideal diet and 29.0% reached ideal PA (All  $P < 0.05$ ). Compared to NAFLD without sarcopenia, NAFLD sarcopenia patients were older, female, Hispanic, obese (77.6% vs. 60.1%), hypertensive (74.7% vs. 65.3%) and diabetic (28.7% vs. 18.2%) (All  $P < 0.05$ ) with significantly lower rates of ideal diet (2.4% vs. 7.0%) and lower ideal PA (22.7% vs. 39.1%) (All  $P < .001$ ). After adjusting for all confounders (obesity, hypertension, hyperlipidemia, diabetes, and advanced fibrosis), NAFLD subjects with ideal diet and PA were less likely to have sarcopenia (Odds Ratio [OR] = 0.27 [95% confidence interval: 0.09–0.79] and 0.46 [0.30–0.72], respectively). These findings were not observed among adults without NAFLD. Finally, sarcopenia was independently associated with increased mortality among both with NAFLD (Hazard Ratio [HR] = 2.03 [1.28–3.22]) and non-NAFLD (HR = 1.53 [1.01–2.32]) subjects.

**Conclusion:** Poor diet and physical activity are associated with sarcopenia in NAFLD. Sarcopenia is an important predictor of mortality.

**PO-1849**

**A3907, a novel orally available inhibitor of the apical sodium-dependent bile acid transporter, improves key clinical markers of non-alcoholic steatohepatitis in obese diet-induced and biopsychically confirmed mouse models**

Peter Akerblad<sup>1</sup>, Erik Lindström<sup>1</sup>, Jan Mattsson<sup>1</sup>, Patrick Horn<sup>1</sup>, Pål Lundin<sup>1</sup>, Sara Straniero<sup>2</sup>, Bo Angelin<sup>2</sup>, Kirstine Tølbøl<sup>3</sup>, Sanne Veidal<sup>3</sup>, Michael Feigh<sup>3</sup>, Arun Sanyal<sup>4</sup>. <sup>1</sup>Albireo Pharma, Inc.; <sup>2</sup>Karolinska Institutet at Karolinska University Hospital Huddinge; <sup>3</sup>Gubra Aps; <sup>4</sup>Virginia Commonwealth University  
 Email: peter.akerblad@albireopharma.com

**Background and aims:** Bile acids (BAs) are signalling molecules involved in lipid, glucose, and energy homeostasis; elevated BA levels are associated with non-alcoholic steatohepatitis (NASH). BA

## POSTER PRESENTATIONS

transporter inhibition is a potential therapeutic option for treatment of NASH. To explore effects in NASH of systemic inhibition of apical sodium-dependent bile acid transporter (ASBT), we developed A3907, a potent ASBT inhibitor with high oral bioavailability. A3907 has potential to inhibit bile acid reuptake in the ileum, bile ducts, and kidney and increase BA elimination by faecal and urinary routes. Effects of A3907 were investigated in 2 obese diet-induced mouse models of NASH.

**Method:** Leptin-deficient *ob/ob* mice and diet-induced obese (DIO)-NASH mice were pre-fed GAN (Gubra-Amylin NASH) diet. Before treatment, animals underwent liver biopsy for histological confirmation of liver pathology (steatosis score  $\geq 2$ ; fibrosis stage  $\geq 1$  [*ob/ob*-NASH] or  $\geq 2$  [DIO-NASH]). A3907 or vehicle was given by oral gavage once daily for 10–16 weeks.

**Results:** In *ob/ob*-NASH mice, A3907 treatment (3–45 mg/kg) significantly reduced plasma transaminases, total cholesterol, and liver weight after 10 weeks vs vehicle. After 16 weeks in DIO-NASH mice, A3907 10–30 mg/kg significantly reduced plasma transaminases, total cholesterol, total BAs, and liver weight. Terminal histological assessment in both mouse models revealed that liver steatosis and percentage of hepatocytes with lipid droplets were reduced with A3907 vs vehicle. Markers of liver inflammation (eg, galectin-3) and number of inflammatory foci were also significantly reduced with A3907. Notably, A3907 significantly improved Non-alcoholic Fatty Liver Disease (NAFLD) Activity Score by  $\geq 2$  points vs vehicle in  $>50\%$  of *ob/ob*-NASH mice at 30 mg/kg and  $>60\%$  of DIO-NASH mice at 10 mg/kg. A3907 10, 30, and 45 mg/kg also significantly prevented fibrosis stage progression vs vehicle in  $>50\%$  of *ob/ob*-NASH mice. In DIO-NASH mice, A3907 10 and 30 mg/kg significantly reduced liver fibrosis determined by histological staining vs vehicle. A3907 also reduced liver collagen 1a1 and alpha-smooth muscle actin levels in both models.

**Conclusion:** In *ob/ob*-NASH and DIO-NASH mice, A3907 treatment improved key plasma and liver histological markers of NASH. Importantly, A3907 improved NALFD Activity Score and demonstrated no worsening in fibrosis stage. These findings introduce A3907 as a novel intervention for treatment of NASH and fibrotic progression.

### PO-1897

#### Men and women display different predictive biomarkers of NASH: a machine learning approach

Gerard Baiges<sup>1</sup>, Elisabet Rodríguez-Tomás<sup>2</sup>, Helena Castañe<sup>2</sup>, Anna Hernández-Aguilera<sup>3</sup>, Salvador Fernández-Arroyo<sup>4</sup>, Jordi Camps<sup>3</sup>, Jorge Joven<sup>1,2,3</sup>. <sup>1</sup>Institut d'Investigació Sanitària Pere Virgili, Reus, Spain; <sup>2</sup>Rovira i Virgili University, Medicine and Surgery, Tarragona, Spain; <sup>3</sup>Hospital Universitari Sant Joan de Reus, Reus, Spain; <sup>4</sup>EURECAT, Centre for Omics Science, Reus, Spain  
Email: gerardbaiges93@gmail.com

**Background and aims:** Metabolic dysfunction-associated fatty liver disease (MAFLD) is a progressive disease, and it is considered one of the most important causes of liver transplantation. Unfortunately, there is currently no treatment or disease-modifying therapy, despite hundreds of studies being conducted. Predicting which patients with hepatic steatosis will suffer a progression to steatohepatitis (NASH) is difficult. However, there are a great needed of discerning those at highest risk of progressive liver disease to manage properly. In the big data era, using learning algorithms can help us to discover a biomarker with the capacity to discern each stage of the disease specific to sex. This approach is a way to identify the best sets of metabolites that are predictive of disease and are less invasive than hepatic biopsies.

**Method:** Fifty-nine women and forty-three men with morbid obesity candidates to bariatric surgery were classified into the non-NASH group (38 in women and 18 in men) and NASH group (21 in women and 25 in men). Biological samples such as plasma, liver, visceral (omental) and subcutaneous (abdominal) were used to perform a multi-omics (energy metabolism, one-carbon, lipidomics) analysis to build a predictive model, using machine learning algorithms, with the capacity to discern each stage of the disease.

**Results:** We found that our predictive model identifies a different set of metabolites depending on the sex. Concretely, the hepatic oxaloacetate and the visceral pentadecenoyl-carnitine were identified as the most important variable to predict NASH in women. By contrast, the hepatic DG 34:1, and pyruvate, alpha-ketoglutarate blood circulation was the main predictor of NASH in men.

**Conclusion:** The use of learning algorithms is a useful tool to work toward personalized medicine and help us to identify new ways of treatment and biomarker detection specific to sex and in the metabolic context we want.

### PO-1916

#### Co-stimulatory signals mediated by ICOS/ICOS-L dyad influence the differentiation of liver NASH-associated macrophages (NAMs)

Naresh Naik Ramavath<sup>1</sup>, Laila lavanya Gadipudi<sup>1</sup>, Alessia Provera<sup>1</sup>, Luca Casimiro Gigliotti<sup>1</sup>, Elena Boggio<sup>1</sup>, Nausicaa Clemente<sup>1</sup>, Umberto Dianzani<sup>1</sup>, Emanuele Albano<sup>1</sup>, Salvatore Sutti<sup>1</sup>. <sup>1</sup>University Of East Piedmont, Health Sciences, Novara, Italy  
Email: lailalavanya1993@gmail.com

**Background and aims:** The Inducible T-cell Co-Stimulator (ICOS) present on T lymphocytes and its ligand ICOSL (B7 h) expressed on myeloid cells are member of the B7/CD28 family and play multiple roles in immunity by regulating T-cell activation/survival and antibodies production. Recent evidence indicates that reverse signalling involving ICOSL is also important in directing the differentiation of monocyte-derived cells. In this study, we have investigated the possible involvement of ICOS-ICOSL dyad in modulating macrophages functions during the evolution of non-alcoholic steatohepatitis (NASH).

**Method:** ICOS and ICOSL were investigated in experimental models of NASH based on mice feeding with choline/methionine deficient (MCD) or a cholesterol-enriched Western diets.

**Results:** In animal models of NASH, ICOS was selectively up-regulated on CD8+ T cells in parallel with an expansion of ICOSL-expressing CD11b+/F4-80+ monocytes/macrophages (MoMFs). Mice deficient for ICOSL receiving the MCD diet for 6 weeks had milder steatohepatitis. This effect was confirmed in mice fed with the Western diet for 24 weeks that also showed the lack of ICOSL greatly reduced the development of liver fibrosis. Recent studies have shown that NASH associated MoMFs display a specific phenotype characterized by the expression of the Triggering Receptor Expressed on Myeloid cells 2 (TREM2) and by the production of pro-fibrogenic mediators such as osteopontin (OPN) and galectin-3 (Gal-3). Liver TREM2, OPN and Gal-3 were strongly up-regulated in mice with NASH and the lack of ICOSL significantly reduced them without influencing liver MoMFs prevalence. Moreover, immunohistochemistry for OPN and Gal-3 confirmed the presence in NASH livers of diffuse crown-like macrophage aggregates positive for OPN and Gal-3 that were markedly reduced in ICOSL-/- mice.

**Conclusion:** Altogether these data indicate that ICOS present on CD8+ T cells provides critical signals to ICOSL-expressing liver MoMFs that allow them to maintain a pro-inflammatory and pro-fibrogenic phenotype that characterizes NASH-associated macrophages (NAMs) and suggest ICOS/ICOSL dyad as a possible target for therapeutic interventions.

**Blockade of IL-1 signaling in hepatocytes reduces tumor growth in a mouse model of NAFLD-related HCC**

Nadine Gehrke<sup>1</sup>, Beate Straub<sup>2</sup>, Marcus-Alexander Wörns<sup>1</sup>, Peter Galle<sup>1</sup>, Jörn Schattenberg<sup>1</sup>. <sup>1</sup>University Medical Center of the Johannes Gutenberg University Mainz, I. Department of Medicine, Mainz, Germany; <sup>2</sup>University Medical Center of the Johannes Gutenberg University Mainz, Institute of Pathology, Mainz, Germany  
Email: nadine.gehrke@unimedizin-mainz.de

**Background and aims:** Non-alcoholic fatty liver disease (NAFLD), especially its progressive form non-alcoholic steatohepatitis (NASH), represents an increasingly important cause of hepatocellular carcinoma (HCC); however, little is known about the molecular drivers involved. Given pathophysiological roles of IL-1 in inflammation and metabolism, we used hepatocyte-specific IL-1 receptor type 1 (IL-

1R1) knockout (*Il1r1*<sup>Hep-/-</sup>) mice to examine the contribution of this pathway in NAFLD-associated hepatocarcinogenesis.

**Method:** Diethylnitrosamine (DEN, 25 mg/kg body weight) was given i.p. to 2-week-old, male *Il1r1*<sup>Hep-/-</sup> mice and wild-type (WT) littermates. From 6 weeks of age the mice were fed either a high-fat, high-carbohydrate diet (HFD) or a control diet (n = 7–13/genotype and diet) until sacrifice at 24 weeks of age.

**Results:** All DEN-injected mice fed the HFD developed significant obesity, hyperlipidemia, and hyperglycemia; however *Il1r1*<sup>Hep-/-</sup> mice were less susceptible to elevations of fasting glucose (378.2 vs. 444.3 mg/dl, p = 0.08) and HOMA-IR levels (31.4 vs. 49.7). Regarding liver pathology, IL-1R1 deficiency had no major impact on HFD-induced hepatomegaly, increase in serum transaminase activity and histologically confirmed macrovesicular steatosis. Macroscopic liver tumors arose with an incidence of 100% in both genotypes in response to DEN/HFD and an average of 15.1 vs. 18.1 nodules in

## POSTER PRESENTATIONS

*Il1r1*<sup>Hep-/-</sup> vs. WT livers. Remarkably, the average tumor size was 2.5-fold reduced in *Il1r1*<sup>Hep-/-</sup> mice. Also histopathological examination of the left lateral liver lobe revealed a 2.7-fold reduction in dysplastic foci >1 mm in transgenic compared to WT mice (p = 0.08). In both genotypes, DEN/HFD induced an increase in intrahepatic F4/80<sup>+</sup> macrophages, Ly6C<sup>+</sup> monocytes and NK cells and a concomitant decline in the proportion of CD4<sup>+</sup> and CD4<sup>+</sup>CD25<sup>+</sup> T cells, irrespective of IL-1R1. By contrast, only WT mice presented a significantly elevated percentage of CD8<sup>+</sup> T cells. Likewise, DEN/HFD led to increased levels of various pro-inflammatory and chemotactic cytokines, but upregulation of IL-1 $\alpha$ , TNF- $\alpha$  and TGF- $\beta$  was significantly higher in *Il1r1*<sup>Hep-/-</sup> vs. WT livers, whereas NF- $\kappa$ B p65 activity was diminished (p = 0.08).

**Conclusion:** There is early evidence from this mouse model of NAFLD-driven HCC, that inhibition of the IL-1R1 pathway in hepatocytes leads to reduced tumor growth. It remains to be determined whether improved insulin sensitivity and/or inflammatory processes in *Il1r1*<sup>Hep-/-</sup> mice are critical for reduced tumor burden.

### PO-1986

#### The rs599839 A>G variant disentangles cardiovascular risk and hepatocellular carcinoma in NAFLD patients

Marica Meroni<sup>1</sup>, Miriam Longo<sup>1,2</sup>, Erika Paolini<sup>1,2</sup>, Emilia Rita De Caro<sup>1</sup>, Anna Alisi<sup>3</sup>, Luca Miele<sup>4</sup>, Giuseppina Pisano<sup>1</sup>, Marco Maggioni<sup>1</sup>, Giorgio Soardo<sup>5</sup>, Luca Valenti<sup>1</sup>, Anna Ludovica Fracanzani<sup>1</sup>, Paola Dongiovanni<sup>1</sup>. <sup>1</sup>Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milano, Italy, General Medicine and Metabolic Diseases, Milan, Italy; <sup>2</sup>Università degli Studi di Milano, Italy, Department of Pharmacological and Biomolecular Sciences, Milan, Italy; <sup>3</sup>Bambino Gesù Children Hospital-IRCCS, Rome, Italy, Research Unit of Molecular Genetics of Complex Phenotypes, Italy; <sup>4</sup>Area Medicina Interna, Gastroenterologia e Oncologia Medica, Fondazione Policlinico Universitario A. Gemelli IRCCS, Rome, Italy; <sup>5</sup>7Clinic of Internal Medicine-Liver Unit Department of Medical Area (DAME) University School of Medicine, Udine, Italy and Italian Liver Foundation AREA Science Park-Basovizza Campus, Trieste, Italy Email: paola.dongiovanni@policlinico.mi.it

**Background and aims:** Dyslipidemia and cardiovascular events are hallmark of non-alcoholic fatty liver disease (NAFLD), which ranges from steatosis to hepatocellular carcinoma (HCC). The rs599839 A>G variant, is localized in the CELSR2-PSRC1-SORT1 genetic cluster, which regulates both lipid handling and microtubule destabilization and spindle assembly during mitotic processes. The rs599839 variant has been previously associated with coronary artery disease (CAD), however its impact on metabolic traits and liver damage in NAFLD patients has not been investigated yet.

**Method:** We evaluated the effect of the rs599839 variant in 1380 biopsied NAFLD patients (Overall cohort) of whom 121 have HCC (NAFLD-HCC), in 500,000 individuals from the UK Biobank Cohort (UKBCC) and in 366 HCC samples from The Cancer Genome Atlas (TCGA). Hepatic PSRC1, SORT1 and CELSR2 expressions were evaluated by RNAseq in a subset of patients (n = 125).

**Results:** The rs599839 variant was associated with reduced circulating LDL, carotid intima-media thickness, carotid plaques, and hypertension (p < 0.05) in NAFLD patients and with protection against dyslipidemia in UKBCC. The G allele was associated with higher risk of HCC (p < 0.05) in the Overall cohort. Hepatic PSRC1, SORT1 and CELSR2 expressions were increased in NAFLD patients carrying the rs599839 variant (p < 0.0001). SORT1 mRNA levels negatively correlated with those of genes involved in lipoprotein turnover (p < 0.0001) and with circulating lipids. Conversely, PSRC1 expression was positively related to that of genes implicated in cell proliferation (p < 0.0001). In TCGA, PSRC1 over-expression promoted tumor stage and grade worsening and it correlated with genes involved in cell cycle progression (p < 0.05).

Figure: Association of the rs599839 variant with HCC (1380 NAFLD patients (Overall cohort) of whom 121 have HCC). Multivariable nominal logistic regression analysis adjusted for age, sex, BMI, T2D, presence of PNPLA3 I148M, TM6SF2 E167K and MBOAT7 T alleles at ° additive or +recessive model. CI: confidence interval.

**Conclusion:** In sum, the rs599839 A>G variant improves dyslipidemia thus protecting against CAD in NAFLD patients, but as one it might promote HCC development by modulating SORT1 and PSRC1 expressions which impact on lipid metabolism and cell proliferation, respectively.

### PO-2033

#### TM6SF2/PNPLA3/MBOAT7 loss-of-function genetic variants impact on NAFLD development and progression both in patients and in in vitro models

**Background and aims:** The I148M PNPLA3 and E167K TM6SF2 variants alongside the rs641738 polymorphism in MBOAT7/TMC4 locus represent the main genetic predictors of non-alcoholic fatty liver disease (NAFLD). We knocked-out MBOAT7 in HepG2 cells, homozygous for the I148M PNPLA3 (MBOAT7<sup>-/-</sup>), which developed giant lipid droplets (LDs). We aimed to: 1) investigate the synergic impact of the 3 risk variants on liver disease severity and hepatocellular carcinoma (HCC) in NAFLD patients; 2) generate in

Figure: (abstract: PO-2033): Representative TEM images of LDs, ER tubules, and degenerative mitochondria (black arrows) obtained by ultrathin 70 nm sections of hepatocytes (bar scale: 1  $\mu$ m)

*in vitro* models of NAFLD by silencing *TM6SF2* in both HepG2 (*TM6SF2*<sup>-/-</sup>) and *MBOAT7*<sup>-/-</sup> cells (*MBOAT7*<sup>-/-</sup>*TM6SF2*<sup>-/-</sup>).

**Method:** 1380 biopsied NAFLD patients including 121 HCC were stratified by a semi-quantitative score ranging from 0 to 3 according to the number of *PNPLA3*, *TM6SF2* and *MBOAT7* at-risk variants. *TM6SF2* was silenced in HepG2 cells through CRISPR/Cas9. Organelles' morphology was assessed by transmission electron microscopy (TEM). Lipidomics was performed by LCMS-QTOF.

**Results:** At multivariate analysis adjusted for age, sex, BMI and diabetes, the co-presence of the 3 risk alleles correlated with the histological degree of steatosis ( $p < 0.0001$ ), necroinflammation ( $p < 0.0001$ ), ballooning ( $p = 0.004$ ) and fibrosis ( $p < 0.0001$ ). At nominal logistic regression analysis adjusted as above, patients carrying the 3 variants showed ~2-fold higher risk of fibrosis $>2$  ( $p = 0.0003$ ), cirrhosis ( $p = 0.0007$ ) and HCC ( $p = 0.01$ ). *TM6SF2* silencing induced micro-vesicular LDs accumulation (median size: 0.87  $\mu$ m<sup>2</sup>) in *TM6SF2*<sup>-/-</sup> cells, whereas the *MBOAT7*<sup>-/-</sup>*TM6SF2*<sup>-/-</sup> developed both micro/macro LDs (median size: 4.60  $\mu$ m<sup>2</sup>). Lipidomic analysis revealed that the amount of saturated/monounsaturated triacylglycerols was increased in cells lacking *TM6SF2* gene, while the polyunsaturated ones were reduced. *TM6SF2* deletion strongly affected endoplasmic reticulum (ER) and mitochondrial architecture and the compound knockout showed the highest levels of ER/oxidative stress and DNA damage ( $p < 0.05$ ). *TM6SF2* deletion increased proliferative rate, more so in *MBOAT7*<sup>-/-</sup>*TM6SF2*<sup>-/-</sup> cells ( $p < 0.05$ ), which represent the first model generated *in vitro* which may fully reproduce features of NAFLD individuals bearing all the 3 at-risk variants.

**Conclusion:** The co-presence of the 3 at-risk mutations impacts on NAFLD spectrum, in humans and experimental models. *TM6SF2* silencing alone or combined with I148M *PNPLA3* and *MBOAT7* deletion affects LDs' distribution and contributes to hepatocellular damage and proliferation.

**PO-2055**

**The I148M *PNPLA3* variant mitigates Niacin beneficial effects: how the genetic screening in Non-alcoholic Fatty Liver Disease (NAFLD) patients gains value**

Erika Paolini<sup>1,2</sup>, Miriam Longo<sup>1,3</sup>, Marica Meroni<sup>1</sup>, Gemma Malaspina<sup>1</sup>, Emilia De Caro<sup>1</sup>, Annalisa Cespiati<sup>1</sup>, Rosa Lombardi<sup>1</sup>, Anna Ludovica Fracanzani<sup>1</sup>, Paola Dongiovanni<sup>1</sup>.

<sup>1</sup>General Medicine and Metabolic Diseases, Fondazione IRCCS Cà Granda Ospedale Maggiore Policlinico, Milan, Italy, Milan, Italy; <sup>2</sup>Department of Pharmacological and Biomolecular Sciences, Università degli Studi di Milano, Milan, Italy, Milan, Italy; <sup>3</sup>Department of Clinical Sciences and Community Health, Università degli Studi di Milano, Milan, Italy, Milan, Italy

Email: paola.dongiovanni@policlinico.mi.it

**Background and aims:** The *PNPLA3* p.I148M variant is the major genetic predictor of NAFLD and nutrients modulate its impact on fat accumulation. Vitamin B3 (niacin) reduces triglycerides (TGs) synthesis and ROS production in NAFLD patients. However, the interplay between niacin and I148M genotype in the context of NAFLD has not been explored yet. Therefore, this study aims to: 1) assess the dietary and circulating levels of niacin in NAFLD patients stratified according to the presence of the I148M variant; 2) evaluate the beneficial effect of niacin in terms of lipid metabolism and oxidative stress in hepatoma cells (HepG2), carrying the I148M mutation, and in which steatosis was mimicked through palmitic acid (PA) exposure.

**Method:** We enrolled 172 patients with non-invasively assessed NAFLD. Dietary niacin was collected from a food questionnaire. Niacin serum levels were quantified by ELISA. Hepatic expression of genes related to NAD metabolism was evaluated by RNAseq in biopsied bariatric NAFLD patients (n = 125). HepG2 cells were treated with niacin 0.5 mM and/or PA 0.5 mM.

## POSTER PRESENTATIONS

**Results:** At bivariate analysis NAFLD patients showed reduced dietary niacin ( $p=0.01$ ). The p.I148M variant was correlated with lower levels of alimentary and circulating niacin ( $p=0.01$  and  $p<0.05$  vs non-carriers, respectively). At multivariate analysis, adjusted for sex, BMI, alimentary niacin and severe steatosis the p.I148M mutation was associated with reduced circulating niacin (beta = -18.01; CI: -35.6–0.57;  $p=0.03$ ), suggesting that it may independently modulate niacin systemic availability. The hepatic expression of NAPRT, the first enzyme of NAD biosynthesis, was decreased in p. I148M carriers ( $p=0.006$ ). In HepG2 cells, treatment with niacin and/or PA increased NADH levels ( $p<0.05$ ), consistently with niacin's role as NAD precursor. Niacin alone or with PA reduced intracellular fat ( $p<0.05$ ), upregulating the lipoproteins' export (MTTP;  $p<0.05$  vs control) and the release of HDL rather than LDL was higher after niacin exposure ( $p<0.05$ ). Niacin decreased ROS production even after PA stimulus ( $p<0.05$  vs control) and ameliorated cell viability subsequently PA-induced lipotoxicity ( $p<0.05$  vs PA).

**Conclusion:** Niacin levels are reduced in the presence of severe steatosis and more so in patients carrying the I148M variant. In HepG2 cells niacin supplementation reduces hepatic fat accumulation and oxidative stress.

	Estimate (β)	95% C.I.	P-value
Sex, Male	12.46	-7.48-32.41	0.21
BMI (Kg/m <sup>2</sup> )	-1.49	-5.64-2.96	0.50
Alimentary Niacin	-0.10	-0.37-0.15	0.42
Steatosis >2	-5.46	-22.68-11.76	0.53
PNPLA3 I48M, yes	-19.74	-37.68-1.80	0.03

At multivariate analysis, adjusted for sex, BMI, alimentary niacin, and severe steatosis the presence of the p.I148M mutation is significantly associated with reduced circulating niacin levels in 172 NAFLD patients (beta = -18.01; CI: -35.6 - 0.57;  $p=0.03$ ), suggesting that it may independently modulate niacin systemic availability.

### PO-2123

#### Liver Biopsy Graph Neural Networks for automated histologic scoring using the NASH CRN system

Jason Wang<sup>1</sup>, Maryam Pouryahya<sup>1</sup>, Kenneth Leidal<sup>1</sup>, Harsha Pokkalla<sup>1</sup>, Dinkar Juyal<sup>1</sup>, Zahil Shanis<sup>1</sup>, Aryan Pedawi<sup>1</sup>, Quang Le<sup>1</sup>,

Victoria Mountain<sup>1</sup>, Sara Hoffman<sup>1</sup>, Jackie Honerlaw<sup>1</sup>, Murray Resnick<sup>1</sup>, Michael Montalto<sup>1</sup>, Andrew Beck<sup>1</sup>, Katy Wack<sup>1</sup>, Ilan Wapinski<sup>1</sup>, Oscar Carrasco-Zevallos<sup>1</sup>, Amaro Taylor-Weiner<sup>1</sup>.

<sup>1</sup>PathAI, Boston, United States

Email: amaro.taylor@pathai.com

**Background and aims:** Clinical trials in non-alcoholic steatohepatitis (NASH) require pathologic review of liver biopsies. Manual review is limited by inter- and intra-pathologist variability. While "black box" convolutional neural networks (CNNs) can standardize scoring of NASH histology, their application is limited by interpretability. Here, we describe a novel graph neural network (GNN) approach that combines interpretability with performance for NASH scoring.

**Method:** Whole-slide images (WSI) of 639 HandE and 633 trichrome NASH liver biopsies from clinical trial participants (EMINENCE, NCT02784444) were scored by 3 pathologists for NAFLD Activity (NAS 0–8) and its 3 components— inflammation (0–3), steatosis (0–3), and ballooning (0–2), and for fibrosis (0–4), respectively, and split into train, validation and test sets. A pathologist network annotated WSIs for tissue regions. Using the annotations on training set images, CNNs were trained to generate pixel-level predictions of 13 HandE and 5 trichrome classes (e.g., hepatocytes, bile duct etc.). WSIs were then converted into directed graphs via pixel-clustering (Birch method) and graph construction (treating each cluster as a node, directed edges were drawn between each node and its 5 nearest nodes). Each node was characterized by spatial and biological features (e.g., cluster size, bile duct pixels, etc.). GNNs were trained to grade biopsies for NAS and its 3 components (HandE), and fibrosis (trichrome). To account for inter-pathologist variability, we implemented a mixed-effects model to learn pathologist-specific biases during training (discarded during testing).

**Results:** GNN predictions were concordant with median pathologist scores (test set): linearly-weighted Cohen's kappa of 0.613 (NAS), 0.758 (steatosis), 0.584 (inflammation), 0.614 (ballooning), and 0.507 (fibrosis). Learned pathologist biases showed that scoring was consistently biased across tasks (Pathologist 1 scored lower than consensus, mean bias -0.459; Pathologist 3 scored higher, 0.495). In

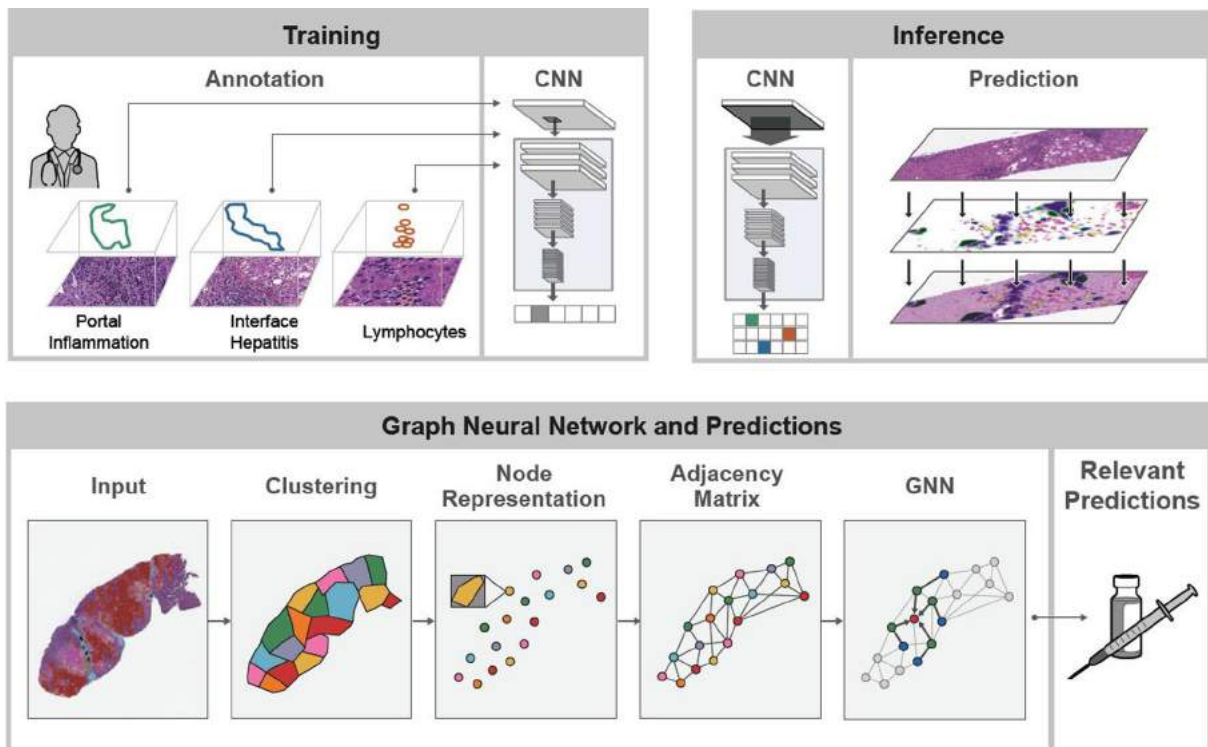

Figure: (abstract: PO-2123)

addition, we observed pathologist task-specific biases (inflammation saw minimal bias, fibrosis was highly biased).

**Conclusion:** Our approach recapitulates pathologist scorings for NAS, its 3 components, and fibrosis. Performance was comparable to that of published “black-box” models trained on larger datasets, demonstrating data efficiency. Our approach also enabled investigation of systematic biases among pathologists and NASH scoring tasks.

**PO-2161**

**Human hepatocyte PNPLA3-148M exacerbates rapid non-alcoholic fatty liver disease development in chimeric mice**

Email: ydj2001@med.cornell.edu

**Background and aims:** Non-alcoholic fatty liver disease (NAFLD) is a rapidly emerging global health problem associated with metabolic syndrome and predisposing genetic polymorphisms, most strikingly an isoleucine to methionine substitution in patatin-like phospholipase domain-containing protein 3 (PNPLA3-I148M). Despite mechanistic studies in rodent models and cell lines, the role of the 148M variant in human NAFLD progression remains to be further elucidated. Here we established a NAFLD model to study the impact of hypercaloric feeding in liver chimeric mice with PNPLA3-148I or -148M human grafts.

**Method:** Livers of immunodeficient *Fah*<sup>-/-</sup> mice (FNRG) were repopulated with primary human hepatocytes (PHH) from PNPLA3-148I or 148M donors. Once high human liver chimerism was achieved, mice were subjected to a Western-Style Diet (WD) consisting of sucrose in drinking water and a high fat (HFD). In addition, both PNPLA3 variants were overexpressed in PHH from a PNPLA3-148I homozygous donor prior to engraftment and chimeric mice were challenged with a WD or HFD.

**Results:** As early as 4 weeks on WD, humanized mice developed dyslipidemia, impaired glucose tolerance, and steatohepatitis

selectively in the human graft, followed by pericellular fibrosis after 8 weeks of WD feeding. The PNPLA3-148M variant, either from a homozygous 148M PHH donor or overexpressed in a homozygous 148I PHH background, caused microvesicular steatosis, more active steatohepatitis, and Mallory Denk body formation in chimeric livers of mice on hypercaloric diets.

**Conclusion:** PNPLA3-148I human hepatocytes develop steatosis and steatohepatitis with mild activity in chimeric mice on a hypercaloric diet. The PNPLA3-148M variant in human hepatocytes caused more active steatohepatitis. These models will facilitate mechanistic studies into the role of PNPLA3 in fatty liver disease progression. Human liver chimeric mice will also provide a platform to examine other human risk alleles associated with advanced fatty liver diseases.

**PO-2186**

**Imaging by Desorption electrospray ionization mass spectrometry detects changes in lobular patterns of lipids in non-alcoholic fatty liver disease**

Patcharamon Seubnooch<sup>1</sup>, Pavitra Kumar<sup>1</sup>, Mojgan Masoodi<sup>2</sup>, Marie V. St-Pierre<sup>1</sup>, David Bélet<sup>1</sup>, Matteo Montani<sup>3</sup>, Umara Rafiqi<sup>3</sup>, Emmanuelle Claude<sup>4</sup>, Aurel Perren<sup>3</sup>, Jean-François Dufour<sup>1,5</sup>. <sup>1</sup>Hepatology, Department for BioMedical Research, University of Bern, Bern, Switzerland; <sup>2</sup>Institute of Clinical Chemistry, Inselspital, Bern University Hospital, Bern, Switzerland; <sup>3</sup>Institute of Pathology, University of Bern, Bern, Switzerland; <sup>4</sup>Waters Corporation, Wilmslow, United States; <sup>5</sup>University Clinic for Visceral Surgery and Medicine, Inselspital, Bern, Switzerland

Email: jean-francois.dufour@dbmr.unibe.ch

**Background and aims:** Hepatic lipid accumulation is the hallmark of non-alcoholic fatty liver disease (NAFLD). The liver lobules display metabolic zonation and therefore lipidomics analysis of liver homogenates fails to provide information on the distribution of metabolites. However, a new mass spectrometry imaging technique called Desorption Electrospray Ionization (DESI-MS) does provide spatial metabolomics information and localization directly from tissue sections. Thus, our aim was to develop spatial lipidomics using DESI-MS to study hepatic lipids changes in NAFLD.

**Method:** Frozen liver sections from control (n = 5) or NAFLD mice (n = 5) fed a high fat diet (Teklad TD.120528) were analyzed using a DESI-MS (Waters Corporation, USA) in both positive and negative ionization modes over the mass range m/z 100 to 1200. Imaging was performed at 50 μm spatial resolution and 50 μm/s scan rate. The solvent consisted of methanol: water (98:2 v/v). The sensitivity and quality of imaging data were optimized via sprayer tip, geometric parameters of the sprayer source, sprayer parameters (nebulizing gas

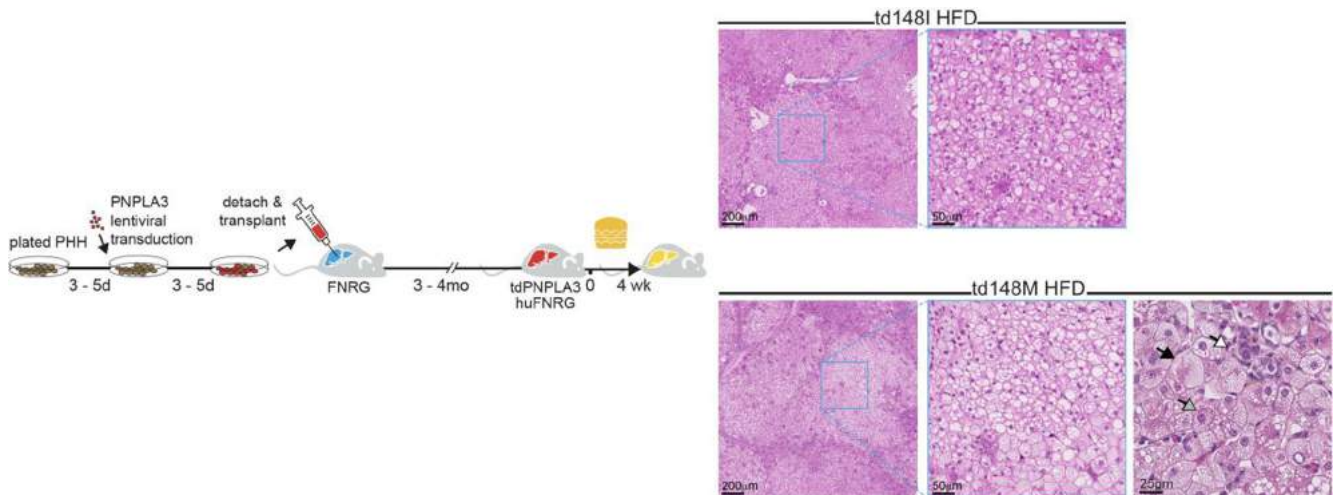

Figure: (abstract: PO-2161)

Figure: (abstract: PO-2186): Lipid metabolite distribution across the liver lobule.

and solvent flow rates) and mass spectrometry parameters to obtain the highest intensity.

**Results:** Oil Red O staining showed grade 3 steatosis in all NAFLD livers. Sirius Red staining showed a 4.5-fold increase in fibrosis in NAFLD ( $p < 0.05$ ). We detected 1,102 metabolites out of which 866 were significantly different between control and NAFLD livers. Triacylglycerols (TGs), diacylglycerols (DGs) and unsaturated fatty acids were higher in NAFLD liver than in control liver by 3.9-fold, 14.0-fold and 2.9-fold ( $p < 0.001$ ), respectively. Controls showed uneven distribution of TGs, DGs, phosphatidylcholines (PCs) and phosphatidylserines (PSs) across the liver lobule. NAFLD livers failed to show these zonation patterns (Figure 1). In particular, PCs were more abundant in the periportal zones than in the pericentral zones of controls, whereas PCs were evenly distributed in NAFLD livers. In fact, PCs were 5-fold ( $p < 0.001$ ) less abundant in NAFLD periportal zones.

**Conclusion:** DESI-MS allows the determination of the spatial distribution of lipid species across the liver lobule. NAFLD triggers a more uniform lobular distribution of TGs, DGs, PCs and PSs.

#### PO-2210

##### A 3D *in vitro* screening-based discovery approach for selecting and prioritizing NASH drug candidates

Simon Ströbel<sup>1</sup>, Radina Kostadinova<sup>1</sup>, Jana Rupp<sup>1</sup>, Katia Fiaschetti<sup>1</sup>, Agnieszka Pajak<sup>1</sup>, Katarzyna Sanchez<sup>1</sup>, Manuela Bieri<sup>1</sup>, Armin Wolf<sup>1</sup>, Eva Thoma<sup>1</sup>. <sup>1</sup>InSphero AG, Schlieren, Switzerland  
Email: radina.kostadinova@insphero.com

**Background and aims:** Non-alcoholic steatohepatitis is a severe progressive disease characterized by lipid accumulation, inflammation and fibrosis in the liver. To date, there are no approved drugs for NASH treatment and drug development has been impeded by the lack of predictive *in vitro* models reflecting the complex pathology of NASH. The aim of the study was to develop a human 3D *in vitro* NASH spheroid microtissue, based on a scaffold-free co-culture of primary hepatocytes, Kupffer cells, liver endothelial cells, and hepatic stellate cells for high-throughput-compatible drug efficacy testing.

**Method:** Upon exposure to defined lipotoxic and inflammatory stimuli, such as free fatty acids and LPS in media containing high levels of sugar and insulin, our 3D NASH model displayed key disease pathophysiological features within 10 days of treatment. We established methods for assessing characteristic and quantifiable markers for NASH drug efficacy testing, including assays and end

points for measuring triglyceride assays, secretion of pro-inflammatory cytokines/chemokines (Luminex), and secretion of pro-collagen type I/III (HTRF/ELISA).

**Results:** We observed increases in intracellular triglyceride content as indicator of lipid accumulation and the secretion of inflammatory markers such as IL-6, MIP-1alpha, TNF-alpha, IL-10, MCP-1 and IL-8 in our NASH-induced model as compared to the untreated control. Further, we detected increased fibril collagens deposition and secretion of procollagen type I and III peptides under NASH conditions. Whole transcriptome analysis of NASH-induced microtissue versus control revealed activation of pathways and differential regulation of genes associated with key lipid metabolism, inflammation, and fibrosis induction. Treatment with the anti-NASH TGF-beta antibody and ALK5i (TGFβRI inhibitor) concentration dependently decreased secretion of pro-collagen type I/III. Decreased deposition of fibrosis based on quantification of Sirius-Red-stained tissues (PharmaNest) was observed in the presence of anti-TGF-beta antibody and ALK5i. Importantly, biochemical readouts for 3D models treated with NASH drug candidates (Selonsertib and Firsocostat) were indicative of disease progression and the results generally reflected documented clinical observations.

**Conclusion:** In summary, using this rapid, high-throughput-compatible 3D NASH model for drug candidate efficacy testing represents a promising approach for selection and decision making of the most effective drug candidates to move further in the development.

#### PO-2276

##### Ripk3 depletion improves mitochondrial bioenergetics and function in experimental NAFLD

Tawhidul Islam<sup>1</sup>, Marta B. Afonso<sup>1</sup>, Ricardo Amorim<sup>2</sup>, Veronique Lenoir<sup>3</sup>, Vlad Ratziu<sup>4,5,6</sup>, Paulo J. Oliveira<sup>2</sup>, Rui E. Castro<sup>1</sup>, Carina Prip-Buus<sup>3</sup>, Jérémie Gautheron<sup>6,7</sup>, Cecília M. P. Rodrigues<sup>1</sup>. <sup>1</sup>Research Institute for Medicines (iMed.Ulisboa), Faculty of Pharmacy, Universidade de Lisboa, Lisbon, Portugal; <sup>2</sup>Center for Neuroscience and Cell Biology (CNC), UC Biotech Building, Universidade de Coimbra, Coimbra, Portugal; <sup>3</sup>Institut Cochin, Inserm, CNRS UMR8104, Université Paris Descartes, Paris, France; <sup>4</sup>Assistance Publique-Hôpitaux de Paris (AP-HP), Pitié-Salpêtrière Hospital, Department of Hepatology, Paris, France; <sup>5</sup>Sorbonne Université, Inserm, Centre de Recherche des Cordeliers (CRC), Paris, France; <sup>6</sup>Institute of Cardiometabolism and Nutrition

(ICAN), Paris, France; <sup>7</sup>Sorbonne Université, Inserm, Centre de Recherche Saint-Antoine (CRSA), Paris, France  
 Email: cmprodrigues@ff.ul.pt

**Background and aims:** Metabolic harmony between mitochondrial respiratory chain (MRC) activity and mitochondrial fatty acid oxidation is crucial to curb hepatic fat accumulation and restrain reactive oxygen species (ROS) overabundance. We have recently reported that receptor-interacting protein kinase 3 (RIPK3) acts as a lipid metabolism regulator contributing to liver damage, inflammation, fibrosis and carcinogenesis in non-alcoholic fatty liver disease (NAFLD). Here, we aimed to evaluate the role of RIPK3 in the interaction between lipid metabolism and mitochondria in experimental NAFLD.

**Method:** Wild-type (WT) and *Ripk3*<sup>-/-</sup> mice were fed either a choline-sufficient, amino acid-defined control diet (CSAA; n = 38) or a choline-deficient, amino acid-defined diet (CDAA; n = 38) for 32 and 66 weeks. Liver samples were used for measuring MRC activities and evaluating of mitochondrial function. Mechanistic studies were performed in WT and *Ripk3*<sup>-/-</sup> murine AML12 hepatocytes incubated with palmitic acid (PA).

**Results:** The CDAA diet resulted in decreased expression and activities of MRC complexes in WT mice, compared to CSAA-fed WT animals. Strikingly, *Ripk3*<sup>-/-</sup> mice showed an overall protection against CDAA-induced MCR complex impairment, both at 32 and 66 weeks. Similarly, PGC1 $\alpha$ , NRF1, TFAM, NRF2 and MFN2 were down-regulated in CDAA-fed WT mice, but significantly increased in *Ripk3*<sup>-/-</sup> animals. *Ripk3*-deficient mice also showed reduced mitochondrial DNA damage and increased SOD1, SOD2 and SIRT3 levels, contrasting the effect of the CDAA-diet. In WT AML12 cells, PA incubation increased cellular and mitochondrial ROS, preceding

altered mitochondrial morphology and membrane potential, and decreased oxygen consumption rates, a phenotype abrogated by *Ripk3* deficiency. Further, lipid droplet size and number were decreased in PA-loaded *Ripk3*<sup>-/-</sup> AML12 cells, despite similar lipid overload, comparing to WT AML12 cells. Curiously, *Ripk3*<sup>-/-</sup> cells exposed to PA also showed increased lipid droplet-associated PLIN5 levels, suggesting that RIPK3 signalling mediates the interaction between lipids and mitochondria.

**Conclusion:** Overall, impaired MRC complex activity and lipid overload correlate with mitochondrial dysfunction, ROS overproduction and altered mitochondrial metabolism in experimental NAFLD. RIPK3 deficiency restores MRC complex activity, increases ROS detoxification capacity, enhances mitochondrial bioenergetics and function, thus halting NAFLD.

**PO-2322**

**Exposure to environmental contaminants is associated with sex-specific disturbances of hepatic lipid metabolism in non-alcoholic fatty liver disease**

Matej Orešič<sup>1</sup>, Partho Sen<sup>2</sup>, Sami Quadri<sup>3</sup>, Panu Luukkonen<sup>3</sup>, Oddny Ragnarsdóttir<sup>1</sup>, Sirkku Jäntti<sup>3</sup>, Anne Juuti<sup>3</sup>, Johanna Arola<sup>3</sup>, Hannele Yki-Järvinen<sup>3</sup>, Tuulia Hyötyläinen<sup>1</sup>. <sup>1</sup>Örebro University, Sweden; <sup>2</sup>University of Turku, Turku, Finland; <sup>3</sup>University of Helsinki, Helsinki, Finland  
 Email: matej.oresic@oru.se

**Background and aims:** Liver has a vital role in metabolism, distribution, and excretion of exogenous chemicals. The endocrine

Figure: (abstract: PO-2322): Environmental contaminants (ECs) linked with liver fat % and HOMA-IR. A-B) Horizontal bar plots showing ranks ( $\pm$  model coefficients) of different ECs as predictors, using generalized linear regression modeling, adjusted for age and BMI as covariates.

## POSTER PRESENTATIONS

disrupting chemicals (EDCs) may act as a 'second hit' in the progression of NAFLD, advancing the earlier stages of liver pathology such as steatosis to more severe stages. A specific class of EDCs that have been linked with NAFLD are perfluorinated alkyl substances (PFAS), a class of commonly used industrial chemicals that humans are widely exposed to. Due to their structural similarity with fatty acids, PFAS may disrupt hepatic lipid metabolism. Furthermore, functionally, PFAS share some features with bile acids, including similar enterohepatic circulation. Nevertheless, human data linking PFAS exposure and lipid metabolism in the liver are currently lacking. The principal aim of our study was to define the impact of PFAS exposure on hepatic metabolism, with specific focus on bile acid and lipid metabolism.

**Method:** In a well-characterized human NAFLD cohort of 105 individuals, we investigated the impact of PFAS exposure on liver metabolism in the individuals with NAFLD. Average BMI was  $45.65 \pm 5.99$  kg/m<sup>2</sup>, with liver fat content varying between 0% and 80%. We comprehensively characterized both hepatic (liver biopsy) and serum metabolome using four analytical platforms, and measured PFAS in serum. We investigated the association between the NAFLD (liver fat %, NASH grade, fibrosis stage, insulin resistance), PFAS exposure, and metabolome.

**Results:** PFAS exposure was associated with NAFLD (Figure) as well as with changes in hepatic lipid and bile acid metabolism. Importantly, we observed sex-specific association between chemical exposure and NAFLD, linked with sex-specific changes in both hepatic and circulating metabolome. We noticed differences not only in the exposure profiles between the males and females, but, notably, also the impact of the exposure, as characterized both with the impact on metabolome but also on clinical parameters was clearly different between the males and females.

**Conclusion:** Our results implicate that females may be more sensitive to the harmful impacts of PFAS. The results also suggest that the changes reported in the lipid metabolism due to PFAS exposure may be secondary to the interplay of PFAS and bile acids.

### PO-2411

#### Hepatocyte-specific deletion of ERK5 worsens insulin resistance in a murine model of non-alcoholic fatty liver disease

Giovanni Di Maira<sup>1</sup>, Giulia Lori<sup>1</sup>, Benedetta Piombanti<sup>1</sup>, Maria Letizia Taddei<sup>1</sup>, Alessio Menconi<sup>1</sup>, Paola Chiarugi<sup>1</sup>, Cathy Tournier<sup>2</sup>, Elisabetta Rovida<sup>1</sup>, Fabio Marra<sup>1</sup>. <sup>1</sup>University of Florence; <sup>2</sup>University of Manchester  
Email: giovanni.dimaira@unifi.it

**Background and aims:** The extracellular signal-regulated kinase 5 (ERK5) is a member of the mitogen-activated protein kinase family highly expressed in hepatocytes, macrophages and stellate cells. We recently generated hepatocyte-specific ERK5 knock-out mice (ERK5DHep). The aim of this study was to investigate the role of hepatocyte ERK5 in a murine model of NAFLD.

**Method:** ERK5DHep and control mice were fed with a high-fat diet (HFD) for 16 weeks. For glucose tolerance test (GTT) mice were injected with 1 g/kg BW glucose. Insulin tolerance test (ITT) was performed by injecting 0.8 U/kg BW of regular insulin. A murine hepatocyte cell line (MMH) was silenced using lentiviral vectors encoding shRNA for the ERK5 gene. Mitochondrial depolarization was assayed using the TMRE staining protocol. OXPHOS metabolism was measured by Seahorse.

**Results:** ERK5DHep mice exhibited impaired glucose tolerance and reduced insulin sensitivity in comparison to the control group. Bodyweight and food consumption were similar. MMH silenced for ERK5 showed reduced Akt activation following insulin stimulation. In MMH challenged with palmitic acid and then stimulated with insulin, ERK5 knockdown caused a complete abrogation of Akt activation, a reduction in the expression of the insulin receptor as well as an increase in the phosphorylation of IRS-1 at S307. All these events are associated with reduced sensitivity to insulin signaling.

Insulin receptor phosphorylation on S307 may be mediated by JNK, which was more phosphorylated in MMH/shERK5. Measurement of mitochondrial membrane potential indicated a strong depolarization in ERK5-silenced cells, which also showed an impairment of mitochondrial OXPHOS, indicating a profound impact of ERK5 deficiency on mitochondrial functions. In ERK5-silenced cells expression of peroxisome proliferator-activated receptor-gamma coactivator-1 $\alpha$  (PGC-1 $\alpha$ ), a pivotal regulator of mitochondrial biogenesis and function, was up-regulated. Additionally, expression of TRIB3, which negatively regulates insulin signalling through inhibition of Akt and under the control of PGC-1 $\alpha$ , was higher in MMHshERK5 cells, and its expression was further enhanced by palmitic acid. Reduced expression of insulin receptor, and increased expression of PGC-1 $\alpha$  and TRIB3 were also observed in liver tissues from HFD-fed ERK5DHep mice.

**Conclusion:** We have elucidated novel pathways connecting the expression of ERK5 in hepatocytes to the regulation of insulin sensitivity through PGC-1 $\alpha$ , TRIB3, Akt, as well as through insulin receptor and IRS-1.

### PO-2412

#### Combining non-selective beta blockers with FXR agonists towards ameliorating intestinal barrier dysfunction in NASH

Yasmeen Attia<sup>1</sup>, Rasha Tawfiq<sup>2</sup>, Olfat Hammam<sup>3</sup>, Mohamed Elmazar<sup>2</sup>.  
<sup>1</sup>The British University in Egypt, Pharmacology; <sup>2</sup>Faculty of Pharmacy, The British University in Egypt, Pharmacology; <sup>3</sup>Theodor Bilharz Research Institute, Pathology  
Email: yasmeen.attia@bue.edu.eg

**Background and aims:** Bacterial translocation (BT) is a critical trigger in the pathogenesis of non-alcoholic steatohepatitis (NASH) via activation of Toll-like receptors (TLRs). Hence, attempts to manipulate BT and the intestinal microbiome are novel insights to prevent NASH development and progression. The role of non-selective beta blockers (NSBBs) in decreasing gut permeability was highlighted in previous studies. Moreover, the pivotal role of farnesoid X receptor (FXR) in the maintenance of intestinal homeostasis is increasingly recognized along with its crucial involvement in the gut-liver axis. The present study aimed at investigating the effect of combining carvedilol (CAR), a NSBB, to obeticholic acid (OCA), an FXR agonist on BT and, therefore, NASH histopathological features.

**Method:** A combined experimental model of chronic colitis and dietary NASH was used to mimic the clinical presentation of NASH induced by intestinal barrier dysfunction. Eight-week-old male Swiss albino mice were fed a high fat diet for 13 weeks. Colitis was induced by dextran sulfate sodium (DSS) as 0.5% in drinking water applied in cycles each consisting of 7 days DSS followed by 10 days free drinking water. Treatments were started at week 10 at a dose of 5 mg/kg/day, p.o. for OCA and 10 mg/kg/day, p.o. for CAR, either alone or combined for 4 weeks. Intestinal permeability was evaluated using fluorescein isothiocyanate (FITC)-dextran test. Histopathological examination of liver and ileal samples was performed. Immunohistochemical analysis of ileal TLR-4, transforming growth factor (TGF)- $\beta$ 1 expression, junctional adhesion molecule A protein (JAM-A) along with claudin-1 ileal expressions were also estimated.

**Results:** Histopathological changes of NASH observed in the control group were ameliorated in treated groups, especially the one which received a combination of OCA and CAR. Moreover, FITC-dextran fluorescence serum level was reduced in the combination-treated group compared to single treatments ( $p < 0.05$ ). The expression of ileal TLR-4 and TGF- $\beta$ 1 were lower in the OCA+CAR-treated group. Additionally, the ileal expression of JAM-A and claudin-1 were both increased after OCA+CAR treatment ( $p < 0.05$ ).

**Conclusion:** Combining the NSBB, carvedilol, to OCA, decreased BT and mitigated the intestinal barrier dysfunction alongside NASH histopathological features in a combined model of chronic colitis and dietary NASH suggesting its potential use in NASH patients with disrupted intestinal homeostasis.

**PO-2623**

**Myeloid-specific fatty acid transport protein 4 deficiency in mice induces a shift towards M2 macrophages that leads to aggravation of NASH after high-fat/high-cholesterol feeding**

Deniz Göcebe<sup>1</sup>, Chutima Jansakun<sup>1</sup>, Simone Staffer<sup>1</sup>, Sabine Tuma-Kellner<sup>1</sup>, Sandro Altamura<sup>2</sup>, Martina Muckenthaler<sup>2</sup>, Uta Merle<sup>1</sup>, Walee Chamulitrat<sup>1</sup>. <sup>1</sup>Heidelberg Hospital University, Internal Medicine IV, Heidelberg, Germany; <sup>2</sup>Heidelberg Hospital University, Pediatric Oncology, Hematology and Immunology, Heidelberg, Germany  
Email: walee.chamulitrat@med.uni-heidelberg.de

**Background and aims:** Mutations of FATP4 are associated with blood lipids and insulin resistance, and these patients exhibit not only skin hyperkeratosis but also M2/Th2-related allergies and eosinophilia. We hypothesized that FATP4 deficiency in macrophages may contribute to the pathogenesis of NASH because this disease is also linked to type 2 immunity. We determined the effects of myeloid-specific Fatp4 deficiency on macrophage polarization and diet-induced NASH.

**Method:** LysM-Cre Fatp4-deficient mice (KO) with exon 3 deletion were generated. Complete blood counts from male and female control and KO mice were analysed. Cytokine release and gene expression were analysed in bone marrow-derived macrophages (BMDMs) from male mice with or without in vitro LPS for 24 h. Male and female control and KO mice were fed with high-fat (15%)/high-cholesterol (1.25%) (HFHC) diet for 16 weeks. Plasma cytokines, hepatic gene expression, and liver histology were analyzed.

**Results:** Male KO mice showed an increase in % monocytes and granulocytes while female KOs showed a decrease in % monocytes. BMDMs from male KO mice showed an increase in spontaneous release of M2/Th2 IL-4 and IL-13 as well as spontaneous and LPS-induced expression of MCP-1. This deficiency on the other hand attenuated LPS-induced expression and release of M1 TNF- $\alpha$ , IL-6, and IL-1b. After HFHC feeding, both male and female mutants showed a further elevation of plasma IL-4, IL-13, and MCP-1, while that of plasma IL-5 and IL-6 was observed only in female mutants. On the other hand, HFHC-induced elevation of plasma TNF- $\alpha$  was attenuated in both male and female mutants. Strikingly, HFHC feeding induced a marked increase of hepatic steatosis in male mutants but a massive hepatic infiltration of immune cells in female KOs. Both male and female KO mice showed an increase of HFHC-induced liver fibrosis and hepatic expression of MCP-1 protein. Correspondingly, male mutants showed increased mRNA expression of collagen 1a1, collagen 3a1, Timp1, Icam1, and Vcam1.

**Conclusion:** Myeloid-specific Fatp4 deficiency led to a shift from M1 towards M2 cytokines IL-4, IL-13 and MCP-1 at the level of BMDMs and HFHC-induced NASH. Such increase of Th2 immunity led to aggravated liver fibrosis in both male and female mutants. Hepatic steatosis and inflammatory IL-5/IL-6 was prominent in male and female mutants, respectively. Our findings may have some implications for patients with FATP4 mutations who consume HFHC-rich diets.

**PO-2653**

**Blocking the CD47-SIRP $\alpha$  axis in non-alcoholic steatohepatitis enhances necroptotic hepatocyte uptake and improves hepatic fibrosis**

Hongxue Shi<sup>1</sup>, Xiaobo Wang<sup>1</sup>, Brennan Gerlach<sup>1</sup>, Arif Yurdagul<sup>2</sup>, Bishuang Cai<sup>3</sup>, Sharon Zeldin<sup>1</sup>, Luca Valenti<sup>4</sup>, Ira Tabas<sup>1</sup>. <sup>1</sup>Columbia University Irving Medical Center, New York, United States; <sup>2</sup>LSU Health Shreveport, Molecular and Cellular Physiology, Shreveport, United States; <sup>3</sup>Icahn School of Medicine at Mount Sinai, New York, United States; <sup>4</sup>University of Milan, Milano, Italy  
Email: iat1@cumc.columbia.edu

**Background and aims:** Hepatocyte (HC) death is a key event during non-alcoholic steatohepatitis (NASH), but precisely how HC death contributes to NASH progression, particularly the most important

feature of liver fibrosis, remains incompletely understood. In general, cell death causes disease when clearance of dead cells by macrophages (M $\phi$ s) is impaired, leading to leakage of disease-causing factors. Whether poor clearance of dead HCs by liver M $\phi$ s in NASH contributes to disease progression is unknown. In other diseases, dead cell clearance can fail due to inappropriate activation of M $\phi$  SIRP $\alpha$  by CD47 on dead cells, which blocks cell engulfment by M $\phi$ s. In-vitro work has suggested that this scenario can occur when cells die by necroptosis, a form of cell death that has been implicated in NASH. We therefore hypothesized that expression of CD47 on necroptotic HCs (necHCs) in NASH activates SIRP $\alpha$  on NASH liver M $\phi$ s, leading to failed dead HC clearance and promotion of NASH.

**Method:** CD47 and SIRP $\alpha$  were assayed in tissue sections from human and mouse normal and NASH liver. For mouse NASH, male C57BL/6J mice were fed either a high-fat choline-deficient L-amino-defined (CDAA) diet for 12 weeks or a fructose-palmitate-cholesterol (FPC) diet for 16 weeks. We also generated a non-NASH necHC model by injecting mice with AAV8-TBG-mRipk3-2Fv, followed by treatment with a cross-linker to activate RIP3-induced necroptosis in HCs. For all mouse models, causation was tested by administering anti-CD47 or anti-SIRP $\alpha$  antibodies, followed by assessment of engulfment of necHCs by liver M $\phi$ s and NASH fibrosis. For *ex vivo* studies, the engulfment of human and mouse necHCs by primary human and mouse liver M $\phi$ s, respectively, was assayed in the absence or presence of anti-CD47 antibody.

**Results:** The necroptosis signaling markers RIP3 and p-MLKL were increased in human and mouse NASH liver compared with normal liver, and RIP3<sup>+</sup> HCs showed poor association with liver M $\phi$ s. Interestingly, M $\phi$ -SIRP $\alpha$  and HC-CD47 were also increased in human and mouse NASH vs. control liver. *Ex vivo*, liver M $\phi$ s showed poor uptake of necHCs, and this was improved by addition of anti-CD47 or anti-SIRP $\alpha$ . As initial proof-of-concept *in vivo*, we used the inducible mRipk3-2Fv necHC model and showed that anti-CD47 treatment promoted engulfment of necHCs by liver M $\phi$ s and decreased profibrotic gene expression by hepatic stellate cells (HSCs). Most importantly, administration of anti-CD47 or anti-SIRP $\alpha$  antibody to both models of NASH mice enhanced necHC engulfment by liver M $\phi$ s and decreased HSC activation and liver fibrosis.

**Conclusion:** Increased expression of HC-CD47 and M $\phi$ -SIRP $\alpha$  expression occurs in NASH liver and is associated with poor clearance of necHCs, and blocking the CD47-SIRP $\alpha$  axis in NASH enhances necHC clearance and reduces liver fibrosis. These findings define a new mechanism contributing to NASH progression with potential therapeutic implications.

**PO-2732**

**Core liver homeostatic networks: implications in therapeutic target discovery, pre-clinical studies, and innovative trial designs**

Saeed Esmaili<sup>1</sup>, Jacob George<sup>1</sup>. <sup>1</sup>Westmead Institute for Medical Research, Storr Liver Centre, Westmead, Australia  
Email: saeed.esmaili@sydney.edu.au

**Background and aims:** Findings about chronic complex diseases are always difficult to extrapolate from animal models to humans. These have led to efforts to develop more relevant pre-clinical models. We aimed to develop a framework using imperfect pre-clinical models for therapeutic target discovery. We reasoned that organs may have core network modules that are preserved between species and are predictably altered when homeostasis is disrupted. To explore this, we used pre-clinical models of fatty liver disease, human fatty liver, and human liver cancer datasets. We hypothesized that the mechanisms that maintain hepatic homeostasis in mice and humans are largely preserved.

**Method:** To test this idea, we challenged mice with diets containing different combinations of sucrose (HS) and cholesterol (Chol2%) with and without cholic acid (CA) for 8 weeks (6 diets). We applied weighted gene co-expression network analysis (WGCNA) on RNA\_Seq; similar analyses were undertaken in healthy and diseased

## POSTER PRESENTATIONS

human fatty liver and in liver cancer. Subsequently, we investigated the preservation of gene co-expression modules between datasets to find “core modules” for homeostasis.

**Results:** Histology indicated the presence of marked hepatic immune infiltration in diets that contained both CA and cholesterol. RNA sequencing of liver from mice fed the 6 diets followed by WGCNA reduced thousands of genes to a small number of transcriptionally coherent modules. Likewise, we performed WGCNA on human fatty liver and 3 human liver cancer datasets: TCGA, and ICGC (France, Japan). The core homeostatic disturbance in human HCC and fatty liver could be depicted by preserved modules. We termed these modules “core modules.” The core modules demonstrated disease specific behaviour (up- or down-regulation). Some of the components of core modules predicted liver cancer patient survival. We identified module eigengene quantitative trait loci (module-eQTL) for these predictive modules, targeting of which may improve patient outcomes.

**Conclusion:** Despite the dissimilarities between models, we highlight a framework for using pre-clinical models to understand fatty liver and liver cancer pathogenesis. In addition, we provided a network concept for understanding homeostatic perturbations. This approach can be developed for a core-based homeostatic network medicine approach and adopted for Complex Innovative trials Designs (CIDs).

### PO-2858

#### **Role of the nuclear receptor Farnesoid X Receptor in the immune functions of the intestine in the pathophysiological context of Non-alcoholic SteatoHepatitis**

Margaux Nawrot<sup>1</sup>, Simon Peschard<sup>1</sup>, Emmanuelle Vallez<sup>1</sup>, Emilie Dorchies<sup>1</sup>, Olivier Molendi-Coste<sup>1</sup>, Laurent Pineau<sup>1</sup>, Anne Taillieux<sup>1</sup>, David Dombrowicz<sup>1</sup>, Bart Staels<sup>1</sup>, Sophie Lestavel<sup>1</sup>.  
<sup>1</sup>Univ. Lille, Inserm, CHU Lille, Institut Pasteur de Lille, U1011-, EGID, F-59000 Lille, France  
Email: margaux.nawrot@univ-lille.fr

**Background and aims:** In metabolic disorders such as Non-alcoholic SteatoHepatitis (NASH), tight junctions of the intestinal epithelium are disorganised which leads to disrupted intestinal barrier and to intestinal inflammation which will spread in the whole organism as low grade inflammation. The bile acid nuclear receptor FXR (Farnesoid X Receptor) is recognized to play an important role in energy homeostasis. Whole body and intestinal FXR Knock-Out (int<sup>fl</sup>FXR KO) mice are both protected against high fat diet-induced obesity and insulin resistance, although whole body FXR KO mice under normal diet show an increase of intestinal permeability. The aims of this study are to decipher whether the intestinal immune functions are under the control of epithelial FXR and whether that may participate to NASH pathogenesis.

**Method:** We have generated int<sup>fl</sup>FXR KO mice by crossing villin-Cre and FXR-floxed mice. We then analyzed the immune cell distribution in small intestine of int<sup>fl</sup>FXR KO and control mice under chow diet or high fat/high sucrose 1% cholesterol (HFHS) diet for 24 weeks. We performed an immunophenotyping on cells purified from the lamina propria and the intra-epithelial space by using a large panel of 18 appropriated antibodies to identify subtypes of immune cells by flow-cytometry (Fortessa 20X).

**Results:** Under chow diet, 10 week-old int<sup>fl</sup>FXR KO mice compared to their littermate controls displayed an increase of the population of T lymphocytes (LT) in the lamina propria of small intestine, which can be attributed to an increase of cytotoxic LT CD8 + cells parallel to a decrease of LT helpers CD4 + cells. At 32 week-old, we observed no more change in the amount of LT between the 2 genotypes, but rather

a change of quality of cytotoxic LT CD8 + population with an increase of resident T cells and a decrease of recruited T cells in the intestinal tissue of the int<sup>fl</sup>FXR KO mice. After 24 weeks of HFHS diet, the int<sup>fl</sup>FXR KO mice displayed an increase of LT CD8 + population in their intestinal intra-epithelial space compared to their littermate controls. **Conclusion:** We have shown that targeted intestinal FXR invalidation changes the intestinal immune profile under standard and HFHS diets, suggesting that FXR in the intestinal epithelium controls gut immunity. Molecular mechanisms remain to be deciphered and the impact of these intestinal modifications on NASH are under investigation.

### PO-2883

#### **The intestinal barrier is modified in mice suffering from non-alcoholic steatohepatitis**

Simon Peschard<sup>1</sup>, Margaux Nawrot<sup>1</sup>, Laurent Pineau<sup>1</sup>, Joel Haas<sup>1</sup>, Olivier Molendi-Coste<sup>1</sup>, David Dombrowicz<sup>1</sup>, Bart Staels<sup>1</sup>, Sophie Lestavel<sup>1</sup>.  
<sup>1</sup>Univ. Lille, Inserm, CHU Lille, Institut Pasteur de Lille, U1011-, EGID, F-59000 Lille, France  
Email: simon.peschard.etu@univ-lille.fr

**Background and aims:** Non-alcoholic steatohepatitis (NASH) is frequently observed in the context of obesity, type 2 diabetes and metabolic syndrome. Growing body of evidence highlights the importance of altered gut-liver dialogue in this pathology. We decided to study the intestinal barrier function in a well characterized NASH mouse model with a special focus on two of its components, the physical barrier with tight-junction proteins and the immunological barrier with the characterization of immune cells in the intestinal tissue.

**Method:** Eight week old C57Bl6/J male mice were fed for 24 weeks with a high fat/high sucrose diet supplemented with cholesterol to induce NASH, and compared to their littermate controls under chow diet. Liver and gut samples were collected for histological and transcriptomic analysis. Immunophenotyping was performed on cells purified from the lamina propria of the small intestine and colon by using a Percoll gradient after EDTA treatment and collagenase digestion. A panel of 18 antibodies was used to identify immune cell subtypes by flow cytometry (Fortessa X20). Results were analyzed using FlowJo software.

**Results:** After 24 weeks of NASH-diet and as expected, the histology of murine liver was consistent with the pathological history of the human disease, combining weight gain, hepatomegaly and increase of plasmatic markers of hepatic cytolysis. Liver histology shows an increase of steatosis and fibrosis in NASH mice compared to their controls. Moreover, an increase of F4/80, TNFalpha and IL-1beta mRNA expression was observed in the liver of NASH-diet fed mice. A decrease of almost all CD8+ lymphocyte populations was observed in the lamina propria of small intestine, with no change in CD4+ lymphocytes. Intestinal B lymphocytes, macrophages, dendritic cells and eosinophils were not affected by the NASH-diet. In colonic lamina propria of NASH mice, we observed an increase of TCRalpha/beta CD4+ cells and a decrease of TCRgamma/delta CD8+ cells. The expression of JAM-A, a protein of the tight junction complexes, is also decreased in the colon of NASH animals.

**Conclusion:** We have now shown that our NASH mouse model displays a modified intestinal immunological barrier and an altered expression of component of tight junctions. Whether these modifications are the leading cause of the hepatic dysfunctions remains to be elucidated. It will be now of importance to decipher the molecular mechanisms involved in the modifications of the intestinal barrier induced by the NASH-diet.

**NAFLD: Therapy**

**PO-159**

**Target engagement and evidence of efficacy with PXL770, a novel direct AMP-Kinase activator, in a 4-week PK/PD trial in patients with NAFLD**

Vlad Ratziu<sup>1</sup>, Julie Dubourg<sup>2</sup>, David Moller<sup>2</sup>, Sébastien Bolze<sup>2</sup>, Sophie Bozec<sup>2</sup>, Pascale Fouqueray<sup>2</sup>, Kenneth Cusi<sup>3</sup>, Stephen Harrison<sup>4</sup>. <sup>1</sup>Institute for Cardiometabolism and Nutrition, Paris, France; <sup>2</sup>Poxel SA, Lyon, France; <sup>3</sup>University of Florida, Division of Endocrinology, Diabetes and Metabolism, Gainesville, United States; <sup>4</sup>Summit Clinical Research, San Antonio, United States  
Email: vlad.ratziu@inserm.fr

**Background and aims:** NAFLD is characterized by hepatic lipid accumulation and progresses to non-alcoholic steatohepatitis NASH. Type 2 diabetes (T2D) and metabolic syndrome are common comorbidities and drivers of disease. AMPK activation improves insulin sensitivity, increases lipid oxidation, decreases hepatic de novo lipogenesis (DNL), improves inflammation, and reduces fibrogenesis. Metabolic dysfunction (including T2D) is associated with lower endogenous AMPK activity. PXL770 is a new direct allosteric AMPK activator. In human and mouse primary cells, PXL770 inhibits DNL in hepatocytes, cytokine release from macrophages and stellate cell activation. In NASH and T2D rodent models, it improves core NASH parameters including steatosis, inflammation, ballooning and fibrogenesis, and improves insulin sensitivity and glycemic control. Thus, PXL770 has potential to independently target the root causes and core features of NASH, while simultaneously improving insulin sensitivity and glycemic control. Here we sought to establish targets engagement, PK and safety of PXL770 in NAFLD patients.

**Method:** In a randomized, double-blind, parallel design clinical trial, 12 obese non-diabetic patients with NAFLD received PXL770 500 mg orally once daily and 4 received placebo for 4 weeks. NAFLD was diagnosed based on a fibroscan CAP >300 db/m and insulin resistance

(HOMA-IR >2.5). Hepatic fractional DNL (assessed by 2H incorporation into palmitate), in response to oral fructose challenge, was measured on days -1 and 28 using mass isotopomer distribution analysis. An OGTT was conducted on days -2 and 27. Additional plasma efficacy, safety parameters and PK concentrations were assessed at several time points.

**Results:** PXL770 treatment decreased the peak DNL by -21% (p = 0.005) and the AUC by -15% (p = 0.03) vs. baseline. Both mean total and incremental glucose AUC during the OGTT were improved vs. baseline with PXL770 by -10% (p = 0.023) and -25% (p = 0.03), respectively. In addition, significant improvements in several indices of insulin sensitivity were measured: HOMA-IR - 37% (p = 0.0134), Matsuda +37% (p = 0.0136), OGIS +16% (p = 0.0123). Safety and tolerability were similar to placebo and PK parameters were similar to prior results with healthy subjects (terminal T1/2 ≈ 25 hr).

**Conclusion:** These results support the continued development of PXL770, the first direct AMPK activator to be studied in patients, and the potential utility of AMPK activation in NASH and other potential indications.

**PO-230**

**Semaglutide in patients with non-alcoholic steatohepatitis: subgroup analysis of a randomised, placebo-controlled phase 2 trial**

Sven Francque<sup>1</sup>, Mette Kjaer<sup>2</sup>, Steen Ladelund<sup>2</sup>, Takeshi Okanoue<sup>3</sup>, Lyudmila Mateva<sup>4</sup>, Ichhya Shrestha<sup>2</sup>, Stephen Harrison<sup>5</sup>. <sup>1</sup>Antwerp University Hospital, Antwerp, Belgium; <sup>2</sup>Novo Nordisk A/S, Søborg, Denmark; <sup>3</sup>Kyoto Prefectural University of Medicine, Kyoto, Japan; <sup>4</sup>University Hospital St. Ivan Rilski, Sofia, Bulgaria; <sup>5</sup>University of Oxford, Oxford, United Kingdom  
Email: sven.francque@uza.be

**Background and aims:** Patients with non-alcoholic steatohepatitis (NASH) represent a heterogeneous group in which it is important to assess the efficacy of treatments across subpopulations. In a double-blind, placebo-controlled, phase 2 trial in patients with NASH and fibrosis stage (F) 1–3, significantly more achieved NASH resolution without worsening of fibrosis with the glucagon-like peptide-1

In all randomised patients (fibrosis stage 1–3). Patients without biopsy at 72 weeks are counted as non-responders. \*p value for interaction between treatment and subgroup (Type 2 diabetes [yes or no]; †HbA<sub>1c</sub> [≥7%, <7%, or non-type 2 diabetes]). CI, confidence interval; ELF, enhanced liver fibrosis; HbA<sub>1c</sub>, glycated haemoglobin; LSM, liver stiffness measurement.

Figure: (abstract: PO-230)

## POSTER PRESENTATIONS

receptor agonist semaglutide versus placebo (primary end point evaluated in patients with F2-3 only, 58.9% vs 17.2%;  $p < 0.0001$ ). This *post-hoc* exploratory analysis of the trial (NCT02970942) assessed whether patient and disease characteristics influenced the effect of semaglutide versus placebo on NASH resolution.

**Method:** Adult patients with biopsy-confirmed NASH and fibrosis stage F1-3 were randomised to once-daily subcutaneous semaglutide 0.1, 0.2 or 0.4 mg, or placebo for 72 weeks. The primary end point of resolution of NASH with no worsening of fibrosis was evaluated across several subgroups based on gender, age, type 2 diabetes, body weight, body mass index, fibrosis stage, enhanced liver fibrosis score, and liver stiffness measurement by FibroScan. Subgroups based on baseline characteristics were analysed for heterogeneity (interaction) in treatment differences in the primary end point.

**Results:** A total of 320 patients were randomised to semaglutide 0.1 mg ( $n = 80$ ), 0.2 mg ( $n = 78$ ), 0.4 mg ( $n = 82$ ) or placebo ( $n = 80$ ). In all randomised patients (F1-3), NASH resolution without fibrosis worsening at 72 weeks was achieved by significantly more patients receiving semaglutide 0.4 mg compared with placebo (56.1% versus 20.0%;  $p < 0.0001$ ). Semaglutide 0.4 mg was associated with a numerical benefit in regards to the proportion of patients with NASH resolution and no worsening of fibrosis across all subgroups (Figure). There were no significant treatment by subgroup interactions between semaglutide and placebo for achievement of NASH resolution without worsening of fibrosis at 72 weeks. Similar results were seen with semaglutide 0.1 and 0.2 mg (data not shown).

**Conclusion:** A consistent beneficial effect of semaglutide on the primary end point of NASH resolution without fibrosis worsening was observed across a variety of subgroups based on baseline characteristics, suggesting similar efficacy across a range of patients.

### PO-231

#### Effect of subcutaneous semaglutide on quality-of-life in patients with non-alcoholic steatohepatitis

Manuel Romero Gomez<sup>1</sup>, Andrew Austin<sup>2</sup>, João Diogo da Rocha Fernandes<sup>3</sup>, Steen Ladelund<sup>3</sup>, Anne-Sophie Sejling<sup>3</sup>, Ichhya Shrestha<sup>3</sup>, Arun Sanyal<sup>4</sup>. <sup>1</sup>UCM Digestive Diseases, Virgen del Rocio University Hospital, Institute of Biomedicine of Seville, University of Seville, Seville, Spain; <sup>2</sup>University Hospitals of Derby and Burton NHS Foundation Trust, Derby, United Kingdom; <sup>3</sup>Novo Nordisk A/S, Søborg, Denmark; <sup>4</sup>Virginia Commonwealth University School of Medicine, Richmond, VA, United Kingdom  
Email: mromerogomez@us.es

**Background and aims:** Although often considered to be asymptomatic, non-alcoholic steatohepatitis (NASH) can have a detrimental effect on health-related quality of life (HRQoL). In a phase 2 trial, treatment with the glucagon-like peptide-1 receptor agonist semaglutide resulted in significantly more patients achieving NASH resolution without worsening of fibrosis compared with placebo, as well as improvements in fibrosis biomarkers, body weight and glycaemic control. Here, we report the effects of semaglutide on patient-reported outcomes of HRQoL in this trial (NCT02970942).

**Method:** A double-blind, placebo-controlled study randomised adult patients with biopsy-confirmed NASH and fibrosis stage (F) 1-3 to once-daily subcutaneous semaglutide 0.1, 0.2 or 0.4 mg, or placebo for 72 weeks. Changes from baseline in Short Form-36 (SF-36) individual sub-domains, and physical and mental component summary scores were assessed at week 72.

**Results:** A total of 320 patients were randomised to semaglutide 0.1 mg ( $n = 80$ ), 0.2 mg ( $n = 78$ ), 0.4 mg ( $n = 82$ ) or placebo ( $n = 80$ ). At 72 weeks, treatment with semaglutide 0.4 mg was associated with significantly greater improvements than placebo in the domains of bodily pain, physical functioning, role limitations due to physical health problems, social functioning and vitality (Figure). Numerically

Data for all randomised patients during the in-trial period, analysed using an ANCOVA model with missing data derived by multiple imputation from placebo group. Data for semaglutide 0.1 mg and 0.2 mg doses not shown (ETD versus placebo all non-significant, except social functioning for 0.1 mg dose,  $p = 0.0022$ ). MIDs, which are defined as the smallest difference in score which patients perceive as beneficial, are from the SF-36 Manual and Interpretation Guide and refer to mean group differences rather than responder definitions for individuals. ANCOVA, analysis of covariance; CI, confidence interval; ETD, estimated treatment difference; MID, minimum important difference; sema, semaglutide; SF-36, Short Form-36.

Figure: (abstract: PO-231)

greater but non-significant improvements were also seen in other domains. Estimated treatment differences between semaglutide 0.4 mg and placebo were larger than the minimum clinically important difference for all domains except role-physical. Physical component summary scores were also significantly improved with semaglutide 0.4 mg versus placebo; this improvement was significantly greater in patients with NASH resolution than without (mean [SD] change from baseline 3.0 [6.7] versus 1.2 [6.6];  $p = 0.014$ ). No significant differences in physical and mental components were observed between semaglutide 0.1 or 0.2 mg and placebo. There were no significant correlations observed between changes in SF-36 domains and NASH resolution or changes in body weight, enhanced liver fibrosis score or FibroScan-liver stiffness measurement.

**Conclusion:** This is the first evidence that once-daily subcutaneous semaglutide has a clinically important effect on HRQoL in patients with NASH and stage F1-3 fibrosis. Increased focus on and better understanding of patient-centered outcomes are needed in future research of treatments for NASH.

**PO-337**

**Funded referral to a commercial weight loss provider is effective in achieving weight loss in Non-alcoholic fatty liver disease**

Iain Hay<sup>1</sup>, Sarah Roxburgh<sup>1</sup>, Mairi Blair<sup>1</sup>, Helen Cairns<sup>2</sup>, Jude Morris<sup>2</sup>, Matthew Priest<sup>2</sup>, Ewan Forrest<sup>1</sup>, Stephen Barclay<sup>1</sup>. <sup>1</sup>Glasgow Royal Infirmary, Gastroenterology, Glasgow, United Kingdom; <sup>2</sup>Queen Elizabeth University Hospital, Gastroenterology, Glasgow, United Kingdom

Email: iain.hay@nhs.scot

**Background and aims:** Non-alcoholic fatty liver disease (NAFLD) is increasingly prevalent, affecting 30% of the population. EASL guidelines recommend a target of 7–10% weight loss. From 2016, patients with NAFLD were eligible for a funded 12 week weight loss programme with the commercial provider “Weight Watchers” (WW) via our health board. Those achieving 5% weight loss were eligible for a further 12 week programme. We sought to evaluate engagement, and outcomes of patients referred.

**Method:** Patients with NAFLD referred from liver clinics to WW between 2016 and 2020 were identified by Glasgow Weight Management Services, who provided data on attendance, completion and weight loss. Clinical data, including alcohol use, diabetes, adverse events, and liver stiffness measurements (LSM) were obtained from patient records. Patients were characterised as attenders if  $\geq 1$  session attended. Those still attending at time of data collection were excluded. Baseline parameters were compared according to attendance.

**Results:** 326 patients were included, of whom 168 (51.5%) attended  $\geq 1$  session (mean 8 ( $\pm 4$ )) and 84 (25.8%) completed 12 weeks. Attenders were older, and more likely to be female and diabetic (figure 1). 131/168 (77.9%) lost weight, 63/168 (37.5%)  $\geq 5\%$  and 44/168 (26.2%)  $\geq 7\%$ . Similar rates of weight loss were seen in those with cirrhosis;  $\geq 5\%$  (16/45, 35.6%) and  $\geq 7\%$  (11/45, 24.4%). No patients with cirrhosis experienced decompensation. Amongst 24 attenders with pre and post LSMs, mean LSM fell from 10.3 kPa ( $\pm 3.0$ ) to 8.25 kPa ( $\pm 4.0$ ),  $p = 0.029$ .

**Conclusion:** An offer of funded commercial provider weight loss sessions had moderate acceptance amongst patients with NAFLD. Amongst attenders, 1 in 3 lost the target weight loss for ongoing funded sessions, and 1 in 4 achieved EASL recommended weight loss. Commercial weight loss providers may be a useful health intervention for patients with NAFLD. Further work to understand barriers to uptake amongst younger patients and men may help increase uptake.

	Total n = 326	Attended		p
		Yes (168)	No (158)

**MET642, an FXR agonist with a unique chemotype, demonstrates a safe, sustained profile in a 14-day randomized study in healthy subjects**

Richard Pencek<sup>1</sup>, Kyoung-Jin Lee<sup>1</sup>, Jonathan Lee<sup>1</sup>, Hubert Chen<sup>1</sup>.

<sup>1</sup>Metacrine, Inc., San Diego, United States

Email: rpencek@metacrine.com

**Background and aims:** Farnesoid X receptor (FXR) agonists have been validated to benefit patients with non-alcoholic steatohepatitis (NASH), although improvements in therapeutic index for the class remain elusive. MET642 is a novel, non-bile acid FXR agonist with enhanced potency and sustained FXR engagement in preclinical studies. We conducted a double-blind, placebo (PBO)-controlled, single-ascending dose and 14-day multiple-ascending dose phase 1 study in healthy subjects to determine the safety, tolerability, pharmacokinetics (PK) and pharmacodynamics (PD) of MET642.

**Method:** Healthy men and women aged 18–50 years-old were randomized to MET642 or PBO (6:2 allocation). The primary objective was to assess the safety and tolerability of MET642. Secondary objectives were to establish the PK and PD profiles of MET642, with PD assessed by plasma 7 $\alpha$ -hydroxy-4-cholesten-3-one (C4) and fibroblast growth factor 19 (FGF19).

**Results:** Both single (10, 30, 100, 300 mg) and multiple (2.5, 5, 7.5, 10 mg) doses of MET642 were safe and well-tolerated. MET642 exhibited sustained PK and PD profiles with once-daily oral dosing. There were dose-dependent increases in maximum concentration (0.03–0.10  $\mu$ g/ml), exposure (0.4–1.7  $\mu$ g $\cdot$ h/ml) and elimination half-life (28–71 hrs) on the final day of dosing. MET642 repressed plasma C4 levels and final day area-under-the-curve ( $\downarrow$ 53–95%, Table) relative to PBO, with repression observed throughout 24 h post-dosing. Increased FGF19 levels were observed, although these results were not statistically significant. There were no serious adverse events, and all adverse events were mild-moderate in severity. MET642 was associated with isolated, transient increases in alanine aminotransferase in some participants, unaccompanied by clinical symptoms or adverse changes in other liver chemistries. MET642 did not increase low-density lipoprotein cholesterol (LDL-C) or cause generalized pruritus—two adverse events frequently seen in patients with NASH.

	PBO (n=8)	2.5 mg (n=6)	5 mg (n=6)	7.5 mg (n=6)	10 mg (n=6)
AUC <sub>0-24</sub> (h $\cdot$ $\mu$ g/L)	597	280	49	80	28
% suppression		53%	92%	87%	95%
p values		<0.05	<0.001	0.01	<0.001

AUC data are the geometric least square mean for the final day study PK assessment.  
p-values for comparisons of MET642 to placebo AUC are derived from type III sums of squares.

Figure: Comparison of final dose day plasma C4 area under the curve (AUC) for MET642 and placebo

**Conclusion:** MET642, a novel FXR agonist, demonstrated sustained target engagement and an encouraging safety and tolerability profile—including a lack of adverse LDL-C effects or pruritus—in healthy subjects after 14 days of daily oral dosing.

## POSTER PRESENTATIONS

PO-435

### Hyperammonemia and intrahepatic microcirculation disorders and its correction at the non-alcoholic steatohepatitis patients with initial stages of liver fibrosis

Tatiana Ermolova<sup>1</sup>. <sup>1</sup>North-Western State Medical University Named After I.I.Mecnikov, Internal Medicine and Faculty, St.-Petersburg, Russian Federation  
Email: t.v.ermolova@mail.ru

**Background and aims:** Ammonia is new potential therapeutic target for chronic liver diseases. Some experimental studies demonstrated effect of hypoammonemic drugs for decrease of activity of hepatic stellate cells, improvement of endothelial function, liver microcirculation and prevention of liver fibrogenesis. Aims of our study: are to estimate blood level of ammonia, intrahepatic microcirculation and efficacy of ornithine (Hepa-Merz) for correction of such disorders at the chronic liver diseases.

**Method:** We investigated 36 non-alcoholic steatohepatitis (NASH) and 35 HCV patients with initial fibrosis 0–2 stages. Level of ammonia was estimated by biochemical method (PocketChem BA, Arcray, Japan) in capillary blood at the patients and 29 healthy individuals (control). Intrahepatic hemodynamics are determined by polyhepatography (PHG)-modified hepatic impedansometry, non-invasive method for integral estimation of intrahepatic blood flow by checking of tissue resistance to weak electric current. PHG registers a blood flow in projection of zone of hepatic right, left lobes and spleen, integral body impedansography. For correction of blood flow disorders we used hypoammonemic drug ornithine (Hepa-Merz) in dosage 3 grams 2 times daily 4 weeks. Efficacy of LOLA we looked in 2 and 4 weeks via the control PHG and control of ammonia.

**Results:** Analysis of PHG demonstrated, that at all patients we revealed a liver microcirculation disorders- increased blood resistance, abnormal forms and amplitude of waves in sinusoidal level (out flow zone) at NASH patients and presinusoidal level (inflow zone) at viral patients. Level of ammonia in the NASH patients was 137.2 umol/L, in control group-39.2 umol/L ( $p < 0.001$ ). Hyperammonemia was higher at the NASH patients, compared with viral patients higher (102.3 umol) ( $p < 0.01$ ). Analysis of efficacy of Hepa-Merz showed, that it was effective for correction of hepatic hemodynamic disorders at all patients, in 2 weeks of the treatment we observed normalization or improvement of the wave form, in 4 weeks-wave amplitude. Level of ammonia was decreased in 2 weeks.

**Conclusion:** NASH patients with initial stages of liver fibrosis are characterized by hyperammonemia, which is more pronounced in comparison with viral hepatitis. NASH is accompanied by disorders of intrahepatic microcirculation disorders in out flow zone. LOLA improved liver microcirculation and decreases of blood ammonia level at the NASH and HCV patients.

PO-627

### Hepatic magnesium accumulation upon cyclin M4 (CNNM4) silencing improves NASH

Email: mlmartinez@cicbiogune.es

**Background and aims:** Perturbations of intracellular magnesium ( $Mg^{2+}$ ) homeostasis have implications for cell physiology. In particular, deficiencies of the cation have been identified in cirrhosis and liver cancer, whereas the supplementation of the cation has proved to reduce mortality derived from liver diseases. Among all magnesium proteins, the cyclin M family, CNNM, perform key functions in the transport of  $Mg^{2+}$  across cell membranes. Although they have been previously characterized to interact with phosphatases of regenerating liver (PRLs) involved in tumour development, the role of CNNMs in the liver remains poorly understood.

**Method:** Clinical characterization of serum  $Mg^{2+}$  levels and hepatic CNNM4 expression. Primary hepatocytes cultured under methionine and choline deprivation. In vivo rodent NASH models: 0.1% methionine and choline-deficient and choline-deficient high-fat diets. *Cnnm4* was silenced using siRNA, in vitro with DharmaFECT and in vivo with InvivoFectamine or siRNA conjugated to N-acetylgalactosamine.

**Results:** Patients with NASH showed hepatic CNNM4 overexpression and dysregulated  $Mg^{2+}$  levels in the serum. *Cnnm4* silencing ameliorated hepatic lipid accumulation, inflammation and fibrosis in the rodent NASH models. Mechanistically, CNNM4 knockdown in hepatocytes induced cellular  $Mg^{2+}$  accumulation, reduced endoplasmic reticulum stress and increased microsomal triglyceride transfer activity, which promoted hepatic lipid clearance by increasing the secretion of very-low-density lipoprotein. The conjugation of siRNA with GalNAc allows a stable and effective delivery to the liver.

**Conclusion:** Hepatic CNNM4 is a valuable therapeutic target for treating NASH.

**PO-668**

**Safety and pharmacokinetics of DUR-928 in hepatic function impaired subjects**

Jaymin Shah<sup>1</sup>, Katherine Pozo<sup>2</sup>, Deborah Scott<sup>2</sup>, WeiQi Lin<sup>2</sup>. <sup>1</sup>Durect, Clinical Pharmacology, Cupertino, United States; <sup>2</sup>Durect, Clinical, Cupertino, United States  
Email: jaymin.shah@durect.com

**Background and aims:** DUR-928 is an endogenous small molecule that epigenetically modulates the expression of genes that regulate lipid biosynthesis, inflammation, cell survival, and tissue regeneration. DUR-928 is in clinical development for the treatment of alcohol-associated hepatitis, COVID-19, and NASH. Animal studies with DUR-928 have shown high first-pass effect in the liver following oral dosing. The objective of this study was to assess the safety and pharmacokinetics (PK) of DUR-928 in subjects with hepatic impairment (HI).

**Method:** This was a Phase I open-label, study to assess the safety, tolerability, PK, and effect on biomarkers of DUR-928 in subjects with HI. The severity of HI was defined by Child-Turcotte-Pugh (CP) scores with mild HI being CP 5–6, moderate HI CP 7–9, and severe HI CP 10–15. This study enrolled 10 moderate HI, 7 severe HI, and 10 matched control subjects (MCS) with normal liver function, matched by age, gender and BMI. All subjects received a single oral dose of 200 mg DUR-928 and were followed for 7 days. Plasma concentrations of DUR-928 and its metabolite, 25HC, were determined for up to 48 hours post-dose.

**Results:** DUR-928 was well tolerated in all 27 subjects with no AEs or SAEs reported in the study. The exposure of DUR-928 (C<sub>max</sub> and AUC) was increased with the severity of HI as compared to the MCS. Notably, the half-life of DUR-928 was increased and the clearance was decreased with the severity of HI as compared to the MCS. The clearance of DUR-928 was decreased by 70% and 88% in subjects with moderate HI and severe HI, respectively, as compared to the MCS. The mean time to maximum concentration of the drug (T<sub>max</sub>) ranged from 2.8 to 4.3 hours across all study groups. Previously, we reported that C<sub>max</sub> and AUC of DUR-928 in subjects with mild HI were not different from that in MCS, although the clearance of DUR-928 was slightly decreased. Cell death markers, cleaved CK-18 (M30) and full-length CK-18 (M65), were also measured in all subjects. Mean changes from baseline of M30 was –28% (p = 0.0001) in subjects with moderate HI and –15% (p = 0.0004) in subjects with severe HI at 12-hour post-dose. The change of M65 was –15% (p = 0.464) and –9% (p = 0.291) in subjects with moderate and severe HI, respectively, at 12-hour post-dose.

**Conclusion:** DUR-928 was well tolerated in all subjects with HI, including severe HI. As expected, HI resulted in higher exposure due to slower clearance of DUR-928 than MCS.

**PO-757**

**Fenofibrate is safe and mitigates increases in serum triglycerides in NASH patients treated with the combination of the ACC inhibitor firsocostat and the FXR agonist cilofexor: A randomized trial**

Eric Lawitz<sup>1</sup>, Bal Raj Bhandari<sup>2</sup>, Peter Ruane<sup>3</sup>, Anita Kohli<sup>4</sup>, Eliza Harting<sup>5</sup>, Catherine Jia<sup>5</sup>, Jay Chuang<sup>5</sup>, Ryan Huss<sup>5</sup>, Chuhan Chung<sup>5</sup>, Robert Myers<sup>5</sup>, Rohit Loomba<sup>6</sup>. <sup>1</sup>Texas Liver Institute, University of Texas Health San Antonio, San Antonio, TX, USA, United States; <sup>2</sup>Delta Research Partners, Bastrop, LA, USA, United States; <sup>3</sup>Ruane Clinical Research, Los Angeles, CA, USA, United States; <sup>4</sup>Arizona Liver Health, Chandler, AZ, USA; <sup>5</sup>Gilead Sciences, Inc., Foster City, CA, USA, United States; <sup>6</sup>University of California at San Diego, San Diego, CA, USA, United States  
Email: ryan.huss@gilead.com

**Background and aims:** In patients with advanced fibrosis due to NASH, treatment with the FXR agonist cilofexor (CILO) and the acetyl-CoA carboxylase (ACC) inhibitor firsocostat (FIR) led to histologic and biochemical improvements but was associated with

hypertriglyceridemia in some patients. Our aim was to evaluate the safety and efficacy of fenofibrate (FENO) and icosapent ethyl (Vascepa<sup>®</sup>, VAS) to mitigate increases in serum triglycerides (TG) in NASH patients treated with CILO+FIR.

**Method:** Patients with suspected NASH and fibrosis (by biopsy or liver stiffness by transient elastography  $\geq 9.9$  kPa or MRE  $\geq 2.88$  kPa) with TG  $\geq 150$  and  $< 500$  mg/dL were randomized to treatment with VAS 2 g orally twice daily (n = 33) or FENO 145 mg orally once daily (n = 33) for two weeks, followed by the addition of CILO 30 mg and FIR 20 mg daily for 6 weeks (NCT02781584). Randomization was stratified by screening TG ( $< vs \geq 250$  mg/dL). Safety parameters, lipids, and liver biochemistry were monitored.

**Results:** Overall, 69% of patients had diabetes and 82% were obese. At baseline (BL), median (IQR) TG were 177 mg/dL (154, 205) in the VAS group and 190 mg/dL (144, 258) in the FENO group, including 13% and 31% with TG  $\geq 250$  mg/dL, respectively. After two weeks of VAS or FENO monotherapy, median changes in TG were –12 mg/dL (–33, 7 [p = 0.0898 vs BL]) and –32 mg/dL (–76, 6 [p = 0.0121 vs BL]; Figure), respectively. Following 6 weeks of combination treatment with CILO +FIR, median change from BL in TG was +41 mg/dL (16, 103 [p < 0.0001 vs BL]) in the VAS group and –2 mg/dL (–42, 54 [p = 0.9206 vs BL]) in the FENO group. In patients with BL TG  $\geq 250$  mg/dL, changes at week 6 (W6) were +99 mg/dL (–29, 185) and –61 mg/dL (–128, –8), respectively. From BL to W6, median relative improvements in ALT (VAS: –16%; FENO: –37%), AST (–6%; –15%), and GGT (–13%; –34%) were observed in both groups. During combination therapy, treatment-emergent Grade 3 TG elevations (500–1000 mg/dL) were observed in 2 patients in each group, all with BL TG  $\geq 250$  mg/dL. Combinations were well tolerated; most adverse events (AEs) were Grade 1–2 and there were no discontinuations due to AEs. Prior to initiating CILO+FIR, one VAS-treated patient with BL TG of 2,540 mg/dL discontinued VAS after 8 days due to persistent TG elevation  $> 500$  mg/dL.

Shaded area indicates 2-week pre-treatment period with VAS or FENO monotherapy. CILO+FIR added to VAS or FENO between Weeks 0 and 6. \* p < 0.05 vs BL by Wilcoxon signed-rank test.

Figure: Serum triglycerides in patients treated with VAS or FENO in combination with CILO+FIR

**Conclusion:** In NASH patients with hypertriglyceridemia treated with the combination of CILO+FIR, icosapent ethyl and fenofibrate are well tolerated, but fenofibrate more effectively mitigates increases in serum triglycerides.

#### Anti-fibrotic potential of a novel long-acting Glucagon/GIP/GLP-1 triple agonist, HM15211, in preclinical models of fibrosis

Jung Kuk Kim<sup>1</sup>, Jong Suk Lee<sup>1</sup>, Seon Myeong Lee<sup>1</sup>, Jae Hyuk Choi<sup>1</sup>, Hyunjoon Kwon<sup>1</sup>, Enu Jin Park<sup>1</sup>, Sung Min Bae<sup>1</sup>, Dae Jin Kim<sup>1</sup>, Young Hoon Kim<sup>1</sup>, In Young Choi<sup>1</sup>. <sup>1</sup>Hanmi Pharm. Co., Ltd., Seoul, Korea, Rep. of South  
Email: iychoi@hanmi.co.kr

**Background and aims:** Fibrosis due to NASH remains a major cause of liver-related mortality. However, no approved drug is available despite accelerated drug development. Although potential benefit of GLP-1RA has been proposed, semaglutide recently failed to improve fibrosis despite efficacy in NASH resolution, suggesting that additional mechanism is required to deliver therapeutic effects on fibrosis. To overcome these unmet needs of GLP-1RA, a novel long-acting Glucagon/GIP/GLP-1 triple agonist, HM15211, has been developed. Here, we evaluated potential effect of HM15211 in animal models of fibrosis, and investigated underlying mechanism *in vitro*.

**Method:** Mice fed with AMLN diet were concomitantly treated with thioacetamide (AMLN/TAA mice) for 16 weeks. To establish diet-induced NASH and fibrosis model, mice were fed with choline-deficient and high fat diet (CD-HFD mice) for 16 weeks. HM15211 was subcutaneously administered during last 8 weeks, and acylated GLP-1 or GLP-1/GIP agonist were included. After treatment, hepatic hydroxyproline (HP) and collagen content were measured. Additional liver tissue samples were subjected to qPCR for evaluation of relevant marker gene expression. For mechanistic study, LX2 cell and rat primary hepatic stellate cell (HSC) were used.

**Results:** HM15211 treatment significantly reduced HP content (-53.1% vs. Veh.) and Sirius red positive area (-70.6% vs. Veh) in AMLN/TAA mice. Similarly, HM15211 treatment was associated with reduction of hepatic (-53.9, -41.4 and -51.9% vs. vehicle for alpha-SMA, TIMP-1 and collagen expression) and blood (-49.3, -48.0 and -49.1% vs. vehicle for TIMP-1, PIIINP and hyaluronic acid level) surrogate markers for fibrosis. In CD-HFD mice, HM15211 treatment showed greater reduction in hepatic HP and collagen contents (-4.2, -10.0, -31.2% vs. vehicle for acylated GLP-1, acylated GLP-1/GIP, HM15211) compared to acylated GLP-1 or GLP-1/GIP. Similar benefits of HM15211 were also observed when measuring hepatic expression of fibrosis markers such as TGF-beta and collagen. In LX2 cell and rat primary HSC, HM15211 treatment significantly reduced collagen production by TGF-beta via negatively affecting Smad signalling.

**Conclusion:** Based on these results, HM15211 may be a novel therapeutic option for liver fibrosis due to NASH. Hence, mechanistic studies highlight direct inhibitory effect of HM15211 on HSC activation. Human efficacy study is ongoing to assess the clinical relevance of these findings.

### PO-838

#### Combination of an acetyl-CoA carboxylase inhibitor and fibroblast growth factor 19 reduced tissue triglyceride content and fibrosis in human precision-cut liver slices

Wen-Wei Tsai<sup>1</sup>, Lee Borthwick<sup>2</sup>, Jelena Mann<sup>2</sup>, Jamie Bates<sup>1</sup>, James L. Trevasakis<sup>1</sup>. <sup>1</sup>Gilead Sciences, Foster City, United States; <sup>2</sup>FibroFind LTD, Gateshead, United Kingdom  
Email: wenwei.tsai1@gilead.com

**Background and aims:** Inhibition of the acetyl-CoA carboxylase (ACC) isozymes ACC1 and ACC2 results in inhibition of fatty acid synthesis and stimulation of fatty acid oxidation that may reduce lipotoxicity in non-alcoholic steatohepatitis (NASH). ACC inhibition also inhibits activation of hepatic stellate cells. Fibroblast growth factor 19 (FGF19) is secreted from the ileum in response to bile acid absorption. In the liver, FGF19 signals through FGF receptor 4 to reduce bile acid synthesis and regulate glucose and lipid metabolism. Combination of firsocostat (FIR), an ACC1/2 inhibitor (ACCi), and cilofexor, an FXR agonist that stimulates FGF19 release, led to

improvements in liver histology and biomarkers in patients with NASH. The aim of this study was to evaluate the effects of an ACCi and FGF19, alone or in combination, on lipid and fibrosis in human precision-cut liver slices (PCLS).

**Method:** Human PCLS were prepared from resected, non-fibrotic liver tissue of three donors and equilibrated for 24 h to allow the post-slicing stress period to elapse. PCLS were then stimulated with a mix of lipids conjugated to bovine serum albumin for 2 days. Subsequently, PCLS were stimulated with the same lipid cocktail plus transforming growth factor  $\beta$ 1 (TGF $\beta$ 1)/platelet-derived growth factor  $\beta\beta$  (PDGF $\beta\beta$ ) for a further 3 days. The ACCi (an analog of FIR), FGF19, or the combination were administered prophylactically from the time of lipid stimulation for a total of 5 days. PCLS culture media, including lipids, TGF $\beta$ 1/PDGF $\beta\beta$ , and compounds, were changed daily. **Results:** Stimulation of the human PCLS with lipids and TGF $\beta$ 1/PDGF $\beta\beta$  induced lipid accumulation and fibrosis as determined by an increase of tissue triglycerides, lipid droplets by Oil Red O staining (ORO) and positive area of alpha smooth muscle actin ( $\alpha$ SMA) and Picrosirius Red (PSR) staining, without reducing cell viability. ACCi, FGF19, or the combination reduced tissue triglycerides in all three donors but only combination treatment consistently reduced ORO-positive area in all three donors. The combination of ACCi and FGF19 reduced  $\alpha$ SMA-positive area in all donors and PSR-positive area in two out of three donors; however, ACCi or FGF19 alone had limited effect on  $\alpha$ SMA or PSR.

**Conclusion:** The combination of an ACCi and FGF19 inhibited triglyceride accumulation and fibrosis in human PCLS stimulated with lipids and TGF $\beta$ 1/PDGF $\beta\beta$  over 5 days. These data are consistent with improvements in steatosis and fibrosis observed in NASH patients treated with FIR and cilofexor combination therapy, and suggest a translational model to evaluate future NASH therapies.

### PO-849

#### Treatment of a non-alcoholic steatohepatitis cirrhotic patients with resmetirom: baseline characteristics and effects on safety, biomarkers and imaging

Stephen Harrison<sup>1</sup>, Naim Alkhouri<sup>2</sup>, Rebecca Taub<sup>3</sup>, Manal Abdelmalek<sup>4</sup>, Guy Neff<sup>5</sup>. <sup>1</sup>Oxford, Hepatology, Oxford, United Kingdom; <sup>2</sup>Arizona Liver Institute; <sup>3</sup>Madrigal Pharmaceuticals, Research and Development, Conshohocken, United States; <sup>4</sup>Duke University, Gastroenterology and Hepatology, Durham, United States; <sup>5</sup>Covenant Research, Sarasota, United States  
Email: rebeccataub@yahoo.com

**Background and aims:** MAESTRO-NAFLD-1 is a 52-week 1200 subject phase 3 randomized double blind placebo-controlled NASH clinical trial to study safety and biomarker effects of resmetirom, a selective thyroid hormone receptor beta agonist, in NASH patients with F1-F4 fibrosis identified using non-invasive biomarkers and imaging (NCT04197479). A goal of this "real life" NASH study is to identify non-invasive markers that correlate with individual patient response to resmetirom treatment. The 36-week Phase 2 resmetirom NASH study provided preliminary evidence of an association between MRI-PDFF (magnetic resonance imaging-proton density fat fraction) reduction and NASH resolution and fibrosis reduction on serial liver biopsy. This study includes an open label active treatment arm in NASH cirrhotic patients.

**Method:** MAESTRO-NAFLD-1 eligibility requires at least 3 metabolic risk factors, fibroscan kilopascals (kPa) consistent with  $\geq$ F1 fibrosis stage, and MRI-PDFF $\geq$ 8% (no MRI-PDFF threshold required for NASH cirrhosis). The primary and key secondary end points of MAESTRO-NAFLD-1 include safety, relative percent reduction of MRI-PDFF (week 16), LDL cholesterol (LDL-C) (week 24), Apolipoprotein B and triglycerides, and PRO-C3 (week 52). Baseline characteristics were compared between enrolled NASH cirrhotic patients and patients with liver biopsy documented NASH enrolled in the MAESTRO-NASH phase 3 trial. Initial analyses of safety, imaging and biomarkers were conducted in NASH cirrhotic patients.

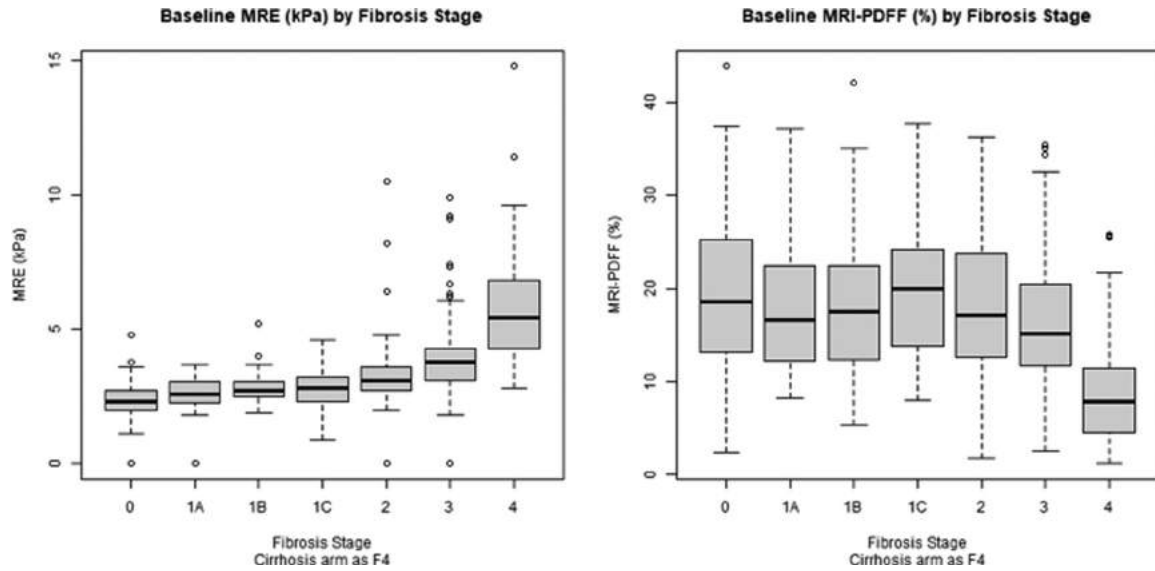

Figure: (abstract: PO-849)

**Results:** 108 well-compensated NASH cirrhotic patients were enrolled in the open label arm. Demographics include mean age 62.7 (9.0 (SD)), female 64%, BMI 35.5 (7.5), diabetes 66%, hypertension 71%, dyslipidemia >70%, mean ASCVD score 16%, hypothyroid 30%, 46.3% on statins, MRE (kPa 5.9 (2.2)), fibroscan (kPa 24.5 (15.1)), and mean MRI-PDFF of 7.9% (5%), consistent with F4 stage NASH. Cirrhotic compared to non-cirrhotic NASH patients (n >1000) had statistically significantly higher MRE (p < 0.0001) and lower MRI-PDFF (p < 0.0001) (Figure). In cirrhotic patients, 34.1% had PDFF ≤5% and 37.8% ≥8% at baseline, unrelated to steatosis grade on biopsy. At baseline NASH cirrhotic subjects with <8% compared with ≥8% PDFF had higher MELD (p = 0.0045), AST/ALT (p = 0.0001), MRE (p = 0.027), SHBG (p = 0.0003), and lower ALT (p = 0.002), platelets (p = 0.0059) and CAP (p = 0.037). In subjects with baseline PDFF ≥8%, resmetirom lowered PDFF by mean 30% and MRE by 0.4 kPa at week 16 (# with week 16 data will be expanded in presentation). In NASH cirrhotic subjects, resmetirom reduced LDL-C (20%), triglycerides (25%), and ApoB (19%) independent of baseline PDFF. Resmetirom was safe and well-tolerated.

**Conclusion:** NASH cirrhosis is associated with significantly higher MRE and lower PDFF than non-cirrhotic NASH. NASH cirrhotic subjects with lower baseline PDFF may represent a more advanced subtype.

**PO-851**

**Study on multi-target engagement effect of a novel long-acting Glucagon/GIP/GLP-1 triple agonist, HM15211, in animal model of NASH**

Jong Suk Lee<sup>1</sup>, Jung Kuk Kim<sup>1</sup>, Seon Myeong Lee<sup>1</sup>, Jae Hyuk Choi<sup>1</sup>, Hyunjoo Kwon<sup>1</sup>, Eun Jin Park<sup>1</sup>, Jong Soo Lee<sup>1</sup>, Dae Jin Kim<sup>1</sup>, Sang Hyun Lee<sup>1</sup>, In Young Choi<sup>1</sup>. <sup>1</sup>Hanmi Pharm. Co., Ltd., Korea, Rep. of South  
Email: iychoi@hanmi.co.kr

**Background and aims:** Since multiple biological pathways are involved in NASH progression, the approaches targeting multiple aspects should be required for effective treatment of NASH and eventually fibrosis. Recently, novel roles of incretin, especially glucagon and GIP in addition to GLP-1, have been demonstrated beyond metabolism such as inflammation and fibrosis. Thus, optimal use of these incretins simultaneously could be a promising strategy for NASH treatment. To address this and provide novel treatment option for NASH, HM15211, a long-acting Glucagon/GIP/GLP-1 triple agonist, was developed. Here, we evaluated potential benefits of

HM15211 by comparing its therapeutic effect with NASH drug candidates in high-fat diet induced mouse model of NASH.

**Method:** AMLN-diet induced NASH mice were administered either with HM15211 or NASH drug candidates (study 1: obeticholic acid (OCA), study 2: acylated GLP-1 or GLP-1/GIP agonist) for 12 weeks, followed by histological analysis. Additional liver tissue samples were subjected to qPCR analysis for related marker gene expression. For mechanistic study for anti-inflammation, THP-1 cell was used.

**Results:** In study 1, HM15211 treatment more efficiently normalized hepatic TG contents (-48.9%, -93.0% vs. vehicle for OCA, HM15211) and steatosis score compared to OCA (2.9, 2.1, 0.1 for vehicle, OCA, HM15211). Consistently, HM15211 treatment significantly reduced histological score for lobular inflammation (1.6, 1.1, 0.9 for vehicle, OCA, HM15211) and ballooning (1.4, 0.7, 0.0 for vehicle, OCA, HM15211) greater than OCA. Notably, while all individuals treated with HM15211 achieved NASH resolution criteria, only 14.3% achieved it after OCA treatment. In study 2, therapeutic effect of HM15211 was further compared with incretin analogs, and greater improvement in all sub-components of NAS was confirmed compared to acylated GLP-1 or GLP-1/GIP, highlighting potential benefits of multi-target engagement of HM15211 over other incretin analogs as well as FXR agonist for NASH treatment. Mechanistically, PMA-induced THP-1 cell adhesion and subsequent cytokine secretion such as TNF-alpha and IL-1beta were significantly attenuated by HM15211, explaining, at least in part, the underlying mechanism for its therapeutic effects observed *in vivo*.

**Conclusion:** Therefore, HM15211 may be a novel therapeutic option for NASH treatment. Efficacy study in biopsy proven NASH subjects is ongoing to assess the clinical relevance of these finding.

**PO-889**

**Digital pathology with artificial intelligence analyses reveal new dynamics of treatment-induced fibrosis regression in non-alcoholic steatohepatitis**

Nikolai V. Naoumov<sup>1</sup>, Dominique Brees<sup>1</sup>, Juergen Loeffler<sup>1</sup>, Elaine Chng<sup>2</sup>, Yayun Ren<sup>2</sup>, Patricia Lopez<sup>1</sup>, Dean Tai<sup>2</sup>, Arun Sanyal<sup>3</sup>, Sophie Lamle<sup>1</sup>. <sup>1</sup>Novartis Pharma AG, Basel, Switzerland; <sup>2</sup>HistoIndex Pte. Ltd, Singapore; <sup>3</sup>Virginia Commonwealth University School of Medicine, Richmond, United States  
Email: nikolai.naoumov@novartis.com

**Background and aims:** Liver fibrosis is a dynamic process and a key prognostic determinant for clinical outcomes in non-alcoholic steatohepatitis (NASH). Current staging systems are static

Figure: (abstract: PO-889): Changes in liver fibrosis between baseline and end of treatment

assessments of fibrosis and lack sensitivity in capturing fibrosis regression. Advances in second harmonic generation/two-photon excitation fluorescence (SHG/TPEF) microscopy provide a standardized and reproducible approach for quantification of NASH features on a linear scale. The aim of this exploratory analysis was to understand the fibrosis dynamics and its relation to steatosis reduction after treatment with tropifexor (TXR), a non-bile acid farnesoid X receptor (FXR) agonist, in patients with NASH participating in FLIGHT-FXR study (NCT02855164).

**Method:** Unstained sections from 198 paired liver biopsies (baseline [BL] and end of treatment [EOT]) from 99 patients with NASH (fibrosis stage F2-F3) who received placebo (PBO; n = 34), TXR 140 µg (n = 37) or TXR 200 µg (n = 28) for 48 weeks were examined. Hepatic fat (qSteatosis) and liver fibrosis (qFibrosis) were quantitated using SHG/TPEF microscopy (Hepatology 2020;71:1953–66). Changes in septa morphology, collagen fiber parameters, and zonal distribution within liver lobules were also assessed quantitatively.

**Results:** TXR treatment led to dose-dependent reduction in qSteatosis (mean change: PBO, -0.25; TXR140, -0.6 [p = 0.047]; TXR200, -0.95 [p < 0.001]). There were strong correlations between qSteatosis and the results with magnetic resonance imaging-proton dense fat fraction (MRI-PDFF) at week 48 (r = 0.851) and for steatosis reduction BL to EOT (r = 0.709). qFibrosis analyses revealed fibrosis regression in a greater proportion of patients, than conventional microscopy (Figure). TXR led to a marked reduction in perisinusoidal fibrosis. Concomitant zonal quantitation of fibrosis and steatosis revealed that patients with greatest qSteatosis reduction had a marked reduction in perisinusoidal fibrosis. The changes of fibrous septa (thinning and reduction in collagen fiber parameters [number, length, width]) were greater with TXR200 vs placebo.

**Conclusion:** Following therapies that reduce hepatic lipid load and lipotoxicity, fibrosis regression is initially seen in the perisinusoidal regions, around areas of steatosis reduction. Digital pathology provides new insights in the dynamics of fibrosis regression, which are not captured by conventional staging systems.

**PO-981**

**Aldafermin reduces hydrophobic bile acids in a 24-week, randomized, double-blind, placebo-controlled, multicenter study in patients with non-alcoholic steatohepatitis**

Arun Sanyal<sup>1</sup>, Lei Ling<sup>2</sup>, Guy Neff<sup>3</sup>, Cynthia Guy<sup>4</sup>, Mustafa Bashir<sup>4</sup>, Angelo Paredes<sup>5</sup>, Juan Frias<sup>6</sup>, Ziad H. Younes<sup>7</sup>, James F. Trotter<sup>8</sup>, Nadege T. Gunn<sup>9</sup>, Sam Moussa<sup>10</sup>, Anita Kohli<sup>11</sup>, Kristen Nelson<sup>12</sup>, Mildred Gottwald<sup>12</sup>, William Chang<sup>12</sup>, Andrew Yan<sup>12</sup>, Alex DePaoli<sup>12</sup>, Hsiao Lieu<sup>12</sup>, Stephen Harrison<sup>13</sup>. <sup>1</sup>Virginia Commonwealth University, Richmond, United States; <sup>2</sup>NGM Biopharmaceuticals, South San Francisco, United States; <sup>3</sup>Covenant Research and Clinics, Florida; <sup>4</sup>Duke University, Durham, United States; <sup>5</sup>Brooke Army Medical Center, San Antonio, United States; <sup>6</sup>National Research Institute, Los Angeles, United States; <sup>7</sup>Gastro One Research, Germantown, United States; <sup>8</sup>Texas Digestive Disease Consultants, Dallas, United States; <sup>9</sup>Pinnacle Clinical Research, Austin, United States; <sup>10</sup>Adobe Clinical Research, Tucson, United States; <sup>11</sup>Arizona Liver Health, Chandler, United States; <sup>12</sup>NGM Biopharmaceuticals, South San Francisco, United States, <sup>13</sup>Pinnacle Clinical Research, San Antonio, United States  
 Email: lling94080@yahoo.com

**Background and aims:** Higher serum bile acid levels are associated with an increased risk of cirrhosis and liver-related morbidity and mortality. Serum bile acids correlate with portal hypertension, and can predict decompensation, liver failure and transplant-free survival in chronic liver disease (Horvatits et al., 2017). Aldafermin, an engineered FGF19 analog, potently inhibits bile acid synthesis via the suppression of CYP7A1, which encodes the first and rate-limiting enzyme in the classic bile acid synthetic pathway. Here we report results from a secondary analysis of aldafermin on circulating bile acid profile in a 24-week, randomized, double-blind, placebo-controlled trial in patients with NASH.

**Method:** 78 subjects were randomized 1:2 to receive placebo (n = 25) or aldafermin 1 mg (n = 53) SC QD for 24 weeks at 9 US study sites. Key inclusion criteria included biopsy-proven NASH with NAS $\geq$ 4, F2 or F3 fibrosis and absolute liver fat content  $\geq$ 8%. Fasting serum samples were collected at day 1 and week 24. Concentrations of

individual bile acids and 7 $\alpha$ -hydroxy-4-cholesten-3-one (a surrogate of hepatic CYP7A1 activity) were measured by mass spectrometry methods. Bile acid hydrophobicity indices were determined according to Heuman et al (J Lipid Res 1989).

**Results:** Aldafermin treatment reduced concentrations of deoxycholic acid (DCA), glycodeoxycholic acid (GDCA), glycocholic acid (GCA) and glychochenodeoxycholic acid (GCDCA), with changes of  $-0.6$   $\mu\text{mol/L}$ ,  $-0.7$   $\mu\text{mol/L}$ ,  $-0.6$   $\mu\text{mol/L}$  and  $-0.9$   $\mu\text{mol/L}$  at week 24 ( $p < 0.001$  vs placebo for all comparisons), corresponding to relative changes of  $-70\%$ ,  $-56\%$ ,  $-60\%$  and  $-25\%$ , respectively, in subjects receiving aldafermin. In contrast, placebo-treated subjects had increases in these bile acids ( $+83\%$ ,  $+219\%$ ,  $+87\%$  and  $+51\%$  for DCA, GDCA, GCA and GCDCA, respectively). No reductions in tauroconjugated bile acids were seen with aldafermin treatment. Furthermore, aldafermin lowered total CA, total CDCA, total DCA, total primary bile acids and total secondary bile acids. The ratio of glycine to taurine conjugates (G/T ratio), as well as the ratio of (CA + DCA) to (CDCA + LCA), were decreased with aldafermin treatment.

**Conclusion:** Administration of aldafermin produced significant reductions in bile acids, and the major hydrophobic bile acids in particular. The preferential reduction of the more hydrophobic, glycine-conjugated bile acids, rather than the more hydrophilic, taurine-conjugated, bile acids by aldafermin resulted in a lower G/T ratio and reduced bile acid toxicity.

**PO-1082**

**Atherosclerotic cardiovascular risk assessment in a 24-week, randomized, double-blind, placebo-controlled study of aldafermin**

Nadege T. Gunn<sup>1</sup>, Lei Ling<sup>2</sup>, Guy Neff<sup>3</sup>, Cynthia Guy<sup>4</sup>, Mustafa Bashir<sup>4</sup>, Angelo Paredes<sup>5</sup>, Juan Frias<sup>6</sup>, Ziad H. Connelly<sup>11</sup>, Kristen Nelson<sup>12</sup>, Mildred Gottwald<sup>12</sup>, William Chang<sup>12</sup>, Andrew Yan<sup>12</sup>, Alex DePaoli<sup>12</sup>, Hsiao Lieu<sup>12</sup>, Stephen Harrison<sup>13</sup>. <sup>1</sup>Pinnacle Clinical Research, Austin, United States; <sup>2</sup>NGM Biopharmaceuticals, South San Francisco, United States; <sup>3</sup>Covenant Research and Clinics, United States; <sup>4</sup>Duke University, United States; <sup>5</sup>Brooke Army Medical Center, United States; <sup>6</sup>National Research Institute, United States; <sup>7</sup>Gastro One Research; <sup>8</sup>Texas Digestive Disease Consultants; <sup>9</sup>Adobe Clinical Research; <sup>10</sup>Arizona Liver Health; <sup>11</sup>Labcorp; <sup>12</sup>NGM Biopharmaceuticals; <sup>13</sup>Pinnacle Clinical Research  
Email: lling94080@yahoo.com

**Background and aims:** Aldafermin is an engineered FGF19 analogue that inhibits bile acid synthesis and regulates metabolic homeostasis. In a 24-week, randomized, double-blind, placebo-controlled study in NASH patients with serial liver biopsies, aldafermin treatment resulted in liver fat reduction, fibrosis improvement and NASH resolution. However, aldafermin increased serum cholesterol levels by inhibiting CYP7A1, which encodes the rate-limiting enzyme in the conversion of cholesterol to bile acids. Here we report results on cardiovascular risk assessment and key lipoproteins implicated in atherosclerosis from this study.

**Method:** 78 subjects were randomized 1:2 to receive PBO (n = 25) or aldafermin 1 mg (n = 53) SC QD for 24 weeks. Key inclusion criteria included biopsy-proven NASH with NAS $\geq$ 4, stage 2–3 fibrosis and absolute liver fat content  $\geq$ 8%. As pre-specified in the protocol, subjects were to start with rosuvastatin if statin naïve or switch to rosuvastatin if already on statin therapy, to treat LDL-C elevations of  $>10$  mg/dL from baseline. Atherosclerotic cardiovascular disease (ASCVD) risk scores were calculated per ACC/AHA guidance. Triglyceride and cholesterol content in the triglyceride-rich lipoproteins (TRL), and concentrations of apolipoprotein B (ApoB) and apolipoprotein A1 (ApoA1), were measured at baseline and week 24.

**Results:** At baseline, mean ASCVD risk scores were 15.0% and 11.6% in the aldafermin and placebo groups, respectively. At week 24, a greater reduction from baseline in the ASCVD risk score was observed in the

aldafermin group compared to placebo ( $-3.4\%$  and  $-1.2\%$  in absolute ASCVD score in aldafermin and placebo groups, respectively,  $p = 0.032$  vs placebo). Both triglyceride and cholesterol content in TRL declined in subjects treated with aldafermin but not placebo ( $-27\%$  and  $-17\%$  for triglyceride and cholesterol content,  $p = 0.006$  vs placebo for both comparisons). The aldafermin group, but not the placebo group, had reductions in the pro-atherogenic lipoprotein ApoB ( $-11\%$ ,  $p = 0.002$  vs baseline) and increases in the anti-atherogenic lipoprotein ApoA1 ( $+6\%$ ,  $p = 0.037$  vs baseline). No significant change in other lipids and lipoprotein particles was seen in the aldafermin group compared to placebo at week 24. No patients experienced cardiovascular events during the study.

**Conclusion:** Aldafermin-associated cholesterol increase can be safely managed with a statin. At the end of treatment, an overall favorable cardiovascular risk profile was achieved in the aldafermin arm.

**PO-1112**

**Analysis of non-invasive biomarker tests in the Phase 2 FASCINATE-1 Study of FASN Inhibitor TVB-2640**

Marie O'Farrell<sup>1</sup>, Katharine Grimmer<sup>1</sup>, Cristina Alonso<sup>2</sup>, Laura Millán<sup>2</sup>, Bill McCulloch<sup>1</sup>, Rohit Loomba<sup>3</sup>, George Kemble<sup>1</sup>. <sup>1</sup>Sagimet Biosciences, San Mateo, United States; <sup>2</sup>OWL Metabolomics, Derio, Spain; <sup>3</sup>University College San Diego, San Diego, United States  
Email: marie.ofarrell@sagimet.com

**Background and aims:** FASN synthesizes palmitate and is the last committed step in the de novo lipogenesis (DNL) pathway. FASN is an attractive target in NASH; not only does DNL cause steatosis and generate lipotoxins, but it is necessary for activation and fibrogenic activity of human liver stellate cells. TVB-2640 is an oral, first-in-class, small molecule reversible FASN inhibitor. In the Phase 2 study FASCINATE-1 (NCT03938246), TVB-2640 reduced liver fat by 9.6% at 25 mg ( $p = 0.053$ ), and 28.1% at 50 mg ( $p = 0.001$ ). MRI-PDFF responder rates (reduction  $\geq$ 30%) were 11% in placebo, 23% at 25 mg, and 61% at 50 mg ( $p = 0.001$ ). A comprehensive panel of non-invasive tests (NITs) was included to investigate biomarkers of FASN inhibition and response.

**Method:** The efficacy and biomarker analyses included 85 patients (27, 30, 28 for pbo, 25 mg and 50 mg respectively). Assays included metabolomic profiling of approx. 400 species, tripalmitin as a marker of FASN activity, ELF, ProC3, CK-18 M30 and M65, FGF21 and adiponectin. Genotyping of relevant SNPs was done in approx. 16 patients. The objective was to correlate liver fat response with NITs and gain insight into mechanism and patient response.

**Results:** TVB-2640 treatment reduced median tripalmitin levels by 25% (25 mg) and 55% (50 mg,  $p < 0.001$ ) at wk 12 compared to baseline, evident by wk 4 (only 50 mg tested). MRI-PDFF responders had highest decreases in tripalmitin, indicating a FASN-mediated effect on liver fat. Metabolomic profiling showed that in placebo patients, very few metabolites were altered over time. TVB-2640 (50 mg) decreased levels of several diglycerides and triglycerides at wk 12, most notably species with shorter chains and greater saturation consistent with inhibition of FASN. A number of glycerophospholipids were also reduced. Palmitate is a building block for the ceramide and sphingomyelin classes which can mediate lipotoxicity. Several species were significantly decreased by TVB-2640 at 50 mg, but not at 25 mg. As previously shown, fibrosis markers ProC3 and TIMP1 decreased, and adiponectin and FGF21 increased with TVB-2640 treatment. Additional bioinformatics and SNP analysis is ongoing, to explore associations with changes in liver fat, tripalmitin and fibrosis markers.

**Conclusion:** FASCINATE-1 results show that TVB-2640 decreased liver fat and decreased markers of inflammation and fibrosis, consistent with mechanism and preclinical results. TVB-2640 will be tested in a Phase 2b liver biopsy study in NASH and liver histology end points will be assessed in conjunction with NIT analysis.

#### Efficacy Signals Of 4-Week Oral DUR-928 in NASH Subjects

Eric Lawitz<sup>1</sup>, Tarek Hassanein<sup>2</sup>, Douglas Denham<sup>3</sup>, Michael Waters<sup>4</sup>, Brian Borg<sup>5</sup>, Gwenaelle Mille<sup>6</sup>, Deborah Scott<sup>6</sup>, Andy Mikszta<sup>6</sup>, John Culwell<sup>6</sup>, Dave Ellis<sup>6</sup>, James Brown<sup>6</sup>, WeiQi Lin<sup>6</sup>. <sup>1</sup>Texas Liver Institute, University of Texas Health San Antonio, San Antonio, United States; <sup>2</sup>Southern California Research Center; <sup>3</sup>Clinical Trials of Texas; <sup>4</sup>eStudySite; <sup>5</sup>Southern Therapy and Advanced Research; <sup>6</sup>Direct Email: lawitz@txliver.com

**Background:** DUR-928 is an endogenous sulfated oxysterol and an epigenetic regulator. It has been shown to stabilize mitochondria, reduce lipotoxicity, regulate inflammatory responses, promote cell survival, and stimulate hepatic regeneration in cultured cells and in animal models.

Recently, we reported that daily oral DUR-928 for 4 weeks was well tolerated in subjects with NASH and had overall improvement in liver enzymes, liver fat content by MRI-PDFF, serum lipid profiles, and certain biomarkers<sup>1</sup>. Here we present further analysis of efficacy signals from this trial.

**Method:** A total of 65 subjects with F1-F3 NASH, defined by either liver biopsy or phenotype, with a baseline hepatic fat content  $\geq 10\%$  by MRI-PDFF, completed this randomized, open-label, multi-center trial, of whom 62 also completed the 4-week follow-up period. All subjects received daily oral DUR-928 at 50 mg or 150 mg QD, or 300 mg BID (600 mg/day) for 4 weeks.

**Results:** In addition to overall improvement in multiple parameters in all 3 dose groups as reported earlier<sup>1</sup>, hepatic stiffness by TE and MRE, measured before and after dosing, changed by  $-11\%$  (TE) or  $-6\%$  (MRE) in the 50 mg,  $-7\%$  (TE) or  $4\%$  (MRE) in the 150 mg, and  $-2\%$  (TE) or  $0\%$  (MRE) in the 600 mg groups.

At the end of 4-week dosing, plasma levels of pro-C3, a liver fibrosis marker, were decreased from baseline by  $-8\%$ ,  $-1\%$ , and  $-5\%$  in the 50 mg, 150 mg, and 600 mg groups, respectively. At 2-week post-dose follow-up, pro-C3 levels were  $-7\%$ ,  $8\%$ , and  $1\%$  from baseline in the 50 mg, 150 mg, and 600 mg groups, respectively.

Overall improvement was also observed in insulin resistance (by HOMA-IR) after 4-week DUR-928 treatment. At the end of dosing, HOMA-IR was  $-22\%$ ,  $-18\%$ , and  $1\%$  from baseline in the 50 mg, 150 mg, and 600 mg groups, respectively. At 2-week post-dose follow-up, it was  $-10\%$  from baseline in the 50 mg group, and  $17\%$  and  $3\%$  in the 150 mg and 600 mg groups, respectively.

**Conclusion:** Daily oral DUR-928 (50–600 mg) for 4 weeks in F1-F3 NASH subjects was well tolerated and resulted in overall improvement in liver enzymes, liver fat content by MRI-PDFF, serum lipid profiles, liver stiffness by TE and MRE, insulin resistance, and biomarkers (including the liver fibrosis marker, pro-C3). The results suggest that epigenetic regulation of gene expression and their signalling pathways is an attractive approach to treat NASH. Further

study of DUR-928 in subjects with metabolic disorders, such as NASH, is warranted.

### PO-1314

#### The role of reduction in liver fat content (MRI-PDFF) and ALT in predicting treatment response in NASH: A secondary analysis of the randomized, controlled BALANCED trial

Rohit Loomba<sup>1</sup>, Erik Tillman<sup>2</sup>, Chen Hu<sup>3</sup>, Reshma Shringarpure<sup>4</sup>, Erica Fong<sup>4</sup>, Brittany de Temple<sup>4</sup>, Tim Rolph<sup>4</sup>, Andrew Cheng<sup>4</sup>, Kitty Yale<sup>4</sup>, Stephen Harrison<sup>5</sup>. <sup>1</sup>University of California, San Diego, Gastroenterology, San Diego, United States; <sup>2</sup>Akero Therapeutics, South San Francisco, United States; <sup>3</sup>Medpace Inc.; <sup>4</sup>Akero Therapeutics; <sup>5</sup>Pinnacle Clinical Research, San Antonio, United States Email: roloomba@health.ucsd.edu

**Background and aims:** Efruxifermin (EFX) treatment resulted in significantly greater reduction in liver fat content (LFC) as assessed by MRI-PDFF after 12 wks compared to placebo, and was associated with NASH resolution and fibrosis improvement at wk 16–20 liver biopsy assessment.<sup>1</sup> Because of the consistently large reductions of liver fat, this study provides a unique dataset to evaluate the utility of a decline in serum ALT of  $\geq 17$  U/L among MRI-PDFF responders ( $\geq 30\%$  decline) for predicting histologic response in NASH when used alone or combined with normalization of liver fat ( $\leq 5\%$  by MRI-PDFF) at wk 12. The aim of this secondary analysis of the BALANCED<sup>1</sup> trial was to examine the utility of a threshold response for ALT in predicting resolution of NASH among a treated population who achieved a  $\geq 30\%$  relative reduction of liver fat.

**Methods:** This analysis included a subset of patients who had both MRI-PDFF at baseline and wk 12, and baseline and end-of-treatment liver biopsy (n=42). All 42 patients achieved a  $\geq 30\%$  relative reduction in LFC at wk 12, and response to histologic end points was compared for ALT responders and ALT non-responders.

**Results:** Among the MRI-PDFF responders, the mean age, BMI, baseline NAS and LFC were 52y, 37 kg/m<sup>2</sup>, 5.5 and 18.9% for ALT responders (N=28) and 54y, 36 kg/m<sup>2</sup>, 5.4 and 19.6%, for ALT non-responders (N=14), respectively. ALT responders were twice as likely as ALT non-responders to achieve NASH resolution. Among ALT responders who also achieved normalization of LFC ( $\leq 5\%$ ) the odds of achieving NASH resolution were even higher (Table 1). The AUROC (95% CI) of ALT decline by  $\geq 17$  U/L to predict NASH resolution was 0.7410 (0.5561, 0.9260). ALT responders were also more likely to achieve the composite end point of NASH resolution and fibrosis improvement.

Table 1: Odds Ratios for Predicting Histologic Responses by ALT Responder Status (MRI-PDFF responders with available post-treatment biopsies)

Marker	Histologic end point	Odds Ratio (95% CI)
ALT response	NASH Resolution	2.077 (0.554, 7.788)
ALT response and normalization of liver fat ( $<5\%$ )	NASH Resolution	2.667 (0.738, 9.629)
ALT response	NASH Resolution and Fibrosis improvement	2.842 (0.522, 15.465)

<sup>1</sup>Harrison et. al. 2020. Hepatology, 72; 1S; 6A.

**Conclusion:** Among MRI-PDFF responders, a decline in serum ALT of at least 17 U/L is a robust marker in predicting NASH resolution for EFX and potentially other metabolic therapies with a potent anti-steatotic effect.

**PO-1359**

**Anti-oxidant, anti-inflammatory, and anti-fibrotic properties of triterpenic acids and phenylpropanoids on in vitro models of non-alcoholic steatohepatitis**

Noel Salvoza<sup>1,2</sup>, Chiara Bedin<sup>3</sup>, Andrea Saccani<sup>3</sup>, Claudio Tiribelli<sup>1</sup>, Natalia Rosso<sup>1</sup>. <sup>1</sup>Fondazione Italiana Fegato Onlus, Basovizza, Italy; <sup>2</sup>Philippine Council for Health Research and Development, Taguig, Philippines; <sup>3</sup>ABRESEARCH srl, Brendola, Italy  
Email: noel.salvoza@fegato.it

**Background and aims:** There is no approved pharmacological treatment for NASH. Preliminary data showed hepatoprotective properties of triterpenic acids ABRTA22 (TA) and phenylpropanoids ABRPP09 (PP) in animal models of steatosis but the molecular mechanisms underlying the beneficial effects are still elusive. We assessed the effects of both compounds in a well-established *in vitro* models of steatosis and early-stage NASH.

**Method:** Monocultures of human hepatocytes (HuH7) and simultaneous co-cultures (SCC) of human hepatocytes (HuH7) and hepatic stellate cells (LX2) were exposed to free fatty acid (FFA) alone or in combination with TA (10 nM; 50 nM; 100 nM) and PP (0.1 μM; 10 μM; 40 μM). Intracellular FFA accumulation was assessed by flow cytometry using Nile Red assay; the expression of genes involved in inflammation and fibrogenesis were quantified by RT-PCR. The generation of reactive oxygen species (ROS) and collagen deposition were also determined.

**Results:** Exposure of HuH7 cells to FFA induced a 40% (p < 0.001) increase in ROS generation and up-regulation of pro-inflammatory genes, IL-8 (1.7-fold, p < 0.05) and TNF-alpha (2.5-fold, p < 0.01). The exposure of SCC to FFA significantly increased both COL1A1 gene expression and extracellular collagen deposition. Co-treatment of either TA and PP and FFA resulted in a reduction of ROS generation but only PP showed a potent antioxidant effect at all concentrations (p < 0.05; p < 0.01 vs FFA). Addition of TA resulted in a non-significant reduction in IL-6 and IL-8 expressions but a significant down-regulation of TNF-alpha at 10nM and 50nM (p < 0.05). Likewise, PP reduced the expression of all the cytokines, with significant down-regulation in TNF-alpha at 0.1 μM and 10 μM (p < 0.05). Both compounds decreased COL1A1 gene expression (1.7-folds, p < 0.05 vs FFA) and extracellular collagen deposition (50%, p < 0.05 vs FFA) at the lowest concentration. In both models, treatment of TA or PP in the absence of FFA did not induce any effects in the extent of steatosis, inflammation, ROS generation, and collagen deposition.

**Conclusion:** Either triterpenic acids ABRTA22 (TA) or phenylpropanoids ABRPP09 (PP) reduces the FFA-related inflammation and ROS generation. Of notice, both compounds reduce collagen deposition suggesting their possible use in a clinical setting.

**PO-1762**

**Correlation between changes in liver fat content and improvements in serum markers of liver injury, fibrosis, metabolism, and in histologic parameters following treatment with efruxifermin**

Stephen Harrison<sup>1</sup>, Peter Ruane<sup>2</sup>, Bradley Freilich<sup>3</sup>, Guy Neff<sup>4</sup>, Rashmee Patil<sup>5</sup>, Cynthia Behling<sup>6</sup>, Chen Hu<sup>7</sup>, Reshma Shringarpure<sup>8</sup>, Brittany de Temple<sup>8</sup>, Erik Tillman<sup>8</sup>, Tim Rolph<sup>8</sup>, Andrew Cheng<sup>8</sup>, Kitty Yale<sup>9</sup>. <sup>1</sup>Pinnacle Clinical Research, San Antonio, United States; <sup>2</sup>Ruane Clinical Research Group Inc, Los Angeles, United States; <sup>3</sup>Kansas City Research Institute, Kansas City, United States; <sup>4</sup>Covenant Research LLC, Sarasota, United States; <sup>5</sup>South Texas Research Institute, Edinburg, United States; <sup>6</sup>Pacific Rim Pathology, San Diego, United States; <sup>7</sup>Medpace, Cincinnati, United States; <sup>8</sup>Akero Therapeutics, South San Francisco, United States; <sup>9</sup>Akero Therapeutics, South San Francisco, United States  
Email: kyale@akerotx.com

**Background and aims:** Efruxifermin (EFX), a long-acting FGF21 analog, achieved the primary end point of significant reduction in liver fat in the Phase 2a BALANCED study.<sup>1</sup> This analysis evaluated the

association between changes in liver fat content (LFC) and markers of liver injury, fibrosis, metabolic parameters and histologic features following treatment with EFX.

**Methods:** Of 80 randomized patients, 68 had available MRI-PDFF assessments at baseline and Wk 12. Correlations between change in LFC and change in markers of interest at Wk 12 were performed in patients with non-missing values for both parameters at baseline and Wk 12. Markers of glycemic control were assessed in the subset of patients with Type 2 Diabetes (T2D, n = 35). MRI-PDFF responders, defined by a ≥30% reduction in liver fat at Wk 12, were eligible for a liver biopsy; post-treatment biopsies were available for 42 patients.

Table 1: Results

A. Correlation Between Relative (%) Reduction from Baseline in LFC and % Change from Baseline for Serum Markers		
Marker	Spearman Correlation Coefficient	P Value
<i>All Patients with non-missing Wk 12 values (N = 67)</i>		
ALT	0.5315	<b>&lt;0.0001</b>
Pro-C3	0.5824	<b>&lt;0.0001</b>
Pro-C3/C3M Ratio	0.4560	<b>0.0001</b>
Triglycerides	0.5986	<b>&lt;0.0001</b>
<i>Patients with Type 2 Diabetes (N = 35)</i>		
Adiponectin	-0.6426	<b>&lt;0.0001</b>
HbA1c	0.6064	<b>0.0001</b>
B. LFC Normalization and Improvements in NASH Histology		
Change in LFC	Histologic End point	Odds Ratio (95% CI) <sup>a</sup> P value <sup>b</sup>
LFC normalization	NASH Resolution	4.083 (1.122, 14.863) <b>0.0365</b>
LFC normalization	NAS Reduction by ≥4	6.429 (1.662, 24.860) <b>0.0068</b>

<sup>a</sup>Wald 95% CI;

<sup>b</sup>Fisher's exact test

<sup>1</sup>Harrison et al. 2020. Hepatology, 72; 1S; 6A.

**Results:** All EFX-treated patients with MRI-PDFF at Wk 12 (n = 48) demonstrated ≥30% relative reduction in LFC compared to 2 patients on placebo.<sup>1</sup> Magnitude of reduction in LFC at Wk 12 correlated significantly with extent of reduction in ALT, Pro-C3, Pro-C3/C3-M ratio and triglycerides (**Table 1A**), and for patients with T2D, with extent of improvements in adiponectin and HbA1c. Patients who normalized LFC (≤5%) had significantly higher odds of achieving NASH resolution (NAS=0 for ballooning, ≤1 for inflammation) or improvement in NAS by ≥4 (**Table 1B**).

**Conclusions:** Treatment with EFX resulted in a significant reduction in LFC which correlated with improvements in markers of liver injury, fibrosis, metabolic parameters and histologic features. EFX treatment has the potential to significantly improve all aspects of the pathophysiology of NASH with fibrosis.

**KS-356, a novel inhibitor of TGF-beta superfamily signaling, improves obesity and obesity-related hepatic steatosis by inhibition of TGF-beta/Smad3 signaling pathway in high-fat diet-induced mice**

Kisoo Pakh<sup>1</sup>, Sang Gil Lee<sup>2,3</sup>, Chanmin Joung<sup>2</sup>, Sungeun Kim<sup>1</sup>, Sang Geon Kim<sup>3,4</sup>, Won-Ki Kim<sup>2</sup>. <sup>1</sup>Korea University Anam Hospital, Department of Nuclear Medicine, Korea, Rep. of South; <sup>2</sup>Korea University, Institute for Inflammation Control, Korea, Rep. of South; <sup>3</sup>Seoul National University, College of Pharmacy and Research Institute of Pharmaceutical Sciences, Korea, Rep. of South; <sup>4</sup>Dongguk University, College of Pharmacy, Korea, Rep. of South  
Email:

**Background and aims:** Obesity-induced inflamed visceral adipose tissue (VAT) secretes pro-inflammatory cytokines thereby promoting

## POSTER PRESENTATIONS

systemic inflammation and insulin resistance which further exacerbate obesity-associated non-alcoholic fatty liver disease (NAFLD). TGF- $\beta$ /Smad3 signaling has a crucial role in the inflammatory events within the VAT. Here, we investigate whether KS-356, a novel anti-inflammatory synthetic small molecule compound, can inhibit TGF- $\beta$ /Smad3 signaling thereby exhibiting therapeutic effect against inflamed VAT and subsequent NAFLD in high-fat diet-induced mice.

**Method:** NAFLD was induced by a high-fat diet (60% fat) for 20 weeks using the male C57BL/6 mice. KS-356 (50 mg/kg) was orally given daily for 20 weeks. In vivo VAT- and systemic inflammation were measured by using  $^{18}\text{F}$ -fluorodeoxyglucose positron emission tomography and C-reactive protein levels. Both insulin tolerance- and glucose tolerance test were performed to assess the status of insulin resistance and glucose intolerance. Histological and molecular analyses were performed on harvested liver and VAT.

**Results:** KS-356 inhibited TGF- $\beta$ /Smad3 signaling pathway and remarkably suppressed high-fat diet-induced VAT inflammation and its related systemic inflammation. Furthermore, KS-356 significantly improved insulin sensitivity with glucose homeostasis and reduced hepatic steatosis.

**Conclusion:** KS-356 mitigates the development of NAFLD through attenuation of VAT inflammation. Our novel findings support the potential use of KS-356 as a therapeutic drug for NAFLD.

### PO-1851

#### Significant lipid lowering by ASC41 oral tablet, a liver targeted THR $\beta$ agonist, in a phase I randomized, double-blind, placebo controlled single- and multiple-ascending dose study

Jinzi Wu<sup>1</sup>, Melissa Palmer<sup>2</sup>, Handan He<sup>3</sup>, Jiao Zheng<sup>4</sup>, Shengdan Nie<sup>4</sup>, Zhili Chen<sup>5</sup>. <sup>1</sup>Gannex Pharma Co., Ltd, Shanghai, China; <sup>2</sup>Gannex Pharma Co., Ltd, Shanghai, China; <sup>3</sup>Gannex Pharma Co., Ltd, R andamp, D department, Shanghai, China; <sup>4</sup>People's Hospital of Hunan Province, Clinical Trial Research Center, Changsha, China; <sup>5</sup>Gannex Pharma Co., Ltd, Clinical operation Department, Shanghai, China

**Background and aims:** ASC41 is a small molecule prodrug and selectively cleaved in hepatic tissue by the action of cytochrome P450 isozyme 3A4, to release a pharmacologically active metabolite, ASC41-A, which is a potent and selective thyroid hormone receptor beta (THR $\beta$ ) agonist. The aim of this study was to evaluate the safety, tolerability, pharmacokinetics and lipid lowering potential of ASC41 oral tablets in subjects with low-density lipoprotein cholesterol (LDL-C) >110 mg/dL.

**Method:** This phase I trial was a randomized, double-blind, placebo controlled single- and multiple-ascending dose study in 65 subjects with elevated LDL-C (>110 mg/dL). ASC41 has been formulated in commercially ready oral tablets developed in-house using proprietary technology. In the single-ascending dose (SAD) portion of the study, subjects were treated with 1 mg (n = 15), 2 mg (n = 15), 5 mg (n = 15), 10 mg (n = 10) or 20 mg (n = 10) ASC41 oral tablets or matching placebo tablets. In the multiple-ascending dose (MAD) portion of the study, subjects were treated with 1 mg (n = 15), 2 mg (n = 15) or 5 mg (n = 15) ASC41 oral tablets or matching placebo tablets, QD for 14 days. A washout period of at least 14 days was required between SAD and MAD portions of this study.

**Results:** In the SAD study, data suggested that ASC41 was safe and well tolerated up to a dose of 20 mg. ASC41 oral tablet formulation showed dose-proportional pharmacokinetic profiles from 1 mg to 20 mg. In the MAD study, data showed that after 14 days of oral QD dosing, subjects demonstrated clinically meaningful and statistically significant reductions in LDL-C and triglycerides compared to placebo, with no significant impact on HDL-C (table 1). ASC41 was tolerable and had a benign adverse event (AE) profile at all doses following 14-day treatment, without grade 3 or above AEs, no serious adverse events or premature discontinuations. In addition, ASC41 displayed dose-proportional pharmacokinetic profiles from 1 mg to 5 mg following 14-day QD dosing.

Table 1. Placebo-adjusted relative change (mean) from baseline after 14 days of once daily oral dosing of ASC41 tablets

	1 mg (n=12)	2 mg (n=12)	5 mg (n=12)
Placebo-adjusted LDL-C reduction	-0.42%	-11.94%	-19.99%
P-value vs placebo	p=0.947	p=0.052	p=0.002
Placebo-adjusted triglyceride reduction	-39.43%	-31.06%	-34.49%
P-value vs placebo	p=0.002	p=0.029	p=0.015
Placebo-adjusted TC reduction	-1.48%	-8.53%	-10.71%
P-value vs placebo	p=0.766	p=0.142	p=0.030
Placebo-adjusted HDL-C reduction	8.11%	-2.54%	-0.22%
P-value vs placebo	p=0.135	p=0.668	p=0.962

**Conclusion:** These data supported advancement of the ASC41 clinical program for the indication of NASH. The successful development of commercially-ready oral tablet formulation will accelerate ASC41 clinical development.

### PO-1908

#### Significant Improvement of NAFLD Activity Scores and Liver Fibrosis by ASC41, a Selective THR- $\beta$ Agonist, in High Fat Diet Induced NASH SD Rats

Jinzi Wu<sup>1</sup>, Handan He<sup>2</sup>, Xiaodong Li<sup>3</sup>, Bailing Yang<sup>1</sup>, Eiketsu Sho<sup>4</sup>. <sup>1</sup>Gannex Pharma Co., Ltd; <sup>2</sup>Gannex Pharma Co., Ltd, China; <sup>3</sup>Gannex Pharma Co., Ltd, China; <sup>4</sup>KCI Biotech (Suzhou) Inc., China  
Email: lingjie.jiang@ascltis.com

**Background and aims:** Thyroid hormone receptor  $\beta$  (THR- $\beta$ ) agonism has been reported to be an effective strategy to reduce low-density lipoprotein-cholesterol (LDL-C) and triglycerides for non-alcoholic steatohepatitis (NASH) treatment. ASC41 is a small molecule, hepatic targeting, potent and selective thyroid hormone receptor beta (THR- $\beta$ ) agonist prodrug, which is converted to its pharmacologically active metabolite ASC41-A by CYP3A4 in the liver. A phase I clinical trial of ASC41 tablets conducted in China demonstrated clinically meaningful and statistically significant reductions in LDL-C and triglycerides compared to placebo.

The objective of this study was to evaluate efficacy of ASC41 on high fat diet (HFD) induced NASH male SD rats with streptozotocin (STZ) and diethylnitrosamine (DEN) injection.

**Method:** Rats with STZ and DEN injection were used to promote diabetes and liver fibrosis, respectively. Newborn rats received two STZ injections on the 2nd day and 7th day after birth, respectively. After a 2-week lactation, a DEN injection was given and followed by lactation for another 4 weeks. 10 newborn male rats receiving neither STZ nor DEN injection were defined as normal control animals. 50 male rats with STZ and DEN injections were selected and randomly divided into 5 groups as model+vehicle group, comparator group (MGL3196 5 mg/kg), ACS41 0.5 mg/kg, ACS41 1.5 mg/kg, ACS41 4.5 mg/kg. All rats were fed with HFD (60KCal% Fat+1.25% Cholesterol+0.5% cholate) by oral gavage for 8 weeks, and ASC41 and MGL3196 were given 1 week after HFD feeding, once per day for 7 weeks. LDL-c were measured. Livers were collected for pathological detection.

**Results:** ASC41 demonstrated dose-dependently reductions in liver steatosis, inflammatory cell infiltration, ballooning change and total non-alcoholic fatty liver disease activity score (NAS). ASC41 at 1.5 mg/kg and 4.5 mg/kg showed higher NAS reductions relative to MGL3196 at 5 mg/kg (p = 0.01 and P < 0.001) (Figure 1).

Figure 1: Improvement in NAS after 7-week treatment. NAS, non-alcoholic fatty liver disease activity score, was defined as the sum of steatosis, ballooning and inflammation score.

Figure 2: Improvement in fibrosis after 7-week treatment.

ASC41 at 0.5 mg/kg showed a 23.9% reduction in NAS score and a 14.4% reduction in liver fibrosis, similar to MGL3196 at 5 mg/kg (Figure 2). ASC41 at 1.5 mg/kg and 4.5 mg/kg both showed a significant decrease in serum LDL-C.

**Conclusion:** ASC41 demonstrated NAS reductions and anti-fibrotic benefits in the HFD+DEN+STZ rat NASH Model. The current efficacy data supported the advancement of ASC41 into clinical trials in human.

**PO-1961**

**Significant improvement of NAFLD activity scores and liver fibrosis by ASC42, a novel non-steroidal FXR agonist, in high fat diet induced NASH mice**

Jinzi J. Wu<sup>1</sup>, Xiaodong Li<sup>1</sup>, Handan He<sup>1</sup>, Eiketsu Sho<sup>2</sup>, Jinhua Chen<sup>1</sup>.  
<sup>1</sup>Gannex Pharma Co., Ltd, Shanghai, China; <sup>2</sup>KCI Biotech (Suzhou) Inc., Suzhou, China  
 Email:

**Background and aims:** Farnesoid X receptor (FXR) agonists have shown to benefit patients with non-alcoholic steatohepatitis (NASH).

ASC42 is A novel non-steroidal, selective, potent FXR agonist and its phase I clinical trial is currently being conducted in the United States. The objective of this study was to evaluate the therapeutic efficacy of ASC42 on high fat diet induced NASH model in male C57BL/6 mice with streptozotocin (STZ) and diethylnitrosamine (DEN) injection.

**Method:** Mice with STZ and DEN injection were used to promote diabetes and liver fibrosis, respectively. Newborn mice received STZ injection on the 2nd day after birth. After a 2-week lactation, a DEN injection was given and followed by lactation for another 4 weeks. 10 newborn male mice receiving neither STZ nor DEN injection were defined as normal control animals. 50 male mice with STZ and DEN injection were randomly divided into 5 groups, the model+vehicle, comparator compound (OCA 30 mg/kg), ASC42 3 mg/kg, ASC42 10 mg/kg and ASC42 30 mg/kg. All rats were fed with HFD (60KCal % Fat + 1.25% Cholesterol + 0.5% cholate) by oral gavage for 8 weeks, and ASC42 and OCA were given 1 week after HFD feeding, once per day for 7 weeks. Livers were collected for pathological detection.

**Results:** ASC42 demonstrated dose-dependently reductions in liver steatosis, inflammatory cell infiltration, ballooning change and total non-alcoholic fatty liver disease activity score (NAS). ASC42 at 30 mg/kg showed a significantly higher NAS reduction relative to OCA at 30 mg/kg (p < 0.001). ASC42 at 3 mg/kg showed a 46.2% reduction in NAS score and a 15.2% reduction in liver fibrosis, similar to OCA at 30 mg/kg (Figures 1 and 2). Total glyceride in liver exhibited a dose-proportional decrease in ASC42-treated mice.

Figure 1: Improvement in NAS after 7-week treatment. NAS, non-alcoholic fatty liver disease activity score, was defined as the sum of steatosis, ballooning and inflammation score.

Figure 2: Improvement in fibrosis after 7-week treatment.

## POSTER PRESENTATIONS

**Conclusion:** ASC42 demonstrated NAS reductions and anti-fibrotic benefits in the STZ+DEN+HFD rat NASH Model. These data supported the advancement of ASC42 into clinical trials in human.

### PO-1992

#### Genetic ablation of TMEM86B (lysoplasmalogenase) modulates endogenous plasmalogens and is a potential therapy for non-alcoholic fatty liver disease

Sudip Paul<sup>1,2</sup>, Anh Nguyen<sup>1</sup>, Thy Duong<sup>1</sup>, Graeme Lancaster<sup>2,3</sup>, Peter Meikle<sup>1,2</sup>. <sup>1</sup>Baker Heart and Diabetes Institute, Metabolomics, Melbourne, Australia; <sup>2</sup>Faculty of Medicine, Nursing and Health Sciences, Clayton, Australia; <sup>3</sup>Baker Heart and Diabetes Institute, Haematopoiesis and Leukocyte Biology, Melbourne, Australia  
Email: sudip.paul@baker.edu.au

**Background and aims:** Plasmalogens are a sub-class of glycerophospholipids that possess important structural and functional roles. Their deficiency has been observed in multiple disease conditions including neurological, cardiometabolic and liver diseases. Accordingly, modulating endogenous plasmalogen levels has been suggested as a therapeutic strategy. However, an effective way to increase multiple endogenous plasmalogen species has not been established. Here, we evaluated lysoplasmalogenase (TMEM86B), a key plasmalogen catabolising enzyme, as a novel target for plasmalogen modulation. We also tested the potential of this plasmalogen modulation approach in protecting against non-alcoholic fatty liver disease (NAFLD).

**Method:** We generated global and hepatocyte-specific *Tmem86b* knockout mice and characterised their plasma and hepatic lipidomes. Hepatocyte-specific *Tmem86b* knockout (*Tmem86b*<sup>Liver KO</sup>; *Tmem86b*<sup>flox/flox</sup>, *Alb-Cre*) and floxed control (*Tmem86b*<sup>flox/flox</sup>) mice were further exposed to chow and high-fat diet (40%kcal fat, 2% cholesterol and 20% fructose; HFHCF) for 4, 12 and 24 weeks. Metabolic, biochemical, histopathological, and liquid-chromatography mass-spectrometry based lipidomic analyses were performed. **Results:** Mice with a homozygous global inactivation of *Tmem86b* (*Tmem86b*<sup>KO</sup>) were phenotypically normal but, importantly, had higher hepatic and plasma plasmalogens as well as higher lysoplasmalogens compared with wild-type (WT) mice. Similarly, *Tmem86b*<sup>Liver KO</sup> had elevated hepatic and plasma plasmalogens and lysoplasmalogens compared with floxed control mice.

Importantly, fat mass gain was significantly lower in *Tmem86b*<sup>Liver KO</sup> mice relative to control mice in response to a HFHCF diet. *Tmem86b*<sup>Liver KO</sup> mice also had significantly lower levels of liver function markers in plasma as well as significantly lower liver weights, less hepatic injury and lower hepatic glycerolipid content compared with control mice following HFHCF diet exposure for 4, 12 and 24 weeks. Our data demonstrate that deletion of *Tmem86b* increases endogenous plasmalogen levels, and successively provides protection against exacerbated fat mass gain and liver pathologies associated with HFHCF diet feeding in mice.

**Conclusion:** The findings suggest that targeting TMEM86B may be an effective therapeutic strategy for the prevention and management of NAFLD.

### PO-2006

#### Anti-inflammatory and anti-fibrotic effects of icosabutate as mono- or combination therapy with a GLP-1 receptor agonist, a FXR agonist or an ACC inhibitor in a dietary mouse model of progressive fibrosis

David A. Fraser<sup>1</sup>, Jacob Nøhr-Meldgaard<sup>2</sup>, Tore Skjaeret<sup>1</sup>, Sanne Veidal<sup>2</sup>, Michael Feigh<sup>2</sup>, Stephen Harrison<sup>3</sup>. <sup>1</sup>Northsea Therapeutics, Netherlands; <sup>2</sup>Gubra ApS, Denmark; <sup>3</sup>Radcliffe Dept of Medicine, University of Oxford  
Email: david.fraser@northseatherapeutics.com

**Background and aims:** Icosabutate (ICOSA), a semi-synthetic eicosapentaenoic acid derivative, is currently in clinical development for the treatment of NASH with fibrosis (NCT04052516, results pending). To assess if additional anti-inflammatory and/or anti-fibrotic effects could be achieved via combination therapy, a comparison of ICOSA, firsocostat [FIR, a liver-targeted acetyl-coenzyme A carboxylase (ACC 1/2) inhibitor], semaglutide [SEMA, an injectable glucagon-like 1 (GLP-1) receptor agonist] or obeticholic acid [OCA, a farnesoid-X receptor agonist] as monotherapy was performed in a choline-deficient, L-amino acid defined high-fat dietary (CDAH-HFD) mouse model. The effect of combining ICOSA with either FIR, SEMA or OCA was simultaneously assessed.

**Method:** Male C57BL/6J mice were fed CDAH-HFD (A16092003, Research Diets) for 6 weeks before treatment start. A baseline group (n = 12) was terminated at study start. CDAH-HFD fed mice [n = 10–12 per group] received daily per oral (PO) treatment with vehicle (corn

Values expressed as mean of n = 9-12 + SEM, Dunnett's test one-factor linear model  
\*\*: P < 0.01, \*\*\*: P < 0.001 compared to Vehicle

Figure: (abstract: PO-2006)

oil), ICOSA (112 mg/kg), OCA (30 mg/kg), SEMA (30 nmol/kg SC), FIR (5 mg/kg) as monotherapy or combinations of ICOSA + either SEMA, OCA or FIR (all dosing as for monotherapy) for 8 weeks. Inflammation and fibrosis was assessed in terminal liver biopsy by IHC, biochemical and morphometric assays.

**Results:** SEMA induced a 26% loss of bodyweight ( $p < 0.001$ ) relative to baseline as both mono- and combination therapy. As monotherapy, icosabutate was the only anti-inflammatory compound, reducing inflammatory foci by 47% ( $p < 0.001$  vs vehicle, see figure) with no significant effect observed for other compounds. A similar pattern was observed with galectin-3 (a macrophage marker), where only icosabutate achieved a significant reduction ( $-28\%$ ,  $p < 0.001$  vs vehicle). All ICOSA combinations achieved significant reductions of both inflammatory foci and galectin-3, the most pronounced effect achieved by ICOSA + SEMA ( $-73\%$  and  $-45\%$  for inflammatory foci and galectin-3 respectively,  $p < 0.001$  vs vehicle). Icosabutate was also the only compound that induced a significant anti-fibrotic effect as monotherapy as measured by sirius red (SR)-morphometry (see figure) whilst both ICOSA and SEMA significantly reduced hydroxyproline (HYP) content (by 33 and 22% respectively, both  $p < 0.001$  vs vehicle). All combination therapies achieved significant reductions in fibrosis, the most pronounced effects observed for ICOSA + SEMA ( $-46\%$  and  $-45\%$  for SR-morphometry and HYP respectively, both  $p < 0.001$  vs vehicle).

**Conclusion:** As monotherapy, ICOSA is a more potent anti-inflammatory/anti-fibrotic compound than SEMA, OCA or FIR in a dietary mouse model of advanced fibrosis. The ability of SEMA to induce weight loss amplified the beneficial effects of ICOSA on inflammation and fibrosis and provides an attractive combination option for the treatment of fibrosing NASH in humans.

**PO-2099**

**Development of a disease-mimicking model for NASH and liver fibrosis in a triple cell-type, spheroid-based liver-on-chip platform with microfluidics**

Haysam Ahmed<sup>1</sup>, Georgios Galaris<sup>1</sup>, Karin Toet<sup>1</sup>, Hossein Eslami Amirabadi<sup>1</sup>, Elsbet Pieterman<sup>1</sup>, Robert Ostendorf<sup>1</sup>, Roeland Hanemaaijer<sup>1</sup>, Bob van de Water<sup>2</sup>, Ivana Bobeldijk<sup>1</sup>, Evita van de Steeg<sup>1</sup>, Geurt Stokman<sup>1</sup>. <sup>1</sup>TNO, Metabolic Health Research, Leiden, Netherlands; <sup>2</sup>Leiden Academic Centre for Drug Research, Division of Drug Discovery and Safety, Leiden, Netherlands  
Email: geurt.stokman@tno.nl

**Background and aims:** Despite ongoing efforts there is currently no effective therapeutic treatment available for non-alcoholic steatohepatitis (NASH). Several drug candidates have failed clinical trials due to lack of efficacy, underlining the need for predictive preclinical models. To this end we developed a disease-mimicking *in vitro* model which closely resembles the pathophysiology of liver fibrosis induced by lifestyle factors.

**Method:** Primary human hepatocytes, Kupffer cells, and stellate cells were cultured in a matrix-free environment resulting in formation of uniformly-sized spheroids. Fatty acids, carbohydrates, and immunological factors were used to recapitulate development and progression of NASH. A novel, customized liver-on-chip was 3D-printed using proprietary material that has very low drug adsorption to circumvent the shortcomings of the widely used polydimethylsiloxane (PDMS). Spheroids were cultured under static conditions or subjected to continuous pump-driven flow. The effect of different experimental drugs on disease development was examined. Steatosis was determined by LipidTox accumulation. Expression of secreted protein markers of inflammation, fibrosis, hepatocyte function and viability was determined by specific ELISA's. Collagen deposition in the cell-matrix fraction was examined using a quantitative protein assay.

**Results:** Induction of NASH resulted in hepatocyte steatosis, expression of inflammatory cytokines, expression of secreted protein markers for fibrosis, and deposition of collagen in the

cell-matrix fraction of the liver spheroids. Exposure to fatty acids and carbohydrates under flow conditions resulted in a more homogenous distribution and size of lipid droplets per individual hepatocyte and per spheroid cross section, as compared to more variable droplet size under static conditions. Collagen deposition was about 3-fold higher than in controls in both static and flow conditions, and inhibited by treatment with an ALK5 inhibitor. Under static conditions, single drug treatment with PPAR agonists, FXR agonists, inhibitors of lipogenesis, or a pan-caspase inhibitor, showed varying effects on the degree of steatosis, expression of inflammatory or fibrosis markers, but had no significant effect on collagen deposition when compared to vehicle-treated NASH controls. In contrast, a combination treatment using drugs with different modes of action reduced collagen deposition compared to vehicle-treated NASH controls.

**Conclusion:** We present a disease-mimicking cell model for NASH and fibrosis that results in collagen production under static and flow conditions. The model is responsive to pharmacological interventions. We will further investigate the effect of microfluidic flow on the therapeutic efficacy of reference compounds and compounds currently in clinical trials as single or combination treatment.

**Inhibition of integrin alphaVbeta1 and alphaVbeta6 by a small molecule inhibitor attenuated liver fibrosis and tumor formation in an advanced mouse NASH model**

Dipankar Bhattacharya<sup>1</sup>, Richard Chen<sup>2</sup>, Min Lu<sup>2</sup>, Lia Luus<sup>2</sup>, Adrian Ray<sup>2</sup>, Bryce Harrison<sup>2</sup>, Bruce Rogers<sup>2</sup>, Scott Friedman<sup>1</sup>. <sup>1</sup>Icahn School of Medicine at Mount Sinai, Division of Liver Diseases, New York, United States; <sup>2</sup>Morphic Therapeutic, Inc., Waltham, United States  
Email: dipankar.bhattacharya@mssm.edu

**Background and aims:** Integrins alphaVbeta1 and alphaVbeta6 have been implicated in liver fibrosis due to their reported involvement in TGFbeta activation. Therefore, dual inhibition of both integrins may be more efficacious in non-alcoholic steatohepatitis (NASH). Here we tested a potent, selective, and orally bioavailable small molecule inhibitor of alphaVbeta1/beta6 in a mouse model of advanced NASH that progresses to hepatocellular carcinoma (HCC).

**Method:** NASH was induced in 8-week old male C57BL/6J mice ( $n = 10$ /group) with Western Diet (WD), sugar water, and low-dose weekly carbon tetrachloride (CCl<sub>4</sub>) injection for 12 weeks (WD\_CCl<sub>4</sub>) (doi. 10.1016/j.jhep.2018.03.011). Mice were then orally treated with vehicle (phosphate-buffered saline), a selective small molecule alphaVbeta1/beta6 dual inhibitor (MR-cpd3) (60 mg/kg), or obeticholic acid (OCA) (30 mg/kg) once daily for an additional 12 weeks. End points including liver histology, Picro-Sirius Red staining (PSR), tumor quantification, and gene expression were analyzed at the end of the study.

**Results:** Messenger RNA levels of integrin alphaV and beta6 were significantly elevated in the WD\_CCl<sub>4</sub> model, associated with severe fibrosis and enhanced ductular reaction. Oral administration of MR-cpd3 or OCA resulted in reduced fibrosis as measured by PSR area and Collagen 1A1 mRNA levels ( $p < 0.01$ ). Unlike OCA, which decreased NAFLD activity score (NAS), treatment with MR-cpd3 did not alter NAS, indicating a distinct mechanism of anti-fibrosis by the dual alphaVbeta1/beta6 inhibitor. Expression of alpha smooth muscle actin (alphaSMA) and platelet-derived growth factor receptor beta genes were also significantly downregulated by MR-cpd3 treatment ( $p = 0.04$  and  $p = 0.002$ , respectively). Consistent with the mRNA and PSR staining results, collagen 1A1 ( $p = 0.01$ ) and alphaSMA ( $p = 0.0007$ ) protein levels are similarly decreased by MR-cpd3. While all vehicle-treated NASH animals developed HCC, MR-cpd3 and OCA administration resulted in an increased number of tumor free animals (36% and 20%, respectively). Oral administration of the MR-cpd3 did not affect body weight, food intake, or water consumption.

**Conclusion:** Treatment with a small molecule integrin alphaVbeta1/beta6 dual antagonist significantly diminishes liver fibrosis and progression to HCC in an advanced NASH model induced by

**Background and aims:** Metabolic-associated fatty liver disease (MAFLD) is a complex liver disease and comprehends a group of conditions being the massive accumulation of fat in the liver the main feature. Mechanistic target of rapamycin (mTOR) pathway plays an essential role in lipid metabolism and development of MAFLD. In recent years, the regulation of DEP domain-containing mTOR-interacting protein (DEPTOR), a negative regulator of mTOR pathway, has been involved in the alteration of lipid homeostasis. It is known that DEPTOR is degraded by SCF (Skp1-Cullin-F box proteins) E3 ubiquitin ligase, which needs to be neddylated to be active. Neddylation is a reversible ubiquitin-like post-translational modification upregulated in many diseases, including MAFLD. Therefore, we decided to evaluate the potential use of Pevonedistat (MLN4924), a neddylation inhibitor, in MAFLD therapy through regulation of mTOR signaling.

**Method:** Neddylation inhibition was evaluated in mouse isolated hepatocytes. Moreover, male adult C57BL/6 mice (3-month old) fed either with 0.1% methionine and choline deficient diet (0.1%MCD diet) or with a choline-deficient high fat diet (CD-HFD) were used.

After 2 weeks of 0.1%MCD diet or 3 weeks of CD-HFD, mice were treated during 2 or 3 more weeks, depending on the diet, with Pevonedistat (60 mg/Kg) by oral gavage each 4 days. The effects of neddylation specific inhibition were also evaluated in male adult C57BL/6 AlfpCre mice infected with AAV-DIO-shNEDD8 and maintained on CD-HFD for 6 weeks. Finally, the impact of hepatic neddylation in patients with MAFLD as well as the potential use of NEDD8 serum levels for MAFLD diagnostic purposes were evaluated. **Results:** Neddylation inhibition using Pevonedistat, as well as silencing Nedd8 (neural precursor cell expressed, developmentally down-regulated 8) reduced lipid accumulation in oleic acid-stimulated mouse primary hepatocytes. Likewise, pharmacological neddylation inhibition and Nedd8 hepatic knockdown ameliorates liver steatosis preventing lipid peroxidation, hepatic oxidative stress and inflammation in mouse models of diet induced MAFLD. Increased Deptor levels and concomitant repression of mTOR signalling when neddylation is inhibited, is associated with augmented fatty acid oxidation and reduced lipid content. Deptor silencing in isolated mouse hepatocytes abolishes the anti-steatotic effects mediated by neddylation inhibition. Finally, serum NEDD8 levels correlate with hepatic neddylation both during disease progression in the clinical setting and during disease regression by therapeutic approaches in pre-clinical models.

Figure:

**Conclusion:** Overall, upregulation of DEPTOR, driven by neddylation inhibition, is proposed as a novel effective target and therapeutic approach to tackle MAFLD. Besides, the results obtained enable to pose serum NEDD8 as a potential non-invasive biomarker in MAFLD.

#### Oral LPCN 1144 treatment significantly reduced liver fat and key liver injury markers in biopsy confirmed NASH subjects: Results of a Phase 2 randomized controlled study

Kongnara Papangkorn<sup>1</sup>, Kilyoung Kim<sup>2</sup>, Benjamin Bruno<sup>3</sup>, Nachiappan Chidambaram<sup>1</sup>, Mahesh Patel<sup>4</sup>, Anthony DelConte<sup>5</sup>, Michael Charlton<sup>6</sup>, Mary Rinella<sup>7</sup>, Arun Sanyal<sup>8</sup>. <sup>1</sup>Lipocine Inc, Randd, Salt Lake City, United States; <sup>2</sup>Lipocine Inc, Product Development, Salt Lake City, United States; <sup>3</sup>Lipocine Inc, Clinical Affairs, Salt Lake City, United States; <sup>4</sup>Lipocine Inc, Salt Lake City, United States; <sup>5</sup>Saint Joseph's University, Philadelphia, United States; <sup>6</sup>University Of Chicago Medicine, Hepatology, Chicago, United States; <sup>7</sup>Northwestern Medicine Digestive Health Center, Hepatology, Chicago, United States; <sup>8</sup>Virginia Commonwealth University, Internal Medicine, Richmond, United States  
Email: kk@lipocine.com

**Background and aims:** Non-alcoholic Steatohepatitis (NASH) is a common cause of liver disease and is on a trajectory to become the

most common indication for liver transplantation in Western Europe and the United States. In large multi-ethnic cross-sectional studies, low testosterone (T) levels are independently predictive of fatty liver. Hepatic steatosis (measured by MRI-PDFF), together with serum transaminase levels, specifically alanine aminotransferase (ALT) and aspartate aminotransferase (AST), are predictive of liver pathology and histology in NASH subjects. LPCN 1144 is an oral prodrug of endogenous Testosterone (T) under development for treatment of noncirrhotic NASH. Therapy with d-alpha tocopherol has previously been shown to improve biochemical (ALT) and histological features of NASH albeit in a non-diabetic population. Currently, LPCN 1144 is being investigated for safety and efficacy in a 36-week randomized, double-blind, paired biopsy, placebo-controlled phase 2 LIFT ("Liver Fat intervention with oral Testosterone") study (NCT04134091). Here, we present the topline results post 12 weeks of treatment.

**Method:** Fifty-six adult male NASH subjects with F1-F3 fibrosis were randomized 1:1:1 to three arms (Treatment A: n = 18 with an oral dose of 142 mg T equivalent twice daily, Treatment B: n = 19 with an oral dose of 142 mg T equivalent formulated with 238 mg of d-alpha tocopherol acetate twice daily, and Placebo: n = 19 with matching placebo twice daily). The primary end point was change from baseline (BL) in hepatic fat fraction via MRI-PDFF. Change from BL of ALT, and AST were secondary end points post 12 weeks of treatment.

**Results:** Baseline levels of hepatic fat fraction, ALT, and AST for all groups were 19.2%, 51.4 U/L, and 33.3 U/L, respectively. As shown in the Figure, both treatment arms met the primary end point of liver fat reduction with statistical significance compared to placebo (p < 0.001). Approximately two thirds of patients treated with either LPCN 1144 treatment experienced greater than 30% reduction in liver fat. Both ALT and AST were significantly (p < 0.05 vs placebo) reduced with either LPCN 1144 treatment. Furthermore, Treatment B comprising d-alpha tocopherol amplified reduction of the liver injury markers in this population. During the 12 weeks of treatment, the observed rate and severity of Treatment Emergent Adverse Events in both the treatment arms were comparable to the placebo arm.

Treatment	Hepatic fat fraction†			ALT			AST		
	N	Absolute CBL (%)	Relative CBL (%)	N	Absolute CBL (U/L)	Relative CBL (%)	N	Absolute CBL (U/L)	Relative CBL (%)
Placebo	18	-1.7	-9.3	17	+1.8	+11.5	17	+2.8	+7.1
A	17	-8.0***	-39.9***	16	-9.4*	-4.2	16	-4.9*	-4.8
B	17	-9.4***	-46.8***	19	-22.4***	-33.2***	19	-10.4***	-20.4**

\* < 0.05, \*\* < 0.01, \*\*\* < 0.001 vs placebo; † Hepatic fat fraction with baseline ≥ 5% liver fat; CBL: Change from baseline

Figure:

**Conclusion:** LPCN 1144 treatment substantially and significantly improved the key non-invasive markers of liver health in male patients with biopsy confirmed NASH with fibrosis. LPCN 1144's treatment potential for NASH resolution and/or fibrosis improvement is under evaluation in the ongoing LIFT trial.

**PO-2290**

**Aminotransferase improvements in patients with non-alcoholic steatohepatitis are associated with fibrosis regression in the REGENERATE study**

Mary Rinella<sup>1</sup>, Jean-François Dufour<sup>2,3</sup>, Quentin Anstee<sup>4</sup>, Zobair Younossi<sup>5</sup>, Rohit Loomba<sup>6</sup>, Arun Sanyal<sup>7</sup>, Thomas Capozza<sup>8</sup>, Tanya Granston<sup>9</sup>, Martin Bonacci<sup>10</sup>, Aldo Trylesinski<sup>10</sup>, Vlad Ratziu<sup>11</sup>.

Email: marurinella68@gmail.com

**Background and aims:** The interim analysis of the REGENERATE study showed obeticholic acid (OCA) 25 mg treatment significantly improved liver histology in patients with non-alcoholic steatohepatitis (NASH) and fibrosis. Elevations in aminotransferases are associated with adverse liver-related outcomes in NASH. Here, we evaluate the utility of alanine aminotransferase (ALT) and aspartate aminotransferase (AST) as markers of treatment response to OCA in patients with NASH.

**Method:** Changes in ALT (upper limit of normal [ULN] = 55 U/L) and AST (ULN = 34 U/L) were assessed systematically at 1, 3, 6, 12, and 18 months in 931 NASH patients with stage 2 or 3 fibrosis randomized 1:1:1 to placebo (PBO), OCA 10 mg, or OCA 25 mg in REGENERATE (intent-to-treat population). Least-square mean (LSM) and 95% confidence intervals (CIs) of percentage change from baseline in ALT and AST were analyzed using a mixed-effect repeated-measures model.

**Results:** Baseline characteristics were well-balanced across treatment arms: ALT 79 ± 53 U/L; AST 58 ± 36 U/L; 44% F2, 56% F3. Aminotransferase values were >ULN for ALT in 60% (7% >3xULN), and for AST in 74% (9% >3xULN) of patients. Rapid, progressive, and dose-dependent improvement in ALT and AST was seen across PBO, OCA 10 mg, and OCA 25 mg arms, which at Month 18 was: ALT LSM change (95% CI), respectively, -4.9% (-10.7-0.9), -23.2% (-28.9- to -17.4) and -31.9% (-37.7- to -26.1) and in AST, -8.7% (-12.1- to -5.2), -13.4% (-16.8- to -9.9), and -19.4 (-22.8- to -15.9). ALT and AST LSM reductions in OCA arms vs PBO were seen regardless of patient ULN status at baseline. In all patients, ALT/AST reduction was associated with probability of fibrosis regression at Month 18, ranging from approximately 20%, 95% CI (14-27) to 45% (37-54) with any reduction in ALT (>0%-100%) and between approximately 20%, 95% CI (25-38) to 43% (35-57) with any reduction in AST (>0%-100%). Interestingly, even with increases of ≤40% in AST or ALT there was still a small probability of fibrosis regression (<20%). Analysis of changes in ALT and AST in individual patients showed that more patients had improvements on OCA than PBO at Month 18 (FIG 1).

**Conclusion:** OCA resulted in consistent dose-dependent improvement of ALT and AST. Patients with reductions in ALT or AST were up to twice as likely to have fibrosis improvement than those whose ALT or AST increased. The REGENERATE study is ongoing and will continue through clinical outcomes for verification and description of clinical benefits of OCA in treatment of NASH.

Patients with unchanged ALT at Month 18: placebo, n=1; OCA 10 mg, n=4; OCA 25 mg, n=1.

Patients with unchanged AST at Month 18: placebo, n=4; OCA 10 mg, n=2; OCA 25 mg, n=0.

Email: maya.margalit@89bio.com

**Background and aims:** FGF21 is an endogenous hormone regulating carbohydrate, lipid and energy metabolism. FGF21 analogs improve liver and metabolic abnormalities in non-alcoholic steatohepatitis (NASH). BIO89-100 is a glycoPEGylated FGF21 with promising tolerability and pharmacodynamic effects and potential for QW or Q2W dosing.

**Method:** This Phase 1b/2a trial enrolled 81 subjects with liver fat  $\geq 10\%$  by MRI-PDFF and either biopsy-confirmed NASH (BC-NASH) or phenotypic NASH (PNASH: central obesity with either type 2 diabetes mellitus or with evidence of liver injury by ALT or FibroScan elastography score above defined thresholds). Subjects were randomized to 12 weeks of treatment at one of 6 doses (3, 9, 18 or 27 mg QW; 18 or 36 mg Q2W) or placebo (PBO). Key end points were safety, tolerability, pharmacokinetics, change in liver fat fraction measured by MRI-PDFF and liver and metabolic markers.

**Results:** Baseline characteristics were generally similar between pooled BIO89-100 v. pooled PBO groups, and between BC-NASH v. PNASH subjects. At week 13, all BIO89-100 dose groups showed significant relative reduction v. PBO of up to 70% ( $p < 0.001$ ) in MRI-PDFF. Up to 88% of BIO89-100 subjects achieved  $\geq 30\%$  MRI-PDFF reduction v. baseline ( $p < 0.001$ ). Decreased steatosis was accompanied by decreased LFV of up to 305 ml and up to 65% v. baseline ( $p < 0.001$ ). (Table 1) Significant decreases in ALT vs. PBO were observed with BIO9-100, maximal with 27 mg QW (30U/L decrease from baseline,  $p < 0.001$ ), also prominent in the subgroup ( $n = 17$ ) with baseline ALT  $> 45U/L$  (35U/L decrease from baseline,  $p < 0.05$ ). Metabolic benefits of BIO89-100 included significant reductions in triglycerides (TG; up to 28% in overall population, up to 49% in the subgroup [ $n = 15$ ] with baseline TG  $\geq 200$  mg/ml), non-HDL cholesterol and LDL-C and increased adiponectin (up to 61%).

There were no deaths or related serious adverse events; one BIO89-100 treated subject discontinued due to a related adverse event (AE: localized skin rash). Mild increased appetite was the most common treatment-related AE. The frequency of gastrointestinal AEs was comparable to PBO.

**Conclusion:** In subjects with NASH, BIO89-100 led to significant and clinically meaningful reductions in liver fat fraction and volume assessed by MRI-PDFF with concurrent metabolic benefits and a favorable safety and tolerability profile. A Phase 2b study in NASH is planned and there is an ongoing proof of concept study in patients with severe hypertriglyceridemia.

Table 1: MRI-PDFF and LFV Summary

**Background and aims:** Non-alcoholic fatty liver disease (NAFLD) is rapidly emerging as one of the most common causes of chronic liver disease and an important risk factor for HCC. Due to limited success of currently available therapeutic options, there is an urgent need to define new approaches for NAFLD-induced HCC. TR-beta1-selective thyromimetics possessing T3-related effects on lipid metabolism without overt cardiotoxic effects of thyroid hormone, may represent such a strategy. The aim of this study was to investigate whether a novel liver-directed TR-beta1 agonist, TG68, may dampen/attenuate fully established non-alcoholic steatohepatitis (NASH) and display an anti-fibrotic effect in a mouse model of NAFLD.

**Methods:** A nutritional model of NAFLD consisting of feeding a high fat diet (HFD) was used. C57BL/6 mice were fed a HFD for 18 weeks prior to the administration of the new thyromimetic TG68 at different concentrations, in drinking water for additional 2 weeks. The efficacy of TG68 was compared with Resmetirom (MGL-3196), that recently entered Phase 3 clinical trial for patients with non-alcoholic steatohepatitis (NASH). The effect of TG68 was evaluated by histological parameters, as well as by immunohistochemistry and qRT-PCR. Blood samples were collected for clinical chemistry and determination of serum lipid levels.

**Results:** TG68 significantly improved liver histology by reducing hepatic triglycerides and NASH score in HFD-fed mice, similar to what observed following treatment with MGL-3196. Such impact on liver steatosis was associated with breakdown of fatty acids as evaluated by increased fatty acid beta-oxidation. A reduction in serum ALT, AST and TGs was also reported. The anti-steatogenic effect was accompanied by activation of TR-beta-target genes, as confirmed by increased expression of deiodinase 1 following treatment with TG68. Administration of TG68 affected also inflammatory and fibrotic pathways.

**Conclusion:** Our results indicate that the novel, liver specific TR-beta1 agonist, TG68, significantly reduces HFD-induced NASH in mice and, therefore, may provide a novel therapeutic opportunity for NAFLD-induced HCC.

### High prevalence of low normal or overtly hypogonadal levels of testosterone observed in histologically established NASH subjects in LiFT Study

Benjamin Bruno<sup>1</sup>, Kilyoung Kim<sup>2</sup>, Kongnara Papangkorn<sup>3</sup>, Nachiappan Chidambaram<sup>3</sup>, Mahesh Patel<sup>4</sup>, Anthony DelConte<sup>5</sup>, Arun Sanyal<sup>6</sup>. <sup>1</sup>Lipocine Inc, Clinical Affairs, Salt Lake City, United States; <sup>2</sup>Lipocine Inc, Product Development, Salt Lake City, United States; <sup>3</sup>Lipocine Inc, RandD, Salt Lake City, United States; <sup>4</sup>Lipocine Inc, Salt Lake City, United States; <sup>5</sup>Saint Joseph's University, Philadelphia, United States; <sup>6</sup>Virginia Commonwealth University, Internal Medicine, Richmond, United States  
Email: kk@lipocine.com

**Background and aims:** Non-alcoholic Steatohepatitis (NASH) is an advanced state of non-alcoholic fatty liver disease ("NAFLD") and can progress to fibrotic or cirrhotic liver and eventually hepatocellular carcinoma/liver cancer. About three to eight percent among non-alcoholic fatty liver (NAFL) population (30–40% of US population) progress to NASH. There is no FDA approved drug for NAFLD/NASH. Both estrogen and androgen receptors are expressed in the liver and influence hepatic metabolism and other pathways relevant to NASH. Moreover, a study of liver disease in men undergoing androgen deprivation therapy (ADT) suggests patients receiving ADT were significantly more likely to develop NAFLD. A previous single-arm study revealed that NAFL is highly prevalent in hypogonadal males (~66%). Furthermore, there is significant overlap in co-morbidities associated with NASH and hypogonadism in adult males. Currently, LPCN 1144 is being investigated for safety and efficacy in a phase 2 LiFT ("Liver Fat intervention with oral Testosterone") study (NCT04134091). Here, we report prevalence of hypogonadism and low testosterone (T) levels in the LiFT study.

**Method:** LiFT is a randomized, double-blind, placebo-controlled, multi-center, three-arm, 36-week study. 183 adult male subjects had biopsies in screening, and 56 biopsy-confirmed NASH subjects were randomized. Baseline data were analyzed to identify the prevalence of hypogonadism and low testosterone levels (using LC-MS/MS) in the study.

**Results:** 181 suspected NASH male subjects underwent biopsy and had either T measured or a historical diagnosis of hypogonadism. Over two thirds (128 of 181) of these subjects had total T levels <300 ng/dL (lower limit of normal) or history of hypogonadism, and 81% had low-normal T levels, <400 ng/dL. Of the 56 randomized subjects with histologically established NASH, 63% (35/56) had total T levels <300 ng/dL or history of hypogonadism, and 84% had T levels <400 ng/dL. Independently, mean T levels were 315 ng/dL for all biopsied subjects, and the randomized NASH subjects. 46% (16/35) of the hypogonadal, biopsy-confirmed NASH subjects had no prior diagnosis of hypogonadism despite having mean T levels <300 ng/dL (211 ± 70 ng/dL).

**Conclusion:** The LiFT study demonstrates a high prevalence of low-normal or overtly hypogonadal levels of T in biopsied patients with suspected or established NASH. A significant portion of NASH subjects may have undiagnosed hypogonadism or low T. Apparently, male adult NASH patients are likely to have compromised androgen signaling with possible associated symptoms of androgen deficiency such as sarcopenia, skeletal fragility, sexual/mood disorder, and/or anemia. Men with NAFLD/NASH should be routinely screened for hypogonadism and vice versa. The effect of oral T therapy on NASH is under investigation in the ongoing LiFT trial.

### Canagliflozin and Non-Alcoholic Fatty Liver Disease in Patients with Type 2 Diabetes Mellitus (CaNAFLD)-A Secondary Analysis of Two Randomized Controlled Trials

Angel Borisov<sup>1,2</sup>, Alexander Kutz<sup>3</sup>, Emanuel Christ<sup>2</sup>, Tuyana Boldanova<sup>1</sup>, Christine Bernsmeier<sup>1</sup>, Markus Heim<sup>1</sup>, Fahim Ebrahimi<sup>1,2</sup>. <sup>1</sup>Clarunis Universitäres Bauchzentrum Basel

Standort Universitätsspital, Gastroenterology and Hepatology, Basel, Switzerland; <sup>2</sup>Universitätsspital Basel, Endocrinology, Diabetes and Metabolism, Basel, Switzerland; <sup>3</sup>Kantonsspital Aarau, Aarau, Switzerland

Email: f.ebrahimi@outlook.com

**Background and aims:** Non-alcoholic fatty liver disease (NAFLD) is highly prevalent among patients with type 2 diabetes (T2DM), however no approved pharmacological treatment exists. While sodium glucose cotransporter 2 inhibitors (SGLT2i) have shown to decrease glycemia, blood pressure, body weight, and albuminuria in patients with T2DM, data from large randomized clinical trials on liver-related outcomes are lacking.

**Method:** This is a secondary analysis of two randomized controlled cardiovascular and renal outcome trials: CANVAS (NCT01032629) and CANVAS-R (NCT01989754). Patients with T2DM and high cardiovascular risk were randomly assigned to receive canagliflozin or placebo and were followed for a duration of up to 6 years. The primary end point of this study was a composite of a reduction of alanine aminotransferase (ALT) levels more than 30% or ALT normalization (decrease <30IU/L). Secondary outcomes included achievement of weight reduction of 5% or 10%, and improvement of non-invasive fibrosis scores (NAFLD fibrosis score; FIB-4 score). Data were provided by Yale Open Data Access (Project ID 2020 4409).

**Results:** We included 10'135 patients with T2DM. The majority of patients was male (64.2%) with a mean age of 61.8 years and a 13.5 years mean duration of diabetes. Of those, 2781 patients (27.4%) had elevated ALT levels (>30 IU/L) at baseline. These patients had a higher body weight (94.9 kg vs. 88.4 kg), elevated diastolic blood pressure (79.1 mmHg vs. 77.2 mmHg), higher glycemic indices and lipid parameters when compared to patients with normal ALT levels. The rate of the primary outcome was achieved in 35.6% of patients receiving canagliflozin compared to 26.2% with placebo, yielding an odds ratio (OR) of 1.55 (95% CI, 1.42–1.65; p < 0.001). Treatment with canagliflozin was associated with lower NAFLD fibrosis and FIB-4 scores (p < 0.001). Weight reduction of more than 10% was achieved in 38.5% of patients with canagliflozin compared to 16.1% with placebo (OR 3.49; 95% CI, 2.94–4.15; p < 0.001).

**Conclusion:** In two large randomized controlled trials involving patients with T2DM and risk of metabolic liver disease, treatment with canagliflozin resulted in a significant improvement of liver-related outcomes when compared to placebo.

## Non-invasive assessment of liver disease except NAFLD

---

PO-818

### Transient splenic elastography predicts high-risk esophageal varices in patients with noncirrhotic portal hypertension

Joel Silva<sup>1</sup>, Hélder Cardoso<sup>1</sup>, Rui Gaspar<sup>1</sup>, Guilherme Macedo<sup>1</sup>. <sup>1</sup>São João University Hospital Center, Porto, Portugal  
Email: jom\_73@hotmail.com

**Background and aims:** Non-cirrhotic portal hypertension (NCPH) comprise a heterogeneous group of liver diseases that cause portal hypertension without cirrhosis, leading to a high risk of hemorrhage from esophageal varices. In contrast to cirrhotic portal hypertension, there are no non-invasive predictors of high-risk varices (HRV) described in the literature for NCPH. The aim of this study was to evaluate whether transient splenic elastography (TSE) or other non-invasive assessments of portal hypertension could predict HRV in patients with NCPH.

**Method:** Prospective, single center study of patients with NCPH who underwent a single timepoint evaluation with transient liver and spleen elastography, gastroscopy and laboratory tests. The study was

performed from January to September 2020. Patients were divided in two groups based on the presence of HRV. The relation between TSE, transient liver elastography, spleen size and platelet count to presence of HRV was evaluated.

**Results:** Of 42 patients with NCPH who met inclusion criteria, 50% (21/42) presented HRV. The etiology of NCPH was extrahepatic portal thrombosis in 20 (47.6%), idiopathic in 18 (42.9%) and adult polycystic liver disease in 4 (9.5%). In univariate analysis, TSE (median, 58.4 vs. 28.3,  $p=0.009$ ) and spleen size (median, 17.5 vs. 14.5,  $p=0.013$ ) associated with HRV. No statistically significant relationship was found between the presence of HRV and platelet count or transient liver elastography (TLE). In multivariate analysis, TSE was the only variable related to HRV (OR 1.21, 95% CI 1.02–1.38). TSE is able to predict HRV in our population (AUROC 0.878; 95% CI 0.751–1.000). TSE >35.4 kPa presents 93.3% sensitivity, 60% specificity, 90.9% negative predictive value, 73.7% positive predictive value, positive likelihood ratio of 2, 34 and negative likelihood ratio of 0.10.

Figure: ROC curve for spleen transient elastography in prediction of high-risk varices in gastroscopy. AUROC was 0.878 (95%CI 0.751–0.985;  $p<0.001$ ).

**Conclusion:** In our population of patients with NCPH, TSE is useful in predicting HRV. TLE, spleen size and platelet count are not related to HRV.

**PO-1047**

**Jaundice detection by deep convolutional neural network using smartphone images**

Tung-Hung Su<sup>1</sup>, Jia-Wei Li<sup>2</sup>, Shann-Ching Chen<sup>3</sup>, Pei-Ying Jiang<sup>1</sup>, Jia-Hong Kao<sup>1</sup>, Cheng-Fu Chou<sup>2</sup>. <sup>1</sup>National Taiwan University Hospital, Division of Gastroenterology and Hepatology, Department of Internal Medicine, Taiwan; <sup>2</sup>National Taiwan University, Department of Computer Science and Information Engineering, Taiwan; <sup>3</sup>Compal Electronics, Taiwan  
Email: tunghungsu@gmail.com

**Background and aims:** Jaundice usually indicates severe hepatic or biliary diseases and prompt management is needed. The degree of jaundice correlates with the severity of illness, and jaundice is easily confirmed by checking serum total bilirubin (T-Bil) level. Ideally, self-identification of jaundice is the key for its early detection, because a careful inspection may detect jaundice with a T-Bil >2 or 3 mg/dL. However, self-monitoring of jaundice is not easy for people without training, so a correct diagnosis is usually delayed. We aimed to

investigate the capability of early jaundice detection by smartphone images.

**Method:** We conducted a prospective study to enroll healthy volunteers and patients with jaundice. They all have recent data of T-Bil level as reference standard. The facial images were taken by smartphones with a color checker. These images were first normalized for brightness and color temperature, and followed by deep convolutional neural network based facial landmark detection and scleral segmentation. The average sRGB color of sclera were measured, and the color was converted to CIE LAB. A Support Vector Machine model using the LAB color of patient's both sclera was used to classify the presence of jaundice determined by a T-Bil 2 or 3 mg/dL, respectively. Overall, 80% of the images were used as the training set with a 10-fold cross-validation in the training phase. The remaining 20% of the images were used as the testing set.

**Results:** A total of 108 patients had been enrolled with 146 facial images being collected. There were 105, 10, and 31 scleral images with a T-Bil level <2, 2–3, and >=3 mg/dL, respectively. At the training phase, if the T-Bil level was set at 3 mg/dL, the area under the receiver operating characteristics curve (AUROC), sensitivity, specificity, positive predictive value (PPV), and negative predictive value (NPV) on the validation set are 0.983, 0.883, 0.978, 0.933, and 0.968, respectively. If the T-Bil level was set at 2 mg/dL, these values are 0.988, 0.867, 0.965, 0.925, and 0.959, respectively. At the testing phase, if the T-Bil level was set at 3 mg/dL, the AUROC, sensitivity, specificity, PPV, and NPV on testing set are 0.979, 0.833, 0.958, 0.833, and 0.958, respectively. If the T-Bil level was set at 2 mg/dL, these values are 0.986, 0.909, 0.947, 0.909, and 0.947, respectively.

Figure:

**Conclusion:** Our data demonstrates the capability of jaundice detection by smartphone captured images with good performance. This platform may be applied in the scenario of self-monitoring or telemedicine.

**Background and aims:** Baveno VI criteria and expanded-Baveno VI criteria have safely circumvented screening endoscopy among populations enriched with hepatitis C virus and alcoholic-related compensated cirrhosis. The study aimed to optimize the criteria in cohorts enriched with hepatitis B virus (HBV)-infected patients for single-use screening and dynamic monitoring of varices needing treatment (VNT).

**Method:** A total of six cohorts with compensated cirrhosis were enrolled, including: (1) a real-world cohort; (2) a multicenter validation cohort; (3) an international validation cohort; (4) a multicenter anti-HBV cohort; (5) a dynamic monitoring longitudinal cohort; (6) a multicenter, clinical practice cohort.

**Results:** We enrolled 3, 353 patients with compensated cirrhosis from 52 university hospitals in China and Singapore. In real-world cohort (65% [830/1, 274] HBV), Baveno VI criteria (platelets >150 × 10<sup>9</sup>/L and liver stiffness <20 kPa) would have spared 30% (387/1274) of esophagogastroduodenoscopy (EGD) and missed 3.6% (14/387) of VNT, while expanded-Baveno VI criteria (platelets >110 × 10<sup>9</sup>/L and liver stiffness <25 kPa) would have spared 53% (675/1, 274) of EGDs but missed 6.2% (42/675) of VNT. Meanwhile, using new CHES criteria (platelets >110 × 10<sup>9</sup>/L and liver stiffness <19 kPa) would have spared 46% (585/1, 274) of EGD and missed 4.9% of VNT (29/585). In the multicenter validation cohort, international validation cohort and anti-HBV cohorts, CHES criteria would have spared more EGD than Baveno VI criteria (Figure). Notably, employing CHES criteria in a dynamic monitoring longitudinal cohort would have spared 41% (56/138) and 54% (63/116) of EGD, and missed 1.8% (1/56) and 0% of VNT for the first and secondary monitoring, respectively (Figure). In the prospective clinical practice cohort-guided by CHES criteria, 75% (367/491) of EGD were spared after applying CHES criteria, with a VNT rate of 36% (45/124) in those undergoing EGD.

**Conclusion:** CHES criteria were superior to Baveno VI criteria and expanded-Baveno VI criteria for the screening and monitoring of varices in patients with predominantly HBV-related compensated cirrhosis.

 Pharmacology, Salamanca, Spain  
 Email: jjgmarin@usal.es

**Background and aims:** A common feature in many liver diseases is impaired biliary secretion, which is not always evidenced by routine serum biochemical markers of liver function. Although normal bile acid (BA) uptake/secretion into bile accurately reflects healthy hepatobiliary function, serum levels can be affected by other factors altering BA pool size or enterohepatic circulation. We have aimed at developing a non-invasive strategy to carry out real-time evaluation of the hepatobiliary function based on the efficient liver handling of BAs and their derivatives.

**Method:** Using organic chemistry “click” technology, several BA species were linked to fluorochromes with near-infrared (NIR) emission wavelength, whose fluorescence can cross the abdominal wall and be extracorporeally detected. One of these compounds, named NIRBAD1 was chosen for preclinical evaluation. Selective NIRBAD1 uptake by hepatocytes has been investigated *in vitro* and *in vivo*. Extracorporeal determination of NIRBAD1 in rat liver was carried out with a high-sensitive (3.2 MP) CCD camera (Luminescent Image Analyzer LAS-4000 imaging system, Fujifilm Life Science).

**Results:** CHO cells were genetically manipulated to stably express hepatic BA transporters NTCP, OATP1B1, and OATP1B3. The uptake of 10  $\mu\text{M}$  NIRBAD1 in the absence and the presence of 100  $\mu\text{M}$  taurocholic acid (TCA) revealed that OATP1B3, and moderately OATP1B1, but not NTCP mediated TCA-inhibitible NIRBAD1 uptake. NIRBAD1 administration (i.v.) to anesthetized control rats was followed by its rapid disappearance from blood and secretion into bile. This time-course matched the dynamic of NIR fluorescence detected in the liver either directly by laparotomy or trans-abdominally in the intact animal (Figure). Serum markers of liver and kidney toxicity were not altered by NIRBAD1. The impaired hepatobiliary function was mimicked by phalloidin administration (i.v., 75  $\mu\text{g}/100\text{ g b.wt.}$ ). This procedure rapidly reduced (~50%) bile flow, which was accompanied by decreased NIRBAD1 bile output and a slower disappearance from blood. This was consistent with more prolonged retention in the liver. The half-life of extracorporeal NIR fluorescence was  $\approx 5$  min in controls, but longer (>2-fold) in phalloidin treated rats.

**Conclusion:** Novel BA derivatives with NIR fluorescence could be used as probes for the assessment of the hepatobiliary function by real-time extracorporeal non-invasive methods.

**Diagnostic Accuracy of Transient Elastography in Diagnosing Clinically Significant Portal Hypertension in Patients with Chronic Liver Disease: A Systematic Review and Meta-analysis**

Ashish Kumar<sup>1</sup>, Anil Arora<sup>1</sup>, Praveen Sharma<sup>1</sup>,  
 Shrihari Anikhindi<sup>1</sup>, Naresh Bansal<sup>1</sup>, Mandhir Kumar<sup>1</sup>,  
 Piyush Ranjan<sup>1</sup>, Munish Sachdeva<sup>1</sup>. <sup>1</sup>Sir Ganga Ram Hospital, Institute  
 of Liver, Gastroenterology, and Pancreatico-Biliary Sciences, Delhi, India  
 Email: ashishk10@yahoo.com

**Background and aims:** Transient elastography (TE) has been proposed as a promising non-invasive alternative to hepatic venous pressure gradient (HVPG) for diagnosing clinically significant portal hypertension (CSPH). However, previous studies have yielded conflicting results. We aimed to evaluate the correlation between liver stiffness measurement using TE and HVPG and the performance of TE in diagnosing CSPH (HVPG  $\geq 10$  mmHg).

**Method:** We conducted a systematic review and meta-analysis by searching PubMed and Scopus databases for relevant literature evaluating the clinical usefulness of TE for diagnosing CSPH in patients with chronic liver disease.

**Results:** Twenty-six studies (including 4337 patients with valid TE and HVPG readings) met our inclusion criteria. The median correlation coefficient of TE with HVPG was 0.70 (range 0.36 to 0.86). The weighted mean of optimal cut-off of liver stiffness value for diagnosing CSPH was 22.8 kPa (95% CI, 22.7–23.0 kPa). The summary sensitivity and specificity were 79% (95% CI, 74–84%) and 88% (95% CI, 84–91%), respectively. The area under the hierarchical summary receiver operating characteristic (HSROC) curve was 0.91 (95% CI, 0.88–0.93) according to the bivariate model. There was significant heterogeneity in the results, which was well explained by the variable liver stiffness cut-offs used in the studies. The meta-regression plot revealed that as the optimal cut-off increased, the sensitivity decreased, the specificity increased, and vice versa.

**Conclusion:** Liver stiffness measurement by TE correlates well with HVPG, and a liver stiffness cut-off value of 22.8 kPa shows a high accuracy for diagnosing CSPH. Thus, use of TE should be integrated into clinical practice for non-invasive diagnosis of CSPH.

Figure: (abstract: PO-1696): Forest plot of sensitivity and specificity of TE for diagnosis of CSPH.

**A novel liver-specific fibrosis biomarker, PRO-C18L, can predict response to antifibrotic treatment, with a peroxisome proliferator activated receptor - $\gamma$  agonist, in patients with chronic hepatitis C**  
 Ida Villesen<sup>1,2</sup>, Lasse Langholm<sup>1</sup>, Diana Leeming<sup>1</sup>, Zachary Goodman<sup>3</sup>, Keyur Patel<sup>4,5</sup>, Morten Karsdal<sup>1</sup>, Detlef Schuppan<sup>6,7</sup>, Mette Juul Nielsen<sup>1</sup>. <sup>1</sup>Nordic Bioscience, Fibrosis, Herlev, Denmark; <sup>2</sup>University of Copenhagen, BRIC, Denmark; <sup>3</sup>Inova Fairfax Hospital, Hepatic Pathology Consultation and Research, United States; <sup>4</sup>University of Toronto, Division of Gastroenterology and Hepatology, Canada; <sup>5</sup>Duke University, Durham, United States; <sup>6</sup>Johannes Gutenberg University, University Medical Center, Mainz, Germany; <sup>7</sup>Harvard Medical School, Beth Israel Deaconess Medical Center, United States  
 Email: ifv@nordicbio.com

**Background and aims:** Fibrosis is characterized as excess accumulation of extracellular matrix (ECM) in a given organ. Recently the qualitative composition of the fibrotic liver ECM has emerged as a key determinant of prognosis and survival in advanced liver disease. Type XVIII collagen is a sinusoidal basement membrane collagen harbouring a liver-specific long isoform expressed primarily by hepatocytes, suggested to associate with a repair response to hepatic injury. Here we investigate if a novel biomarker for the liver isoform of type XVIII collagen, PRO-C18L, could predict responders to an antifibrotic treatment with peroxisome proliferator activated receptor (PPAR)- $\gamma$  agonist: Farglitazar, in a retrospective cohort of patients with chronic hepatitis C (CHC).

**Method:** Plasma samples of 127 CHC patients with mild to moderate fibrosis (Ishak score 2–4) who had failed prior interferon- $\alpha$  treatment were included in the study (NCT 00244751). Patients received a daily doses of farglitazar 0.5 or 1.0 mg (n = 87), or placebo (n = 40) for 52 weeks. A baseline (BL) and end-of-treatment biopsy was taken and matched with blood sampling. The representative biopsies were centrally read using the Ishak score and patients were defined as regressors or progressors, characterized as at least one stage decrease or increase, respectively, in the Ishak fibrosis score at week 52, or as stable, defined as no change in Ishak score at week 52. Serological levels of PRO-C18L were analyzed at BL and at 52 weeks.

**Results:** 11/5 patients on placebo, 24/15 on Farglitazar progressed/regressed, respectively, while the rest remained stable. Patients with high BL levels of PRO-C18L (above 2.56 ng/ml) were found more prone to have a treatment response. This was shown by the change in PRO-C18L from BL to week 52. Thus, patients below median levels of PRO-C18L (<2.56 ng/ml) at BL showed no change with treatment (p = 0.6) while patients above median did (p = 0.05). These results were further supported by the histological assessment by the end of the study. Thus, when separating patients into tertiles based on BL level of PRO-C18L, the patients in the highest tertile had a significant proportion of regressors with treatment. This was not found in the lowest tertile.

**Conclusion:** The novel biomarker of hepatic repair response to injury, PRO-C18L, predicted responders to treatment at BL. PRO-C18L is there for a promising novel biomarker, to predict and follow the evolution of liver fibrosis with treatment.

## POSTER PRESENTATIONS

PO-2094

### Quantitate MR can identify paediatric patients with quiescent disease who may benefit from a change in treatment

Elizabeth Shumbayawonda<sup>1</sup>, Kamil Janowski<sup>2</sup>, Andrea Dennis<sup>1</sup>, Helena Thomaidis-Brears<sup>1</sup>, Matt Kelly<sup>1</sup>, Maciej Pronicki<sup>3</sup>, Wiesława Grajkowska<sup>3</sup>, Małgorzata Woźniak<sup>2</sup>, Piotr Pawliszak<sup>4</sup>, Elżbieta Jurkiewicz<sup>4</sup>, Rajarshi Banerjee<sup>1</sup>, Piotr Socha<sup>2</sup>. <sup>1</sup>Perspectum, Oxford, United Kingdom; <sup>2</sup>Centrum Zdrowia Dziecka, Department of Gastroenterology, Hepatology, Nutritional Disorders and Pediatrics, Warszawa, Poland; <sup>3</sup>Centrum Zdrowia Dziecka, Department of Pathology, Warszawa, Poland; <sup>4</sup>Centrum Zdrowia Dziecka, Department of Diagnostic Imaging, Warszawa, Poland  
Email: elizabeth.shumbayawonda@perspectum.com

**Background and aims:** Autoimmune hepatitis (AIH) is monitored using liver biochemistry and histology, however, liver biopsy is invasive, and carries the risk of pain and bleeding. MR-derived iron corrected T1 (cT1) is a promising metric that has demonstrated utility in monitoring and predicting remission loss in AIH. cT1 interquartile range (IQR), a marker of disease heterogeneity, has also shown utility in patient management. The aim of this study was to investigate the utility of imaging markers to stratify those with active from those with quiescent disease and thus identify those who would not require a follow-up biopsy but may benefit from a change in treatment.

**Method:** In 21 biopsy-confirmed AIH paediatric patients (aged 13 ± 3 years) who had a repeat monitoring biopsy after ± 16 months, those with active disease were defined as having both lobular and portal inflammation >1 on monitoring biopsy. The number of patients in biochemical remission (ALT < 40 I U/L and AST < 40 I U/L) was assessed. The potential of both blood markers (AST, ALT, GGT, IgG, bilirubin, albumin, gamma globulins) and imaging markers (derived using LiverMultiScan®) to discriminate those who had active disease from those with quiescent disease was investigated. Accuracy of each biomarker was determined using area under the receiver operator characteristic curve (AUC).

**Results:** 9/21 patients had quiescent disease while 12/21 had active disease on monitoring biopsy. Moreover, 18/21 were in biochemical remission at follow-up. Patients with quiescent disease had lower mean cT1: 793 ± 47 ms compared to those with active disease cT1 of 819 ± 47 ms. cT1 IQR was the best imaging marker (AUC: 0.8 [0.57–1]) while GGT (AUC: 0.73 [0.5–0.96]) was the best blood marker to

identify those with quiescent disease. By combining blood with imaging markers (GGT + cT1 IQR), the diagnostic utility was improved to AUC: 0.84 [0.66–1] (Fig. 1). Moreover, when the definition of active disease was extended to include those with fibrosis >2, the combined marker of cT1 IQR and GGT performed the best with AUC: 0.8 [0.59–1], and thus highlighted the strength of combining imaging and blood markers in patient management.

**Conclusion:** The combination of imaging and blood markers shows utility in identifying paediatric patients with quiescent disease, thus offering a potential non-invasive alternative to repeat biopsy. Further work exploring the utility of cT1 IQR in the AIH clinical pathway is warranted.

PO-2184

### Serum miRNA profiling for the differential diagnosis of distal cholangiocarcinoma from pancreatic diseases

André F. Tomás<sup>1</sup>, André L. Simão<sup>1</sup>, Luis Muñoz-Bellvis<sup>2</sup>, Ainhoa Lapitz<sup>3</sup>, Luis Bujanda<sup>4</sup>, Pedro Miguel Rodrigues<sup>3</sup>, Jesus Maria Banales<sup>3</sup>, Jose Marin<sup>5</sup>, Cecília M. P. Rodrigues<sup>1</sup>, Rocio IR Macias<sup>5</sup>, Rui E. Castro<sup>1</sup>. <sup>1</sup>Research Institute for Medicines (iMed. ULisboa), Faculty of Pharmacy, Universidade de Lisboa, Lisbon, Portugal; <sup>2</sup>Service of General and Gastrointestinal Surgery, University Hospital of Salamanca, IBSAL, CIBERONC, Salamanca, Spain; <sup>3</sup>Department of Liver and Gastrointestinal Diseases, Biodonostia Health Research Institute, Donostia University Hospital, University of the Basque Country (UPV/EHU), CIBERehd, Ikerbasque, San Sebastian, Spain; <sup>4</sup>National Institute for the Study of Liver and Gastrointestinal Diseases (CIBERehd, Carlos III Health Institute), Madrid, Spain; <sup>5</sup>Experimental Hepatology and Drug Targeting (HEVEPHARM), University of Salamanca, Biomedical Research Institute of Salamanca (IBSAL), CIBERehd, Salamanca, Spain  
Email: adlsimao@ff.ulisboa.pt

**Background and aims:** When distal cholangiocarcinomas (dCCAs) cross the pancreatic head, it is clinically challenging to distinguish them from pancreatic ductal adenocarcinomas (PDACs) or even benign pancreatic diseases (BPDs) by using currently available imaging techniques or established biomarkers. Moreover, all these disease conditions share similar clinical symptoms. In that regard, serum microRNAs (miRNA/miRs) have been emerging as novel potential biomarkers for diseases. Thus, we aimed to profile global serum miRNA expression changes in human patients with dCCA, PDAC and BPDs in order to identify potential candidates for the

Active disease

AST: 55 IU/L  
ALT: 87 IU/L  
Fibrosis: 5  
Portal inflammation: 3  
Lobular inflammation: 2  
cT1: 917 ms

Quiescent disease

AST: 21 IU/L  
ALT: 20 IU/L  
Fibrosis: 0  
Portal inflammation: 0  
Lobular inflammation: 1  
cT1: 749 ms

Figure: (abstract: PO-2094): A. Diagnostic accuracy of individual blood and imaging markers to identify AIH patients with quiescent disease. B. cT1 maps for a patient with active disease (left) and quiescent disease (right).

differential diagnosis of these diseases, which would have a direct impact on their specific treatment.

**Method:** Serum samples were obtained from patients with histopathologic confirmation of dCCA (n = 35) or PDAC (n = 38), as well as from BPD patients (with cysts (n = 22) or with chronic pancreatitis (n = 20), or from healthy subjects (n = 45), with complete anthropometric, biochemical and clinical characterization. Serum miRNAs were isolated using the miRNeasy Serum Advanced Kit and sample pools from each group were analyzed using TaqMan Advanced miRNA Human Serum array cards. cel-miR-39-3p was used as an exogenous spike-in control. Selected miRNAs were validated by TaqMan Advanced Real-Time RT-PCR.

**Results:** Real time RT-PCR array analysis revealed distinct serum miRNA expression profiles between all groups of patients. Upon individual validation, miRNAs found to be mostly differentially expressed in dCCA included miR-95-3p and miR-154-5p, up- and down-regulated, respectively, comparing with PDAC, but also with BPD and healthy controls. Of note, miR-204-5p and miR-200c-3p were particularly elevated in BPD patients with cysts or with chronic pancreatitis, respectively, comparing with dCCA. In addition, the levels of these miRNAs were found to be independent of the patient gender or the presence of selected liver disease risk factors. Moreover, serum miR-154-5p levels negatively correlated with GGT, while both miR-204-5p and miR-200c-3p positively correlated with patients' age. Of note, in dCCA patients, miR-95-3p levels positively correlated with carbohydrate antigen19-9 (CA19-9), a non-specific tumor marker commonly used to help in the diagnosis of CCA and PDAC.

**Conclusion:** In conclusion, analysis of serum levels of specific miRNAs, including miR-95-3p and miR-154-5p, may allow for the differential diagnosis of dCCAs from both benign and malignant pancreatic diseases, as well as correlations with clinical features of patients. Further validation in independent cohorts could translate into the use of miRNAs as accurate biomarkers for dCCA early diagnosis. (OLD-HEPAMARKER, 0348\_CIE\_6\_E; V Beca de Investigación Carmen Delgado/Miguel Pérez-Mateo, Spain; PTDC/MED-PAT/31882/2017, Portugal; COST Action CA18122, EUROCHOLANGIO-NET).

**Validation of non-invasive criteria for diagnosis of clinically significant portal hypertension in compensated advanced chronic liver disease of different etiologies in an asian cohort**

Ankur Jindal<sup>1</sup>, Samagra Agarwal<sup>2</sup>, Sanchit Sharma<sup>2</sup>, Manoj Kumar<sup>1</sup>, Anoop Saraya<sup>2</sup>, Shiv Kumar Sarin<sup>1</sup>. <sup>1</sup>Institute of Liver and Biliary Sciences, Hepatology, New Delhi, India; <sup>2</sup>AIIMS Hospital, Gastroenterology and Human Nutrition Unit, New Delhi, India  
Email: shivsarin@gmail.com

**Background and aims:** Non-invasive diagnosis of clinically significant portal hypertension (CSPH) using simple classification criteria is important in centres where hepatic venous pressure gradient (HVPG) measurement is not routinely practiced. We aimed to validate the recently published non-invasive criteria to predict CSPH in compensated advanced chronic liver disease (cACLD) of different etiologies in an Asian cohort.

**Method:** In this retrospective study, consecutive patients of cACLD of different etiologies with anthropometry, liver stiffness measurement (LSM), HVPG and blood investigations records were included. CSPH was defined as HVPG>10 mm Hg. A LSM ≥25 kPa and LSM ≤15 kPa plus platelets ≥150 × 10<sup>9</sup>/L were evaluated as a non-invasive rule-in and rule-out criteria for CSPH respectively. The NASH-ANTICIPATE model (composite of BMI, platelets and LSM) was tested to evaluate CSPH in patients with NASH with BMI>30 kg/m<sup>2</sup>.

**Results:** 626 patients (mean age:44.7 ± 13.5 years, 72.4% males) with alcohol (30.3%), non-alcoholic steatohepatitis (26.4%), hepatitis C (16.6%), hepatitis B (10.2%) related cACLD were included. CSPH was present in more than 80% patients of all etiologies except HBV (62.5%). Non-invasive rule-in criteria had a positive predictive value (PPV) >90% for all etiologies except in HBV (PPV- 80.8%) and in patients with HCV with BMI>30 kg/m<sup>2</sup> (PPV-75%). Non-invasive rule-out criteria were insufficient with 0-60% patients of different etiologies having CSPH despite satisfying both rule-out criteria. The NASH-ANTICIPATE model had a high specificity (100%) but a suboptimal sensitivity (68%) to detect CSPH in patients with obese NASH.

**Conclusion:** Utility of non-invasive rule-in criteria depends on prevalence of CSPH in population being assessed, with limited

Figure: (abstract: PO-2319): Bar diagram showing overall prevalence of CSPH (red), prevalence of CSPH in patients with LSM>25 kPa (rule-in criteria), (dark green color), prevalence of CSPH in patients with rule out criteria and BMI>30 kg/m<sup>2</sup> (light green), prevalence of CSPH in patients with LSM<15 kPa and platelets less than 150000/mm<sup>3</sup> (rule-out criteria) (blue color) and rule out criteria plus BMI<30 kg/m<sup>2</sup> (pink color) across different etiologies of cACLD.

## POSTER PRESENTATIONS

value in HBV related CLD and in obese patients with HCV. Rule out criteria for CSPH are suboptimal for excluding CSPH across most etiologies and better criteria are needed before they can be used in clinical practice.

### PO-2370

#### Evaluation of the newly proposed criteria for clinically significant portal hypertension using platelets and transient elastography

Kristian Podrug<sup>1,2</sup>, Vladimir Trkulja<sup>3</sup>, Marko Zelenika<sup>4</sup>, Tomislav Bokun<sup>4</sup>, Tonci Bozin<sup>4</sup>, James O'Beirne<sup>5</sup>, Ivica Grgurevic<sup>6</sup>.

<sup>1</sup>University Hospital centre Split, Department of Gastroenterology and Hepatology, Split, Croatia; <sup>2</sup>University Hospital centre Split, Department of Gastroenterology and Hepatology, Split, Croatia; <sup>3</sup>University of Zagreb School of Medicine, Department of Pharmacology, Zagreb, Croatia;

<sup>4</sup>University hospital Dubrava, Department of Gastroenterology, Hepatology and Clinical Nutrition, Zagreb, Croatia; <sup>5</sup>University of Sunshine Coast, Department of Hepatology, Australia; <sup>6</sup>University of Zagreb School of Medicine, University Hospital Dubrava, Department of Gastroenterology, Hepatology and Clinical Nutrition, Zagreb, Croatia  
Email: kpodrug@gmail.com

**Background and aims:** New non-invasive criteria for diagnosing clinically significant portal hypertension (CSPH) have been proposed recently (Pons M. et al. Am Journal Gastroenterol 2020). We aimed to evaluate performance of the proposed criteria in a cohort of patients with compensated chronic liver disease.

**Methods:** We evaluated diagnostic performance of liver stiffness measurement (LSM) by transient elastography and Platelet count (Plt) for CSPH in a cohort of patients with available results of hepatic venous pressure gradient (HVPG) measurements and liver biopsy performed due to suspicion of compensated advanced chronic liver disease (cACLD). Newly proposed non-invasive criteria evaluated here were:  $LSM \geq 25$  kPa for ruling-in, and  $Plt \geq 150 + LSM \leq 15$  kPa for ruling-out CSPH. Only patients >18 years of age, who gave informed consent were included, whereas those with conditions known to affect results of LSM (ALT>5x ULN, liver congestion, extrahepatic biliary obstruction, infiltrative liver neoplasms) were not. Presence of cACLD was confirmed on liver biopsy in patients with bridging fibrosis or cirrhosis.

**Results:** The cohort included 76 patients [78.9% men, median age 62 (34–76) years, 30% obese, mostly suffering from alcoholic (36.8%) or non-alcoholic fatty liver (30.3%) disease], 61 (80.3%) of whom had cACLD, 40 (52.6%) had HVPG  $\geq 10$  mmHg (CSPH) and 43 (56.6%) had  $Plt \geq 150$ .  $LSM \geq 25$  kPa had 88.9% (95% CI 73.9–96.9) specificity to rule-in, whereas  $Plt \geq 150 + LSM \leq 15$  kPa had 100% (95% CI 73.5–100) sensitivity to rule-out CSPH. By these criteria it was possible to classify correctly 49/76 (64.5%) patients for the presence of CSPH. With increasing BMI, at any given value of Plt, higher LSM was needed for a certain probability of having CSPH.

**Conclusion:** By using these simple new non-invasive criteria almost 65% of patients could be classified correctly for the presence of CSPH. This might facilitate early recognition of CSPH among patients with cACLD and timely introduction of non-selective beta blockers considering the results from PREDESCI trial.

### PO-2386

#### Dynamic liver function tests and liver elastography in cardiac amyloidosis-preliminary data from AmyKoS

Sandra Ihne<sup>1</sup>, Oliver Goetze<sup>2</sup>, Stefan Frantz<sup>3</sup>, Hermann Einsele<sup>4</sup>, Stefan Knop<sup>4</sup>, Stefan Stoerk<sup>3</sup>, Andreas Geier<sup>2</sup>. <sup>1</sup>University Hospital of Würzburg, Department of Internal Medicine II/Hematology, Comprehensive Heart Failure Center (CHFC), Interdisciplinary Amyloidosis Center of Northern Bavaria, Würzburg, Germany;

<sup>2</sup>University Hospital of Würzburg, Internal Medicine II/Hepatology, Interdisciplinary Amyloidosis Center of Northern Bavaria, Würzburg, Germany; <sup>3</sup>University Hospital of Würzburg, Internal Medicine I/ Cardiology, Comprehensive Heart Failure Center (CHFC), Interdisciplinary Amyloidosis Center of Northern Bavaria, Würzburg,

Germany; <sup>4</sup>University Hospital of Würzburg, Internal Medicine II/ Hematology, Interdisciplinary Amyloidosis Center of Northern Bavaria, Würzburg, Germany  
Email: ihne\_s@ukw.de

**Background and aims:** Cardiac involvement (CA) indicates a poor prognosis in both light chain (AL) and transthyretin (ATTR) amyloidosis. Concomitant hepatic manifestation in AL amyloidosis clinically defined by elevated alkaline phosphatase (AP) levels and/or hepatomegaly even worsens outcome. Staging systems for CA are based on congestion-sensitive cardiac biomarkers NT-proBNP and troponin. We aimed to differentiate primary (amyloid deposition) from secondary liver affection (congestion) in amyloidosis. ATTR amyloidosis acts as example for secondary liver affection, AL amyloidosis is a model for both.

**Method:** Participants of the prospective amyloidosis cohort study AmyKoS with proven AL, ATTR and excluded systemic amyloidosis underwent detailed work-up including extensive laboratory tests, echocardiography, vibration controlled transient elastography (VCTE) and <sup>13</sup>C-methacetin breath test (MBT).

**Results:** From November 2017 until April 2020, 79 patients with proven AL (n = 30; mean age 64.0 ± 8.1 years), ATTR (n = 29; mean age 74.9 ± 7.2 years) and excluded systemic amyloidosis (controls; n = 20; mean age 60.8 ± 11.7 years) were evaluated. CA was found in 17 AL (AL-CA; 57%) and 26 ATTR (ATTR-CA; 90%) amyloidosis patients.

AL-CA vs ATTR-CA vs controls showed heart failure with preserved ejection fraction with elevation of NT-proBNP 9601.3 ± 13988.5 pg/ml vs. 2782.6 ± 2290.8 pg/ml vs. 344.1 ± 685.8 pg/ml.

ESC criteria of acute heart failure (AHF) were fulfilled in 35% vs 35% vs. 0%, edema was apparent in 47% vs 31% vs 20%, and distended liver veins in 12 vs 12 vs 0%. Elevated AP levels (74.8 ± 22.7 vs 85.8 ± 41.0 vs 70.3 ± 18.5 U/l) were accompanied by reduced liver synthesis capacity.

VCTE revealed increased liver stiffness (5.0 ± 2.0 vs 7.9 ± 4.5 vs 4.4 ± 0.9 kPa, p = 0.008) in ATTR-CA associated with hypervolemia (Spearman's rho for edema 0.57, p = 0.009; distended hepatic veins 0.45, p = 0.047) and NT-proBNP (0.58; p = 0.007), but not with other standard parameters (e.g. NYHA stage, LVEF, cardiac output, wall thickness) and presence of AHF. Cumulative percentage dose of <sup>13</sup>C recovery (cPDR) after 10–30 minutes in MBT correlates with AP and cardiac output, but not with parameters of hypervolemia.

**Conclusion:** Robust and generally applicable parameters for distinction of primary and secondary liver affection are needed in CA. Liver stiffness represents an indicator of hypervolemia and congestion; cPDR correlates with cardiac output, an acknowledged prognostic marker.

### PO-2476

#### Development and multicenter external validation of FIB-6; a novel, machine-learning, simple bedside score to rule out severe liver fibrosis and cirrhosis in patients with chronic hepatitis C

**Background and aims:** We developed and validated a non-invasive diagnostic index based on routine laboratory parameters for predicting the stage of hepatic fibrosis in patients with chronic hepatitis C (HCV).

**Method:** Machine learning with random forests algorithm was used to develop a non-invasive index using retrospective data of 7238 biopsy proven chronic hepatitis C (CHC) patients from two centers; derivation dataset (n = 1821) and validation set in the second center (n = 5417). ROC curve analysis was used to define cutoffs for different stages of fibrosis. Performance of the new score was externally validated in cohorts from two other sites in Egypt (n = 560) and in seven different countries (n = 1317). Results were also compared with three established tools (FIB-4, APRI, and AAR).

**Results:** Age, aspartate, and alanine aminotransferases, alkaline phosphatase, albumin (g/dL), and platelet count (/cm3) correlated with the biopsy-derived stage of liver fibrosis in the derivation cohort and were used to construct the model for predicting the fibrosis stage, resulting in an FIB-6 index. Applying the cutoffs from the ROC curve analysis of the derivation group in the validation groups indicated very good performance in ruling out cirrhosis (negative predictive value [NPV]=97.7%), severe fibrosis (NPV=90.2%), and significant

fibrosis (NPV=65.7%). In the external validation groups, FIB-6 demonstrated higher sensitivity and NPV than FIB-4, APRI, and AAR. **Conclusion:** FIB-6 score is an accurate, simple, non-invasive test for ruling out advanced fibrosis and liver cirrhosis in chronic hepatitis C patients better than APRI, FIB-4 and AAR.

**PO-2936**

**Improving the Accuracy of Non-Invasive Tests for Prediction of Cirrhosis in Chronic Hepatitis Delta: Insights from 230 Patients of the D-LIVR Study**

## POSTER PRESENTATIONS

invasive scoring systems to diagnose or exclude cirrhosis in HDV, including aspartate aminotransferase-to-platelet ratio index (APRI), fibrosis index based on four factors (FIB-4), Fibrotest™ and Stiffness (Fibroscan®).

**Method:** Demographic, histologic and clinical laboratory data from the first 230 randomized patients in the on-going Phase 3 HDV D-LIVR trial (NCT03719313) were evaluated. D-LIVR is the largest, global registrational study in HDV, investigating Lonafarnib, the first and only oral agent in development for HDV. All patients had a baseline liver biopsy to diagnose cirrhosis. The prediction of cirrhosis with non-invasive evaluation was based on established scales and cut-off values of APRI >2, FIB-4 >3.27, Fibrotest >0.74, Fibroscan >12.5 kPa.

**Results:** Patients with cirrhosis (n = 67) when compared to patients without cirrhosis (n = 163) were older (mean age 48.5 vs 43.0 years,  $p = 0.0008$ ) with a trend toward obesity (BMI >30 kg/m<sup>2</sup>) (23.9% vs 11.7%,  $p = 0.08$ ). There was no statistical difference between these two groups regarding baseline levels of ALT, glucose, albumin, bilirubin, HBsAg quantification, HDV RNA or HBV DNA. APRI >2, FIB-4 >3.27, Fibrotest >0.74 correlated with cirrhosis ( $r$  coefficient,  $p$  values). However, a large proportion of patients with cirrhosis (55–64%) were not identified as cirrhotic by these scores. Few (8–11%) patients without fibrosis were misclassified as having cirrhosis. Stiffness (Fibroscan >12.5 kPa) was correlated with cirrhosis ( $r$  coefficient,  $p$  values), however (41.8%) were missed by the scores and a large proportion (53.4%) of patients without fibrosis were misclassified as having cirrhosis. A combination of APRI <2 and Fibroscan <12.5 kPa correctly had a NPV of 96.9% for excluding cirrhosis. A combination of FIB-4 <3.27 and Fibroscan >12.5 had a NPV of 96.3% for excluding cirrhosis.

**Conclusion:** APRI, FIB-4, Fibrotest and Fibroscan are not accurate predictors of cirrhosis in chronic HDV patients. However, the combination of serum markers (APRI <2 or FIB-4 <3.27) and elasticity (Fibroscan <12.5 kPa) can exclude the presence of cirrhosis. For patients who do not meet these criteria, a liver biopsy may be

performed for the diagnosis of cirrhosis. Liver biopsy is currently the most reliable method for detection of cirrhosis in this population.

**Keywords:** APRI; Chronic hepatitis D; FIB-4; Cirrhosis.

### Nurses and Allied Health Professionals

#### PO-190

#### Patients with LIVER CIRRHOSIS-SATISFACTION in a NURSE-LED outpatient clinic

Marie Louise Sjoedin Hamberg<sup>1</sup>, Sabine Greve Danielsen<sup>1</sup>, Lene Dupont<sup>1</sup>, Hanne Bennick<sup>1</sup>, Marthe Forbord Huss Joensson<sup>1</sup>, Mette Lehmann Andersen<sup>1</sup>, Ane Soegaard Teisner<sup>1</sup>, Anne Kjaergaard Danielsen<sup>1</sup>. <sup>1</sup>Herlev Gentofte Hospital, Dept. of Gastroenterology, Herlev, Denmark  
Email: marie.louise.sjoedin.hamberg.01@regionh.dk

**Background and aims:** Patients with decompensated cirrhosis—regardless of etiology—often belong to an exposed and marginalized group of patients due to a broad variety of causes, e.g. the cognitive impact of hepatic encephalopathy (HE) and the stigmatization caused by the diagnosis alone. Consequently, for an outpatient there may be a corresponding need for easy access, continuity, frequent support and close follow-up. In 2017, to address this we implemented a nurse led outpatient clinic with a patient-centered approach. Since then we've continuously strived to increase patient participation and in 2020 we decided to conduct a survey to explore patient satisfaction within areas as involvement and level of information (fig.1).

**Method:** Patients with cirrhosis were recruited consecutively during their scheduled visits in the nurse-led clinic regardless of cause (e.g. medicine adjustments or paracentesis). All participants gave written consent and could only participate once. Data were collected using a

### Results on patient satisfaction

Figure: (abstract: PO-190): shows mean values of the 19 questions on satisfaction. Participants rated every question on a 5-point Likert scale ranging from Not at all to To a very large extent. Other options (not shown) were Don't know and Not relevant for me.

compound questionnaire with questions derived from a validated questionnaire on patient satisfaction. A research assistant with no prior knowledge of participants administered the final questionnaire with reference to the visit just completed. Besides primary outcome data on satisfaction (figure 1), demographic data, comorbidity, self-estimated health and data on treatment for liver cirrhosis were collected.

**Results:** 81 participants were screened over a 5-month period. 67 patients accepted participation, 60% men and 40% women. Distribution by age showed 60% over 66 years. Visits related to HE accounted for 42%, ascites issues for 36%. Educational background showed 51% with higher education, 35% were trained and only 3% had no education. A majority of 82% had retired or were off sick leave. Most of participants (66%) lived alone.

Patients demonstrated great readiness to participate (83%) and they expressed feeling safe and well known by nursing staff (figure 1). The information given was deemed useful and patients felt involved in decision making to some extent. Regarding involvement of relatives (question 8) and information on side effects of new medication (question 13) respectively 54% and 45% answered *not relevant*.

**Conclusion:** Concluding, results show a high degree of overall satisfaction. However, availability and ways of communication other than the physical visits (question 15 and 16) are areas to be developed. Knowing from literature that this group of patients commonly expresses gratefulness to a very large extend our positive results need to be acknowledged in this light.

**PO-205**

**A new prediction equation for estimating body weight in cirrhotic patients with refractory ascites**

Bruna Cherubini Alves<sup>1</sup>, Moiséli Luchi da Cruz<sup>2</sup>, Antonio de Barros Lopes<sup>3</sup>, Camila Saueressig<sup>1</sup>, Valesca Dall'Alba<sup>1,2,4</sup>.  
<sup>1</sup>Universidade Federal do Rio Grande do Sul, Graduate Program: Sciences of Gastroenterology and Hepatology, Porto Alegre, Brazil; <sup>2</sup>Universidade Federal do Rio Grande do Sul, Undergraduate Course of Nutrition, Porto Alegre, Brazil; <sup>3</sup>Hospital de Clínicas de Porto Alegre, Division of Gastroenterology and Hepatology, Porto Alegre, Brazil; <sup>4</sup>Hospital de Clínicas de Porto Alegre, Division of Nutrition and Dietetics, Porto Alegre, Brazil  
 Email: brunacherubini@gmail.com

**Background and aims:** Decompensated cirrhosis is marked by fluid retention, malnutrition, and high mortality. Ascites can impair the nutritional assessment, by overestimating body weight (W), under-diagnosing malnutrition. These factors may also compromise the adequate establishment of dietary needs. Dietetic guidances indicate subtracting 2.2–14 kg or 5–15% of the measured W according to the degree of ascites, however, there is a lack of evidence to substantiate these values. Thus, this study aims to develop a new prediction equation to estimate the dry W (DW) of patients with refractory cirrhotic ascites.

**Method:** Cross-sectional study, that included patients with decompensated cirrhosis undergoing large-volume paracentesis. Height (H) were measured and W, immediately before and after paracentesis. For the prediction of DW, a linear regression model was performed using as predictor variables: gender, H, and pre-paracentesis W (preW), as response variable: post-paracentesis W (postW). Three-way interaction was used to test the joint effect of these predictors. The capacity of this model to predict the postW was evaluated comparing it with the currently used predictions through the intraclass correlation coefficient (ICC) and the mean square error (MSE).

**Results:** Twenty patients were included, 16 were male. Moderate ascites was the most prevalent grade (n = 18). The mean (range) of ascitic fluid drained was 6.6 (0.45–16.0) L, and the difference of Wpre and Wpost was -6.8 (-0.7–15.7) kg. The prediction equation for estimating DW is presented in Table 1, in gender format. ICC values showed that all predictions measures were strongly correlated (r > 0.95). In comparison with current predictions, our model showed the

highest ICC (r = 0.97) and the lowest MSE (=7.70), comparing with the current predictions (MSE = 18.63, when the preW is adjusted from absolute values and MSE = 12.75 when adjusted from percentage values), indicating more accurate prediction.

Table 1: Prediction equations to estimate dry weight in patients with refractory cirrhotic ascites

Male	DW = -11.4 + 1.2 * Wpre + 0.125 * H - 0.002 * Wpre * H
Female	DW = -40.6 + 1.2 * Wpre + 0.331 * H - 0.030 * Wpre * H

**Conclusion:** This new prediction equation showed high reliability as a W adjustment tool for patients with refractory cirrhotic ascites. Further research is required to validate this prediction equation.

**PO-511**

**Health status perception and patient experience in liver cancer patients participating in Nurse-led Educational Programs**

Neus Llarch<sup>1</sup>, Gemma Iserte<sup>2</sup>, Núria Granel<sup>2</sup>, Víctor Sapena<sup>3</sup>, Marco Sanduzzi Zamparelli<sup>4</sup>, Sergio Muñoz Martínez<sup>4</sup>, Marta Campos Gomez<sup>1</sup>, Alejandro Forner<sup>3</sup>, Jordi Bruix<sup>3</sup>, María Reig<sup>3</sup>.  
<sup>1</sup>BCLC Group, ICMDiM. Hospital Clinic Barcelona, CIBERehd., Barcelona, Spain; <sup>2</sup>BCLC Group, ICMDiM. Hospital Clinic Barcelona, Barcelona, Spain; <sup>3</sup>BCLC Group, Liver Unit, ICMDiM. Hospital Clinic Barcelona, CIBERehd., Barcelona, Spain; <sup>4</sup>BCLC Group, Liver Unit, Hospital Clinic Barcelona, Fundacio Clinic per la Recerca Biomèdica, Barcelona, Spain  
 Email: nllarch@clinic.cat

**Background and aims:** Efficacy, security and experience are the 3 pillars of quality of care. Efficacy and security have been demonstrated in several studies, but the experience of patients in liver cancer has not yet been reported in the literature. Our aim is to evaluate the perceived health status and experience of liver cancer patients after being part of the BCLC-Educational Programs.

**Method:** Prospective study assessing patients' experience with the validated questionnaires IEXPAC and EQ-5D-3L. Population was distributed in two groups: patients with no previous contact with BCLC group (BCLC-Naive) and patients included in an educational program conducted by Advanced Practice Nurses. In this last group patient questionnaires were classified according to whether the assessment was done prior to the educational program (BCLC-experience) or during the follow-up in time-points 2, 6 or 12 months (BCLC-FUP).

**Results:** From February 2019 to December 2020, 116 patients were included (83.5% males, median age of 67, 96.7% with hepatocellular carcinoma and 3.3% cholangiocarcinoma) and they filled out 182 questionnaires. Some of the 65 patients who were in Educational Programs answered more than 1 questionnaire due to treatment migration.

At the time of this first analysis, we analyzed the 124 questionnaires corresponding to 51 BCLC-naive and 73 BCLC-experience patients. The health perception was 70/100 in both groups and the IEXPAC was 6.1 in BCLC-naive and 7 in BCLC-experience; respectively. The same score of IEXPAC and EQ-5D-3L was observed in ECOG-PS 0 patients (n = 44 BCLC-naive/n = 63 BCLC-experience patients) when analyzed separately.

The best scored IEXPAC items in the BCLC-experience questionnaires were "They ask me and help me to follow my treatment plan," "They are well-coordinated to offer me good care" and "They care about my well-being." The lowest scored items were "They encourage me to talk with other patients", "They help me find information online" and "I use the internet and mobile phone to check my medical history."

**Conclusion:** This is the first analysis worldwide of patient health status perception and experience in liver cancer. Patients' perception is 70/100. Patient Experience reflects the nurses' role, the impact of nurse intervention and the need to explore alternative channels of communication with patients.

Email: granel@clinic.cat

**Background and aims:** The eradication of hepatitis C virus (HCV) doesn't abolish the risk of hepatocellular carcinoma (HCC) development. Several factors are associated to it after achieving sustained virological response (SVR). Our aim is to describe lifestyle changes in patients with SVR after direct antiviral agents (DAA) and evaluate their adherence to a nurse-led HCC screening program.

**Method:** Single-centre, observational and prospective study. The screening program started within the 1st month of SVR and includes: ultrasound, laboratory, anthropometric measurements and questionnaires on lifestyle habits. All these procedures were done by the nurse and physician every 6 months until cancer development, death or lost to follow-up. This first analysis evaluated patients until the 4th year of follow-up.

**Results:** We included 182 patients, 2 of them were lost before the first US. The 180 analyzed patients were: males (51.6%), 65.9% were cirrhotic and 92.5% of them Child-Pugh A. Median body mass index (BMI) was 27.1 [24.9–29.6] and the waist-hip ratio 0.94 [0.89–1] in men and 0.84 [0.79–0.88] in women at the time of SVR. 19.2% of patients were smokers, 30.8% consumed alcohol, 48.8% coffee and 54.9% did physical activity at baseline. During the 54.7 [49.9–58.2] months median follow-up, 9 patients developed HCC (all were cirrhotic). Median time to HCC development was 30.7 [24.5–35.9] months. A total of 19 patients out of the 21 with cancer (7 out of 9 HCC and 11 out of 12 other cancers) had a baseline BMI >24. A significant increase in BMI [0.2 (CI95%: 0.02–0.38)] at 6 months was observed and this change was maintained in the following time-points.

There wasn't a significant change in coffee consumption but a trend for increasing physical activity was registered at 2 and 3 years of follow-up ( $p=0.08$  and  $0.09$ , respectively). A significant increase in alcohol consumption in the same time intervals ( $p=0.007$  and  $p=0.02$ ; respectively) was observed, while the number of patients who didn't answer the alcohol related questions increased from 2.7% to 10.3% at 3 years of follow-up.

The adherence to the HCC screening program at 6 months, and 1, 2, 3 and 4 years were 98%, 97%, 92%, 90% and 80%, respectively.

**Conclusion:** The adherence to the nurse-led liver cancer screening program was very high. We observed an increase in the physical activity but also an increase of alcohol consumption and BMI which may represent an additional risk factor for HCC development at long term.

PO-1221

### Importance of a clinical pharmacist specialized in hepatitis C treatment for the management of potential drug-drug interactions in a multidisciplinary ECHO® hepatitis C expert team

Yaroslav Filippov<sup>1</sup>, Claire Wartelle-Bladou<sup>2,3</sup>, Jocelyne Parent<sup>4</sup>, Valérie Martel-Laferrrière<sup>3,5,6</sup>, Suzanne Brissette<sup>2,3</sup>, Barbara Kotsoros<sup>2</sup>, Suzanne Marcotte<sup>1,3</sup>, Dominic Martel<sup>1,3</sup>. <sup>1</sup>Centre hospitalier de l'Université de Montréal (CHUM), Département de pharmacie, Montreal, Canada; <sup>2</sup>CHUM, Service de médecine des toxicomanies, Montreal, Canada; <sup>3</sup>Centre de recherche du CHUM (CRCHUM), Montreal, Canada; <sup>4</sup>Université de Montréal, Réseau universitaire intégré de santé et de services sociaux (RUISSS), Montreal, Canada; <sup>5</sup>CHUM, Microbiologie, infectiologie, Montreal, Canada; <sup>6</sup>Université de Montréal, Faculté de médecine, département de microbiologie, infectiologie et immunologie, Montreal, Canada  
Email: dominic.martel.chum@ssss.gouv.qc.ca

**Background and aims:** ECHO® CHUM hepatitis C program was launched in 2017. This “hub and spokes” model enables linking of an interdisciplinary hepatitis C virus (HCV) expert team with community-based healthcare professionals. De-identified clinical cases are presented during teleclinics. A clinical pharmacist specialized in HCV treatment is part of the ECHO® expert panel. We sought to evaluate the prevalence and severity of potential drug-drug interactions (DDIs) between direct-acting antivirals (DAAs) and co-medications in cases discussed throughout the program.

**Method:** Cases presented between April 2017 and March 2020 were included. Data were collected prospectively using case presentation forms and recommendations issued by the hub. Occurrence and severity of potential DDIs for each available DAA regimen were determined using two online interaction checkers. Cases were excluded in case of missing information on co-medications. Subgroup analyses were done using the Chi-square test.

**Results:** Overall, 75 cases were discussed during the study period and 73 patients were included. Most patients (77%) were past or active intravenous drug users or had a psychiatric illness (56%). The median number of comedications per patient was 4 and 36 (49%) patients were on at least five drugs. In total, 49 patients (67%) were at risk for at least one potential DDI with any available DAA, including 13 (18%) taking contraindicated comedications. Patients on five or more drugs had a higher likelihood of DDI with any DAA (92% (95%CI 78–98) vs. 45% (95% CI 30–63);  $p<0.0001$ ). Nevertheless, the number of potential DDIs per antiviral regimen was low (less than 16%). Among the 139 different comedications in the study, 24 (17%) could present a potential DDI with any DAA regimen while 6 (4%) were identified as contraindicated. Drugs most frequently involved with DDIs were proton pump inhibitors, antipsychotics, statins and antiretrovirals. Out of the 63 pharmacological interventions from the hub, 41% pertained to the management of DDIs, while 29% and 18% of recommendations regarded comorbidities and adverse events/adherence respectively.

**Conclusion:** Assessment of DDIs is key in HCV care. Most cases discussed in this ECHO® program led to various pharmacological recommendations. A pharmacist with clinical expertise in HCV treatment should be part of the interdisciplinary expert ECHO® team. As most DDIs can be managed, they should not be a barrier to the initiation of HCV treatment.

PO-1353

### Randomized controlled study: investigation of the effect of exercise on liver function tests, fatigue and quality of life in patients with liver cirrhosis

Hülya Keskin<sup>1</sup>, Aynur Türeyen<sup>2</sup>, Ulus Akarca<sup>3</sup>. <sup>1</sup>Mardin Artuklu University Health Science Faculty, Nursing Department, Mardin, Turkey; <sup>2</sup>EGE University Nursing Faculty, Internal Medicine Nursing Department, Izmir, Turkey; <sup>3</sup>EGE University Faculty Of Medicine, Department of Gastroenterology, Izmir, Turkey  
Email: hulya\_k@hotmail.com

**Background and aims:** This randomized controlled study aimed to determine the effect of the exercise program to be applied in patients with cirrhosis on the patient's biochemistry parameters, quality of life, fatigue level, depression, and quality of sleep.

**Method:** The study population consisted of 84 patients, including the physical exercise group (PE, n = 27), the breathing exercise group (BE, n = 29), and the no intervention group (NI, n = 28). An exercise program (5 minutes warm-up, 30 minutes walking, 5 minutes cooldown) and a 10-minute breathing exercise were requested 7 days a week for 3 months in PE and BE patients, respectively. The patients were trained on how to perform the exercises and all the patients were followed up by phone calls on the exercise days and on the same days for the NI group to motivate the patients. Personal Information Form, 6-Minute Walking Test, Body Mass Index (BMI) Assessment Form, SF-36 Quality of Life Scale, Biochemistry Parameters Assessment Form, Child-Pugh Score Assessment Form, Beck's Depression Inventory, Fatigue Severity Scale, Pittsburgh Sleep Quality Index (PSQI) were completed by face-to-face interviews at the beginning and the end of the study period. Differences between the data at the onset and at the end within the groups were tested by the Wilcoxon test. Comparisons of the differences of the groups were performed with GLM repeated measures. SPSS (IBM SPSS Statistics for Windows, Version 25.0. Armonk, NY: IBM Corp.) and R 4.0.2 software (R software, version 4.0.2, package: nparLD, R Foundation for Statistical Computing, Vienna, Austria; <http://r-project.org>) were used for the statistical analyzes.

	NI	6,8±3,1	6,8±2,8	
	BE	6,5±3	4,6±2,6	

Figure:

**Results:** As shown in the table, significant changes were found in some liver function tests, 6-MWT, all sub-dimensions of quality of life, total sleep quality scores, depression, and fatigue levels of the patients at the end of the study, comparing to the beginning of the study. Most of the positive effects were seen in the PE group, suggesting that PE has a favorable effect on the quality of life, well-being, sleep quality, and depression in cirrhotic patients.

**Conclusion:** Implementing non-pharmacological, inexpensive, and easily applicable exercise programs contribute positively to the management of patients with cirrhosis. Nurses should be trained to teach patients how to exercise and how to maintain an exercise program.

**PO-1525**

**Nurse intervention optimizes the care of patients with hepatocellular carcinoma under systemic treatment**

Gemma Iserte<sup>1</sup>, Neus Llarch<sup>1</sup>, Núria Granel<sup>1</sup>, Víctor Sapena<sup>2</sup>, Marta Campos Gomez<sup>2</sup>, Marco Sanduzzi Zamparelli<sup>3</sup>, Sergio Muñoz Martínez<sup>3</sup>, Alejandro Forner<sup>1,2</sup>, Jordi Bruix<sup>1,2</sup>, María Reig<sup>1,2</sup>. <sup>1</sup>Hospital Clinic i Provincial de Barcelona, Oncologia Hepàtica BCLC, Barcelona, Spain; <sup>2</sup>CIBERehd, BCLC Group, Hospital Clinic i Provincial de Barcelona, Barcelona, Spain; <sup>3</sup>Fundació, BCLC Group, Hospital Clinic i Provincial de Barcelona, Barcelona, Spain  
Email: giserte@clinic.cat

**Background and aims:** Telephone visits have been part of Nurse Educational Programs for years and are a follow-up tool for liver cancer patients. This tool allows a fluid communication between the patient and the multidisciplinary team, as well as the early identification of treatment side effects, optimizing the management of patients. The aim of this study is to evaluate the impact of advanced practice nurse intervention (APN) managing unscheduled phone visits in patients with advanced hepatocellular carcinoma (HCC) in second and/or third line oral treatment.

**Method:** A retrospective, observational and descriptive study of patients who started second and/or third line treatment in a tertiary referral center (BCLC) from 01/2017 to 01/2020, and their phone calls received until 07/2020 or until discontinuation of treatment.

**Results:** Forty-one patients with advanced HCC started second or third line treatment; 20 of these patients received treatment with regorafenib and 23 with cabozantinib (2 patients received regorafenib in second line and later cabozantinib in third line). 408 phone calls were registered, 25% of which belonged to confinement period for COVID19 (March 14–June 21, 2020).

In our cohort (36% in regorafenib and 49% in cabozantinib), APNs resolved 100% of administrative consultations and 43% of phone calls related to health problems including potential toxicities of medication or cirrhosis decompensations. In second line cabozantinib patients, APNs resolved up to 73.5% of phone calls related to potential drug toxicity. In only 3.3% of phone calls related to health, patients were referred to the emergency department.

**Conclusion:** Telephone consultations managed by the APNs have a positive impact on the outpatient management of patients with HCC in systemic treatment and have been key to maintaining these treatments active during the COVID19 restrictions. The number of patients referred to the emergency department has been low, avoiding unnecessary saturation of the emergency services.

Public Health

PO-251

**Definition of healthy ranges for alanine aminotransferase levels: a 2020 update**

Serena Pelusi<sup>1</sup>, Luca Valenti<sup>1</sup>, Cristiana Bianco<sup>1</sup>, Ferruccio Ceriotti<sup>2</sup>, Alessandra Berzuini<sup>1</sup>, Laura Iogna Prat<sup>3</sup>, Roberta Trotti<sup>1</sup>, Guido Alessandro Baselli<sup>1</sup>, Roberta D'Ambrosio<sup>4</sup>, Massimo Colombo<sup>5</sup>, Emmanuel Tsochatzis<sup>3</sup>, Mirella Fraquelli<sup>4</sup>, Daniele Prati<sup>1</sup>. <sup>1</sup>Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy, <sup>2</sup>Department of Transfusion Medicine and Hematology, <sup>3</sup>Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico Milan, Clinical Laboratory, Italy; <sup>4</sup>Royal Free Hospital and UCL, London, UK, UCL Institute for Liver and Digestive Health; <sup>5</sup>Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico Milan, Italy, Department of Gastroenterology and Hepatology, CRC "A.M. and A. Migliavacca" Center for Liver Disease; <sup>5</sup>IRCCS San Raffaele Hospital, Liver Center, Milan, Italy Email: serenapelusi@libero.it

**Background and aims:** The changing epidemiology of liver disease, and modifications in the recommended analytical methodology call for a re-evaluation of the upper reference limits (URL) of alanine aminotransferase (ALT).

The aim of this study was to examine the determinants of ALT and to redefine the URL.

**Method:** We examined 21, 296 apparently healthy blood donors (age 18–65). The URL were tested for the ability to predict severe liver fibrosis estimated by liver stiffness in a subset of 447 participants with dysmetabolism.

ALT levels were measured by the new International Federation of Clinical Chemistry (IFCC) standardized test. Serum ALT values were fitted by generalized linear models. Sex-specific ALT-URL were estimated by the 95th centile in individuals without risk factors for liver disease.

**Results:** Independent predictors of ALT levels were male sex, higher body mass index, glucose, cholesterol, triglycerides and ferritin levels, hypertension, and younger age ( $p < 0.001$ ). Updated URL were identified at 42 U/L in males ( $n = 4, 855$ ), and 30 U/L in females ( $n = 4, 340$ ), approximately 30% lower than those recommended by IFCC. Due to the higher sensitivity compared to the currently available thresholds, the updated URL conferred the ability to detect steatosis and liver fibrosis in individuals with dysmetabolism (OR 2.61, 1.24–5.47,  $p = 0.006$  and OR 4.90, 1.50–15.96,  $p = 0.008$ , respectively), though with a limited accuracy.

**Conclusion:** Metabolic alterations are the major ALT determinants in healthy individuals. Updated ALT-URL at 40/32 in males/females predict liver disease related to dysmetabolism. Using the new IFCC standardized method, ALT thresholds are substantially higher than with the previous one. The limited awareness that both laboratory techniques are still in use should be regarded as a possible source of medical errors.

PO-260

**Risk factors for chronic hepatitis B among 0.5 million Chinese adults**

Elizabeth Hamilton<sup>1</sup>, Ling Yang<sup>1</sup>, Iona Millwood<sup>1</sup>, Zhengming Chen<sup>1</sup>. <sup>1</sup>Big Data Institute, Nuffield Department of Population Health, The University of Oxford, Oxford, United Kingdom Email: elizabeth.hamilton@univ.ox.ac.uk

**Background and aims:** Hepatitis B Virus (HBV) is one of the most common chronic viral infections in the world, and is an important public health issue in China, where approximately one-third of all global cases occur. It causes up to 80% of liver cancers in China, which is a leading cause of morbidity and mortality. Although there has been large progress in reducing childhood HBV infection with

universal vaccination at birth, the infection burden and associated disease among adults, particularly those in middle-age, has remained high. Despite this, robust evidence regarding risk factors for chronic HBV in Chinese adults is limited. We therefore aimed to describe HBV prevalence and examine cross-sectional factors associated with chronic HBV in a large cohort of middle-aged adults in China.

**Method:** The China Kadoorie Biobank (CKB) is a cohort of 0.5 million adults aged 30–79 years recruited from ten geographically diverse sites in China between 2004 and 2008. Participants underwent an interview-administered questionnaire at baseline including questions about demographic, socioeconomic, behavioral and lifestyle factors, and Hepatitis B surface antigen (HBsAg) was measured. Logistic regression models were constructed to estimate adjusted odds ratios for associations between baseline factors and HBsAg positivity.

**Results:** The overall prevalence of HBsAg was 3.0%, which varied markedly by region—Haikou had the highest prevalence at 5.5%, while Sichuan had the lowest prevalence at 1.7%. After multivariate adjustment, factors associated with higher risk of HBsAg positivity included male sex, younger age, no formal education, working in a factory, history of blood transfusion and poor self-rated health. Factors associated with lower risk of being HBsAg positive included having a household fridge, higher waist-hip-ratio and reporting occasional or regular alcohol intake.

**Conclusion:** A rigorous understanding of risk factors for HBsAg persistence in Chinese adults may help inform targeted screening and timely treatment among high-risk adults, to prevent progression to cirrhosis and liver cancer. Future work will include investigation of genetic determinants of chronic HBV.

Figure: Select factors associated with chronic hepatitis B infection in 0.5 million Chinese adults

PO-424

**Simplified test and treat protocols for population level screening and elimination of hepatitis B and hepatitis C in Uzbekistan**

Erkin Musabaev<sup>1</sup>, Shakhlo Sadirova<sup>1</sup>, Shokhista Bakieva<sup>1</sup>, Krestina Brigida<sup>1</sup>, Homie Razavi<sup>2</sup>, Rick Dunn<sup>2</sup>, Kathryn Razavi-Shearer<sup>2</sup>. <sup>1</sup>Research Institute of Virology, Tashkent, Uzbekistan; <sup>2</sup>Center for Disease Analysis Foundation, Lafayette, United States Email: drmusabaev1956@gmail.com

**Background and aims:** An estimated 3.5 million people are infected with hepatitis B virus (HBV) or hepatitis C virus (HCV) in Uzbekistan. This study tested the feasibility of eliminating HBV and HCV if the

testing and treatment protocols were simplified to support a national program.

**Method:** Nurses were trained to use rapid HCV antibody and hepatitis B surface antigen (HBsAg) to screen patients at polyclinics. Rapid creatinine and human immunodeficiency virus (HIV) tests were used to test HBsAg+ patients before they were referred to General Practitioners (GPs) for treatment. Core antigen/polymerase chain reaction (PCR), creatinine and AST-to-Platelet-Ratio Index (APRI) was collected for HCV+ cases. Cirrhotic patients were referred to a specialist while other patients were referred to GPs who were trained by specialists to treat patients. A centralized registry was used to collect patient data as they moved from screening to prescription refill.

**Results:** More than 60,000 people were screened over six months at polyclinics. 70% of HBV+ were linked to care and 86% of patients received a prescription. 57% of HCV+ were linked to care and 84% of viremic patients received a prescription in spite of lower patient engagement with healthcare systems due to COVID-19. There were large geographic variations in HBV and HCV prevalence across Tashkent and nationally.

**Conclusion:** A simplified test/treat protocol can be used to screen, link to care and treat large numbers of HCV+ and HBsAg+ patients using nurses and GPs who are accessible throughout the country. Patients with advanced liver disease still require consultation with a liver specialist. The study also highlighted hotspots in the country that could be prioritized in a national program.

#### PO-425

##### Modelling the potential effectiveness of different screening and treatment strategies for hepatitis c during pregnancy in Ukraine

Nadia Hachicha Maalej<sup>1</sup>, Intira Jeannie Collins<sup>2</sup>, AE Ades<sup>3</sup>, Karen Scott<sup>2</sup>, Ali Judd<sup>2</sup>, Elizabeth Chappell<sup>2</sup>, Yazdan Yazdanpanah<sup>1,4</sup>, Sylvie Deuffic-Burban<sup>1</sup>. <sup>1</sup>Université de Paris, Inserm UMR 1137 IAME, France; <sup>2</sup>Medical Research Council Clinical Trials Unit, University College London, United Kingdom; <sup>3</sup>School of Social and Community Medicine, University of Bristol, United Kingdom; <sup>4</sup>Service de Maladies Infectieuses et Tropicales, Hôpital Bichat-Claude Bernard, Paris, France  
Email: nadia.hachicha@inserm.fr

**Background and aims:** Ukraine has a concentrated epidemic with ~2 million people living with HCV. There is a high burden in key subgroups, including people who have injected drugs, and among people living with HIV. Pregnant women with HCV RNA have a risk of vertical transmission (VT) of about 5%, and almost twofold higher in HCV/HIV-coinfected women with unsuppressed HIV. Results from a recent Phase I clinical trial reported good safety of direct-acting antiviral (DAA) regimen from the second trimester of pregnancy with high maternal HCV cure by delivery and no VT. We explored the potential impact of different HCV screening and treatment strategies during pregnancy on maternal cure and VT in Ukraine.

**Method:** A Markov model simulated a hypothetical cohort of 570,000 pregnant women per year. The model assessed the short-term effectiveness of five different HCV screening and treatment strategies ranging from (S0) standard of care (SOC) of targeted screening and deferred treatment to after end of breastfeeding, (S1) optimal targeted screening (WHO recommendations) and deferred treatment to (S4) universal antenatal screening and DAAs during pregnancy for all women with HCV RNA. This models parameters are based on data from the literature, data from a survey of pregnant/post-partum women in Ukraine and assumptions (top of figure). Probabilities of VT were based on estimates from a Bayesian model using data from three European HCV cohorts. Key outcomes were proportions of HCV RNA women diagnosed and cured by delivery and infants with VT.

**Results:** S0 would detect 79% women with HCV RNA in pregnancy and 0% cured by delivery (bottom of figure). This compares to 94% diagnosed and 0% cured in S1 with WHO optimal targeted screening and deferred treatment. While S4, universal screening of all pregnant women and DAAs during pregnancy, would result in the highest

proportion of women diagnosed and cured by delivery (71%), and result in the lowest risk of VT (4.7% vs 11.5% in S0 and S1).

**Conclusion:** This is one of the first models to explore the potential benefits of different HCV screening and treatment strategies in pregnancy in a high-burden middle-income country setting, which will be critical in informing future care and policy as more safety/efficacy data emerge. Universal screening and treatment would achieve positive maternal and infant outcomes although our model does not take into account costs, or spontaneous HCV clearance in children.

#### PO-504

##### Innovative linkage model to re-engage lost-to-follow-up individuals in the national hepatitis C elimination program of Georgia

Amiran Gamkrelidze<sup>1</sup>, Alexander Turdziladze<sup>1</sup>, Maia Tsreteli<sup>1</sup>, Vladimer Getia<sup>1</sup>, Ana Aslanikashvili<sup>1</sup>, Lia Gvinjilia<sup>2</sup>, Tinatin Kuchuloria<sup>2</sup>, Irina Tskhomelidze<sup>2</sup>, Shaun Shadaker<sup>3</sup>, Paige A. Armstrong<sup>3</sup>, Maia Japaridze<sup>4</sup>, Sonjelle Shilton<sup>4</sup>. <sup>1</sup>National Center for Disease Control and Public Health Georgia, Tbilisi, Georgia; <sup>2</sup>The Task Force for Global Health, Tbilisi, Georgia; <sup>3</sup>National Center for HIV/AIDS, Viral Hepatitis, STD and TB Prevention, CDC, Division of Viral Hepatitis, Atlanta, United States; <sup>4</sup>Foundation for Innovative New Diagnostics, Switzerland  
Email: a.gamkrelidze@ncdc.ge

**Background and aims:** In 2015, Georgia launched a national hepatitis C virus (HCV) elimination program with the goal of reducing the country's HCV prevalence by 90%. By implementing systematic screening, and expanding harm reduction services and diagnostic capacity, 72% of the adult population had been screened for HCV by the end of 2020. However, referral of anti-HCV positive individuals for viremia testing, and subsequent enrollment in the treatment program, remains a challenge. In 2019, the National Center for Disease Control and Public Health partnered with the Foundation for Innovative New Diagnostics (FIND) to pilot a project to promote linkage to care for individuals who screened positive for HCV antibody (anti-HCV) but did not receive a viremia test.

**Method:** Anti-HCV positive individuals lost-to-follow-up residing in the 5 largest regions in Georgia were included in the pilot. Individuals with no documented viremia test results were randomly selected from the national database. Selected individuals were located and counselled via phone or home visit by trained epidemiologists and primary healthcare physicians and referred to an HCV care and treatment facility. If the first attempt was unsuccessful, one repeat attempt was made to contact the individual. Incentives were provided to the regional health personnel for each patient that was successfully linked to care, defined as anyone who presented for viremia testing.

**Results:** In December 2019, out of 7,130 antibody positive persons without viremia testing, a total of 5,313 (75%) were followed-up, of which 3,859 (73%) were reached. The remaining could not be reached, had moved, or emigrated. Of those contacted, 2,972 (77%) presented for viremia testing, of whom 1,685 (57%) were positive for HCV RNA or core antigen. Overall, 887 (53%) persons with chronic HCV infection were linked to care and enrolled in the HCV treatment program, which differed geographically; 46% of persons from urban areas were enrolled, compared to 57% of those in rural areas.

**Conclusion:** As Georgia nears elimination goals, ensuring all patients who screen positive for anti-HCV are linked to care is increasingly important. This pilot demonstrates the effectiveness of incentive-based active case follow-up. The project also demonstrates that individuals considered lost-to-follow-up can be re-engaged in HCV care. Lessons learned from this project are particularly relevant during the COVID-19 pandemic, when disruptions of care can compromise progress toward hepatitis elimination.

## POSTER PRESENTATIONS

HCV screening and treating strategies	Uptake of screening strategies		Uptake of treatment
	Absence of HCVRF*	At least one HCVRF*	
S0=current standard of care with limited risk-based screening targeting HIV+ women (assumption: 100% screened for HIV during pregnancy and thus aware of their HIV status) and no treatment in pregnancy (SOC)	75%	87% when HIV+, 79% otherwise	0%
S1=S0+optimal screening of all women with HCV risk factors (HCVRF*)	75%	96% <sup>1</sup>	0%
S2=S1+DAA treatment in pregnancy for HCV-positive women with VT risk factors (VTRF) (i.e. HIV-co-infection, high HCV viral load>6 log-IU/ml)	75%	96% <sup>1</sup>	77% <sup>1</sup> of +VTRF
S3=S2+Universal screening of all pregnant women and targeted treatment of women with VTRF	96% <sup>1</sup>	96% <sup>1</sup>	77% <sup>1</sup> of all HCV+ women
S4=S3+Universal treatment of all HCV-positive women during pregnancy	96% <sup>1</sup>	96% <sup>1</sup>	

\*HCVRF, HCV risk factors<sup>2</sup>: Persons who have received medical or dental interventions in health-care settings where infection control practices are substandard, Persons who have received blood donors for HCV was initiated or in countries where serological testing of blood donations for HCV is not routinely performed, People who inject drugs (PWID), Persons who have had tattoos, body piercing or scarification procedures done where infection control practices are substandard, Children born to mothers infected with HCV, Persons with HIV infection, Persons who use/have used intranasal drugs, Prisoners and previously incarcerated persons; +VTRF, VT risk factors once screened: presence of HIV infection and/or high HCV viral load>6 log-IU/ml, treatment is assumed to start from 7<sup>th</sup> month of pregnancy

(1) Acceptability of HCV screening and DAA treatment among pregnant and post-partum women in Ukraine: 96% were in favour of free universal HCV screening in pregnancy with little variation by HCV and HIV status; 77% of women would take DAAs in pregnancy if there was clear evidence they were safe

(2) WHO guidelines 2016

**Healthcare restrictions due to COVID-19 impaired liver care, lowered patient satisfaction and increased liver-related mortality**

Lukas Hartl<sup>1,2</sup>, Georg Semmler<sup>1,2</sup>, Benedikt S. Hofer<sup>1,2,3</sup>, Nawa Schirwani<sup>1</sup>, Mathias Jachs<sup>1,2</sup>, Benedikt Simbrunner<sup>1,2,3</sup>, David JM Bauer<sup>1,2</sup>, Teresa Binter<sup>1,2</sup>, Katharina Pomej<sup>1,2</sup>, Matthias Pinter<sup>1,2</sup>, Michael Trauner<sup>1</sup>, Mattias Mandorfer<sup>1,2</sup>, Thomas Reiberger<sup>1,2,3</sup>, Bernhard Scheiner<sup>1,2</sup>. <sup>1</sup>Medical University of Vienna, Division of Gastroenterology and Hepatology, Department of Internal Medicine III, Vienna, Austria; <sup>2</sup>Medical University of Vienna, Hepatic Hemodynamic Lab, Vienna, Austria; <sup>3</sup>Medical University of Vienna, Christian Doppler Lab for Portal Hypertension and Liver Fibrosis, Vienna, Austria

Email: thomas.reiberger@meduniwien.ac.at

**Background and aims:** The first wave of COVID-19 necessitated re-allocation of health care resources. We compared (i) chronic liver disease (CLD) patient perceptions on care quality and (ii) trends in elective and emergency admissions prior to (12/2019–02/2020), and during (03/2020–05/2020) healthcare restrictions.

**Method:** A tele-survey of outpatients (cohort-1) was conducted and written questionnaires (cohort-2) were distributed to in- and outpatients. All admissions to the Vienna General Hospital, Division of Gastroenterology/Hepatology (12/2019–05/2020) were assessed.

**Results:** In cohort-1, 279 (cirrhosis: 73.1%, hepatocellular carcinoma [HCC]: 14.7%, liver transplant recipients [LT]: 12.2%) and in cohort-2, 138 patients (non-cirrhosis: 31.9%, cirrhosis: 45.7%, HCC: 15.9%, LT: 6.5%) were included. 32.6% of cohort-1 and 72.5% of cohort-2 had

tele-medical contact during COVID-19. 57.3% of cohort-1 patients trying to reach their treating physician found this to be difficult or impossible. 32.1% of cohort-2 patients felt insufficiently informed about potential consequences of COVID-19 on CLD and 33.1% were concerned about negative effects of the pandemic on their CLD. Satisfaction with treatment declined significantly in cohort-1 (VAS 0–10:  $9.0 \pm 1.6$  to  $8.6 \pm 2.2$ ;  $p < 0.001$ ) and non-significantly in cohort-2 ( $8.9 \pm 1.6$  to  $8.7 \pm 2.1$ ;  $p = 0.182$ ).

The number of hospital admissions was lower during COVID-19, but percentages of emergency (+6.3%) and intensive care unit (ICU; +6.7%) admissions significantly increased compared to pre-COVID-19. Non-electively admitted cirrhotic patients had higher Model for End-Stage liver disease (MELD;  $25.5$  [IQR14.2] vs.  $17.0$  [8.8] points;  $p = 0.003$ ),  $\Delta$ MELD (difference to last MELD;  $3.9 \pm 6.3$  vs.  $8.7 \pm 6.4$  points;  $p = 0.008$ ), CLIF-C acute decompensation (AD;  $61.5 \pm 11.5$  vs.  $54.0 \pm 11.7$  points;  $p = 0.011$ ) and  $\Delta$ CLIF-C AD score ( $12.6 \pm 8.3$  vs.  $5.0 \pm 8.6$  points;  $p < 0.001$ ) than pre-COVID-19. Admitted patients more often progressed to severe/refractory ascites (63.3% vs. 30.6%;  $p = 0.012$ ), required immediate ICU admission more frequently (26.7% vs. 5.6%;  $p = 0.034$ ) and had higher 30-day liver-related mortality (30.0% vs. 8.3%;  $p = 0.028$ ).

**Conclusion:** COVID-19 profoundly impacted on liver care. Patient satisfaction decreased and reaching physicians in emergency situations was often difficult, resulting in hospitalization of sicker CLD patients and increased liver-related mortality. Strategies for improved tele-medical care and early treatment of complications are crucial.

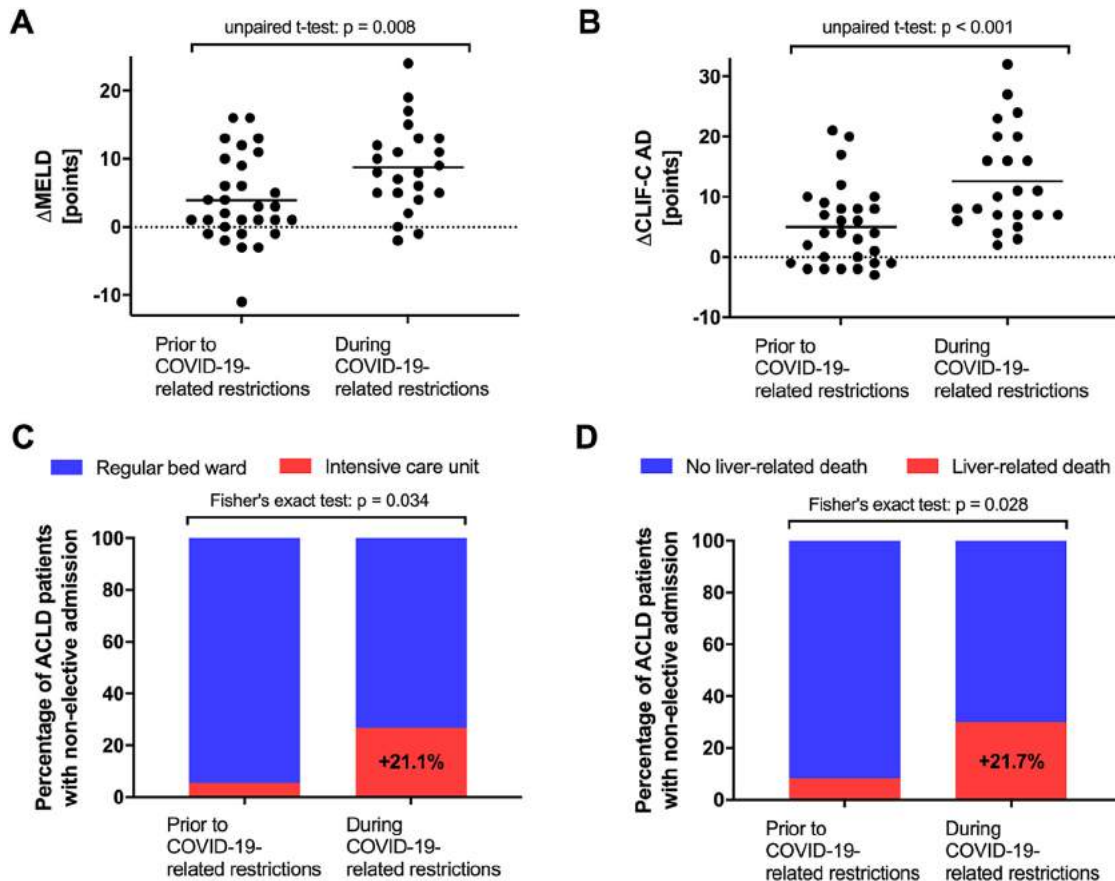

Figure: (abstract: PO-533)

## POSTER PRESENTATIONS

PO-539

### Promoting Hepatitis Virus Screening Test at Worksite in Japan Using Nudge Theory compared with Full Subsidies

Masaaki Korenaga<sup>1</sup>, Jun Fukuyoshi<sup>2</sup>, Keiko Korenaga<sup>3</sup>, Tatsuya Kanto<sup>1</sup>.  
<sup>1</sup>National Center for Global Health and Medicine, The Hepatitis Information Center, Ichikawa, Chiba, Japan; <sup>2</sup>Keio University, Department of Preventive Medicine and Public Health; <sup>3</sup>Funabashi Central Hospital, Funabashi, Chiba, Japan  
Email: dmkkorenaga@hospk.ncgm.go.jp

**Background and aims:** Despite the importance of hepatitis screening for decreasing liver cancer mortality, screening rates remain low in Japan. Previous studies show that full subsidies increase screening uptake, but full subsidies are costly and difficult to implement in low resource settings. Alternatively, applying nudge theory to the message design could increase screening at lower costs. This study examined the effects of both methods in increasing hepatitis virus screening rates at worksites.

**Method:** About 1,500 employees from a Japanese transportation company received client reminders for an optional hepatitis virus screening before their general health checkups. Groups A and B received a client reminder designed based on the principles of 'Easy' and 'Attractive', while the Control Group received a client reminder not developed using nudge theory. Additionally, hepatitis virus screening was offered to the Control Group and Group A for a co-payment of JPY 612, but was fully subsidized for Group B. The hepatitis virus screening rates among the groups were compared and the risk ratios of Group A and Group B to the Control Group were also calculated. To adjust for unobservable heterogeneity per cluster, the regression analysis was performed using generalized linear mixed models.

**Results:** The screening rate was 21.2%, 37.1%, and 86.3% for the Control Group, Group A, and Group B, respectively. And the risk ratio for Group A was 1.753 and that of Group B was 4.079. The odds ratio for Group A was 3.031 and that of Group B was 28.324, estimated using generalized linear mixed models. However, the cost-effectiveness (incremental cost-effectiveness ratio (ICER)) of the nudge-based reminder with the full subsidies was lower than that of only the nudge-based reminder.

**Conclusion:** While fully subsidized screening led to the highest hepatitis screening rates, modifying client reminders using nudge theory significantly increased hepatitis screening uptake at lower costs per person.

PO-640

### Using the copula method to accurately estimate the impact of body mass index and alcohol consumption on liver disease

Daniel Ohrenstein<sup>1</sup>, Laura Webber<sup>1</sup>, Maria Buti<sup>2</sup>, Helena Cortez-Pinto<sup>3</sup>, Peter Jensen<sup>4</sup>, Pierre Nahon<sup>5</sup>, Francesco Negro<sup>6</sup>, Nick Sheron<sup>7</sup>, Marieta Simonova<sup>8</sup>, Shira Zelba-Sagi<sup>9</sup>, Lise Retat<sup>1</sup>, Jeffrey Lazarus<sup>10</sup>.  
<sup>1</sup>HealthLumen, London, United Kingdom; <sup>2</sup>Hospital Universitari Vall d'Hebron, Department of Internal Medicine, Barcelona, Spain; <sup>3</sup>University of Lisbon, Centro de Nutrição e Metabolismo, Lisbon, Portugal; <sup>4</sup>Aarhus University, Department of Clinical Epidemiology, Aarhus, Denmark; <sup>5</sup>Université Paris, Hospital Jean-Verdier, Paris, France; <sup>6</sup>University Hospitals of Geneva, Department of Pathology and Immunology, Geneva, Switzerland; <sup>7</sup>University of Southampton, Population Hepatology Research Group, Southampton, United Kingdom; <sup>8</sup>Military Medical Academy, Department of Gastroenterology, Sofia, Bulgaria; <sup>9</sup>University of Haifa, Department of Nutrition, Haifa, Israel; <sup>10</sup>Barcelona Institute for Global Health (ISGlobal), Hospital Clínic, University of Barcelona, Barcelona, Spain  
Email: lise.retat@healthlumen.com

**Background and aims:** To project the burden of non-communicable disease (NCD) such as liver disease we must calculate the joint relative risks (JRRs) associated with risk factors such as body mass index (BMI) and alcohol consumption. These JRR calculations rely on the estimated prevalence of the risk factors, and the prevalence estimates are ideally based on longitudinal data. Unfortunately, studies to collect longitudinal data are costly and time-consuming, whereas cross-sectional studies are easily accessible and often have larger sample sizes. In the absence of longitudinal data, joint prevalence distributions are calculated using approximate methods. The validated copula method (often used in finance) is applied here.

**Method:** The copula method uses a multidimensional inverse cumulative density function to estimate a joint distribution from univariate BMI and alcohol prevalence distributions and their correlation coefficient (see Figure 1). JRRs for chronic liver disease (CLD) were estimated with data from two cross-sectional epidemiological studies: The National Health and Nutrition Examination Survey from the United States and the Health Survey for England. These estimates were validated against published values that were calculated using longitudinal data.

**Results:** Estimates of the JRRs for CLD generated via the copula method were found to be in accordance with the literature. For moderate drinkers (1–14 cl/week), we calculated JRRs of 0.8, 1.1 and 1.3 for healthy, overweight and obese BMIs respectively, all within the confidence intervals reported. For heavy drinkers (>15 cl/week), we

Figure: (abstract: PO-640): (a) Sample from a multivariate Gaussian with correlation  $\eta$  (the correlation between the two risk factors). (b) The sample is transformed using the inverse Gaussian cumulative distribution function (CFD) to generate a sample with uniform marginals while retaining the correlation—this distribution is the copula. (c) Transform this sample with the univariate CDFs for each risk factor to generate the estimated joint distribution. This process ensures the approximate distribution has the appropriate correlation and marginals.

calculated JRRs of 3.5, 4.5 and 4.8 for healthy, overweight and obese BMIs respectively, again in line with previous work.

**Conclusion:** This study demonstrated that the copula method is a valid and useful tool for estimating JRRs for liver disease. This approximation provides the flexibility to model interaction effects between multiple interacting risk factors and is applicable to other NCDs. Furthermore, the ability to make such an estimation with cross-sectional data (without relying on expensive longitudinal studies) is clearly advantageous to epidemiological modelling and public health applications.

**PO-739**

**Micro-elimination of Hepatitis C in prisons of Punjab, India**

Kanudeep Kaur<sup>1</sup>, Sanjay Sarin<sup>1</sup>, Praveen Kumar Sinha<sup>2</sup>, Virendra Singh<sup>3</sup>, Sonjelle Shilton<sup>4</sup>, Gagandeep Singh Grover<sup>5</sup>.

<sup>1</sup>Foundation for Innovative New Diagnostics, New Delhi, India; <sup>2</sup>Additional Director General of Prisons, Department of Prisons, Punjab, Chandigarh, India; <sup>3</sup>Post Graduate Institute of Medical Education and Research, Department of Hepatology, Chandigarh; <sup>4</sup>Foundation for Innovative New Diagnostics, Geneva, Switzerland; <sup>5</sup>Directorate of Health Services, Department of Health and Family Welfare, Chandigarh, India Email: kanudeep.kaur@finddx.org

**Background and aims:** The State of Punjab, India, has a population of 27.7 million with an estimated anti-HCV prevalence of >20% in high-risk group of prisoners. However, very few prisoners are diagnosed and treated for HCV while incarcerated. The Punjab Department of Health Services (DHS) and Punjab Department of Prisons in partnership with FIND (Foundation for Innovative New Diagnostics) embarked on a program to eliminate HCV among inmates in 9 central prisons that contain over 80% of the total prison population in Punjab.

**Method:** Anti-HCV antibody rapid diagnostic test (RDT) was performed at the time of admission of inmates. Inmates with positive HCV RDT results received reflex blood draw for HCV RNA testing and pre-treatment investigations. Liver staging was determined by APRI score (non-cirrhotic is APRI <2 and cirrhotic as APRI >2). Non-cirrhotic patients were initiated on treatment dispensed by the prison pharmacist and overseen by the prison medical officer trained by DHS. Cirrhotic cases were referred to specialist for further evaluation. Post Graduate Institute of Medical Education and Research, Chandigarh, a tertiary referral hospital is conducting OPD via telemedicine to effectively manage the complicated cases remotely due to COVID-19. Twelve weeks after completion of therapy, another HCV RNA test was done to evaluate for SVR12.

**Results:** From 20<sup>th</sup> November 2019 to 31 December 2020, 14240 prisoners had been screened for HCV, of those 3201 (22%) were HCV antibody positive, 2883 (90%) received an RNA test, of which 2036 tested positive for HCV RNA. Of the HCV RNA positive 1282 (63%) have been initiated on treatment to date, with 322 (40%) completing SVR testing and 295 (92%) achieving SVR. The majority (96.8%) of cases were non-cirrhotic and HIV/HCV co-infection accounted for 5% of those who screened positive.

Figure:

**Conclusion:** To date the project screened 88% of the prison population for HCV and linked 63% of those confirmed for infection to treatment. This shows that micro-elimination in Punjab Prisons is

feasible. Increased efforts are being made to ensure treatment continuation and SVR testing post release as well as to facilitate telemedicine such that complicated cases which would once have been referred to tertiary hospital can be managed in the prisons due to Covid-19 related pressures on the health care system. The experience gained by the prison system through this project builds capacity to expand HCV care to district and sub-district correctional facilities in the future.

**PO-785**

**RECONVOCC : Can we recouvene chronic hepatitis C patients who were lost to follow-up ?**

Email: aabergel@chu-clermontferrand.fr

**Background and aims:** Hepatitis C virus (HCV) elimination by 2030, as targeted by the World Health Organization (WHO), requires that 90% of people with chronic hepatitis C (CHC) be diagnosed and 80% treated. France is one of the countries engaged in this viral elimination strategy. In the RECONVOCC study we assessed the effectiveness of a recall strategy. This project was initiated by the "Federation des Pôles de Référence Hépatites" (FPRH) and the main objective was to recall patients with CHC who were lost to follow-up in 14 French academic centers.

**Method:** The study population consists of patients HCV positive seen in 14 hospitals from 2003 to 2018 who were not cured. The patient should be lost to follow-up for over 18 months and be born after 1934. RECONVOCC takes place in 2 phases. The first, based on patient databases and medical records identified eligible patients including those tested in the virology department and followed by non hepatologists. To contact them and obtain information on HCV status, several methods were used such as townhall databases, hospital entry offices, health insurance databases, contacting patients or general practitioners or gastroenterologists or other specialists by phone or by letter... The second part corresponds to the inclusion of patients in the care process with data collection. The case report form used is REDCAP.

**Results:** Out of a total of 38387 patients identified as HCV positive, approximately 2/3 came from the hepatology department. To date RECONVOCC's investigative work identifies 560 patients still carrying HCV. Of the 194 patients included in the eCRF, 62% (121/194) were men. Mean age was 56 ± 13 years. 142/194 (72%) were treatment naïve. Thirty per cent of patients (58/194) had clinically significant fibrosis (F2-F3-F4). 46% (89/194) of patients were intravenous drug abusers. Genotypes 1a (30%) and 1b (15%) were the most frequent. 94 (48%) patients had a known co-morbidity. The most commonly cited reason for stopping hepatology monitoring were the lack of information for 39% of patients included and the low severity of liver fibrosis. The average duration of the follow-up break was more than 6 years. Until now 120 patients have already started treatment.

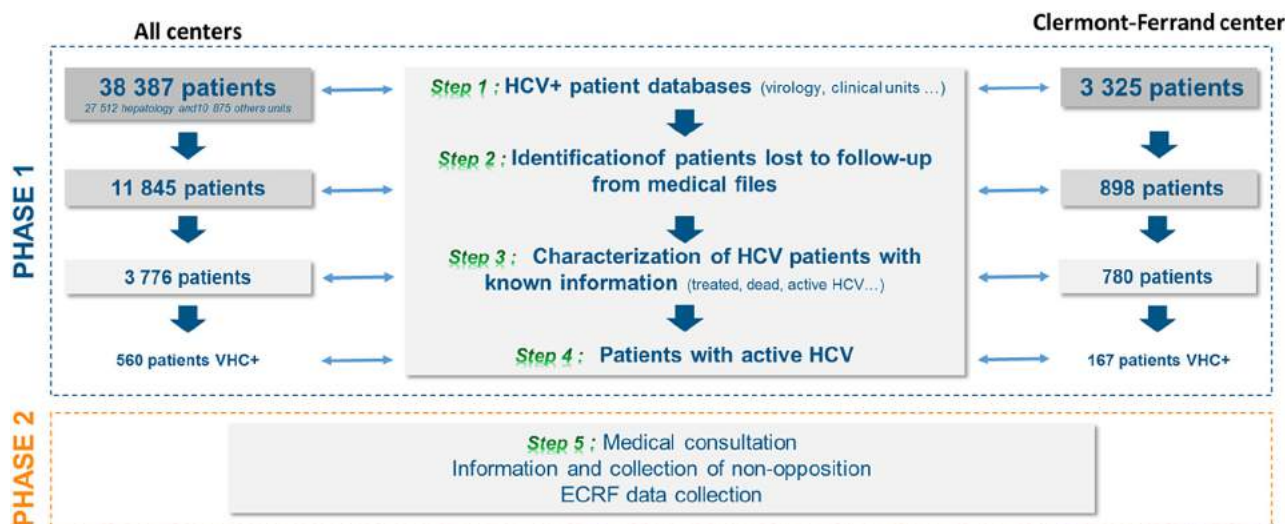

Figure: (abstract: PO-785): Distribution of RECONVOCC patients in December 2020

**Conclusion:** This work shows that there is still a high number of patients infected with the HCV who have not yet benefited from treatment with direct antiviral agents. Patients who were lost to follow-up should be reconvened to achieve HCV elimination in 2030. The study is still underway. This study was supported by Abbvie.

Email: victor.deledighen@chu-bordeaux.fr

**Introduction:** It is unclear whether the identification of individuals at risk of cirrhosis using non-invasive tests can be used in tertiary centers. We prospectively tested whether automatically calculated fibrosis-4 index (FIB-4) could improve the identification of individuals with unknown liver disease.

**Methods:** From September 2019 to March 2020, FIB-4 was automatically calculated in all patients (18–70 yrs) who attended the University Hospital and had a blood sample with platelets and transaminases. Patients from intensive care, oncology, gynecology or hepatology units were excluded. In case of FIB-4 >2.67, all medical records were reviewed to exclude patients for whom a cause of false positive FIB-4 was found (known thrombopenia or cytopenia, known chronic liver disease, acute event with elevated transaminases or thrombopenia). At last, all other patients were proposed to attend our hepatology unit for clinical examination and liver stiffness measurement. At the end, patients were classified as having liver disease when liver stiffness measurement LSM (FibroScan®) was >6 kPa (and its cause), no liver disease, or unknown (patients who did not attend our unit).

**Results:** A total of 16, 100 FIB-4 were automatically calculated in the LIS (GLIMS). Main results are indicated on Figure. FIB-4 was >2.67 in 1, 165 patients (7.3%). Among them, 809 were considered to have false positive FIB-4. Therefore, 356 patients had an elevated FIB-4 result that needed a second step (2.2% from 16 100 patients). These patients came from the main following units: Emergency (n = 158), cardiology (n = 52), internal medicine (n = 46), gastroenterology (n = 18) and

endocrinology (n = 17). At this time (the study is going on), 107 patients (30.1%) already attended our hepatology unit. Among them, 50 patients had LSM ≤6 kPa and were considered as “no liver disease.” However, among these patients, 14 (28%) had elevated AUDIT questionnaire (>8) and were referred to GP. A total of 57/107 patients (53.3%) were considered having a chronic liver disease. These patients came from emergency (n = 19), cardiology (n = 14), and endocrinology (n = 6) units. Main causes of chronic liver disease were: alcoholic liver disease (n = 24, 42.1%), NAFLD (n = 15, 26.3%), heart failure (n = 12, 21.1%). At last, 25/57 patients (43.9%) had LSM >15 kPa.

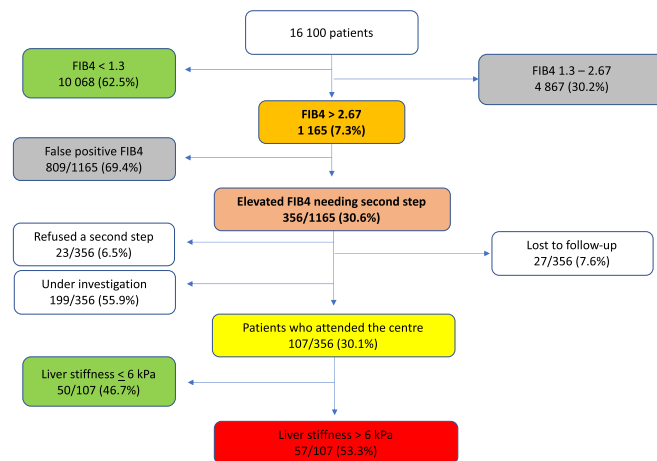

Figure:

**Conclusion:** In this study, conducted in a general population without known chronic liver disease, we found that automatically calculated FIB-4 allows the identification of individuals with suspected severe liver disease in 30.6% of cases. After liver stiffness measurement, 53.3% of these patients had chronic liver disease (liver stiffness ≥6 kPa). Automatically calculated FIB4 should be implemented in all hospitals because it allows detection of patients with severe liver disease without overloading the units since only 30% of patients require a confirmatory examination.

**A novel approach to age cohort screening for hepatitis C in the primary care setting of a large urban health care setting with linkage to care**

David Bernstein<sup>1</sup>, Tanya Louis<sup>1</sup>, Nitzan Roth<sup>1</sup>, Sanjaya Satapathy<sup>1</sup>.

<sup>1</sup>Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Hempstead, United States

Email: dbernste@northwell.edu

**Background and aims:** New York (NYS) mandates the offering of hepatitis C testing for adults born between 1945–1965 and the CDC recently updated its screening guidelines to recommend one time screening of all people aged 18 and above. Despite these recommendations, it is estimated that more than 50% recommended candidates for HCV screening are not screened and therefore many with underlying disease are not identified. When patients with HCV are identified, current direct acting anti-viral therapy is curative in >95% of patients and is available to all in NYS. Northwell Health, the largest health system in New York State provides primary care services in 10 counties with a population of >10million people. HCV is under-diagnosed in this service area and most primary care providers are not appropriately screening for HCV. We hypothesize that the use of patient navigators to educate primary care providers about HCV screening will improve diagnosis and linkage of care of newly diagnosed HCV patients to treating physicians.

**Method:** Training materials and databases were developed and nurse educators were trained in all aspects of HCV infection. Nurse educators visited primary care practices to discuss the NYS law mandating HCV screening for all people born between 1945–1965 and revisited these practices to reinforce study goals and establish a process for screening and linkage to care to health care providers.

**Results:** From the time period April 1, 2018 to March 1, 2020, 31062 previously unscreened adult patients born between 1945–1965 in outpatient family medicine, geriatrics, internal medicine and OB/GYN offices had HCV antibody testing with reflex testing to HCVRNA by PCR if HCV AB was positive. 30383 tests were negative. 679 patients had a positive HCV AB (2.1%) and 155 (0.49%) were HCVRNA positive. Of the 679 who tested positive, 57.1% were female, 42.9% male, 54% Caucasian, 17% Black, 16% Latino and 8% Asian. 155/679 HCV AB positive patients were HCVRNA positive (22.8%). Of the 155 HCVRNA positive patients, 49% (76) successfully completed DAA therapy and had a sustained virological response, 27.1% (42) are currently on DAA therapy, 13.5% (21) were linked to a treating physician and declined DAA therapy when offered, 6.5% (10) expired before seeing a HCV treatment provider and 3.9% (6) were lost to follow-up.

**Conclusion:** In this large, diverse health care system, 2.1% of the previously unscreened patients born between 1945–1965 are HCV AB positive and 0.49% have active disease. The use of patient navigators increased the linkage to care with all patients referred to a treatment provider. Despite increased screening and highly effective HCV therapies, 13.5% of patients still declined curative HCV therapy. Better education regarding the safety and affordability of HCV therapies is needed to overcome societal misconceptions still held by a significant percentage of HCV positive patients in our community.

**Baseline characteristics of a large multi-site chronic HBV electronic health record-based cohort in the UK**

Cori Campbell<sup>1,2</sup>, Tingyan Wang<sup>1,2</sup>, Eleanor Barnes<sup>1,3</sup>, Philippa Matthews<sup>1,3,4</sup>. <sup>1</sup>Peter Medawar Building for Pathogen Research, Nuffield Department of Medicine, University of Oxford, Oxford, United Kingdom; <sup>2</sup>NIHR Oxford Biomedical Research Centre, Big Data Institute, University of Oxford, Oxford, United Kingdom; <sup>3</sup>Oxford University Hospitals NHS Foundation Trust, Oxford, United Kingdom; <sup>4</sup>Department of Infectious Diseases and Microbiology, John Radcliffe Hospital, Oxford University Hospitals NHS Foundation Trust, Oxford, United Kingdom

Email: corijcam@gmail.com

**Background and aims:** Nearly 300 million people worldwide are chronically infected with hepatitis B virus (HBV), which is the leading cause of global liver cancer deaths. The UK HBV population is not well characterised but understanding the burden of disease is crucial to optimise case finding and clinical service provision.

**Method:** We included CHB patients from QResearch, a primary-care database in England of individual-level patient records from 1727 general practices, aged ≥18 years with a diagnostic record of CHB between 1999 and 2019. Baseline was defined as the first record of CHB.

Figure:

Characteristics	n (%), ormean (SD)
Total	7952 (100)

NAFLD	137 (1.7)
Cirrhosis	232 (2.9)
Varices/ascites	133 (1.7)
End-stage liver disease	25 (0.3)

**Results:** We identified 7952 CHB patients (61% male). Mean follow-up was 7.3 years. At baseline, 74% of patients were aged <45 years, 44% were residing in the most deprived geographical regions, and >50% were non-white. 1.8%, 2.9% and 3.7% of patients had record of non-alcoholic fatty liver disease (NAFLD), cirrhosis and varices/ascites,

## POSTER PRESENTATIONS

respectively. Prevalence of extra-hepatic comorbidities was low, however 9.5% and 5.8% of patients had hypertension and diabetes, respectively. Sex and ethnicity were significantly associated with deprivation ( $p < 0.001$ ). Within 3 years of diagnosis 145 (1.8%) patients were on antiviral treatment.

**Conclusion:** The UK CHB morbidity burden is concentrated in young, deprived, non-white individuals among whom a minority are treated. Further research is required to identify factors associated with different disease outcomes and to assess benefits of wider treatment.

#### Performance of screening strategies for primary prophylaxis of variceal bleeding in patients with compensated cirrhosis: a cost-effectiveness analysis

Shanshan Lin<sup>1</sup>, Chuan Liu<sup>1</sup>, Zonglin He<sup>2</sup>, Ye Gu<sup>3</sup>, Yan Wang<sup>3</sup>, Qing Yang<sup>3</sup>, Jianbo Shao<sup>4</sup>, Guohong Ge<sup>4</sup>, Shengqiang Zhou<sup>4</sup>, Guo Zhang<sup>5</sup>, Wenjuan Wang<sup>5</sup>, Xing Wang<sup>6</sup>, Bin Wu<sup>6</sup>, Wai-Kit Ming<sup>2</sup>, Xiaolong Qi<sup>1</sup>. <sup>1</sup>CHES Center, Institute of Portal Hypertension, The First Hospital of Lanzhou University, Lanzhou, China; <sup>2</sup>School of Medicine, Jinan University, Guangzhou, China; <sup>3</sup>Portal Hypertension Center, The Sixth People's Hospital of Shenyang, Shenyang, China; <sup>4</sup>Department of Liver Disease, The Third People's Hospital of Zhenjiang, Zhenjiang, China; <sup>5</sup>Department of Gastroenterology, The People's Hospital of Guangxi

Zhuang Autonomous Region, Nanning, China; <sup>6</sup>Department of Gastroenterology, The Third Affiliated Hospital of Sun Yat-Sen University, Guangzhou, China  
Email: qixiaolong@vip.163.com

**Background and aims:** Screening tools including esophagogastroduodenoscopy (EGD) and non-invasive methods (Baveno VI criteria) have been recommended to be performed in clinical practice in order to identify the high-risk patients and prevent the first episode of variceal bleeding in compensated cirrhosis. In this study, we aimed to examine the cost-effectiveness of screening tools, and to provide evidence-based information for decision and policy making.

**Method:** We developed an analytic decision model in which Markov models were embedded. Clinical parameters were derived from published literature and meta-analysis. Meanwhile, medical costs were collected in Chinese yuan from multi-level hospitals in China and converted into US dollars at an exchange rate of 6.53 yuan per dollar. Deterministic and probabilistic sensitivity analyses are followed. Our model was calculated over a five-year horizon.

**Results:** Patients categorized in the no screening scenario faced both the highest total cost of \$1421 per patient and the lowest life expectancy of 4.74 years per patient, and therefore the no screening strategy was dominated and excluded. Screening with Baveno VI criteria had the cheapest medical cost of \$1022 per patient, and

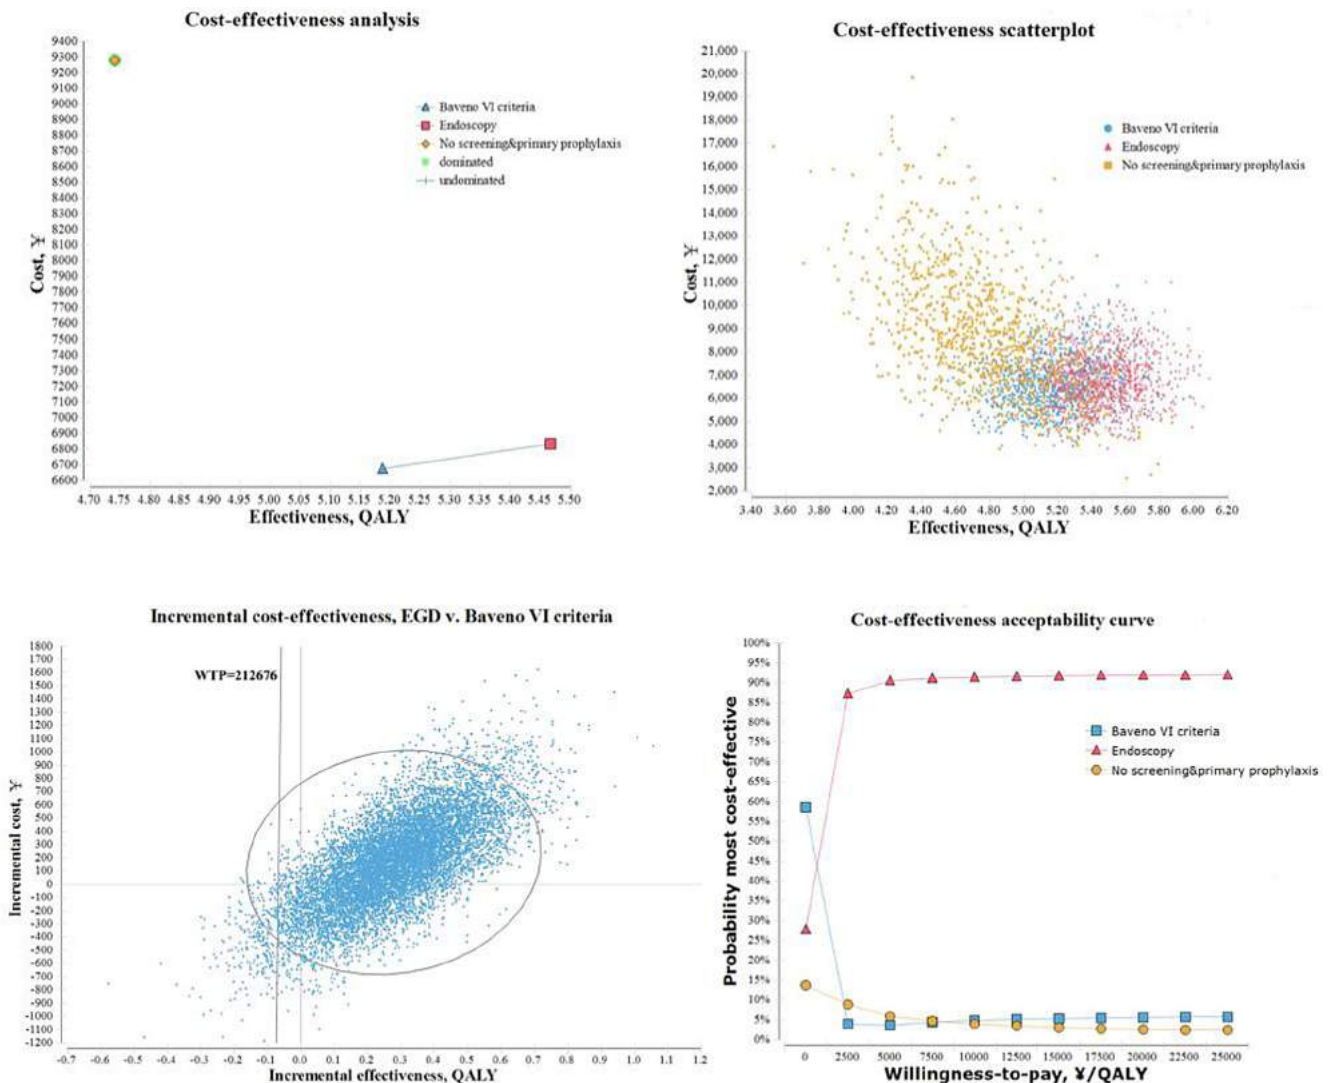

Figure: (abstract: PO-1330)

patients who underwent EGD screening gained the highest life expectancy of 5.47 years per patient. Compared to the Baveno VI criteria strategy, the incremental cost-effectiveness ratio of EGD strategy was \$89.28 per quality-adjusted life-year. The results were sensitive to the probability of low-risk patients detected by EGD. In terms of cost-effectiveness ratio, the strategies of EGD and Baveno VI criteria were both cost-effective according to the threshold. Additionally, the possibility of selecting EGD screening is 93.4%, however, if the capability of Baveno VI criteria of detecting high-risk patients improved or the willingness-to-pay was lower than \$91.4 per patient per quality-adjusted life-year, screening with Baveno VI criteria will emerge as a preferred strategy.

**Conclusion:** Scenarios of screening with EGD or Baveno VI criteria are both cost-effective. The preference of decision depends on the variation of key parameters and the willingness-to-pay of decision makers. The consideration of spared endoscopy rate and dynamic follow-up will improve the screening value of Baveno VI criteria in routine practice.

**PO-1341**

**Active search to retrieve lost-to follow-up HCV patients (RELINK-C strategy): health and economic value**

Joan Martínez-Camprecios<sup>1,2</sup>, Raquel Domínguez-Hernández<sup>3</sup>, Cristina Marcos-Fosch<sup>1</sup>, Ariadna Rando<sup>4,5</sup>, Mar Riveiro-Barciela<sup>1,6</sup>, Francisco Rodríguez Frias<sup>6,7,8</sup>, Miguel Ángel Casado<sup>9</sup>, Rafael Esteban<sup>1,6</sup>, Maria Buti<sup>1,6</sup>. <sup>1</sup>Hospital Universitari Vall d'Hebron, Liver Unit, Internal Medicine Department, Barcelona, Spain; <sup>2</sup>Universitat Autònoma de Barcelona, Medicine department, Bellaterra, Spain; <sup>3</sup>Pharmacoeconomics and Outcomes Research Iberia (PORIB), Health Economics, Madrid, Spain; <sup>4</sup>Hospital Universitari Vall d'Hebron, Department of Microbiology, Barcelona, Spain; <sup>5</sup>Universitat Autònoma de Barcelona, Department of Microbiology, Bellaterra, Spain; <sup>6</sup>CIBERehd, Instituto Carlos III, CIBERehd, Barcelona, Spain; <sup>7</sup>Clinical Laboratories Hospital Universitari Vall d'Hebron, Biochemistry Department, Barcelona, Spain; <sup>8</sup>Hospital Universitari Vall d'Hebron, Liver Pathology Unit, Biochemistry and Microbiology Departments, Barcelona, Spain; <sup>9</sup>Pharmacoeconomics and Outcomes Research Iberia (PORIB), CEO, Madrid, Spain

Email: rdominguez@porib.com

**Background and aims:** Spain is on track to eliminate Hepatitis C (HCV) infection by 2030 after treating more than 140, 000 chronic infected individuals in the last six years. This public health challenge

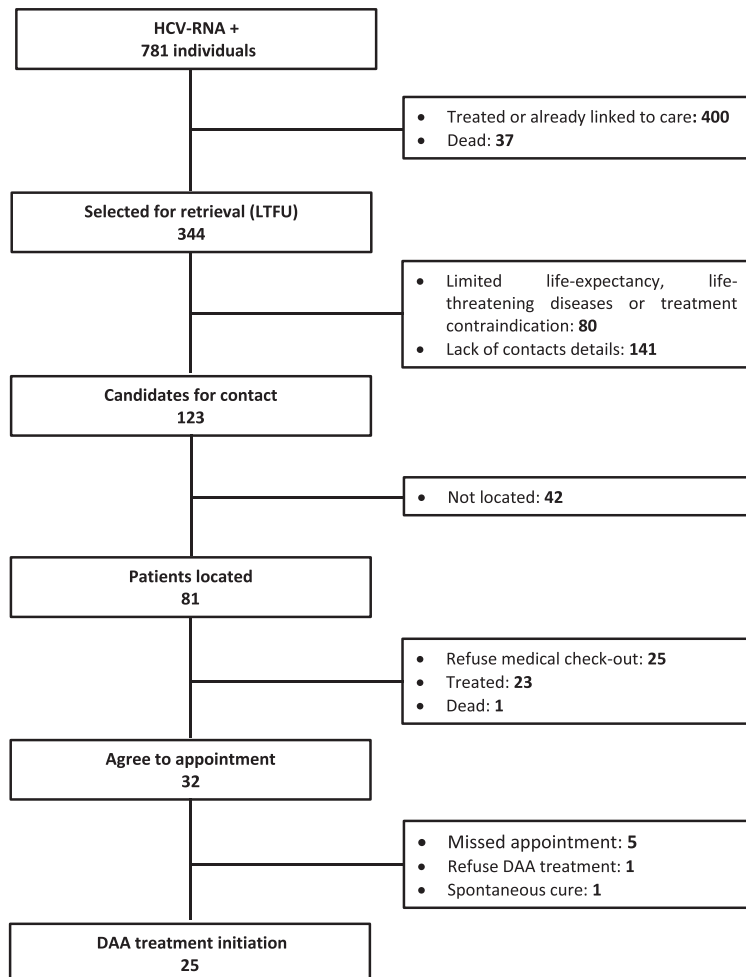

Figure 1. Flowchart of HCV viremic cases from year 2019, patients selected for retrieval or lost to follow-up (LTFU), candidates for contact, patients located and patients who finally initiate direct-acting antiviral (DAA) treatment.

Figure: (abstract: PO-1341)

## POSTER PRESENTATIONS

is leading physicians and authorities to design new strategies in order to increase diagnosis of unknown HCV cases or to retrieve untreated or lost-to-follow-up (LTFU) patients. The aim of this study was to retrieve LTFU HCV viremic patients who could benefit from treatment (RELINK-C strategy) and to evaluate its effectiveness and economic value.

**Method:** The RELINK-C strategy is based on a retrospective search (January to December 2019) for HCV-RNA+ve cases from the central laboratory department of the Barcelona north health area (450, 000 inhabitants) followed by medical records review. Individuals who were LTFU or with an unresolved infection were selected for retrieval. Candidates were contacted by phone (5 maximum attempts) for diagnosis and treatment assessment. Cost of RELINK-C was estimated along with lifetime health and economic outcomes of RELINK-C vs non-intervention through a Markov model based on candidates for HCV treatment with available contact information.

**Results:** 781 HCV-RNA+ve cases were detected. Of those, 344 (44%) were LTFU and selected for retrieval and among them, 123 were candidates for contact. Reasons for not contacting 80 of the cases were limited life expectancy, life-threatening diseases or HCV treatment contraindication and patients lack of contact details among 141 cases. Upon the phone calls, 81 patients were located, of whom 32 agreed to an appointment with the physician (25 refused medical check out, 23 were already treated and 1 had died). Finally, 27 patients attended the appointment and 25 started DAA treatment (1 spontaneous cure, 1 refused treatment) (Figure 1).

The investment associated to RELINK-C strategy (search and diagnosis) was €13, 877. Model based on the 123 patients, excluding 23 patients already treated, 1 death and 1 spontaneous cure, showed that treating 25 patients in RELINK-C strategy vs no patients treated in non-intervention decreases mortality by 23% and liver complications by 22–27% (greater impact on decompensated cirrhosis), generating €278, 534 savings associated to liver complications management.

**Conclusion:** RELINK-C enabled 25 of the 81 located patients to receive HCV treatment and has shown to be an efficient strategy to help in achieving Hepatitis C elimination.

### PO-1374

#### Optimizing diagnostic algorithms to advance HCV elimination in Italy: A cost effectiveness evaluation

Andrea Marcellusi<sup>1</sup>, Francesco Saverio Mennini<sup>2</sup>, Murad Ruf<sup>3</sup>, Claudio Galli<sup>4</sup>, Alessio Aghemo<sup>5</sup>, Maurizia Brunetto<sup>6</sup>, Massimo Andreoni<sup>2</sup>, Sergio Babudieri<sup>7</sup>, Loreta Kondili<sup>8</sup>. <sup>1</sup>Tor Vergata University of Rome, Rome, Italy; <sup>2</sup>Tor Vergata University of Rome, Rome, Italy; <sup>3</sup>Gilead Sciences Europe Ltd, Public Health, Medical Affairs, Uxbridge, United Kingdom; <sup>4</sup>Abbott Diagnostics Infectious Diseases, Rome, Italy; <sup>5</sup>Humanitas Research Hospital, Milan, Italy; <sup>6</sup>University of Pisa, Pisa, Italy; <sup>7</sup>University of Sassari, Sassari, Italy; <sup>8</sup>Istituto Superiore di Sanità, National Center for Global Health, Rome, Italy  
Email: loreta.kondili@iss.it

**Background and aims:** Italy is the country with the greatest burden of hepatitis C virus (HCV) infection in Western Europe. There is a political will for HCV elimination and 71.5 million euros have been allocated to a free-of-charge screening in the 1969–1989 birth cohorts and the key populations. We aimed to evaluate the cost effectiveness of different diagnostic algorithms considering the complete patient journey from screening to treatment completion, within the available screening budget in Italy.

**Method:** A Cost-effectiveness analysis, simulating six screening diagnostic algorithms to detect HCV active infection in the targeted birth cohort (1969–1989) was conducted (Figure). A Markov model for liver disease progression with a 20-years' time horizon and health care system perspective was used. The diagnosis of active HCV infection is made by the detection of antibodies (HCV-Ab), either by rapid or phlebotomy-based assays, followed by HCV-RNA or HCV core antigen (HCV-AG) confirmatory testing either on a second sample (2 visits) or by Reflex testing (1 visit). The rate of individuals that will end up as undiagnosed and unlinked to care has been evaluated by the estimates of false negatives by each assay and by the patient re-attendance drop-off at each screening step based on literature data. Age, fibrosis stage, treatment effectiveness, DAA costs and liver disease costs were used to evaluate the quality-adjusted life-years (QALY) and the incremental cost-effectiveness ratios (ICER) of

#### Six testing options for active HCV infection: Allocation in the decision tree

Figure: (abstract: PO-1374)

different diagnostic algorithms. The reference option was considered the algorithm that produced the lowest QALYs. The cost effectiveness threshold was 25.000 €/QALY.

**Results:** The reference option resulted the Rapid HCV-Ab+HCV-AG (859, 361 QALYs). The highest effectiveness (QALYs = 974, 458) was obtained by HCV RNA Reflex testing followed by HCV-AG Reflex testing. HCV RNA Reflex testing produced a highly cost-effective ICER (873€/QALY) with € 66, 274.00 screening costs (lower than the dedicated screening fund). Reflex testing (single visit) versus two patients' visits diagnostic algorithms, likely due to lesser patient attendance drop-off, yielded always higher QALYs with a very low ICERs (560 and 635 €/QALY for HCVAG and HCV-RNA, respectively). Reflex testing (both HCV RNA and AG HCV) was highly cost-effective in 100% of the 5, 000 probabilistic simulations

**Conclusion:** Reflex testing using either HCV RNA or HCV-AG is the most cost effective and sustainable with the dedicated screening fund in Italy. Our data confirm the EASL clinical practice guidelines recommending Reflex testing as it has the highest cost effectiveness compared to the other screening pathways.

**PO-1421**

**The 2010 HIV outbreak among people who inject drugs in Athens, Greece could have been prevented if the undetected 2009 HCV outbreak had been detected: A mathematical modeling study**

Ilias Gountas<sup>1</sup>, Georgios Nikolopoulos<sup>2</sup>, Giota Touloumi<sup>3</sup>, Anastasios Fotiou<sup>4</sup>, Angelos Hatzakis<sup>3</sup>, Kyriakos Souliotis<sup>1</sup>. <sup>1</sup>University of Peloponnese, Faculty of Social and Political Sciences, Greece;

<sup>2</sup>University of Cyprus, Medical School, Cyprus; <sup>3</sup>National and Kapodistrian University of Athens, Department of Hygiene, Epidemiology and Medical Statistics, Medical School; <sup>4</sup>Athens University Mental Health, Neurosciences, and Precision Medicine Research Institute (UMHRI), National Monitoring and Documentation Centre for Drugs, Greece

Email: eliaoun@gmail.com

**Background and aims:** Several studies on People Who Inject Drugs (PWID) have shown that when hepatitis C virus (HCV) prevalence increases, the PWID community is at increased risk for a Human Immunodeficiency Virus (HIV) outbreak. This relationship has been

confirmed in Athens, Greece; an HCV and an HIV outbreak emerged among PWID of Athens in 2009 and 2010, respectively. The HCV outbreak was not detected at all, while that of HIV was identified in 2011. The main HIV-interventions started in early 2012. Public health interventions to the PWID population are beneficial for more than one disease. In the case of Athens, given that HCV and HIV share common transmission routes, HIV-interventions reduced HIV incidence by 78% and indirectly HCV incidence by 64.8%. This study aims to assess what the courses of the HCV and HIV outbreaks and their economic consequences would have been if HCV outbreak had been detected and integrated interventions had started 1- or 2- years earlier.

**Method:** A dynamic, stochastic, individual-based model was used to simulate HCV and HIV transmission among PWID. The model was calibrated to reproduce the observed HCV and HIV epidemiological parameters among PWID of Athens, Greece. We examined the effect of non-detection, 1- or 2-years earlier detection scenarios, and compared them to the status quo scenario. The time-horizon of the analysis was 2002–2019 so as to capture the second-order transmission effects.

**Results:** Under the status-quo scenario and during 2009–2019, the cumulative HCV and HIV cases were 6480 (95% Credible intervals (CrI) 6000, 6900) and 1360 (95% CrI: 400, 2600), respectively. If the HCV outbreak had been detected and the integrated interventions initiated 1- or 2- years earlier, 440 and 970 new HCV cases and 740 and 1110 new HIV cases could be averted by 2019, respectively (Figure). Under the non-detection scenario, 2800 and 7030 additional PWID would have been infected with HCV and HIV compared to the status quo by 2019, respectively. Concerning the costs of treating the new cases for both diseases, if there was an efficient notification system to detect the HCV outbreak, 40.9–65.8 million euros could have been saved.

**Conclusion:** HCV prevalence can quantify the intensity of injecting risk behaviors among PWID. If the HCV outbreak had been detected and promptly responded, the HCV outbreak would have been substantially blunted, the HIV outbreak would have been prevented and 40.9–65.8 million euros could have been saved

Figure: (abstract: PO-1421)

## POSTER PRESENTATIONS

### PO-1426

#### A discrete choice experiment about patients' and clinicians' preferences for the meet-test-treat approach to HCV management

Massimo Andreoni<sup>1</sup>, Nicola Coppola<sup>2</sup>, Antonio Craxi<sup>3</sup>, Stefano Fagioli<sup>4</sup>, Ivan Gardini<sup>5</sup>, Alessandra Mangia<sup>6</sup>, Felice Alfonso Nava<sup>7</sup>, Patrizio Pasqualetti<sup>8</sup>. <sup>1</sup>Infectious Diseases, Roma, Italy; <sup>2</sup>Infectious Diseases, Department of Mental Health and Public Medicine, Italy; <sup>3</sup>Department of Gastroenterology, Italy; <sup>4</sup>Gastroenterology and Transplant Hepatology; <sup>5</sup>EpaC Onlus; <sup>6</sup>Liver Unit; <sup>7</sup>Penitentiary Medicine and Drug Abuse Unit; <sup>8</sup>Department of Public Health and Infectious Disease, Roma, Italy  
Email: patrizio.pasqualetti@uniroma1.it

**Background and aims:** The meet-test-treat strategy could help reduce the incidence of chronic hepatitis C virus (HCV), increasing the proportion of diagnosed infected subjects and improving their access to treatment. The aim of this study was to investigate the opinion of relevant target populations on the practicability, effectiveness and best modalities of this approach, in Italy.

**Method:** An online cross-sectional survey was delivered to hospital patients with HCV, patients from drug addiction services (SerD), hospital physicians and SerD healthcare providers (SerD HCP). The questionnaires were divided into four sections: 1. socio-demographic characteristics, 2. characteristics of the care pathway (possible answers were ranked in order of importance), 3. discrete choice experiment (DCE) comparison of possible care pathways, 4. DCE comparison of treatment characteristics.

**Results:** The survey was completely answered by 190 hospital clinicians, 142 SerD HCPs, 372 hospital patients, and 131 SerD patients. For hospital clinicians, the most important attributes of a diagnostic-therapeutic pathway were a high compliance to treatment (relative importance [RI] 22%) and a short time to treat (RI 19%), while a 4-month delay of treatment was not acceptable. For SerD HCPs, although the care setting was not deemed important in comparison with other attributes, a significant preference for "inside the service" versus "outside the service" was present (preference weight = +0.09; 95% CI: +0.01–0.16). Among hospital patients, the most important attribute was the time of Meet-Test-Treat (RI 26%). For addicted subjects followed-up by SerD, the most important attribute of a diagnostic therapeutic pathway was compliance to test (RI 23%). Finally, SerD patients showed a significant preference for being cared for HCV within the SerD versus being cared in other centers (preference weight = +0.29; 95% CI: +0.19–0.38). SerD patients, in comparison with hospital patients, were less interested in the absence of adverse events, while they considered more important the low number of pills per day.

**Conclusion:** In the perspective of HCPs and of lay people, the diagnostic process should be rapid and thorough, and treatment should be tolerable. SerD patients should be met and cared in healthcare structures familiar to them.

### PO-1431

#### Value assessment of sofosbuvir-based regimens for (chronic) hepatitis C in Spain

Rafael Esteban<sup>1,2</sup>, Raquel Domínguez-Hernández<sup>3</sup>, Miguel Ángel Casado<sup>4</sup>. <sup>1</sup>Hospital Universitari Vall d'Hebron, Liver Unit, Internal Medicine Department, Barcelona, Spain; <sup>2</sup>CIBERehd, Instituto Carlos III, CIBERehd, Barcelona, Spain; <sup>3</sup>Pharmacoeconomics and Outcomes Research Iberia (PORIB), Health Economics, Madrid, Spain; <sup>4</sup>Pharmacoeconomics and Outcomes Research Iberia (PORIB), CEO, Madrid, Spain  
Email: rdominguez@porib.com

**Background and aims:** The treatment of chronic hepatitis C virus (HCV) with direct-acting antivirals has undergone a spectacular revolution, contributing to the World Health Organization (WHO) global strategy of HCV elimination by 2030. The aim of the study was to estimate the clinical and economic value of Sofosbuvir (SOF)-based regimens for a target population of 85, 959 chronic HCV patients,

from the Spanish National Health System (NHS) perspective, treated with SOF-based regimens during 2015–2019, compared to previous therapeutic strategies (PTS; peginterferon and ribavirin in double/triple therapy with telaprevir or boceprevir).

**Method:** To assess the impact of the SOF-based regimens, a previously developed lifetime Markov model was adapted simulating the disease evolution of HCV. In SOF-based regimens, all patients (100%) were treated regardless of their fibrosis stage with sustained virological response (SVR) of 93–98%, obtained from real-world data. In PTS, only  $\geq$ F2 patients were treated according to clinical practice (38%) with an average SVR of 61% taken from published literature. The results reported included the number of patients with HCV-related mortality, decompensated cirrhosis (DC), hepatocellular carcinoma (HCC) and liver transplantation (LT) avoided cases; total costs and quality-adjusted life years (QALYs) were calculated applying an annual 3% discount rate.

**Results:** Compared to PTS, during lifetime, SOF-based regimens reduced DC by 89% (-14, 372 cases), HCC by 77% (-9, 473 cases) and LT by 84% (-1, 878 cases), decreasing the cost associated to liver complications management in €770 million. SOF-based regimens also decreased liver-related mortality by 82% (-15, 810). Besides, SOF-based regimens gained 310, 765/QALYs, saving €274 million (considering drugs, monitoring, and management of HCV complications).

**Conclusion:** For Spain, which is on a path to achieving HCV elimination within the next decade following WHO goals, SOF based regimens offer value in terms of lowering HCV-related liver disease burden and generating significant cost savings for the Spanish NHS.

### PO-1480

#### Epidemiological evaluation of the liver cirrhosis in Albania: comparison with the historical data and indications to antiviral treatment appropriateness

Xhimi Tata<sup>1,2</sup>, Adriana Babameto<sup>3</sup>, Liri Cuko<sup>3</sup>, Leonardo Baiocchi<sup>4</sup>, Luigina Ferrigno<sup>5</sup>, Maria Giovanna Quaranta<sup>5</sup>, Loreta Kondili<sup>5</sup>. <sup>1</sup>Istituto Superiore di Sanità, National Center for Global Health, Rome; <sup>2</sup>University Nostra Signora del Buon Consiglio, Tirana, Albania; <sup>3</sup>University Hospital Center of Tirana, Liver Unit, Tirana, Albania; <sup>4</sup>Tor Vergata University of Rome, Rome, Italy; <sup>5</sup>Istituto Superiore di Sanità, National Center for Global Health, Rome, Italy  
Email: loreta.kondili@iss.it

**Background and aims:** Albania is a developing Mediterranean country, previously reported to be highly endemic for HBV infection. In Albania, HBV infection has been the main risk factor of liver cirrhosis affecting mainly young age individuals. HBV vaccination (in the newborns since 1995 and in high risk groups since 2000) and changes in the dietary habits/alcohol intake might have changed the weight of etiological factors of liver cirrhosis in the recent years. The aim of this study was to evaluate the prevalence of viral hepatitis infections (HBV, HDV, HCV) and of alcohol abuse in Albanian patients with liver cirrhosis, consecutively admitted during the year 2019 to the Liver Unit of the University Hospital Centre of Tirana, compared with previous data. The final goal is to properly address targeted public health interventions regarding diagnosis and antiviral treatment appropriateness.

**Method:** Demographic, alcohol abuse, clinical, virological and treatment data of patients consecutively admitted to the hospital during the study period, in the Albania's most important tertiary liver-care centre, were prospectively collected. Available data, collected in the same manner, during the years 1995 and 2005 were also evaluated. Chi square test were used for non-parametric variables;  $p < 0.05$  was considered significant.

**Results:** The prevalence of viral hepatitis markers and of alcohol intake was evaluated in 120, 99 and 106 Albanian patients with cirrhosis admitted to the hospital during 2019, 2005 and 1995 respectively. A decrease of HBsAg prevalence (27% vs 70 vs. 78%) ( $p < 0.05$ ), increase of alcoholic liver disease (HBsAg and anti-HCV

negative) (56% vs 21% vs 17%) ( $p < 0.05$ ) and unchanged HCV prevalence (14% vs 11% vs 11%) were observed in patients admitted to the hospital during 2019/2020 vs 2005 vs 1995 respectively. HDV infection was tested only in 12.5% of HBsAg positive patients of them 50% were anti-HDV positive. HCC was diagnosed in 9% of overall patients, of them 73% HBV correlated. Of the 32 patients with HBV liver cirrhosis, 19% were treated with Tenofovir with unknown HBV DNA measurements during the hospital admission, the remaining HBsAg patients were diagnosed for the first time with cirrhosis and were untreated. 38% of patients with HCV infection were relapsers of previous DAA treatment, the remaining were HCV RNA negative following a DAA treatment in the cirrhosis stage.

**Conclusion:** Alcohol abuse was the main etiological factor of liver cirrhosis, as in several European countries. Despite the decreasing prevalence by anti-HBV vaccination, HBV infection remain an important etiological factor of liver cirrhosis and of HCC development. Hepatitis Delta is not properly diagnosed in Albanian patients. The increase of awareness of alcohol induced liver damage, early diagnosis and appropriate HBV and HCV treatment before reaching severe liver damage is of a paramount importance in Albania.

Changes in the prevalence of HBV, HCV and alcohol abuse over time in Albanian patients with liver cirrhosis

Email: zobair.younossi@inova.org

**Background and aims:** The pandemic of COVID-19 is responsible for morbidity and mortality worldwide. Patients with pre-existing chronic diseases incur substantial burden from both the infection and disruption of life caused by the pandemic mitigation measures. The aim was to assess the impact of COVID-19 pandemic on patients with CLD.

**Method:** CLD patients who were previously enrolled in our Global Liver Registry were invited to complete COVID-19 survey with 23

items. Questions included whether patients were infected with COVID-19, details of the illness for those infected, and the overall pandemic-related disruption of life.

**Results:** 1994 CLD patients completed the survey [20% chronic hepatitis B (CHB), 18% chronic hepatitis C (CHC), and 62% non-alcoholic fatty liver disease (NAFLD); age  $48 \pm 13$  years, 53% male]. Of the survey completers, 8.2% ( $n = 164$ ) had COVID-19. Of those, 82% were diagnosed by a laboratory test, 92% had least one symptom, and 76% received treatment for their symptoms. COVID-19 infected patients were ill for mean  $13 \pm 11$  days, 62% received antivirals, and 21% were hospitalized. No patients reported the need for mechanical ventilation. Of all survey completers, 11% reported that pandemic had an impact on their liver disease; these rates were not different between those who were and were not infected ( $p = 0.37$ ). COVID-19-infected patients' self-reported health scores due the pandemic were lower ( $6.6 \pm 2.2$  on a 1–10 scale with 10 being perfect health) than in those not infected ( $7.4 \pm 2.2$ ) ( $p < 0.0001$ ). Life Disruption Event Perception (LDEP) questionnaire revealed that 78% of COVID-19 infected patients and 65% of patients without COVID-19 reported worsening in at least one aspect of their daily life (food/nutrition, exercise, social life, vocation/education, financial situation, housing, or healthcare) ( $p = 0.0005$ ). The most profound worsening was reported for social life (70% and 57%), exercise (49% vs. 39%) and financial situation (39% vs. 30%) (all  $p < 0.02$ ). The need for continued supportive care was independently associated with having had COVID-19 infection after adjustment for location, demographic parameters, etiology of liver disease, and non-liver comorbidities (odds ratio = 1.96 (1.23–3.11),  $p = 0.0045$ ).

**Conclusion:** Patients with CLD experienced a substantial burden of COVID-19 pandemic on their daily lives. Social, financial and exercise aspects were the most commonly impacted. The need for supportive care in CLD was associated with COVID-19 infection.

Email: horvath.gabor@hepatologia.hu

**Background:** The proportion of people infected with HCV in prisons can be up to ten times higher compared to the general population, primarily due to the high rate of prior intravenous drug use among inmates.

**Aims:** In Hungary, a hepatitis C screening campaign and treatment for screened patients began in prisons in 2007. We summarize the results collected in the last 13 years and our experience with the treatment.

## POSTER PRESENTATIONS

**Method:** Between 2007 and 2019, screening for anti-HCV antibodies and HCV PCR was performed on a voluntary basis in Hungarian prisons several times a year. Treatments were performed under the guidance of hepatologists who visited the institutions monthly. Patients were supervised by prison medical staff. Data were collected from Hepatology Centers, the Health Registry of Prisons, and the Hepreg computer program.

**Results:** HCV screening programs and treatments are in place in 84% of Hungarian prisons. A total of 29,395 patients underwent anti-HCV screening during the study period. Anti-HCV positive result was detected in 2075 cases, or 7% of the participants. HCV PCR positivity was confirmed in 1252 cases, representing 4.26% of the screened inmates. 792 (63%) patients from the HCV PCR positive population were put on treatment. Data were collected from 527 patients, including 380 on interferon-based therapy and 147 on direct-acting antiviral (DAA) treatment. Only 144 patients received full treatment, while 39% of IFN-based treatments and 8.8% of DAA treatments were terminated prematurely. On the results available at the end of treatment (EOT) + 24 weeks, sustained virologic response (SVR) rate was 86%.

**Conclusion:** We wish to demonstrate that the “test and treat” policy is feasible and effective at micro-eliminating HCV from a high risk group, prison inmates, where the proportion of prior intravenous drug users is excessively high.

Table 1: Data of treated patients from 2012

Number of patients	527
sex (male/female)	498/29

#### The “Caserta Model”: a way for HCV free Hospitals, a simplified procedure for HCV micro-elimination

Vincenzo Messina<sup>1</sup>, Arnolfo Petruzzello<sup>2</sup>, Elena Tripaldelli<sup>3</sup>, Angela Annicchiarico<sup>4</sup>, Tommaso Sguglia<sup>4</sup>, Mario Massimo Mensorio<sup>5</sup>, Alfredo Matano<sup>4</sup>, Patrizia Cuccaro<sup>6</sup>, Paolo Maggi<sup>7</sup>, Nicola Coppola<sup>8</sup>. <sup>1</sup>A.O. S. Anna e S. Sebastiano di Caserta, UOC Malattie Infettive, Caserta, Italy; <sup>2</sup>A.O. S. Anna e S. Sebastiano di Caserta, Patologia Clinica, Caserta, Italy; <sup>3</sup>A.O. S. Anna e S. Sebastiano di Caserta, Patologia Clinica, Caserta, Italy; <sup>4</sup>A.O. S. Anna e S. Sebastiano di Caserta, DIREZIONE SANITARIA, Caserta, Italy; <sup>5</sup>A.O. S. Anna e S. Sebastiano di Caserta, DIREZIONE SANITARIA, Caserta, Italy; <sup>6</sup>A.O. S. Anna e S. Sebastiano di Caserta, DIREZIONE SANITARIA, Caserta, Italy; <sup>7</sup>A.O. S. Anna e S. Sebastiano di Caserta, UOC Malattie Infettive, Caserta, Italy; <sup>8</sup>università della campania, UOC Malattie Infettive, Napoli, Italy  
Email: vincenzomessina.ce@libero.it

**Background and aims:** the patients evaluated or recovered for surgery care are usually tested for HCV infection. HCV Ab positive patients are often not referred to a specialist evaluation for further analysis and diagnosis or treatment when necessary. The aim of the present study was to evaluate in S. Anna and S. Sebastiano Hospital of Caserta the prevalence of HCV Ab positive patients and HCV active infection, the awareness of HCV infection and the prevalence of those already treated with DAA in all tested patients

**Method:** evaluate all patient observed near S. Anna e S. Sebastiano Hospital resulted HCV Ab positive between January 2019 and December 2019 and tested for HCV Ab. Every monthly results record was evaluated in the following month by a specialist who, after consulting the regional care database (SaniArp) examined first the patients single position excluding by the recall list those died and those already treated with DAA, than contacted by phone call every HCV Ab positive patient for an active counselling. All the contacted patients were invited to have a free of charge specialistic consultation as a part of the ongoing care pathway.

**Results:** between January 2019 and December 2019, 14396 patients were overall tested for HCV Ab for any care in our hospital. 529 were HCV Ab positive, 199 female and 329 male (median age 69; IQR 54–78) 252 were admitted in medical units (pneumo 1, geriatrics 4, medicine 19, nephrol 21, emergency 13, resuscitation 6, neurol 2, heart 39, oncology 12, infectious dis. 92, gastro 14, outpatients 29) and 277 in surgery units (Fig. 1 eye 45, E.N.T 8, orthop 16, dental 48, neuro 22, vascular 16, heart 11, elective 67, urology 23, emergency 12, gynec 9). From the regional record 243 resulted already treated with DAA and were excluded by a recall, while 10 resulted died during hospitalization. If we exclude from the evaluation those admitted in Infectious diseases and Gastroenterology (106) the global prevalence of HCV Ab detection was 2.9% and resulted higher in surgery units 1.9% than in medical ones 1%. All patients contacted and invited for consultation accepted to be evaluated. About the HCV Ab positivity 145 were unaware of their condition, 73 were aware but unsure what to do because of the constantly ALT normal levels, 68 resulted HCV RNA negative and overall 194 were linked to DAA care.

**Conclusion:** an extensive HCV Ab testing during hospital care especially in surgery units and active surveillance on the testing results could be a simple and effective procedure for identify HCV Ab

positive patients and enhance the linkage to care. It could be assumed as an innovative simplified procedure for micro-elimination of HCV infection.

**Planning the Hepatitis C elimination in Cyprus: A modeling study**

Ilias Gountas<sup>1</sup>, Ioanna Yiasemi<sup>2</sup>, Evi Kyprianou<sup>2</sup>, Christos Mina<sup>2</sup>, Chrysanthos Georgiou<sup>3</sup>, Petros Katsioloudes<sup>4</sup>, Andri Kouroufexi<sup>5</sup>, Anna Demetriou<sup>6</sup>, Elena Xenofontos<sup>7</sup>, Georgios Nikolopoulos<sup>1</sup>.

<sup>1</sup>University of Cyprus, Medical School, Cyprus; <sup>2</sup>Cyprus National Addictions Authority, Cyprus Monitoring Centre; <sup>3</sup>Nicosia General Hospital; <sup>4</sup>Evangelistria Medical Centre; <sup>5</sup>Pharmaceutical Services, Ministry of Health; <sup>6</sup>Health Monitoring Unit, Ministry of Health; <sup>7</sup>Department of Internal Medicine, Limassol General Hospital  
Email: eliaoun@gmail.com

**Background and aims:** Hepatitis C virus (HCV) infection is a major global public health problem. In the Republic of Cyprus, the prevalence of chronic HCV (CHC) among the general population is estimated at 0.6%, while the CHC prevalence among people who inject drugs (PWID) is estimated at 43%. The direct-acting antivirals (DAAs) that are capable to eliminate HCV, are not yet available in Cyprus. However, when DAAs become available, a long-term strategic plan to guide elimination efforts will be needed to maximize treatment effect. The aim of the study is to determine the programmatic targets to eliminate HCV in the Republic of Cyprus.

**Method:** A dynamic, stochastic, individual-based model of HCV transmission, disease progression, and of cascade of care was calibrated to data from the Republic of Cyprus. The model stratifies the population into two groups: infected general population and PWID population. We assumed that the ongoing HCV transmission is limited to the PWID group. PWID moves to the infected general population if they are infected when they stop injection. A variety of test, prevention, and treatment strategies concerning the general population, PWID, or both were examined. The time horizon of our analysis was until 2034.

**Results:** Under the status quo scenario, the model predicted that 75 (95% Credible intervals (CrI): 60, 91) and 575 (95% CrI: 535, 615) liver-related deaths and new infections would occur by 2034, respectively. Launching an expanded treatment program, without screening interventions, would result in modest outcomes regarding CHC prevalence (16.6% reduction in 2034 compared to 2020) and liver-related deaths (10 deaths would be prevented compared to the status quo scenario by 2034).

Implementing a test and treat strategy in the general population, without any intervention in the PWID population, would be sufficient to achieve the mortality target but not the incidence target.

To achieve HCV elimination in Cyprus, 3080 (95% CrI: 3000, 3200) patients need to be diagnosed and treated by 2034 (2680 from the general population and 400 from PWID) (Figure) and harm reduction coverage among PWID should be increased by 3% per year (from 25% in 2020 to 67% in 2034).

Figure:

**Conclusion:** Elimination of HCV is a demanding public health strategy, which requires significant interventions both among the general population and in high-risk groups. To achieve the elimination targets, 3080 (95% CrI: 3000, 3200) patients need to be diagnosed and treated between 2021–2034.

**PO-1666**

**Telemedicine improve HCV elimination among Italian people who use drugs: an innovative therapeutic model to increase the adherence to treatment into addiction care centers.**

Valerio Rosato<sup>1</sup>, Riccardo Nevola<sup>1</sup>, Vincenza Conturso<sup>2</sup>, Pasquale Perillo<sup>1</sup>, Teresa Le Pera<sup>2</sup>, Ferdinando Del Vecchio<sup>2</sup>, Ernesto Claar<sup>1</sup>, <sup>1</sup>Ospedale Evangelico Betania, Liver Unit, Napoli, Italy; <sup>2</sup>A.S.L. Napoli 1 Centro, DS32 SerD, Napoli, Italy  
Email: valeriosato@gmail.com

**Background and aims:** HCV infection is very common among people who use drugs (PWUDs), who are usually considered “difficult-to-treat” patients due to adherence or reinfection concerns. Despite the high tolerability and efficacy of direct antiviral agents (DAAs), the linkage-to-care still remains an important gap for HCV elimination in Southern Italy. In this observational prospective study, we evaluated an innovative tailored remote model of care in order to reduce time to treat and improve the adherence to treatment of PWUDs.

**Method:** PWUDs with HCV were enrolled from January 2017 to December 2020 from one addiction care center in Southern Italy, where a complete hepatologic assessment, including blood chemistry, ultrasound and transient elastography examination, was provided. DAAs treatment was tailored on clinical features, performing also a daily administration during outpatient visit, and remote monitored by hepatologic specialists through phone or video calls. Adherence was evaluated on the accomplishment of therapy or on the percentage of visits attend.

**Results:** From a total of 690 active PWUDs, 135 had an active HCV infection and were enrolled in study. The characteristics of populations are reported in table. The median time from HCV diagnosis to treatment start was no longer than 3 weeks. We recorded 6 cases of drop-out and only one case of reinfection, obtaining a sustained virological response at week 12 (SVR12) in 98, 5% of cases with only 2 treatment failure.

## POSTER PRESENTATIONS

Reinfection	1 (0, 7)
SVR 12, n (%)	133 (98, 5)

OST: opioid substitution therapy; SVR 12: Sustained Virological Response at week 12

\*Evaluated with transient elastography: F0–1 (<7, 1kPa), F2–3 (7, 1–13 kPa), F4 (>13, 1kPa)

**Conclusion:** We obtained a high SVR12 (98, 6%), providing a complete hepatologic assessment within addiction care center, tailoring the drug administration and performing a remote hepatologic stewardship. Our therapeutic model should improve the time to treat and the adherence to treatment in PWUDs.

### PO-1713

#### Liver Transplant Wait-List Trends in Young American Adults

George Philip<sup>1</sup>, Jennifer Flemming<sup>2</sup>, Harriet Richardson<sup>3</sup>, Lawrence Hookey<sup>4</sup>. <sup>1</sup>Queen's University, Kingston, Canada; <sup>2</sup>Queen's University, Medicine, Kingston, Canada; <sup>3</sup>Queen's University, Public Health Sciences, Kingston, Canada; <sup>4</sup>Queen's University, Medicine, Kingston, Canada  
Email: George.philip@queensu.ca

**Background and aims:** Cirrhosis refers to end stage liver disease and it is the final common pathway for all chronic liver diseases (CLDs). Recent data illustrates that mortality secondary to cirrhosis is increasing in the United States (US) and is highest among young adults. Whether these trends are also occurring in Liver Transplant (LT) wait-list candidates however has not been well established. This study aimed to describe the epidemiology of LT wait-listing trends in

\*Evaluated with transient elastography: F0–1 (<7, 1kPa), F2–3 (7, 1–13 kPa), F4 (>13, 1kPa)

the US over the past two decades stratified by age at listing, cirrhosis etiology, and sex.

**Methods:** We conducted a retrospective population-based study from 2002–2018, examining all adult LT wait-listed patients in the US. Patients ≥ 20 years at the time of LT listing were identified from the Scientific Registry of Transplant Recipients (SRTR) database. Annual standardized incidence proportions were calculated from US census data. Poisson regression was used to assess changes in the annual incidence of LT wait-listing stratified by age, sex, and cirrhosis etiology and described by incidence rate ratios (IRR).

**Results:** A total of 216, 936 unique individuals were included. The median age at LT wait-listing was 57 years (Range: 20–83; IQR: 51–62), with 68% being male, and 11, 312 individuals (5.2%) were <40 years at listing. The most common etiologies of cirrhosis were HCV, alcohol-related liver disease (ALD), and non-alcoholic fatty liver disease (NAFLD). The age and sex standardized incidence proportion of LT wait-listing more than doubled in both young and older adults over the study period (<40: 0.16/100, 000 in 2002 to 0.28/100, 000 in 2018; ≥ 40: 2.2/100, 000 in 2002 to 4.34/100, 000 in 2018). Using poisson regression, the etiologies with the highest annual IRR were ALD (<40: IRR 1.11, 95% CI 1.10–1.12, p < .001; ≥ 40 IRR 1.06, 95% CI 1.06–1.07, p < .001) and NAFLD (<40: IRR 1.13, 95% CI 1.10–1.15, p < .001; ≥ 40: IRR 1.16, 95% CI 1.15–1.16, p < .001). The rate of waitlisting for ALD in young females was higher than males (IRR 1.11, 95% CI 1.10–1.12, p < .001) Conversely, the listing rate for NAFLD was lower in young females compared to young males (IRR 0.97, 95% CI 0.97–0.98, p < .001).

**Conclusion:** The incidence of LT wait-listing is increasing in both young and older adults in the US driven primarily by ALD and NAFLD. In young adults, rates of listing are increasing most in young women with ALD and men with NAFLD. These data support ongoing efforts to identify young adults with ALD and NAFLD where public health interventions can prevent the development of cirrhosis and liver-related complications.

### PO-1813

#### General population testing for hepatitis B in Australia: a cost-effectiveness analysis

Yinzong Xiao<sup>1,2</sup>, Nick Scott<sup>1,3</sup>, Alexander Thompson<sup>2,4</sup>, Margaret Hellard<sup>1,2,3</sup>, Jess Howell<sup>1,4</sup>. <sup>1</sup>Burnet Institute, Melbourne, Australia; <sup>2</sup>University of Melbourne, Parkville, Australia; <sup>3</sup>Monash University, Clayton, Australia; <sup>4</sup>St. Vincent's Hospital Melbourne, Fitzroy, Australia  
Email: yinzong.xiao@student.burnet.edu.au

**Background and aims:** In Australia, an estimated 0.9% of the population were living with chronic hepatitis B (CHB) in 2018, but only around 68% were diagnosed, well below the national and WHO targets, which are to achieve a diagnosis coverage of 80% by 2022 and 90% by 2030, respectively. Current practice of CHB testing is primarily voluntary testing promoted by symptoms or risk assessment, leading to missed opportunities of CHB diagnosis due to its asymptomatic nature, and inadequately implemented risk assessment in primary care. Testing for CHB in general population via opportunistic testing

(e.g. testing people present to a GP) may provide a viable solution. This study used a Markov model to assess the economic impacts of a general population CHB testing strategy in Australia.

**Method:** The model calculated costs, disability-adjusted life-years (DALYs) and incremental cost-effectiveness ratio (ICER) among people living with CHB in Australia in 2018–2030 in two scenarios compared to status quo: using a general population testing strategy to achieve 1) national diagnosis coverage target by 2022; or 2) WHO diagnosis coverage target by 2030. A healthcare funders perspective was taken; total costs include testing costs (regardless of results), implementation costs (assumed to either cost nothing if via opportunistic testing, or cost A\$85 per person screened), and direct medical costs of disease management. The general population testing strategy was assumed to have a 0.9% positive rate.

**Results:** Compared to status-quo, reaching the national or WHO diagnosis targets through a general population testing program (if via opportunistic testing) required an additional A\$319 million (+19%) or A\$333 million (+20%) between 2018–2030, respectively, and had ICERs of A\$37, 528 and A\$37, 541 per DALY averted, respectively. The ICERs for both scenarios remained under A\$50, 000 per DALY averted when testing positive rate was above 0.63%. If the testing program has a unit implementation cost of A\$85 per person tested, total costs increased to A\$2, 160 million and A\$2, 184 million for achieving national and WHO diagnosis coverage targets, respectively, with ICERs of A\$60, 138 and A\$60, 145 per DALY averted, but were below A\$50, 000 if the test positivity rate was above 1.12%.

**Conclusion:** A general population hepatitis B testing strategy is likely to be cost-effective compared with current testing practice in Australia to reach national and WHO diagnosis coverage targets.

**PO-1817**

**Decreased hepatitis B and C testing in Ontario, Canada during the first wave of the COVID-19 pandemic**

Erin Mandel<sup>1</sup>, Adriana Peci<sup>2</sup>, Kirby Cronin<sup>2,3</sup>, Harry Janssen<sup>1,4</sup>, Vanessa Tran<sup>2,5</sup>, Mia Biondi<sup>4,6</sup>, Jordan Feld<sup>1,4,7</sup>. <sup>1</sup>University Health Network, Toronto Centre for Liver Disease, Toronto, Canada; <sup>2</sup>Public Health Ontario Laboratory, Toronto, Canada; <sup>3</sup>Public Health Agency of Canada, National Microbiology Laboratory, Canada; <sup>4</sup>University Health Network, Viral Hepatitis Care Network (VIRCAN) Study Group, Toronto Centre for Liver Disease, Canada; <sup>5</sup>University of Toronto, Department of Laboratory Medicine and Pathobiology, Toronto, Canada; <sup>6</sup>Western University, Arthur Labatt Family School of Nursing, London, Canada; <sup>7</sup>University of Toronto, Institute of Medical Sciences, Toronto, Canada  
Email: erin.mandel@uhnresearch.ca

**Background and aims:** The COVID-19 pandemic has significantly disrupted care across many clinical areas with particular impact on the screening for, and management of, chronic medical conditions. We examined trends in hepatitis B (HBV) and C (HCV) testing in Ontario, Canada to determine how the first wave of COVID-19 impacted management of these chronic conditions.

**Method:** We extracted de-identified data from the provincial public health laboratory in Ontario, Canada for HBV and HCV testing from January 1, 2019 until August 31, 2020. Total and unique test volumes were evaluated for hepatitis B surface antigen (HBsAg), HBV DNA, HCV antibody (Ab) and HCV RNA testing stratified by age, sex, region and test indication. Prenatal HBV screening was evaluated separately. Changes in testing volumes were analysed by comparing percent and absolute changes over time.

**Results:** COVID-19 first emerged in Ontario in late January 2020 with near-immediate impact on health service provision. We compared testing volumes from February-August 2019 to those from February-August 2020. Compared to 2019, HCV Ab testing (screening) in 2020 decreased 30% and HCV RNA testing decreased 36%. Pre-treatment HCV RNA testing decreased by 43% and post-treatment sustained virologic response testing decreased by 36%. For HBV, HBsAg testing decreased 29% and HBV DNA testing by 33%. While pre-treatment HBV DNA decreased by 38%, on-treatment monitoring decreased by

only 14%. Trends were consistent when testing volumes were stratified by age, region, and sex; however, prenatal HBV testing volumes remained stable. Test volumes for all tests were increasing prior to 2019 with increased awareness of viral hepatitis elimination targets. No non-prenatal test type returned to pre-pandemic levels by August 2020, recovering to 75% for HCV Ab, 64% for HCV RNA, 77% for HBsAg and 82% for HBV DNA compared to tests in 2019.

Figure:

**Conclusion:** Significant decreases in HBV and HCV testing occurred in Ontario during the first wave of the COVID-19 pandemic. Screening for HCV as well as pre- and post-treatment RNA testing were greatly affected and did not return to pre-pandemic testing levels by the end of the first wave. HBV screening and pre-treatment testing were similarly reduced, but HBV on-treatment monitoring was not as severely impacted. Strategies to maintain and ultimately increase screening, diagnosis and treatment initiation will be required to ensure the pandemic does not derail progress toward viral hepatitis elimination in Canada.

**PO-1862**

**Predictors of loss to follow-up in an outpatient cirrhotic population**

Joana Vieira Barbosa<sup>1,2</sup>, Qua Tran<sup>3</sup>, Brian Malinn<sup>1</sup>, Rosa L. Yu<sup>4</sup>, Michael Curry<sup>1</sup>, Michelle Lai<sup>1</sup>. <sup>1</sup>Beth Israel Deaconess Medical Center, Harvard Medical School, Division of Gastroenterology and Hepatology, Boston, United States; <sup>2</sup>Lausanne University Hospital and University of Lausanne, Division of Gastroenterology and Hepatology; <sup>3</sup>Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, Pharmacy Department, Boston, United States; <sup>4</sup>Beth Israel Deaconess Medical Center, Harvard Medical School, Department of Internal Medicine, Boston, United States  
Email: jvieirab@bidmc.harvard.edu

**Background and aims:** Cirrhosis is a major cause of morbidity and mortality with an increasing burden over the last decades. Due to the high risk of liver-related complications, periodic surveillance is key in the management of these patients. However, adherence to surveillance programs is suboptimal and measures to anticipate loss to follow-up (LTFU) are lacking. The aim of our study was to investigate the factors associated with loss to FU in an outpatient cirrhotic population, screened in a tertiary liver center.

**Method:** We analyzed data from all adult patients with cirrhosis evaluated in the Beth Israel Deaconess Medical Center outpatient Liver Clinic from 2018 to 2020. Patients with cirrhosis were identified from our internal electronic database, using International Classification Diseases-10 codes. Deceased patients or those with a previous diagnosis of hepatocellular carcinoma (HCC) were excluded. The outcome of interest was LTFU, defined as the absence of liver appointment and/or abdominal ultrasound in the last 9 months. Analysis was performed using logistic regression and results were reported as odds ratio (OR) and 95% confidence interval (95% CI).

## POSTER PRESENTATIONS

### UNIVARIATE ANALYSIS

Age: OD 0.78, 95% CI 0.71 – 0.87,  $p < 0.001$   
 Insurance status: OD 0.84, 95% CI 0.75 – 0.93,  $p = 0.001$   
 Diabetes: OD 0.67, 95% CI 0.53 – 0.86,  $p = 0.001$   
 BMI  $\geq 30$  Kg/m<sup>2</sup>: OD 1.42, 95% CI 1.08 – 1.89,  $p = 0.013$   
 FIB-4  $\geq 2.67$ : OD 1.36, 95% CI 1.09 – 1.71,  $p = 0.007$   
 Alcohol-related disease: OD 2.02, 95% CI 1.54 – 2.66,  $p < 0.001$   
 Decompensated cirrhosis: OD 2.66, 95% CI 2.09 – 3.39,  $p < 0.001$

### MULTIVARIATE ANALYSIS

Age: OD 0.76, 95% CI 0.63 – 0.93,  $p = 0.006$   
 Insurance status: OD 1.31, 95% CI 0.90 – 1.93,  $p = 0.162$   
 Diabetes: OD 1.08, 95% CI 0.74 – 1.58,  $p = 0.684$   
 BMI  $\geq 30$  Kg/m<sup>2</sup>: OD 1.63, 95% CI 1.15 – 2.32,  $p = 0.006$   
 FIB-4  $\geq 2.67$ : OD 0.83, 95% CI 0.57 – 1.19,  $p = 0.316$   
 Alcohol-related disease: OD 1.56, 95% CI 1.04 – 2.32,  $p = 0.030$   
 Decompensated cirrhosis: OD 2.18, 95% CI 1.41 – 3.36,  $p < 0.001$

Figure: (abstract: PO-1862)

**Results:** Of 1742 consecutive adult patients with cirrhosis (57% male, mean age  $61 \pm 12$  years), 461 (26.5%) were LTFU. Patients LTFU were younger (mean age: 59 vs 62 years,  $p < 0.001$ ), more likely to be obese (BMI  $\geq 30$  kg/m<sup>2</sup>: 50% vs 41%,  $p = 0.013$ ), have alcohol-related cirrhosis (46% vs 29%,  $p < 0.001$ ), and have decompensated cirrhosis (34% vs 16%,  $p < 0.001$ ) compared to patients without LTFU. In univariate analysis, clinical factors significantly associated with LTFU included age, insurance status, diabetes, BMI  $\geq 30$  kg/m<sup>2</sup>, FIB-4 score  $\geq 2.67$ , alcohol-related cirrhosis and decompensated cirrhosis. In multivariate logistic regression including all the above clinical factors, only younger age (OR 0.76, 95% CI 0.63–0.93,  $p = 0.006$ ), BMI  $\geq 30$  kg/m<sup>2</sup> (OR 1.63, 95% CI 1.15–2.32,  $p = 0.006$ ), alcohol-related cirrhosis (OR 1.56, 95% CI 1.04–2.32,  $p = 0.030$ ) and decompensated cirrhosis (OR 2.18, 95% CI 1.41–3.36,  $p < 0.001$ ) independently, significantly predicted LTFU (Figure 1).

**Conclusion:** In a large population of patients with cirrhosis, younger age, obesity, alcohol-related cirrhosis and liver decompensation were significant predictors of LTFU. Implementation of a targeted intervention program in this high-risk population to optimize surveillance rates and management is warranted.

### PO-1877

#### Feasibility, effectiveness, and lessons learned from the introduction of decentralised HCV testing and treatment at primary healthcare clinics in three regions in Malaysia

Sonjelle Shilton<sup>1</sup>, Jessica Markby<sup>1</sup>, Xiaohui Sem<sup>1</sup>, Sasikala Siva<sup>2</sup>, Rozainanee Binti Mohd Zain<sup>3</sup>, Caroline Menetrey<sup>2</sup>, Fazidah Binti Yuswan<sup>4</sup>, Nazrila Hairizan Binti Nasir<sup>4</sup>, Isabelle Andrieux-Meyer<sup>2</sup>, Philippa Easterbrook<sup>5</sup>, Muhammad Radzi Abu Hassan<sup>6</sup>. <sup>1</sup>Foundation for Innovative New

Diagnosics; <sup>2</sup>Drugs for Neglected Diseases initiative; <sup>3</sup>Institute for Medical Research; <sup>4</sup>Ministry of Health Malaysia; <sup>5</sup>World Health Organization; <sup>6</sup>CRC Hospital Sultanah Bahiyah  
 Email: sonjelle.shilton@finddx.org

**Background and aims:** To achieve the global targets for elimination of hepatitis C virus (HCV), substantial scale-up in access to testing and treatment is needed. This will require decentralisation of testing and treatment to primary care settings and task-shifting to non-specialists. A Hepatitis C Elimination through Access to Diagnostics (HEAD-Start) study was carried out in Malaysia to evaluate the feasibility and effectiveness of decentralised HCV testing using rapid diagnostic tests (RDTs) and treatment in primary healthcare clinics (PHCs) among high-risk populations.

**Method:** This observational study was conducted between December 2018 and December 2019 at 25 PHCs in three regions. Patients were tested based on routine clinical indications for an HCV test, in accordance with national guidelines. Each PHC was linked to one or more hospitals, for referral of patients for confirmatory testing, pre-treatment assessment bloods and a FibroScan to assess the presence of cirrhosis. Confirmation of HCV viremia by RNA testing was performed on plasma samples sent from hospitals to a reference laboratory in Kuala Lumpur using the Roche cobas® 4800 HCV assay. The majority of non-cirrhotic patients were referred back to PHCs for treatment.

**Results:** A total of 15366 adults were screened at the 25 PHCs during the study period. Of the 2020 HCV antibody-positive, 73.3% (1481/2020) had a confirmatory viral load test, 83.8% (1241/1481) were HCV RNA-positive, 79.9% (991/1241) completed pre-treatment assessments, 63.8% (632/991) had treatment initiated, 82.0% (518/632) completed treatment, 68.0% (352/518) were eligible for a sustained virological response (SVR) cure assessment, 59.4% (209/352) had a SVR cure assessment, and SVR was achieved in 96.7% (202/209)

patients. There were significant differences in treatment initiation (71.0%, 475/669 versus 48.8%, 157/322;  $p < 0.001$ ) and treatment completion (90.5%, 430/475 versus 56.1%, 88/157;  $p < 0.001$ ) according to whether patients were treated at PHCs or at hospitals respectively. Comparable SVR rates ( $>95\%$ ) were achieved in those treated at PHCs and at hospitals.

RDT, rapid diagnostic test; SVR, sustained virological response; Tx, treatment

Figure:

**Conclusion:** This study demonstrated the effectiveness and feasibility of a simplified decentralised HCV testing and treatment model in primary healthcare settings, targeting high-risk groups in Malaysia. There were good outcomes across the cascade of care, and decentralisation of treatment at PHCs improved uptake and completion of treatment.

**PO-1903**

**SEAL program-Early detection of liver fibrosis and cirrhosis by screening of the general population**

Nagel Michael<sup>1</sup>, Anita Arslanow<sup>1</sup>, Marc Nguyen-Tat<sup>1</sup>, Marcus-Alexander Wörns<sup>1</sup>, Matthias Reichert<sup>2</sup>, Franz Josef Heil<sup>3</sup>, Dagmar Mainz<sup>3</sup>, Gudula Zimmer<sup>4</sup>, Burkhard Zwerenz<sup>5</sup>, Johannes Jäger<sup>6</sup>, Harald Binder<sup>7</sup>, Erik Farin-Glattacker<sup>7</sup>, Bogatyreva Lioudmila<sup>7</sup>, Fichtner Urs<sup>7</sup>, Graf Erika<sup>7</sup>, Stelzer Dominikus<sup>7</sup>, Reyn van Ewijk<sup>8</sup>, Julia Ortne Dr.<sup>9</sup>, Louis Velthuis<sup>9</sup>, Frank Lammert<sup>2</sup>, Galle Peter R.<sup>1</sup> Prof. Dr.<sup>1</sup>Department of Internal Medicine I, University Medical Center Mainz, Mainz, Germany; <sup>2</sup>Saarland University Medical Center, Department of Internal Medicine II; <sup>3</sup>German Gastroenterology Association (bng); <sup>4</sup>General Practitioners' Association Saarland, Germany; <sup>5</sup>General Practitioners' Association Rhineland-Palatinate, Germany; <sup>6</sup>Saarland University, Center for General Medicine; <sup>7</sup>University of Freiburg, Institute of Medical Biometry and Statistics; <sup>8</sup>Johannes Gutenberg University Mainz, Department of Economics; <sup>9</sup>Johannes Gutenberg University Mainz, Department of Controlling  
Email: michael.nagel@unimedizin-mainz.de

**Background and aims:** Most patients with liver cirrhosis are detected at a late stage of their disease. In approximately 75%, diagnosis is based on the development of complications such as ascites or bleeding. At this stage causative treatment interventions are less successful or impossible. Screening for liver health and disease is not included in standard medical check-up programs. The SEAL program (Structured Early Detection of Asymptomatic Liver Cirrhosis) investigates the feasibility, effectiveness and cost-benefit assessment of a general screening for liver fibrosis and cirrhosis.

**Method:** As part of the SEAL program, 16, 000 insured persons from a large German health insurance company will be offered additional testing of liver enzymes as part of a nationwide primary care program (check-up 35) in two German states, i.e. Rhineland-Palatinate and Saarland. In case of elevated transaminases, the APRI score as a liver fibrosis risk score is calculated. If the APRI score is suggestive for liver disease, patients are referred to a gastroenterologist for further differential diagnostic assessment. Patients suspected to have relevant liver fibrosis are referred to a liver center for further hepatologic workup. End points include data on the epidemiology of

elevated liver enzymes, cost-benefit assessments and prevalence of liver fibrosis in a general population.

**Results:** To date, more than 12000 patients have been enrolled. The average age of patients is 62 years. Of the examined patients, 11% and 6% presented with increased ALT and AST values with a maximum of 3828 U/l and 434 U/l, respectively. In 499 patients a known liver disease was already present at inclusion. Nevertheless, 11% of patients without known liver disease had pathologically elevated transaminases. 307 patients showed elevated transaminases and a conspicuous APRI score above 0.5, 76% of whom had no known liver disease. Up to now, referral for further diagnostics has been initiated in 245 patients

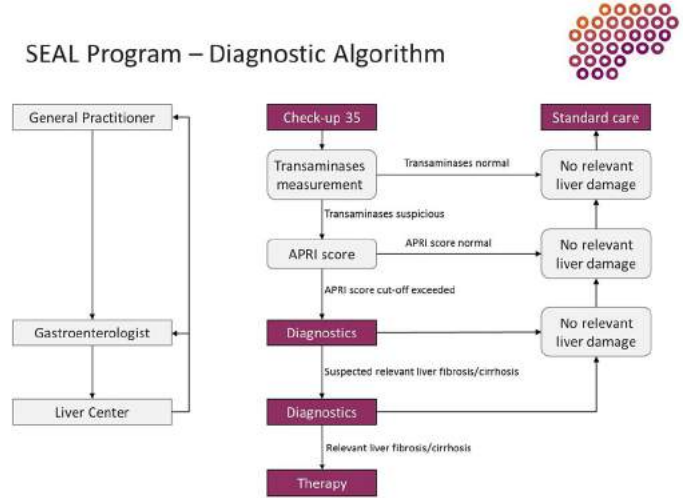

Figure:

**Conclusion:** The establishment of an early diagnosis of liver diseases is controversially discussed by professionals and in the literature. The initial data indicates that a relevant group of the population suffers from an increase in transaminases. The SEAL project will provide further data on feasibility, effectiveness and cost-benefit assessment in the German health care system and will contribute substantial evidence to the meaningfulness of such a measure.

**PO-1936**

**A global systematic review of efforts to accelerate the elimination of hepatitis C virus (HCV) through micro-elimination**

Jeffrey Lazarus<sup>1</sup>, Camila Picchio<sup>1</sup>, Christopher Byrne<sup>2</sup>, Javier Crespo<sup>3</sup>, Massimo Colombo<sup>4</sup>, Graham Cooke<sup>5</sup>, Gregory Dore<sup>6</sup>, Jason Grebely<sup>6</sup>, John Ward<sup>7</sup>, Trenton White<sup>1</sup>, John Dillon<sup>2,8</sup>. <sup>1</sup>Barcelona Institute for Global Health (ISGlobal), Hospital Clínic, University of Barcelona, Barcelona, Spain; <sup>2</sup>Division of Molecular and Clinical Medicine, University of Dundee School of Medicine, Ninewells Hospital, Dundee, United Kingdom; <sup>3</sup>Gastroenterology and Hepatology Department, University Hospital Marques de Valdecilla. Research Institute Valdecilla-IDIVAL, Santander, Spain; <sup>4</sup>Department of Medicine, Humanitas Hospital, Rozzano, Italy; <sup>5</sup>Division of Infectious Diseases, Faculty of Medicine, Imperial College London, London, United Kingdom; <sup>6</sup>The Kirby Institute, UNSW Sydney, Sydney, Australia; <sup>7</sup>Coalition for Global Hepatitis Elimination, The Task Force for Global Health, Atlanta, United States; <sup>8</sup>Department of Gastroenterology, Ninewells Hospital and Medical School, Dundee, United Kingdom  
Email: Jeffrey.Lazarus@isglobal.org

**Background and aims:** Despite the availability of highly effective therapies, many countries have yet to develop programmes to reach the targets for hepatitis C virus (HCV) elimination. Micro-elimination aims to reduce this gap through targeted efforts among specific sub-populations. This review reports on the effectiveness of the micro-elimination approach, which population cohorts were targeted most frequently by micro-elimination initiatives, and to evaluate to what

## POSTER PRESENTATIONS

extent the initiatives reported follow the criteria proposed for a successful micro-elimination approach to HCV.

**Method:** A search of the published literature was carried out in PubMed/Medline between 2013 and 2020. A grey literature search and manual search of relevant conference abstracts between 2017–2019 was performed. Inclusion criteria included studies published after 2013 with measurable outcomes that were published in English or Spanish where the main objective of the study was micro-elimination in a specific sub-population. Reviews and mathematical modelling studies were excluded. Data from publications that met the inclusion criteria were extracted and summarised based on the four criteria defining HCV micro-elimination: having a plan, the presence of achievable time-bound targets, a multistakeholder process, and ongoing monitoring.

**Results:** Thirty published manuscripts met the inclusion. The majority (80%) of studies came from high-income settings (Figure), included persons who are incarcerated (26%) or people who use drugs (16%), and 86% reported at least three out of four of the key components of micro-elimination. A total of 93% of the manuscripts included a clear plan for achieving micro-elimination in their intended target population and reported monitoring their outcomes. Twenty-six manuscripts reported treatment outcomes in the study population to calculate the sustained virologic response (SVR), which ranged from 15% to 100% with a median SVR of 86.5% in the included manuscripts.

**Conclusion:** Micro-elimination is a strategic approach to achieving the WHO elimination targets that should be adapted to local contexts and epidemiological profiles. Despite the demonstrated effectiveness of this approach in several settings, we found little published data on micro-elimination efforts, particularly in low- and middle-income countries. Existing literature highlights the micro-elimination interventions that can be scaled-up to eliminate HCV in target sub-populations and help launch national programmes.

### PO-1990

#### The unmet needs of living with non-alcoholic steatohepatitis (NASH) in Europe and Canada: results from a multi-country survey

Jeffrey Lazarus<sup>1</sup>, Fabienne Marcellin<sup>2</sup>, Camelia Protopopescu<sup>2</sup>, Aldo Trylesinski<sup>3</sup>, José Luis Calleja Panero<sup>4</sup>, Carrieri Patrizia<sup>2</sup>.

<sup>1</sup>Barcelona Institute for Global Health (ISGlobal), Hospital Clínic, University of Barcelona, Barcelona, Spain; <sup>2</sup>Aix Marseille Univ, INSERM, IRD, SESSTIM, Sciences Économiques and Sociales de la Santé and Traitement de l'Information Médicale, Marseille, France; <sup>3</sup>Intercept Pharmaceuticals, London, United Kingdom; <sup>4</sup>Liver Unit, Puerta de Hierro University Hospital, Universidad Autónoma de Madrid, CIBERehd, Madrid, Spain

Email: Jeffrey.Lazarus@isglobal.org

**Background and aims:** Non-alcoholic fatty liver disease (NAFLD) is increasing worldwide and trends are closely related to those of obesity epidemics. Non-alcoholic steatohepatitis (NASH) is

characterized by the presence of inflammation, ballooning and steatosis. The strongest driver of clinical outcomes is fibrosis, present in ~85% of NASH and 10% of NAFLD patients. Currently, healthier lifestyles and multidisciplinary care can improve the prognosis. Little is known about patients' knowledge of and experience with NASH and related care. We conducted a multi-country survey to better document NASH patients' knowledge, care, expectations and unmet needs.

**Method:** We recruited 1411 adults with NASH in Canada, France, Germany, Italy, Spain and the United Kingdom (UK), who were registered on the online patient community platform Carecity. Participants were invited to answer a questionnaire detailing their knowledge of and experience with NASH and related care. The dataset was weighted to enable inter-country comparison.

**Results:** The number of participants (54% men) per country ranged from 218 (Italy) to 276 (UK). Sex-age distributions were similar across all countries. Twenty-three percent of the participants reported feeling overwhelmed when diagnosed with NASH. Despite 19% reporting 3 or more comorbidities, 61% did not know their liver fibrosis status and 30% reported that it had been over a year since their last fibrosis assessment (Figure). Seventy-one percent of those without comorbidities thought their NASH was at an early stage. Even if 88% of participants were recommended lifestyle changes by their physician to manage NASH, only 14% reported being able to fully adhere to these. Thirty-two and 34% reported little to no understanding about liver fibrosis or cirrhosis consequences, respectively and 57% reported having little to no understanding of the signs indicative of deteriorating NASH. Only 14% reported having a good understanding of how NASH progresses over time.

**Conclusion:** Despite the negative clinical outcomes of NASH, patients' information about the disease, its associated risks and management were found to be very insufficient. Conducting multi-target campaigns to inform healthcare professionals and people at potential risk about the importance of regular screening and promoting patient educational programmes to support behavioural changes to prevent NAFLD progression should be urgently included in the international clinical and public health agenda.

#### Patient recall of physician's explanation of fibrosis stages

#### Time since last fibrosis stage check

**PO-2014**

**The emergency department, a new setting for HBV screening in populations with limited linkage to the health care system in a high-income country**

Jordi Llaneras<sup>1</sup>, Ana Barreira<sup>2</sup>, Ariadna Rando Segura<sup>3</sup>, Juan Bañares<sup>4</sup>, Beatriz Meza<sup>1</sup>, Lourdes Ruiz<sup>4</sup>, Joana Rita Marques<sup>4</sup>, Arnau Monforte<sup>4</sup>, Olimpia Orozco<sup>1</sup>, Mar Riveiro Barciela<sup>2,5</sup>, Fernando Rodrigo-Velásquez<sup>3</sup>, Francisco Rodríguez-Frías<sup>3</sup>, Maria Arranz<sup>1</sup>, Rafael Esteban<sup>2,5</sup>, Maria Buti<sup>2,5</sup>. <sup>1</sup>Emergency Department, Hospital Vall Hebron, Barcelona, Spain; <sup>2</sup>Liver Unit, Internal Medicine Department, Hospital Universitari Vall d'Hebron, Vall d'Hebron Barcelona Hospital Campus, Barcelona, Spain; <sup>3</sup>Biochemistry and Microbiology Department, Hospital Vall Hebron, Barcelona, Spain; <sup>4</sup>Department of Internal Medicine, Hospital Vall Hebron, Barcelona, Spain; <sup>5</sup>Centro de Investigación Biomédica en Red de Enfermedades Hepáticas y Digestivas (CIBERehd), Instituto de Salud Carlos III, Madrid, Spain  
Email: jllaneras@vhebron.net

**Background and aims:** Universal vaccination against hepatitis B virus (HBV) has led to a significant reduction in hepatitis B-related complications. Despite this, there is still a significant number of people with HBsAg infection who are diagnosed at late stage of the disease. The emergency department (ED) offers the possibility of HBV screening, especially in population limited linkage to health care system.

**Method:** Prospective single-centre study in academic hospital involving screening and linkage to specialty care of hepatitis B. HBsAg screening was performed in individuals (>16 years) presenting to the ED requiring phlebotomy for medical reasons.

**Results:** Of the 7, 259 patients who were screened during one year (Feb-20 to Feb-21) in the ED, 43 (0.6%) patients were HBsAg positive. The median age was 64 years and 67% were male. Baseline characteristics of HBsAg positive patients are shown in the table. Risk factors for HBV infection were observed in less than 5% of cases and the majority (97%) were HBeAg negative. There were no cases of HIV, HCV or HDV co-infection. Caucasian race (81%) was predominant followed by African American (8%). Sixteen (37%) subjects were unaware of their infected status. Twenty-two (81%) patients with known HBV infection were already followed-up by a Liver specialist, and the remaining 5 (19%) had abandoned controls. No HBsAg-positive patients aged <40 years were born in Spain, country with an established HBV vaccination program in newborns and adolescent. The 3 cases HBsAg positive <40 years were from Sub-Saharan Africa and Eastern Europe. 14 (33%) patients had cirrhosis assessed by FIB-4 >3.25. Ten of new diagnosis patients were linked to care. Patients who were not referred were due to low life expectancy, severe cognitive impairment, or severe social problems.

Figure:

	HBsAg positive (N = 43)
Male, n (%)	29 (67%)
Age (years), Md (IQR)	67 (52–81)
Caucasian, n (%)	35 (81%)
PWID, n (%)	1 (2%)
Alcohol consumption, n (%)	7 (16%)
Prior transfusion of blood products, n (%)	2 (5%)
Surgical interventions in childhood, n (%)	4 (9%)
Psychiatric disorder, n (%)	9 (21%)
Patients' infection unawareness, n (%)	15 (35%)
ALT (U/L), Md (IQR)	24 (14–36)
MELD-NA, Md (IQR)	11 (9–16)
FIB-4, Md (IQR)	2.02 (1.21–4.35)
Late diagnosis (FIB-4 >3.25), n (%)	14 (33%)
Fibrosis F3-F4, n (%)	7 (24%)
HBeAg, n (%)	1 (29%)
antiHDV, n (%)	0 (0%)
Patients with new diagnosis referred to hepatologist, n (%)	10 (23%)

**Conclusion:** Despite vaccination programs, HBsAg persists in general population as a silent infection, mainly in those groups with limited access to the Health Care system. Current migratory movements favour the re-emergence of HBV infection in young patients in the absence of new-born vaccination programs. Screening for HBV infection in emergency departments can be a useful tool to rescue patients with unknown HBV infection and ensure appropriate follow-up.

**PO-2032**

**Disclosure of non-alcoholic steatohepatitis (NASH) diagnosis and fear of discrimination: results from a multi-country survey**

Jeffrey Lazarus<sup>1</sup>, Fabienne Marcellin<sup>2</sup>, Achim Kautz<sup>3</sup>, Vanessa Hebditch<sup>4</sup>, Aldo Trylesinski<sup>5</sup>, José Luis Calleja Panero<sup>6</sup>, Carrieri Patrizia<sup>2</sup>. <sup>1</sup>Barcelona Institute for Global Health (ISGlobal), Hospital Clínic, University of Barcelona, Barcelona, Spain; <sup>2</sup>Aix Marseille Univ, INSERM, IRD, SESSTIM, Sciences Économiques and Sociales de la Santé and Traitement de l'Information Médicale, Marseille, France; <sup>3</sup>UG, Cologne, Germany; <sup>4</sup>British Liver Trust, Bournemouth, United Kingdom; <sup>5</sup>Intercept Pharmaceuticals, London, United Kingdom; <sup>6</sup>Liver Unit, Puerta de Hierro University Hospital, Universidad Autonoma de Madrid, CIBERehd, Madrid, Spain  
Email: Jeffrey.Lazarus@isglobal.org

**Background and aims:** People with non-alcoholic steatohepatitis (NASH) may experience stigma and discrimination, not only due to co-occurrence of stigmatised conditions such as obesity, diabetes and poor social conditions, but also because of possible representations of this liver disease, often erroneously related to unhealthy alcohol use. We conducted a multi-country survey to better document how and to what extent people living with NASH disclose their diagnosis.

**Method:** We enrolled 1411 adult individuals with NASH in Canada, France, Germany, Italy, Spain and the United Kingdom (UK). Participants completed an online questionnaire that collected data on their experience with their disclosure of NASH diagnosis and fear of discrimination. To enable inter-country comparisons, the dataset was weighted-with respect to a general distribution-by age and gender of people with NASH.

**Results:** The number of participants per country ranged from 218 (Italy) to 276 (UK). Most participants were men (54%). A fifth (19%) reported three or more comorbidities, and 32% reported insufficient understanding about liver fibrosis consequences. Three in four (74%) felt confident about explaining how lifestyle changes can impact the development of cirrhosis. In terms of how well they were able to explain their disease to others, 17%, 48% and 37% reported not at all well, quite well and very well, respectively. With regard to NASH diagnosis disclosure, 84% reported disclosing it to their close family, 61% to friends, 32% to co-workers and 25% to their supervisor. However, only 41% felt comfortable speaking about NASH with their family. As for the fear of alcohol-related discrimination, very few (13%) reported avoiding the term “non-alcoholic” when speaking about NASH.

**Conclusion:** Overall, people diagnosed with NASH disclosed their disease to others, even in the workplace, and did not avoid associating it with alcohol use when referring to it. Considering the prevalence of overweight/obesity in NASH patients in the countries included, a NASH diagnosis may change their self-identity from a person living with a physically stigmatised condition to one living with liver disease. As lifestyle changes remain difficult for people with NASH, multidisciplinary care and therapeutic education are needed to reverse the course of the disease.

### PO-2039

#### Anticipated timing of hepatitis C virus elimination in the Netherlands and the impact of COVID-19

Marleen van Dijk<sup>1</sup>, Sylvia Brakenhoff<sup>2</sup>, Cas J. Isfordink<sup>3,4</sup>, Wei-Han Cheng<sup>5</sup>, Robert De Knecht<sup>2</sup>, Sophie Willemsse<sup>6</sup>, Marc van der Valk<sup>4</sup>, Joost Ph Drenth<sup>1</sup>. <sup>1</sup>Radboudumc, Gastroenterology and Hepatology, Nijmegen, Netherlands; <sup>2</sup>Erasmus Medical Centre, Rotterdam, Netherlands; <sup>3</sup>University Medical Centre Utrecht, Gastroenterology and Hepatology, Utrecht, Netherlands; <sup>4</sup>Amsterdam Infection and Immunity Institute, Amsterdam University Medical Centre, Amsterdam, Netherlands; <sup>5</sup>Abbvie Pharmaceuticals, Health Economics and Outcomes Research, Chicago, United States; <sup>6</sup>Amsterdam University Medical Centre, Gastroenterology and Hepatology, Amsterdam, Netherlands

Email: marleen.vandijk@radboudumc.nl

**Background and aims:** The Netherlands has committed itself to eliminate hepatitis C virus (HCV) infection, according to the World Health Organization (WHO) elimination targets. A recent analysis suggested that elimination will only be reached by 2035 in the Netherlands. Recently, a nationwide HCV elimination project (CELINE) has harvested new data on the Dutch HCV epidemic. Therefore, this study aims to provide an updated analysis on elimination progress in the Netherlands.

**Method:** A previously published Markov model was used to map the path to HCV elimination. Prevalence data from 2016, treatment data from 2000–2019 and unpublished CELINE data were used as inputs. In the “Status Quo” scenario, we assumed a 10% decrease in diagnosis and treatment levels in 2020, as compared to 2019. From 2021 onwards, diagnosis and treatment levels stayed constant. In the “Gradual Decrease” scenario, starting in 2020, we assumed an annual decrease of 10% in both diagnoses and treatments. Finally, a two-year delay in elimination as a result of COVID-19 was modelled. We assumed a decrease of 42% in both diagnosis and treatment levels for 2020 and 2021. We anticipated that these levels would either rise again to “Status Quo” values in 2022 and remain constant afterwards (“Two-year COVID-19 Delay”), or would increase to “Status Quo” values in 2022, followed by an annual decrease of 10% (“Post-recovery Gradual Decrease”). WHO mortality, diagnosis, and treatment targets for 2030 were considered; the incidence target was disregarded, due to the very low incidence in the Netherlands ( $\leq 5$  per 100,000).

**Results:** Following the “Status Quo” and “Gradual Decrease” scenarios, the Netherlands would reach the WHO targets by 2027 and 2032, respectively. The “Two-year COVID-19 Delay” would result in elimination by 2028, and the “Post-recovery Gradual Decrease” scenario would result in elimination by 2030 (see Table). The annual number of treatments needed in 2020–2030 was 381.

**Conclusion:** The Netherlands is on track to reach HCV elimination by 2030. COVID-19 does not seem to have a profound impact on the WHO HCV elimination goals. This might be because HCV incidence is so low and because the threshold of 381 annual treatments is more than met in the majority of years. It is, however, vital that HCV elimination remain high on the agenda.

Figure:

Year of achieving WHO elimination target	Status Quo	Gradual Decrease	Two-year COVID-19 Delay	Post-recovery Gradual Decrease
Liver-related mortality	2020	2020	2022	2022
Diagnosis	2027	2032	2028	2030
Treatment	2026	2028	2026	2027

### PO-2047

#### HCV screening of immigrants at arrival: an opportunity to linkage to care of a population with limited access to health care system

Mar Riveiro Barciela<sup>1,2,3</sup>, Begoña Treviño<sup>4</sup>, Nuria Serre<sup>4</sup>, Ariadna Rando Segura<sup>5,6</sup>, Fernando Salvador<sup>4</sup>, Ana Barreira<sup>1,3</sup>, Adriana Palom<sup>1,7</sup>, Elena Vargas Accarino<sup>1,7</sup>, Diana Pou<sup>4</sup>, Luisa Roade<sup>1,2,3</sup>, Israel Molina<sup>4</sup>, Francisco Rodríguez-Frías<sup>5</sup>, Maria Buti<sup>1,2,3</sup>. <sup>1</sup>Universitat Autònoma de Barcelona, Department of Medicine; <sup>2</sup>Centro de Investigación Biomédica en Red Enfermedades Hepáticas y Digestivas (CIBEREHD); <sup>3</sup>Hospital Universitario Vall d'Hebron, Liver Unit, Department of Internal Medicine; <sup>4</sup>Vall d'Hebron-Drassanes PROSICS Barcelona, Tropical Medicine and International Health Unit; <sup>5</sup>Hospital Universitario Vall d'Hebron, Biochemistry and Microbiology Department; <sup>6</sup>VHIR-Vall d'Hebron Institut de Recerca; <sup>7</sup>VHIR-Vall d'Hebron Institut de Recerca, Liver Unit

Email: mar.riveiro@gmail.com

**Background and aims:** Several studies have shown that the prevalence of Hepatitis C virus (HCV) is higher in immigrants than autochthonous population. Besides migrants have a limited access to the Health Care system. Centers that attend these subjects at their arrival could play an important role in the HCV screening and the linkage to care of these individuals.

**Method:** All migrants attending the Drassanes Center that runs the International Health Program of Catalonia Health Institute were tested for anti-HCV antibodies between January and December 2020. In anti-HCV-positive serum samples, a reflex HCV-RNA test was automatically performed. HCV-RNA-positive subjects were evaluated by the Liver Unit for assessment of antiviral therapy

**Results:** HCV screening was carried out in 820 individuals: 60.7% were male, mean age  $33 \pm 14$  years. The vast majority (99.4%) of individuals were not aware of their HCV status. The anti-HCV prevalence was 2.1% (18 cases), with 4 (25%) out of 16 subjects testing positive for HCV-RNA (0.49% of the overall cohort). Most prevalent origin of screened subjects and the prevalence of anti-HCV by regions were: East Europe (Number of tested subjects = 23, rate of anti-HCV positivity = 13%), Southern Asia (72, 8.3%), Central Africa (48, 8.3%), West Africa (119, 1.7%), Central America (71, 1.4%), North Africa (122, 0.8%), South America (248, 0.4%), Central Europe (112, 0%), and Western Asia (17, 0%). Countries with the highest rate of anti-HCV antibodies were: Ukraine (2/8, 25%), Equatorial Guinea (4/28, 14.3%) and Pakistan (5/48, 10.4%). In the figure countries with screened individuals and with positive anti-HCV patients are summarized. Only 4 (22%) HCV-positive individuals were aware of the HCV infection. Anti-HCV prevalence differed according to the region of origin ( $p < 0.001$ ) and baseline AST (46 vs 28,  $p = 0.01$ ), though age (33.7 vs 33.4,  $p = 0.91$ ), male sex (66.7% vs 60.6%,  $p = 0.40$ ), mean ALT (41 vs 26,  $p = 0.261$ ), platelets (265 vs 262,  $p = 0.84$ ), APRI (0.49 vs 0.31,  $p = 0.215$ ) and FIB-4 score (1.11 vs 0.8,  $p = 0.206$ ) were similar. All 4 HCV-RNA-positive individuals are currently under therapy and to date the adherence has been high.

**Conclusion:** Screening of HCV at arrival allows to detect a high rate of HCV infections in migrant population from Central Asia, Sub-Saharan Africa and Eastern Europe. The majority of them were unaware of HCV infection. Despite that, adherence to linkage to care is high.

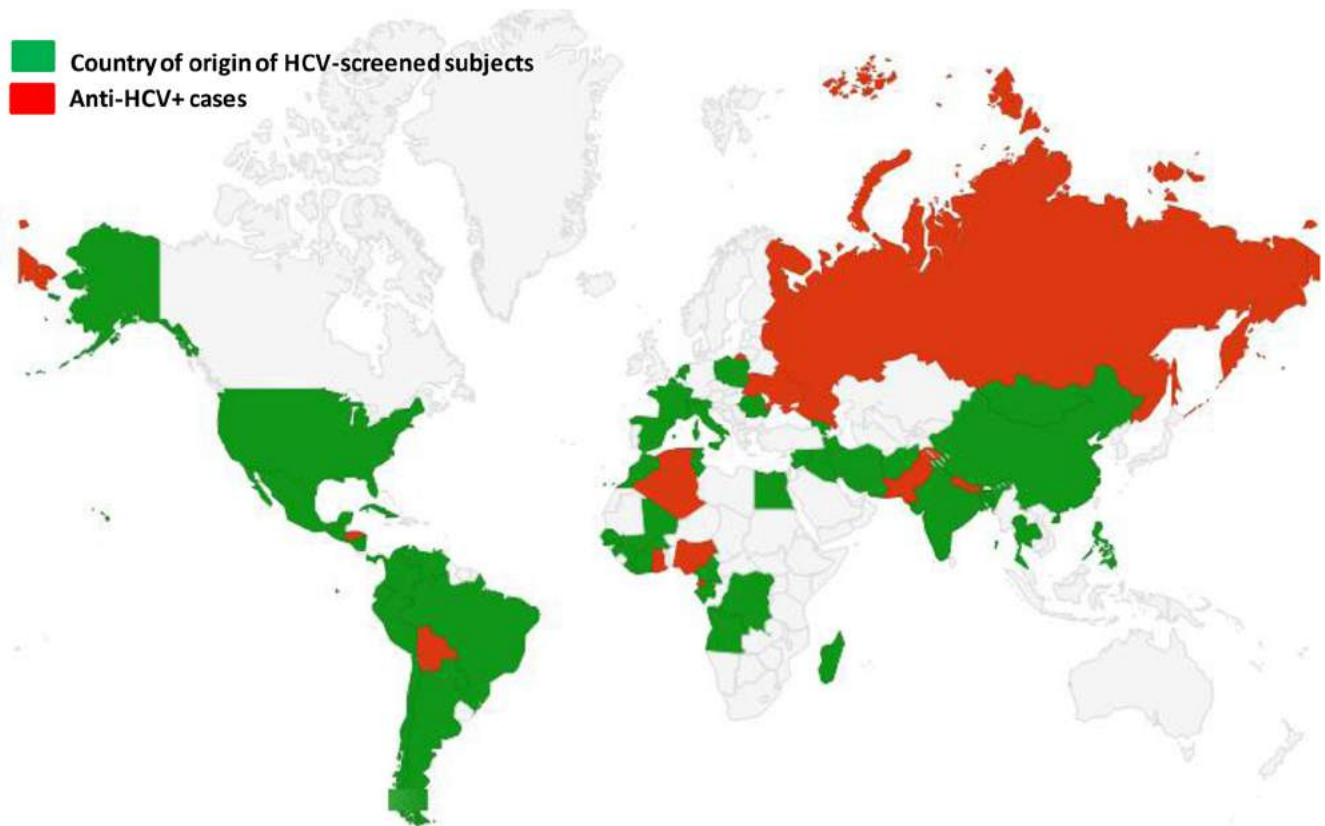

Figure: (abstract: PO-2047)

**PO-2059**  
**Characterizing stigma related to non-alcoholic fatty liver disease (NAFLD) and obesity: a Twitter discourse analysis**

Jeffrey Lazarus<sup>1</sup>, Shira Zelber-Sagi<sup>2,3</sup>, Christine Kakalou<sup>4</sup>, Adam Palayew<sup>5</sup>, Christina Karamanidou<sup>4</sup>, Christos Maramis<sup>4</sup>, Pantelis Natsiavas<sup>4</sup>, Marcela Villota<sup>1</sup>, Camila Picchio<sup>1</sup>, Carrieri Patrizia<sup>6</sup>. <sup>1</sup>Barcelona Institute for Global Health (ISGlobal), Hospital Clínic, University of Barcelona, Barcelona, Spain; <sup>2</sup>Department of Gastroenterology Tel Aviv Medical Center, Tel Aviv, Israel; <sup>3</sup>School of Public Health, University of Haifa, Haifa, Israel; <sup>4</sup>Institute of Applied Biosciences, Centre for Research and Technology Hellas, Thessaloniki, Greece; <sup>5</sup>McGill Department of Epidemiology, Biostatistics, and Occupational Health, Montreal, Canada; <sup>6</sup>Aix Marseille Univ, INSERM, IRD, SESSTIM, Sciences Economiques and Sociales de la Santé and Traitement de l'Information Médicale, Marseille, France  
 Email: Jeffrey.Lazarus@isglocal.org

**Background and aims:** Non-alcoholic fatty liver disease (NAFLD) and non-alcoholic steatohepatitis (NASH) are stigmatised conditions, partly due to “non-alcoholic” being in the name, but also because obesity is the most common comorbidity. Stigma is pervasive in social media and can contribute to reduced care-seeking and poorer health outcomes for those with NAFLD and NASH. We examined how stigma concerning NAFLD, NASH and obesity manifest on the social media platform Twitter.

**Method:** We retrieved Twitter data from May to December 2019 by using self-developed software and lexicon for NAFLD, NASH and stigmatising obesity terms. Next, three experts independently annotated a random data sample. We initially identified stigma and

obesity tweets that intersected with NAFLD/NASH, but due to the limited number of posts identified, we conducted a secondary analysis with a new subset of data with tweets only referring to obesity. Over 5, 000 tweets of the obesity dataset were annotated as either positive, neutral or negative (stigmatising); this corpus was used as a training set for a self-made Natural Language Processing software, which was used to identify sentiment clusters on 193, 747 randomly sampled tweets, exploiting a machine learning approach.

**Results:** After omission of tweets that were not in English (<10%), we retrieved 16, 835 tweets for NAFLD and 2, 376 for NASH from around the world (Figure). Upon sampling a subsection of these tweets (1, 130 for NAFLD and 535 for NASH), we found that there was limited NAFLD and NASH discourse on Twitter relating to obesity (NAFLD: 14.1%; NASH: 8.0%) and stigma (NAFLD: 2.2%; NASH: 0.5%) and that, overall, tweet content involved scientific discourse (NAFLD: 11.8%; NASH: 16.7%) and general liver information (NAFLD: 43.5%; NASH: 24.8%). By contrast, for the analysis of the 193, 747 classified obesity tweets, the algorithm classified 40% of tweets as relevant and, of this group, 85.2% were negative (stigmatising), 13.7% were neutral and 1.0% were positive.

**Conclusion:** NAFLD related tweets mostly indicate an unmet need for information. The stigmatising content of tweets related to obesity was frequent and its dissemination on social media can exacerbate stigmatising attitudes. As obesity-related stigma is associated with reduced engagement in care and lifestyle modification, which is the recommended treatment for NAFLD, interventions to further investigate and potentially reduce stigma in social media should be included in the liver health agenda.

Adjusted <i>P</i> value				9.39E-57		0.72		1.00		0.14		1.00		1.00		1.00

**Background and aims:** India has a significant burden of hepatitis C virus (HCV) infection and has committed to achieving national elimination by 2030. This will require a substantial scale-up in access to testing and treatment. The “HEAD-Start Project” in Delhi compared the feasibility and effectiveness of three different models of decentralised HCV testing and treatment among the general population.

**Method:** A prospective observational study was conducted using HCV rapid diagnostic tests (RDTs) to were used to screen the general population at either:—Arm 1: 5 district hospital (DH) outpatient clinics (one-stop shop for testing and treatment), Arm 2: 15 polyclinics (PCs) with referral to DH for viral load (VL) testing and treatment, and Arm 3: 62 screening camps (SCs) with referral to DH for treatment.

**Results:** Between January and September 2019, 37, 425 participants were screened for HCV, 21, 792 (58%) in Arm 1, 9, 822 (26%) in Arm 2, and 5, 811 (16%) in Arm 3. The median (IQR) age of participants was 35 (26–48) years, with 50.4% male and 49.6% female. Positivity rates were 2.1% (Arm 1, 3.1%; Arm 2, 0.4%; and Arm 3 1.1%; adjusted *p* <0.001 (comparing all arms)). Arm 1 also had consistently high levels of uptake of VL (98.3%), and treatment (85.4%), in contrast to lower VL uptake (51.2%) in Arm 2, and lower treatment uptake in Arm 3 (38.5%).

**Conclusion:** Delivery of testing and treatment at a single site (district hospitals) resulted in a higher yield of HCV seropositive cases and treatment uptake compared with decentralised testing sites of polyclinics and testing camps and referral for VL and/or treatment to the DGH. Lessons for implementation and scale-up include opportunity for higher case-finding yield among outpatients at district hospitals with good linkage to care, as well as potential for future provision of HCV testing with treatment at polyclinics.

**PO-2093**

**Micro-elimination of hepatitis C achieved in HIV co-infected persons in Slovenia: analysis of HCV infection in a national HIV cohort**

Jasna Cernosa<sup>1</sup>, Zala Pirnat<sup>1</sup>, Janez Tomažič<sup>1,2</sup>, Tomaz Vovko<sup>1</sup>, Blaž Pečavar<sup>1</sup>, Gabriele Turel<sup>1</sup>, Maja Plesko<sup>1</sup>, Manja Kordis<sup>1</sup>, Barbara Kokosar Ulcar<sup>1</sup>, Mateja Zalaznik<sup>1</sup>, Jelka Meglič<sup>1</sup>, Mario Poljak<sup>3</sup>, Jeffrey Lazarus<sup>4</sup>, Mojca Maticic<sup>1,2</sup>. <sup>1</sup>UKC-Clinic for Infectious Diseases and Fever Conditions, Ljubljana, Slovenia; <sup>2</sup>Faculty of Medicine, University of Ljubljana, Ljubljana, Slovenia; <sup>3</sup>Institute of Microbiology and Immunology, Faculty of Medicine, University of Ljubljana, Slovenia; <sup>4</sup>ISGlobal, Barcelona, Spain  
Email: jasnacernosa@gmail.com

**Background and aims:** In Slovenia, management of all persons infected with the human immunodeficiency virus (HIV) among whom men who have sex with men (MSM) predominate, has been centralised at one medical centre, where regular hepatitis C virus (HCV) screening has been performed since the mid-1990s. With the advent of direct-acting antivirals, a national “test-and-treat” strategy for HCV elimination in this sub-population was launched. The aim of this study was to evaluate epidemiological, virological and clinical characteristics of HIV/HCV co-infected and compare them with an HIV mono-infected cohort.

**Method:** All HIV-infected persons in Slovenia that tested anti-HCV positive were identified from the national HIV cohort registry at the Clinic for Infectious Diseases, University Medical Centre Ljubljana, and included retrospectively. Those who presented with HCV RNA positivity were further analysed. Demographic, virological and clinical data were extracted from their medical records and compared to a control group of 90 randomly selected HIV mono-infected patients, currently managed at the same clinic.

**Results:** Of 704 HIV-infected persons, 52 (7.4%) presented as anti-HCV. Twelve were excluded: 6/52 (11.5%) died prior to HCV treatment, 2/52 (3.8%) were lost to follow-up and 4/52 (7.7%) spontaneously cleared HCV with no reinfection. Of 40 HIV/HCV RNA positive (82.5% males), 38/40 (95%) were successfully treated for HCV and 2/40 (5%) are currently receiving treatment. Genotype 1 was predominant (19/38, 50%), followed by genotypes 4 (11/38, 28.9%), 3 (7/38, 18.4%), 1+4 (1/38, 2, 6%) and 2a/2c (1/38, 2.6%). At first presentation, HCV/HIV coinfection was detected in 14/40 (35%); HCV was diagnosed prior to HIV infection in 4/40 (10%), and during HIV infection in 22/40 (55%). HCV reinfection was detected in 7/40 (17.5%): 4/7 (57.1%) MSM, 2/7 (28.6%) injected drugs, and 1/7 (14.3%) reported both. Compared to HIV-mono-infected, HIV/HCV coinfection were significantly younger at first presentation (*p*=0.000859), when they significantly less frequently presented with HIV latency period (*p*=0.199) and end-stage HIV infection (*p*=0.0077), and they more frequently reported injecting drug use (30% vs. 7.2%) whereas significantly fewer were MSM (*p*=0.0052).

**Conclusion:** In Slovenia, HCV micro-elimination in HIV-infected persons was achieved in 2018. However, regular screening of persons living with HIV, particularly those at high-risk of infection or reinfection still needs to continue.

PO-2097

### Impact of COVID-19 pandemic on referral of patients with liver disease to a liver transplant center

Giacomo Germani<sup>1</sup>, Monica Pellone<sup>1</sup>, Alberto Ferrarese<sup>1</sup>, Alberto Zanetto<sup>1</sup>, Sarah Shalaby<sup>1</sup>, Giovanni Carretta<sup>2</sup>, Daniele Donato<sup>2</sup>, Umberto Cillo<sup>3</sup>, Paolo Feltracco<sup>4</sup>, Paolo Persona<sup>4</sup>, Eugenio Serra<sup>4</sup>, Martina Gambato<sup>1</sup>, Marco Senzolo<sup>1</sup>, Francesco Paolo Russo<sup>1</sup>, Patrizia Burra<sup>1</sup>. <sup>1</sup>Padova University Hospital, Multivisceral Transplant Unit, Padova, Italy; <sup>2</sup>Padova University Hospital, Directional Hospital Management, Padova, Italy; <sup>3</sup>Padova University Hospital, Hepatobiliary Surgery and Liver Transplant Center; <sup>4</sup>Padova University Hospital, Anesthesia and Intensive Care Unit, Padova, Italy  
Email: germani.giacomo@gmail.com

**Background and aims:** Access to liver transplantation (LT) can be affected by several barriers resulting in delayed referral and increased risk of mortality. Therefore, hub-and-spoke networks have been implemented in order to manage patients with liver disease. However, the COVID-19 pandemic may have significantly changed this scenario, as most of medical resources have been allocated for the care of patients with SARS-CoV-2 infection. This study aimed to assess the influence of COVID-19 pandemic on referrals of patients with liver disease to a LT Center.

**Method:** An integrated referral program was developed since October 2017 at Multivisceral Transplant Unit, Padova University Hospital. All consecutive adult patients with liver disease referred for the first time using this referral program from October 2017 to December 2020 were prospectively collected. Clinical characteristics were analyzed overall and according to era of referral (pre-COVID-19 era:10.2017–02.2020; COVID-19 era:03.2020–12.2020).

**Results:** 231 patients with liver disease were referred over the study period (men 61%, mean  $\pm$  SD age: 54  $\pm$  10 years). End-stage liver disease was the most common underlying condition (78.3%), followed by acute liver injury/acute liver failure (17.3%). During COVID-19 pandemic, the rate of referred patients showed a stable trend, if compared with the previous period (5.1 patients/month vs. 6.1 patients/month), also when only in-patient referrals were considered (pre-COVID-19 era vs. COVID-19 era: 2.9 vs. 3.2 patients/month). Considering 181 patients with cirrhosis, underlying etiology ( $p=0.22$ ), severity of liver disease (MELD score: 21  $\pm$  7 vs. 20  $\pm$  8;  $p=0.44$ ), and inpatient referrals (42% vs. 51%;  $p=0.34$ ) did not differ between pre-COVID-19 and COVID-19 eras. There was a decreasing rate of ICU admission for cirrhosis-related complications during COVID-19 pandemic (22% vs. 34%;  $p=0.3$ ), with an increased in-hospital transplant-free mortality (41% vs. 30%;  $p=0.3$ ). The overall rate of ICU admission of inpatients showed a decreasing, although not statistically significant trend during COVID-19 pandemic (18.7% vs. 31.7%;  $p=0.16$ ).

**Conclusion:** Our results did not show a significant decrease in the number of referrals and type of indications during the COVID-19 pandemic; however, the in-hospital transplant free mortality showed an increasing trend, which could be the consequence of a decreasing rate of ICU admissions. Taken together, these factors confirmed the importance of a referral network for the care of patients with liver disease, but also how the COVID-19 pandemic may influence the short-term outcome of patients with liver disease.

PO-2103

### Changhua-Integrated Program to Stop Hepatitis C Infection (CHIPS-C) of Taiwan

Tsung-Hui Hu<sup>1</sup>, Wei-Wen Su<sup>2</sup>, Chi-Chao Yang<sup>3</sup>, Chi-Chieh Yang<sup>4</sup>, Sam Li-Sheng Chen<sup>5</sup>, Yen-Po Yeh<sup>6</sup>, Hsiu-Hsi Chen<sup>7</sup>. <sup>1</sup>Kaohsiung Chang Gung Memorial Hospital, and Chang Gung University College of Medicine, Kaohsiung, Taiwan, Taiwan; <sup>2</sup>Changhua Christian Hospital, Changhua, Taiwan, Changhua, Taiwan; <sup>3</sup>Changhua Hospital, Ministry of Health and Welfare, Changhua, Taiwan; <sup>4</sup>Show Chwan Memorial Hospital, Changhua, Taiwan, Changhua, Taiwan; <sup>5</sup>School of Oral Hygiene, College of Oral Medicine, Taipei Medical University, Taipei,

Taiwan, Taipei, Taiwan; <sup>6</sup>Changhua County Public Health Bureau, Changhua, Taiwan, Changhua, Taiwan; <sup>7</sup>Graduate Institute of Epidemiology and Preventive Medicine, College of Public Health, National Taiwan University, Taipei, Taiwan  
Email: dr.hu@msa.hinet.net

**Background and aims:** Taiwan government has set an ambitious target of achieving 80% of treatment coverage for the patients with HCV by the year 2025. We selected a demonstration region, Changhua County, which is located in the central part of Taiwan, has 27 townships comprising a total of 1,289,000 residents. The prevalence rate of hepatitis C virus (HCV) infection was 3.4% in the population aged more than 40 years based on previous study. We developed a novel integrated model of HCV treatment delivery by combining the micro-elimination approach for special and general populations of patients since 2019 in Changhua country, led by the county's health authority.

**Method:** The present program is quite different from the previous screening models held by single or elective hospital in the past. There will be two population targets. For general population, HCV RNA screening will be conducted in 27 township health centers for those anti-HCV were positive (3803 patients since 2012 surveillance) but without tests of viremia. Furthermore, we plan to screen new 40,000 residents in three years and identify approximately 1360 (40,000  $\times$  3.4%) patients infected with HCV who have not been discovered. For the focused populations, the patient lists of special populations were all already established in the system of Changhua County Public Health Bureau. The screening and treatment will further be performed in hemodialysis centers (ESRD), prison (prisoners), health centers (DM and CKD), and hospitals (ESRD, CKD, DM, HIV-HCV co-infection, and IV drug users).

**Results:** The achievement of HCV micro-elimination: defined as the definition of HCV elimination by WHO criteria as diagnosis more than 90% and treatment more than 80% of the population. Until now, micro-elimination was achieved in four special populations. They are dialysis patients in 31 hemodialysis centers (prevalence 11.0% of 3657 patients, 100% diagnosed and 94% treated); HIV infected patients in five responsible hospitals (prevalence 44.55% of 855 patients, 99.77% diagnosed, and 89.66% treated); intravenous drug addicts with replacement therapy in five responsible hospitals (prevalence 90.34% of 384 patients, 99.74% diagnosed, and 95.54% treated); prisoners (prevalence 39.77% of 3258 patients, 92.38 diagnosed, 90.97% treated). We have also achieved micro-elimination of diabetes or chronic kidney disease population (prevalence 6.1% of 14309 patients, 91.9% diagnosed, and 91.1% treated) in 27 local health centers of the county. For the patients of diabetes and chronic kidney disease, who have been registered in all hospitals of the county as 92175 patients (prevalence rate 6.7%), 73% were screened for HCV, and 81% of documented HCV were treated until now.

**Conclusion:** It is expected to accelerate the achievement of hepatitis C eradication via the novel community model established in this project (led by public authority instead of hospital).

Email: Jeffrey.Lazarus@isglobal.org

**Background and aims:** Non-alcoholic fatty liver disease (NAFLD) is the most prevalent chronic liver disease globally, causing a substantial burden of ill health. However, it is widely absent within national health policies and strategies. This global study aimed to assess how prepared countries are to address NAFLD.

**Method:** Liver health experts from 162 countries were invited to participate in a survey covering relevant national policies and strategies, guidelines, civil society engagement, clinical management and epidemiologic data. Where feasible, survey data were validated against documents and where needed clarifications sought from country experts. Data were coded into 6 domains (policies, guidelines, civil awareness, epidemiology, detection and management) and responses categorised as high-, medium- or low-level based on predefined criteria. Multiple correspondence analysis (MCA) was conducted and the coordinates along the first dimension were used as raw untransformed scores for each country. Three reference standards (high, medium and low) were included to contextualize responses, with overall policy scores ranging from 0 to 100.

**Results:** Experts from 102 countries completed the survey (median experts per country team = 5; min = 1, max = 9, IQR = 4). No country was in the high-level for all 6 domains. For 5 domains, the smallest

Figure: Global NAFLD policy index score and country rank (n = 102).

Figure: (abstract: PO-2108)

## POSTER PRESENTATIONS

proportion of countries were in the high-level category while the largest proportion were in the low-level, the exception being the guidelines domain, where the smallest proportion of countries were in the medium-level. For the policies domain, all countries were in the low-level. For detection, Belgium, the Czech Republic, India, Iran, Lebanon and Moldova were in the high-level. For the epidemiology domain, Australia, Germany, Iran and Spain were in the high-level. The first dimension of the MCA explained 55.9% of the variation. Iran (51.8) had the highest overall preparedness score, followed by India (40.5) and the United Kingdom (35.1). Thirty-two countries (31%) had a preparedness score of zero (Figure).

**Conclusion:** No country was found to be well prepared to address NAFLD, with a large proportion of countries having an overall score of zero. Our findings highlight the need for greater attention for NAFLD within national health agendas. As positive scores do not necessarily indicate policy adoption, e.g., into routine clinical practice, these results can assist countries in identifying priority actions to improve their preparedness.

### PO-2127

#### The road to hepatitis C virus elimination: entering the final stretch or chasing a moving finish line?

Ragnheidur H. Fridriksdottir<sup>1</sup>, Sigurdur Olafsson<sup>1,2</sup>, Valgerdur Runarsdottir<sup>3</sup>, Ingunn Hansdottir<sup>3,4</sup>, Thorarinn Tyrfinngsson<sup>3</sup>, Thorvardur J. Björnsson<sup>1,2</sup>, Birgir Johannsson<sup>6</sup>, Bryndis Sigurdardottir<sup>6</sup>, Arthur Löve<sup>2,7</sup>, Guðrún Erna Baldvinsdóttir<sup>7</sup>, Ubaldo Benitez Hernandez<sup>5</sup>, Maria Heimisdóttir<sup>8</sup>, Magnús Gottfredsson<sup>2,5,6</sup>. <sup>1</sup>Landspítali-National University Hospital of Iceland, Department of Gastroenterology and Hepatology, Reykjavik, Iceland; <sup>2</sup>University of Iceland, Faculty of Medicine, School of Health Sciences, Reykjavik, Iceland; <sup>3</sup>SAA National Center for Addiction Medicine, Reykjavik, Iceland; <sup>4</sup>University of Iceland, Faculty of Psychology, School of Health Sciences, Reykjavik, Iceland; <sup>5</sup>Landspítali-National University Hospital of Iceland, Department of Science, Reykjavik, Iceland; <sup>6</sup>Landspítali-National University Hospital of Iceland, Department of Infectious Diseases, Reykjavik, Iceland; <sup>7</sup>Landspítali-National University Hospital of Iceland, Department of Virology, Reykjavik, Iceland; <sup>8</sup>Icelandic Health Insurance, Reykjavik, Iceland  
Email: sigurdol@landspitali.is

**Background and aims:** The World Health Organization (WHO) set goals of eliminating hepatitis C virus infection (HCV) as a major health threat by 2030. In 2016, a nationwide program, Treatment as Prevention for Hepatitis C (TraP HepC) was initiated in Iceland, offering treatment with direct acting antivirals (DAAs) to all infected during 36 months (phase 1) followed by a second phase (ongoing) to reach remaining patients and all new and/or reinfections without restrictions. In addition, diagnostic efforts were scaled up and access to needles and syringes were improved. During the first 36 months >95% of all diagnosed in the country received treatment with DAAs and WHO service coverage targets were reached.

**Method:** We compared patient characteristics receiving first treatment with DAAs during phase 1 of TraP HepC (1/2016–2/2019) with those who subsequently entered the program (2/2019–12/2020; phase 2) using the nationwide clinical data collected in the TraP HepC program.

**Results:** During phase 1, a total of 835 infections were diagnosed in 791 individuals. Of those 729 (92%) were evaluated, and 782 treatments initiated for 705 individuals. In the second phase 140 individuals were evaluated and 127 treatments were initiated. During phase 1, 77 (11%) patients had more than one treatment initiations compared to 44 (35%) during phase 2. Mean age was lower in period 2 (45 vs 39 years). Proportion of patients with country of birth outside Iceland increased from 13% to 28%. Homelessness affected 7% and 17% in phase 1 and 2, respectively. Similarly, 84% gave history of IDU and 39% had injected recently (within 6 months) in phase 1, whereas during phase 2, 79% of patients reported IDU and 61% recent

injection. In phase 2, 46% were treated for acute infection (one positive PCR) compared to 6% in phase 1. In phase 2, 83% of patients born in Iceland had injected recently.

**Conclusion:** Although treatment responses have been excellent overall, a small population of patients who are prone to reinfections due to relapsing injection drug use and sharing of needles pose a significant challenge to elimination of HCV in the country. Furthermore, imported cases constitute an increasing proportion of new cases. Currently, patients are increasingly started on treatment immediately following diagnosis to reduce subsequent spread of HCV. In order to succeed, elimination programs need to be adaptable and responsive to changing needs of people who inject drugs and people with different backgrounds.

### PO-2131

#### A clinical and molecular epidemiological survey of hepatitis C in Blantyre, Malawi suggests an historic mechanism of transmission

Alexander Stockdale<sup>1,2</sup>, Benno Kreuels<sup>3,4</sup>, Isaac T. Shawa<sup>1,5</sup>, James Meiring<sup>6</sup>, Deus Thindwa<sup>1,7</sup>, Niza Silungwe<sup>1</sup>, Karen Chetcuti<sup>8</sup>, Elizabeth Joekes<sup>2</sup>, Maurice Mbewe<sup>1</sup>, Pratiksha Patel<sup>1</sup>, Rabson Kachala<sup>9</sup>, Priyanka Patel<sup>1</sup>, Jane Mallewa<sup>5,10</sup>, Peter Finch<sup>5,10</sup>, Chris Davis<sup>11</sup>, Rajiv Shah<sup>11</sup>, Lily Tong<sup>11</sup>, Anna da Silva Filipe<sup>11</sup>, Emma Thomson<sup>11</sup>, Anna Maria Geretti<sup>2</sup>, Melita Gordon<sup>1,2</sup>. <sup>1</sup>Malawi-Liverpool-Wellcome Trust Clinical Research Programme, Blantyre, Malawi; <sup>2</sup>University of Liverpool, Liverpool, United Kingdom; <sup>3</sup>Bernhard Nocht Institute for Tropical Medicine, Hamburg, Germany; <sup>4</sup>University Medical Center Hamburg-Eppendorf, Hamburg, Germany; <sup>5</sup>College of Medicine, Blantyre, Malawi; <sup>6</sup>University of Oxford, United Kingdom; <sup>7</sup>London School of Hygiene and Tropical Medicine, United Kingdom; <sup>8</sup>College of Medicine, Blantyre, Malawi; <sup>9</sup>Ministry of Health Malawi, Lilongwe, Malawi; <sup>10</sup>Queen Elizabeth Central Hospital, Blantyre, Malawi; <sup>11</sup>Centre For Virus Research, Bearsden, United Kingdom  
Email: a.stockdale@liverpool.ac.uk

**Background and aims:** Hepatitis C virus (HCV) is a leading cause of liver disease worldwide. There are no previous representative community HCV prevalence studies from southern Africa (with the exception of island nations) and very limited genotypic data. Epidemiological data are required to inform an effective public health response.

**Method:** We conducted a community census-based random sampling serological survey, and a hospital-based study of prospectively enrolled patients with cirrhosis and hepatocellular carcinoma (HCC) in Blantyre, Malawi. We tested participants with a 4<sup>th</sup> generation HCV antigen/antibody ELISA (Monolisa, Bio-Rad), confirmed with PCR (GeneXpert, Cepheid), used line immunoassay (Inno-LIA HCV, Fujiribio) for RNA-negative participants. We did target-enrichment whole-genome HCV sequencing (NextSeq, Illumina).

**Results:** Among 96,386 censused individuals, we randomly selected 1661 people aged ≥16 years for HCV testing and sampled in participants' homes. Population-standardised HCV RNA prevalence was 0.2% (95% CI 0.1–0.5). Among 238 prospectively recruited hospital patients, HCV RNA prevalence was 1.9% in patients with cirrhosis and 5.0% with HCC. Mapping showed that HCV RNA+ patients were from peri-urban areas surrounding Blantyre. Community and hospital HCV RNA+ participants were older than comparator HCV RNA negative populations (median 53 vs 30 years for community,  $p=0.01$  and 68 vs 40 years for hospital,  $p<0.001$ ). Endemic HCV genotypes were 4v (50%), 4r (30%) and 4w (10%).

**Conclusion:** In the first representative census-based community serological study in southern Africa, HCV was uncommon in the general population, centred on peri-urban areas, and was attributable for <5% of liver disease. HCV was observed among older people, suggesting an historic mechanism of transmission. Genotype 4r, which has been associated with treatment failure with ledipasvir and daclatasvir, is endemic.

Figure: Maximum likelihood phylogenetic tree: full-length hepatitis C sequences from Malawi aligned to 117 genotype 4 sequences

**PO-2152**

**Modelling clinical outcomes of NASH in the United States stratified by presence of type 2 diabetes**

Zobair Younossi<sup>1,2</sup>, Radhika Tampi<sup>2</sup>, Gail Fernandes<sup>3</sup>, Joe Yang<sup>3</sup>, Adnan Alsumali<sup>3</sup>, Hardik Goswami<sup>3</sup>, Fatema Nader<sup>4</sup>. <sup>1</sup>Inova Health System, Department of Medicine, Falls Church, United States; <sup>2</sup>Inova Health System, Betty and Guy Beatty Center for Integrated Research, Falls Church, United States; <sup>3</sup>Merck, Kenilworth, United States; <sup>4</sup>Center for Outcomes Research in Liver Diseases, DC, United States  
Email: zobair.younossi@inova.org

**Background and aims:** Certain populations with non-alcoholic steatohepatitis (NASH) are at higher risk of progression, leading to increased rates morbidity and mortality. We aim to estimate the clinical outcomes of the prevalent NASH population in the U.S. as of 2019 and compare outcomes stratified by presence or absence of type 2 diabetes (T2DM).

**Method:** We used a Markov cohort model to compare the clinical outcomes of NASH patients with T2DM to those with NASH without T2DM. Nine health states were included—four liver fibrosis stages (F0-F3), compensated and decompensated cirrhosis (CC and DCC), hepatocellular carcinoma (HCC), first year post-liver transplant (1yPLT) and post liver transplant beyond first year (PLT) states. Three mortality states were used including background all-cause mortality, cardiovascular mortality, and liver-related mortality. The time horizon was 20 years with 1-year cycles. Prevalence of NASH and T2DM as well as transition probabilities were taken from literature. Health utility values were derived from utility scores from patients

with NASH and used to calculate quality-adjusted life years (QALYs) which were discounted 3% annually.

**Results:** Total NASH prevalence in the adult U.S. population was 11.2 million. Within this population, 5.3 million (47%) had diagnosed T2DM. Over the twenty-year horizon, NASH patients without T2DM accounted for 61.4 thousand LTs, 1.1 million liver-related deaths, 0.87 million cardiovascular deaths, and 50 million QALYs accumulated. The proportion of the NASH population with T2DM accounted for 46.2 thousand LTs, 1.2 million liver-related deaths, 0.9 million cardiovascular deaths, and 40 million QALYs accumulated.

**Conclusion:** Although the proportion of NASH patients without T2DM is larger than proportion of NASH with T2DM, liver-related and cardiovascular mortality is higher in patients with NASH and T2DM. In addition, the NASH with T2DM is expected to accumulate fewer QALYs than NASH without T2DM. Overall, presence of T2DM in NASH is associated with worse outcomes

Figure: Table: Clinical outcomes of total NASH cohort when stratified by presence of T2DM

	Cohort Size	Liver Transplants	Liver Related Deaths	Cardiovascular Deaths	QALYs
NASH without T2DM	5,914, 752 (52.7%)	61,473 (57.1%)	1,132, 808 (47.5%)	870, 327 (49.3%)	50, 141, 675
NASH with T2DM	5,301, 294 (47.3%)	46,201 (42.9%)	1,251, 795 (52.4%)	895, 953 (50.7%)	40, 407, 165
Total NASH Cohort	11,216, 046

## POSTER PRESENTATIONS

**Background and aims:** The aim of the present study was to determine the recent changing trends in the etiology and other clinical features of cirrhotic patients in Turkey.

**Method:** The study group included cirrhotic patients who were admitted to outpatient hepatology clinics in 24 tertiary centers of Turkey between July 2019 and December 2020. Cirrhosis was defined clinically, biochemically, radiologically and histologically when available. International Classification of Diseases-10 codes were used to identify cirrhosis and its complications. Data were entered in an electronic case report form (CRF) from each center and reviewed retrospectively. Etiology of cirrhosis in present data set is compared with the historical cirrhosis series.

**Results:** A total of 4836 cirrhotic patients, with at least 6 months of follow-up were included to the study. The mean age was  $61.5 \pm 13.7$  years and the patients were predominantly male (55%). Forty-five per cent of the patients had compensated and 55% of the patients had decompensated cirrhosis: 48% of the patients were classified as Child-Pugh class A, 38% as Child-Pugh class B and 14% as Child-Pugh class C. Ascites (54%) was the most common decompensating event, followed by hepatic encephalopathy (15%), variceal bleeding (15%) and hepatorenal syndrome (1.8%). The mean MELD and MELD Na scores were  $11.4 \pm 5.0$  and  $11.9 \pm 5.8$ , respectively. Twenty-one percent of the patients had high MELD score ( $>15$ ), and 19% were on the transplant waiting list.

Chronic viral hepatitis was the most common cause of cirrhosis (43.2%). Hepatitis B virus (HBV) infection was the main etiology in the overall cohort (31.2%), followed by cryptogenic cirrhosis (CC, 19.2%), hepatitis C virus (HCV) infection (12.0%), non-alcoholic fatty liver disease (NAFLD)-related cirrhosis (11.9%), alcohol-related liver disease (9.6%), autoimmune liver diseases (6.2%) and miscellaneous (9.9%). Interestingly, the proportion of CC was higher than expected. On admission, 517 patients (10.6%) had HCC and 123 (2.5%) had an extrahepatic malignancy. Female breast cancer (16%), colon cancer (14%) and hematologic malignancy (14%) were the most common extrahepatic malignancies.

**Conclusion:** HBV and HCV are the main etiology of cirrhosis in Turkey. The prevalence of HBV-related cirrhosis is declining (when compared to historic control it was nearly 45%), while the prevalence of HCV and NAFLD-related cirrhosis are increasing.

### PO-2387

#### Implementation of a coordinated hepatocellular carcinoma screening program in an outpatient liver center

Joana Vieira Barbosa<sup>1,2</sup>, Qua Tran<sup>3</sup>, Brian Malinn<sup>4</sup>, Rosa L. Yu<sup>5</sup>, Michael Curry<sup>4</sup>, Michelle Lai<sup>4</sup>. <sup>1</sup>Beth Israel Deaconess Medical Center, Harvard Medical School, Division of Gastroenterology and Hepatology; <sup>2</sup>Lausanne University Hospital and University of Lausanne, Division of Gastroenterology and Hepatology, Lausanne, Switzerland; <sup>3</sup>Beth Israel Deaconess Medical Center, Harvard Medical School, Pharmacy Department, Boston, United States; <sup>4</sup>Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, Division of Gastroenterology and Hepatology, Boston, United States; <sup>5</sup>Beth Israel Deaconess Medical Center, Harvard Medical School, Department of Internal Medicine, Boston, United States  
Email: jvieirab@bidmc.harvard.edu

**Background and aims:** Hepatocellular carcinoma (HCC) is a leading cause of cancer-related death worldwide. Although guidelines recommend regular HCC screening in all patients with cirrhosis, adherence is often suboptimal and measures to optimize HCC surveillance are lacking. We aimed to investigate the feasibility and success rate of implementing a targeted HCC screening program to improve patient surveillance.

**Method:** We analyzed data from consecutive adult patients with cirrhosis evaluated in the Beth Israel Deaconess Medical Center outpatient Liver Clinic from 2018 to 2020. Patients with cirrhosis were identified from our internal electronic database, using International Classification Diseases-10 codes. Patients with a

previous diagnosis of HCC or deceased were excluded. Loss to follow-up (LTFU) was defined as the absence of liver appointment and/or abdominal ultrasound in the last 9 months. Patients with LTFU and their primary providers were contacted by postal mail and electronic mail via a secure patient portal with a response card to send back with either request to schedule an appointment or to inform us that they are followed elsewhere.

**Results:** Out of 1742 consecutive adult patients with cirrhosis, there were 461 (26.5%) LTFU. Among those LTFU, 273 (59.2%) were male, mean age was  $59 \pm 12$  years and 312 (67.7%) were of Caucasian race. We obtained 51 (11.1%) mail replies from patients and 56 (12.1%) mail replies from primary providers. Over a period of 7 months since the implementation of the HCC screening program, a total of 82/461 (17.8%) were successfully rescheduled, of whom 30/82 (36.6%) had presented with a decompensated cirrhosis at their last visit. 25/461 (5.4%) patients responded declining to reschedule likely due to getting care elsewhere. We observed no significant differences in demographic variables including age, sex, ethnicity, insurance or marital status, or clinical parameters, such as BMI, diabetes, hypertension, dyslipidemia, FIB-4 values, etiology of cirrhosis or rates of decompensated cirrhosis, between patients successfully rescheduled versus those unable to FU.

**Conclusion:** Implementation of a coordinated HCC screening intervention using postal and electronic mail resulted in 18% rate of response from patients previously LTFU, with 77% of patients not responding. Additional outreach strategies—such as telephonic contact—to increase response rates and improve outcomes warrant further investigation in further studies.

### PO-2424

#### An interactive, country specific, online tool to assess the cost-effectiveness of different hepatitis C testing pathways to inform hepatitis C elimination

Madeline Adee<sup>1</sup>, Yueran Zhuo<sup>1,2,3</sup>, Tiannan Zhan<sup>1</sup>, Rakesh Aggarwal<sup>4</sup>, Muhammad Radzi Abu Hassan<sup>5</sup>, Jagpreet Chhatwal<sup>1,3</sup>, Sonjelle Shilton<sup>6</sup>. <sup>1</sup>Massachusetts General Hospital Institute for Technology Assessment, Boston, United States; <sup>2</sup>Mississippi State University College of Business; <sup>3</sup>Harvard Medical School; <sup>4</sup>Jawaharlal Institute of Postgraduate Medical Education and Research, Puducherry, India; <sup>5</sup>Clinical Research Centre, Hospital Sultanah Bahiyah, Malaysia; <sup>6</sup>Foundation for Innovative New Diagnostics  
Email: madee@mgh.harvard.edu

**Background and aims:** In order to meet the World Health Organization goal of eliminating hepatitis C virus (HCV) as a public health threat by 2030, HCV testing must be scaled up. However, most countries do not have widespread testing programs in place, and cost is a burden to implementation. We created an interactive online tool to allow countries to assess the cost-effectiveness of custom testing pathways, and we present a case study evaluating alternative testing pathways in Malaysia.

**Method:** We utilized a previously validated microsimulation model of HCV disease progression, where states are defined by METAVIR stages F0-F4, decompensated cirrhosis (DC), hepatocellular carcinoma (HCC), and liver-related death (LRD). We adapted this model to simulate the epidemiology of HCV in different countries. Country-specific model results are then run in an online tool, where users can input HCV antibody and viremia prevalence, target screening rate, and direct-acting antiviral (DAA) cost. Users can compare custom diagnostic pathways—with sequential steps of screening, confirmation, liver staging, and monitoring—where they can specify the test used, cost, and patient follow-up rate for each step of each pathway. In a high-risk cohort of 10,000 people with a viremia prevalence of 11.5% in Malaysia, we evaluated three testing pathways: (P1) patients moved at each step, (P2) patients moved at each step with higher follow-up, and (P3) one-stop shop. We compared them to no screening (NS). All persons in the cohort received antibody screening, and subsequent follow-up rates were pathway specific. Cost per

Figure: (abstract: PO-2424)

course of treatment was \$300 (USD), and results were analyzed over a 30-year time horizon.

**Results:** The one-stop shop pathway (P3), which eliminated loss to follow for confirmation testing by completing RNA testing on site immediately for all antibody positive, was cost-saving compared to the other pathways and to no screening. Per cohort of 10,000 people in the general population of Malaysia, this pathway would result in saving \$7.2 million (USD), gaining 1,882 QALYs, and prevent 173 cases of DC, 101 cases of HCC, and 175 HCV-related deaths compared to no screening (Figure). The majority of cost-savings comes from averted HCV sequelae management costs.

**Conclusion:** Our interactive tool can help identify optimal HCV testing pathways under different settings of HCV epidemiology, costs of different tests, patient follow-up rates, and on-site availability of diagnostics.

**PO-2483**

**The impact of universal hepatitis B vaccine on the trend of hepatitis B virus attributable liver cancer from Global Burden of Disease Study 2017**

Wen-Qiang He<sup>1</sup>, Li Chenxi<sup>2</sup>. <sup>1</sup>University of New South Wales; <sup>2</sup>Independent Researcher, Australia  
Email: wen-qiange@unsw.edu.au

**Background and aims:** Few studies have reported that the neonatal vaccination against hepatitis B virus (HBV) has reduced the risk of liver cancer. We aim to understand the trends of HBV-attributable liver cancer overall and by age as well as the impact of universal neonatal HBV vaccine on HBV-attributable liver cancer by age, in particular among children, adolescents and young adults.

**Method:** We retrieved data from Global Burden Disease study to estimate trends of HBV-attributable liver cancer by region and age from 1990 to 2017 and Hepatitis B 3<sup>rd</sup> dose (HepB3) vaccine data from World Health Organization to assess its impact on these trends for children (0–14 years), adolescents and young adults (15–29 years), adults (30–64 years) and elders (65+ years). Change of cancer cases, age-standardized incidence rate (ASR), and estimated annual percentage change (EAPC) were used to quantify the trends of HBV-attributable liver cancer.

**Results:** Although the global number of HBV-attributable liver cancer has increased from 219,830 (95% UI: 201,200–241,570) in 1990 to 403,960 (95% UI: 378,260–434,130) in 2017, it decreased among children (from 2,080 to 1,430), adolescents and young adults (from 10,890 to 9,090). In terms of ASR, overall reduction was observed globally by an average of –0.45% (95% CI: –0.62 to –0.29) per year in the same period with the highest reduction in adolescents and young adults at EAPC of –3.02 (95% CI: –3.57 to –2.46). As for six regions by HepB3 vaccine coverage, apart from the ten countries without universal

vaccination against HBV till the end of 2017, the average national HepB3 vaccine coverage and year of vaccination of the rest 185 countries or territories was 84% (range: 20% to 98.6%) and 18 years (range: 3 to 31 years). Over the period, decrease of cancer cases was only observed from countries with vaccine coverage greater than 80% for children (from 1,435 to 731) and adolescents and young adults (from 9,175 to 6,815). The ASR has decreased from all the five regions with universal HBV vaccination program, while it has increased in the region without universal vaccination and the highest increase was found among children with EAPC of 1.97 (95% CI: 1.71–2.23).

**Conclusion:** Significant reduction of HBV-attributable liver cancer among children was mainly due to the universal HBV vaccination. However, the increasing trend of HBV-attributable liver cancer in region without universal HBV vaccination suggested the necessity of introducing universal immunization against HBV.

**PO-2586**

**Uptake of Direct Acting Antivirals for treatment of hepatitis C in human immunodeficiency virus/hepatitis C co-infected children and adolescents in the Russian Federation**

Fariyah Malik<sup>1</sup>, Giuseppe Indolfi<sup>2</sup>, Inga Latysheva<sup>3</sup>, Evgeny Voronin<sup>3</sup>, Rebecca Lundin<sup>4</sup>, Nataliia Levina<sup>5</sup>, Claire Thorne<sup>1</sup>, Anna Turkova<sup>6</sup>.  
<sup>1</sup>UCL Great Ormond Street Institute of Child Health, London, United Kingdom; <sup>2</sup>University of Florence and Meyer Children's University-Hospital, Department Neurofarba, Firenze, Italy; <sup>3</sup>Republican Clinical Hospital of Infectious Diseases, Saint-Petersburg, Russian Federation; <sup>4</sup>Hospital Burlo Garofolo, Institute for Maternal and Child Health, IRCCS, Trieste, Italy; <sup>5</sup>Fondazione Penta Onlus, Padova, Italy; <sup>6</sup>Medical Research Council Clinical Trials Unit, University College London, London, United Kingdom  
Email: fariyah.malik.18@ucl.ac.uk

**Background and aims:** Direct acting antivirals (DAAs) have revolutionised hepatitis C (HCV) treatment in adults and children. HIV/HCV co-infected children are at risk of advanced disease progress and are identified by professional society guidelines as a priority group for HCV treatment. The Russian Federation (RF) Paediatric HIV Programme is committed to treating all HIV/HCV children and adolescents once drugs are approved for them. For adolescents ≥12 years, Glecaprevir/Pibrentasvir (G/P) became available through the government programme in late 2019. Within the Russian European Alliance for research (REACH), we aimed to explore HCV therapeutic management practices and policies for children and adolescents with HIV/HCV co-infection and to evaluate treatment availability and utilisation.

**Method:** A web-based survey was distributed to clinicians at 20 AIDS centres in October 2020, with a 95% response rate. The survey collected aggregated data on numbers of HIV/HCV co-infected

## POSTER PRESENTATIONS

Figure: (abstract: PO-2483) **The trends of HBV-attributable liver cancer among children, adolescents and young adults.** The change of cancer cases from 1990 to 2017 for children (A), adolescents and young adults (B). The EAPC for children (C), adolescents and young adults (D). HBV, hepatitis B virus; EAPC, estimated annual percentage change.

children (<18 years) under current care by age group, sex, HCV genotype (GT), and HCV treatment history, plus details of policies or guidelines for identification, monitoring and treatment of paediatric HCV.

**Results:** 125 HIV/HCV co-infected children were in follow-up (61 female), ranging from 0 to 39 per centre. 29 children (23%) were aged <6 years, 26 (21%) 6–<12 years and 70 (56%) 12–17 years. Most were vertically infected (n = 92, 74%). Genotype GT was available for 94 (75%) children, of whom 60 (64%) had GT1, 32 (34%) GT3 and 2 (2%) GT2. 10 clinics used DAAs only (53%), 5 clinics interferon- or DAA-based treatments (26%), and 2 did not treat children for HCV (table 1). DAAs were only prescribed for adolescents ≥12 years. 50 (71%) HIV/HCV coinfected adolescents were treated with G/P.

Table:

	Number of AIDS centres where DAAs are indicated for treatment of adolescents n = 19	Number of HIV/HCV coinfected adolescents having received DAAs n = 70
Sofosbuvir	3 (16%)	1 (1%)
Daclatasvir	2 (11%)	0
Sofosbuvir/Ledipasvir	3 (16%)	0
Sofosbuvir/Velpatasvir	4 (21%)	0
Glecaprevir/Pibrentasvir	15 (79%)	50 (71%)

**Conclusion:** DAA treatment uptake was high for HIV/HCV coinfected adolescents in the RF. Most of those in care at responding clinics were treated soon after approval of pangenotypic formulations. Access to treatment for younger children needs expansion as DAAs are licensed for these age groups.

### PO-2596 Hepatitis C Virus Microelimination is Feasible During COVID-19 Pandemic in Centers for Addiction Treatment Users

Silvia Acosta-López<sup>1</sup>, Esther Rodríguez Candelaria<sup>1</sup>, Luz Goretti Santiago Gutiérrez<sup>2</sup>, Juan Carlos Fernández Molina<sup>3</sup>, Pilar Díaz Ruiz<sup>4</sup>, Magdalena Lara<sup>5</sup>, María del Carmen Martínez-García<sup>3</sup>, Ana Laserna Ramos<sup>2</sup>, David Rodríguez Galloway<sup>2</sup>, Rosa Lidia González-Guerra<sup>3</sup>, Angelina Rodríguez Pérez<sup>2</sup>, Ruth Suarez Darias<sup>1</sup>, Antonio González Rodríguez<sup>1</sup>, Teresa De la Rosa Vilar<sup>2</sup>, Francisco Andrés Pérez Hernández<sup>1</sup>. <sup>1</sup>Hospital Universitario Nuestra Señora de Candelaria, Liver Unit, Santa Cruz de Tenerife, Spain; <sup>2</sup>San Miguel Adicciones, San Miguel Adicciones, San Cristóbal de La Laguna, Spain; <sup>3</sup>ANTAD, ANTAD, Santa Cruz de Tenerife, Spain; <sup>4</sup>Hospital Universitario Nuestra Señora de Candelaria, Pharmacy, Santa Cruz de Tenerife, Spain; <sup>5</sup>Hospital Universitario Nuestra Señora de Candelaria, Microbiology Department  
Email: sacostalopez9@gmail.com

**Background and aims:** To eliminate hepatitis C (HCV) infection is necessary to implement protocols in high prevalence but low adherence populations, like the centers for addiction treatment users (CAT). We have previously reported high sustained viral response (SVR) in this population with the Fast-Track Consultation Protocol (FT). Covid-19 pandemic (C19) has elicited to modifications of the health assistance and, consequently, HCV elimination. The aim of this study is to analyse the differences in diagnosis, adherence and response to HCV treatment in CAT users after the onset of C19.

**Method:** FT include screening and treatment supervision in CAT and hospital assistance in a single day (diagnosis and prescription). During pandemic, telemedicine and treatment dispensation at CAT were started. Demographic, clinical variables, adherence to treatment and SVR were included. Differences between pre-Covid19 pandemic (pC19) (March 2019 to February 2020) and covid pandemic (C19) (March 2020 to February 2021) in terms of SVR were analysed by using non-parametric tests.

**Results:** No significant differences between the two studied groups were identified in demographic and clinical variables and, interestingly, in the prevalence of active drug consumption or the presence of psychiatric disorders (table 1). During pC19, 390 patients were included and 33% were HCV positives; during C19, 115 patients were included (11% HCV positives). 139 patients started treatment in pC19, while 41 patients were treated during the C19 (8 were on treatment at the time of this analysis). 90.6% and 93.8% patients completed the treatment in pC19 and C19, respectively (p = .440). SVR was achieved in 90.6% of patients and 87.9% of patients in the pC19 and C19 groups, respectively (p = .632).

**Conclusion:** HCV elimination in CAT users has been feasible during C19 by adapting the FT protocol. It has achieved similar rates of adherence to treatment and SVR than in the pC19 and is not affected by basal vulnerability conditions.

Figure: Table 1: Differences in demographic and clinical features between pC19 and C19 groups.

	pC19 (n = 139) N (%)	C19 (n = 41) N (%)	p value
Gender (M:F)	126:13	34:7	.167
Age	49.5 [SD = 6.9]	47.5 [SD = 7.4]	.235
Liver Fibrosis			.286
F0-2	82 (59)	25 (65.8)	
F3-4	57 (41)	13 (34.2)	
Active Drug Consumption* (yes)	72 (51.8)	25 (61)	.373
Homeless (yes)	16 (11.5)	3 (7.3)	.019
Psychiatric disorders (yes)	40 (28.8)	10 (24.4)	.693
Psychotropic drug (yes)	72 (51.8)	18 (43.9)	.477

M: male. F: female.

**Proportion, characteristics, and outcome of chronic hepatitis B who are 'linked to care' in Korea: A nationwide retrospective longitudinal study**

Young Cheol Ju<sup>1</sup>, Dae Won Jun<sup>1,2</sup>, Eileen Yoon<sup>2</sup>, Sang Bong Ahn<sup>3</sup>, Yun Jin Kim<sup>4</sup>, Mindie Nguyen<sup>5</sup>. <sup>1</sup>Graduate school of Biomedical Science and Engineering, Hanyang University, Department of Translational Medicine; <sup>2</sup>Hanyang University Hospital, Hanyang University College of Medicine, Department of Internal Medicine; <sup>3</sup>Nowon Eulji Medical Center, Eulji University College of Medicine, Department of Internal Medicine; <sup>4</sup>Biostatistical Consulting and Research Laboratory, Medical Research Collaborating Center, Hanyang University; <sup>5</sup>Division of Gastroenterology and Hepatology, Stanford University Medical Center, Palo Alto, CA, USA

Email: noshin@hanyang.ac.kr

**Background and aims:** Apart from the prevalence of chronic hepatitis B (CHB), linkage to care rate is less well characterized. We aimed to characterize the proportion of CHB patients who have been linked to care, their characteristic and long-term outcomes.

**Method:** This was a retrospective longitudinal cohort study using the Korean National Health Insurance Service database data from 2002 to 2018. Our operational definition of in-care CHB patients includes those who had at least two clinic or hospital visits that were associated with a CHB diagnostic code during study period (2002–2006). The period from 2007 to 2018 was used for long-term follow-up of this selected population.

**Results:** Of the estimated 1,545,377 CHB patients during the study period, 553,085 patients (35.8%) were found to be linked to care, with lower rate in men (35.7% in men vs. 36.0% in women) (p = 0.006). The linkage to care rate was highest in the 40–49 year age group (48.5%), and lowest in the 20–29 year age group (29.4%). Interestingly, linkage to care rate was higher in the rural than metropolitan area (39.1% vs. 35.7%, p < 0.0001). The 15-year cumulative incidence of hepatocellular carcinoma and overall survival rates among linked to care CHB patients were 18.2% and 93.8%, respectively.

**Conclusion:** Two thirds (64.2%) of CHB Koreans are under inadequate care. Those who are male, dwelling in metropolitan, not in life transitioning period need to be focused for improvement of linkage to care rate in Korean CHB population.

**PO-2861**

**Projecting the prevalence of obesity- and alcohol- related non-communicable diseases in France, the Netherlands and Romania from 2020 to 2030 using multi-risk microsimulation methods**

Lise Retat<sup>1</sup>, Timothy Coker<sup>1</sup>, Laura Webber<sup>1</sup>, Maria Buti<sup>2</sup>, Helena Cortez-Pinto<sup>3</sup>, Peter Jepsen<sup>4</sup>, Jeffrey Lazarus<sup>5</sup>, Nick Sheron<sup>6</sup>, Pierre Nahon<sup>7</sup>, Francesco Negro<sup>8</sup>, Marieta Simonova<sup>9</sup>, Shira Zelber-Sagi<sup>10</sup>. <sup>1</sup>HealthLumen, Modelling Department, London, United Kingdom; <sup>2</sup>Liver Unit, Department of Internal Medicine, Hospital Universitario Vall d'Hebron, Barcelona, Spain; <sup>3</sup>Centro de Nutrição e Metabolismo, University of Lisbon, Lisbon, Portugal; <sup>4</sup>Department of Clinical Epidemiology, Aarhus University, Aarhus, Denmark; <sup>5</sup>Barcelona Institute for Global Health (ISGlobal), Hospital Clínic, University of Barcelona, Spain; <sup>6</sup>Population Hepatology Research Group, University of Southampton, Southampton, UK; <sup>7</sup>Université Paris, Hospital Jean-Verdier, Paris, France; <sup>8</sup>Department of Pathology and Immunology of the University Hospitals of Geneva, Geneva, Switzerland; <sup>9</sup>Department of Gastroenterology, HPB Surgery and Transplantology, Military Medical Academy, Sofia, Bulgaria; <sup>10</sup>School of Public Health, Department of Nutrition, Health and Behavior, University of Haifa, Haifa, Israel  
Email: lise.retat@healthlumen.com

**Background and aims:** Obesity prevalence is increasing across Europe, contributing to increasing liver and cardiovascular disease, already adversely affected by levels of alcohol consumption. Quantifying the epidemiological and economic burden of these risk factors will provide evidence for governments and other stakeholders to design and implement appropriate interventions and policies. This study quantifies the burden of liver diseases, and coronary heart disease (CHD), impacted by body mass index (BMI) and alcohol as joint risk factors, in France, Netherlands and Romania from 2020 to 2030.

**Method:** A validated multi-risk microsimulation model was employed [1]. Dynamic, representative virtual populations of the three countries were generated based on population data. Country-specific epidemiological and cost data for chronic liver diseases (CLD), liver cancer, and CHD were extracted from published sources. Morbidity and costs of diseases were projected to 2030 based on trends in increasing obesity and static alcohol consumption. The impact of an illustrative scenario in which BMI is reduced by 1% and alcohol consumption by 5% was assessed.

## POSTER PRESENTATIONS

**Results:** For France, obesity is projected to increase by over 10% between 2020 to 2030. Cumulative incidence was estimated to increase from 12741, 10730, 14083 cases in 2020 to 136132, 123390, 164297, of CLD, liver cancer, cirrhosis cases respectively in 2030. Under the intervention scenario, the reduced burden in disease incidence corresponds to direct cost savings in 2030 of €376.67 m (liver cancer) and €518.96 m (cirrhosis). In the Netherlands, obesity is projected to increase across all age groups for both sexes by 2030. The cases avoided for each disease category under the intervention scenario were projected to lead to direct cost savings in 2030 of €7.1 m (CLD), €6.4 m (liver cancer), €9.95 m (cirrhosis). In Romania, obesity is projected to decrease between 2020 and 2030. Under the intervention scenario, this would lead to around 91, 200 and 10, 000 liver cirrhosis and CLD cases avoided.

**Conclusion:** We demonstrate the effect of rising obesity rates on liver diseases, assuming no changes in current alcohol consumption, as well as the associated economic burden to the French, Dutch and Romanian healthcare systems. These data suggest that policies designed to impact on both risk factors may be of benefit.

[1] Pérez-Ferrer et al. Inequalities in smoking and obesity in Europe predicted to 2050: Findings from the EConDA project. *Scand J Public Health*. 2018 Jul;46 (5):530–540. doi: 10.1177/1403494818761416.

### PO-2872

#### COVID-19 pandemic and the impact on hospitalization of alcohol related liver disease-A retrospective cohort study in a secondary care setting

Wei Jin Lim<sup>1</sup>, Yen Miao<sup>1</sup>, Ka Kit Li<sup>1</sup>, Heidi Whitsey<sup>1</sup>, Jithin Jith<sup>1</sup>, Michael Taylor<sup>1</sup>. <sup>1</sup>University Hospitals of Leicester, Gastroenterology, United Kingdom  
Email: lwjin90@hotmail.com

**Background and aims:** The COVID 19 pandemic has put unprecedented pressure on health care system around the world. Data have suggested strategies used in controlling infection such as lockdown have been associated with an increase in alcohol usage. In addition, evidence has also suggested an increase in avoidance to seek medical care due to COVID concerns. The downstream effects of such behaviours may inevitably result in increased morbidity and mortality of patient with alcohol related liver disease (ARLD). Our study aims to describe the characteristics of ARLD patients hospitalised in the COVID 19 pandemic year comparing to the year before, in a teaching hospital setting.

**Method:** Hospital admission for alcoholic related liver disease between April to September month for year 2019, and year 2020 were obtained. Information for baseline characteristic, prognostic scoring, morbidity and mortality were obtained from local Sunquest ICE and Nervecentre software. Data were tabulated and analysed. Chi-Square test of independence was applied for statistical significance.

**Results:** Number of ARLD admissions increased by 50% from 102 in year 2019, to 153 in year 2020. Incidence of alcoholic hepatitis increased from 30.4% to 69.2% ( $p < 0.001$ ), with incidence of first presentation ARLD increased from 5.9 to 37.9% ( $p < 0.001$ ). Only 2 (1.3%) contracted COVID 19 infection. There are no statistically significant differences in CLIF-C acute decompensation score, acute-on-chronic liver failure grade, Glasgow alcoholic hepatitis score, and overall 6-months mortality rate.

**Conclusion:** Our study has shown an increase in decompensated alcohol related liver disease hospitalization rate and alcoholic hepatitis during the COVID 19 pandemic. Our data add to the increasing evidence of the co-lateral damage created in the wake of the on-going pandemic and highlight the challenges ahead as a result of increasing incidence of patient with ARLD. COVID 19 pandemic presents a valuable learning opportunity for us to re-evaluate and reshape how hepatology services may be delivered to improve the outcome of patient with ARLD during the post pandemic recovery phase.

### PO-2904

#### Impact of Universal Automated Hepatitis C Screening with Treatment and Cure in a Primary Care Based Practice

Su Wang<sup>1</sup>, Ruth Brogden<sup>1</sup>, Binghong Xu<sup>1</sup>, Jaymie Yango<sup>1</sup>, Naomi Fox<sup>2</sup>, Eric Handler<sup>3</sup>, Mary Adedeji<sup>1</sup>. <sup>1</sup>RWJBarnabas Health, Center for Asian Health and Viral Hepatitis Programs, Florham Park, United States; <sup>2</sup>Saint Barnabas Medical Center, Nursing Education and Research, Livingston, United States; <sup>3</sup>Saint Barnabas Medical Center, Emergency Department, Livingston, United States  
Email: su.wang@rwjbh.org

**Background and aims:** Liver cancer is the third most common cancer death in the world and viral hepatitis being a leading cause. An estimated 2.4 million people in the United States (US) are living with hepatitis C (HCV), but more than half are not yet aware. Injection drug use remains a major driver of transmission, and in the US, acute HCV incidence has been highest in those 20–29 years of age. In response to the changing epidemiology, the US Centers for Disease Control and Prevention (CDC) updated their HCV screening recommendations for all adults to be tested at least once except in settings where the prevalence of HCV infection is  $< 0.1\%$ . We sought to scale up HCV screening in a 577-bed community hospital with an Emergency Department (ED) of 100, 000 yearly visits, by modifying our electronic medical record (EMR) to automate HCV screening and provide linkage-to-care (LTC).

**Method:** The EMR modified to automate test orders for hepatitis screening beginning March 2018. HCV testing was triggered by year of birth (1945–1965) then expanded to universal (age  $> 18$ ) in January 2020 and from the ED initially and then adding the inpatient units. When the test order is placed (HCV Ab with reflex to HCV RNA), nurses are notified of patient eligibility. Alerts of HCV positive results are sent to staff, and the patient navigator (PN) also receives a real-time secure text message. The PN reaches out and works individually with patients to arrange LTC for evaluation and treatment.

**Results:** From Mar 2018 to Mar 2021, a total 50, 873 of HCV screenings were conducted with 259 (0.5%) found to have current HCV infection and 128 (49.4%) were newly diagnosed. LTC rate was 86.9%. Starting January 2021, individuals born outside the 1945–65 birth cohort made up 75.8% of those screened and 41.0% of the infected. Totally 110 HCV infections were found via universal screening, 31 (28.2%) are younger than the birth cohort, and 14 (12.7%) are older. Of those LTC, 47 HCV patients were seen at PCP. Genotypes 1a and 1b are the most common. We initiated 39 HCV therapy and 34 were cured (confirmed sustained virologic response at 12 weeks).

**Conclusion:** The ongoing opioid epidemic necessitates more universal HCV screening strategies to identify individuals living with hepatitis C infection across the lifespan. Our study demonstrated that close to half of those infected were born outside of the original CDC recommended birth cohort and included people both younger and older. Scaling up screening through automated EMR based screening and utilizing frontline primary care practices are ways of integrating hepatitis services. Such approaches will be critical to reduce liver cancer rates and eliminate hepatitis.

## Rare liver diseases (including paediatric and genetic)

### PO-106

#### Social outcomes in patients with biliary atresia: a systematic review

Emma Alexander<sup>1</sup>, William Greaves<sup>2</sup>, Hrisheekesh Vaidya<sup>3</sup>, Charlotte Burford<sup>1</sup>, Vandana Jain<sup>1</sup>, Marianne Samyn<sup>1</sup>. <sup>1</sup>King's College Hospital, United Kingdom; <sup>2</sup>UCL Medical School, United Kingdom; <sup>3</sup>Northwick Park Hospital, United Kingdom  
Email: emma.alexander5@nhs.net

**Background and aims:** Biliary atresia is the most common indication for liver transplant in childhood. Following improved medical outcomes for children with biliary atresia, a new clinical and research focus is on promoting long-term well-being and quality of life. We therefore aimed to systematically review the social outcomes of patients with biliary atresia (BA).

**Method:** A systematic review of Medline, EMBASE, Global Health, Maternity and Infant Care Database was conducted in April 2020, supplemented by reference searching, with NHLBI scoring for quality appraisal. Protocol registered on PROSPERO (CRD42020178846).

**Results:** 55 studies met inclusion criteria (39 cohort, 11 cross-sectional, five case-control), including 5, 156 participants from 16 countries. BA post liver transplant (LT) (18 studies), native liver survival (NLS) (16 studies), mixed LT/NLS (16 studies) and 5 of other cohorts (e.g. listed for LT) were incorporated. Study outcomes included; education (n = 39), employment (n = 19), pregnancy (n = 24), and social functioning (n = 25). Patients with BA had lower school functioning scores than controls, with no difference when comparing those with and without LT. The need for additional educational support ranged between 2% and 48% of children. Adult patients with BA were employed at high rates (range 60–100%), with no difference between post-LT and NLS cohorts when compared in 1 study. Successful pregnancies were reported in 19 studies, with mostly small sample sizes. In 6/7 NLS studies mentioning pregnancy, complications included derangement in liver function and variceal bleeding secondary to portal hypertension. Social functioning scores did not significantly differ from healthy controls when compared in 7/9 studies.

**Conclusion:** Existing evidence on social outcomes for children and adolescents with BA is predominantly from non-controlled, single centre studies and based on parental surveys. The current findings suggest that school functioning is lower compared to peer groups and not influenced by having a liver transplant. Employment outcomes are encouraging and pregnancy considered an at-risk period. These findings provide justification for routine psychosocial assessment of these patients during follow-up and larger multi-centre collaborations in order to develop the evidence base for future patients.

### PO-299

#### Clinical and radiological characterisation of Polycystic Liver Disease

Benjamin Giles<sup>1</sup>, Alison Dimmer<sup>1</sup>, Zeshan Riaz<sup>1</sup>, Joanna Dowman<sup>1</sup>, Andrew Fowell<sup>1</sup>, Richard Aspinall<sup>1</sup>. <sup>1</sup>Portsmouth Hospitals University NHS Trust, Gastroenterology and Hepatology, Portsmouth, United Kingdom  
Email: r.j.aspinall@doctors.org.uk

**Background and aims:** Patients with Polycystic Liver Disease (PLD) have a wide range of symptom severity and disease course but little is known about the clinical impact of PLD in the United Kingdom. The aim of our study was to examine the spectrum of PLD including severity, cyst phenotype, symptoms and treatment in a large, secondary care population over a 10-year period.

**Method:** We systematically searched radiology reports from 2011–2020 at a major acute hospital serving a catchment population of 675,000. “Polycystic” and “multiple cysts” were used as search terms to identify patients, excluding those without liver or renal cysts. Electronic patient records were interrogated to collect demographics, clinical information and radiology. Images were reviewed to confirm numbers and sizes of cysts.

**Results:** We identified 484 patients with multiple liver cysts; 211 with isolated PLD and 273 with both liver and kidney cysts. Of the available imaging, 133/234 (57%) met the accepted definition of PLD (>10 liver cysts). Overall, 39/484 (8%) had symptoms from hepatic cysts whereas 26/133 (20%) meeting the PLD definition were symptomatic with abdominal pain being the most common symptom (85%). The mean age of first reporting PLD symptoms was 56 (range 36–84 years). Females were a higher proportion of both symptomatic patients (72%) and those requiring treatment (82%). Symptoms correlated with cyst number, occurring in 0–10 cysts 6/101 (6%), 11–20 cysts 6/42 (14%), >20 cysts 20/91 (22%) respectively. Cyst size similarly impacted symptoms and 218/229 (95%) of patients with small (<5 cm) liver cysts were asymptomatic. The mean largest cyst size was 4.0 cm (range 0.3–14.8) in asymptomatic people and 8.6 cm (range 4.3–21.0) in those with symptoms. Only 16/484 (3%) received targeted treatment for hepatic cysts with fenestration being the most common procedure performed, followed by resection and liver transplantation. No patients received somatostatin analogues during the study period.

**Conclusion:** This is the largest systematic study of a PLD population from the UK and describes the clinical spectrum of disease. We found patients with multiple simple liver cysts rarely became symptomatic or required treatment. However, defined PLD was more severe in females with a higher rate of symptoms and need for specialist treatment. Symptomatic disease increased when multiple hepatic cysts exceeded 10 in number or grew larger than 5 cm. Our data informs the natural history of PLD including the need to access appropriate care for symptomatic disease and highlights the importance of the recently established UK PLD Registry [<https://clinicaltrials.gov/ct2/show/NCT04645251>].

### PO-323

#### Liver phenotype of adults with alpha-1 antitrypsin deficiency in the UK Biobank and in an international, multi-center cohort

**Background and aims:** Alpha-1 antitrypsin deficiency (AATD) is caused by mutations in the *SERPINA1* gene and leads to lung and liver disease. While the susceptibility to liver disease in individuals homozygous for the Pi\*Z variant (genotype Pi\*ZZ) is well established, the effects of the more prevalent Pi\*S variant remain to be investigated. To analyze the most relevant AATD genotypes on a population-based level, we evaluated individuals of the United Kingdom Biobank (UKB) and corroborated the results in an international cohort.

**Method:** We examined 17 006 Pi\*MZ, 1014 Pi\*SS, 864 Pi\*SZ, 138 Pi\*ZZ individuals, and 422 506 non-carriers in the UKB. The presence of the ICD10 diagnoses liver fibrosis/cirrhosis (K74.0-2, -6) and primary liver cancer (C22.0) was assessed and compared to known genetic liver disease modifiers. The confirmatory cohort consisted of 1104 systematically evaluated subjects from ten European countries and the US with available liver stiffness measurements (LSM).

**Results:** Pi\*MZ and Pi\*SZ individuals presented with elevated AST values, however Pi\*ZZ subjects showed the highest AST values. All five genotypes displayed significantly higher ALT values than non-carriers. Mean ALP values were the highest in Pi\*SZ subjects. Pi\*SS individuals harbored slightly elevated ALT values, but no other abnormalities.

The ICD10 diagnosis fibrosis/cirrhosis (A) was 20 times more frequent in Pi\*ZZ participants (21.7[8.8–53.7],  $p < 0.0001$ ) and moderately enriched in Pi\*SZ (3.1[1.2–8.2],  $p = 0.027$ ) and Pi\*MZ subjects (1.7[1.2–2.2];  $p = 0.001$ ). The odds of having primary malignant neoplasm of the liver (B) was significantly increased in Pi\*ZZ and Pi\*SZ individuals. For both ICD codes, the genotypes Pi\*ZZ and Pi\*SZ conferred similar or greater risk factors than known genetic liver disease modifiers. LSM values from the international cohort confirmed the intermediate liver fibrosis burden of Pi\*SZ subjects compared to non-carriers and Pi\*ZZ individuals.

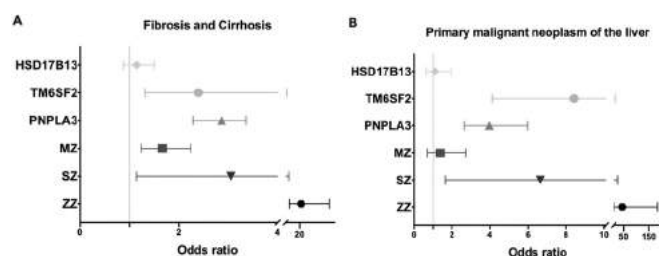

Figure: Adjusted odds ratios of ICD10 diagnoses in Pi\*MZ, Pi\*SZ, and Pi\*ZZ subjects; and homozygous carriers of *PNPLA3* p.I148M (rs738409), *HSD17B13*:T (rs72613567), or *TM6SF2* p.E167K (rs5854926) variants, all compared to corresponding non-carriers.

**Conclusion:** Our study defines the liver phenotype of the most common AATD genotypes and enables evidence-based clinical management. For the first time, it provides reliable data on Pi\*SZ individuals as well as AATD-associated predisposition to liver cancer.

### PO-561

#### Recent portal venous system thrombosis associated with Cytomegalovirus disease: results of a multicenter study

Chloé De Broucker<sup>1</sup>, Aurélie Plessier<sup>2</sup>, Isabelle Ollivier Hourmand<sup>3</sup>, Sébastien Dharancy<sup>4</sup>, Jean Paul Cervoni<sup>5</sup>, Christophe Bureau<sup>6</sup>, Philippe Sogni<sup>7</sup>, Odile Gorla<sup>8</sup>, Olivier Corcos<sup>9</sup>, Kamal Zekrini<sup>2</sup>, Payance Audrey<sup>2</sup>, Hortense Davy<sup>2</sup>, Nadhira Fidouh<sup>10</sup>, Yazdan Yazdanpanah<sup>10</sup>, Dominique Valla<sup>2</sup>, Rautou Pe<sup>2</sup>. <sup>1</sup>Hôpital de Poissy Saint Germain, Service de maladies infectieuses et tropicales, Poissy, France; <sup>2</sup>Hôpital Beaujon, Hepatology, Clichy, France; <sup>3</sup>CHU Caen, Service d'hépatogastro-entérologie et nutrition, Caen; <sup>4</sup>CHRU Lille, Service d'hépatologie, Lille, France; <sup>5</sup>CHU Besançon, Service d'hépatogastro-entérologie, Besançon, France; <sup>6</sup>Hôpital Rangueil, Service d'hépatologie, Toulouse Cedex 9, France; <sup>7</sup>Hôpital Cochin, Service d'Hépatologie, Paris, France; <sup>8</sup>CHU Rouen, Service d'hépatogastro-entérologie, Rouen, France; <sup>9</sup>Hôpital Beaujon, Gastroenterology, Clichy, France; <sup>10</sup>Hôpital Bichat, Service de maladies infectieuses et tropicales, Paris, France

Email: pierre-emmanuel.rautou@aphp.fr

**Background and aims:** Recent non-malignant non-cirrhotic portal venous system thrombosis (PVT) is a rare condition. Among risk factors for PVT, cytomegalovirus (CMV) disease is usually listed based on few reported cases. The aim of this study was to determine characteristics and outcome of patients with PVT associated with CMV disease.

**Method:** We conducted a French multicenter retrospective study comparing patients with recent PVT and CMV disease ("CMV positive";  $n = 23$ ) with patients with recent PVT for whom CMV testing was negative ("CMV negative";  $n = 53$ ) or unavailable ("CMV unknown";  $n = 299$ ). Diagnosis of CMV disease was based on: anti-CMV IgM with low avidity of IgG or IgG seroconversion ( $n = 13$ ); organ injury with a detectable CMV deoxyribonucleic acid (DNA) on biopsy ( $n = 1$ ); significant plasma CMV DNA in immunodepression ( $n = 1$ ); detectable anti-CMV IgM ( $n = 8$ ).

**Results:** As compared with patients from the "CMV negative" and "CMV unknown" groups, patients from the "CMV positive" group were younger (51, 47 and 36 years-old, respectively), had more frequently fever (19%, 20% and 48%, respectively), higher heart rate (80, 76 and 105 beat per minute, respectively), higher lymphocyte count (1.6, 1.7 and 3.1 G/L, respectively) and higher serum ALT levels (30, 43 and 99 UI/L, respectively) ( $p \leq 0.01$  for all comparisons). Frequency of immunosuppression, of abdominal inflammation, extension and localization of PVT were similar between the three groups. Thirteen out of 23 "CMV positive" patients had another risk factor for thrombosis. Besides CMV disease, number of risk factors for thrombosis was similar between the 3 groups. Prothrombin gene mutation was more frequent in "CMV positive" patients (22%) than in the "CMV negative" (4%,  $p = 0.01$ ) and "CMV unknown" (8%,  $p = 0.03$ )

groups. Complete recanalization at 24 months was not associated with CMV status (hazard ratio = 1.957 in multivariate analysis, p = 0.225).

**Conclusion:** In patients with recent PVT, signs of viral syndrome should raise suspicion of CMV disease. CMV disease does not seem to influence thrombosis extension nor recanalization. More than half “CMV positive” patients have another risk factor for thrombosis, with a particular link with prothrombin gene mutation. Identification of CMV infection does not deter from performing an extensive screening for risks factors for thrombosis and should not influence decision on the duration of anticoagulation.

**PO-570**

**Portal vein recanalization for severe portal hypertension related to chronic non-cirrhotic extrahepatic portal vein obstruction: long term results**

Artru Florent<sup>1</sup>, Naik Viotti-Violi<sup>2</sup>, Christine Sempoux<sup>3</sup>, Joana Sofia Vieira Barbosa<sup>1</sup>, Arnaud Hocquet<sup>2</sup>, Fabio Becce<sup>2</sup>, Eleni Moschouri<sup>1</sup>, Rafael Duran<sup>2</sup>, Montserrat Fraga Christinet<sup>1</sup>, Darius Moradpour<sup>1</sup>, Pierre-Emmanuel Rautou<sup>4</sup>, Alban Denys<sup>2</sup>. <sup>1</sup>Centre hospitalier universitaire vaudois, Gastroentérologie et hépatologie, Lausanne, Switzerland; <sup>2</sup>Centre hospitalier universitaire vaudois, Radiodiagnostic et radiologie interventionnelle, Lausanne, Switzerland; <sup>3</sup>Centre hospitalier universitaire vaudois, Institut universitaire de pathologie, Lausanne, Switzerland; <sup>4</sup>Hôpital Beaujon, service d'hépatologie, Clichy, France  
Email: flo\_artru@hotmail.com

**Background and aims:** We aimed to evaluate the long-term outcome of patients with chronic non-cirrhotic extrahepatic portal vein obstruction (CNC-EHPVO) with severe portal hypertension who underwent portal vein recanalization (PVR) and to determine factors predicting PVR failure and stent dysfunction.

**Method:** This retrospective study included all patients who underwent PVR without TIPSS insertion in the context of CNC-EHPVO at Lausanne University Hospital, Switzerland between 01.2000 and 12.2019. Stent dysfunction was defined as complete occlusion of the stent or new onset of portal hypertension-related symptoms.

Table 1: Main characteristics of patients at recanalisation procedure

	Overall cohort (N = 31)
Indication for recanalization, N (%)	
GI bleeding	13 (42)
Abdominal pain	7 (23)
Prior to abdominal surgery	4 (12)
Portal cholangiopathy	3 (10)
Ascites	1 (3)
Other	3 (10)
Pattern of CNC-EHPVO according to Marot [1], N (%)	
1	16 (52)
2	12 (38)
3	3 (10)
Extension of thrombosis, N (%)	
Limited to portal vein	3 (10)
Splenic or mesenteric vein	13 (42)
Both splenic and superior mesenteric vein	15 (48)
Complete occlusion of the portal vein, N (%)	27 (87)
Duration between diagnosis and recanalisation, months	9 (2–49)

[1] PMID 30503174.

**Results:** 31 patients were included. Risk factors for CNC-EHPVO were thrombotic disorder (N = 12, 39%), pancreatitis (N = 10, 32%) and abdominal surgery (N = 9, 29%). Main characteristics at the time of PVR are presented in Table 1. PVR was successful in 27 patients (87%). PVR failure was associated with extension within the intrahepatic portal tract (Marot et al [1], p = 0.005) and recanalisation for recurrent abdominal pain (p = 0.02). Adverse events occurred in 6 patients (20%) without any fatal event. A majority of patients (N = 21; 78%) were anticoagulated after successful PVR. Long-term anticoagulation was administered in 18 patients (67%). After a median follow-up of 50 months (22–76), 7 patients developed stent dysfunction. Five of them underwent a second PVR with 3 successful procedures. Five-year survival free of stent dysfunction was 70% (95% CI: 51–89). Partial occlusion before PVR (p = 0.002), PVR for recurrent abdominal pain (p = 0.03) and higher hemoglobin level (p = 0.04) were associated with stent dysfunction at 5 years while anticoagulant therapy was not.

**Conclusion:** In selected patients with CNC-EHPVO and severe portal hypertension, PVR was feasible and safe. Complications of CNC-EHPVO are controlled in almost 3/4 of the patients at 5 years.

**PO-737**

**Genetic haemochromatosis, a common disorder but are General Practitioners still unaware? A qualitative study**

Gerri Mortimore<sup>1,2</sup>, Amelia Woodward<sup>3</sup>. <sup>1</sup>University of Derby, Health and Social Care, Derby, United Kingdom; <sup>2</sup>Haemochromatosis UK, Education Programme Manager, Spalding, United Kingdom; <sup>3</sup>University of Derby, Research, Derby, United Kingdom  
Email: g.mortimore@derby.ac.uk

**Background:** Genetic haemochromatosis (GH) is the most common genetic disorder in Caucasians<sup>1</sup>. This is confirmed by data from the UK Biobank study which revealed that approximately 380, 000 people in the UK have GH<sup>2</sup>. Despite its prevalence, Freedom of Information requests from UK hospital Trusts revealed that only 20, 698 are currently being treated in the UK<sup>3</sup> and only 1:5000 people are diagnosed with it<sup>4, 5</sup>, despite research indicating that 1:113 people have GH in Northern Ireland and Scotland, and 1:150 people in England and Wales<sup>2</sup>

GH causes the body to absorb excess iron which can lead to systematic iron overload within internal organs such as the liver, pancreas, heart, and joints; eventually causing inflammation and tissue damage. If left untreated it may lead to cirrhosis of the liver and a ten-fold risk of hepatocellular carcinoma in men<sup>6</sup>. Early symptoms of GH are non-specific such as fatigue, abdominal and joint pain and as such, may be considered inconsequential by General Practitioners (GP's), resulting in a delay in diagnosis and treatment, which consists of lifelong therapeutic venesections

To date there has been little research examining patient's thoughts and experiences of being diagnosed and treated for GH, a disorder which, if diagnosed late, can cause significant harm

**AIMS:** A phenomenological study to explore patient experiences of living with genetic haemochromatosis and the effect of this on their lives and family.

**Method:** Data was collected using semi-structured interviews with a sample of 22 male and female patients with haemochromatosis who responded to a poster advertising the study. Patients had been diagnosed between 1–30 years. The interview using broad themes covered their experience of diagnosis and treatment. The interviews were recorded and transcribed verbatim. Analysis of the data was conducted using a thematic analysis

**Results:** There were number of common themes that came out of the interviews around the diagnostic process. Most of the patients interviewed talked about experiencing a delay, in some cases of many years, from first presentation of symptoms to their GP to final diagnosis. Many of the patients felt that GPs lacked knowledge of genetic haemochromatosis and talked about how GPs were unable to give them any detailed information about the disease. Several

## POSTER PRESENTATIONS

patients were only diagnosed once they saw a locum doctor not their normal family GP.

**Conclusion:** Early detection and treatment for GH depends on increased knowledge of GPs. This qualitative study identified that patients perceive there to be gaps in understanding GH diagnosis and treatment. Ensuring GPs are aware of GH and the strategies for diagnosis could result in improved patient care. These findings indicate that improved education for GPs regarding GH may be beneficial to improve patient care for this condition and potentially reduce delays in diagnosis and life-saving treatment

### PO-891

#### An innovative treatment for Primary Hyperoxaluria Type 1 based on specific gene correction and hepatic direct cell reprogramming

Virginia Nieto-Romero<sup>1,2</sup>, Aida García-Torralba<sup>1,2</sup>, Andrea Molinos-Vicente<sup>1,2</sup>, Ramon García-Escudero<sup>3</sup>, Eduardo Salido<sup>4</sup>, Jose Segovia<sup>1,2</sup>, Maria Garcia-Bravo<sup>1,2</sup>. <sup>1</sup>Biomedical Innovation Unit, Centro de Investigaciones Energéticas, Medioambientales y Tecnológicas (CIEMAT) and Centro de Investigación Biomédica en Red de Enfermedades Raras (CIBERER), Madrid, Spain; <sup>2</sup>Instituto de Investigación Sanitaria Fundación Jiménez Díaz (IIS-FJD, UAM), Unidad Mixta de Terapias Avanzadas, Madrid, Spain; <sup>3</sup>Molecular Oncology Unit (CIEMAT), Biomedical Research Institute i+12, University Hospital 12 de Octubre, and Centro de Investigación Biomédica en Red de Cáncer (CIBERONC), Madrid, Spain; <sup>4</sup>Hospital Universitario de Canarias, Universidad La Laguna. Centro de Investigación Biomédica en Red de Enfermedades Raras (CIBERER), Pathology Department, Tenerife, Spain  
Email: virginia.nieto@externos.ciemat.es

**Background and aims:** Liver transplantation is nowadays the only definitive curative treatment for many inherited metabolic liver disorders such as Primary Hyperoxaluria Type 1 (PH1). This is a rare genetic disorder caused by alanine:glyoxylate aminotransferase (AGT) deficiency, a hepatic enzyme involved in glyoxylate metabolism. Due to the shortage of liver donors, developing new therapeutic approaches for the treatment of these diseases is essential.

Liver cell replacement therapy appears as a promising alternative to liver transplant. However, the use of primary human hepatocytes or hepatocyte like cells generated from iPSCs, is limited by the difficulty to expand and generate completely functional mature hepatocytes, in addition to the safety issues in the case of iPSCs.

**Method:** To face this challenge we propose the combination of site-specific gene correction and direct cell reprogramming for the generation of autologous phenotypically healthy induced hepatocytes (iHeps) from PH1 patient skin-derived fibroblasts. Following this strategy would be possible to obtain high amounts of corrected hepatocyte-like cells, avoiding the potentially tumorigenic steps of iPSC generation.

**Results:** We obtained AGXT gene corrected cells by two different CRISPR/Cas9 based strategies. In a first strategy, accurate specific point mutation correction (c.853T-C) was achieved by homology-directed repair (HDR) with ssODN harboring the wild-type sequence. In the second strategy, an enhanced version of AGXT cDNA was inserted near the transcription start codon of the endogenous gene, constituting an almost universal correction strategy for PH1 mutations.

Direct reprogramming of fibroblasts into iHeps was conducted by lentiviral overexpression of hepatic transcription factors and in vitro culture in defined media. Transcriptome analysis of iHeps generated from healthy donors, as well as from PH1 and gene corrected patient-derived fibroblasts, has demonstrated the hepatic identity of the resulting iHeps. Demonstration of in vitro and in vivo functionality and disease phenotype reversion of gene corrected-PH1 iHeps is ongoing.

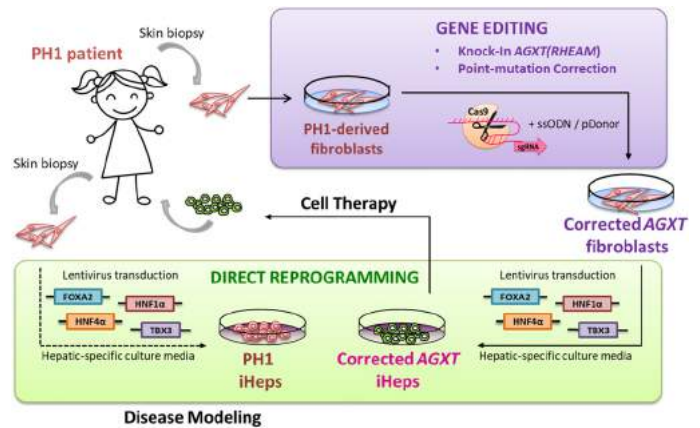

Figure:

**Conclusion:** The development of these advanced therapies will set up an alternative cellular source to replace endogenous deficient hepatocytes with autologous functional corrected cells for many genetic liver disorders. In addition, patient-derived iHeps would be a useful tool as in vitro disease model.

### PO-996

#### Non-invasive biomarkers for assessment of esophageal variceal bleeding risk in patients with non-cirrhotic portal hypertension

Hangfei Xu<sup>1</sup>, Yu Wang<sup>2</sup>, Zhenhua Fan<sup>3</sup>, Hui Liu<sup>4</sup>, Fuliang He<sup>2</sup>, Yongping Yang<sup>5</sup>, Fuquan Liu<sup>3</sup>, Ji-Dong Jia<sup>2</sup>, Huiguo Ding<sup>1</sup>. <sup>1</sup>Beijing You'an Hospital, affiliated with Capital Medical University, Department of Gastroenterology and Hepatology, Beijing, China; <sup>2</sup>Beijing Friendship Hospital, affiliated with Capital Medical University, Department of Hepatology, Beijing, China; <sup>3</sup>Beijing Shijitan Hospital, affiliated with Capital Medical University, Department of Interventional Therapy, Beijing, China; <sup>4</sup>Beijing You'an Hospital, affiliated with Capital Medical University, department of pathology, Beijing, China; <sup>5</sup>The Fifth Medical Center, Chinese PLA General Hospital, Comprehensive liver cancer Department, Beijing, China  
Email: dinghuiguo@ccmu.edu.cn

**Background and aims:** To verify the value of Baveno VI criteria and expanded Baveno VI criteria in rolling out the high-risk varices (HRV) in patients with non-cirrhotic portal hypertension (NCPH), and to explore the predictiveness of liver stiffness × spleen diameter/platelet count score (LSPS) and platelet count/spleen diameter ratio (PSR) for the risk of esophageal varices (EV) bleeding in patients with NCPH.

**Method:** One hundred and eleven patients of NCPH were enrolled at three tertiary medical centres, and 204 patients with hepatitis B cirrhosis served as controls. Of NCPH, 70 cases of idiopathic non-cirrhotic portal hypertension (INCPH) and 41 cases of chronic non-tumoral non-cirrhotic portal vein thrombosis (PVT) were included. According to the severity of EV under endoscopy, it was divided into low-risk varices (LRV) (no/mild EV) and HRV (moderate/severe EV). The ability of Baveno VI criteria and expanded Baveno VI criteria to exclude the presence of HRV was validated in NCPH and hepatitis B cirrhosis patients. LSPS and PSR were calculated for all patients. And diagnostic applicability was assessed by the area under the receiver operator curve (AUC).

**Results:** Based on gold standard of endoscopy, among INCPH/PVT patients who met the Baveno VI criteria and expanded Baveno VI criteria, the respective risk of missing HRV was 50%/30% and 53.8%/50%. In INCPH patients, there was no evidence for statistically significant difference in PLT, spleen diameter, LSM, LSPS and PSR between LRV and HRV. The assessment of the risk of EV bleeding was insufficiency with respective AUC of LSPS and PSR of 0.564 (95%CI 0.426–0.703, P = 0.372) and 0.592 (95%CI 0.457–0.727, P = 0.202). In PVT patients, there were significant differences in PLT, spleen diameter, LSPS and PSR between two groups. The AUC of LSPS and

PSR were 0.796 (95%CI, 0.651–0.941, P=0.003) and 0.833 (95%CI, 0.706–0.961, P=0.001), respectively. In patients with hepatitis B cirrhosis, the Baveno VI and expanded Baveno VI criteria have a lower risk of missing HRV of 0% and 5.4%, respectively. The respective AUC of LSPS and PSR were 0.867 and 0.789 (p <0.05).

**Conclusion:** The Baveno VI and expanded Baveno VI criteria have a higher risk of missing HRV in INCPH and PVT patients. LSPS and PSR may be useful in assessing the risk of EV bleeding in PVT patients.

**PO-1108**

**Hepatic venous pressure gradient in non-cirrhotic portal hypertension – is it worth measuring?**

Hangfei Xu<sup>1</sup>, Yu Wang<sup>2</sup>, Zhenhua Fan<sup>3</sup>, Hui Liu<sup>4</sup>, Fuliang He<sup>2</sup>, Peng Li<sup>1</sup>, Yuening Zhang<sup>1</sup>, Yongping Yang<sup>5</sup>, Fuquan Liu<sup>3</sup>, Ji-Dong Jia<sup>2</sup>, Huiguang Ding<sup>1</sup>. <sup>1</sup>Beijing You'an Hospital, affiliated with Capital Medical University, Department of Gastroenterology and Hepatology, Beijing, China; <sup>2</sup>Beijing Friendship Hospital, affiliated with Capital Medical University, Department of Hepatology, Beijing, China; <sup>3</sup>Beijing Shijitan Hospital, affiliated with Capital Medical University, Department of Interventional Therapy, Beijing, China; <sup>4</sup>Beijing You'an Hospital, affiliated with Capital Medical University, department of pathology, Beijing, China; <sup>5</sup>The Fifth Medical Center, Chinese PLA General Hospital, Comprehensive liver cancer Department, Beijing, China  
Email: dinghuiguang@ccmu.edu.cn

**Background and aims:** Hepatic venous pressure gradient (HVPG) ≥10mmHg is the independent predictor of hepatic decompensation events in cirrhosis. High HVPG signals increased risk of mortality. Non-cirrhotic portal hypertension (NCPH), especially prehepatic or presinusoidal portal hypertension, often have a normal or mildly elevated HVPG. A proportion of NCPH patients still have high HVPG (≥10mmHg). The difference of clinical characteristics and outcomes between high HVPG and low HVPG (<10mmHg) is unknown.

**Method:** 64 cases of NCPH patients with HVPG were enrolled in three tertiary medical centres. Based on HVPG, 26 patients were classified into high HVPG group, 38 patients were in low HVPG group. Baseline characteristics and follow-up date (variceal bleeding, ascites, liver transplantation and death) was compared between two groups.

**Results:** Between both groups of patients, mean age, gender characteristics, ALT, AST, albumin, bilirubin and liver stiffness measurement were not significantly different. The Child-Pugh score in high HVPG group was higher compared with those in low HVPG group (7 (6–8) vs 5 (5–7); P=0.008). At presentation, the prevalence of ascites in high HVPG group is significantly higher than low HVPG group (72% vs 32.4%; P=0.002), while the degree of esophageal varices, variceal bleeding at baseline was similar in the 2 groups. The median follow-up period was 14.8 months (IQR 12.5–20.9) in high HVPG group and 16.4 months (IQR 14.4–23.5) in low HVPG group (p = 0.262). Overall, the 3-year probability of liver transplantation-free survival was similar in high HVPG group compared with low HVPG group (95.5% vs 97.2% P = 0.76). Among all patients, no one developed uncontrolled ascites during follow-up. The 1-, 2-year actuarial probability of being free of bleeding were 86.4%, 86.4% in high HVPG group and 84.1%, 73.6% in low HVPG group respectively, showing no significant difference (p = 0.62).

**Conclusion:** Despite that some patients have higher HVPG, the value of HVPG in patients with NCPH to predict mortality and assess the progression of portal hypertension is limited.

**PO-1243**

**Direct oral anticoagulants (DOACs) for off-label use in patients with Budd Chiari Syndrome (BCS)**

Georg Semmler<sup>1,2</sup>, Katharina Pomej<sup>1,2</sup>, David JM Bauer<sup>1,2</sup>, Lorenz Balcar<sup>1,2</sup>, Benedikt S. Hofer<sup>1,2,3</sup>, Benedikt Simbrunner<sup>1,2,4</sup>, Matthias Pinter<sup>1,2</sup>, Michael Trauner<sup>1</sup>, Mattias Mandorfer<sup>1,2</sup>, Thomas Reiberger<sup>1,2,4</sup>, Bernhard Scheiner<sup>1,2</sup>. <sup>1</sup>Medical University of

Vienna, Department of Internal Medicine III, Division of Gastroenterology and Hepatology, Vienna, Austria; <sup>2</sup>Medical University of Vienna, Vienna Hepatic Hemodynamic Lab, Vienna, Austria; <sup>3</sup>Medical University of Vienna, Christian Doppler Lab for Portal Hypertension and Liver Fibrosis, Vienna, Austria; <sup>4</sup>Medical University of Vienna, Christian Doppler Laboratory for Portal Hypertension and Liver Fibrosis, Vienna, Austria

Email: thomas.reiberger@meduniwien.ac.at

**Background and aims:** Budd Chiari Syndrome (BCS) is a rare vascular liver disease with long-term anticoagulation by vitamin-K antagonists (VKAs) being recommended by current guidelines. Direct oral anticoagulants (DOACs) do not interfere with INR/MELD and do not require routine monitoring, but their use in BCS is off-label. Here we report our experience with DOACs in BCS.

**Method:** 14 patients with BCS were considered for this longitudinal cohort study. Data on the clinical course on anticoagulant therapy and efficacy/safety of DOACs were longitudinally collected.

**Results:** Mean age at BCS presentation was 37.2 ± 16.8 years. Overall, 78.6% (11/14) had previous/current hepatic decompensation, and 92.9% (13/14) showed signs of clinically significant portal hypertension (CSPH; n = 12 splenomegaly, n = 11 varices, n = 9 ascites, n = 4 variceal bleeding). 62.5% (5/8) had concomitant portal vein thrombosis/splanchnic-vein-thrombosis, four were JAK-2 positive (2 suffering from essential thrombocytosis and 2 were additionally carrying the Factor-V-Leiden-mutation), and one patient suffered from anti-phospholipid-syndrome.

During a median follow-up of 98 (22–267) months, eight patients (57.1%) received DOAC treatment (edoxaban: n = 6, apixaban: n = 1, dabigatran: n = 1) for a median of 26 (6–69) months. 75.0% (6/8) patients were switched from LMWH (n = 3) or VKA (n = 3) to DOAC after disease stabilization/improvement, while 25.0% (2/8) of BCS patients were directly started with DOAC. Complete response was achieved or maintained in 7/8 patients including two patients with TIPS prior to DOAC initiation.

Three major bleedings (37.5%) occurred during DOAC therapy (n = 2 upper-GI-bleeding, n = 1 HCC rupture) but DOAC treatment was continued in all patients after bleeding control. Two deaths (n = 1 spontaneous bacterial peritonitis, n = 1 HCC) occurred while on DOAC therapy.

**Conclusion:** DOACs seem to be effective and safe for long-term anticoagulation in patients with BCS, but confirmation by larger prospective studies is needed.

**PO-1244**

**The prevalence of PSYCHIATRIC comorbidities in WILSON'S DISEASE**

Merjem Begic<sup>1</sup>, Samantha Graf<sup>1</sup>, Daniel König<sup>1</sup>, Benjamin Vyssoki<sup>1</sup>, Karin Kozbial<sup>2</sup>, Albert Stättermayer<sup>2</sup>, Petra Munda<sup>2</sup>, Peter Ferenci<sup>2</sup>.

<sup>1</sup>Medical University of Vienna, Department of Psychiatry and Psychotherapy, Division of Social Psychiatry, Vienna, Austria; <sup>2</sup>Medical University of Vienna, Department of Medicine III, Division of Gastroenterology and Hepatology, Vienna, Austria  
Email: merjem.begic@meduniwien.ac.at

**Background and aims:** Psychiatric manifestations may precede neurological signs and hepatic symptoms in the early stages of Wilson disease (WD). Furthermore, some patients may develop psychiatric problems after initiation of treatment. Data on the frequency of psychiatric symptoms vary worldwide. Our goal was to determine the prevalence of psychiatric comorbidities in patients with WD currently undergoing treatment at the University Hospital of Vienna.

**Method:** From August 2020 until January 2021, all adult patients with WD were invited to participate in our prospective clinical trial. The patients who signed their consent were asked to complete three questionnaires (Beck Anxiety Inventory [BAI], Beck Depression Inventory [BDI] and WHO Disability Assessment Schedule 2.0

## POSTER PRESENTATIONS

[WHODAS 2.0], followed by a structured interview (Mini-International Neuropsychiatric Interview [MINI]).

**Results:** Twenty-four patients (13 male [m] and 11 female [f]) with WD, with a mean age of 41.5 years, m/f = 43.8/38.7 years, were included. Sixteen patients (m/f = 7/9; 66, 7%) presented primarily with hepatic symptoms, and 8 patients (m/f = 6/2; 33%) with neurologic symptoms. In eighteen patients (m/f = 10/8; 75%) the testing revealed psychiatric comorbidities: 8 (m/f = 6/2) had a psychiatric diagnosis, 10 patients (m/f = 4/6) showed symptoms of psychiatric disorders of subclinical relevance such as mild anxiety disorder and 5 patients (m/f = 4/1) had light to moderate depression. The most common psychiatric comorbidities were major depression (m/f = 3/1; 16.6%), generalized anxiety disorder (m/f = 2/1; 12.5%), agoraphobia (m/f = 2/1; 12.5%) and panic disorder (m/f = 1/1; 8.3%). All 3 Patients with generalized anxiety disorder and 2 patients (m/f = 1/1) with agoraphobia also had major depression. In 2 male patients with major depression, psychotic disorder was documented. Out of these one was later admitted to the psychiatric clinic. Hypomania was observed in 2 patients (m/f = 1/1), and social phobia in 1 male patient. 6 patients did not meet the criteria for a psychiatric diagnosis.

**Conclusion:** With a high prevalence rate of psychiatric comorbidities (75%) in patients with WD, the study underscores the importance of adequate screening and treatment of such disorders. Concomitant psychiatric treatment could substantially increase therapy adherence and quality of life in patients with WD.

### PO-1285

#### An integrated analysis of long-term clinical safety in maralixibat-treated participants with Alagille syndrome

Rakesh Raman<sup>1</sup>, Will Garner<sup>1</sup>, Pamela Vig<sup>1</sup>, Ed Tucker<sup>1</sup>. <sup>1</sup>Mirum Pharmaceuticals, Foster City, United States  
Email: rraman@mirumpharma.com

**Background and aims:** Maralixibat (MRX) is an apical sodium-dependent bile acid transport inhibitor that interrupts enterohepatic recirculation of bile acids, thus reducing pruritus and cholestasis. The safety database of MRX comprises over 1600 participants, which includes participants with Alagille syndrome (ALGS). In this analysis, we present an overview of clinical safety for an integrated population of MRX-treated participants with ALGS.

**Method:** An analysis of safety data, which included a review of treatment-emergent adverse events (TEAEs) and laboratory data, was conducted across an integrated safety population comprising five Phase 2 clinical studies of MRX-treated participants with ALGS (N = 86). Doses of MRX ranged from 66.5 micrograms/kg once daily to 380 micrograms/kg twice daily. A data cut was taken on 1 December 2019.

**Results:** Of the 86 participants, the median duration of exposure to MRX was 32.3 months (range 0.03–60.9 months), including 19 participants who so far have received treatment for  $\geq 4$  years. Most TEAEs were mild to moderate in severity. A total of 22 participants had a serious adverse event (AE); 3 were related to MRX. Ten participants had an AE leading to discontinuation of MRX. The most common AEs were diarrhea and abdominal pain. These events were mostly transient in nature (median duration of 2 days and 1 day, respectively), mild to moderate in severity, and resolved with no action taken with MRX. Review of laboratory data showed asymptomatic spontaneous rises in serum alanine aminotransferase (ALT) in some participants; however, these appeared to be consistent with the natural history of ALGS and were not dose dependent. The increases were not associated with concomitant rises in aspartate aminotransferase, bilirubin, or clinical sequelae. No other clinically significant trends were observed, including for fat-soluble vitamins.

**Conclusion:** A long-term analysis of the safety data across the integrated ALGS population revealed most TEAEs to be mild to moderate in severity. Diarrhea and abdominal pain were the most common AEs, were mostly transient in nature, and resolved without any action taken. ALT rises were not associated with clinical sequelae and appeared to be consistent with the natural history of the disease.

This analysis demonstrates that  $>4$  years of treatment with MRX is well tolerated and has an acceptable safety profile. Forty-one patients from this ALGS population continue to receive ongoing MRX treatment.

### PO-1354

#### Wilson Disease is associated with prevalent neuropsychiatric comorbidity

Eva Pfister<sup>1</sup>, Kirsten Müller-Vahl<sup>2</sup>, Carolin Fremer<sup>2</sup>, Imeke Goldschmidt<sup>1</sup>, Norman Junge<sup>1</sup>, Eva Bültmann<sup>3</sup>, Amelie Stalke<sup>1,4</sup>, Ulrich Baumann<sup>1</sup>. <sup>1</sup>Paediatric Gastroenterology and Hepatology, Hannover Medical School, Hannover, Germany; <sup>2</sup>Psychiatry, Socialpsychiatry and Psychotherapy, Hannover Medical School, Hannover, Germany; <sup>3</sup>Diagnostic and Interventional Neuroradiology, Hannover Medical School, Hannover, Germany; <sup>4</sup>Department of Human Genetics, Hannover Medical School, Hannover, Germany  
Email: pfister.eva-doreen@mh-hannover.de

**Background and aims:** To characterize a single centre cohort of children with Wilson disease (WD) with a focus on clinical and radiological findings, and long-term outcome of neuropsychiatric comorbidity.

**Methods:** All patients diagnosed with WD in childhood at Hannover medical School born after 1970 were retrospectively reviewed. Follow-up was carried out through an outpatient visit or structured telephone interview. In a subgroup of patients aged  $<18$  years prospective specific neuropsychiatric assessment including Paediatric Quality of Life Inventory™, Children's Color Trail Test™, Global Assessment Scale for Wilson's Disease, Mini International Neuropsychiatric Interview for children and adolescents, and Global Dystonia Severity Rating Scale was performed. All cranial MRIs were systematically reviewed and re-evaluated.

**Results:** Data from 93 paediatric WD patients (n = 58 female, n = 35 male, n = 1 genetically confirmed) was included. Presenting features of WD were elevated liver enzymes (n = 34), acute liver failure (n = 25), chronic liver disease (n = 15), and primary neuropsychiatric manifestation (n = 4; between the ages 5 and 17 years). 15 patients were asymptomatic at the time of diagnosis. Over time, 26 patients received liver transplantation (LTx). Within the long-term period of up to 40 years, 9 patients died, 11 were lost to follow-up, while 73 patients (7–48, median 21 years) are still alive.

The most recent medication of these 73 patients is D-Penicillamine (n = 39), Trentine (n = 7), D-Penicillamine + Zinc (n = 3) and Zinc monotherapy (n = 3). 4 patients were non-compliant. 17 patients receive immunosuppressive therapy after LTx. During follow-up 17/71 patients reported neurological-only, 4/71 psychiatric-only, and 4/71 neurological and psychiatric symptoms despite Wilson-specific therapy. Cranial MR showed pathological findings in 18/36 patients. Typical WD associated changes were detected in basal ganglia and brain stem, in patients with impaired liver synthetic function abnormalities in the pallidum were also noted. In addition, in 11 children we found an age-atypical accentuation of white matter changes and cerebellar fissures as a sign of a slight reduction in the volume of the cerebellum. In the prospective specific neuropsychiatric assessment conducted in 15 paediatric patients, abnormalities in at least one test were detected in each.

**Conclusion:** WD can manifest with neuropsychiatric symptoms as early as preschool age. Mild and clinically undiagnosed neuropsychiatric symptoms are common in paediatric WD patients and may be missed on general assessment. Children and adolescents may have radiological features including but not limited to copper deposition in basal ganglia. Despite use of current therapies, patients develop neurological and/or psychiatric complications. Current therapeutic options in childhood appear to be insufficient to address this comorbidity.

**PO-1500**

**Dose adjustment of chelators based on urinary copper excretion after a drug free holiday-the first step to personalized medicine in patients with Wilson disease**

Karin Kozbial<sup>1</sup>, Albert Staettermayer<sup>1</sup>, Alexander Pilger<sup>2</sup>, Petra Munda<sup>3</sup>, Michael Trauner<sup>3</sup>, Peter Ferenci<sup>3</sup>. <sup>1</sup>Medical University of Vienna, Gastroenterology and Hepatology, Vienna, Austria; <sup>2</sup>Medical University of Vienna, Department of Laboratory Medicine, Vienna; <sup>3</sup>Medical University of Vienna, Department of Gastroenterology and Hepatology, Vienna, Austria  
Email: karin.kozbial@meduniwien.ac.at

**Background and aims:** In Wilson disease (WD) increased serum “free copper (Cu)” is considered to be toxic and is commonly calculated by subtracting ceruloplasmin (CPL)-bound Cu from the total serum Cu concentration (non-CPL plasma copper [NCC]). Unfortunately, correct estimation of NCC by current immunological methods is difficult, and with  $\geq 20\%$  negative NCC results of questionable value. Another approach to estimate “free Cu” is the 24-h urinary Cu excretion after an intentional drug holiday (U24CuDF).

The aim of the study was to investigate the feasibility of dose adjustment of chelators in long-term treated patients with WD based on U24CuDF.

**Method:** U24CuDF was measured repeatedly in 19 patients with WD on long-term treatment (>5 years) with chelators (D-Penicillamine (D-PA): 8, trientine-2HCl (TRI):10; combination of D-PA/zinc:1; m/f:11/8; mean age: 40.4 years (SD $\pm$ 9.9); hepatic:17, neurologic 2; cirrhosis: 4). Urine was collected on the third day of an intentional drug holiday. Urinary Cu concentrations were measured by graphite furnace atomic absorption spectrometry. Treatment was adapted depending on U24CuDF: if U24CuDF was <50  $\mu$ g on subsequent visits chelator dose was decreased; if it was >50  $\mu$ g the dose remained unchanged or was increased.

**Results:** U24CuDF (median:42.5  $\mu$ g/24 h [range:11.3–167]) was lower than Cu excretion measured on drug intake (375  $\mu$ g/24 h [85–1495],  $p < 0.001$ ). In 11 patients (57.9%) U24CuDF was <50  $\mu$ g/24 h, in 8 (42.1%) it was >50  $\mu$ g. In 9 of the 11 patients with normal U24CuDF D-PA dose was reduced (1500 mg/d to 1250 mg/d in 1, 1500 to 1000 in 2, 1000 to 750 in 2, and 750 to 500 in 4). Follow-up of >one year was available in 6: in four U24CuDF remained <50  $\mu$ g, in two values were slightly above 50  $\mu$ g. No change in clinical parameters was noted. Two patients with severe psychiatric symptoms with an initially normal U24CuDF had values >50  $\mu$ g/24 h during follow-up visits, dose was not changed. One of them was hospitalized repeatedly, the other died one month after the last visit (probably suicide).

Seven of the 8 patients with U24CuDF>50  $\mu$ g were on TRI; in 3 of them the dose was increased, however no follow-up is yet available. The other patients continued the previous therapy.

**Conclusion:** U24CuDF is a useful parameter for dose adjustment in WD patients on long-term treatment with chelators. It may be a first step to individualize treatment in these patients. Furthermore it helps to identify patients with insufficient drug adherence. Further prospective studies are needed.

**PO-1522**

**Voices of Italian patients with Wilson’s disease: results from a quality survey**

Massimo Zuin<sup>1</sup>, Giuseppe Maggiore<sup>2</sup>, Georgios Loudianos<sup>3</sup>, Gabriella Nebbia<sup>4</sup>, Raffaele Iorio<sup>5</sup>, Fabiola Didato<sup>5</sup>, Salvatore Dilorenzo<sup>6</sup>, Margherita Matarazzo<sup>5</sup>. <sup>1</sup>ASST Santi Paolo e Carlo, Milano, Italy; <sup>2</sup>Ospedale Bambino Gesù, Rome, Italy; <sup>3</sup>Ospedale Microcitamico, Cagliari, Italy; <sup>4</sup>IRCCS Cà Granda Ospedale Maggiore Policlinico-Clinica Pediatrica, Milano, Italy; <sup>5</sup>University of Naples Federico II, Dipartimento di Scienze Mediche Traslazionali, Napoli, Italy; <sup>6</sup>Italian Association of Wilson’s Disease, Maduria, Italy

**Background and aims:** Wilson’s disease (WD) is a rare autosomal recessive disorder in which defective biliary excretion of copper leads

to its accumulation, particularly in the liver and brain. Early diagnosis and adherence to life-long therapy is needed for disease control, although often problematic. Disease characteristics and prospected life-long medical care may impact on disease experience and patient’s quality of life. The aim of this work is to investigate different aspects related to WD patients in Italy, including disease experience and quality of life.

**Method:** A qualitative survey proposed by the Italian Association of WD Patients was distributed within the WD patients’ network.

**Results:** 151 patients participated to the survey and 125 (83%), including 52% women and 69% over 18, provided complete questionnaires. The disease was found to have been accidentally diagnosed in most patients (69%) by abnormal liver function tests. Surprisingly, 42% of these patients were misdiagnosed even if they presented some typical symptoms that could appear to be suspected WD disease. The timing of diagnosis was variable: pediatric cases were diagnosed within 12 months from the symptom onset, thanks to family screening. On the other hand, adults received a delayed diagnosis, ranging from 2 to 5 years. As expected, D-Penicillamine was used as initial treatment in 66% of patients, while Zinc and Trientine were used in 22% and 12% of patients, respectively. However, at the time of the survey, the proportion of patients on Penicillamine was almost halved due to adverse events, leading to a switch of patients on Trientine or on Zinc therapy. Regarding therapy satisfaction, 76% of patients were not satisfied with ongoing therapy and suggested how it might be an ideal therapy (Fig. 1). WD had a negative impact on school performance in 41% of students and led to change/interruption of job-activities in 36% of adults. Finally, when the quality of life was evaluated, 26% of patients considered it sufficient or limited, mainly due to daily fatigue and anxiety.

Fig. 1: Satisfaction of therapy and characteristics of an ideal therapy suggested by WD patients

**Conclusion:** 1) There is a need to strengthen the medical specialists’ knowledge regarding the WD as part of their general training. 2) The development of new therapies, more effective and easier to tolerate is desirable with the aim to ameliorate WD patients’ quality of life.

**PO-1641**

**Long-term treatment with odevixibat improves multiple sleep parameters in patients with progressive familial intrahepatic cholestasis: a pooled responder analysis from the phase 3 PEDFIC studies**

Richard Thompson<sup>1</sup>, Pier Luigi Calvo<sup>2</sup>, Winita Hardikar<sup>3</sup>, Patrick Horn<sup>4</sup>, Elke Lainka<sup>5</sup>, Cara Mack<sup>6</sup>, Quanhong Ni<sup>4</sup>, Lise Kjems<sup>4</sup>. <sup>1</sup>Institute of Liver Studies, King’s College London; <sup>2</sup>Regina Margherita Children’s Hospital, Azienda Ospedaliera Città della Salute e della Scienza di Torino, Turin, Italy; <sup>3</sup>Royal Children’s Hospital; <sup>4</sup>Albireo Pharma, Inc.; <sup>5</sup>University Duisburg-Essen; <sup>6</sup>Children’s Hospital Colorado, University of Colorado School of Medicine  
Email: lise.kjems@albireopharma.com

**Background and aims:** Patients with progressive familial intrahepatic cholestasis (PFIC) may experience severe pruritus that results in considerable sleep disturbance. In the phase 3 PEDFIC 1 (P1) and

## POSTER PRESENTATIONS

PEDFIC 2 (P2) studies, odevixibat reduced serum bile acids (sBA), improved pruritus, and was generally well tolerated in patients with PFIC. Using pooled data from these studies, we describe changes in several sleep parameters in patients who responded to odevixibat treatment (Rs) vs treatment non-responders (NRs).

Table:

Change from baseline to weeks:	sBA or Pruritus Response			
	Yes (n = 48)		No (n = 28)	
	n	Mean	n	Mean
% Days with scratching associated with bleeding				
1-4	47	-16.8	28	-6.5
21-24	34	-30.9	22	3.2
45-48	18	-41.5	2	12.5
% Days needing help falling asleep				
1-4	47	-23.1	28	-10.4
21-24	34	-56.1	22	-4.9
45-48	18	-73.0	2	-1.8
% Days needing soothing				
1-4	47	-22.5	28	-6.0
21-24	34	-58.8	22	7.8
45-48	18	-74.6	2	4.2
% days sleeping with caregiver				
1-4	47	-23.1	28	-3.1
21-24	34	-48.5	22	3.1
45-48	18	-69.1	2	0.0
Number of awakenings				
1-4	47	-3.1	28	1.3
21-24	34	-1.9	22	1.5
45-48	18	-11.0	2	-4.3
<i>Value at timepoint:</i>				
CGIC, moderately or very much better, %				
4	42	57.1	26	30.8
24	32	59.4	21	33.3
48	18	88.9	4	25.0
CaGIC, moderately or very much better, %				
4	39	48.7	28	25.0
24	27	70.4	21	23.8
48	15	93.3	3	33.3

**Method:** P1 was a 24-week, randomized, placebo-controlled study in children with PFIC1 or PFIC2, and P2 is an ongoing, 72-week, extension study in patients with any type of PFIC. Across these studies, 77 patients have received odevixibat and are included in this pooled analysis. Patient sleep was evaluated based on caregiver report using the PRUCISION scale and via the clinician- or caregiver-reported Global Impression of Change (CGIC or CaGIC, respectively) sleep scales. Treatment response was defined as an sBA response (sBAs <65 or <102  $\mu\text{mol/L}$  for patients with PFIC1 and PFIC2, respectively) or a pruritus response (a  $\geq 1$ -point drop from baseline in pruritus score).

**Results:** Mean decreases in caregiver-reported percentage of days with scratching associated with bleeding, needing help falling asleep, and needing soothing were greater among Rs vs NRs (Table). At week 48, clinicians and caregivers reported that  $\geq 88\%$  of Rs had moderately or very much better sleep since starting odevixibat (Table).

**Conclusion:** Patients with PFIC and odevixibat treatment response had substantial improvements in caregiver- and clinician-reported

sleep. These effects occurred rapidly and continued over time. The improvement in sleep is likely linked to the improved pruritus observed in patients who responded to odevixibat.

### PO-1665

#### Substantial clinical benefits with odevixibat treatment across progressive familial intrahepatic cholestasis genetic deficiencies: subgroup analysis of serum bile acids, pruritus, and safety using pooled data from the PEDFIC 1 and 2 studies

Richard Thompson<sup>1</sup>, Patrick Horn<sup>2</sup>, Roderick H.J. Houwen<sup>3</sup>, Florence Lacaille<sup>4</sup>, Quanhong Ni<sup>2</sup>, Philip Stein<sup>2</sup>, Mary Elizabeth Tessier<sup>5</sup>, Carrie Thompson<sup>2</sup>, Jennifer Vittorio<sup>6</sup>, Lise Kjems<sup>2</sup>. <sup>1</sup>Institute of Liver Studies, King's College London, London, United Kingdom; <sup>2</sup>Albireo Pharma, Inc., Boston, United States; <sup>3</sup>Wilhelmina Children's Hospital and University Medical Center, Utrecht, Netherlands; <sup>4</sup>Hôpital Universitaire Necker-Enfants Malades, Paris, France; <sup>5</sup>Baylor College of Medicine/Texas Children's Hospital, Houston, United States; <sup>6</sup>Columbia University Medical Center, New York, United States

Email: lise.kjems@albireopharma.com

**Background and aims:** Odevixibat is an ileal bile acid transporter inhibitor in development to treat cholestatic liver diseases. The phase 3 PEDFIC 1 (P1) and PEDFIC 2 (P2) studies assessed odevixibat in patients with progressive familial intrahepatic cholestasis (PFIC) via serum bile acid (sBA) response and change in pruritus. We describe a pooled analysis of these outcomes in patients with PFIC1 (familial intrahepatic cholestasis 1 [FIC1] deficiency) or PFIC2 (bile salt export pump [BSEP] deficiency). For those with PFIC2, BSEP subtype was also examined (subtype 1: at least 1 p.D482G or p.E297G mutation; subtype 2: at least 1 missense mutation but not p.D482G or p.E297G). **Method:** This 48-week subgroup analysis included pooled data from P1 (consisting of a 24-week, placebo-controlled treatment period in patients with PFIC1 or PFIC2) and P2 (an ongoing, 72-week, open-label extension study in patients from P1 or new patients with any type of PFIC, where all patients receive odevixibat). sBA response (ie,  $\geq 70\%$  reduction from baseline or sBAs  $\leq 70 \mu\text{mol/L}$ ), change in pruritus based on positive pruritus assessments (PPAs) at the patient level (ie, scratching score  $\leq 1$  or a  $\geq 1$ -point drop from baseline on the PRUCISION instrument), and treatment-emergent adverse events (TEAEs) were assessed.

**Results:** Of 77 patients who received odevixibat, 20 had PFIC1 (26%) and 51 (66%) had PFIC2. BSEP subtype 1 or 2 were present in 13 (26%) and 36 (71%) patients with PFIC2, respectively (2 additional patients with BSEP subtype 3 were not included in this analysis). During the analysis period,  $\geq 50\%$  of patients met sBA response criteria, regardless of genotype (Figure; panel A). Mean PPAs were above 60% for patients with PFIC2 (including BSEP subtypes 1 and 2); mean PPAs for patients with PFIC1 were 48% (Figure; panel B). Incidence of TEAEs in odevixibat-treated patients with PFIC1 or PFIC2 (80% each) and BSEP subtype 1 and 2 (77% and 86%, respectively) in the pooled population was comparable to that of placebo-treated patients in P1 (85%). Most TEAEs were mild or moderate, self-limiting, and considered by the investigator as not related to study drug.

**Conclusion:** Patients with PFIC1 or PFIC2 had substantial benefits with odevixibat treatment, including reductions in sBAs and improvement in pruritus symptoms. Long-term treatment with odevixibat was well tolerated, regardless of PFIC classification or BSEP subtype.

**PO-1718**

**Genetic analysis and phenotypic correlation in ductal plate malformation**

Meha Bhuvu<sup>1</sup>, Richard Sandford<sup>2</sup>, Griffiths Bill<sup>1</sup>. <sup>1</sup>Addenbrooke's Hospital, Hepatology, United Kingdom; <sup>2</sup>Addenbrooke's Hospital, Clinical Genetics, United Kingdom  
Email: mehajib@aol.com

**Background and aims:** Ductal plate malformation (DPM) includes polycystic liver disease (PCLD), multiple biliary hamartomas (MBH), congenital hepatic fibrosis (CHF) and Caroli disease. We sought to identify the genetic basis of a cohort of hitherto undefined DPM.

**Method:** 34 unrelated adults with presumed congenital liver disease underwent extended genetic analysis via a clinical exome panel (PKD1, PKD2, PKHD1, SEC63, PRKCSH, GANAB, ALG8, DNAJB11, LRP5). Clinical details and phenotypic correlation were analysed.

**Results:** Of the 34 patients screened, genetic variants were identified in 20:

Heterozygous variants in GANAB (n = 4: 3 females, 1 male, mean age 56) were associated with a variety of mild PCLD phenotypes (with/without renal cysts, with Caroli's and with MBH). Variants were pathogenic in 2 cases and VUS in 2 cases (both deleterious).

Heterozygous variants in PRKCSH (n = 2: both female, mean age 62) were associated with PCLD without renal cysts including 1 VUS (deleterious) and 1 novel pathogenic variant in a patient considered for liver transplantation.

Heterozygous variants in the SEC63 (n = 4: 3 female, 1 male, mean age 60) were associated with largely asymptomatic PCLD mostly without renal cysts including 3 pathogenic (all novel) and one VUS (deleterious).

PKD1 (n = 3) and PKD2 (n = 2) heterozygous gene variants (4 pathogenic/2 novel) were associated with polycystic kidney and liver disease. All 5 were female (mean age 48) and with significant FH. Variants in PKHD1 (n = 5: 4 male, 1 female, mean age 67) were mostly compound heterozygous and had a variety of phenotypes including CHF (n = 2, both liver transplanted), CHF/MBH (n = 1, portal hypertension), MBH/Caroli (n = 1, kidney transplanted) and PCLD without renal cysts (n = 1).

No genetic variants were identified in 14/34 including 3 CHF, 3 MBH and 8 PCLD patients.

**Conclusion:** Patients with DPM display a spectrum of disease phenotypes ranging in severity from asymptomatic, incidental diagnosis to end-stage liver disease. We identified the genetic cause in nearly 60% of a previously undefined cohort of DPM patients and discovered several novel variants. Of note, a significant proportion had meaningful variants in GANAB, PRKCSH and SEC63. PRKCSH and SEC63 variants were associated with isolated PCLD. GANAB and PKHD1 mutations were associated with mixed phenotypes, the latter found in mostly males and with a strong propensity for CHF. GANAB and SEC63 phenotypes were mild. Our findings support the use of bespoke gene panels in suspected DPM.

**PO-1722**

**Epidemiology and burden of Progressive Familial Intrahepatic Cholestasis: Systematic review**

Tracey Jones-Hughes<sup>1</sup>, Joanna Campbell<sup>1</sup>, Louise Crathorne<sup>1</sup>, Velichka Valcheva<sup>2</sup>. <sup>1</sup>Roboleo and Co Ltd, York, United Kingdom; <sup>2</sup>Albireo Pharma, VP Medical Affairs Europe  
Email: tracey@roboleo.com

**Background and aims:** Progressive familial intrahepatic cholestasis (PFIC) is a rare but severe group of liver disorders of autosomal recessive inheritance, affecting an estimated 1 in 50,000 children worldwide. PFIC is characterized by severe pruritus and malabsorption, with rapid progress and ultimately liver failure. For children and their parents, PFIC is an extremely distressing disease. Significant pruritus can lead to severe cutaneous mutilation and, without surgery or liver transplant (LT), PFIC is typically fatal by age 20. The aim of this study was to conduct a systematic review of published evidence on the epidemiology and burden of PFIC.

**Method:** Databases including MEDLINE and Embase were searched for publications on PFIC prevalence, incidence or natural history, and the economic burden or health-related quality of life of patients with PFIC. Preferred Reporting Items for Systematic Reviews and Meta-Analyses guidelines were followed.

**Results:** Three systematic reviews and twenty-two studies were eligible for inclusion for the epidemiology of PFIC including a total of 2,603 patients. Where reported, study periods ranged from 3 to 33 years. Local population prevalence of PFIC was reported in three studies, ranging from 9.0% to 12.0% of children admitted with cholestasis, acute liver failure, or splenomegaly.

The most detailed data come from the NAPPED study where findings for PFIC2 patients show a serum bile acid concentration below 102 μmol/L predicted native liver survival of >15 years following surgical bile diversion.

Burden of disease was mainly reported through health-related quality of life (HRQL), rates of surgery and survival. Rates of biliary diversion and liver transplant varied widely depending on study period, sample size and PFIC type, with many patients having multiple surgeries and progressing to liver transplant. This renders data unsuitable for comparison.

**Conclusion:** Using robust and transparent methods, this systematic review summarises our current knowledge of PFIC. The epidemiological overview is highly mixed and dependent on presentation and PFIC subtype. Only two studies reported HRQL and mortality results were variable across different subtypes. Lack of data and extensive heterogeneity severely limit understanding of this disease area, particularly variation around and within subtypes.

#### Circulating Fn14 is associated with pathogenic TH17 polarization in children with sclerosing cholangitis and inflammatory bowel disease

Simon Lam<sup>1</sup>, Immaculeta Osuji<sup>2</sup>, Annika Yang vom Hofe<sup>2</sup>, Ruchi Singh<sup>2</sup>, Cyd Castro Rojas<sup>2</sup>, Astha Malik<sup>2</sup>, Jonathan Dillman<sup>3</sup>, Divya Sharma<sup>4</sup>, Rebekah Karns<sup>2</sup>, Rana Herro<sup>5</sup>, Alexander Miethke<sup>2</sup>.

 Email: simon.lam@albertahealthservices.ca

**Background and aims:** Sclerosing cholangitis (SC) including primary sclerosing cholangitis (PSC) and autoimmune sclerosing cholangitis (ASC) are highly associated with inflammatory bowel disease (IBD), most commonly ulcerative colitis (UC), and SC-IBD may represent a unique IBD phenotype. We previously reported Th17.1 polarization in liver tissue, using both liver RNAs-seq and multi-parameter immunofluorescence, to segregate with SC-IBD. In the present study, we aim to discover biomarkers that selectively segregate with SC-IBD.

**Method:** Circulating plasma proteins were assayed by Slow Off-rate Modified Aptamer (SOMAscan) technology on children in 2 separate cohorts of SC-IBD and healthy controls (HC) (A: SC-IBD = 17, mean age = 15.4 years, male = 10, UC = 8; HC = 13, mean age = 17.8 years, male = 7; B: SC-IBD = 11, mean age = 16.1 years, male = 9, UC = 8; HC = 8, mean age = 14.1 years, male = 3). Significantly differentially expressed proteins determined by Wilcoxon Rank Sum test and corrected using a false discovery rate of <5% in cohort A were validated in cohort B using logistic regression. Spearman rank order correlation was used to correlate significant circulating plasma proteins and liver biochemistries.

**Results:** Of 1305 circulating plasma proteins assayed, 215 proteins were nominally significant between SC-IBD and HC in cohort A. Pathways related to TH1 and TH2 cell differentiation, TNF, and IL-17 signaling pathways were upregulated in children with SC-IBD. Ten of these 215 proteins were validated in cohort B with increased concentrations of CXCL8, TIMP1, FGF23, FCGR3B, PIGR, SCARB2, TNFRSF1A and Fn14, while ACY1 and CTSD were the only proteins with decreased concentrations in SC-IBD compared to HC. SC-IBD had a 3.7-fold increase in Fn14 compared to HC, highest among all validated proteins (Table 1). Concentrations of circulating Fn14 correlated with AST (rs = 0.40, p = 0.03) and GGT (rs = 0.37, p = 0.04).

Table 1: Mean concentrations<sup>†</sup> of significantly differentially expressed circulating plasma proteins in children with SC-IBD compared to HC assayed by SOMAscan

Protein	HC	SC-IBD	Fold Change (SC-IBD/HC)	Corrected p value
Fn14	377	1398	3.71	<0.001
SCARB2	441	872	1.98	<0.001
PIGR	12040	18706	1.55	<0.001
TNFRSF1A	1423	1962	1.38	<0.001
CXCL8	2407	3229	1.34	<0.001
TIMP1	482	500	1.04	<0.001
FCGR3B	2225	2265	1.02	<0.001
ACY1	16734	16609	0.99	<0.001
CTSD	1462	1421	0.97	<0.001

<sup>†</sup>Concentrations of proteins expressed as relative fluorescent units (RFU) calibrated to a standard curve

**Conclusion:** Large scale plasma proteomic analysis discovered circulating Fn14 to segregate with pediatric SC-IBD and to correlate with biomarkers of SC liver disease. Fn14 was previously shown to promote TH17 polarization in autoimmune conditions like rheumatoid arthritis. The role of Fn14 in driving hepatic TH17.1 requires further investigations.

### PO-1809

#### Efficacy, safety, and tolerability of seladelpar in patients with compensated liver cirrhosis due to primary biliary cholangitis (PBC): a pooled analysis of phase 2 and phase 3 studies

**Background and aims:** Patients with PBC and compensated cirrhosis can progress to decompensation with its associated complications, liver transplantation or death. PBC patients with an incomplete response or intolerance to UDCA have an unmet need to slow disease progression. Seladelpar, a selective PPAR delta agonist, has shown potent anti-cholestatic and anti-pruritic activity in PBC studies. We now report a pooled analysis from two studies assessing the efficacy, safety, and tolerability of seladelpar in PBC patients with compensated cirrhosis.

**Method:** Eligible PBC patients with an inadequate response or intolerance to UDCA (ALP  $\geq 1.67 \times$  ULN) were enrolled into an open-label phase 2 study (EudraCT 2016-002996-91) or a placebo (Pbo)-controlled phase 3 study (EudraCT 2018-001171-20). Cirrhosis was diagnosed using liver biopsy, imaging tests, or liver elastography. Patients received oral Pbo, seladelpar 5 mg or 10 mg once daily + UDCA if tolerated. Efficacy analyses at 3 months included composite response (ALP  $< 1.67 \times$  ULN, ALP decrease of  $\geq 15\%$  and total bilirubin [TB]  $\leq$  ULN), ALP % change, ALP  $\leq$  ULN, and changes in liver function. Safety was assessed for 3 months.

**Results:** Of 384 enrolled patients, 53 had compensated cirrhosis (Child-Pugh A: Pbo [n = 7], 5 mg [n = 22], and 10 mg [n = 24]). Baseline characteristics included: 92% female, mean age 58 yrs, 94%

on UDCA, ALP 287 U/L, TB 0.92 mg/dL, ALT 50 U/L, AST 49 U/L, GGT 228 U/L, albumin 3.96 g/dL, and platelets  $197 \times 10^3/\mu\text{L}$ . After 3 months, 39 patients were treated. The composite end point was met in 50% (9/18) of 5 mg and 63% (10/16) of 10 mg groups compared to none in Pbo (0/5). Reductions in ALP in the 5 mg (-31%, -82 U/L) and 10 mg groups (-41%, -114 U/L) were greater than Pbo (-2.6%, -8.7 U/L). ALP was normalized in 3 patients in each seladelpar group (17–19%) but none in Pbo. Changes in ALT were -15%, -6%, and -32% in Pbo, 5 and 10 mg groups, respectively. Total bilirubin, platelets, albumin, and INR remained stable. One patient in 10 mg discontinued due to AE (pruritus). Three patients had an SAE: 2 on 5 mg (febrile neutropenia, procedural pain) and 1 on 10 mg (angina pectoris), all unrelated to study drug. Efficacy, tolerability, and safety in patients with compensated cirrhosis were comparable to that of non-cirrhotic patients.

**Patients with PBC and Compensated Liver Cirrhosis**

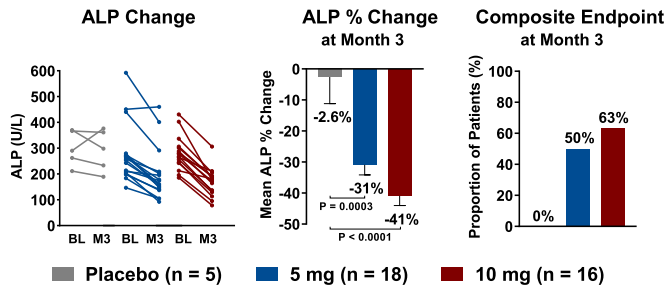

Figure:

**Conclusion:** Seladelpar appeared safe and was well tolerated and may provide an effective treatment option for patients with compensated liver cirrhosis due to PBC.

**PO-1811**

**Odevixibat effects on cholestasis-related parameters: Analysis of pooled data from the PEDFIC 1 and PEDFIC 2 studies in children with progressive familial intrahepatic cholestasis**

Email: lise.kjems@albireopharma.com

**Background and aims:** Odevixibat, an ileal bile acid transporter inhibitor, is in development to treat cholestatic liver diseases. In the phase 3 PEDFIC 1 (P1) and PEDFIC 2 (P2) studies, odevixibat treatment reduced serum bile acids (sBAs) and improved pruritus in patients with progressive familial intrahepatic cholestasis (PFIC). Using pooled data from these studies, we analysed changes in parameters of cholestasis, pruritus, and hepatic laboratory markers and compared patients who responded to odevixibat treatment (Rs) with non-responders (NRs).

**Method:** P1 was a 24-week, randomized, placebo-controlled study in children with PFIC1 or PFIC2, and P2 is an ongoing, 72-week extension study in patients with any type of PFIC. In this pooled analysis, spanning 48 weeks, 77 patients have received odevixibat (PFIC1, n = 20; PFIC2, n = 51; PFIC3, n = 5; MYO5B deficiency, n = 1; overall median exposure: 37 weeks). Two responder definitions were examined: 1) sBA response (ie, sBAs <65 or <102  $\mu\text{mol/L}$  for PFIC1 and PFIC2, respectively) and 2) sBA response or pruritus response (ie, a  $\geq 1$ -point drop from baseline in PRUCISION score).

**Results:** Rates of sBA Rs and sBA or pruritus Rs were 31% and 57%, respectively, at weeks 0–24, 48% and 60% at weeks 25–36, and 59% and 65% at weeks 37–48. Among all odevixibat-treated patients, mean change from baseline (CFB) to week 48 in alanine aminotransferase (ALT) and total bilirubin was -82 U/L and -18  $\mu\text{mol/L}$ , respectively. In general, Rs had greater mean CFB (ie, improvements) vs NRs in these hepatic laboratory parameters with long-term odevixibat treatment (Table) that started as early as week 4 and increased over time.

Table:

Liver Enzyme Levels	sBA Response		sBA or Pruritus Response	
	Yes	No	Yes	No
	n (%)	Mean (SE)	n (%)	Mean (SE)
ALT, U/L				
Baseline	24 (39)	124 (33)	38 (63)	82 (18)
CFB→wk 4	23 (39)	-28 (37)	36 (16)	21 (24)
CFB→wk 24	19 (40)	-67 (42)	28 (11)	-10 (27)
CFB→wk 48	15 (63)	-112 (57)	9 (22)	-32 (48)
Total bilirubin, $\mu\text{mol/L}$				
Baseline	24 (39)	27 (7)	38 (63)	74 (16)
CFB→wk 4	23 (39)	-8 (4)	36 (9)	-10 (11)
CFB→wk 24	19 (40)	-23 (8)	28 (10)	-19 (7)
CFB→wk 48	15 (63)	-25 (11)	9 (14)	-6 (9)

<sup>a</sup>Responder rate  $[(n/(n + m)) \times 100]$ .

**Conclusion:** Patients with PFIC who responded to odevixibat treatment had sustained improvements in cholestasis-related parameters that were not observed to the same extent in treatment non-responders.

**PO-1828**

**Genetic mutation and cystic fibrosis-associated liver disease at the time of diagnosis in children: A correlational study**

Alejandra Marisela Sabillon-Mendoza<sup>1</sup>, Rubén Peña Velez<sup>1</sup>, Flora Zarate<sup>1</sup>, Jaime Ramirez<sup>1</sup>. <sup>1</sup>Instituto Nacional de Pediatría, Gastroenterología y Nutrición, Ciudad de México, Mexico  
Email: alesabillon@yahoo.com

**Background and aims:** It is estimated that 10 to 15% of patients with cystic fibrosis have liver disease (CFLD), this negatively impacts the evolution of the disease, it has been reported that dysfunction of the transmembrane conductance regulator (CFTR) has a direct effect on the cholangiocyte function, finally the spectrum of complications ranges from cholestasis, progressive fibrosis, biliary obstruction to focal biliary cirrhosis. Around 2000 mutations in CFTR have been determined and classified according to their functional defect, however, none of them have been associated with CFLD, accepting that this is due to the interaction of environmental factors,

## POSTER PRESENTATIONS

medications, infections and malnutrition. Our objective was to determine if there is a correlation between the most frequent CF mutations and liver disease in children at the time of diagnosis.

**Method:** Retrospective, observational and analytical study, 82 files of children diagnosed with cystic fibrosis were reviewed, 43 had a certain mutation, the diagnosis of liver disease was based on analytical, imaging or histopathology tests, an APRI index was performed to establish grade fibrosis.

**Results:** 82 records of children diagnosed with cystic fibrosis, the male gender predominated in 54%, the median age at the time of diagnosis was 10 months, it was observed that 59% of the children presented elevation of ALT by cut-off point for gender, the ultrasound was altered in 39%. There was an association between changes in USG and elevation of ALT ( $p = 0.024$ ). This led to the performance of liver biopsies in five patients, finding variable degrees of fibrosis and macro and microvesicular steatosis.

The APRI index was correlated with other variables of liver and canalicular injury, finding a correlation as shown in Table 1.

Figure:

	APRI index	"p" value
ALT	0.612	$p < 0.001$
GGT	0.594	$p < 0.001$
DB	0.359	$p < 0.001$
FA	0.047	$p = 0.675$
INR	0.195	$p = 0.80$

Of the patients with an APRI index greater than 0.5, 3 had a *F508del* mutation, 2: *6542X*, 1: *N1303K*, those with an APRI index greater than 1.5, a patient with a *F508del* mutation and another with a *p. Phe1078Ile* mutation. The analysis of variance between the mutations showed a difference in the degree of liver injury  $p = 0.03$  according to the genetic variant.

**Conclusion:** At diagnosis there is liver injury in 59% of children with CF, and some degree of fibrosis was observed in 29% of children. Larger studies are needed to look at the influence of the genetic mutation on the development of liver disease. In this study, we observed greater liver damage in the *F508del*, *6542X* mutations.

### PO-1833

#### Odevixibat therapy improves clinically meaningful end points in children with progressive familial intrahepatic cholestasis: Data from the PEDFIC 1 and PEDFIC 2 trials

Richard Thompson<sup>1</sup>, Lorenzo D'Antiga<sup>2</sup>, Emmanuel Gonzales<sup>3</sup>, Saul Karpen<sup>4</sup>, Lise Kjems<sup>5</sup>, Kathleen Loomes<sup>6</sup>, Cara Mack<sup>7</sup>, Quanhong Ni<sup>5</sup>, Henkjan Verkade<sup>8</sup>, Patrick Horn<sup>5</sup>. <sup>1</sup>Institute of Liver Studies, King's College London; <sup>2</sup>Azienda Ospedaliera Papa Giovanni XXIII; <sup>3</sup>Hôpital Bicêtre, AP-HP, Université Paris-Saclay, Hépatinov, Inserm U 1193; <sup>4</sup>Emory University School of Medicine; <sup>5</sup>Albireo Pharma, Inc.; <sup>6</sup>Children's Hospital of Philadelphia; <sup>7</sup>Children's Hospital Colorado, University of Colorado School of Medicine; <sup>8</sup>University of Groningen, Beatrix Children's Hospital/University Medical Center Groningen  
Email: patrick.horn@albireopharma.com

**Background and aims:** Odevixibat, an ileal bile acid transporter inhibitor, is in development to treat cholestatic liver diseases. Here, we describe key outcomes with odevixibat in children with progressive familial intrahepatic cholestasis (PFIC) based on pooled analysis of data from the phase 3 PEDFIC 1 (P1; NCT03566238) and PEDFIC 2 (P2; NCT03659916) studies.

**Method:** This pooled analysis covers up to 48 weeks of odevixibat treatment from P1 and through the planned P2 interim data cut (median duration of exposure as of 15 July 2020: 37 weeks; range: 1–108 weeks). The following outcomes are described: change in serum bile acids (sBAs), change in pruritus score (measured using the

PRUCISION scale; range: 0–4), evaluation of growth and sleep parameters, and safety monitoring. Mean values are shown.

**Results:** Across the P1 and P2 studies, 77 patients received odevixibat. At baseline, sBAs and pruritus scores were 250  $\mu\text{mol/L}$  ( $n = 77$ ) and 2.9 ( $n = 76$ ), respectively. Four weeks after starting odevixibat, sBAs had decreased by 88  $\mu\text{mol/L}$  ( $n = 68$ ) and pruritus score decreased by 0.7 ( $n = 75$ ). At the end of the analysis period, sBAs had decreased from baseline by 213  $\mu\text{mol/L}$  in patients with available data ( $n = 24$ ) and pruritus score dropped by 1.4 ( $n = 32$ ). Height Z scores increased from  $-1.9$  at baseline ( $n = 75$ ) to  $-0.8$  at week 48 ( $n = 20$ ; Figure, panel A). Similar improvements were observed for weight Z scores (baseline:  $-1.1$  [ $n = 75$ ]; week 48:  $-0.0$  [ $n = 21$ ]; Figure, panel B). Odevixibat-treated patients had changes from baseline to weeks 37–48 in observer-reported percentage of days seeing blood due to scratching [ $-25\%$ ], needing help falling asleep [ $-52\%$ ], needing soothing [ $-51\%$ ], and sleeping with caregiver [ $-40\%$ ]. Overall, drug-related treatment-emergent adverse events (TEAEs) were reported in 32 of 77 (42%) patients, but no drug-related serious TEAEs were reported. Four patients had TEAEs leading to treatment discontinuation.

**Conclusion:** In children with PFIC, odevixibat treatment for up to 48 weeks was well tolerated and associated with clinically meaningful effects on sBAs, pruritus, growth, and sleep parameters.

### PO-1843

#### Pretreatment serum bile acid parameters and predictability of response to odevixibat, an ileal bile acid transport inhibitor, in children with progressive familial intrahepatic cholestasis

Henkjan Verkade<sup>1</sup>, Folkert Kuipers<sup>1</sup>, Quanhong Ni<sup>2</sup>, Velichka Valcheva<sup>2</sup>, Patrick Horn<sup>2</sup>, Jan Mattsson<sup>2</sup>, Per-Goran Gillberg<sup>2</sup>, Lise Kjems<sup>2</sup>. <sup>1</sup>University of Groningen, Beatrix Children's Hospital/University Medical Center Groningen; <sup>2</sup>Albireo Pharma, Inc.  
Email: h.j.verkade@umcg.nl

**Background and aims:** Odevixibat, an orally administered, selective inhibitor of the ileal bile acid transporter, reduced serum bile acids (sBAs) and pruritus in children with progressive familial intrahepatic cholestasis (PFIC) type 1 or 2 in the phase 3, 24-week, double-blind PEDFIC 1 study. Here, we evaluated whether pretreatment sBA parameters could predict response to odevixibat using data from PEDFIC 1.

**Method:** This analysis included children with PFIC aged 0.5–18 years with elevated sBAs and significant pruritus who were treated with odevixibat 40  $\mu\text{g/kg/day}$  ( $n = 23$ ) or 120  $\mu\text{g/kg/day}$  ( $n = 19$ ) in PEDFIC 1. We analysed pretreatment sBA composition using liquid chromatography–tandem mass spectrometry, quantifying serum concentrations of total BAs, primary (cholate, chenodeoxycholate) and secondary (deoxycholate, lithocholate) BAs, and ursodeoxycholate (UDCA). We also quantified pretreatment serum concentrations of 7 $\alpha$ -hydroxy-4-cholesten-3-one (C4). Pretreatment parameters were analysed in treatment responders (Rs; ie, patients with sBAs  $\leq 70$   $\mu\text{mol/L}$  or reduced  $\geq 70\%$  and/or a  $\geq 1$ -point drop in observer-reported pruritus score from baseline to end of treatment) vs non-responders (NRs).

**Results:** Median baseline UDCA concentration was 55.6  $\mu\text{mol/L}$  in the 31/42 patients who used UDCA as treatment and 0.2  $\mu\text{mol/L}$  in the 9/42 patients who did not use UDCA. Proportion of Rs was 16/23 and 8/19, respectively, in the 40 and 120  $\mu\text{g/kg/day}$  dose groups; groups were combined for analysis (overall Rs, 24/42 [57%]). The fraction of Rs was similar with (56%) and without UDCA use (60%). Before starting odevixibat, Rs and NRs had median total sBA concentrations of 194.1 and 269.3  $\mu\text{mol/L}$ , respectively, composed of primary BAs (182.7 and 205.9  $\mu\text{mol/L}$ ), secondary BAs (0.3 and 0.3  $\mu\text{mol/L}$ ), and UDCA (52.9 and 28.8  $\mu\text{mol/L}$ ). Median pretreatment serum C4 concentrations were 2.0 ng/ml in Rs and 3.3 ng/ml in NRs.

**Conclusion:** Response to odevixibat treatment in patients with PFIC type 1 or type 2 was not associated with pretreatment serum

Figure: (abstract: PO-1833)

concentrations of total, primary, or secondary BAs, or of C4, a marker for BA synthesis rate. Neither UDCA use nor pretreatment serum concentration of UDCA was associated with subsequent response to odevixibat. Interestingly, the low relative serum concentration of secondary BAs before treatment apparently did not preclude subsequent response to odevixibat in these patients.

**PO-2040**

**Single-centre experience with follow-up of patients with acute porphyria**

Barbora Nováková<sup>1</sup>, Jaromír Petrtýl<sup>1</sup>, Iva Subhanová<sup>2</sup>, Daniela Záhorská<sup>3</sup>, Libor Vitek<sup>2</sup>, Pavel Martásek<sup>3</sup>, Radan Bruha<sup>1</sup>.  
<sup>1</sup>First Faculty of Medicine, Charles University and General University Hospital in Prague, 4th Department of Internal Medicine-Department of Hepatogastroenterology, Prague 2, Czech Republic; <sup>2</sup>First Faculty of Medicine, Charles University and General University Hospital in Prague, Institute of Medical Biochemistry and Laboratory Diagnostics, Prague 2, Czech Republic; <sup>3</sup>First Faculty of Medicine, Charles University and General University Hospital in Prague, Department of Paediatrics and Inherited Metabolic Disorders, Prague 2, Czech Republic  
 Email: cizkova.barbora@gmail.com

**Background and aims:** Acute porphyria is a rare metabolic disease, typically autosomal dominant inherited. It manifests itself in acute attacks, triggered by various stimuli, leading to many life-threatening complications. According to the rarity of acute porphyria, even single center follow-up studies are not so common. Therefore, we aim to present information about the patients diagnosed between 1959 and 2018 with acute porphyria in our center including type of porphyria, clinical symptoms, family history and genetics.

**Method:** We surveyed our clinical and laboratory data plus the results of genetic screening.

**Results:** 215 patients and relatives were diagnosed with acute porphyria (Acute intermittent porphyria (n = 86), Porphyria variegata (n = 68), Hereditary coproporphyria (n = 59), undefined type (n = 2)). At least 48% of patients have shown to be symptomatic (n = 104). 93% of symptomatic patients had abdominal manifestation, in 35% combined with neurological and in 7% with psychiatric symptoms, 20% had all three symptoms (abdominal, neurological and psychiatric) and 4% patients had neuropsychiatric symptoms only. Acute attack was induced by medicaments (23%) or by other causes (stress 16%, infection 12%, and hormonal changes 9%) and in 40% remained unknown. Importantly, two or more acute attacks were present in at least 62% of symptomatic acute porphyria cases (n = 64) including

10% of recurrent attacks (n = 10), see Figure. Cutaneous symptoms were present in at least 75% of cases of Porphyria variegata and in 17% of Hereditary coproporphyria cases. 51% of patients reported positive family history of acute porphyria (42 multi-member families, n = 174). The clinical penetrance of acute porphyria in patients diagnosed genetically by family screening was 17%.

**Clinical manifestation of acute porphyria (N=215)**

Figure:

**Conclusion:** Based on long term follow-up of patients with acute porphyria at least 62% of symptomatic cases developed repeated attacks, mostly manifested by abdominal symptoms. Nevertheless, the clinical penetrance of acute porphyria diagnosed by family screening is low.

**PO-2090**

**A 3-proteomic score to improve the clinical management of childhood liver cancer**

**Background and aims:** Hepatoblastoma (HB) is the main liver tumor in childhood. However, it is a rare tumor with an annual incidence of 1 case per million children. Therapeutic options for advanced tumors are limited, with a 3-year event free survival (EFS) below 35% (Semeraro et al, Eur J Cancer 2013). Gene expression and methylation studies have improved our knowledge on HB and revealed up to three HB molecular prognostic subtypes (Cairo-Armengol et al, Cancer cell 2008; Carrillo-Reixach et al, J Hepatol, 2020). Therefore, our aim is to perform the first proteomic study of HB and identify new prognostic biomarkers and dysregulated pathways.

**Method:** In total, 184 pediatric patients with liver cancer were included. A training set of 22 tumor and non-tumor snap-frozen samples from 14 HB patients were profiled by 2D-DiGE-MALDI-TOF and Label Free. Pathway analysis was performed using random walk and restart and fast-gene set enrichment analysis. Prognostic biomarkers were identified by supervised analysis using R and validated by immunohistochemistry (IHC) in an independent set of 509 FFPE samples from 170 pediatric patients with liver cancer. Impact of the prognostic biomarkers in other cancers was performed using the TCGA database. Tumor growth studies of selected biomarkers was assessed *in vivo* and *in vitro* using HB cell lines and xenografts.

**Results:** We identified 173 tumor deregulated proteins ( $p < 0.05$ ,  $FC \geq 1.5$ ). Overexpressed proteins were involved on the activation of cell-cycle, extracellular matrix, EIF2, PI3 K/Akt and mTOR pathways whereas underexpressed proteins belonged to pathways related to hepatic functions. The unsupervised analysis revealed two tumor clusters (PC-1, PC-2) associated with the C1/C2 transcriptomic subtypes ( $p < 0.03$ ) and pathological features of poor prognosis ( $p < 0.05$ ). The supervised analysis comparing PC-2 vs PC-1 tumors identified 341 differently expressed proteins ( $p < 0.01$ ,  $FC \geq 1.5$ ). We selected 3 proteins (CKAP4, C1QBP and CRYL1) which its differential expression was validated by Western blot in PC-2 vs PC-1 tumors but also as compared with non-tumor liver samples ( $p < 0.0015$ ). A 3-protein score was defined by combining the 3 biomarkers and it was significantly associated to patient survival in the training ( $p = 0.0083$ ) and in the validation set using IHC ( $p = 1.59 \times 10^{-14}$ ). Moreover, the 3-protein score was an independent prognostic factor (HR:12.02, IC:4.19–34.51,  $p < 0.0001$ ) for pediatric liver cancer patients and also for adult HCC, cholangiocarcinoma, lung, kidney, prostate, thyroid and thymus cancer patients. Finally, *in vitro* and *in vivo*

experiments showed that the inhibition of CKAP4 impaired significantly tumor growth ( $p < 0.05$ ).

**Conclusion:** We identified a prognostic 3-protein score that could be easily applied at the clinical practice to improve clinical management of childhood liver cancer and other adult tumors.

### PO-2120

#### Treatment with seladelpar in patients with primary biliary cholangitis (PBC) and prior experience with obeticholic acid (OCA) or fibrates

Aliya Gulamhusein<sup>1</sup>, Guy Neff<sup>2</sup>, Aparna Goel<sup>3</sup>, Marlyn J. Mayo<sup>4</sup>, Carmen Stanca<sup>5</sup>, Christopher Bowlus<sup>6</sup>, Lisa Forman<sup>7</sup>, Pietro Invernizzi<sup>8</sup>, Frederik Nevens<sup>9</sup>, Ehud Zigmund<sup>10</sup>, Eli Zuckerman<sup>11</sup>, Ke Yang<sup>12</sup>, Yun-Jung Choi<sup>12</sup>, Alexandra (Sasha) Steinberg<sup>12</sup>, Charles McWherter<sup>12</sup>, Kris Kowdley<sup>13</sup>. <sup>1</sup>Toronto General Hospital, Toronto, Canada; <sup>2</sup>Covenant Research, Sarasota, United States; <sup>3</sup>Stanford Hospital, Stanford, United States; <sup>4</sup>University of Texas Southwestern, Dallas, United States; <sup>5</sup>NYU Langone Health, New York, United States; <sup>6</sup>University of California Davis Medical Center, Sacramento, United States; <sup>7</sup>University of Colorado, Aurora, United States; <sup>8</sup>ASST di Monza-Azienda Ospedaliera San Gerardo, Rozzano, Italy; <sup>9</sup>UZ Leuven, Leuven, Belgium; <sup>10</sup>Tel Aviv Sourasky Medical Center PPDs, Tel Aviv-Yafo, Israel; <sup>11</sup>Lady Davis Carmel Medical Center, Haifa, Israel; <sup>12</sup>CymaBay Therapeutics, Newark, United States; <sup>13</sup>Liver Institute Northwest, PLLC, Seattle, United States Email: asteinberg@cymabay.com

**Background and aims:** Up to 40% of PBC patients (pts) taking ursodeoxycholic acid (UDCA) therapy do not achieve their biochemical treatment response. In this population, OCA or fibrates are often initiated as second-line therapy. Seladelpar, a potent and selective PPAR delta agonist, has shown potent anti-cholestatic and anti-inflammatory activity in PBC studies. This is a pooled analysis of 2 clinical studies to evaluate seladelpar in PBC patients who were previously treated with OCA or fibrates.

#### PBC patients with prior experience with OCA and Fibrates

Figure:

**Method:** Pts with PBC who had an inadequate response to UDCA/intolerance to UDCA and an  $ALP \geq 1.67x$  upper limit of normal (ULN) were enrolled into an open-label Phase 2 study (EudraCT 2016-002996-91) or a placebo-controlled Phase 3 study (EudraCT 2018-001171-20). Analyses were performed on pts treated with OCA or fibrates prior to the study entry. Efficacy was assessed on pts treated

with either seladelpar 10 mg, 5 mg, or placebo (Pbo) for 3 months, by analysing a composite responder rate (ALP <1.67 × ULN, ALP decrease ≥15% and TB ≤ULN), ALP ≤1 × ULN, ALP % change from baseline, and other markers of liver function. Safety was assessed over 1 year.

**Results:** A total of 71 (18%) of 384 enrolled pts in Phase 2 and Phase 3 studies had prior experience with OCA (47), fibrates (16), or both (8). In the 10 mg, 5 mg, and Pbo groups mean baseline values, respectively, were: ALP 307 U/L, 345 U/L, and 334 U/L; ALT 48 U/L, 55 U/L, and 48 U/L; total bilirubin of 0.77 mg/dL, 0.85 mg/dL, and 0.71 mg/dL. 51 pts were treated for 3 months: 10 mg n = 19, 5 mg n = 20 and Pbo n = 12. The composite end point was met in 79%, 40% and 8% pts in the 10 mg, 5 mg, and Pbo groups, respectively. ALP normalized in 21% pts in the 10 mg group, and 0% in the 5 mg or Pbo groups. Mean changes in ALP were -45%, -31%, and -9% in the 10 mg, 5 mg, and Pbo groups. Mean total bilirubin changes were -9%, -3% and +3%, and mean ALT changes were -21%, -13%, and -7%. Safety analysis was performed in 71 pts. Four pts had an SAE (3 pts on 5 mg and 1 pt on Pbo), all unrelated; treatment was discontinued due to AE in 2 pts: (1) ALT/AST elevation and (2) gastroesophageal reflux disease, both on 5 mg. AE of pruritus was noted in 7%, 15%, and 18% in the 10 mg, 5 mg, and Pbo groups, respectively.

**Conclusion:** In PBC pts with prior treatment with OCA or fibrates and ALP ≥1.67 × ULN, seladelpar appeared to be safe, well tolerated and showed meaningful and dose dependant improvement in biochemical markers of cholestasis.

#### PO-2204

##### Modeling phenotypic heterogeneity of Glycogen Storage Disease type Ia liver disease in mice by somatic CRISPR/Cas9-mediated gene editing

Martijn Rutten<sup>1</sup>, Terry Derks<sup>2</sup>, Nicolette Huijman<sup>1</sup>, Trijnie Bos<sup>3</sup>, Niels Kloosterhuis<sup>1</sup>, Kees van de Kolk<sup>4</sup>, Karin Wolters<sup>1</sup>, Mirjam Koster<sup>1</sup>, Rachel Thomas<sup>5</sup>, Alain de Bruin<sup>1,5</sup>, Bart van de Sluis<sup>1</sup>, Maaik Oosterveer<sup>1</sup>. <sup>1</sup>University Medical Center Groningen, Pediatrics, Groningen, Netherlands; <sup>2</sup>Beatrix Children's Hospital, University Medical Center Groningen, Section of Metabolic Diseases, Groningen, Netherlands; <sup>3</sup>University Medical Center Groningen, Laboratory Medicine, Groningen, Netherlands; <sup>4</sup>University Medical Center Groningen, The Central Animal Facility, Gronsai (Groningen Small Animal Imaging Facility), Groningen, Netherlands; <sup>5</sup>Utrecht University, Dutch Molecular Pathology Center, Faculty of Veterinary Medicine, Utrecht, Netherlands  
Email: m.g.s.rutten@umcg.nl

**Background and aims:** Patients with Glycogen Storage Disease type Ia (GSD Ia) primarily present with life-threatening hypoglycemia and display severe liver disease characterized by hepatomegaly. Despite strict dietary management, long-term complications still occur, amongst which liver tumor development. Variations in residual glucose-6-phosphatase (G6PC) activity likely contribute to phenotypic heterogeneity in biochemical symptoms and complications between patients. In addition, the molecular mechanisms that contribute to this heterogeneity remain largely unresolved. Incomplete insight into the relationship between residual G6PC activity and mechanisms poses major challenges to provide optimal healthcare and quality of life for GSD Ia patients. The currently available GSD Ia animal models are not suitable to systematically investigate the relationship between hepatic G6PC activity and phenotypic heterogeneity, or the contribution of gene-gene interactions in the liver. To meet these needs, we generated and characterized a novel hepatocyte-specific GSD Ia mouse model using somatic CRISPR/Cas9-mediated gene editing.

**Method:** Male hepatocyte-specific Cas9-expressing mice (ROSA26-LSL-Cas9 knock-in mice × Alb-Cre mice) were injected with various titers (0.1–1.0 × 10<sup>11</sup> particles) of adenovirus particles containing three sgRNAs targeting G6pc exon 1 in comparison to mice administered control adenovirus (empty vector, 1.0 × 10<sup>11</sup> particles).

Animals were sacrificed 4 weeks or 18 months after virus injection for organ and blood collection.

**Results:** Hepatic G6pc editing reduced hepatic G6PC activity up to 98% and resulted in fasting hypoglycemia, hypertriglyceridemia, hepatomegaly, hepatic steatosis, and an increased liver tumor incidence. This approach was furthermore successful to simultaneously modulate hepatic G6PC and ChREBP, a transcription factor that is activated in GSD Ia and protects against hepatic steatosis under these conditions. Importantly, it also allowed us to model a spectrum of GSD Ia phenotypes in terms of hepatic G6PC activity, fasting hypoglycemia, hypertriglyceridemia, hepatomegaly and hepatic steatosis.

**Conclusion:** In conclusion, we show that somatic CRISPR/Cas9-mediated gene editing of hepatic G6pc in mice opens new perspectives for translational research on GSD Ia. This approach will likely contribute to novel and personalized treatments for GSD Ia and other genetic liver diseases.

#### PO-2324

##### Incidence and impact of PYLEPHEBITIS in PYOGENIC LIVER ABSCESS

Nicolas Drilhon<sup>1</sup>, Paul Janvier<sup>2</sup>, Geoffrey Rossi<sup>2</sup>, Francois Durand<sup>2</sup>, Agnes Lefort<sup>2</sup>, Olivier Roux<sup>2</sup>. <sup>1</sup>Hospital Beaujon AP-HP, 92, Clichy, France; <sup>2</sup>Hospital Beaujon AP-HP, Clichy, France  
Email: nicolas.drilhon@gmail.com

**Background and aims:** Prevalence of pylephlebitis in patients with pyogenic liver abscess (PLA) remains unclear and its treatments debated. We aimed at describing the prevalence of pylephlebitis and its impact on PLA management and outcomes in a large cohort of patients treated for PLA.

**Method:** All the 332 patients hospitalized for PLA in our tertiary care center were screened from January 2010 to May 2018. Patients with history of chronic liver disease, liver transplantation or at risk for another cause of portal vein thrombosis (i.e.: acute pancreatitis or abdominal surgery in the last 15 days, local neoplasia) were excluded. All CT-scans were individually reviewed by an expert radiologist. Poor outcome was defined as primary treatment failure (PTF), death within 3 months after the diagnosis, or recurrence.

Overall, 96 patients (68% male, median age 62 years) with PLA were included. A microbiological documentation was found in 68 (71%): and *E. coli* (20/68 isolates, 29%) and *Klebsiella* spp. (18/68 isolates, 26%) were the most frequent micro-organisms found. Median duration of antibiotic treatment was 28 days and drainage was performed in 75 patients. Thirty-eight patients (40%) had portal or hepatic vein thrombosis: among them 27 (71%) had portal, 13 (34%) had hepatic vein thrombosis and 2 (5%) had both. Patients with pylephlebitis had more abscess at diagnosis (median number 2 vs 1, p = 0, 02) than patients without. Among patients with pylephlebitis, 17 (45%) received curative anticoagulation (AC) treatment, including 4 (11%) already receiving AC for another indication at diagnosis. Twenty-one (20%) patients had poor outcomes (14 had PTF, 4 died, 3 recurrences) with a median follow-up of 143 days. Pylephlebitis was not associated with poor outcomes (HR = 1.3, CI95% [0, 5–3, 4], p = 0, 581).

**Conclusion:** The prevalence of pylephlebitis in patient with PLA was 40%, mainly involving portal vein and 45% of patients with pylephlebitis received curative AC therapy. Pylephlebitis was not associated with a poor outcome.

#### PO-2392

##### Liver Involvement is rare during COVID-19 Infection in Children

Cigdem Arıkan<sup>1</sup>, Esra Polat<sup>2</sup>, Hacer Akturk<sup>3</sup>, Sirin Guven<sup>2</sup>, Fidan Khalilova<sup>3</sup>. <sup>1</sup>Koc University School of Medicine, Pediatric Gastroenterology Hepatology/KUTTAM, Istanbul, Turkey; <sup>2</sup>SBU Sancaktepe Training and Teaching Hospital, Pediatric Gastroenterology Hepatology, Istanbul; <sup>3</sup>Koc University School of Medicine  
Email: cigdemarikanmd@yahoo.com

## POSTER PRESENTATIONS

Several studies reported deranged liver enzyme levels ranging from 14% to 74% COVID-19 patients. However, there is no sufficient data which described liver test abnormalities in children with COVID-19. We evaluated the frequency of liver test abnormalities and clinical characteristics of children with COVID-19.

**Methods:** Medical records of 726 patients (mean  $\pm$  SME 114.5  $\pm$  2.5 months; male/female: 375/351) with laboratory-confirmed COVID-19 between April 2020 and September 2021 were reviewed and clinical characteristics, liver tests (aspartate aminotransferase (AST), alanine aminotransferase (ALT), alkaline phosphatase (ALP), gamma glutamyl transpeptidase (GGT), total bilirubin (TBIL) and lactate dehydrogenase (LDH) at admission and peak during follow-up retrieved retrospectively. Children who had not liver tests were excluded from study. Patients categorized according to clinical status (asymptomatic, mild, moderate and severe disease). AST ALT elevations classified as less than 2  $\times$  upper limit of normal (ULN), 2–5 $\times$  ULN and more than 5 $\times$ ULN. Comorbidities, outcome and frequency of liver injury were analyzed by SPSS.

**Results:** 425 children included into the study and AST, ALT, GGT and LDH abnormalities detected in 17.6%, 9.5%, 0.6% and 18.7% of children during follow-up. AST and ALT elevation were lower than 2 ULN in 94.7 and 90.3%, respectively. None of them showed more than 5 $\times$  ULN. Most of them had asymptomatic or mild disease (96.7%). In terms of disease severity, we did not find significant difference between normal and abnormal liver test groups. Liver test abnormalities were not found related to disease severity, presence of comorbid conditions (immunosuppression, malignancy, transplantation), antibiotic-antiviral treatment, age and gender (table 1). Absolute lymphocyte count was significantly low in children with moderate and severe disease compared to mild and asymptomatic children (1400  $\pm$  338 vs 3178  $\pm$  117p = 0.013). Progressive liver disease or liver failure was not observed and all of them alive.

Table 1:

	Asymptomatic-mild n = 363	Moderate-severe n = 62	p
Age (months)	109.7 $\pm$ 2.5	115.1 $\pm$ 8.9	0.56
AST IU	30 $\pm$ 2.5	22 $\pm$ 2	0.27
ALT IU	22.5 $\pm$ 2	18 $\pm$ 2.6	0.59
GGT IU	21 $\pm$ 6	26 $\pm$ 3.2	0.73
LDH IU	413 $\pm$ 114	392 $\pm$ 128	0.69
TBIL mg/dl	1.2 $\pm$ 0.2	1.3 $\pm$ 0.3	0.86

Data are given mean  $\pm$  SEM.

**Conclusion:** Liver test abnormalities detected in minority of patients in this cohort. This could be related to milder course of COVID -19 in children, lack of comorbid conditions such as hypertension, diabetes, coronary heart disease.

### PO-2628

#### Novel Copper Protein Speciation method for calculating Serum Non Ceruloplasmin Copper: A comparative analysis

Timothy Morley<sup>1</sup>, C. Omar Kamlin<sup>1</sup>, Heidi Goenaga-Infante<sup>2</sup>, Koenraad D'Hollander<sup>3</sup>, Stuart McDougall<sup>4</sup>. <sup>1</sup>Orphalan, United Kingdom; <sup>2</sup>National Measurement Laboratory LGC group, United Kingdom; <sup>3</sup>IDDI, Belgium; <sup>4</sup>Quotient Sciences, United Kingdom  
Email: tim.morley@orphalan.uk

**Background and aims:** US and European guidelines recommend calculated serum non-ceruloplasmin-bound copper (NCC; free copper index) for the diagnosis and management of Wilson disease (WD) with a target range of 50 to 150 mcg/L. Standard of care involves incubating patient serum with EDTA to chelate Copper (Cu) from proteins other than ceruloplasmin (Cp). This ultrafiltrate captures NCC complexes and may result in an underestimation of NCC. As a result, the immunological and enzymatic assays used to determine NCC are not universally adopted by clinicians. The aim of this study is to compare standard of care EDTA ultra-centrifugation (NCC-EDTA)

method with a novel Cu protein speciation (NCC-CuSp) assay in WD patients.

**Method:** NCC CuSp quantification is a two step process; inductively coupled mass spectrometry (ICP-MS) to measure total Cu followed by liquid chromatography (LC) ICP-MS to calculate the relative amount of caeruloplasmin bound copper (Cp-Cu) as a percentage of total Cu in the sample. LC-ICP-MS determines Cp-Cu indirectly by the speciation of copper containing proteins (Cp, albumin and  $\alpha$ -2-macroglobulin). The relative concentration of Cp-Cu is calculated [ (% Abundance of Cu-Cp) / ([Total Serum Cu]) where Cp-Cu is determined from peak area of Cp-Cu as a percentage of total Cu peak area. NCC-CuSp = Total Cu minus Cp-Cu. WD patients enrolled in a clinical trial had blood samples taken for NCC evaluation by both methods at screening and 9 visits every 4 weeks thereafter. Paired data were compared using Bland Altman (BA) analysis, where the standard deviation (SD) of the difference of paired measurements was calculated based on a mixed model, taking into account repeated measures for each subject.

**Results:** 511 paired samples were available from 73 patients. The BA plot (figure 1a) shows a mean difference of 10.04, with (2SD) limits of agreement (-32.97, 53.05) microgram/L; these limits capture 489 out of 511 observations (Fig. 1a). In the scatter plot (Fig. 1b), the diagonal line has slope 1, indicating a higher NCC-CuSp value compared to NCC-EDTA for observations below the diagonal. Within the target range of 50 to 150 mcg/L, 264 (52%) and 360 (70%) of the 511 samples were detected with NCC-EDTA and NCC-CuSp respectively. Of the 360 NCC-CuSp in the range, only 234 (65%) were paired with NCC-EDTA; 126 (35%) registering as <50 mcg/L (red box).

**Conclusion:** Agreement between NCC-EDTA and NCC-CuSp is moderate. On average, compared with NCC-CuSp, NCC-EDTA produces lower NCC values; falling more frequently below the 50–150 mcg/L range, and this may be important for clinical decision making.

### PO-2667

#### Three-fold increased risk for death in Budd-Chiari syndrome compared to matched controls-population-based cohort study

Fredrik Åberg<sup>1</sup>, Linnea Widman<sup>2</sup>, Rupesh Rajani<sup>3</sup>, Hannes Hagström<sup>3,4</sup>. <sup>1</sup>Helsinki University Hospital and University of Helsinki, Department of Transplantation and Liver Surgery., Helsinki, Finland; <sup>2</sup>Karolinska Institutet, Biostatistics Core Facility, Sweden; <sup>3</sup>Karolinska University Hospital, Stockholm, Sweden; <sup>4</sup>Karolinska Institutet, Department of Medicine, Huddinge, Sweden  
Email: hannes.hagstrom@ki.se

**Background and aims:** Patients with Budd-Chiari syndrome (BCS) have a high risk of overall and liver-specific mortality, but this has not been quantified on a population level nor compared against the general population.

**Method:** We performed a register-based study, identifying all patients in Sweden with a recorded diagnosis of BCS in the nationwide Patient Register between 1987 and 2016. Cases with BCS were matched by age, sex and living location with up to ten reference individuals from the general population. Data on cause-specific mortality was obtained from the Causes of Death Register. Cox regression was used to investigate rates of all-cause and cause-specific mortality.

**Results:** A total of 478 patients with BCS were matched with 4603 reference individuals. 56% were men and median age was 57.7 years. 39% of patients with BCS had a recorded diagnosis of a precipitating risk factor, and 13% had an underlying liver disease. During a median follow-up of 5.1 years, 248 (52%) of patients with BCS died compared with 1416 (31%) of reference individuals.

Figure: (abstract: PO-2628) NCC Data (paired) in Bland Altman plot and individual in scatter plot

Figure: Kaplan-Meier curve of the risk of overall mortality in patients with Budd-Chiari (cases) and matched reference individuals (controls).

The incidence of overall mortality was 71/1000 person-years (PY) in BCS compared with 29/1000 PY:s in reference individuals. This translated to an adjusted hazard ratio (aHR) of 3.0 (95%CI = 2.6–3.5, figure 1). The rate of liver-related death was particularly high (incidence rate 6.9/1000 vs 0.2/1000; aHR = 47.6, 95%CI = 16.5–137.4), but the most common cause of death was cardiovascular disease (incidence rate 25/1000 vs 13/1000; aHR = 2.2, 95%CI = 1.7–2.9). 33 patients with BCS (6.9%) underwent liver transplantation.

**Conclusion:** Patients with BCS in Sweden during the study period had a 3-fold higher risk of death compared to general population reference individuals. While the risk of liver disease mortality was in relative terms highest, most patients died from cardiovascular causes.

**PO-2697**

**Defining the range of healthy volunteer non ceruloplasmin copper using a new Copper Protein Speciation assay**

Timothy Morley<sup>1</sup>, C. Omar Kamlin<sup>1</sup>, Heidi Goenaga-Infante<sup>2</sup>, Maria Estela del Castillo<sup>2</sup>, Koenraad D'Hollander<sup>3</sup>. <sup>1</sup>Orphalan, United Kingdom; <sup>2</sup>National Measurement Laboratory LGC group, United Kingdom; <sup>3</sup>IDDI, Belgium  
 Email: tim.morley@orphalan.uk

**Background and aims:** US and European guidelines recommend calculated non-ceruloplasmin-bound copper (NCC; free copper index) for the diagnosis and management of Wilson Disease (WD). A serum sample from collected blood is incubated with EDTA to chelate copper (Cu) from proteins other than ceruloplasmin followed by calculation of NCC using either immunological or enzymatic technologies to determine ceruloplasmin concentration. These methods are unreliable and not universally adopted by clinicians. The aim of this study is to produce normative data for a novel NCC copper protein speciation assay (NCC-CuSp).

**Method:** NCC-CuSp quantification is a two-step process; inductively coupled mass spectrometry (ICP-MS) to measure total Cu followed by liquid chromatography (LC) ICP-MS to calculate the relative amount of ceruloplasmin bound copper (Cp-Cu) as a percentage of total Cu in the sample. LC-ICP-MS determines Cp-Cu indirectly by the speciation of copper containing proteins (Cp, albumin and alpha-2-macroglobulin). The relative concentration of Cp-Cu is calculated [ (% Abundance of Cu-Cp) / ([Total Serum Cu]) where Cp-Cu is determined from peak area of Cp-Cu as a percentage of total Cu peak area. NCC-CuSp = Total Cu minus Cp-Cu. Blood samples from 50 healthy adult volunteers were obtained for determining NCC-CuSp using ICP-MS/LC-CIP-MS and descriptive statistics generated. Normality of the data was tested using a Shapiro-Wilk test. Reference interval limits were calculated using a nonparametric method (2.5<sup>th</sup> and 97.5<sup>th</sup> percentiles). This method makes no assumption about the probability distribution of the observed values. The confidence interval (CI) for the lower and upper limits were calculated using bootstrapping.

**Results:** Fifty volunteers; 25 females and males with a mean (range) age of 40 (21–62) and 40 (20–78) years of whom 60% were Hispanic, participated. Results of the copper speciation are shown in the table. As the hypothesis of normality was rejected, the reference interval was calculated using a non-parametric method. Outliers were consistently present by subgroup (gender, age, race). Two outlying observations (NCC = 310 and 213 mcg/L) were identified using Cook's distance and removed. The lower and upper (90% CI) reference limits are 41.2 (34.5, 42.4) and 148.7 (144.5, 184) mcg/L respectively.

## POSTER PRESENTATIONS

Figure:

	Mean	Median	Q1	Q3	Min	Max	Standard deviation
Total Copper (ng/ml)	1163	1145	987	1303	724	1960	278.7
Cp-Cu relative abundance (ng/ml)	1081	1065	911	1220	414	1870	287.7
Alb-Cu relative abundance (ng/ml)	70	58.2	47.5	74.6	33.3	295	43.8
NCC (mcg/L)	82.2	72.8	56.7	85.3	40	310	45.0

**Conclusion:** A reference interval was established for the novel NCC-CuSp assay based on the results from 50 healthy volunteers. This may be an appropriate safe target range for patients with WD and provide clinicians a target to aim for through dose titration of WD therapies.

### PO-2770

#### Optimization of CRISPR/Cas9 technology for a safer treatment of rare metabolic disorders

**Background and aims:** Gene therapy is the most attractive approach for rare life-threatening monogenic disorders. To date, liver-kidney transplantation is the unique curative therapy for Primary Hyperoxaluria type I (PH1), an inherited disorder associated with mutations in the AGXT gene, that causes a deficiency in hepatic alanine-glyoxylate aminotransferase (AGT). Consequently, oxalate, an insoluble metabolic substrate, accumulates in kidneys causing end-stage renal failure and systemic oxalosis. The inhibition of glyoxylate oxidase (GO), the enzyme implicated in the synthesis of glyoxylate (precursor of oxalate), has been proven to be an efficacious strategy as substrate reduction therapy (SRT) for PH1. Our goal is to develop CRISPR/Cas9-based SRT by editing the *Hao1* gene, encoding GO. Recently, we showed in a PH1 mouse model that CRISPR/Cas9-mediated *Hao1* gene disruption prevented oxalate accumulation and kidney damage, with no signs of toxicity. We have further improved this strategy by 1) increasing the on-target editing

precision using two gRNAs 64-base pair (bp) apart; and 2) combining the two gRNAs and the nickase version of SaCas9 (D10AnSaCas9), to reduce the off-target effect.

**Methods:** Two *Hao1*-specific gRNAs were used in combination with CRISPR/SaCas9 or its nickase-version, both under the control of a liver-specific promoter. They were delivered using an AAV serotype 8. Lastly, a vector co-expressing the nickase together with the two gRNAs was created to decrease the vector dose and increase the safety. Twelve-week-old male *Agxt1<sup>-/-</sup>* mice were administered intravenously with a single dose of AAV-CRISPR vectors and untreated age-matched *Agxt1<sup>-/-</sup>* mice were used as control. 4 weeks after treatment, animals were sacrificed, and livers harvested for molecular and histological analysis.

**Results:** Simultaneous double-strand-breaks led to predictable on-target genome editing since most of the edited sequences had a precise deletion of 64-bp. These modifications led to a decrease in *Hao1* mRNA levels with an overall depletion of GO protein expression. However, the use of two gRNAs might increase the risk of unwanted off-target events. The administration of the same two gRNAs in presence of a nickase Cas9 had equal GO depletion efficacy while greatly reducing the off-target potential, proven by the absence of on-target editing with a nickase/sgRNA complex. Lastly, the combination of the dual-nickase gRNA system in a single vector decreased the effective minimal dose 3-fold.

**Conclusion:** We have developed a safe and efficient CRISPR/SaCas9 SRT for targeted gene disruption by combining two gRNAs binding nearby sequences of *Hao1* and Cas9 nickase in a single vector. The therapeutic effect of this optimized vector in PH1 mice is under evaluation. This strategy could potentially be applied for the treatment of other inherited hepatic metabolic disorders that can benefit from SRT.

Email: abaiges@clinic.cat

**Background and aims:** Vascular liver diseases (VLD) are represented mainly by portosinusoidal vascular disease (PSVD), non-cirrhotic splanchnic vein thrombosis (SVT) and Budd Chiari syndrome (BCS). It is unknown whether patients with VLD represent a high risk population for complications and greater mortality from SarsCov2 infection.

Our objective was to assess the prevalence and severity of SarsCov2 infection among patients with VLD.

**Method:** Retrospective international study analyzing the prevalence and severity of SarsCov2 infection in VLD between March 2020-March 21. Patients from Spain and France were included.

The Spanish VLD database includes 550 patients, of whom we were able to contact 495 (90%): 147 patients with PSVD, 277 with SVT and 71 with BCS. Similarly, the French VLD database comprises 700 patients of whom 489 were contacted (70%): 121 PSVD, 281 SVT and 87 BCS. We compared our data to that of the general population (GP).

**Results:** In the Spanish cohort 57 patients presented SarsCoV2 infection (11.5% of patients with VLD vs 6.5% of Spanish GP): 25 PSVD, 31 SVT and 1 BCS. Regarding age distribution, the prevalence of SarsCoV2 in PSVD between 30–39, 40–49, 50–59, 60–69 and 70–79 years of age was 15%, 24%, 32%, 12% and 5% compared to 7%, 6.5%, 6.4%, 5.3% and 4.5% in GP. In patients with SVT, the prevalence was 6%, 16%, 11%, 12% and 12%.

In the French cohort, 71 patients presented with SarsCoV2 infection (14.5% of patients with VLD vs 8.4% in French GP): 22 PSVD, 41 SVT and 8 BCS. Regarding age distribution, the prevalence of SarsCoV2 in patients with PSVD between 15–44, 45–64 and 65–75 years was 12%, 19%, 22% compared to 7%, 11% and 10.5% in French GP. In patients with SVT, the prevalence was 15%, 17% and 5% and in BCS of 15–44 years and 45–64 years the prevalence was 9% and 12%.

In terms of infection severity, in Spain 11 patients (20%) required hospital admission compared to 7.3% in GP; 1 patient required ICU (1.7% vs 0.7% in GP) and 3 patients died (5.2% vs 1.5% in GP), all of them with SVT. In France, 8 patients required hospital admission (11%), 3 ICU (4%) and 2 patients died (2.8% vs 1.8% in GP), one with PSVD and one with SVT.

We were not able to identify baseline factors (previous decompensation, comorbidity, underlying thrombophilia) correlating with the risk and severity of SarsCov2 infection.

**Conclusion:** Patients with vascular liver disease have a higher prevalence of SarsCov2 infection and associate a higher mortality.

Email: thomas.baumert@unistra.fr

**Background and aims:** Chronic hepatitis B virus (HBV) infection is a leading cause of liver disease and hepatocellular carcinoma (HCC). A key feature of HBV replication is the synthesis of the covalently close circular (ccc)DNA, not targeted by the current treatment and whose elimination would be crucial for viral cure. To date, little is known about cccDNA formation. One major challenge to address this urgent

question is the absence of robust model for the study of cccDNA biology.

**Method:** We established a cell-based HBV cccDNA reporter assay and performed a loss-of-function screen targeting 239 genes encoding for the human DNA damage response machinery.

**Results:** Overcoming the limitations of current models, the reporter assay enables to quantify cccDNA levels using a robust ELISA as a readout. A loss-of-function screen identified 27 candidate cccDNA host factors, including Y box binding protein 1 (YBX1), a DNA binding protein regulating transcription and translation. Validation studies in authentic infection models including primary human hepatocytes revealed a robust decrease in HBV marjers and cccDNA levels following silencing or treatment with drugs targeting YBX1, providing proof-of-concept for the targetability of YBX1 for new antiviral therapy. Chromatin immunoprecipitation qPCR assays confirmed that YBX1 was recruited to HBV genome. In patients, YBX1 expression robustly correlates with both HBV load and liver disease progression, confirming its clinical impact for the HBV life cycle.

**Conclusion:** Our cell-based reporter assay enables the discovery of HBV cccDNA host factors as antiviral targets. YBX1 is a previously undiscovered HBV host-dependency factor targetable for antiviral therapy not only relevant for the HBV life cycle but also for the pathogenesis of virus-induced liver disease and cancer.

Email: barbara.testoni@inserm.fr

**Background and aims:** Unaffected by current antiviral therapies, covalently closed circular DNA (cccDNA) is responsible for Hepatitis B virus (HBV) persistence in infected hepatocytes and represents the key molecule for viral life cycle. cccDNA is a stable chromatinized episome and the template for the six viral mRNAs. Transcription from cccDNA has several peculiar features, among which the fact that all viral RNAs use a common polyadenylation signal (PAS). Mechanisms and factors determining HBV RNA 3' end processing are still poorly defined. This study, therefore, aimed to precisely map the 3' end of HBV transcripts and to decipher the molecular events regulating HBV mRNA transcriptional fidelity.

**Method:** RNA extracted from HBV-infected HepG2-NTCP cells and primary human hepatocytes (PHHs) was subjected to HBV-adapted 3' RACE followed by MinION Nanopore single molecule sequencing. These experiments were combined with RT-qPCR and Northern blot analysis of HBV transcripts, together with chromatin- and RNA-immunoprecipitation (ChIP, CLIP) and functional invalidation of candidate proteins by RNA interference (RNAi).

**Results:** Single molecule sequencing analysis precisely indicated that the majority of HBV mRNAs ended 13 nucleotides downstream of the PAS in both infected PHH and HepG2-NTCP cells. However, in HepG2-NTCP cells, a significant proportion of HBV transcripts displayed a transcriptional readthrough of hundreds of base pairs downstream of this PAS. This readthrough was correlated with a higher expression of the DDX5 and DDX17 RNA helicases in HepG2-NTCP cells compared

## POSTER PRESENTATIONS

Figure: (abstract: PO-258)

to PHHs. Accordingly, RNAi for both helicases triggered an increase in electromobility of HBV RNAs in Northern Blotting without any significant effects on global RNAs levels suggesting a shortening of viral transcripts that was confirmed by the disappearance of the transcriptional readthrough after MinION sequencing. Combination of ChIP and CLIP-qPCR experiments showed that both DDX5 and DDX17 were recruited to cccDNA and RNAs and were required for the recruitment of the termination complex components CPSF6 and NUDT21, known to favor transcriptional readthrough. Finally, repression of DDX5 and DDX17 increased intracellular encapsidated DNA levels suggesting an increased HBV replication.

**Conclusion:** Altogether, our data suggest that optimal viral replication requires a fine tune regulation of the 3' end processing of HBV mRNAs and point to a pivotal role of DDX5/17 helicases and the terminator complex components NUDT21 and CPSF6 in the HBV transcription termination process.

### PO-469

#### Study of the effect of the hepatitis D virus on the hepatitis B virus quasispecies in mice models by a next-generation sequencing approach

Email: david.tabernero@ciberehd.org

**Background and aims:** Hepatitis B virus (HBV) replication does not significantly activate innate immune responses and is strongly affected by the co-infecting hepatitis D virus (HDV), which induces a profound type I Interferon (IFN) response. However, few data about the effects of this interaction over HBV quasispecies (QS) are available. The aim of this study was to analyse, in vivo, the influence of HDV over HBV QS variability, and potential role of IFN response.

**Method:** HBV and HDV replication competent genomes were delivered to the mouse liver using adeno-associated viruses (AAV-HBV and AAV-HDV). As control an AAV carrying the luciferase reporter gene was used (AAV-Luc). Eight-week-old C57BL/6 (WT) (n = 6) and IFN alpha receptor knock out (IFNaR KO) (n = 8) male mice were divided into two different groups (n = 3/4) that were co-infected with AAV-HBV and AAV-Luc (HBV\_mi) or AAV-HBV and AAV-HDV (HBV\_HDV). Intrahepatic RNA was obtained from all mice at day 21 after AAV injection. The HBV-RNA QS was analyzed by next-generation sequencing in 2 independent amplicons including the 5' and 3' ends of HBV X gene (HBX) transcripts: nucleotides (nt) 1255-1611 (5' HBX) and 1596-1912 (3' HBX). The nt changes relative to the master sequences were assessed.

**Results:** A median of 111467 (interquartile range 83999-232731) and 218852 (155171-293022) sequence reads/sample were obtained from 5' and 3' HBX respectively. Analysis of both 5' and 3' HBX amplicons showed that most identified nt changes accumulated in 5' HBX (figure). This analysis showed a total of 22 nt changes in WT mice, all present in HBV\_HDV and only 16 (72.7%) in HBV\_mi. Of 14/16 (87.5%) mean frequencies were HBV\_mi <HBV\_HDV, while in 2 (12.5%) HBV\_mi >HBV\_HDV. IFNaR KO mice showed a total of 39 nt changes, 37 (94.9%) in HBV\_HDV and 28 (71.8%) in HBV\_mi. 26/39 (66.7%) nt changes were observed in HBV\_mi and HBV\_HDV [11/26 (42.3%) mean frequencies were HBV\_mi <HBV\_HDV, in 15/26 (57.7%) HBV\_mi >HBV\_HDV].

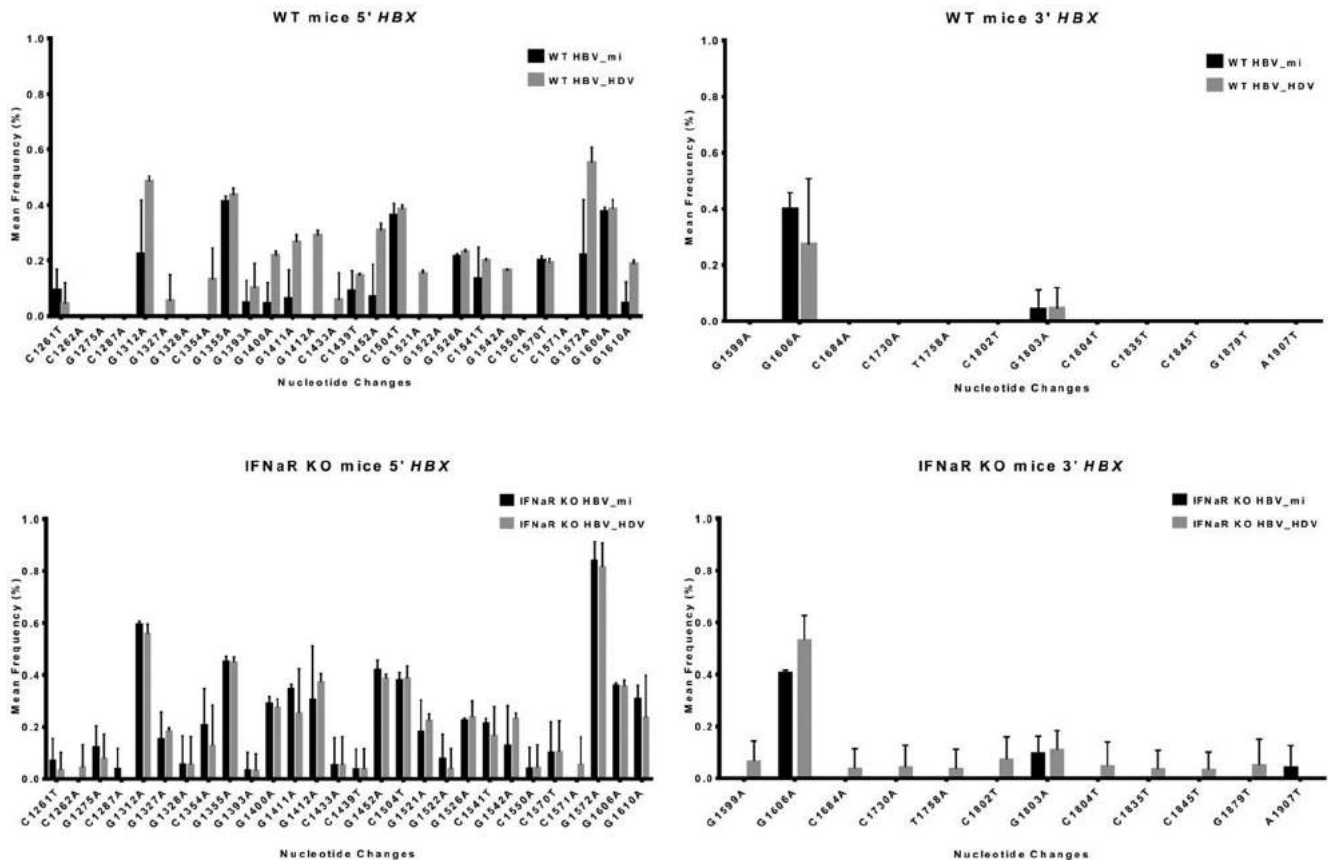

**Conclusion:** The HBV\_HDV WT mice showed higher rates of HBX nt changes in comparison to HBV\_mi, indicating that HDV enhanced HBV QS variability. Interestingly, those differences were reduced in IFNaR KO animals. The 3' HBX showed a higher trend to sequence conservation than 5' HBX, which could be explained by the importance to preserve the essential regulatory sequence motifs included in that region. Funding: Instituto de Salud Carlos III (grant PI18/01436), co-financed by the European Regional Development Fund (ERDF).

### PO-526

#### Real life kinetics of new HBV markers during treatment of chronic hepatitis D with bulevirtide

Charlotte Pronier<sup>1,2</sup>, BOMO Jeremy<sup>2</sup>, Juliette Besombes<sup>1</sup>, Anita Levacher<sup>3</sup>, Segolene Brichler<sup>4,5</sup>, Philippe Gripon<sup>2</sup>, Caroline Jezuquel<sup>3</sup>, Dominique Guyader<sup>3</sup>, Vincent Thibault<sup>1,2</sup>. <sup>1</sup>CHU Pontchaillou, Virology, RENNES, France; <sup>2</sup>Univ Rennes, Inserm, EHESP, Irset (Institut de recherche en santé, environnement et travail) UMR\_S 1085, 2IIEF, RENNES, France; <sup>3</sup>CHU Pontchaillou, Hepatology, RENNES, France; <sup>4</sup>AP-HP, Avicenne, Clinical Microbiology, Bobigny, France; <sup>5</sup>Paris

Nucleotide changes identified in each amplicon, with their mean frequencies and standard deviations (error bars) in each group of mice:  
 • Upper graphs, C57BL/6 (WT) mice with HBV mono-infection (WT HBV\_mi) vs. HBV/HDV co-infection (WT HBV\_HDV). Left graph shows nucleotide changes between positions 1255 – 1611 (5' HBX) and right graph between positions 1596 – 1912 (3' HBX).  
 • Bottom graphs, interferon alpha receptor knock out (IFNaR KO) mice with HBV mono-infection (IFNaR KO HBV\_mi) vs. HBV/HDV co-infection (IFNaR KO HBV\_HDV). Left graph shows nucleotide changes at 5' HBX and right graph at 3' HBX.

Figure: (abstract: PO-469)

13 University, Sorbonne Paris Cité, Inserm, U955, Creteil, France  
 Email: charlotte.pronier@chu-rennes.fr

**Background and aims:** Bulevirtide is a first-in-class entry inhibitor for the treatment of chronic hepatitis D virus (HDV) and hepatitis B virus (HBV) infections. We report the interim results of real life kinetics of new HBV markers on chronically infected HDV patients treated with this recently approved treatment.

**Method:** Nine HDV RNA positive adult patients, mainly men, with compensated liver disease were treated with bulevirtide (2 mg/d SC), pegylated interferon alpha (PegIFN $\alpha$ ) and NUC. Kinetics of HBV markers were evaluated at initiation of treatment and then at months 1, 2, 3, 6, 9 and up to 1 year during treatment.

**Results:** Among these 9 patients infected by genotype 1 HDV except one, most of them were cirrhotics and overweight with a median age of 35 years. Duration of 12, 9 and 3 months of treatment was evenly distributed in three thirds among patients. At initiation of bulevirtide, median ALT was 131 IU/L (IQR 144) and viral markers were as follows. Median HDV viral load (VL) was 7.23 log IU/ml (IQR 2.53). HBV-DNA was <10 IU/ml and HBV-RNA was negative in all patients except one. Median HBsAg was 4.04 log IU/ml (IQR 0.2). HBcrAg was positive in all patients except one (median 4.3 log U/ml; IQR 2). Median anti-HBc IgG level was 62.5 COI (IQR 59.47). No patient had anti-HBs antibodies and all were HBeAg negative, except one. HDV-VL decreased significantly throughout each visit and 7 patients achieved HDV-RNA indetectability. During follow-up, HBsAg titers remained unchanged, HBcrAg status did not change while anti-HBc IgG and ALT tended to decrease overtime. In 3 patients, PegIFN $\alpha$  was stopped

after 1 year of treatment following 6 months of HDV-RNA indetectability (n = 1) or secondary to adverse events (n = 2).

**Conclusion:** Kinetics of viral markers in patients treated by bulevirtide appears highly heterogeneous between individuals and their predictive values remain to be defined. The ongoing follow-up of these markers continues and will be scrutinized after bulevirtide discontinuation. These preliminary results will have to be confirmed in larger cohort of patients.

**PO-611**

**Adaptation of hepatitis C virus to efficient infection of mouse hepatocytes**

Julie Sheldon<sup>1</sup>, Qingong Yuan<sup>1</sup>, Melina Winkler<sup>1</sup>, Nicola Frericks<sup>1</sup>, Yudi Zhang<sup>1</sup>, Richard Brown<sup>2</sup>, Arnaud Carpentier<sup>1</sup>, Natascha Gödecke<sup>3</sup>, Sara Behme<sup>3</sup>, Katharina Rox<sup>4</sup>, Florian Vondran<sup>5</sup>, Stefan Pöhlmann<sup>6</sup>, Dagmar Wirth<sup>3</sup>, Thomas Pietschmann<sup>1</sup>. <sup>1</sup>Twincore, Hannover, Germany; <sup>2</sup>Paul Ehrlich Institute, Langen (Hessen), Germany; <sup>3</sup>Helmholtz Centre for Infection Research, Model Systems for Infection and Immunity, Braunschweig, Germany; <sup>4</sup>Helmholtz Centre for Infection Research, Chemical Biology, Braunschweig, Germany; <sup>5</sup>Medizinische Hochschule Hannover, Klinik für Allgemein-, Viszeral-, und Transplantationschirurgie, Hannover, Germany; <sup>6</sup>German Primate Center, Göttingen, Germany  
 Email: julie.sheldon@twincore.de

**Background and aims:** Approximately 71 million people suffer from a chronic infection with the hepatitis C virus (HCV). Despite effective treatment, viral transmission remains high and a prophylactic vaccine

## POSTER PRESENTATIONS

is not available. The absence of an immune competent HCV animal model limits vaccine research and development. HCV has a narrow species tropism, and naturally infects only humans. However, replication is error-prone giving rise to a vast spectrum of variants (quasispecies) facilitating viral adaptation to changing environments. Here we exploited this property for the generation of a virus population with high replication fitness in primary mouse hepatocytes (PMH).

**Method:** We used a step-wise adaptation procedure culturing HCV between human (Huh-7.5) and mouse liver cells expressing HCV entry factors (MLT-5H) and then further passaged the virus population in primary mouse hepatocytes from entry factor transgenic mice (hOC<sup>hep</sup>) in the presence of a janus kinase signalling inhibitor (ruxolitinib, rux).

**Results:** HCV adaptation increased infectious virus production in the MLT-5H and hOC<sup>hep</sup> PMH + rux by more than 1,000-fold compared to the parental virus. In contrast, infection efficiency of primary human hepatocytes, human pluripotent stem cell-derived hepatocytes, and primary macaque hepatocytes remained similar to parental HCV, suggesting that adaptation was specific to mouse hepatocytes. Mouse-adapted HCV (MAD-HCV) was susceptible to directly-acting antivirals and depended on expression of human hCD81 and hOccludin for infection of PMH cells. MAD-HCV was sensitive to interferon as replication was not detectable in hOC<sup>hep</sup> PMH without rux treatment and because genetic ablation of interferon signalling enhanced virus propagation. Individual or combined knock out of *mCd302* and *mCr11*, two recently discovered liver cell-expressed murine restriction factors, also increased permissiveness to MAD-HCV.

**Conclusion:** This step-wise adaptation procedure is a novel paradigm for exploring the viral determinants that govern species tropism. Moreover, MAD-HCV is an interesting starting point for development of a robust HCV animal model.

### PO-626

#### assembly dynamics and infection efficacy of hepatitis b virus surface protein exchanges in the eight hepatitis d virus genotypes

Wenshi Wang<sup>1,§,\*</sup>, Florian Lempp<sup>1,2,§</sup>, Franziska Schlund<sup>1</sup>, Lisa Walter<sup>1</sup>, Charlotte Decker<sup>1</sup>, Zhenfeng Zhang<sup>1</sup>, Yi Ni<sup>1,2</sup>, Stephan Urban<sup>1,2,\*</sup>. <sup>1</sup>Department of Infectious Diseases, Molecular Virology, University Hospital Heidelberg, Heidelberg, Germany, Heidelberg, Germany; <sup>2</sup>German Centre for Infection Research (DZIF), partner site Heidelberg, Heidelberg, Germany

<sup>§</sup>contributed equally

Email: stephan.urban@med.uni-heidelberg.de

**Background and aims:** Chronic hepatitis D virus (HDV) infections cause the most severe form of viral hepatitis. HDV requires hepatitis B virus (HBV) envelope proteins for hepatocyte entry, particle assembly and secretion. Eight HDV and eight HBV genotypes are presently distinguished. However, comprehensive data of replication competence of the different HDV genotypes is scarce. Furthermore, it is unknown to what extent combination with different HBV envelopes affect virion assembly and infectivity.

**Methods:** We subcloned cDNAs of all HDV and HBV genotypes and performed combinatorial studies on replication competence, assembly dynamics and infection efficacy using Northern Blot, Western Blot, qPCR, in-cell ELISA, quantitative infection and infection inhibition assays.

**Results:** The eight 1.1-fold HDV genotypic cDNA clones initiated HDV replication in transfected HuH7 cells with noticeable differences regarding replication efficacy. The eight HBV-HBsAg-encoding constructs all supported secretion of subviral particles, however profound variations in envelope protein stoichiometry and secretion efficacy were observed. Co-transfection of all HDV/HBV combinations supported particle assembly, however, the respective pseudo-typed HDVs differed with respect to assembly kinetics and infectivity. All HDVs elicited robust and comparable innate immune responses. The

most productive combinations did not correlate to the natural geographic distribution arguing against an evolutionary adaptation of HDV ribonucleoprotein complex to HBV envelopes. We further observed HBV envelope-dependent differences in the activity of the EMA approved entry inhibitor bulevirtide/Hepcludex (formerly myrcludex), however >90% inhibition and full blockade could be achieved at therapeutically applied doses. Possible differences in assembly inhibition by Lonafarnib were also investigated and will be presented.

**Conclusions:** Different genotypes of HDV replicate with variable efficacies. Genotypic variations in HDV and also HBV-envelopes are major determinants for HDV egress, entry efficacy and consequently entry inhibition by Hepcludex or assembly interference by Lonafarnib. These differences possibly influence HDV pathogenicity, immune responses and the efficacy of drug regimens.

Email: christophe.ramier@inserm.fr

**Background and aims:** Hepatitis delta virus (HDV) is a satellite of hepatitis B virus (HBV), both using the Sodium Taurocholate Co-Transporting Polypeptide (NTCP), the main transporter of bile acids (BA) in the liver, to enter hepatocytes. Links between BA and HBV infection are not limited to the entry step as we previously showed that some ligands of the farnesoid X receptor alpha (FXR), the nuclear receptor of BA, acted as inhibitors of HBV replication. Regarding HDV, excepting the role of NTCP in viral entry, putative links between BA metabolism and HDV replication have not been yet explored. We thus wanted to determine whether FXR also played a role in HDV life cycle.

**Method:** *In vitro* HDV mono-infection or HDV/HBV co-infection and super-infection were performed in differentiated HepaRG cells and primary human hepatocytes (PHH). Cells were treated with several FXR ligands: 6-ECDCA, a BA analog and two synthetic ligands, GW4064 and tropifexor. The impact on distinct forms of HDV RNAs was analysed by quantitative PCR and Northern Blot. Analysis of HDV proteins was performed by immunofluorescence (IF) and Western Blot (WB). Viral secretion was studied by HDV RNA quantification in supernatants and infection of naive Huh7.5-NTCP cells.

**Results:** In HDV/HBV super-infection models, a 10-day treatment with 10  $\mu$ M of GW4064 decreased total intracellular HDV RNA by 60% and 40% in HepaRG cells and PHH, respectively. Northern blot showed that both HDV genomic and antigenomic RNAs were affected by treatment. IF staining and WB showed that FXR ligands also decreased intracellular amounts of delta antigens, by around 75% for both small and large forms. Importantly, this inhibitory effect of FXR ligands on HDV replication was also observed in HDV mono-infected HepaRG cells. The specificity of action was confirmed as FXR ligands GW4064, 6-ECDCA and tropifexor showed comparable efficacy and their effects were lost in FXR loss-of-functions experiments. Finally, in HBV/HBV co-infected HepaRG cells, HDV secretion was decreased by 60% and virion specific infectivity by >95%.

**Conclusion:** FXR ligands inhibit *in vitro* HDV replication, independently of their previously identified antiviral properties against HBV, as well as virion secretion and specific infectivity. Mechanisms underlying this inhibitory effect are under investigation. As current therapeutic strategies are limited for HDV-infected patients, FXR may represent a new and attractive target for HDV antiviral therapy.

Email: sofiapp@clinic.cat

**Background and aims:** Chronic hepatitis delta is the most severe form of viral hepatitis and a risk factor for cirrhosis and hepatocellular carcinoma. Little is known about the pathobiology of HBV/HDV infection, due in part to limited experimental models to study HBV and HDV infection and the lack of studies using liver tissue samples from HBV/HDV infected patients. The aim of this study was to explore viral and host factors contributing to chronic hepatitis delta pathogenesis.

**Methods:** Thirty-seven anti-HDV positive patients were included in the study. Intrahepatic and serological HBV and HDV replication markers were determined in prospectively collected liver biopsies and serum samples. To investigate the host response towards HDV, we performed Nanostring gene expression analysis on formalin-fixed paraffin-embedded liver samples.

**Results:** The median age of the patients was 50 years; 68% were male, 70% had liver cirrhosis and 51% were on nucleos (t)ide analog (NA) treatment. All patients had detectable HBsAg (median levels 6251 IU/ml) and 94% were HBeAg negative. Serum HDV-RNA assessment revealed ongoing HDV infection in 25 (68%) patients (HDV+), whereas the remaining 12 (32%) had undetectable HDV-RNA (HDV-). The percentage of patients receiving NA therapy was similar between HDV+ and HDV- patients (48% and 58%, respectively). Serum HDV-RNA concentration correlated with HBsAg ( $r=0.54$ ,  $p=0.010$ ) and HBcrAg ( $r=0.49$ ,  $p=0.041$ ) but not with HBV-DNA levels. Only 4 (16%) HDV+ patients had circulating 3.5 kb HBV-RNA (none of the HDV- patients). In contrast, 3.5 kb HBV-RNA in the liver was detected in 88% of HDV+ versus 43% of HDV- patients ( $p=0.038$ ) and its presence was associated with detectable HBcrAg levels ( $p=0.018$ ). Preliminary gene expression analysis based on a small number of patients (7 HDV+ and 4 HDV-) showed an upregulation of genes related IFN response and proinflammatory pathways in HDV+ patients. Likewise, the immune cell signature of the liver was consistent with an enhanced adaptive and innate infiltrate and a profile of CD8+ T cell exhaustion.

**Conclusion:** Our results suggest that HBV pregenomic RNA might preferentially be translated into HBcrAg rather than packaged and retrotranscribed in HDV+ patients. HDV appears to elicit an IFN and proinflammatory response, which is not capable of eliminating HDV but could modulate HBV replication. A dysfunctional adaptive immune response may contribute to HDV persistence.

**Identification of novel host factors in the patho-biology of Hepatitis B Virus (HBV) infection**

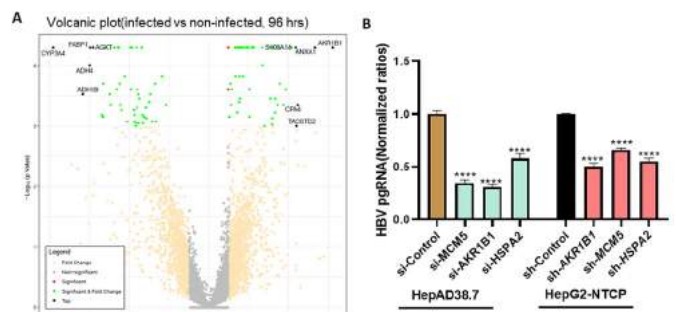

Collins Oduor Owino<sup>1,2,3</sup>, Balakrishnan Chakrapani Narmada<sup>2</sup>, Giridharan Periyasamy<sup>2</sup>, Pablo Bifani<sup>1</sup>, DasGupta Ramanuj<sup>2</sup>. <sup>1</sup>National University of Singapore, Microbiology and Immunology, Singapore, Singapore; <sup>2</sup>Genome Institute of Singapore, Singapore, Singapore; <sup>3</sup>University of Nairobi, Centre for Biotechnology and Bioinformatics, Nairobi, Kenya

**Background and aims:** Even though there is an effective vaccine, HBV infection remains a major threat to global health with over 250 million people chronically infected. The pathogenesis of HBV infection and how it hijacks the host machinery is yet to be fully elucidated. Transcriptomic analysis of HBV infected cells has offered a

valuable tool in identifying HBV-host cell interactions. However, majority of these studies have been carried out in cell models that only partly mimic the complex human liver environment, such as rat primary hepatocytes or hepatoma cells. Therefore, one key caveat in the understanding of host cell factors that influence HBV pathology has been the lack of physiologically relevant, disease models.

**Method:** We hypothesized that host-specific genes that are induced by HBV infection may play important roles in HBV life cycle. Therefore, first we employed whole transcriptomic sequencing of HBV infected primary human hepatocytes (PHH) to identify host gene dysregulation during HBV infection. Next, we employed RNA interference technology to evaluate and validate the function of top-upregulated host factors on HBV gene expression and replication in HepAD38.7 and HepG2-NTCP. Lastly, we explored the expression profiles of these host factors in publicly available micro-array datasets of HBV patients; GSE65359, GSE83148 and GSE14520.

**Results:** Whole transcriptomic sequencing (WTS) in HBV-infected PHH identified multiple host pathways that might play a role during HBV infection including those in epithelial-mesenchymal transition (EMT), Aurora Kinase pathway, and matrisome interactions. Reassuringly, we also identified pathways previously identified to be deregulated during HBV infection including p38 MAPK, cell cycle genes involved in G2/M checkpoint and bile acid metabolism. Gene set enrichment analysis (GSEA) identified numerous upregulated genes during HBV infection including *NXF1*, *SRPK1* and *CDK1* all of which have been previously described to modulate HBV infection. The top-upregulated genes were validated by loss-of function studies and evaluated the effect of loss of function on surface antigen and identified novel factors potentially involved in HBV infection cycle. We report that RNAi-mediated knockdown of *HSPA2*, *AKR1B1* and *MCM5* in HepG2-NTCP live infection model inhibited HBV replication and gene expression. Finally, transcriptomic data analysis microarray datasets of different patient cohorts collectively reveal that expression of these host factors is indeed significantly associated with CHB, liver disease and HBV related HCC.

A: volcano plot showing differential gene expression in HBV infected PHH, B: cells harvested 3 days post-transfection (left) and 10 days post-infection (right), and quantified HBV pgRNA. Data presented as the mean normalized ratio +/- SD between control and si/sh samples, of 3 independent experiments

Figure:

**Conclusion:** Here, we utilized PHH models combined with functional elucidation in orthogonal infection models to identify potential HBV host factors. Altogether this study offers novel insights into the mechanisms of HBV infection as well as a new perspective in the development of host-directed therapies (HDT).

<sup>3</sup>National University of Singapore, Department of Medicine, Singapore, Singapore

Email: chakrapaninb@gis.a-star.edu.sg

**Background and aims:** Chronic Hepatitis B infection can persist in the host liver without causing alarming symptoms for decades and there is much ambiguity in the early processes of the viral life cycle-entry, nuclear transport, HBV cccDNA formation and its implications for liver cancers. HBV-associated hepatocellular carcinoma (HCC) has recently been shown to have multiple, distinct evolutionary clones within a single tumour which could be monoclonal or polyclonal in the nature of HBV infection. Also, the genetic factors in hepatocytes that render susceptibility/resistance to infection at early stage and factors that allow chronic infection remain largely underexplored. We aim to identify the factors affecting host susceptibility and response in patient intrahepatic tissues using single-cell RNA-sequencing technology. This enables investigation of the impact of HBV on specific cell subsets or cell states that help reconstitute the host's transcriptomic changes observed at the single-cell population level which may not otherwise be detectable at the bulk population level.

**Method:** One core biopsy from chronic HBV patient livers, who underwent Nucleoside analogues or Interferon treatment, were freshly dissociated into single cells using Collagenase P. Single cell RNA-seq was performed using 10X Genomics 3' v3 on liver core biopsies from 14 chronic HBV patients, who were either resistant to treatment and carried a high Hepatitis B surface antigen (HBsAg) load (Non-S Loss) or those who have responded to treatment and have lost HBsAg (S Loss). Datasets were aggregated using CellRanger aggr, hierarchical clustering analysis, data normalization, filtering was performed using Seurat and specific marker gene sets were used to annotate the cell types and subtypes.

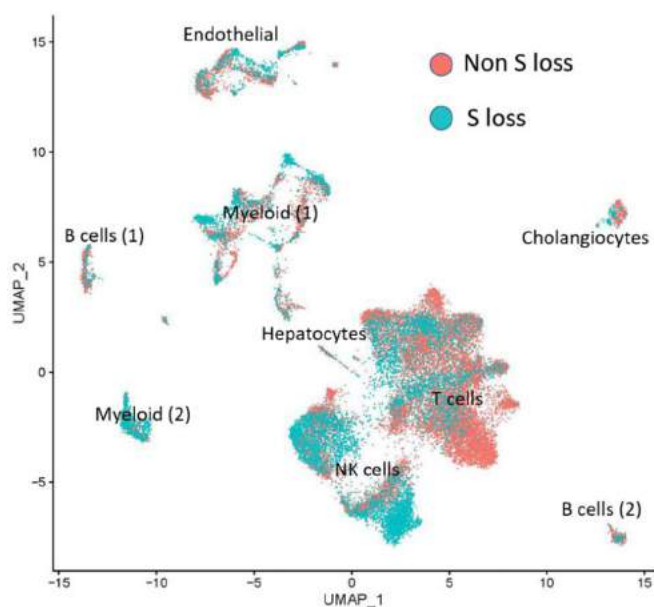

Figure:

**Results:** Unique cell-type/cell-state signatures emerged in S Loss patients from their single cell transcriptomic profiling. We also found evidence for the loss of certain cytotoxic immune cell clusters in S Loss patients upon achievement of functional cure compared to the

Non-S Loss chronic HBV patients. Specific phenotypic signatures were observed in the Cytotoxic T cells (CD8+), regulatory T cells, and NKT cells which are currently being validated by independent flow cytometry and spatial analysis. Figure 1 shows an UMAP of the liver cell types based on their HBsAg status upon treatment, Non-S Loss and S Loss, and key cell types unique to each of the conditions.

**Conclusion:** Creating an atlas of cell types and cell subtypes heterogeneity in chronic HBV patients, responding to or resistant to therapies, will inform us of valuable host-specific cell signatures. These specific signatures will serve to develop effective prognostic biomarkers enhancing prediction of patient response and designing better therapeutics against HBV.

### PO-1305

#### Mechanism of Action of Hepatitis B Virus S-antigen Transport-inhibiting Oligonucleotide Polymers (STOPSTM) Molecules

Cheng Kao<sup>1</sup>, Yuchun Nie<sup>1</sup>, Suping Ren<sup>1</sup>, Rajendra Pandey<sup>2</sup>, Jin Hong<sup>1</sup>, Julian Symons<sup>1</sup>, Leonid Beigelman<sup>2</sup>, Lawrence Blatt<sup>1</sup>. <sup>1</sup>Aligos Therapeutics, Biology, So. San Francisco, United States; <sup>2</sup>Aligos Therapeutics, Chemistry, So. San Francisco, United States  
Email: chekao@gmail.com

**Background and aims:** Functional cure of chronic hepatitis B requires the elimination of serum hepatitis B virus surface antigen (HBsAg). We have developed a series of single-stranded oligonucleotides containing novel chemistry named STOPSTM that significantly reduce HBsAg produced by HBV-infected hepatocytes in vitro. This project aims to elucidate the mechanism whereby STOPSTM cause the reduction of HBsAg.

**Method:** STOPSTM and siRNAs were transfected into HepG2.2.15 cells that contain integrated HBV genomes using Lipofectamine RNAiMax. Proteins from HepG2.2.15 cell lysates that bind STOPSTM were identified using affinity chromatography, tandem mass spectrometry, and searches of the human proteome database. Fluorophore-labeled ALG-10000 in cells was visualized using a Leica SP6 microscope. HBsAg and other HBV proteins were quantified using ELISA and Western blotting. HBV nucleic acids were quantified using a Quantigene and real-time polymerase chain reaction assays.

STOPSTM molecules localize to the cytoplasm of HepG2.2.15 cells (A) and reduces intracellular HBsAg levels in a concentration-dependent manner (B).

Figure:

**Results:** STOPS molecule ALG-10000 was identified in a screen of chemically-modified oligonucleotides for the ability to reduce HBsAg production by HepG2.2.15 cells. ALG-10000 also inhibited HBV infection of primary human hepatocytes. In addition to reducing HBsAg production, ALG-10000 could reduce the level of HBV E-antigen, HBV polymerase, the Core protein, total HBV RNA, and secreted rcDNA in HepG2.2.15 cells. ALG-10000 localized to the cell cytoplasm but did not significantly co-localize with or bind to the HBsAg, indicating that STOPS acts through host-encoded factors. Five host proteins that function in RNA processing, translation, and protein folding/degradation were identified to bind ALG-10000: SRSF1, HNRNPA2B1, GRP78, RPLP1, and RPLP2. Silencing RNAs targeting these host factors reduced the levels of HBsAg and other HBV molecules known to be affected by STOPS. Finally, introduction of ALG-10000 or the knockdown of GRP78, RPLP1 and RPLP2 in cells resulted in increased ubiquitination of HBsAg and proteasome-mediated degradation of HBsAg.

**Conclusion:** STOPS reduce HBsAg production by sequestering select host proteins required for HBV RNA processing, translation and protein degradation.

Email: fabien.zoulim@inserm.fr

**Background and aims:** Chronic Hepatitis B virus (HBV) infection remains a global health burden, since current antiviral strategies are unable to eliminate the virus from infected hepatocytes and, thus, achieve a complete cure. Non-invasive biomarkers are necessary to improve patients' management and the evaluation of new therapies. This study aims at characterizing the compartments containing extracellular HBV RNA, which was recently proposed as a new surrogate marker of cccDNA transcriptional activity.

**Method:** Supernatants from HBV-infected HepG2-NTCP cells and Primary Human Hepatocytes treated or not with lamivudine were collected and processed through sucrose/iodixanol gradient separation, to allow physical separation of extracellular vesicles (EVs) and viral particles according to their buoyant density. Viral and EVs-associated proteins were analyzed by Western Blotting and ELISA, while HBV RNAs were detected by specific droplet digital (dd)PCR and correlated with intracellular viral replicative parameters (HBV-DNA, cccDNA, 3.5 kb HBV-RNA). Nanoparticle tracking analysis (NTA) and mass spectrometry (MS)-based proteomics were used to further characterize the viral and non-viral components.

**Results:** ELISA and western blotting assays for HBs and HBc proteins, together with HBV-DNA quantification after gradient separation showed that virions were found in fractions corresponding to a density of 1,17–1,20 g/ml. CD9 expression, marker of exosomes/EVs, was detected only in lower density fractions (1,07–1,15 g/ml), which were deprived of HBc. ddPCR analysis using assays spanning the 5' region of 3.5Kb RNA or the HBx region suggested that 3.5 Kb RNA is the predominant but not the only viral RNA specie in cell supernatants. HBV-RNAs distribution across gradient fractions showed no significant differences between Lamivudine-treated vs untreated samples. Interestingly, HBV-RNAs were detected not only in virion-like particles and non-enveloped capsids, but also in lighter fractions, suggesting that EVs could also carry secreted HBV-RNA. NTA analysis

confirmed that these fractions were indeed containing EVs in size spanning from 30 to 150 nm and MS analysis revealed a significant enrichment for exosomal proteins (CD63, CD9, TSG101 or HSC70).

**Conclusion:** Our results show evidence for EV containing HBV RNAs and will help understanding the molecular biology of serum HBV RNA secretion. This knowledge will aid the development and interpretation of serum HBV RNAs as a novel biomarker for chronic HBV infection.

**Characterization of circulating hepatitis B virus (HBV) RNA in chronic hepatitis B (CHB) patients**

Doohyun Kim<sup>1</sup>, Delphine Bousquet<sup>1,2</sup>, Marie-Laure Plissonnier<sup>1</sup>, Alexia Paturel<sup>1,2</sup>, Hyoseon Tak<sup>1</sup>, Françoise Berby<sup>1</sup>, Isabelle Bordes<sup>1</sup>, Aaron Hamilton<sup>3</sup>, Marintha Heil<sup>3</sup>, Massimo Levrero<sup>1,2,4,5</sup>, Barbara Testoni<sup>1</sup>, Fabien Zoulim<sup>1,2,4</sup>. <sup>1</sup>INSERM U1052-Cancer Research Center of Lyon (CRCL), Lyon, France; <sup>2</sup>University of Lyon, UMR\_S1052, CRCL, Lyon, France; <sup>3</sup>Roche Molecular Diagnostics, Pleasanton, United States; <sup>4</sup>Croix Rousse hospital, Hospices Civils de Lyon, Department of Hepatology, Lyon, France; <sup>5</sup>Sapienza University of Rome, Department of Internal Medicine-DMISM and the IIT Center for Life Nanoscience (CLNS), Rome, Italy

**Background and aims:** Circulating HBV RNA (cirB-RNA) is emerging as a promising non-invasive biomarker for cccDNA transcriptional activity. However, the molecular characteristics and circulating particles containing cirB-RNA *in vivo* remain to be fully defined.

**Method:** A protocol based on a Iodixanol/Sucrose density gradient ultracentrifugation was set up to separate components of human serum according to their buoyant density. Each density fraction was analysed for HBV DNA/RNA by qPCR and specific droplet digital (dd) PCR. Viral and extracellular vesicles (EVs)-associated proteins were analysed by ELISA and Western Blotting. Nanoparticle tracking analysis (NTA) allowed to detect and quantify EVs content. 5'RACE PCR was used to discriminate cirB-RNA species in patients' serum.

**Results:** Sera from 7 untreated [4 HBeAg (+) and 3 HBeAg (-)] and 1 HBeAg (+) entecavir-treated CHB patients were subjected to density ultracentrifugation. Among the 10 fractions obtained, specific distribution of Dane particles, non-enveloped nucleocapsids and subviral particles was determined by ELISA and Western Blotting for viral proteins, together with quantification of HBV DNA. cirB-RNA was mainly detected in core-associated virion-like particles, but in 2 log<sub>10</sub> less amount than HBV DNA. However, cirB-RNA was the predominant species in lower density fractions (1.17–1.18 g/ml) deprived of viral proteins. The enrichment for EVs in these fractions was confirmed by NTA and detection of CD9 and CD81 EVs markers by western blotting. Distribution of cirB-RNA did not differ significantly in HBeAg (+) vs HBeAg (-) patients and in the entecavir-treated patient. Interestingly, in a serum with low HBsAg expression (570 IU/ml), cirB-RNA was mainly detected in the EVs-enriched fractions. Lastly, 5' RACE analysis identified pgRNA, spliced pgRNA and HBx transcripts as the three main categories of cirB-RNA in patients' serum.

**Conclusion:** Our results indicate that, in CHB patients' serum, EVs-enriched compartment contributes to the circulation of HBV-RNAs besides virion-like particles. Moreover, different HBV-RNA transcripts in addition to pgRNA can be detected *in vivo*. Altogether, these data could significantly contribute to the characterization of cirB-RNAs as new viral biomarker.

This work is supported by the French National Research Agency Investissements d'Avenir program (CirB-RNA project-ANR-17-RHUS-0003).

## PO-1631

### A cell culture model of primary human hepatocytes derived from HBV-infected humanized mice for antiviral drug evaluation

Jan-Hendrik Bockmann<sup>1,2</sup>, Lena Allweiss<sup>1,2</sup>, Katja Giersch<sup>1</sup>, Tassilo Volz<sup>1</sup>, Marc Lutgehetmann<sup>2,3</sup>, Maura Dandri<sup>1,2</sup>. <sup>1</sup>University Medical Center Hamburg-Eppendorf, I. Department of Internal Medicine, Hamburg, Germany; <sup>2</sup>German Center for Infection Research (DZIF), Hamburg-Lübeck-Borstel-Riems partner site; <sup>3</sup>University Medical Center Hamburg-Eppendorf, Department of Medical Microbiology, Virology and Hygiene, Hamburg, Germany  
Email: j.bockmann@uke.de

**Background and aims:** Primary human hepatocytes (PHH) isolated from liver chimeric mice have emerged as an alternative hepatocyte supply for in vitro HBV infection studies. However, high HBV amounts are needed, infection rates remain variable and HBV requires days to build stable cccDNA levels. Our aim was to establish a reproducible in vitro model where stably HBV infected PHHs are isolated from the liver of chronically HBV infected chimeric mice and can be readily used for antiviral studies. Here, we comparatively assessed the antiviral effects of lamivudine and interferon (IFN) in vitro on all viral parameters, including epigenetic silencing of HBV cccDNA and its association with the SMC5/6 complex (Allweiss, Giersch et al., Gut 2021).

**Method:** PHHs were isolated from USG (uPA/SCID/beige/IL2RG<sup>-/-</sup>) mice after 12 weeks of HBV infection by collagenase perfusion, seeded on collagen-coated 24-well plates and cultured for 21 days in Williams' medium E with DMSO. One day after seeding, treatment with 1000 IU/ml IFN- $\alpha$ -2a or 1  $\mu$ M lamivudine was performed. RNA and DNA were isolated from the same wells and HBV DNA, pgRNA and expression of interferon-stimulated genes (ISGs) in cell lysates, as well as HBeAg and HBsAg in supernatants were determined by RT-PCR and CLIA. Furthermore, chromatin immunoprecipitation (ChIP)-qPCR was performed using antibodies for NSE4, a component of the SMC5/6 complex.

**Results:** HBsAg (mean  $2.2 \times 10^2$  IU/ml) and HBeAg (mean  $2.5 \times 10^2$  S/CO) remained stable up to 21 days after seeding. Compared to untreated cells, 14 days of IFN treatment led to a significant reduction of HBV DNA (3.2-fold;  $p = 0.010$ ) and pgRNA (28.4-fold;  $p = 0.024$ ), as well as HBeAg (5.8-fold;  $p = 0.0012$ ) and HBsAg (6.7-fold;  $p = 0.0025$ ). As expected, LAM treatment reduced intracellular HBV DNA (d14: 3.9-fold;  $p = 0.001$ ) but not viral proteins. Vigorous inductions of human ISGs were detected only in IFN treated samples (day7: OAS1: 37-fold,  $p < 0.0001$ ; CXCL10: >500-fold,  $p = 0.0002$ ), which remained enhanced up to day 21. ChIP-qPCR analysis showed a strong association of NSE4 to the cccDNA (8-fold relative increase) only in interferon treated cells, indicating epigenetic cccDNA suppression.

**Conclusion:** PHHs exposed to long-term HBV infection in USG mice maintain stable HBV replication and innate immune responses in culture similar to those determined in vivo. This model can expand preclinical testing of drugs, including those targeting cccDNA activity and intrinsic innate responses.

## PO-1688

### Molecular mechanisms underlying the antiviral activity of a TLR2 agonist on HBV replication in hepatocytes

Manon Desmares<sup>1,2</sup>, Brieux Chardes<sup>1,2</sup>, Caroline Pons<sup>1,2</sup>, Michelet Maud<sup>1,2</sup>, Rivoire Michel<sup>3,4</sup>, Anna Salvetti<sup>1,2</sup>, Julie Lucifora<sup>1,2</sup>, David Durantel<sup>1,2</sup>. <sup>1</sup>INSERM, U1111, International Center for Research in Infectiology (CIRI), Lyon, France; <sup>2</sup>University de Lyon (UCBL1), Lyon, France; <sup>3</sup>INSERM, U1032, Lyon, France; <sup>4</sup>Centre Léon Bérard, Lyon, France  
Email: david.durantel@inserm.fr

**Background and aims:** Pegylated interferon-alpha (peg-IFN) is yet used in clinics, some time in first line, to treat chronically HBV-infected patients, despite its poor safety profile and relative weak efficacy at inducing HBsAg loss. If an immune-stimulator is argued to be an instrumental component of future combination therapies aiming at curing HBV infections, it would be interesting to find

alternatives to peg-IFN. We have previously identified the TLR2 agonist Pam3CSK3, as one of the best agonist to reduce HBV replication, including cccDNA level and activity, in infected hepatocytes (Lucifora et al., Scientific Rep. 2018). Yet the detailed mode of action (MoA) of this potential anti-HBV asset remained elusive. The aim of this study was to precisely decipher the MoA of Pam3CSK4 in vitro, by determining the kinetic of antiviral events, identifying the upstream and most relevant step of blockade of HBV replication, working-out its specificity of action, discovering host-effectors involved in the long-lasting antiviral phenotypes.

**Method:** We used experimentally-HBV-infected differentiated HepaRG cells and primary human hepatocytes (PHH), as well as rather standard molecular and cellular virologic methods to decipher the MoA of Pam3CSK4. This included RNA-seq analyses for the identification of antiviral host-effectors and loss-of-functions studies to validate them.

**Results:** Pam3CSK4 strongly and durably (no rebound within 5-weeks off drug) inhibited HBV replication by engaging the TLR2 innate receptor and canonical NF- $\kappa$ B pathway. The overall long-lasting antiviral phenotype is the double consequence of an immediate effect on HBV RNA biogenesis, by both reduction of RNA transcription and acceleration of RNA decay, as well as a reduction of cccDNA level; the latter phenotype, which kinetically occurs second, reinforce the first, as cccDNA is the main template of HBV RNA synthesis. RNA-seq analyses and loss-of-function approaches allowed the investigation of two host-effectors, respectively MCPIP1 and FEN-1, as involved in the reduction of HBV RNA accumulation and cccDNA level.

**Conclusion:** Using relevant cell culture models, we have uncovered the MoA of Pam3CSK4, a TLR2 ligand, which is currently under preclinical evaluation in a liver-deliverable and nanoparticulate form for the treatment of chronic HBV infections.

## PO-1707

### Cloning and in vivo characterization of a new hepatitis D virus genotype 1 strain from a patient achieving sustained virus response to interferon alpha treatment

Katja Giersch<sup>1</sup>, Nora Goldmann<sup>2</sup>, Lennart Hermanussen<sup>1</sup>, Lennart Hendricks<sup>1</sup>, Tassilo Volz<sup>1</sup>, Jan-Hendrik Bockmann<sup>1,3</sup>, Lena Allweiss<sup>1,3</sup>, Ansgar Lohse<sup>1</sup>, Jörg Petersen<sup>4</sup>, Marc Lutgehetmann<sup>3,5</sup>, Dieter Glebe<sup>2,3</sup>, Maura Dandri<sup>1,3</sup>. <sup>1</sup>University Medical Center Hamburg-Eppendorf, Department of Internal Medicine, Hamburg, Germany; <sup>2</sup>Justus Liebig University, Institute of Medical Virology, National Reference Center for Hepatitis B Viruses and Hepatitis D Viruses, Giessen, Germany; <sup>3</sup>German Center of infection research (DZIF), Hamburg-Lübeck-Borstel-Riems and Giessen-Marburg-Langen partner sites, Germany; <sup>4</sup>IFI Institute for Interdisciplinary Medicine at Asklepios Clinic St. Georg, Hamburg, Germany; <sup>5</sup>University Medical Center Hamburg-Eppendorf, Department of Medical Microbiology, Virology and Hygiene, Hamburg, Germany  
Email: kgiersch@uke.de

**Background and aims:** Pegylated interferon alpha (pegIFN $\alpha$ ) is commonly used for the treatment of hepatitis D virus (HDV) infected patients. However, the mode of action (MoA) of IFN in HDV infected cells remains elusive and only a minority of patients responds to therapy. Previous experimental studies mostly relied on a particular cell culture-derived strain of HDV genotype 1 (AJ000558) (Kuo, Chao, Taylor J Virol. 1989) that resulted insensitive to IFN $\alpha$  in vitro (Zhang et al, J Hep 2018). Contrarily, we showed that a patient-derived HDV-1 strain (HDV-1p) responded to pegIFN $\alpha$  in human liver chimeric mice (Giersch et al, Sci Rep 2017). Our aim was to clone and characterize this IFN sensitive HDV-1 isolate to study the antiviral effects of IFN in infected human hepatocytes.

**Method:** The HDV-1p strain was obtained from a patient later achieving sustained HDV response to IFN therapy. The isolate was passaged in chimeric mice, sequenced and cloned as genome-sense tandem dimer in pcDNA3.1 (+). HDV was generated by co-

transfection of HuH7 cells with plasmids encoding the HDV-1p dimer and hepatitis B virus (HBV) surface proteins. Infectivity of HDV-1p particles was tested *in vitro* using NTCP-expressing HepG2 cells and in HBV infected human liver chimeric mice. HBV/HDV-1p infected mice received pegIFN $\alpha$  twice a week (25 ng/g) for 4 weeks. Mice infected with the HDV (AJ000558) strain were used for comparison. Serum and liver viral loads were analyzed by qRT-PCR, immunofluorescence (IF) staining and RNA *in situ* hybridization.

**Results:** HDV stocks produced *in vitro* showed high infectivity in NTCP-expressing HepG2 cells. In HBV infected humanized mice stable HDV viremia (median  $3 \times 10^7$  copies/ml) was determined 6 weeks post HDV-1p super-infection and around 42% of human hepatocytes displayed HDV antigen (HDAg). PegIFN $\alpha$  reduced HDV (>2log) and HBV viremia (2log) in HBV/HDV-1p infected mice. Strong decrease of all intrahepatic HDV markers led to substantial HDAg negativization (4% HDAg positive cells). In contrast, pegIFN $\alpha$  lowered HBV viremia (2log) in HBV/HDV-1 (AJ000558) infected mice, but did not affect HDV markers in serum and liver, even after extending treatment to 9 weeks.

**Conclusion:** As an alternative to the commonly used HDV strain, we identified and cloned an IFN $\alpha$  sensitive patient derived HDV-1 isolate (HDV-1p) suitable to dissect the MoA of IFN in HDV infection and for assisting the design of therapies aiming to accelerate HDV loss and achieve HDV cure.

**Inducers of the NF- $\kappa$ B pathways impair Hepatitis Delta virus (HDV) replication and strongly decrease progeny infectivity and spreading**

Michelet Maud<sup>1,2</sup>, Dulce Alfaiate<sup>3</sup>, Brieux Chardes<sup>1,2</sup>, Suzanne Faure-Dupuy<sup>4</sup>, Thomas Engleitner<sup>5</sup>, Caroline Pons<sup>1,3</sup>, Rayan Farhat<sup>1,2</sup>, Tobias Riedl<sup>4</sup>, Anne-Flore Legrand<sup>1,2</sup>, Rivoire Michel<sup>6</sup>, Fabien Zoulim<sup>7</sup>, Mathias Heikenwälder<sup>4</sup>, Anna Salvetti<sup>1,2</sup>, David Durantel<sup>1,2</sup>, Julie Lucifora<sup>1,2</sup>. <sup>1</sup>INSERM, U1111, International Center for Research in Infectiology (CIRI), Lyon, France; <sup>2</sup>University of Lyon (UCBL1), Lyon, France; <sup>3</sup>Hospices Civils de Lyon, Lyon, France; <sup>4</sup>Heidelberg University, Heidelberg, Germany; <sup>5</sup>Technische Universität München, München, Germany; <sup>6</sup>Centre Léon Bérard, Lyon, France; <sup>7</sup>Cancer Research Center of Lyon, Lyon, France  
Email: julie.lucifora@inserm.fr

**Background and aims:** Hepatitis Delta Virus (HDV) super-infection of chronically Hepatitis B Virus (HBV)-infected patients is the most aggressive forms of chronic viral hepatitis, with an accelerated progression towards fibrosis/cirrhosis and an increased risk of liver failure, hepatocellular carcinoma, and death. At least 25 million of people would be co-infected with both viruses, ranking this co-infection as one of the most prevalent and most clinically challenging worldwide. While HDV infection is not susceptible to available direct anti-HBV drugs, suboptimal responses are obtained with IFN- $\alpha$  based therapies, and the number of investigational drugs remains limited.

**Method:** We recently established *in vitro* models of HDV super/co-infection of HBV-infected cells based on primary human hepatocytes (PHH) and the HepaRG cell line that are relevant to explore new therapeutics, including immune therapeutics.

**Results:** Using those models, we analyzed the effect of several innate immune-stimulators on HDV replication in chronically infected cells. We further characterized the anti-HDV effects of Pam3CSK4, an agonist of TLR1/2 and BS1, an agonist of the Lymphotoxin Beta Receptor (LT $\beta$ R) that both induced dose dependent reductions of total intracellular HDV RNAs, as well as HDV proteins levels. Off-drug rebound experiments revealed a long-lasting antiviral activity suggesting an irreversible effect on HDV replication and transcription templates. Both molecules negatively affect HDV progeny release and dramatically decrease their specific infectivity.

**Conclusion:** Immune-modulators inducing NF- $\kappa$ B pathways in hepatocytes can strongly inhibit HDV replication, and could be

further developed as efficient therapeutic approaches for HBV/HDV chronically infected patients.

**Viral interference in a hepatitis C virus and hepatitis E virus co-infection system**

Thomas Burkard<sup>1</sup>, Nora Moeller<sup>2</sup>, Kathrin Resner<sup>2</sup>, Leonard Knegendorf<sup>2</sup>, Martina Friesland<sup>2</sup>, Ruth Bröring<sup>3</sup>, Patrick Behrendt<sup>2,4</sup>, Heiner Wedemeyer<sup>4</sup>, Daniel Todt<sup>1,5</sup>, Eike Steinmann<sup>1</sup>. <sup>1</sup>Ruhr-University Bochum, Molecular and Medical Virology, Bochum, Germany; <sup>2</sup>TWINCORE Centre for Experimental and Clinical Infection Research; a joint venture between the Medical School Hannover (MHH) and the Helmholtz Centre for Infection Research (HZI), Institute for Experimental Virology, Hannover, Germany; <sup>3</sup>University Hospital of Essen, Clinic for Gastroenterology and Hepatology, Essen, Germany; <sup>4</sup>Hannover Medical School, Hepatology and Endocrinology, Department of Gastroenterology, Hannover, Germany; <sup>5</sup>European Virus Bioinformatics Center (EVBC), Jena, Germany  
Email: thomas.burkard@rub.de

**Background and aims:** Despite the advent of direct acting antivirals (DAAs) Hepatitis C virus (HCV) continues to constitute a global health problem with an estimated 71 million people being chronically infected, while Hepatitis E virus (HEV) on the other hand is the major cause of acute hepatitis establishing chronic courses only in immunocompromised patients. Clinical and virological information about HCV/HEV co-infections are limited and it is not known whether HCV and HEV influence each other's replication in the hepatocytes. In this study, we aimed to simulate HCV/HEV co-infections in a cell culture model system to assess their mutual influence on each other.

**Method:** We used state-of-the art tissue culture models for HEV and HCV. We assessed replication via transfection of subgenomic viral RNA harboring luciferase or fluorescence reporter, which enabled flow-cytometric or luminescence-based detection of both replicons. Furthermore, coinfection and superinfection experiments with authentic virus were performed and analyzed via indirect immunofluorescence.

**Results:** A novel model system to investigate interaction between HCV and HEV was established. Co-transfection of HCV and HEV RNA at the same time allowed quantification and visualization of viral replication of both viruses, while an exclusion phenotype was observed when HCV cells were super-transfected or infected with HEV. This phenotype could be linked to the activity of the HCV protease non-structural protein 3/4A (NS3/4A), whose overexpression alone inhibited HEV replication and infection. Treating HCV-positive cells with sofosbuvir or telaprevir restored the susceptibility to HEV.

**Conclusion:** This novel experimental model system of HCV/HEV co-infections revealed that, despite possible co-replication and co-infection, HCV interferes with the replication of HEV. This exclusion phenotype was found to be linked to HCV protease NS3/4A. These findings provide new insights into the pathogenesis of HCV-HEV co-infections.

**PO-1917**

**Significant in-Vitro and in-Vivo inhibition of HBsAg and HBV pgRNA with ASC42, a novel non-steroidal FXR agonist**

Jinzi Wu<sup>1</sup>, Xiaodong Li<sup>1</sup>, Handan He<sup>1</sup>, Qiong Zhou<sup>2</sup>. <sup>1</sup>Ascletris Bioscience Co., Ltd, Hangzhou, China; <sup>2</sup>WuXi AppTec (Shanghai) Co., Ltd, China

**Background and aims:** Activation of franesoid X receptor (FXR) may inhibit hepatitis B virus (HBV) replication. The objective of this study was to validate the anti-HBV efficacy of a FXR agonist ASC42 via *in vivo* and *in vitro* studies.

**Method:** Primary human hepatocyte (PHH) cells with HBV infection and AAV/HBV mouse model were used to evaluate ASC42's anti-HBV efficacy. PHH cells were infected by HBV and were treated with ASC42 for 6 days. Mice were intravenously injected with rAAV8-1.3 HBV and were administered with ASC42 for 28 days. The control compound

## POSTER PRESENTATIONS

Figure 1. (abstract: PO-1917) ASC42 inhibits HBsAg and HBV pgRNA in PHH model and AAV/HSV mice model.

was entecavir (ETV) in both studies. HBsAg, HBV pgRNA and HBV DNA were measured in culture medium and in mouse plasma.

**Results:** In PHH model, the control compound ETV showed the expected inhibitory activity on HBV DNA, but had no inhibition on HBV pgRNA and HBsAg, while ASC42 inhibited HBsAg, HBV pgRNA, and HBV DNA dose-dependently, with EC<sub>50</sub> of 0.79 μM, 0.09 μM and 0.62 μM, respectively (Figure 1A–D). In AAV-HBV mice model, after ETV (0.1 mg/kg) monotherapy, HBV DNA in mouse plasma decreased significantly, while HBV pgRNA and HBsAg showed no obvious reduction. ASC42 demonstrated a dose-dependent inhibition of HBV pgRNA, HBsAg, HBV DNA in mouse plasma. High-dose group of ASC42 (60 mg/kg) inhibited HBV pgRNA, HBsAg, and HBV DNA by 0.60 log<sub>10</sub> copy/μL (p < 0.01), 0.38 log<sub>10</sub> IU/μL (p = 0.002), and 0.77 log<sub>10</sub> copy/μL (p < 0.05), respectively, relative to vehicle control group (Figure 1E–F).

**Conclusion:** These in-vitro and in-vivo studies demonstrated that ASC42, a FXR agonist, significantly inhibited HBV DNA, HBV pgRNA and HBsAg, indicating that ASC42 has therapeutic potential to functional cure of HBV infection. The results support the advancement of ASC42 into clinical trials in human.

### PO-1928

#### Unexpected rising in the circulation of HBV complex profiles with HBsAg vaccine-escape mutations in HBV genotype-D: potential implications for HBsAg detection/quantification and vaccination strategies

Lorenzo Piermatteo<sup>1</sup>, Mohammad Alkhatib<sup>1</sup>, Maria Concetta Bellocchi<sup>1</sup>, Rossana Scutari<sup>1</sup>, Ada Bertoli<sup>1,2</sup>, Luca Carioti<sup>1</sup>, Lavinia Fabeni<sup>3</sup>, Miriam Lichtner<sup>4</sup>, Massimo Marignani<sup>5</sup>, Caterina Pasquazzi<sup>5</sup>, Nerio Iapadre<sup>6</sup>, Giustino Parruti<sup>7</sup>, Giuseppina Cappiello<sup>8</sup>, Massimo Andreoni<sup>9</sup>, Loredana Sarmati<sup>9</sup>, Francesca Ceccherini Silberstein<sup>1</sup>, Valentina Svicher<sup>1</sup>, Romina Salpini<sup>1</sup>.

Spallanzani, Virology and Biosafety Laboratories Unit, Rome, Italy; <sup>4</sup>"Sapienza" University, Public Health and Infectious Disease, Rome, Italy; <sup>5</sup>S. Andrea Hospital, Infectious Diseases, Rome, Italy; <sup>6</sup>"San Salvatore Hospital", L'Aquila, Italy; <sup>7</sup>Pescara General Hospital, Infectious Diseases Unit, Pescara, Italy; <sup>8</sup>"S. Pertini" Hospital, Microbiology and Virology Unit, Rome, Italy; <sup>9</sup>Tor Vergata University Hospital, Infectious Diseases, Rome, Italy  
 Email: lorenzo.piermatteo@uniroma2.it

**Background and aims:** Vaccine-escape mutations can alter HBsAg recognition by antibodies challenging vaccine efficacy, promoting immunosuppression-driven HBV-reactivation and impairing HBsAg

detection. Here, we investigate the circulation of vaccine-escape mutations, single or in complex mutational profiles, over time and their impact on serological parameters in HBV genotype-D.

**Method:** This study includes HBsAg sequences from 947 viremic HBV genotype-D infected patients (pts) collected from 2005 to 2019. 21 vaccine-escape mutations are analyzed (Lazarevic, 2014). Next generation sequencing (NGS) is performed by Illumina in a subset of 21 pts to evaluate the intra-patient prevalence of mutations.

**Results:** Median (IQR) HBV-DNA is 3.5 (2.6–5.0) logIU/ml and 4.2% of pts is HBsAg-negative despite HBV-DNA positivity. Overall, 17.7% (168/947) of pts harbors  $\geq 1$  vaccine escape mutation with the highest prevalence in subgenotype-D3 (23% for D3 vs 13.6% for other subgenotypes,  $P < 0.001$ ). Among them, 17.3% (29/168) show complex profiles with  $\geq 2$  vaccine-escape mutations.

NGS shows that vaccine-escape mutations, either single or in complex profiles, occur with an intra-patient prevalence  $>90\%$  in 81% of pts analyzed, suggesting their fixation in viral population. Notably, the proportion of pts with complex profiles of vaccine-escape mutations increased over time: from 0.4% (1/237) in 2005–2009 to 3.0% (12/396) in 2010–2014 and to 5.1% (16/314) in 2015–2019,  $p = 0.007$ , suggesting a progressive increase in the circulation of viral strains with enhanced capability to evade humoral responses. Moreover, the presence of complex mutational profiles correlates with lower HBsAg levels: median (IQR) 40 (0–2905) IU/ml for pts with vs 1688 (348–6090) without complex profiles ( $p = 0.0007$ ).

Focusing on HBsAg-negativity, the presence of complex mutational profiles also correlates with HBsAg-negativity despite HBV-DNA positivity (34.8% with  $\geq 2$  vaccine-escape mutations vs 6.7% and 2.3% with a single or no vaccine-escape mutations is HBsAg-negative,  $p = 0.007$  and  $< 0.0001$ ).

**Conclusion:** A noteworthy fraction of HBV genotype-D infected pts harbors complex profiles of vaccine-escape mutations detected as predominant species. These profiles correlate with lower HBsAg quantification and HBsAg-negativity despite ongoing viral replication. These mutations should be considered for a proper clinical interpretation of HBsAg results and their circulation should be taken into account for the development of novel vaccine formulation.

#### PO-1950

##### An antibody microarray identifies epidermal growth factor receptor as a novel host factor of hepatitis E virus

Jil Alexandra Schrader<sup>1</sup>, Volker Kinast<sup>1</sup>, Ruth Bröring<sup>2</sup>, Florian Vondran<sup>3</sup>, Eike Steinmann<sup>1</sup>. <sup>1</sup>Ruhr-University Bochum, Molecular and Medical Virology, Bochum, Germany; <sup>2</sup>University Hospital Essen, Department for Gastroenterology and Hepatology, Essen, Germany; <sup>3</sup>Medizinische Hochschule Hannover, Klinik für Allgemein-, Viszeral-, und Transplantationschirurgie, Hannover, Germany  
Email: jil.schrader@rub.de

**Background and aims:** Hepatitis E virus (HEV), a (+)-single-stranded RNA virus, is the most common cause of viral hepatitis with more than 20 Mio cases per year. Despite more than 3 Mio symptomatic cases and almost 70 000 death annually, HEV is a long-neglected, still under-reported, -diagnosed and -investigated health burden. Deciphering virus-host-interactions will not only be essential for a detailed understanding of HEV pathogenesis but also endorse the development of novel antiviral strategies targeting viral host factors.

**Method:** Human hepatoma cells and an antibody-based microarray with 613 phosphosite- and 265 pan-specific antibodies were used to detect differences in protein expression and phosphorylation in cell signaling pathways, caused by HEV replication. Resulting hits were validated in infection assays via siRNA mediated knock down, FDA-approved inhibitors as well as by ectopic expression and knock-out of the respective protein.

**Results:** More than 120 changes, including 54 overlapping hits, in protein expression and phosphorylation were detected 12 h and 48 h post HEV challenge. HEV replication induced a phosphorylation of several kinases e.g. mitogen-activated protein kinases as well as the

EGF-Receptor (EGFR). A subsequent siRNA-mini screen of 28 candidates revealed a significant decrease of one half in HEV susceptibility upon EGFR knockdown when compared to control infections. Selective inhibition of EGFR with FDA-approved drugs reduced HEV entry in both hepatoma cells and primary human hepatocytes down to 20%. Of note, viral replication was not affected by pharmacological inhibition of EGFR. In line, CRISPR/Cas9 knock-out of EGFR in HepG2 cells decreased the susceptibility for HEV by one half, but had no effect on viral replication. In contrast, stable EGFR expression in hepatoma cells lead to a three-fold increased HEV susceptibility and the effect could be reversed by treatment with EGFR-specific modulators during the virus inoculation.

**Conclusion:** An antibody microarray technology uncovered that HEV causes a brought mobilization of host cell pathways. An siRNA screen of 28 selected hits validated and specified the effects of the tested genes/proteins. EGFR was identified as a potential novel host factor, playing a role in the entry process of HEV. A detailed analysis of the corresponding, but also further pathways, will define their role for the pathogenesis of HEV and may help to facilitate the development of anti-HEV therapies.

#### PO-1980

##### Quantified integrated hepatitis B virus DNA in relation to other viral markers in chronic hepatitis B patients

Robin Erken<sup>1,2</sup>, Vladimir Loukachov<sup>2</sup>, Karel van Dort<sup>2</sup>, Anne van den Hurk<sup>2</sup>, Bart Takkenberg<sup>1</sup>, Sophie Willemse<sup>1</sup>, Neeltje Kootstra<sup>2</sup>. <sup>1</sup>Amsterdam UMC, locatie AMC, Gastroenterology and Hepatology, Amsterdam, Netherlands; <sup>2</sup>Amsterdam UMC, locatie AMC, Experimental Immunology, Amsterdam, Netherlands  
Email: r.erken@amc.uva.nl

**Background and aims:** ext to the formation of cccDNA, the hepatitis B virus (HBV) can also integrate in the host genome of the hepatocyte. The effect of integrated HBV DNA on the production of viral proteins and viral replication is still unknown, especially since there is no standardized method for the detection of integrated HBV DNA. The aim of our study was to design a PCR detecting and quantifying integrated HBV DNA and analyse the relation between HBV integration and virological activity.

**Method:** Total DNA of HepG2.2.15 cells were used for validation of the multistep Alu-PCR that detects integrated HBV: Integrated HBV DNA was amplified using a specific forward primer for each HBV ORF (S, X, or C) and an Alu reverse primer with a tag sequence. HBV-Alu PCR products were amplified by a nested PCR with a downstream forward HBV ORF primer (S, X or C) and a reverse tag primer. A second nested PCR was performed using HBV ORF specific primers and a detection probe.

Pre-treatment liver tissue samples were available from chronic hepatitis B patients with either a high ( $>20,000$ ,  $n = 38$ ) or low ( $<20,000$ ,  $n = 97$ ) viral load, and controls ( $n = 25$ ). Patients were previously included in two prospective studies investigating the effect of combination treatment with interferon and tenofovir or adefovir. The different integrated HBV-DNA ORF levels were measured in liver tissue and normalized using the  $2^{-\Delta\Delta Ct}$  method. Integrated HBV-DNA levels between groups were compared using a Mann-Whitney U test. Association between the integrated HBV-DNA levels, virological markers, liver damage markers was performed using a Spearman correlation test and corrected for multiple testing.

**Results:** Integrated HBV DNA sequences of ORF S and X but not C were detected and quantified in patients with chronic hepatitis B but not in control samples. ORF S and X integrants correlated with HBV DNA, HBsAg and ALT levels in serum/plasma as well as to HAI scores of liver tissue, all  $p < 0.02$ . The strongest correlations were found between ORF X and: ORF S ( $\rho = 0.655$ ,  $p < 0.001$ ) or plasma HBV DNA ( $\rho = 0.526$ ,  $p < 0.001$ ). Integrated HBV DNA levels did not differ between HBeAg negative and -positive patients although a clear trend ( $p = 0.0501$ ) of lower ORF S levels in HBeAg negative patients was seen.

## POSTER PRESENTATIONS

**Conclusion:** Our Alu-PCR protocol was effective in quantifying the ORF S and X of integrated HBV DNA in chronic HBV patients. Levels of ORF S and X integrants correlated with viral markers in plasma.

### PO-2105

#### Hepatitis B virus surface antigen expression determines hepatic immunity and Kupffer cell functions in HBV-transgenic mice

Stefan Schefczyk<sup>1</sup>, Simon Merz<sup>2</sup>, Xufeng Luo<sup>1</sup>, Martin Trippler<sup>1</sup>, Matthias Hardtke-Wolenski<sup>1</sup>, Ruth Broering<sup>1</sup>. <sup>1</sup>Essen University Hospital, Department of Gastroenterology and Hepatology, Essen, Germany; <sup>2</sup>LaVision BioTec GmbH, Bielefeld, Germany  
Email: stefan.schefczyk@uni-due.de

**Background and aims:** One of the most frequent causes for liver related morbidity and mortality is the chronic Hepatitis B virus (HBV) infection. Pathogenesis of this infection is driven by the adaptive as well as the innate immune system. The present project aims to investigate how HBV surface antigen (HBsAg) affects the hepatic innate and adaptive immune responses, utilizing different HBV-transgenic mouse strains, which show I) inflammation and tumour progression (Alb/HBs), II) Kupffer cell (KC)-mediated interferon responses (HBV-s-mut) or III) neither inflammation nor interferon responses (HBV-s-rec).

**Method:** F4/80 positive KC were prepared after two-step perfusion of murine livers (wildtype, Alb/HBs, HBV-s-mut and HBV-s-rec) followed by MACSbead separation. KC were used in a phagocytosis assay using zymosan bioparticles and analysed by flow cytometry. KC were further visualized using light sheet fluorescence microscopy (LSFM) in ECi cleared mouse liver samples.

**Results:** In term of KC cell count, the HBV-s-mut mouse showed a higher number of KC compared to the other mouse strains. The total KC phagocytic activity was altered in the different HBV-transgenic mouse strains. Scilicet, the Alb/HBs-derived KC showed a significantly decreased phagocytosis activity and the HBV-s-rec-derived KC showed an overall distinct phagocytosis activity. Two populations of F4/80 positive KC (dim and bright) could be identified and independently analysed. Within the F4/80 bright population only the HBV-s-rec showed a significantly altered, namely decreased phagocytosis activity. In the F4/80 dim population the Alb/HBs-derived KC showed a decreased phagocytosis activity, whereas the HBV-s-rec-derived KC showed an altered phagocytosis activity with significantly increased activity at very early (15–60 min) and very late time points (upon 210 min). The HBV-s-mut-derived KC, either total F4/80, dim or bright populations showed phagocytic activities and capacities comparable to the wildtype KC populations. LSFM visualized distinct distribution pattern of the two F4/80 populations within the liver of wildtype and HBV-transgenic mice.

**Conclusion:** The data led to suggest, that the accumulation of the HBsAg in Alb/HBs mice leads to a decreased phagocytosis activity in F4/80 dim population. Interestingly, the production and release of viral particles in HBV-s-rec mice led to an increased phagocytosis pattern in HBV-s-rec-derived F4/80 dim KC. Finally, despite the increased KC number and the known, consistent IFN response in KC from HBV-s-mut mice didn't affect the phagocytosis activity.

### PO-2135

#### A specific deletion pattern in the preS1- and preS2-domain is associated with treatment induced HBsAg loss in chronic hepatitis B

Maria Pfefferkorn<sup>1</sup>, Danilo Deichsel<sup>1</sup>, Madlen Matz-Soja<sup>1,2</sup>, Thomas Berg<sup>1</sup>, Florian van Bömmel<sup>1</sup>. <sup>1</sup>Division of Hepatology, Department of Medicine II, Leipzig University Medical Center, Leipzig, Germany; <sup>2</sup>Leipzig University, Faculty of Medicine, Rudolf Schönheimer Institute of Biochemistry, Leipzig, Germany  
Email: Maria.pfefferkorn@medizin.uni-leipzig.de

**Background and aims:** HBsAg consists of the S (small; SHBs), the preS2 (middle, MHBs) and the preS1 (large; LHBs) proteins, and the proportions of those proteins changes during the development of

HBsAg loss under nucleos (t)ide analogue (NA) treatment. We have investigated whether changes in HBsAg composition during development of functional cure is associated with genomic variants in the coding s gene of HBV.

**Method:** Patients achieving HBsAg loss (n = 15) and patients without serologic response including HBeAg or HBsAg loss (w/o SR; n = 23) during NA treatment were retrospectively analyzed. Proportions of HBsAg proteins were quantified in sera collected before and during treatment. The complete HBV s gene was sequenced in all available serum samples (n = 164) of patients with HBsAg loss and in minimum three sequential samples of patients w/o SR.

**Results:** Among patients with HBsAg loss, 53% (n = 8) showed wildtype s gene before and during NA treatment, whereas 40% (n = 6) developed a double deletion of aa 1–6 and aa 88–129. These deletions are located in the N-terminal regions of the preS1- (LHBs) and the preS2- (MHBs) domain and include the start ATG of both proteins. In samples with the deletions aa 1–6 and aa 88–129, HBV DNA and HBsAg levels were significantly lower as compared to samples with wt. In patients with subsequent HBsAg loss LHBs and MHBs became undetectable 3.9 (0–9) and 11.4 (0–53) months before the loss of total HBsAg. The occurrence of the double deletion lead to a strong decrease of MHBs (%), but not LHBs (%). In patients w/o SR, 74% (n = 17) showed wildtype s genes in all analyzed samples and no patient showed the double deletion of aa 1–6 and aa 88–129.

**Conclusion:** In many patients with HBsAg loss during antiviral treatment a double deletion in the start ATG of the preS1- and preS2-domain was found which is associated with decreased MHBs ratios and possibly with decreased HBV replication. The relevance of those mutations for HBV replication and the process of HBsAg loss need to be studied further.

### PO-2145

#### Conservation, variability and evolution of Hepatitis Delta virus in antigen coding region

Beatriz Pacín<sup>1,2</sup>, Maria Francesca Cortese<sup>1,2</sup>, Josep Gregori<sup>2</sup>, Marta Vila<sup>1,2</sup>, Selene Garcia-Garcia<sup>1,2</sup>, David Tabernero<sup>1,3</sup>, Rosario Casillas<sup>1,2</sup>, Ariadna Rando<sup>1</sup>, Adriana Palom<sup>4</sup>, Mar Riveiro Barciela<sup>3,4</sup>, Francisco Rodríguez-Frías<sup>1,2,3</sup>, Maria Buti<sup>3,4</sup>. <sup>1</sup>Vall D'hebron University Hospital, Biochemistry and Microbiology/Liver Pathology Unit, Barcelona, Spain; <sup>2</sup>Vall D'hebron Research Institute, Barcelona, Spain, Liver Unit, Barcelona, Spain; <sup>3</sup>Instituto De Salud Carlos III, Madrid, Spain, Centro De Investigación Biomédica En Red, Enfermedades Hepáticas y Digestivas (CIBERehd), Madrid, Spain; <sup>4</sup>Vall D'hebron University Hospital, Liver Unit, Internal Medicine Department., Barcelona, Spain  
Email: beatriz.pacin@vhir.org

**Background and aims:** Hepatitis delta virus HDV affects around 5% of hepatitis B virus infected patients causing the most severe form of chronic viral hepatitis. HDV RNA genome encodes just for a protein that exists in two length-dependent isoforms (S- and L-HDAg) following an edition of the canonical stop codon. The HDV is characterized by a high evolutionary rate resulting in a complex viral population (quasispecies, QS) that could influence viral replication and clinical evolution. Mutations in L-HDAg related to escape from adaptive immune response had been associated with more severe hepatitis. Here we analyzed by next generation sequencing (NGS) the L-HDAg quasispecies to identify highly conserved regions and mutations that potentially affect HDV evolution.

**Method:** Ten patients with chronic hepatitis delta (CHD) were enrolled in the study and followed up for an average period of 1.5 years. HDV RNA was extracted from two plasma samples per patient (at inclusion and follow-up). A region in HDAg gene located between nucleotide (nt) 910 to 1270 (amino acid, aa 111–215) was analyzed by NGS (MiSeq Illumina, San Diego, USA). Conservation was calculated by analyzing QS information content. Amino acid substitutions were identified by aligning sample QS with its genotype sequence.

**Sliding window of QS conservation in multiple alignment of HDAG nucleotide sequences.** The sliding window analysis is the result of the mean information content (bits) of the 25-nt long windows with a displacement between them of 1nt obtained by multiple alignment of all haplotypes (blue line) and taking into account their relative frequencies (red line). Green boxes show the highly conserved regions, whereas the highly variable region is highlighted in pink.

Figure: (abstract: PO-2145)

**Results:** A median of 31384, 5 reads/sample was obtained. Two highly conserved regions were observed between nt 1404–1383 (corresponding to aa 159–172) and nt 1502–1483 (aa 191–197) of L-HDAG, whereas high variability was observed between nt 1480–1423 (aa 171–190) (Figure). Of note, conservation index did not change over the time in none of the studied patients. A total of 37 mutated aa positions were identified. Remarkably, in 5/10 patients, 7 aa changes (K113S, V144I/T, P148R, V149 T/A, S159A, T180S, V188M/I) were positively selected over time and located within CD8+ T-cells epitopes. Of note, in 3/5 patients, more than 2 aa changes at epitopes were observed.

**Conclusion:** The HDAG gene seems to be relatively conserved during the time. The HDAG editing domain was highly conserved, agree with its essential role. Other hyper-conserved region was observed, which might suggest an important function in HDV replication. However, some aa changes located into CD8 immune epitopes were selected, suggesting a possible immune escape mechanism as one of the HDV evolution factor. Funding: Instituto de Salud Carlos III (grant PI17/02233), co-financed by the European Regional Development Fund (ERDF).

**PO-2293**

**Low anti-HBc levels are associated with lower risk of virological relapse after discontinuation of nucleos (t)ide analogue therapy in HBe antigen negative patients.**

Valerie Ohlendorf<sup>1</sup>, Maximillian Wuebbolding<sup>1,2,3</sup>, Paul Gineste<sup>4</sup>, Christoph Hoener zu Siederdisen<sup>1</sup>, Birgit Bremer<sup>1</sup>, Heiner Wedemeyer<sup>1,2</sup>, Markus Cornberg<sup>1,2,3</sup>, Benjamin Maasoumy<sup>1,2,3</sup>. <sup>1</sup>Hannover Medical School, Clinic for Gastroenterology, Hepatology and Endocrinology, Hannover, Germany; <sup>2</sup>German Center for Infection Research (DZIF), Braunschweig, Germany; <sup>3</sup>Centre for Individualised Infection Medicine (CiIM), a joint venture of Helmholtz Centre for Infection Research and Hannover Medical School, Hannover, Germany; <sup>4</sup>Abivax, Paris, France  
Email: ohlendorf.valerie@mh-hannover.de

**Background and aims:** EASL guidelines suggest that treatment with nucleos (t)ide analogue (NA) can be stopped in HBeAg negative

patients after three years of viral suppression. However, relapse must be expected in more than half of the patients. Recently, a low level of serum anti-HBc at the time of NA cessation has been linked to a higher risk of relapse in a cohort of predominantly HBeAg positive patients. In this study we investigated the association of serum anti-HBc with relapse after stop of NA therapy in HBeAg negative patients. **Method:** Serum levels of anti-HBc, HBsAg and HBcrAg were determined in 136 HBeAg negative patients, participating in a prospective, multicenter therapeutic vaccination trial (ABX-203, NCT02249988), before Stop of NA therapy or vaccination (baseline). Importantly, vaccination showed no impact on relapse. Virological relapse was defined as HBV DNA >2, 000 IU/ml. Anti-HBc levels were compared between relapsers and off-treatment responders using the Mann-Whitney U test. Optimal anti-HBc thresholds were determined by the Youden-Index. Correlation between anti-HBc, HBsAg and HBcrAg was tested with Spearman correlation.

**Results:** Median age of the patients was 53 years and 75% (n = 102/136) of patients were male. The majority of patients was treated with entecavir (n = 90/136; 66%), while the rest received tenofovir. Median anti-HBc, HBsAg and HBcrAg at baseline was 490 IU/ml, 784 IU/ml and 1585 U/ml, respectively. No significant correlation was found between baseline anti-HBc and HBsAg (r = 0.016, p = 0.85) or anti-HBc and HBcrAg (r = -0.011; p = 0.90). Relapse after NA discontinuation occurred in 68 out of 136 patients (50%). Median anti-HBc was significantly higher among relapsers when compared to off-treatment responders (520 IU/ml vs. 330 IU/ml, p = 0.0098). A baseline anti-HBc-level of 325 IU/ml was determined as optimal cut-off value to predict relapse. Relapse occurred in 35% of patients with an anti-HBc level <325 IU/ml, while this was the case in 60% of those with values ≥325 IU/ml (p = 0.0103; sensitivity 50%, specificity 75%; Figure).

## POSTER PRESENTATIONS

Figure: Cumulative relapse rate after NA cessation according to end of treatment (EoT) by serum anti-HBc baseline levels.

**Conclusion:** In contrast to cohorts of predominantly HBeAg positive patients, lower serum anti-HBc levels are associated with a significantly lower risk of relapse after NA cessation in HBeAg negative patients. As anti-HBc showed no correlation with other virological markers we suggest that it should be further explored when establishing prediction models in the future.

### PO-2474

#### Novel HBV cure strategy: Leveraging HBV pol for infected cell-specific killing-In vivo proof-of-concept

Serhat Gumrukcu<sup>1,2</sup>, Tung Nguyen<sup>1,2</sup>, Michael Bobardt<sup>3</sup>, Philippe Gallay<sup>3</sup>. <sup>1</sup>Seraph Research Institute, Los Angeles, United States; <sup>2</sup>Enochian Biosciences Inc, Los Angeles, United States; <sup>3</sup>The Scripps Research Institute, Department of Immunology and Microbiology, La Jolla, United States

Email: drs@seraphinstitute.org

**Background and aims:** Despite effective treatment and vaccination, Hepatitis B virus (HBV) persists as a global cause of chronic liver disease and mortality responsible for ~ 900, 000 deaths annually. Thus, an effective cure strategy is urgently needed. Current strategies focusing on reducing HBV (ccc)DNA or interrupting viral replication have not been successful. We hypothesized that inducing apoptosis in HBV-infected hepatocytes by “hijacking” HBV *pol* could effectively eradicate infection.

**Method:** A unique, proprietary vector construct expressing a non-functional, non-coding (nc)RNA (HBV Hijack RNA), under liver-specific thyroxine binding globulin (TGB) promoter was packaged in AAV8 particles. HBV Hijack RNA is designed using negative strand of human caspase-9 (casp-9) cDNA flanked by 2 HBV *epsilon* signals (HBV *pol*-specific recognition sequence). HBV *pol*/RT recognizes HBV Hijack RNA and reverse transcribes it to double stranded (ds) DNA expressing casp-9 driven by a strong promoter, to induce apoptosis. We have previously reported *in vitro* and *in vivo* studies validating our proposed mechanism of action. To investigate killing kinetics *in vivo*, we established a xenograft model by transplanting bioluminescent-tagged HBV *pol*-expressing HepG2 cells ( $2 \times 10^5$  cells in 0.1 ml serum-free medium with 50% Matrigel) into nude mice. Once xenografts were detectable, mice were treated with test AAV8 expressing HBV Hijack RNA, or control AAV8 expressing GFP. Along with cage-side general health observations, tumor size was measured daily by an *in vivo* imaging system (IVIS). On day 30 after AAV treatment, mice were sacrificed for evaluation of their liver tissues by immunohistochemistry. The same model was used for dose escalation and toxicity studies.

**Results:** In the kinetics study, bioluminescence measurements showed daily reduction in the target tissue size, starting 2 days after AAV administration. On day 8 there was no visible signal in mice treated with the test vector. Daily growth of target cells was observed in controls (Figure). No liver or treatment-related toxicity was

observed in test vector-treated mice or recrudescence xenograft growth by day 30. Necropsy and dose escalation results will be presented.

Figure:

**Conclusion:** HBV Hijack RNA rapidly cleared HBV-target cells in mice without recrudescence or toxicity by day 30 post-treatment. HBV Hijack RNA could be a promising strategy to cure HBV infection.

#### Mitochondrial stress in patients with chronic hepatitis b and advanced fibrosis

Dimitri Loureiro<sup>1,2</sup>, Issam Tout<sup>1,2</sup>, Morganer Roinard<sup>1,2</sup>, Ahmad Sleiman<sup>1,2</sup>, Boyer Nathalie<sup>1,2</sup>, Stephanie Narguet<sup>1,2</sup>, Nathalie Pons-Kerjean<sup>3</sup>, Corinne Castelnau<sup>1,2</sup>, Nathalie Giuly<sup>1,2</sup>, Vassili Soumelis<sup>4</sup>, Jamel El Benna<sup>2</sup>, Patrick Soussan<sup>5</sup>, Richard Moreau<sup>1,2</sup>, Valérie Paradis<sup>1,2</sup>, Abdel Mansouri<sup>1,2</sup>, Tarik Asselah<sup>1,2</sup>. <sup>1</sup>Hospital Beaujon AP-HP, Hepatology, Clichy, France; <sup>2</sup>Center Recherche Sur L'inflammation, U1149, Paris, France; <sup>3</sup>Hospital Beaujon AP-HP, Service de Pharmacie, Clichy, France; <sup>4</sup>Hospital \_ Saint-Louis Ap-Hp, Laboratoire d'Immunologie et Histocompatibilité, Paris, France; <sup>5</sup>Université de Paris, U1135, Paris, France  
Email: dimitri.loureiro@inserm.fr

**Background and aims:** Mitochondrial DNA is particularly sensitive to oxidative stress and hepatitis B virus (HBV) increases hepatic stress. We postulated that it may cause oxidative damage to mitochondrial DNA, resulting in mitochondrial dysfunction which might account for fibrosis progression in chronic hepatitis B infection (CHB).

**Method:** 136 treatment-naïve CHB mono-infected patients were included. Liver mitochondrial DNA (mtDNA) damage was screened by long PCR and sequencing and levels by Slot blot. The expression of the main genes of cytochrome *c* oxidase subunits, mitophagy, mitochondrial peptidases and chaperonins, TNF $\alpha$  and IL6 were investigated by RT-qPCR and Western-blotting. Patients with advanced fibrosis (F3-F4 Metavir score; n=41) were compared to patients with mild-moderate fibrosis (F0-F2;n=86). *In vitro*, HBV and HBx were expressed in HepG2 cells and the superoxide anion formation was assessed by MitoSox and mtDNA levels by Slot blot.

**Results:** Whereas 100% of patients with F3-F4 fibrosis exhibited multiple mtDNA deletions, 50% of those with F0-F2 fibrosis ( $\kappa^2 = 6.8$ ;  $p < .001$ ) carried a single mtDNA deletion. Significant decreases were observed in F3-F4 compared to F0-F2 for the mRNAs of MT-CO1 ( $0.55 \pm 0.36$  and  $1.20 \pm 0.75$ ,  $p < .001$ ), HSPA9 ( $0.70 \pm 0.28$  and  $1.06 \pm 0.37$ ,  $p < .001$ ), HSPD1 ( $0.83 \pm 0.36$  and  $1.10 \pm 0.44$ ,  $p < .05$ ), Lon Peptidase 1, LONP1 ( $0.83 \pm 0.22$  and  $1.06 \pm 0.33$ ,  $p < .05$ ), Parkinson-juvenile

disease protein 2, PRKN ( $0.45 \pm 0.26$  and  $1.12 \pm 0.57$ ,  $p < .0001$ ), and Phosphatase and Tensin-Induced Putative Kinase-1, PINK1 ( $0.59 \pm 0.17$  and  $1.06 \pm 0.26$ ,  $p < .0001$ ). Liver TNF $\alpha$  mRNA was  $1.72 \pm 0.2$  and  $0.99 \pm 0.2$  ( $p < .05$ ) and IL6 mRNA was  $7.82 \pm 0.90$  and  $1.14 \pm 0.26$  ( $p < .05$ ) in F3-4 and F0-F2, respectively. Protein levels significantly decreased in F3-F4 compared to F0-F2 for MT-CO1, LONP1, PRKN and PINK1. *In vitro*, both HBV or HBx expression significantly ( $p < .05$ ) increased mitochondrial superoxide formation, depleted mtDNA, decreased MT-CO1 expression, increased 3-Nitrotyrosine (3-NT) residues within respiratory chain complexes and inhibited complex I at 24 and 48 h post-transfection.

**Conclusion:** Diverse mtDNA damages were associated with alterations in mitochondrial function, mitochondrial unfolded protein response, mitophagy and inflammation in patients with CHB and advanced fibrosis. *In vitro*, the accumulation of 3-NT on mitochondrial proteins points out a role of the superoxide anion reacting with NO to form mtDNA- and protein-damaging peroxy-nitrite. In addition to the damage caused by reactive species; decreased levels of mitochondrial transcripts lead to mitochondrial dysfunction. Modulating mitochondrial function is therefore an attractive therapeutic strategy to block the progression of fibrosis and prevents CHB.

## Viral hepatitis A-E: Clinical aspects

### PO-1844

#### Global burden of acute hepatitis and its association with socioeconomic development status, 1990–2019

Dan-Yi Zeng<sup>1</sup>, Jing-Mao Li<sup>2</sup>, Jia You<sup>1</sup>, Mei-Zhu Hong<sup>3</sup>, Yueyong Zhu<sup>1</sup>, Jin-Shui Pan<sup>1</sup>. <sup>1</sup>First Affiliated Hospital of Fujian Medical University, Hepatology, Fuzhou, China; <sup>2</sup>Xiamen University, School of Economics, Xiamen, China; <sup>3</sup>Mengchao Hepatobiliary Hospital of Fujian Medical University, Fuzhou, China  
Email: dr\_ezhu@163.com

**Background and aims:** Acute viral hepatitis (AVH) represents an important global health problem, however, progress in understanding AVH has been eclipsed by the priority of combating persistent HBV and HCV infections. An improved understanding of the burden of AVH is needed to inform strategies for global intervention.

**Method:** Age-standardized incidence rate and disability-adjusted life years (DALYs) rate of AVH were extracted from GBD 2019, which were stratified by sex, level of Socio-demographic Index (SDI), and country and territory. The association between burden of AVH and socioeconomic development status, represented in SDI, was also described.

**Results:** In 2019, there was an age-standardized incidence rate of 3615.9 (95% CI 3360.5–3888.3) and an age-standardized DALYs rate of 58.0 (47.3–70.0) per 100 000 person-years, in terms of 4 major AVH. Among major AVH, acute hepatitis A caused the heaviest burden. There was a significant downward trend in age-standardized DALYs rates due to the major AVH from 1990 to 2019. Globally, several regions or countries located in West and Central Africa shouldered the highest age-standardized incidence rates of AVH in 2019. Stratified using SDI, the high SDI, and high-middle SDI locations recorded the lowest incidence rate and DALYs rate of AVH, whereas the low-middle SDI, and low SDI locations possessed the highest-burden of AVH.

**Conclusion:** Pronounced association exists between socioeconomic development status and burden of AVH. Data of GBD 2019 are valuable for policymakers to implement cost-effective interventions for AVH.

Email: fanjianguo@xinhua.com.cn

**Background and aims:** Although concomitant non-alcoholic steatohepatitis (NASH) is common in chronic hepatitis B (CHB) patients, the outcome of NASH in CHB patients remains unclear. This study was aimed to evaluate the incidence and resolution rate of NASH in CHB patients during antiviral treatment.

**Method:** This was a sub-study of a multicenter prospective study on HBV treatment outcomes including patients with or without NASH. The histopathological features of NASH were examined using paired liver biopsies at baseline and week 72. Finally, 297 of 1000 CHB patients (30%) had concomitant steatosis, 182 (18.2%) had NASH.

**Results:** After 72-week entecavir treatment, concomitant steatosis and NASH decreased to 18% (129/727) and 10% (73/727), respectively. Among patients with NASH, the scores of hepatic steatosis, ballooning, lobular inflammation and fibrosis stages all improved (all  $P < 0.001$ ), and 63 of 136 patients (46%) achieved NASH resolution. By multivariable analysis, baseline body mass index (BMI)  $< 23$  kg/m<sup>2</sup> (OR = 2.4, 95% CI: 1.112–5.255,  $P = 0.012$ ) and no weight gain at follow-up (OR = 5.4, 95% CI: 1.443–19.896,  $P = 0.026$ ) were significantly associated with NASH resolution. The rates of serum HBeAg loss, HBeAg seroconversion, undetectable HBV DNA and ALT normalization were similar between patients with or without NASH ( $p = 0.303, 0.652, 0.498$  and  $0.736$ , respectively). Among patients who had no or bland steatosis at baseline, 22 cases (3.7%) had incident NASH. Baseline BMI  $\geq 23$  kg/m<sup>2</sup> (OR = 12.5, 95%CI: 2.813–55.606,  $P = 0.001$ ) and weight gain (OR = 5.1, 95%CI: 1.674–15.694,  $P = 0.005$ ) were predictors of NASH development.

# POSTER PRESENTATIONS

# POSTER PRESENTATIONS

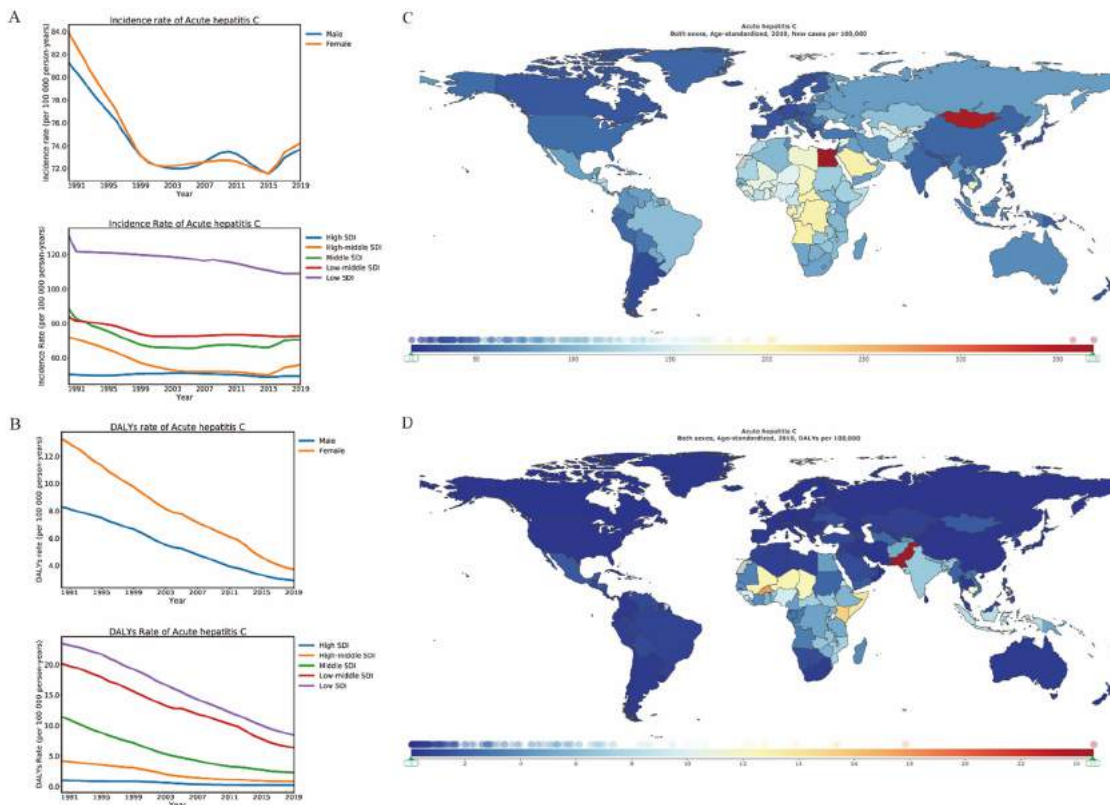

Figure 4: (abstract: PO-1844) Burden of AHC for 204 countries and territories

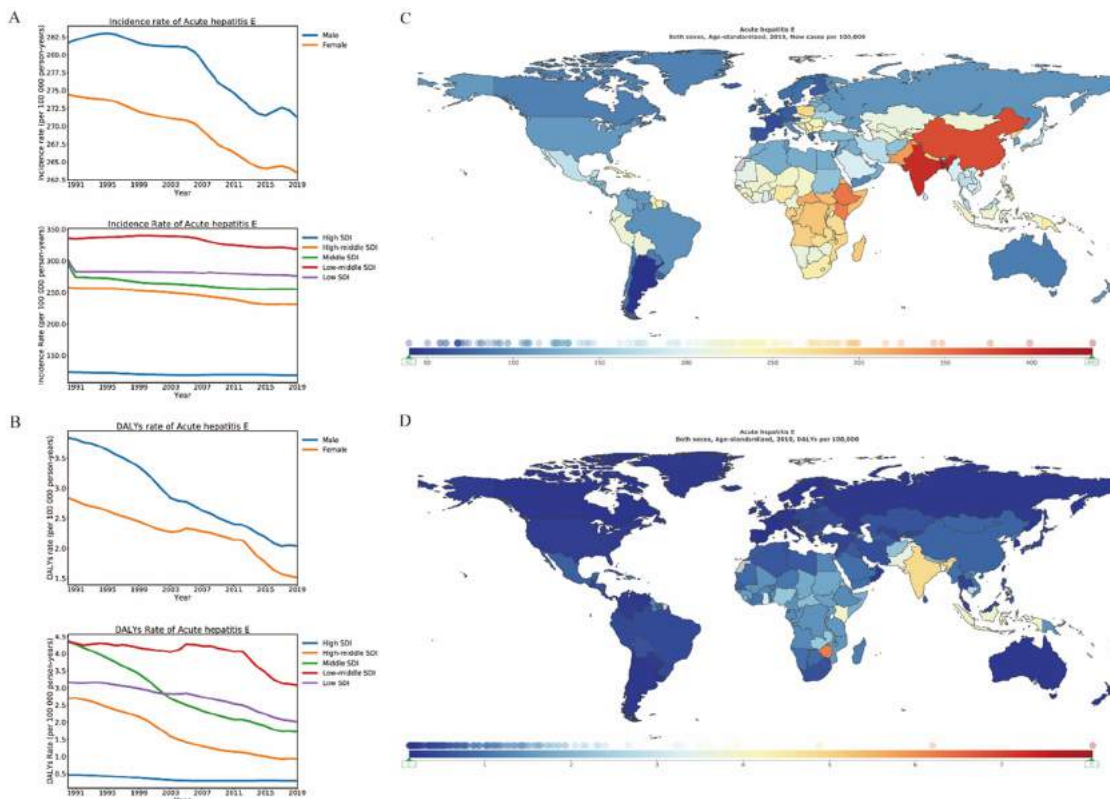

Figure 5: (abstract: PO-1844) Burden of AHE for 204 countries and territories.

Table: Risk factors associated with the outcomes of NASH

	Events	OR	95%CI	P value
<b>NASH resolution</b>				
BMI $\geq$ 23	40%	Ref		
BMI<23	61%	2.42	1.11, 5.26	0.012
Weight gain	17%	Ref		
No weight gain	51%	5.36	1.44, 19.90	0.026
<b>NASH resolution without worsening of fibrosis</b>				
BMI $\geq$ 23	37%	Ref		
BMI<23	56%	2.23	1.04, 4.79	0.040
Weight gain	17%	Ref		
No weight gain	47%	4.46	1.21, 16.48	0.025
<b>NAS decrease <math>\geq</math>2 points</b>				
BMI $\geq$ 23	80%	Ref		
BMI<23	95%	5.16	1.10, 24.12	0.037
Weight gain	61%	Ref		
No weight gain	88%	5.01	1.59, 15.80	0.006
<b>NASH improvement without worsening of fibrosis</b>				
BMI $\geq$ 23	53%	Ref		
BMI<23	73%	2.50	1.10, 5.68	0.028
Weight gain	33%	Ref		
No weight gain	63%	3.45	1.18, 10.09	0.024

**Conclusion:** CHB patients had a high proportion of NASH resolution during antiviral treatment, especially in lean patients without weight gain. The value of weight management in CHB patients during antiviral treatment deserves further evaluation.

**Liver volume measurement predicts development of hepatic encephalopathy in chronic hepatitis b patients**

Jin-Wook Kim<sup>2</sup>, Sumi Kim<sup>3</sup>. <sup>1</sup>College of Medicine, Seoul National University, Seoul, Korea, Rep. of South; <sup>2</sup>Seoul National University Bundang Hospital, Department of Medicine, Seongnam, Korea, Rep. of South; <sup>3</sup>Seoul National University College of Medicine, Korea, Rep. of South

Email: jwook2112@gmail.com

**Background and aims:** Potent antiviral therapy has improved the prognosis of chronic hepatitis B (CHB), but some patients still experience disease progression. Liver volume represents overall hepatic functional reserve and has been used for preoperative planning for hepatic resection. The aim of this study was to determine whether CT-measured liver volume can predict complications of HBV-associated liver cirrhosis such as varix bleeding, ascites, and hepatic encephalopathy development.

**Method:** This study is the retrospective cohort study which included 223 HBeAg-negative CHB patients who received at least two CT scans in a tertiary referral hospital in South Korea. Liver volume was measured on portal venous phase contrast-enhanced CT images. To adjust the effect of body build, liver volume index was calculated, dividing CT-measured liver volume by formula liver volume. Clinical, demographic, and laboratory parameters were independent variables. Varix bleeding, ascites, and hepatic encephalopathy development were dependent variables. By performing multiple logistic regression, independent predictors for complications development were identified.

**Results:** Platelet count ( $\times 10^9/L$ ) was an independent predictor for varix bleeding (odds ratio [OR] = 0.943;  $p = 0.001$ ). Age and sex had significant correlation with ascites development (OR = 1.065 and 3.673 in age and sex, respectively;  $p = 0.018$  and  $0.047$ ). Liver volume didn't show any significant results with varix bleeding and ascites. However, age and liver volume were identified as predictors of hepatic encephalopathy (OR = 1.057 and 10.942 in age and liver volume index, respectively;  $p = 0.015$  and  $0.021$ ).

Figure: Predictors of hepatic encephalopathy development by multiple logistic regression model

Characteristic	Exp (B)	95% CI for exp (B)	P
Age	1.057	1.011–1.106	0.015
Male sex	1.609	0.605–4.277	0.341
Nucleotide Analogue	1.094	0.428–2.795	0.851
AFP (ng/ml)	1.046	0.988–1.108	0.121
Albumin (g/dl)	0.673	0.201–2.248	0.520
Bilirubin (mg/dl)	0.842	0.388–1.829	0.665
PT INR	35.253	0.361–3439.715	0.127
Platelet ( $\times 10^9/L$ )	1.002	0.995–1.009	0.543
Volume Index*	10.942	1.335–89.708	0.021

AFP, alpha-fetoprotein; PT, prothrombin time; CI, confidence interval

**Conclusion:** Liver volume was able to predict future development of hepatic encephalopathy in HBeAg-negative CHB patients.

**PO-408**

**Circulating HBV RNA correlates with intrahepatic covalently closed circular DNA (cccDNA) transcriptional activity in untreated and NUC-treated chronic hepatitis B (CHB) patients**

Email: fabien.zoulim@inserm.fr

**Background and aims:** Quantification of Hepatitis B virus (HBV) RNA in blood circulation (cirB-RNA) across chronic hepatitis B (CHB) phases and during long-term nucleos (t)ide analogues (NUC) treatment and its correlation with intrahepatic viral markers and HBcrAg, the other emerging biomarker of cccDNA transcription, is still lacking.

**Method:** 122 untreated and 30 NUC-treated CHB patients with paired liver biopsy and serum sample, were analyzed for serum HBV DNA, quantitative (q)HBsAg, HBcrAg and alanine aminotransferase (ALT) levels. Liver cccDNA and 3.5Kb RNA were assessed by qPCR and droplet digital PCR (ddPCR) and cccDNA transcriptional activity was calculated as 3.5Kb RNA/cccDNA ratio. Liver histology scores were also available. cirB-RNA was quantified by the Roche HBV RNA investigational assay for use on the cobas® 6800 System (LLOQ 10 cp/ml; linearity range 10 to  $10^7$ cp/ml; LLOD ~3 cp/ml).

**Results:** All untreated HBeAg (+) patients, 74% of HBeAg (-) chronic hepatitis (CH) and 21% of HBeAg (-) chronic infection (CI) patients had detectable cirB-RNA. The 39 cirB-RNA (-) patients (23 HBeAg (-) CI and 16 HBeAg (-) CH) had lower cccDNA (median 0.06 vs 0.3 cp/cell,  $p < 0.0001$ ), 3.5Kb RNA (0.03 vs 10.3,  $p < 0.0001$ ) and 3.5Kb RNA/cccDNA (0.79 vs 8.9,  $p = 0.002$ ) as compared to the cirB-RNA (+) ones. No significant difference was found in qHBsAg levels, while both HBcrAg (median 5.4 vs 2.6 LogU/ml,  $p < 0.0001$ ) and serum HBV DNA (6.2 vs 2.7 LogIU/ml,  $p < 0.0001$ ) were significantly higher in cirB-RNA (+) patients. In HBeAg (-) patients, cirB-RNA significantly correlated with serum HBV DNA ( $R = 0.81$ ,  $p < 0.0001$ ), HBcrAg ( $R = 0.73$ ,  $p < 0.0001$ ), intrahepatic 3.5Kb RNA ( $R = 0.77$ ,  $p < 0.001$ ) and cccDNA

## POSTER PRESENTATIONS

transcriptional activity ( $R = 0.78$ ,  $p < 0.0001$ ), but not with HBsAg and cccDNA levels. A subgroup of cirB-RNA (+) patients with increased cccDNA (0.1 vs 0.03 cp/cell), serum HBV DNA levels (4 vs 2.7 logIU/ml) and fibrosis score was identified among HBeAg (-) HBcrAg (-) patients.

All NUC-treated patients (median treatment duration of 2.6 years) had detectable intrahepatic cccDNA and RNA by ddPCR, albeit at low levels ( $2 \times 10^{-3}$  and  $10 \times 10^{-3}$  cp/cell, respectively). HBcrAg was quantifiable in 77% and cirB-RNA in 40% of patients. cirB-RNA (+) patients showed higher 3.5Kb RNA (0.04 vs 0.002,  $p = 0.009$ ) and cccDNA transcriptional activity (24.1 vs 0.4,  $p = 0.04$ ) levels compared to cirB-RNA (-) ones, but no significant difference in cccDNA amount.

**Conclusion:** Our results support the notion that cirB-RNA detected by Roche HBV RNA investigational assay reflects the transcriptional activity of intrahepatic cccDNA in both untreated and NUC-treated CHB patients.

This work is supported by the French National Research Agency Investissements d'Avenir program (CirB-RNA project-ANR-17-RHUS-0003)

### PO-415 exosomes with mir-574 transfer anti-hbv activity mediated by the interferon from macrophage to hbv-infected hepatocyte

Wenyu Wu<sup>1</sup>, Di Wu<sup>1</sup>, Weiming Yan<sup>1</sup>, Xiaoyang Wan<sup>1</sup>, Dong Xi<sup>1</sup>, Xiaoping Luo<sup>1</sup>, Meifang Han<sup>1</sup>, Qin Ning<sup>1</sup>. <sup>1</sup>Tongji Hospital of Tongji Medical College, Huazhong University of Science and Technology, Department and Institute of Infectious Disease, Wuhan City, Hubei Province, China  
Email: qning@vip.sina.com

**Background and aims:** Interferon alpha (IFN- $\alpha$ ) has proven to be clinically effective in the treatment of chronic hepatitis B (CHB) due to its capability to reduce hepatitis B surface antigen (HBsAg) and hepatitis B virus (HBV) covalently closed circular DNA (cccDNA). However, the underlying mechanisms are not well defined. The purpose of this study is to explore the role of exosomes in the antiviral process of IFN

**Method:** We investigated the anti-HBV activities of exosomes both from pegylated IFN- $\alpha$  (PegIFN- $\alpha$ ) treated patients and the supernatants of IFN- $\alpha$ -treated THP-1 (the human leukemia monocyte cell line) derived macrophages. Then, we identified three upregulated miRNAs in exosomes through miRNA sequencing. By luciferase reporter assay, we found hsa-miR-574-5p reduced pregenomic RNA (pgRNA) and polymerase mRNA levels by binding to the nucleotides 2750–2757 position of HBV genomic sequence.

**Results:** Exosomes from patients and the supernatants exhibited anti-HBV activities including the suppression of supernatant HBsAg, HBeAg, and HBV DNA levels as well as intracellular HBV cccDNA in HBV related cell lines. MicroRNA sequencing revealed that PegIFN- $\alpha$  treatment upregulated exosomal hsa-miR-193a-5p, hsa-miR-25-5p, and hsa-miR-574-5p that could partially inhibit HBV replication and

transcription. The luciferase reporter assay confirmed that hsa-miR-574-5p reduced pgRNA and polymerase mRNA levels by binding to the 2750–2757 position of HBV genomic sequence.

**Conclusion:** Exosomes can transfer IFN- $\alpha$ -related miRNAs from macrophages to HBV-infected hepatocytes, thereby suppressing HBV replication and expression.

### PO-420 A 3-antigen prophylactic hepatitis B virus vaccine confers rapid onset of protection in young adults, age 18–45, compared to a single-antigen hepatitis B virus vaccine

Francisco Diaz-Mitoma<sup>1</sup>, Timo Vesikari<sup>2</sup>, Joanne Langley<sup>3</sup>, Nathalie Machluf<sup>1</sup>, Johanna Spaans<sup>1</sup>, Bebi Yassin-Rajkumar<sup>1</sup>, David Anderson<sup>1</sup>, Vlad Popovic<sup>1</sup>. <sup>1</sup>VBI Vaccines Inc, Massachusetts, United States; <sup>2</sup>Nordic Research Network, Finland; <sup>3</sup>Departments of Pediatrics and Community Health and Epidemiology, Canadian Center for Vaccinology, Canada  
Email: fdiazmitoma@vbivaccines.com

**Background and aims:** Vaccination rates against Hepatitis B Virus (HBV), a leading cause of chronic hepatitis, liver cirrhosis, and hepatocellular carcinoma worldwide, remain low in adults. Adults or children who were not immunized as infants against HBV remain at risk of becoming infected. According to the European Centre for Disease Prevention and Control, 25 to 34-year-olds are the most affected age group for both acute and chronic HBV infections, accounting for 30% of reported cases in 2017 by the 30 EU/EEA Member States. HBV vaccines that are more immunogenic than conventional vaccines, and optimally designed to provide robust and rapid seroprotection, are needed. The overall aim of our clinical trials was to evaluate the speed to seroprotection, immunogenicity, and safety of a 3-antigen (pre-S1/S2/S) prophylactic HBV vaccine in adults less than 45 years of age.

**Method:** Four phase 3 studies assessing kinetics of seroprotection rates (SPR; % of subjects with anti-HBs  $\geq 10$  mIU/ml) in healthy adults aged 18–45 years, vaccinated at months 0, 1 and 6 with 10  $\mu$ g of a 3-antigen HBV vaccine (3A-HBV) vs. 20  $\mu$ g of a single-antigen HBV vaccine, Engerix-B® (1A-HBV), were completed between 2008 and 2020: (1) PROTECT study in Europe, U.S., and Canada, subset age 18–44,  $n = 299$ ; (2) CONSTANT study in Europe, U.S., and Canada,  $n = 2,838$ ; (3) SG-005-05 study in Vietnam,  $n = 379$ ; (4) 38-13-040 study in Russia,  $n = 99$ . Additionally, one phase 4, open-label single-arm study (SciB018) was conducted with 10  $\mu$ g of 3A-HBV in adults aged 20–40 years in Israel,  $n = 91$ .

**Results:** In these 5 studies of healthy, young adults age 18–45 years, vaccination with 3A-HBV achieved a more rapid onset of protection compared to 1A-HBV, with SPRs of 87.2–100.0% (vs. 39.0–89.4%) after 2 doses and 99.2–100.0% (91.1–98.3%) after 3 doses (Figure 1). Rates of mild or moderate injection site pain and tenderness, and myalgia were higher for 3A-HBV than 1A-HBV. No new or unexpected safety signals were observed, and safety and tolerability were consistent with the known profile of study vaccines.

Figure 1: (abstract: PO-420)

**Conclusion:** The 3-antigen prophylactic HBV vaccine rapidly and consistently achieved high rates of seroprotection against hepatitis B in young and healthy adults in multiple clinical studies conducted across different regions of the world.

**PO-460**

**Persistent High HBsAg Levels Predict Lower Risk of Hepatocellular Carcinoma in HBeAg-seropositive Chronic Hepatitis B Patients**

Hsin-Che Lin<sup>1,2</sup>, Rachel Wen-Juei Jeng<sup>3,4</sup>, Jessica Liu<sup>1</sup>, Mei-Hsuan Lee<sup>5</sup>, Richard Batrla-Utermann<sup>6</sup>, Sheng-Nan Lu<sup>7</sup>, Li-Yu Wang<sup>8</sup>, San-Lin You<sup>9</sup>, Chien-Jen Chen<sup>1</sup>, Hwai-I Yang<sup>1</sup>. <sup>1</sup>Academia Sinica, Genomics Research Center, Taipei, Taiwan; <sup>2</sup>Linkou Chang Gung Memorial Hospital, Taoyuan, Taiwan; <sup>3</sup>Linkou Chang Gung Memorial Hospital, Department of Gastroenterology and Hepatology, Taoyuan, Taiwan; <sup>4</sup>Chang Gung University, College of Medicine, Taiwan; <sup>5</sup>National Yang-Ming University, Institute of Clinical Medicine, Taiwan; <sup>6</sup>Roche, Bau 663, Diagnostics, Basel, Switzerland; <sup>7</sup>Kaohsiung Chang Gung Memorial Hospital, Kaohsiung, Taiwan; <sup>8</sup>Mackay Medical College, Taiwan; <sup>9</sup>Fu Jen Catholic University, Department of Public Health, College of Medicine, Taiwan

**Background and aims:** The longitudinal changes of HBsAg level (qHBsAg) and the application in HBeAg positive patients for prediction of hepatocellular carcinoma (HCC) development remain to be studied. Our study aimed to investigate the association between qHBsAg trajectory and risk of HCC in HBeAg positive chronic hepatitis B (CHB) patients.

**Method:** HBeAg positive CHB patients from the REVEAL-HBV cohort (N = 524) who had 2 or more qHBsAg measurements before HBeAg clearance were included. Group-based trajectory modeling (GBTM) was used to identify distinctive groups of longitudinal qHBsAg up to 11-years of follow-up. Serum qHBsAg was measured using Roche Elecsys HBsAg II quant assay (range, 0.05–52,000 IU/ml; Roche Diagnostics, Mannheim, Germany). Development of HCC was ascertained by follow-up examinations and computerized data linkage with National Cancer Registry and National Death Certification profiles. Multivariate adjusted hazard ratios (HRs) and 95% confidence intervals (CIs) were estimated using Cox regression models. Statistic procedures were performed with SAS 9.4. A P value less than .05 was considered statistically significant.

**Results:** A total of 319 HBeAg positive patients who remained HBeAg positive throughout the follow-up duration were included and 9 groups were classified through GBTM. Four groups with less than 5 patients were excluded for further analysis. Remaining groups were then divided into (A) Persistently high group: HBsAg levels persistently >10<sup>4</sup> IU/ml without decline (n = 72), (B) Declining group: low HBsAg levels at baseline or HBsAg level declining to <10<sup>4</sup> IU/ml during observation period (n = 233). Age at baseline, sex and observation duration showed no difference between these two groups, while percentage of abnormal ALT level, genotype C and basal core mutation were significantly higher in declining group (p < 0.05). The annual incidence of HCC in persistently high HBsAg group and declining HBsAg group were 0.37% and 1.16%, respectively (p = 0.03). Univariate analysis showed baseline age over 40, abnormal ALT level and declining HBsAg group were associated with higher risk of subsequent development of HCC. In the multivariate analysis, age over 40 [HR: 4.4 (2.5–7.9), p = <.001], abnormal ALT level [HR: 2.7 (1.4–5.1), p = <.001] and declining HBsAg group [HR: 2.6 (1.1–6.1), p = 0.03] were confirmed to be independent predictors of following development of HCC.

Figure:

Univariate/Multivariate Analysis of HCC Risk in HBeAg-Positive Patients						
	Univariate Analysis			Multivariate Analysis		
	HR	CI	P value	HR	CI	P value
Age						
≥40	4.48	2.51–7.99	<.001	4.43	2.48–7.90	<.001
<40						
ALT						
Abnormal	2.95	1.65–5.26	<.001	2.73	1.44–5.15	<.001
Normal						
HBsAg						
Persistent high						
Declining group	3.31	1.43–7.68	<.001	2.60	1.11–6.09	0.03

**Conclusion:** A group of HBeAg positive patients with lower HCC risk could be identified by their persistently high HBsAg levels through repeated monitoring.

**PO-529**

**Clinical importance of a new, high-sensitivity HBcrAg assay for monitoring chronic hepatitis B and HBV reactivation**

Takako Inoue<sup>1</sup>, Shigeru Kusumoto<sup>2</sup>, Etsuko Iio<sup>3</sup>, Shintaro Ogawa<sup>3</sup>, Takanori Suzuki<sup>4</sup>, Shintaro Yagi<sup>5</sup>, Atsushi Kaneko<sup>6</sup>, Kentaro Matsuura<sup>4</sup>, Katsumi Aoyagi<sup>6</sup>, Yasuhito Tanaka<sup>7</sup>. <sup>1</sup>Nagoya City University Hospital, Department of Clinical Laboratory Medicine, Japan; <sup>2</sup>Nagoya City University Graduate School of Medical Sciences, Department of Hematology and Oncology, Japan; <sup>3</sup>Nagoya City University Graduate School of Medical Sciences, Department of Virology and Liver Unit, Japan; <sup>4</sup>Nagoya City University Graduate School of Medical Sciences, Department of Gastroenterology and Metabolism, Japan; <sup>5</sup>Advanced Life Science Institute, Inc., Research and Development Department, Japan; <sup>6</sup>Fujirebio Inc., Research and Development Division, Japan; <sup>7</sup>Kumamoto University, Department of Gastroenterology and Hepatology, Faculty of Life Sciences, Japan  
Email: tinoue@fg8.so-net.ne.jp

**Background and aims:** Hepatitis B core-related antigen (HBcrAg) is one of the useful biomarkers that have an important role in chronic hepatitis B (CHB). A fully automated high-sensitive chemiluminescent enzyme immunoassay for detection of HBcrAg has been newly developing in Japan. Our aims of this study are to demonstrate the clinical utility of new HBcrAg assay for monitoring CHB and early detection of hepatitis B virus (HBV) reactivation.

**Method:** A new high-sensitive HBcrAg assay (iTACT-HBcrAg, Fujirebio, Inc., Figure) is more inexpensive than HBV DNA test, and can measure HBcrAg within 30 minutes. The sensitivity of iTACT-HBcrAg (2.1 Log IU/ml) is approximately 10-fold higher than that of a conventional HBcrAg assay (G-HBcrAg) (2.8 Log IU/ml). The fundamental assessment of iTACT-HBcrAg was satisfactory. The clinical performance of iTACT-HBcrAg was compared with other HBV markers. 1) Of our CHB patients, serial sera, available from 161 HBeAg-negative CHB patients with persistently undetectable HBV DNA, were measured by iTACT-HBcrAg and G-HBcrAg. 2) Serial sera from 13 HBV-reactivated patients were measured by iTACT-HBcrAg and ultra-high-sensitivity hepatitis B surface antigen (HBsAg) immune complex transfer-chemiluminescent enzyme immunoassay (lower limit of detection; 0.0005 IU/ml, ICT-CLEIA) for comparison with HBV DNA detection. The study protocol was approved by the appropriate institutional ethics review committees.

**Results:** 1) At the last visit where HBV DNA was undetectable in 161 NA-treated patients, HBcrAg was detectable by G-HBcrAg in the sera of 75.2% (121/161) patients and detectable by iTACT-HBcrAg in the sera of 97.5% (157/161) patients; that is, 75.2% (121/161) patients had ≥2.8 Log U/ml and were detectable by G-HBcrAg, and 22.4% (36/161) patients had 2.1–2.8 Log U/ml, which were undetectable by G-HBcrAg.

## POSTER PRESENTATIONS

Figure: (abstract: PO-529)

2) In our HBV-reactivated patients, the primary diseases were hematologic malignancies (10 patients), benign hematologic disease, autoimmune disease and solid cancer (1 patient each). Nine and 2 of 13 HBV-reactivated patients were HBcrAg-positive by iTACT-HBcrAg before and at HBV DNA positivity, respectively. Seven and 4 were HBcrAg-positive by iTACT-HBcrAg before and at being HBsAg-positive by ICT-CLEIA, respectively.

**Conclusion:** iTACT-HBcrAg should be of increased benefit for monitoring anti-HBV treatments for HBeAg-negative patients and HBV reactivation at early phase.

### PO-665

#### Transcriptomic analyses reveal variation of liver inflammation across phases of chronic hepatitis B infection

Ricardo Ramirez<sup>1</sup>, Noe Montanari<sup>2</sup>, Nicholas Van Buuren<sup>1</sup>, Michael Doukas<sup>2</sup>, Abhishek Aggarwal<sup>1</sup>, Christina Moon<sup>1</sup>, Scott Turner<sup>1</sup>, Lauri Diehl<sup>1</sup>, Li Li<sup>1</sup>, Andre Boonstra<sup>2</sup>, Becket Feierbach<sup>1</sup>.  
<sup>1</sup>Gilead Sciences, Inc., Foster City, United States; <sup>2</sup>Erasmus MC, Rotterdam, Netherlands  
 Email: ricardo.ramirez@gilead.com

**Background and aims:** Chronic Hepatitis B (CHB) disease stages are based on serum measurements of HBeAg, viral load, and ALT. With the potential use of immune modulators for HBV cure, understanding the landscape of liver inflammation across CHB disease phases may help identify key patient populations. Though ALT is a useful marker of liver damage, it is an indirect measurement of liver inflammation. To delineate the patterns of inflammation found in CHB patients, we present a transcriptomic analysis of HBV infected liver biopsies

representing the four stages of natural history as well as comorbidities: fibrosis, non-alcoholic steatohepatitis (NASH), and Hepatitis D Virus (HDV) infection.

**Method:** RNA-Seq was performed on 103 FFPE core needle liver biopsies from 94 CHB patients and 9 healthy liver donors for cell type deconvolution and gene set analyses by EPIC and GSVA, respectively. The HBV biopsy set includes 15 immune tolerant (IT), 16 immune active (IA), 23 inactive carrier (IC), 17 HBeAg negative (ENEG), 5 fibrotic, 10 NASH, and 8 HDV samples. IT and healthy samples were re-sequenced using a novel whole exome plus HBV targeted sequencing assay. In addition, we imaged 39 corresponding biopsies using a custom 12-plex immunofluorescent assay (Ultivue InSituPlex).

**Results:** Although Healthy and IT liver transcriptomes clustered together, cell deconvolution found a significant increase in B-cell and T-cell estimates within the IT. IA, IC, and ENEG cohorts all showed an additional increase in B-cell, T-cell, and monocyte gene markers as compared to the IT group. IFN, TNF and IL-6 signaling pathways were significantly upregulated in chronic hepatitis (IA, ENEG) but not in chronic infection (IT, IC) samples. There was no significant correlation between liver HBV mRNA and immune cell estimates. HBV/HDV samples had the highest activity of the cytokine signaling pathways and immune cell content.

**Conclusion:** Our dataset represents the most comprehensive view of CHB, with samples from healthy livers, all phases of HBV chronic infection, and HBV combined with additional liver disease. All phases tend to have higher inflammation than healthy livers. Though characterized by low ALT levels, biopsies from IT and IC patients present gene signatures indicative of immune cell infiltration. HDV/

Figure: (abstract: PO-665)

HBV co-infection results in significant inflammatory disease, potentially exceeding inflammation caused by HBV infection combined with fibrosis or steatosis.

**PO-676**

**An episode of detectable serum hepatitis B virus-DNA level does not affect risk of hepatic decompensation among untreated compensated cirrhosis patient with viral load of <2, 000 IU/ml**

Hye Won Lee<sup>1</sup>, Soo Young Park<sup>2</sup>, Yu Rim Lee<sup>2</sup>, Jae Seung Lee<sup>1</sup>, Seung Up Kim<sup>1</sup>, Jun Yong Park<sup>1</sup>, Do Young Kim<sup>1</sup>, Sang Hoon Ahn<sup>1</sup>, Beom Kyung Kim<sup>1</sup>. <sup>1</sup>Yonsei University College of Medicine, Department of Internal Medicine, Seoul, Korea, Rep. of South; <sup>2</sup>Kyungpook National University, Department of Internal Medicine, Daegu, Korea, Rep. of South  
Email: beomkkim@yuhs.ac

**Background and aims:** Whether antiviral therapy (AVT) is necessary for hepatitis B virus (HBV)-infected compensated cirrhosis patients with low-level viremia (LLV) is still controversial. Herein, we evaluated their natural history.

**Method:** From three academic teaching hospitals, we enrolled untreated compensated cirrhosis patients having persistently serum HBV-DNA <2, 000 IU/ml; LLV group was defined as patients having detectable serum HBV-DNA (20~2, 000 IU/ml) episode at least one time, whereas maintained virological response (MVR) group as remaining patients having persistently undetectable serum HBV-DNA (<20 IU/ml) during the whole follow-up. In case of serum HBV-DNA ≥2, 000 IU/ml, AVT was commenced. The study end point was development of cirrhotic complication event (CCE) such as ascites, spontaneous bacterial peritonitis, hepato-renal syndrome, variceal hemorrhage, hepatic encephalopathy, deterioration of liver function into Child-Pugh class B, and liver transplantation.

**Results:** Among 567 patients finally analyzed, all belonged to Child-Pugh class A. Cumulative CCE risks at 1, 3, 5, and 7 years were also comparable between LLV (n = 391) and MVR (n = 176) groups; 2.2%, 7.5%, 12.8%, and 13.7% vs. 2.4%, 7.8%, 12, 3%, and 14.6%, respectively (p = 0.880). After adjusting for other key variables, LLV (vs. MVR) group was not associated with CCE risk with adjusted hazard ratio (HR) of 1.290 (95% confidence interval [CI] 0.712~2.338; p = 0.402). Through

inverse probability of treatment weighting analysis, similar outcome was also re-produced with p = 0.767; those of LLV vs. MVR groups at 1, 3, 5, and 7 years were 3.2%, 8.1%, 10.9%, and 10.9% vs. 3.1%, 7.2%, 12.8%, and 13.9%, respectively (HR 1.097, 95% CI 0.534~2.254; p = 0.801).

**Conclusion:** An instantaneous LLV episode among untreated patients with compensated cirrhosis does not increase the risk of hepatic decompensation, compared to MVR status. Thus, the benefit from prompt AVT for such a LLV group should be re-evaluated.

**Key words:** Compensated cirrhosis, hepatitis B virus, low-level viremia, decompensation, antiviral therapy

**PO-813**

**Prognosis of severe HBV reactivation in Western countries: role of the MELD score**

Edoardo Poli<sup>1</sup>, Isaac Ruiz<sup>2</sup>, Lucy Meunier<sup>3</sup>, Jérôme Dumortier<sup>4</sup>, Lucia Parlati<sup>5</sup>, Paul Carrier<sup>6</sup>, Nicolas Carbonell<sup>7</sup>, Benjamin Buchard<sup>8</sup>, Carmen Vinaixa<sup>9</sup>, Ilias Kounis<sup>1</sup>, Lea Duhaut<sup>1</sup>, Rodolphe Sobesky<sup>1</sup>, Eleonora De Martin<sup>1</sup>, Bruno Roche<sup>1</sup>, Philippe Ichai<sup>10</sup>, Anne Marie Roque-Afonso<sup>11</sup>, Didier Samuel<sup>1</sup>, Audrey Coilly<sup>1</sup>. <sup>1</sup>Centre Hépatobiliaire, Paul Brousse Hospital, Hepatology, Villejuif, France; <sup>2</sup>Centre Hospitalier de l'Université de Montréal, Hepatology and Liver Transplantation, Montréal, Canada; <sup>3</sup>CHU Montpellier-Hôpital Saint Eloi, Pôle Digestif, Montpellier, France; <sup>4</sup>Hospices Civils de Lyon, Hepatology, Lyon, France; <sup>5</sup>Hôpital Cochin, Hepatology, Paris, France; <sup>6</sup>CHU Dupuytren, Hepatology and Gastroenterology, Limoges, France; <sup>7</sup>Hôpital Saint Antoine, Hepatology and Gastroenterology, Paris, France; <sup>8</sup>CHU Estaing, Hepatology and Gastroenterology, Clermont-Ferrand, France; <sup>9</sup>Hospital Universitari i Politècnic la Fe, Hepatology and Gastroenterology, Valencia, Spain; <sup>10</sup>Centre Hépatobiliaire, Paul Brousse Hospital, Intensive Care Unit, Villejuif, France; <sup>11</sup>Centre Hépatobiliaire, Paul Brousse Hospital, Virology, Villejuif, France  
Email: edoardo.poli88@gmail.com

**Background and aims:** Severe reactivation of hepatitis B virus (HBV) can lead to death or liver transplantation. While trigger events are quite well understood, prognostic factors for short-term liver transplant (LT) -free survival in these patients, particularly in Western countries, are poorly known. MELD score has been

## POSTER PRESENTATIONS

demonstrated to be an interesting prognostic score in an Asian cohort, but a “grey zone” of patients with MELD between 28 and 32 still represent a challenge for the indication and the timing of an urgent LT (Fung J. Hepatology 2020).

**Method:** All patients hospitalized for HBV reactivation with a viral load  $\geq 4$  log IU/ml between January 2014 and April 2020 were included in this retrospective multicenter study. Patients with other causes of ACLF were excluded. The primary outcome was to determine factors associated with 12-week risk of death or need for LT.

**Results:** Sixty-one patients have been included in our study, 47 (77%) males with a median age of 51 years (IQR 40–62), 15 (25%) presenting an extensive hepatic fibrosis ( $\geq F3$ ) at liver biopsy. Trigger events for HBV reactivation have been identified in 41 (67%) patients. During hospitalization, 17 (28%) patients developed hepatic encephalopathy and 20 (33%) have been transferred to an ICU. On admission, mean HBV serum viral load was 6.94 log IU/ml (IQR 5.85–7.96). All patients have been treated with tenofovir (72%) or entecavir (28%). Median follow-up was of 847 days (IQR 305–1440) and overall LT-free survival was of 46%. The 12-week LT-free survival was of 62%, 8 patients died and 15 were transplanted because of hepatic failure within 12 weeks.

Univariate analysis is shown in table 1. At multivariate analysis, MELD score of admission was associated with a higher risk of death or need of LT within 12 weeks (HR 1.13, CI 1.07–1.20;  $p < 0.001$ ).

The AUC of MELD score to predict 12-week mortality or need for LT was 0.757. Mortality or need for LT at 12 weeks was low (<20%) for MELD  $\leq 20$  and high (>70%) for MELD  $\geq 25$ , with a “grey zone” for patients having a MELD = 20–25.

Table:

	Overall cohort n = 61	Transplanted or dead within 12 weeks n = 23	Survivors at 12 weeks without LT n = 38	p
Gender, males	47 (77)	19 (83)	28 (74)	0.420
Age, years	51 (40–62)	57 (50–64)	46 (36–59)	0.054
MELD score	20.1 (16.0– 25.6)	25.6 (20.3– 31.0)	17.3 (14.0– 23.0)	<0.001
ALT, IU/L	1057 (393– 2563)	607 (298– 1352)	1260 (807– 2718)	0.068
Admission HBV DNA, log IU/ml	6.94 (5.85– 7.96)	7.51 (5.87– 8.15)	6.69 (5.69– 7.64)	0.250
Intensive care unit HE during hospitalization	20 (33)	16 (70)	4 (11)	<0.001
Ascites during hospitalization	17 (28)	16 (70)	1 (3)	<0.001
	14 (23)	10 (43)	4 (11)	0.003

**Conclusion:** Our study confirm that admission MELD score can predict the short-term mortality and need for LT in patients with severe HBV reactivation, with lower thresholds in Western countries compared to an Asian cohort. Patients with MELD  $\geq 25$  should be evaluated for LT.

### PO-915

#### METABOLIC dysfunction associated FATTY LIVER disease and adverse clinical outcomes in patients with CHRONIC HEPATITIS B

Laurens van Kleef<sup>1</sup>, Hannah S.J. Choi<sup>2</sup>, Willem Pieter Brouwer<sup>1</sup>, Bettina Hansen<sup>2</sup>, Keyur Patel<sup>2</sup>, Robert De Man<sup>1</sup>, Harry Janssen<sup>2</sup>, Robert De Knecht<sup>1</sup>, Milan Sonneveld<sup>1</sup>. <sup>1</sup>Erasmus MC, University Medical Center, Gastroenterology and Hepatology, Rotterdam, Netherlands;

<sup>2</sup>Toronto General Hospital, University Health Network, Toronto Center for Liver Disease, Toronto, Canada

Email: laurensvankeef@gmail.com

**Background and aims:** A recent consensus document has defined metabolic dysfunction associated fatty liver disease (MAFLD) as hepatic steatosis together with overweight, diabetes and/or a

combination of other metabolic risk factors. The prevalence and clinical relevance of this novel diagnosis is unknown among patients with chronic hepatitis B (CHB). We therefore studied the association between presence of MAFLD (with or without steatohepatitis) and adverse clinical outcomes in patients with CHB.

**Method:** We performed a retrospective, long term follow-up cohort study at two tertiary hospitals. All consecutive patients with CHB who underwent liver biopsy were enrolled. Biopsies were reassessed for the presence of steatosis, degree of fibrosis and presence of steatohepatitis (based on NAFLD activity score  $\geq 3$  and/or histopathologist interpretation). Patients were classified as no fatty liver disease, fatty liver disease without metabolic dysfunction, and MAFLD with or without steatohepatitis and associations with event-free hepatocellular carcinoma (HCC)-free and transplant-free survival were explored.

**Results:** We analyzed 1076 CHB patients of whom 296 (27.5%) had MAFLD. Median follow-up was 9.8 years (IQR: 6.6–14.0) and 107 events occurred in 78 patients, comprising death (n = 43), HCC (n = 36), liver decompensation (n = 21) and liver transplantation (n = 7). Patients with superimposed MAFLD had reduced event free ( $p < 0.001$ , figure), HCC free ( $p < 0.001$ ) and transplant free survival ( $p < 0.001$ ), and findings were consistent in multivariate analysis after adjusting for age, gender, HBeAg status, advanced fibrosis at enrolment and antiviral treatment. Among patients with MAFLD, presence of steatohepatitis did not increase the risk of adverse outcomes ( $p = 0.21$ –0.95). Among patients without MAFLD, presence of fatty liver disease was not associated with reduced event free survival when compared to patients without fatty liver disease ( $p = 0.56$ ).

Figure 1. Association of MAFLD with event-free survival (Kaplan-Meier).

**Conclusion:** In this multicenter study, presence of MAFLD in CHB patients was associated with an increased risk for liver related clinical events and death. Concomitant presence of steatohepatitis did not increase the risk of adverse outcomes. Our findings highlight the importance of metabolic health in patients with CHB and suggest that the prognostic value of a liver biopsy to assess presence of steatohepatitis among patients with MAFLD may need to be reassessed.

### PO-947

#### Immunogenetic diversity predicts viral control in chronic HBV (CHB) patients after discontinuation of direct antiviral treatment

Email: mtueffe1@its.jnj.com

**Background and aims:** Importance of specific human leukocyte antigen (HLA) genotypes as risk factor for many disease-related traits has been well investigated. Recently, it was shown that higher HLA genetic diversity may positively influence cancer immunotherapy efficacy and HIV-1 control. Here we studied whether the genetic build-up of the HLA region in chronic hepatitis B patients (CHB) may predict viral control after discontinuation of direct antiviral treatment.

**Method:** A multi-center, prospective study enrolled 186 CHB patients in their last year treatment regimen with direct antivirals that were followed for up to 2 years after treatment discontinuation. Virological relapse (VR) was defined as HBV DNA  $\geq$ 2000 IU/ml. Clinical relapse (CR) was defined as VR with serum ALT  $\geq$ 80 IU/L. Sustained clinical response (SCR) was defined as absence of VR during the entire follow-up period. DNA samples were collected for HLA-typing. Beside allelic association, HLA evolutionary divergence (HED) score (Pierini et al., MBE, 2018), considering the influence of allele diversity on amino-acid composition, was derived.

**Results:** Of the cohort, 161 patients experienced VR of whom 110 also had a CR. Six patients experienced hepatic flare without VR, and 23 were considered as SCR. Allelic association revealed HLA-B\*51, HLA-C\*07 and HLA-C\*15 alleles as predictive for onset of VR and SCR. No specific allele was associated with onset of CR. High HED score in both class I and class II regions were protective against early onset of VR and CR and predictive for SCR. Performance of the regression models was improved when adding immunogenetic composite markers to established clinical covariates. For instance, odds ratios for contributors in a signature for SCR varied from 10.66 [3.01–44.42] (low HBsAg at treatment end) to 2.34 [0.36–14.12] (HLA-B\*51 alleles), 7.68 [1.29–46.66] (HLA-C\*15 alleles), 5.38 [1.51–21.62] (high HED score class I) and to 11.49 [3.08–57.35] (high HED score class II). The Receiver Operating Characteristic (ROC) curve AUC increased from 0.66 to 0.79 to predict onset of VR, from 0.67 to 0.70 to predict onset of CR, and from 0.67 to 0.89 to predict SCR.

**Conclusion:** The study shows the importance for the first time of HLA class I and the significance of high HLA evolutionary diversity for long term viral control in CHB patients. Host immunogenetic markers can be measured easily in clinic and are major contributors in predicting patient outcome when cessation of direct antiviral treatment is considered.

**PO-1000**

**Association of Vitamin D receptor's CdX-2 polymorphism and related haplotypes in patients with chronic hepatitis B infection in the inactive carrier and chronic hepatitis phases: a case-control study**

Prooksa Ananchuensook<sup>1</sup>, Sirinporn Suksawatamnuay<sup>2</sup>, Panarat Thaimai<sup>2</sup>, Supachaya Sriphoosanaphan<sup>1,2</sup>, Kessarinn Thanapirom<sup>1,2</sup>, Piyawat Komolmit<sup>1,2</sup>. <sup>1</sup>Chulalongkorn University, Thailand; <sup>2</sup>King Chulalongkorn Memorial Hospital, Thailand  
Email: prooksa.anan@gmail.com

**Background and aims:** Vitamin D receptor (VDR) partly regulates host immune system. The association between VDR polymorphisms and severe flare-up hepatitis, cirrhosis and hepatoma in patients with chronic HBV infection were reported in previous studies. Patients with HBV inactive carrier (IC) and chronic hepatitis (CH) phases shows different disease's natural history and risk of complications. We hypothesize that VDR polymorphisms initially influence the host immune status which represented two different phases and consequently leading to HBV-related events.

**Method:** Patients with chronic HBV infection were enrolled from February to August 2020. The IC phase was defined as HBV viral load (VL) <2,000 IU/ml twice for six months apart, without a previous history of HBV treatment. The CH phase was defined as persistent HBV VL >2,000 IU/ml with evidence of hepatic inflammation or fibrosis. Six common VDR genes' single nucleotide polymorphisms (SNP) including *CdX-2*, *GATA*, *FokI*, *BsmI*, *Apal*, and *TaqI*, were studied using TaqMan real-time PCR assay. The difference in allele, genotype, and haplotype frequencies in between groups and linkage disequilibrium (LD) mapping were analyzed using a haplotype inference application.

**Results:** Among 324 enrolled patients, there were 163 and 161 patients in IC and CH respectively. The proportion of male patients is lower in IC (46.0% vs. 68.3%,  $p < 0.001$ ). The mean vitamin D levels were not statistically different between groups. The proportion of alleles frequency of *CdX-2* in IC and CH was 53.7% and 62.7% for G allele and 46.3% and 37.3% for A allele which was statistically significant ( $p = 0.019$ ). The proportion of GG genotype of *CdX-2* was less frequently found in IC compared to CH (27% vs 41%,  $p = 0.028$ ). AA haplotype (*CdX-2/GATA*) and AAC haplotype (*CdX-2/GATA/FokI*) were significantly associated with IC with odd ratio (OR) 1.43,  $p = 0.025$  and 1.98,  $p < 0.001$  respectively. By multivariate analysis, *CdX-2* G/A genotypes was independently associated with IC, with adjusted OR 1.83,  $p = 0.019$ . The SNPs' LD mapping revealed high LD scores of *CdX-2/GATA* and *GATA/FokI* only in CH group.

Figure: Univariate and multivariate analysis of factors associated with HBV inactive carrier (IC) phase.

	Univariate analysis		Multivariate analysis	
	OR (95%CI)	p value	OR (95%CI)	p value
Age	0.99 (0.96–1.02)	0.806		
Gender (male)	0.39 (0.25–0.62)	<0.001*	0.40 (0.25–0.63)	<0.001*
<i>CdX-2</i> genotype				
G/G	–	0.029*	–	0.045*
G/A	1.84 (1.12–3.02)	0.016*	1.83 (1.10–3.04)	0.019*
A/A	1.98 (1.03–3.77)	0.038*	1.85 (0.95–3.58)	0.068
Vitamin D level	1.00 (0.98–1.02)	0.608		

\*Significant p value

**Conclusion:** The results suggest that *CdX-2* G/A genotypes was independently associated with IC status in Thai patients with chronic HBV infection. The difference in LD of the *CdX-2/GATA* and *GATA/FokI* haplotypes in between groups might represent a non-random selection in either group resulting in the variation of immune control.

## POSTER PRESENTATIONS

PO-1115

### Clinical aspect of coronavirus disease 2019 (COVID-19) on HBV infected patients in term of Health Insurance Review and Assessment service data

Young Kul Jung<sup>1</sup>, Gi Hyen Seo<sup>2</sup>, Tae Hyung Kim<sup>1</sup>, Sun Young Yim<sup>3</sup>, Young-Sun Lee<sup>4</sup>, Ji Hoon Kim<sup>4</sup>, Yeon Seok Seo<sup>3</sup>, Hyung Joon Yim<sup>1</sup>, Jong Eun Yeon<sup>4</sup>, Kwan Soo Byun<sup>4</sup>, Soon Ho Um<sup>3</sup>. <sup>1</sup>Korea University Ansan Hospital, Internal Medicine, Ansan-si, Korea, Rep. of South; <sup>2</sup>Health Insurance Review and Assessment Service, Korea, Rep. of South; <sup>3</sup>Korea University Anam Hospital, Korea, Rep. of South; <sup>4</sup>Korea University Guro Hospital, Korea, Rep. of South  
Email: 93cool@hanmail.net

**Background and aims:** Several reports announced chronic liver diseases and cirrhosis are risk factors for COVID (coronavirus disease)-19 infection and poor outcomes. However, there is no large data to report the specific clinical course of COVID-19 patients with chronic hepatitis B virus (HBV) infection. In this study, we aimed to report the clinical course of COVID-19 patients with HBV infection, to provide a reference for clinical treatment of the patients, and also to know whether the use of antiviral agents affects the clinical course. **Method:** We performed a nationwide population-based cohort study using the Korean Health Insurance Review and Assessment database. Claim records were screened for 19, 160 individuals who were diagnosed by the test of COVID-19 until November 2020.

**Results:** Of the 19, 160 patients diagnosed with COVID-19, 675 (3.5%) patients had HBV infection. Among them, 138 (20.4%) patients were receiving antiviral therapy for the purpose of treating hepatitis B. The Mean age was 52.6 years for COVID-19 infection patients and 59.3 years for HBV infected patients; the HBV infected patients were elderly and showed higher rates of concomitant diseases such as diabetes, hypertension, and lung diseases compared with non-HBV infected patients ( $p < 0.001$ ). During the observation period (about 10 months), 1, 524 (8.2%) of overall COVID-19 patients died and 91 HBV-infected patients (13.5%) died of COVID-19 disease ( $p < 0.001$ ). For 675 HBV-infected patients, the mean hospital stay was 19.9 days; of whom 85 patients (12.6%) were admitted to the intensive care unit, 13 patients (1.9%) had liver failure, 54 patients (8%) had acute respiratory failure, and 34 (5%) patients showed acute renal failure. When the overall risk of mortality was assessed for HBV-infected patients with antiviral drugs and without the antiviral drug, the Crude odds ratio (OR) was 1.72 (95% confidence interval (CI), 1.39–2.11),  $P < 0.001$  and 1.96 (95%CI, 1.30–2.87;  $p = 0.001$ ), respectively; which showed that the HBV-infected patients with or without the antiviral treatment had a higher risk of death when exposed to COVID-19. However, after age, sex, and comorbid diseases were corrected, the adjusted OR was 0.97 (95% CI, 0.76–1.23;  $p = 0.823$ ) and 1.01 (95% CI, 0.63–1.59;  $p = 0.952$ ), respectively, and these indicated no difference in mortality risk compared to other patients. In addition, there was no difference in intensive care unit admission rate or hospital stay length after correction.

Figure:

**Conclusion:** In COVID-19 infected patients with chronic liver diseases or cirrhosis caused by HBV infection, they showed a slightly higher mortality rate than those without the diseases. However, In the case of patients treated with the antiviral agent for HBV infection, it can be seen that their mortality rate from COVID-19 does not increase further if there is no cirrhosis or other comorbidity.

PO-1257

### Combination drug interactions of hepatitis B virus (HBV) small interfering RNA (siRNA) and antisense oligonucleotides (ASO) in vitro and in vivo

Hua Tan<sup>1</sup>, Kang Hyunsoon<sup>1</sup>, Yuchun Nie<sup>1</sup>, Rajendra Pandey<sup>2</sup>, John Cortez<sup>2</sup>, Vivek Rajwanshi<sup>2</sup>, David Smith<sup>2</sup>, Lawrence Blatt<sup>2</sup>, Leonid Beigelman<sup>2</sup>, Julian Symons<sup>2</sup>, Jin Hong<sup>2</sup>. <sup>1</sup>Aligos Therapeutics, Virology, South San Francisco, United States; <sup>2</sup>Aligos Therapeutics, South San Francisco, United States  
Email: htan@aligos.com

**Background and aims:** Clinical studies have shown that siRNA's and ASO's targeting HBsAg knockdown are attractive therapeutic options for the treatment of chronic hepatitis B (CHB). We explored the combinations of an siRNA, ALG-125903 (unconjugated form of ALG-125755) and an ASO, ALG-020579 (unconjugated form of ALG-020572) in vitro in dual combinations with each other as well as with other anti-HBV agents such as nucleoside analogs (NA) and Capsid Assembly Modulators (CAM). We also explored the benefits of combining HBV siRNA (GalNac conjugated ALG-125755) and ASO (GalNac conjugated ALG-020572) constructs in the AAV-HBV model to maximize HBsAg reduction by utilizing their non-overlapping cellular pathways.

**Method:** In vitro combination studies were performed using the HepG2.2.15 cell line. ALG-125903 and ALG-020579 were transfected using RNAiMAX into cells in a checkerboard fashion and HBsAg in the supernatant was measured by ELISA (enzyme-linked immunosorbent assay) 4 days post transfection. ALG-125903 or ALG-020579 combinations with CAM and NA were tested similarly with secreted HBV DNA as the end point. Data were analyzed with MacSynergy II software. In vivo, ALG-125755 and ALG-020572 were administered subcutaneously (SC) in AAV-HBV mice as single agents as well as in combination. In the combination group, ALG-125755 was dosed as a single dose of 5 mg/kg on day 0 and ALG-020572 as repeat doses of 5 mg/kg on days 0, 7 and 14. Serial blood collections occurred every 5 days until day 60 for HBsAg ELISA and ALT assays.

**Results:** Combination of ALG-125903 and ALG-020579 in vitro exhibited minor synergy with a synergy volume of 46.01 mM<sup>2</sup>%. Combination of ALG-125755 and ALG-020572 in vivo demonstrated additive effects in HBsAg knockdown without change in serum ALT levels in mice. When tested in pairwise combinations with NA and CAM in vitro, HBV siRNA ALG-125903 or ASO ALG-020579 demonstrated significant synergy (synergy volume of >100 mM<sup>2</sup>%), synergy (25–100 mM<sup>2</sup>%) or additivity (0–25 mM<sup>2</sup>%), respectively. No antagonistic effects were observed.

**Conclusion:** The HBV siRNA, ALG-125755, in combination with the ASO, ALG-020572, demonstrated additive to minor synergy in vitro and in vivo. Further investigation of the strategy to combine HBV siRNA and ASO compounds in CHB clinical trials is warranted.

PO-1309

### Alanine aminotransferase flares and seroclearance in chronic hepatitis B virus patients

Shahed Iqbal<sup>1</sup>, Yuqing Zhang<sup>2</sup>, Ruidong Li<sup>3</sup>, Vlad Malkov<sup>2</sup>, Vithika Suri<sup>4</sup>, John Flaherty<sup>4</sup>, Anuj Gaggar<sup>4</sup>, Jeffrey Wallin<sup>1</sup>. <sup>1</sup>Gilead Sciences, Inc., Biomarker Sciences, FOSTER CITY, United States; <sup>2</sup>Gilead Sciences, Inc., Clinical Data Science, FOSTER CITY, United States; <sup>3</sup>Gilead Sciences, Inc., Research Bioinformatics, FOSTER CITY, United States; <sup>4</sup>Gilead Sciences, Inc., Clinical Research, FOSTER CITY, United States  
Email: shahed.iqbal1@gilead.com

**Background and aims:** Steep increase in alanine aminotransferase (ALT flares) levels in chronic hepatitis B (CHB) patients have been found to be associated with declines in hepatitis B surface antigen (HBsAg) levels and seroclearance (SC). ALT flares can be a marker of immune response to therapy as well as a prognostic marker for CHB. **Method:** Adult ( $\geq 18$  years) CHB patients were identified from the IQVIA Ambulatory EMR database using International Classification of

Disease (ICD)(ICD 9: 070.22–23, 070.32–33 or ICD 10: B18.0, B18.1) or SNOMED (61977001) codes. Patients with HIV disease, cancer, long-term steroid use, chronic liver disease, other hepatitis virus infections, and those who were pregnant were excluded. ALT flares were defined as 5XULN (females:  $\geq 125$  IU/L, males:  $\geq 175$  IU/L). Patients with subsequent negative HBsAg tests or positive hepatitis B surface antibody tests were considered to have SC. Dispensing records provided information on approved hepatitis b antiviral use. Multivariate (age, sex, race, BMI, diabetes, cardiovascular disease) stepwise Cox proportional hazard models were used to determine association between ALT flares and SC by antiviral use.

**Results:** CHB patients (N = 12, 653) diagnosed between 2001–2020 were included (mean age: 49.7 years, 48% men). Patients included Caucasian (39%), Asian (27%), African American (10%) and other races (2%). Around 4% (n = 531) of patients had SC (median time to SC = 820 [121–4516] days) and 189 (1.5%) had ALT flares. Among those with flares, 17 (9.0%) had flares occurring prior to SC. Patients with ALT flares had shorter time to SC (median: 1.7 vs. 2.3 years) and had SC 2X more often when compared to those without flares (Odds Ratio [OR], 95% confidence interval [95% CI] = 2.3[1.4–3.8]). This association was significant in an adjusted model among CHB patients with antiviral use (Hazard Ratio [HR], 95% CI = 3.5[1.4–8.9]) but not among those without antiviral use (HR [95% CI] = 1.5[0.6–4.0]). Race, BMI, having diabetes, or cardiovascular disease were associated with SC (Table).

Table: Association between variables and seroclearance by antiviral use

Variable	Antiviral use (N = 2207)			No antiviral use (N = 10, 446)		
	HR	95% CI	p-value	HR	95% CI	p value
ALT flare	3.5	(1.4–8.9)	0.009	1.5	(0.6–4.0)	0.431
Age $\geq 45$ vs. <45 years				1.6	(1.2–2.1)	0.002
BMI $\geq 30$ vs. <30				1.5	(1.1–2.0)	0.003
African American vs. others				1.5	(1.1–2.0)	0.013
Caucasian vs. others	2.4	(1.3–4.5)	0.006			
Diabetes mellites				1.6	(1.2–2.3)	0.004

HR = Hazard Ratio; CI = Confidence Interval.

**Conclusion:** In this large cohort of CHB patients, ALT flares prior to SC were relatively uncommon. Whether antiviral use is associated with therapeutic flares in a subgroup of patients requires additional research. Further elucidation of underlying pathophysiology and role of other associated factors could provide insight to CHB disease progression and functional cure.

**PO-1340**

**Association between chronic hepatitis B infection and COVID-19: A nationwide case-control study**

Seong Hee Kang<sup>1</sup>, Han Seul Ki<sup>1</sup>, Moon Young Kim<sup>1</sup>, Soon Koo Baik<sup>1</sup>.  
<sup>1</sup>Yonsei University Wonju College of Medicine, Internal Medicine, Wonju, Korea, Rep. of South  
Email: shkang14@yonsei.ac.kr

**Background and aims:** Few studies have reported the impact of coronavirus disease 2019 (COVID-19) in patients with chronic hepatitis B (CHB). We measured the association between underlying CHB and antiviral use with infection rates among patients who underwent severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) testing.

**Method:** In total, 204, 418 patients >20 years old who were tested for SARS-CoV-2 between January and June 2020 were included. For each case patient with a positive SARS-CoV-2 test, random controls were selected from the target population who had been exposed to

someone with COVID-19 but had a negative SARS-CoV-2 test result. We merged claim-based data from the Korean National Health Insurance Service database collected January 1, 2015 and August 18, 2020. End points examined were SARS-CoV-2 infection rate and severe clinical outcomes of COVID-19.

**Results:** The proportion of underlying CHB was lower in COVID-19 positive patients (n = 267, 3.5%) than in COVID-19 negative controls (n = 2482, 5.4%). Underlying CHB was significantly associated with a lower SARS-CoV-2 positivity rate, after adjusting for comorbidities (adjusted odds ratio [aOR] 0.65; p < 0.001). Among patients with confirmed COVID-19, underlying CHB tended to confer a 66% greater risk of severe clinical outcomes of COVID-19, although this value was statistically insignificant. Antiviral agent treatment including tenofovir and entecavir was associated with a reduced SARS-CoV-2 positivity rate (aOR 0.49; p < 0.001), while treatment was not associated with severe clinical outcomes of COVID-19.

**Conclusion:** Patients with CHB who received antiviral agents had a reduced risk of SARS-CoV-2 infection, and no statistically significant indication that they experienced enhanced risk of severe clinical outcomes of COVID-19 was observed.

**PO-1385**

**Risk of Hepatitis B Virus Reactivation in Patients Treated with PD-1 or PD-L1 Inhibitor for Non-Hepatocellular Cancer**

Sun Yoo<sup>1</sup>, Jonggi Choi<sup>1</sup>, Danbi Lee<sup>1</sup>, Ju Hyun Shim<sup>1</sup>, Kang Mo Kim<sup>1</sup>, Young-Suk Lim<sup>1</sup>, Han Chu Lee<sup>1</sup>.  
<sup>1</sup>Asan Medical Center, University of Ulsan College of Medicine, Department of Gastroenterology, Seoul, Korea, Rep. of South  
Email: jkchoi0803@gmail.com

**Background and aims:** Hepatitis B virus (HBV) reactivation is a well-known complication of chronic hepatitis B (CHB) patients undergoing treatment with immunosuppressive agents or cytotoxic chemotherapy. However, the risk of HBV reactivation of Immune checkpoint inhibitors (ICIs) is not as well understood so far.

**Method:** This retrospective case series included non-hepatocellular carcinoma (HCC) cancer patients treated with ICIs who were referred to Asan Medical Center in Seoul, Korea, between January 1, 2015 and September 30, 2020. The primary outcome was the incidence of HBV reactivation.

**Results:** Among 102 Hepatitis B surface antigen (HBsAg) positive patients, 3 patients (2.9%) developed HBV reactivation with a median onset of 54 weeks (range, 38–141 weeks) after ICIs treatment. In all three cases, antiviral agent was not administered prior to ICI treatment. Two of them experienced grade 4 hepatitis and the other experienced grade 2 hepatitis due to HBV reactivation, and all three patients recovered to normal levels of liver function within median of 4 weeks (ranges, 1–6 weeks) after antiviral agent administration. No HBV related fatal outcome occurred.

**Conclusion:** HBV reactivation is a rare event in cancer patients treated with ICIs. No reactivation event was observed in patients who had antiviral prophylaxis prior to ICI treatment. No fatal hepatic adverse event occurred during ICI treatment. Therefore, with screening and regular monitoring for hepatitis B and antiviral prophylaxis, ICIs could be safely administered to cancer patients with HBV infection.

**PO-1510**

**Serum markers of HBV cccDNA transcriptional activity-HBcAg and pre-genomic HBV RNA, pre-treatment HDV RNA and HDV genotype are useful markers in predicting treatment responses to pegylated interferon in HDV infection**

Email: ivana.kraslova@kcl.ac.uk

Table 1: (abstract: PO-1385): Details of patients with HBV reactivation

Patient No.	Patient Characteristics				Baseline			At reactivation			Outcome		
	Age	Gender	Cancer type	ICIs type	HBeAg	HBV DNA (IU/ml)	Antiviral prophylaxis	Onset from first dose of ICIs (weeks)	HBV DNA (IU/ml)	Peak ALT (U/L)		Management	Antiviral treatment
1	55	M	Lung cancer	Pembrolizumab	Positive	Undetectable	No	54	$3.9 \times 10^6$	1177	Delayed ICIs until LFT normalization	TDF	Normalized ALT and HBV DNA within 4 weeks
2	60	F	Ovarian cancer	Pembrolizumab	Negative	Undetectable	No	38	$2.6 \times 10^4$	174	Maintained ICIs with antiviral treatment	TAF	Normalized ALT within 1 week
3	56	M	Renal cell carcinoma	Nivolumab + Ipilimumab	Positive	NA	No	141	$3.8 \times 10^6$	1768	Delayed ICIs until LFT normalization	TDF	Normalized ALT and HBV DNA within 6 weeks

Abbreviations: HBV hepatitis B virus, HBeAg Hepatitis B e antigen, ICIs Immune checkpoint inhibitors, ALT alanine aminotransferase, LFT liver function test, TDF tenofovir disoproxil fumarate, TAF tenofovir alafenamide, NA not available

**Background and aims:** Hepatitis delta virus (HDV) requires HBsAg for propagation. A response to pegylated-interferon (Peg-IFN) treatment is achieved in less than 50% of patients, and unless HBsAg loss is achieved patients are at a risk of late HDV relapse. Novel serum biomarkers-HBcrAg and pre-genomic HBV RNA (pgRNA)-are non-invasive biomarkers that correlate with intrahepatic cccDNA transcriptional activity. The role of new biomarkers in predicting the response to Peg-IFN is not clear. We aimed to compare baseline and post treatment virological serum biomarkers (HBV DNA, HBsAg levels, HBcrAg and pgRNA concentrations, HDV genotypes and HDV RNA viral load) in HDV-positive responders versus non-responders (NR) to Peg-IFN.

**Methods:** Serum samples of 33 HDV RNA-positive patients (median age 38 yrs, 21 (63%) males, 2 (6%) HBeAg+, 12 (36%) with compensated cirrhosis) were tested at the start and 3 years after completing therapy for the following markers: HBsAg levels by Abbott Architect [IU/ml], HBV DNA by TaqMan Roche [IU/ml], HBcrAg by CLEIA Fujirebio [ $\log_{10}$ U/ml] and pgRNA by real-time PCR Abbott Molecular Diagnostic assay (LLQD =  $1.65 \log_{10}$ U/ml), HDV RNA by in-house real-time PCR assay (LLQD = 640 copies/ml) and HDV genotypes by direct sequencing. FIB4 scores were calculated at the same time-points from biochemical and haematological results. The outcome was correlated with the concentrations of these biomarkers. All results are shown as medians.

**Results:** 3 years post Peg-IFN therapy, 15 (45%) patients were HDV RNA negative (responders), (2 patients with HBsAg loss), whereas 18 patients had detectable HDV RNA (NR). Age, HBV DNA (13 vs. 28 IU/ml,  $p = 0.22$ ), HBsAg (6801 vs. 8326 IU/ml,  $p = 0.16$ ) and FIB4 scores (1.42 vs. 1.54,  $p = 0.2$ ) at baseline were similar in responders and NR. However, eventual responders had significantly lower HBcrAg (3.1 vs. 4.3,  $p < 0.01$ ), pgRNA (1.7 vs. 2.3,  $p = 0.04$ ) and HDV RNA (23, 300 vs. 671, 000,  $p = 0.016$ ) levels at baseline than NR. Responders were less likely to have cirrhosis (13% vs. 55%,  $p = 0.03$ ), were more likely male (87% vs. 53%,  $p = 0.03$ ) and were infected with HDV genotype 5 (93% vs. 27%,  $p < 0.01$ ). In NR, although HBV DNA, HBsAg and HDV RNA did not change significantly from the start of treatment, we observed a decline in HBcrAg (4.3 vs. 3.4,  $p < 0.01$ ), pgRNA (2.3 vs. 1.72,  $p < 0.01$ ) and FIB4 score (1.54 vs. 1.31,  $p = 0.05$ ); in contrast HBsAg (6801 vs. 452,  $p < 0.01$ ), as well as HBcrAg (3.1 vs. 2.2,  $p < 0.01$ ), pgRNA (1.7 vs. 0,  $p < 0.01$ ) and FIB4 (1.42 vs. 0.89,  $p < 0.01$ ) reduced significantly in responders.

**Conclusion:** Lower baseline HDV RNA levels, HDV genotype 5 and lower concentrations of markers of cccDNA transcriptional activity were associated with response to Peg-IFN in HDV infection. Lower concentrations of markers of cccDNA transcriptional activity-HBcrAg and pg HBV RNA-may be of greater utility than HBsAg in differentiating the likelihood of long-term response in HDV infection.

**PO-1519 Endoscopic surveillance of esophageal varices could be refined in HBV compensated cirrhotics taking Tenofovir or Entecavir: an 11-year real-life study**

Elisa Farina<sup>1,2</sup>, Alessandro Loglio<sup>1</sup>, Giulia Tosetti<sup>1</sup>, Mauro Viganò<sup>3</sup>, Carmine Gentile<sup>2,3</sup>, Riccardo Perbellini<sup>1</sup>, Marta Borghi<sup>1</sup>, Floriana Facchetti<sup>1</sup>, Sara Colonia Uceda Renteria<sup>4</sup>, Maria Grazia Rumi<sup>3</sup>, Massimo Primignani<sup>1</sup>, Pietro Lampertico<sup>1,2</sup>. <sup>1</sup>Foundation IRCCS Ca' Granda Ospedale Maggiore Policlinico, Division of Gastroenterology and Hepatology, Milan, Italy; <sup>2</sup>Università degli Studi di Milano, CRC "A.M. e A. Migliavacca" per lo Studio e la Cura delle Malattie del Fegato, Dipartimento di Fisiopatologia Medico-Chirurgica e dei Trapianti, Milan, Italy; <sup>3</sup>San Giuseppe Hospital, Division of Hepatology, Milan, Italy; <sup>4</sup>Foundation IRCCS Ca' Granda Ospedale Maggiore Policlinico, Virology Unit, Milan, Italy  
Email: elisa.farina@unimi.it

**Background and aims:** Long-term effective oral therapies improve liver parameters in CHB patients, but the effect on esophageal varices (EV) changes is unknown. We evaluated the risk of EV development/

progression in HBV monoinfected compensated cirrhotics taking TDF/ETV in a real-life setting.

**Method:** 186 Caucasian HBV monoinfected, HCC-free, compensated cirrhotics without high-risk varices (HRV) were enrolled in a longitudinal study from TDF/ETV start to June 2020 (or liver-transplantation). Blood exams and abdominal US were performed every six months, endoscopy according to Baveno (every two or three years in patients without EV or with low risk EV (LRV), respectively.

**Results:** At TDF/ETV start: 61 (21–83) years-old, 80% males, 60% HBV-DNA undetectable, 63% NUCs previously exposed, 73% normal ALT, 56% BMI >25 kg/m<sup>2</sup>, 40% platelets <150, 000/mm<sup>3</sup>, Liver stiffness 8.7 (2.5–60) kPa, spleen length 11 (7–20) cm, 25 (13%) with LRV. During 136 (26–170) months of TDF/ETV, all achieved virological response, 99% normalized ALT, 37 (20%) developed HCC, 4 (2%) non-neoplastic portal vein thrombosis. Overall, 666 endoscopies were performed, median 3 [2–7] per patient: the 11-year cumulative risk of EV development/progression was 5.1% (95%CI 3–10%); no patient bled.

In 25 patients with LRV, EV disappeared in 11 (44%), remained stable in 12 (48%) and progressed to HRV in 2 (8%), after 17 and 77 months, post HCC diagnosis in the second case. Of 161 patients without EV, 7 (4%) developed LRV after 53 (24–67) months (3 concurrent to HCC, p < 0.001), but only 1 subsequently progressed to HRV at HCC onset (at the second follow-up endoscopy). In patients without EV at entry, baseline platelet count (HR 0.97, p=0.004) and spleen length (HR 1.34, p=0.032) were associated with LRV development at univariate analysis, only platelet count (HR 0.96, p=0.028) at multivariate analysis. Baseline platelet count ≤90,000/mm<sup>3</sup> (AUROC 0.70) had 98.05% specificity, 42.86% sensitivity, 50% PPV, 97.42% NPV, accuracy 95.65% for LRV onset during NUC treatment. Overall, in patients without EV at NUCs start, none developed EV after two consecutive follow-up endoscopies.

**Conclusion:** In compensated HBV cirrhotics under TDF/ETV, the 11-year risk of developing/progressing EV is negligible, thus challenging the current surveillance rules in patients without EV at baseline.

**PO-1605**

**Detection of novel biomarkers in HBV-associated chronic hepatitis, liver fibrosis/cirrhosis, and hepatocellular carcinoma utilizing transcriptome sequencing technology**

Dandan Zhao<sup>1</sup>, Wen Zhao<sup>1</sup>, Lu Li<sup>1</sup>, Liu Lingdi<sup>1</sup>, Yuemin Nan<sup>1</sup>. <sup>1</sup>Third Hospital of Hebei Medical University, Department of Traditional and Western Medical Hepatology, Shijiazhuang, China  
Email: nanyuemin@163.com

**Background and aims:** The purpose of this study was to assess novel biomarkers in patients with chronic hepatitis B (CHB), HBV-associated Liver fibrosis (LF)/liver cirrhosis (LC), and HBV-associated hepatocellular carcinoma (HCC).

**Method:** Transcriptome sequencing technology of liver tissue was performed on 4 healthy controls, 5 patients with CHB, 5 patients with LF/LC and on 5 patients with HCC. By using bioinformatics analysis, the hub mRNAs were identified. Quantitative reverse-transcriptase polymerase chain reaction (qRT-PCR) and ELISA were then used to investigate the expression level of screened targets in the four groups.

**Results:** STEM analysis indicated that a total 25 mRNAs showed a gradually increasing trend in the group of healthy control, CHB, LF/LC and HCC; among them, by using WGCNA, the 9 hub mRNAs (SHC1, SLAMF8, IL32, ITGB2, MANF, TC2N, SYNPO, UGP2, EFEMP1) were identified. We used qRT-PCR in 5 liver tissue samples in each group to investigate the expression of selected mRNAs; which found 8 mRNAs showed the same trend. Then we utilized qRT-PCR in 80 PBMC samples and found 3 mRNAs (SHC1, SLAMF8, IL32) showed the same trend. Further validation with a retrospective cohort (n=200) by ELISA utilizing plasma showed that SHC1, SLAMF8 and IL32 levels were significantly higher in HCC patients (10.7 ng/ml, 8.4 ng/ml, 78.3 pg/ml, respectively) than in LF/LC patients (9.7 ng/ml, 7.0 ng/ml, 62.3 pg/ml, respectively), CHB patients (7.5 ng/ml, 6.1 ng/ml, 50.2 pg/ml, respectively), and healthy volunteers (4.4 ng/ml, 5.1 ng/ml,

32.3 pg/ml, respectively). ROC curve analysis revealed that plasma SHC1, SLAMF8 and IL32 could be used to differentiate HCC, LF/LC, CHB and healthy controls from each other. Further, a diagnostic model PSSI (PLT, SHC1, SLAMF8, IL32) was built to discern HCC from LF/LC with high accuracy (auROC = 0.976), LF/LC from CHB (auROC = 0.982), as well as CHB from healthy controls (auROC = 0.998).

**Conclusion:** In summary, our study has identified that SHC1, SLAMF8 and IL32 may serve as novel targets for the diagnosis of liver diseases. Moreover, the combination of PLT, SHC1, SLAMF8 and IL32 confers significant benefit to diagnostic accuracy in differentiating HCC from LF/LC, CHB, as well as healthy controls.

**PO-1622**

**Efficacy of hepatitis B virus vaccines HBVaxpro40 and Fendrix in patients with chronic liver disease in clinical practice**

Diana Horta<sup>1</sup>, Anna Agusti<sup>2</sup>, Montserrat Forne<sup>2</sup>, Agnès Raga<sup>2</sup>, Pablo Ruiz-Ramirez<sup>2</sup>, Juana Maria Hernandez<sup>2</sup>, Maria Esteve<sup>2</sup>.  
<sup>1</sup>Hospital Universitario Mútua de Terrassa, Gastroenterology and Hepatology, Terrassa, Spain; <sup>2</sup>Hospital Universitario Mútua de Terrassa, Terrassa  
Email: diana.horta.s@gmail.com

**Background and aims:** Chronic liver disease results in a lower response rate to the hepatitis b virus (HBV) vaccine at the standard dose. The use of the adjuvanted vaccine Fendrix and adsorbed Vaxpro40 in chronic liver disease is scarce. Prospective observational study in clinical practice using HBVaxpro40 and Fendrix. Aims: 1) to evaluate the effectiveness of HBV vaccines HBVaxpro 40 and Fendrix in patients with chronic liver disease 2) to assess the kinetics of anti-HBs at six months.

**Method:** Non-cirrhotic and cirrhotic liver disease patients with HBV-negative serologic tests were prospectively included. Liver disease was assessed by abnormal liver blood tests (minimum 6 months), elastography, non-invasive markers of fibrosis, ultrasound and biopsy (when available). Patients were vaccinated with HBVaxpro 40 (0, 1 and 6 months) or Fendrix (0, 1, 2 and 6 months) depending on availability. Clinical, blood tests and anti-Hbs levels were collected at 2 and 6 months. A multivariate analysis was performed to evaluate variables associated to vaccine response. Classic response was defined as anti-HBs ≥10 IU/L and non-classic response as anti-HBs ≥100 IU/L.

**Results:** 103 patients were included (mean age 62.4 years; 56.3% males; 36.9 liver cirrhosis, 89.5% of whom were Child A). The aetiology of chronic liver disease was 33% alcohol, 27.2% metabolic, 23.3% virus c hepatitis and 16.5% autoimmune/primary biliary cholangitis. 73 patients were vaccinated with HBVaxpro40 and 30 with Fendrix. There were no significant differences between the two vaccines protocols. The overall response rate was 76.7% (anti-HBs ≥10 IU/L) and 56.2% (anti-HBs ≥100 IU/L). At six months, the overall response rate was 73.3% (anti-HBs ≥10 IU/L) and 46.5% (anti-HBs ≥100 IU/L). In the univariate analysis, male gender, cirrhosis and ultrasound signs of portal hypertension were associated with a lower response rate to vaccination.

In the multivariate analysis, liver cirrhosis increased 10.2 times the likelihood of non-response to the vaccine (OR, 10.2; 95% CI, 3.18–32.71; p < 0.001).

**Vaccination response at two months**

Figure:

# POSTER PRESENTATIONS

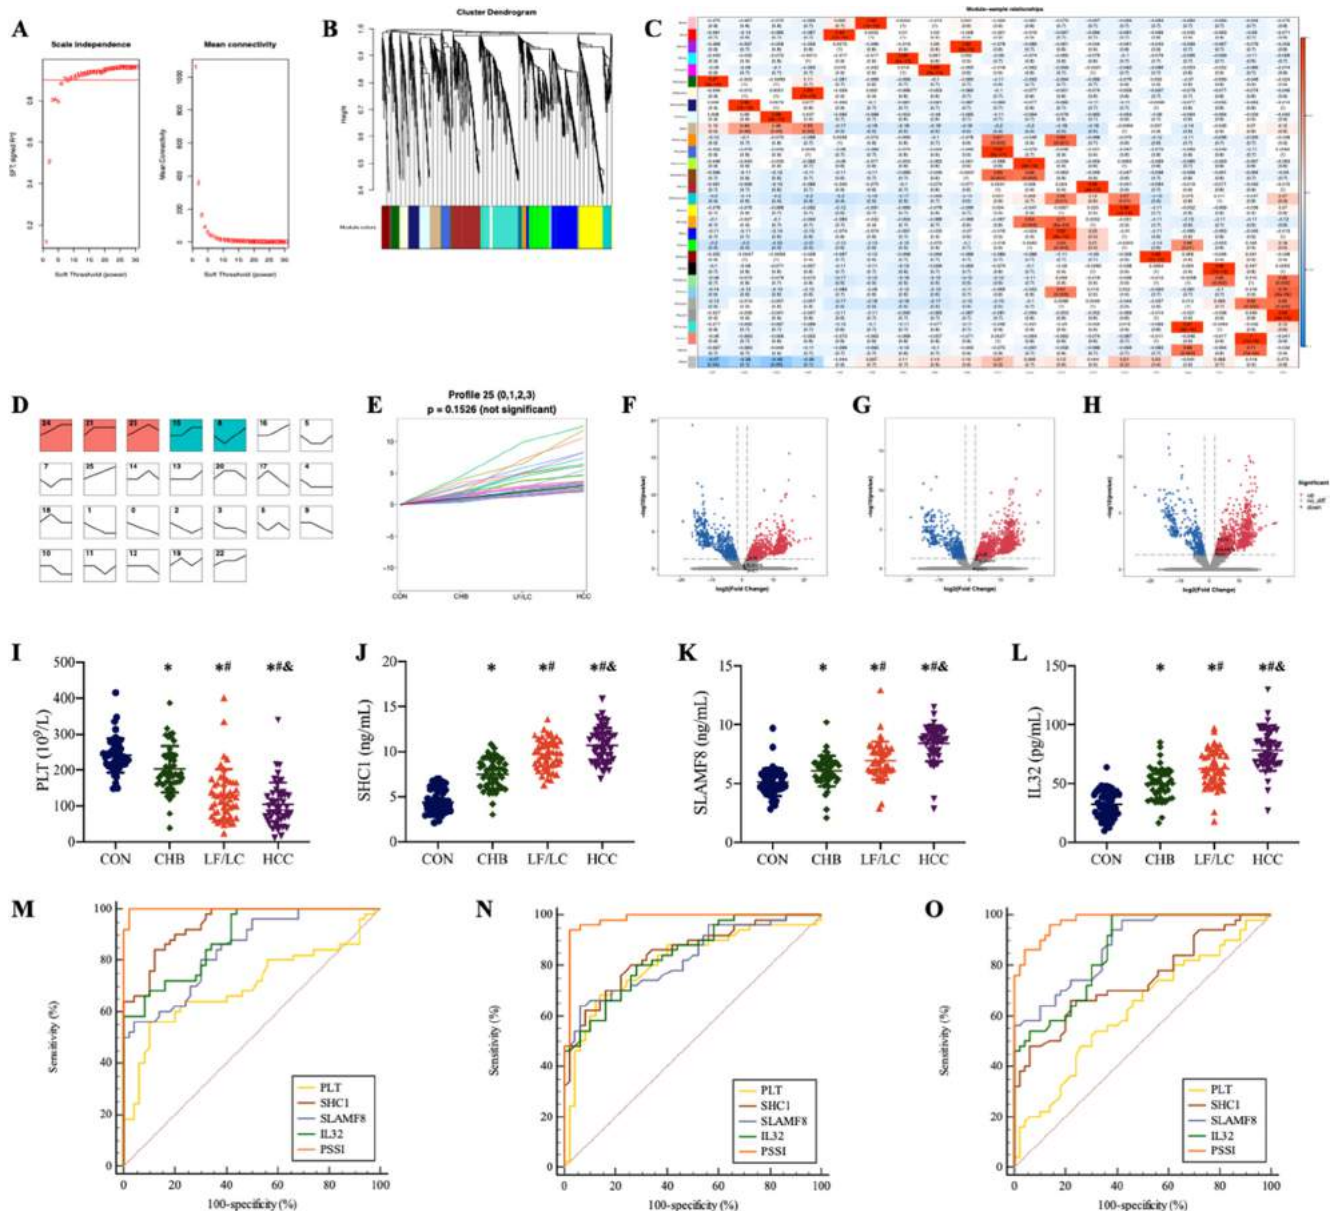

Figure: (abstract: PO-1605)

**Conclusion:** HBVaxpro40 and Fendrix are good HBV vaccinations in patients with chronic liver disease in early stages.

## PO-1725

### Health-related quality of life and stigma related to chronic hepatitis B: a systematic literature review

Vera Gielen<sup>1</sup>, Stuart Kendrick<sup>1</sup>, Rishabh Pandey<sup>2</sup>, Ruchika Mittal<sup>2</sup>, Kajal Thapa<sup>2</sup>, Lee Evitt<sup>1</sup>. <sup>1</sup>GlaxoSmithKline Research and Development, Brentford, London, United Kingdom; <sup>2</sup>Parexel International, Bengaluru, India

Email: vera.x.gielen@gsk.com

**Background and aims:** Chronic hepatitis B (CHB) is associated with substantial morbidity and mortality burden. However, impact of health-related quality of life (HRQoL) is less well considered. Many factors including stigma may have an impact on HRQoL. A systematic literature review (SLR) was conducted to assess HRQoL, health utility values (HUVs; value given to a health state with '0' representing death; '1' perfect health) and impact of stigma in CHB.

**Methods:** SLR methodology was employed. Major databases (Embase; MEDLINE; Cochrane) were searched for literature published Jan-2004 to Feb-2020.

**Results:** Of 2385 abstracts reviewed, 104 studies were found to be relevant (HRQoL, n = 80; HUVs, n = 16; stigma, n = 22). Generic (e.g. SF-36; EQ-5D), liver-disease specific (CLDQ; LDSI; LDQOL) and hepatitis B specific instruments (HBQoL; HQLQ) were used. HBQoL was the most commonly used hepatitis B specific instrument. CHB patients with or without complications reported worse HRQoL for physical and emotional functioning, fatigue, worry and depression vs healthy participants. CHB patients with cirrhosis, liver transplant, and hepatocellular carcinoma (HCC) reported worse HRQoL vs patients without complications. CHB patients without complications had significant improvement in physical health and less improvement in vitality and mental health, emotional and social functioning with nucleos (t)ide analogues; no improvement was observed with interferon treatment. Mean HUVs (range) in states of CHB (carriers: 0.75–0.81; compensated cirrhosis: 0.56–0.89; decompensated cirrhosis: 0.30–0.85; first year post-transplant: 0.54–0.63; subsequent

years post-transplant: 0.62–0.86; HCC: 0.32–0.85) were reported. Stigma impacts willingness to screen, seeking care, diagnosis acceptance, interpersonal relationships and employment among CHB patients and caregivers; higher education, old age and better social status is associated with less stigma.

**Conclusion:** Patients with CHB have impaired HRQoL particularly in mental health, emotional and social functioning with limited or no improvement on these domains with current treatments. Impact on these in clinical practice and trials should be further evaluated with disease specific instruments like HBQoL that focus on psychological well-being and stigma. Social awareness and education to avoid stigma and considering patients' concerns and perception into clinical practice might further reduce the CHB health burden.

**Funding:** GSK (Study 209774).

**PO-1788**

**The incidence and predictors of HCC in REVEAL chronic hepatitis B patients with incident spontaneous HBsAg loss**

Rachel Wen-Juei Jeng<sup>1,2</sup>, Mei-Hung Pan<sup>3</sup>, Jessica Liu<sup>3</sup>, Mei-Hsuan Lee<sup>4</sup>, Richard Batrla-Utermann<sup>5</sup>, Sheng-Nan Lu<sup>6</sup>, Li-Yu Wang<sup>7</sup>, Chien-Jen Chen<sup>3</sup>, Hwai-I Yang<sup>3</sup>. <sup>1</sup>Linkou Chang Gung Memorial Hospital, Department of Gastroenterology and Hepatology, Taiwan; <sup>2</sup>Chang Gung University, College of Medicine, Taiwan; <sup>3</sup>Academia Sinica, Genomic Research Center, Taiwan; <sup>4</sup>National Yang-Ming University, Institute of Clinical Medicine, Taiwan; <sup>5</sup>Roche Diagnostics, Basel, Switzerland; <sup>6</sup>Kaohsiung Chang Gung Memorial Hospital, Department of Gastroenterology and Hepatology, Taiwan; <sup>7</sup>Mackay Medical College, Taiwan  
Email: hiyang@gate.sinica.edu.tw

**Background and aims:** HBsAg loss is an ideal end point for chronic hepatitis B (CHB) treatment. Age >50 and cirrhosis at time of HBsAg loss has been reported as predictors for HCC by meta-analysis. However, information on the incidence and predictors of HCC in incident cases of spontaneous HBsAg loss within untreated long-term follow-up CHB cohort is limited. **Aim:** To investigate the HCC incidence and risk factors in CHB patients who underwent newly spontaneous HBsAg seroclearance

**Method:** A total of 633 patients who newly cleared serum HBsAg out of 4155 CHB patients in REVEAL cohort were enrolled. Patients with HCC diagnosed prior to HBsAg seroclearance were excluded (n = 1). HCC diagnosis was ascertained by follow-up examinations and computerized data linkage with National Cancer Registry and National Death Certification profiles by the end of 2017. Multivariate-adjusted hazard ratios (HRs) and 95% confidence intervals (CIs) were estimated using Cox regression models. Statistic procedures were performed with SAS 9.4. A P value less than .05 was considered statistically significant.

**Results:** A total of 29 patients were diagnosed of HCC during a median (IQR) follow-up duration of 17.5 (0.1–25.5) years after HBsAg seroclearance. The 5-, 10-, 15- and 20-year cumulative incidence of HCC was 1%, 3%, 4% and 5%, respectively. The median age of HBsAg seroclearance was 55.3 year-old; those with subsequent HCC development were slightly older than those without (58.7 vs. 55.1, P = 0.075). Patients diagnosed with cirrhosis before HBsAg seroclearance had a higher incidence of HCC development than those without cirrhosis (annual incidence: 1.37% vs. 0.2%). Older age [Crude HR (95% CI): 1.05 (1.01–1.09), P = 0.015], cirrhosis [Crude HR (95% CI): 6.91 (3.12–15.25), P < 0.0001] are significant factors in univariate analysis while cirrhosis is the only independent predictors of HCC in the multivariate cox regression analysis [adjusted HR (95% CI): 4.02 (1.11–14.66), P = 0.035]. Older age at time of HBsAg loss is the only predictor of HCC in patients without cirrhosis [HR (95% CI): 1.05 (1.00–1.10)] while there's no predictors of HCC in cirrhotic patients before HBsAg loss.

Figure:

**Conclusion:** This is the largest cohort with the longest follow-up duration reporting the HCC incidence and risk factors in CHB patients with newly spontaneous HBsAg seroclearance. Cirrhosis before HBsAg loss is predictive for subsequent HCC development while increasing age is the only risk factor for patients without cirrhosis.

**PO-1789**

**Characterization of the Liver Immune Microenvironment in Chronic HBV Infected Patient Liver Biopsies**

Nicholas Van Buuren<sup>1</sup>, Ricardo Ramirez<sup>1</sup>, Scott Turner<sup>1</sup>, Diana Chen<sup>1</sup>, Vithika Suri<sup>1</sup>, Abhishek Aggarwal<sup>1</sup>, Christina Moon<sup>1</sup>, Sam Kim<sup>1</sup>, Cameron Soulette<sup>1</sup>, Dmytro Korniyev<sup>1</sup>, Neeru Bhardwaj<sup>1,2</sup>, Maria Buti<sup>3</sup>, Henry Chan<sup>4</sup>, Patrick Marcellin<sup>5</sup>, Jeffrey Wallin<sup>1</sup>, Anuj Gaggar<sup>1</sup>, Lauri Diehl<sup>1</sup>, Hongmei Mo<sup>1</sup>, Li Li<sup>1</sup>, Becket Feierbach<sup>1</sup>. <sup>1</sup>Gilead Sciences Inc, Foster City, United States; <sup>2</sup>Foundation Medicine, Cambridge, United States; <sup>3</sup>Hospital Universitari Val d'Hebron, Barcelona, Spain; <sup>4</sup>The Chinese University of Hong Kong, China; <sup>5</sup>Hopital Beaujon, Clichy, France  
Email: nick.vanbuuren@gilead.com

**Background and aims:** Our current knowledge of the interaction between chronic HBV (CHB) infection and the liver immune microenvironment largely comes from animal models and patients with hepatocellular carcinoma (HCC). Here, we describe the liver immune microenvironment from CHB-infected, non-HCC patients from the GS-US-174-0149 clinical trial.

**Method:** Matching FFPE and fresh frozen liver biopsies were collected from immune active patients within the open-label Phase 4 study GS-US-174-0149. We applied bulk RNA-Seq to 53 CHB liver biopsies from 46 patients including eight longitudinal pairs from Baseline and Week 96. The xCell algorithm as well as gene set variance analysis was used to characterize and quantify the immune microenvironment of each sample. Twenty-eight of the 53 samples had matched FFPE biopsies subjected to multiplex immunofluorescence (mIF) using the Neogenomics MultiOmyx™ platform. The biopsies were stained with a custom 12-plex panel including cell segmentation, immune and viral biomarkers. Finally, corresponding serum samples were screened using the MSD Human V-plex Screen Service to identify peripheral correlates for the immune microenvironment.

**Results:** Unsupervised clustering of the transcriptome revealed two unique liver immune signatures from the CHB biopsies. We classified these signatures as Immune High and Immune Low based on the quantification of gene signatures from the liver immune infiltrate.

Immune High

Figure: (abstract: PO-1789)

mIF analysis demonstrated the formation of periportal lymphoid aggregates in Immune High samples (Figure). In addition, single-plex IHC demonstrated that Immune High samples had significantly elevated expression of the PD-1 and PD-L1. High and Low immune microenvironments were independent of patient HBeAg status, serum viral biomarkers or liver antigen burden. Finally, we screened corresponding peripheral samples and identified elevated levels of ICAM-1 and IP-10 as serum biomarkers that strongly correlated with the Immune High gene signature.

**Conclusion:** We utilized transcriptomics and mIF to investigate the CHB liver immune microenvironment. Our data identified different levels of immune cell infiltrates that were independent of viral load and HBeAg status. These findings could have implications for treatment modalities designed to augment an anti-viral immune response.

PO-1810

**A non-invasive model to predict liver histological lesions in chronic hepatitis B patients with persistently normal alanine aminotransferase and detectable viremia**

Qiankun Hu<sup>1</sup>, Wei Xu<sup>1</sup>, Qianqian Wang<sup>1</sup>, Qiang Li<sup>1</sup>, Chenlu Huang<sup>1</sup>, Shuai Tao<sup>1</sup>, Xun Qi<sup>1</sup>, Yi Zhang<sup>1</sup>, Xinyan Li<sup>1</sup>, Xuhua Jiang<sup>1</sup>, Jie Song<sup>1</sup>, Liang Chen<sup>1</sup>, Yuxian Huang<sup>1,2</sup>. <sup>1</sup>Shanghai Public Health Clinical Center, Fudan University, Department of Liver Diseases, Shanghai, China; <sup>2</sup>Huashan Hospital, Fudan University, Department of Infectious Diseases, Shanghai, China

**Background and aims:** This study aimed to develop a non-invasive model to predict significant liver histological changes (SLHC), which is the histological indication for antiviral therapy in chronic hepatitis

Figure: (abstract: PO-1810): Comparison of the diagnostic performance of the SLHC index with other non-invasive models in the estimation set (A) and validation set (B).

B (CHB) patients with persistently normal alanine aminotransferase (PNALT) and detectable HBV DNA.

**Method:** 398 CHB patients with PNALT and detectable HBV DNA who underwent liver biopsy were divided into the estimation set (n = 256) and the validation set (n = 142). Logistic regression analysis was performed to identify independent predictors of SLHC. Then a novel model index was developed to predict SLHC.

**Results:** 82 (32.0%) patients and 50 (35.2%) patients had SLHC in the estimation set and validation set, respectively. Multivariate analysis identified aspartate aminotransferase (AST), cholinesterase (ChE) and liver stiffness measurement (LSM) as independent predictors for SLHC (all p < 0.05). The SLHC index consisting of AST, ChE and LSM was developed to predict SLHC, which yielded an AUROC of 0.824 and 0.816 in the estimation set and validation set, respectively. More importantly, compared with other established non-invasive models, the SLHC index presented significantly better diagnostic performance in identifying patients with or without SLHC.

**Conclusion:** The SLHC index provided a high accuracy in predicting histological indication for antiviral therapy in CHB patients with PNALT and detectable HBV DNA.

**PO-1876**

**Novel shapelet patterns for time series classification (TSC) for AFP and ALT to predict HCC in patients with chronic hepatitis B on antiviral treatment**

Vicki Wing-Ki Hui<sup>1,2</sup>, Guozhong Li<sup>3</sup>, Shiwen Li<sup>4</sup>, Terry Cheuk-Fung Yip<sup>2,5</sup>, Yee-Kit Tse<sup>2,5</sup>, Vincent Wai-Sun Wong<sup>2,5</sup>, Grace Lai-Hung Wong<sup>2,5</sup>, Bryon Koon-Kau Choi<sup>4</sup>. <sup>1</sup>The Chinese

University of Hong Kong, Department of Medicine and Therapeutics, Hong Kong; <sup>2</sup>Medical Data Analytic Centre (MDAC); <sup>3</sup>Hong Kong Baptist University, Department of Computer Science, Hong Kong; <sup>4</sup>Hong Kong Baptist University, Department of Computer Science; <sup>5</sup>The Chinese University of Hong Kong, Department of Medicine and Therapeutics Email: wonglaihung@cuhk.edu.hk

**Background and aims:** Alpha-fetoprotein (AFP) is the most widely used biomarker for hepatocellular carcinoma (HCC) surveillance, which is criticized for its high false-positive rate in patients with raised alanine aminotransferase (ALT) levels. Time-series shapelets are discriminative subsequences, recently found effective for time series classification (TSC). We aimed to identify novel shapelets for accurate TSC of ALT and AFP levels to predict HCC in patients with chronic hepatitis B (CHB) who had received antiviral treatment.

**Method:** This was a territory-wide retrospective observational cohort study in Hong Kong. We identified CHB patients who received entecavir or tenofovir treatment. Serial serum AFP and ALT levels from baseline (start of antiviral) to 6 months prior HCC (HCC group) or to last visit (no HCC group) were analyzed. A novel efficient shapelet discovery method was adopted to identify novel shapelets of the time series of AFP alone or AFP and ALT to predict HCC.

**Results:** 35, 516 CHB patients were included; mean age was 51.6 ± 12.7 years; 21865 (61.6%) patients were male and 2, 429 (6.8%) patients had clinical evidence of cirrhosis. 1, 571 HCC occurred in a 49.1 ± 31.2 months of follow-up. Two representative shapelets of AFP alone and AFP and ALT are showed in Figure 1. The accuracy of the shapelet patterns for TSC increased from 64.31% for AFP alone, to 84.31% for combining AFP and ALT.

**Conclusion:** Novel shapelet patterns for TSC of serum AFP and ALT levels achieve higher accuracy than those of AFP alone to predict HCC in CHB patients.

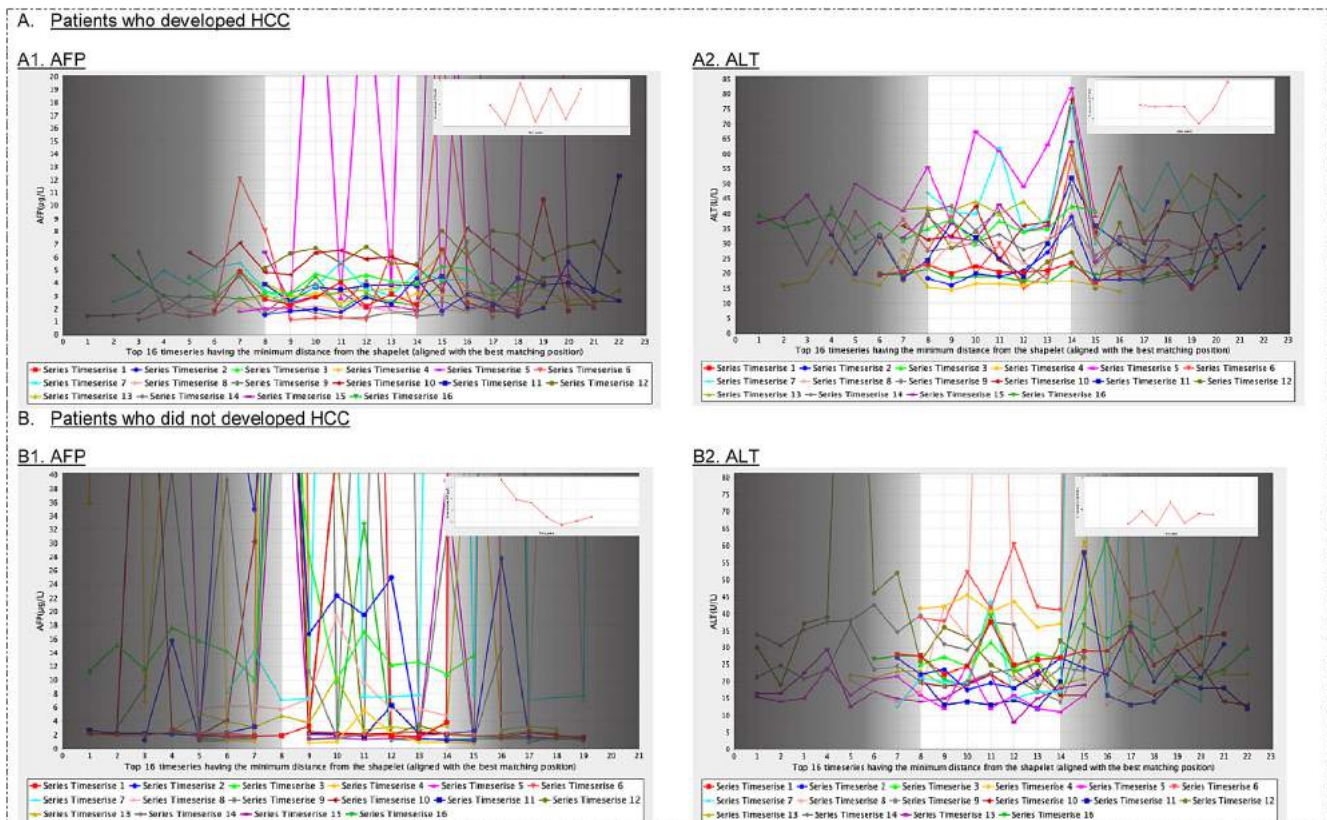

Figure: (abstract: PO-1876) The most heavy-weighted shapelet for A. patients who developed HCC and B. patient who did not developed HCC. (A) Patients who developed HCC; (B) Patients who did not developed HCC.

## POSTER PRESENTATIONS

### PO-1982

#### Association between plasma miRNA-200-3p and transcriptional activity of hepatic cccDNA in chronic hepatitis B

Vladimir Loukachov<sup>1,2</sup>, Karel van Dort<sup>1,2</sup>, Bart Takkenberg<sup>3</sup>, Henk Reesink<sup>4</sup>, Neeltje Kootstra<sup>1,2</sup>. <sup>1</sup>Amsterdam UMC, location AMC, Experimental Immunology, Amsterdam, Netherlands; <sup>2</sup>Amsterdam Infection and Immunity Institute, Amsterdam, Netherlands; <sup>3</sup>Amsterdam UMC, location AMC, Department of Gastroenterology and Hepatology, Amsterdam, Netherlands; <sup>4</sup>Leiden University Medical Center (LUMC), Department of Gastroenterology and Hepatology, Leiden, Netherlands  
Email: v.loukachov@amsterdamumc.nl

**Background and aims:** Chronic hepatitis B (CHB) infection is a serious health problem worldwide and with the current treatment a functional cure is only achieved in 3–7% of the patients due to persistence of covalently closed circular DNA (cccDNA) in the liver, resulting in ongoing production of HBsAg and HBV-RNA. At present only pegylated interferon can target this cccDNA pool, however several experimental therapies are under investigation. Since cccDNA is best determined in liver tissue, surrogate markers in plasma are of interest to monitor the effect of these new therapies. As miRNA are promising biomarkers in numerous diseases, in this study the plasma levels of various miRNAs expressed in CHB patients were compared with the respective hepatic cccDNA levels and degree of HBV transcriptional activity.

**Method:** For this study pretreatment plasma samples of 54 CHB patients, either HBeAg negative (n = 30) or positive (n = 24), were available for analysis. RNA was isolated from plasma and the expression levels of the specific miRNAs were measured using qPCR. DNA and RNA was isolated from liver tissue samples and cccDNA and pregenomic RNA (pgRNA) levels were measured by qPCR. Transcriptional activity of cccDNA was defined as the pgRNA/cccDNA ratio. Association between miRNA expression levels, cccDNA levels and cccDNA transcriptional activity was performed using a Spearman correlation test.

**Results:** The plasma expression levels of miR-122-5p, miR-10b-5p, miR-192-5p, miR-194-5p, miR-30c-5p, let-7e-5p, miR-125b-5p, miR-146b-5p, miR-193b-3p and miR-215 were associated with hepatic cccDNA levels (p < 0.01) but no correlation was observed for cccDNA transcriptional activity. Next, the HBeAg negative and positive groups were analyzed separately. In the HBeAg positive patients expression levels of let-7e-5p, miR-122-5p and miR-143-3p (p < 0.05) were found to be associated with cccDNA levels, however no correlation was observed for the cccDNA transcriptional activity. In the HBeAg negative patients no correlation between the expression levels of miRNAs and cccDNA was found, however the expression levels of plasma miR-200a-3p level was correlated (p = 0.01) with cccDNA transcriptional activity in the liver.

**Conclusion:** The expression levels of various miRNAs in plasma was associated with hepatic cccDNA levels in CHB patient. Plasma expression levels of miR-200a-3p was associated with HBV transcriptional activity in the liver in HBeAg negative CHB patients only.

### PO-1996

#### HBV reactivation can be predicted by combined highly-sensitive HBV markers: implications for an optimized management of HBsAg-negative/anti-HBc-positive oncohematological patients

Mohammad Alkhatib<sup>1</sup>, Romina Salpini<sup>1</sup>, Vincenzo Malagnino<sup>2</sup>, Carlotta Cerva<sup>2</sup>, Lorenzo Piermatteo<sup>1</sup>, Arianna Battisti<sup>1</sup>, Ada Bertoli<sup>1</sup>, Maria Cantonetti<sup>3</sup>, William Arcese<sup>3</sup>, Francesca Ceccherini Silberstein<sup>1</sup>, Carlo Federico Perno<sup>4</sup>, Massimo Andreoni<sup>2</sup>, Loredana Sarmati<sup>2</sup>, Valentina Svicher<sup>1</sup>. <sup>1</sup>University of Rome "Tor Vergata", Department of Experimental Medicine, Rome, Italy; <sup>2</sup>University of Rome "Tor Vergata", Clinical Infectious Disease, Department of System Medicine, Rome, Italy; <sup>3</sup>University of Rome "Tor Vergata", Department of Hematology, Stem Cell Transplant Unit, Rome, Italy; <sup>4</sup>IRCCS Bambino Gesù' Pediatric Hospital, Department of Diagnostic and Laboratory Medicine, Rome, Italy  
Email: mohammad-alkhatib@hotmail.com

**Background and aims:** HBV-reactivation (HBV-R) is still a challenging issue in HBsAg-negative/anti-HBc-positive patients with oncohematological diseases. Here, we examine the role of HBV markers in predicting HBV-R in these patients.

**Method:** This study includes 107 HBsAg-negative/anti-HBc-positive oncohematological patients, receiving anti-HBV prophylaxis for ≥18 months after stopping immunosuppression (EASL guidelines) and prospectively monitored every 3 months. 61/107 patients completed prophylaxis and were monitored for a median time of 41 (35–47) months after prophylaxis completion. The role of HBV markers in predicting HBV-R is evaluated by testing 831 serum samples for highly-sensitive HBsAg (Fujirebio, HS-HBs; lower limit of quantification [LLOQ]: 5mIU/ml), HBV-DNA (Roche, LLOQ: 20IU/ml), quantitative anti-HBs and anti-HBc (Fujirebio). HBV-R is defined as serum HBV-DNA ≥20IU/ml (Seto, 2016).

**Results:** At baseline, all patients have undetectable HBV-DNA and 67.3% is anti-HBs positive (median [IQR]: 152[47–976]mIU/ml). HBV-R occurs in 17/107 (15.9%) patients: 6 during and 11 after completing prophylaxis (up to 27 months after prophylaxis completion). At HBV-R, median (IQR) HBV-DNA is 44 (27–40509)IU/ml, ALT >ULN for 44% (median [IQR]: 81[49–541]U/L), and ≥1 immune-escape mutation is detected in 50% of patients.

By serological markers analysis, the combination of anti-HBc >3COI and anti-HBs persistently or declining to <50mIU/ml is a predictive factor for HBV-R (OR[95%CI]: 9.1[2.7–30.2]; 63% of patients with vs 15% without this combination experiences HBV-R, P < 0.001). This combination predicts HBV-R also in the subset of patients completing prophylaxis (OR[95%CI]: 8.8[2.0–38]; 55% of patients with vs 14% without this combination experiences HBV-R, P = 0.005).

Furthermore, by monitoring of virological markers, the positivity, confirmed in ≥2 time-points, to HS-HBs (detection failed by routinely used HBsAg-assays) and/or to HBV-DNA (detected below LLOQ) strongly increases HBV-R risk after completing prophylaxis (OR[95% CI]: 24[3.7–157.4]; 50% of patients positive to HS-HBs and/or HBV-DNA vs 4% never positive to these markers experiences HBV-R, P = 0.001).

**Conclusion:** HBV-R frequently occurs in anti-HBc-positive/HBsAg-negative oncohematological patients, particularly after completing prophylaxis and selects for viral strains with enhanced potential to evade humoral response. The integrated monitoring of accurate HBV-markers can guide to identify patients at higher HBV-R risk who need an extended prophylaxis.

### PO-2134

#### The association of serum hepatitis B core antibody and liver inflammation in HBeAg-negative chronic hepatitis B patients with normal ALT and detectable HBV DNA

Kefang Yao<sup>1</sup>, Jian Wang<sup>2</sup>, Xiaomin Yan<sup>2</sup>, Guiyang Wang<sup>2</sup>, Yali Xiong<sup>2</sup>, Shengxia Yin<sup>2</sup>, Xin Tong<sup>2</sup>, Rui Huang<sup>2</sup>, Chao Wu<sup>1,2</sup>. <sup>1</sup>Nanjing Drum Tower Hospital, Clinical College of Nanjing Medical University; <sup>2</sup>Nanjing Drum Tower Hospital, The Affiliated Hospital of Nanjing University Medical School  
Email: dr.wu@nju.edu.cn

**Background and aims:** The association of serum hepatitis B core antibody (anti-HBc) levels and liver inflammation is not clear in HBeAg-negative chronic hepatitis B (CHB) patients with normal alanine aminotransferase (ALT) and detectable HBV DNA. We attempted to evaluate the association of serum anti-HBc levels and liver inflammation in these patients.

**Method:** A total of 117 HBeAg-negative CHB patients with normal ALT and detectable HBV DNA who underwent liver biopsy were included. Serum anti-HBc levels were detected by commercial immunoassays (Abbott GmbH and Co. KG). The association between liver inflammation and anti-HBc levels was analyzed.

**Results:** Approximately 43.6% (51/117) of the HBeAg-negative CHB patients with normal ALT and detectable HBV DNA showed significant liver inflammation (≥G2). Serum anti-HBc levels significantly

correlated with liver inflammation grades ( $r=0.511$ ,  $p<0.001$ ). Multivariate logistic analysis showed that serum anti-HBc levels were independently associated with significant liver inflammation (OR 1.513, 95%CI 1.112–2.058,  $p=0.008$ ). The receiver operating characteristic (ROC) curve indicated that serum anti-HBc levels could predict significant liver inflammation (AUC = 0.773,  $P < 0.001$ ) with the cut-off values of 10.87 S/CO.

Figure 1: Flow diagram of patient selection.

Figure 2: Proportion of patients with different immune status of entire CHB patients (A) and distribution of CHB patients with different gray zones (B).

Figure 3: Distribution of CHB patients with different immune status according to age (A) and sex (B).

**Conclusion:** A significant proportion of HBeAg-negative CHB patients with normal ALT and detectable HBV DNA showed significant liver inflammation. The anti-HBc levels could be used to predict significant liver inflammation in HBeAg-negative CHB patients with normal ALT and detectable HBV DNA.

**PO-2261**

**Changing demographic-clinic-pathologic profiles of newly diagnosed carriers of chronic hepatitis B virus infection across two decades: a single Italian reference center report**

Gabriele Ricco<sup>1</sup>, Patrizia Bleve<sup>1</sup>, Barbara Coco<sup>1</sup>, Daniela Cavallone<sup>1</sup>, Piero Colombatto<sup>1</sup>, Filippo Oliveri<sup>1</sup>, Veronica Romagnoli<sup>1</sup>, Antonio Salvati<sup>1</sup>, Ferruccio Bonino<sup>2</sup>, Maurizia Brunetto<sup>1,2,3</sup>.

 Email: maurizia.brunetto@unipi.it

**Background and aims:** Hepatitis B Virus (HBV) epidemiology burden is rapidly evolving worldwide. We studied the viral, clinical, pathologic and demographic characteristics of two cohorts of consecutive chronic hepatitis B surface antigen (HBsAg) carriers who presented at a single Italian reference center across the last 2 decades.

**Method:** All [1847, 70.0% native-born and 30.0% Immigrants] HBsAg carriers evaluated at the Hepatology Unit of the University Hospital of Pisa, Italy from January 2000 to December 2019 were included in the analysis and grouped according to decade of first evaluation [856 (46.3%) between 2000 and 2009 (first cohort, 1C), 991 (53.7%) between 2010 and 2019 (second cohort, 2C). Groups comparison included the characteristics listed in the Table by  $\chi^2$  or Mann-Whitney nonparametric test.

**Results:** The 2 cohorts differed significantly ( $p < 0.001$ ) for: gender (higher female number in 2C, 28–38%, higher in immigrants); origin

## POSTER PRESENTATIONS

and HBV genotype [increased immigrants rate in 2C, (14.7–43.3%) and increased non-D genotype in 2C, (18.7–33.2%)]; HBV infection phase [more HBeAg negative infection in 2C (ENI, 30.6–46.9%); coinfections (lower HCV, higher HDV in 2C); liver disease severity (cirrhosis from 28.9 to 17.8% from 1C to 2C); non-viral disease co-factors [higher overweight (27.6–36.6%) and metabolic syndromes (9.6–16.2% in 2C)]; previous therapy [untreated (78.5–88.7% in 2C)]. The HCC prevalence decreased not significantly (6.3% in 1C, 4.3% 2C). Primary infections raised (3.1–4.5%) in non-vaccinated Italians with HBV-genotypes prevalent in immigrants.

<sup>a</sup>Grey Zone: HBeAg positive/HBeAg negative individuals with viremia persistently <20000 IU/mL and normal ALT.

Figure:

**Conclusion:** The HBV infection epidemiology significantly changed in Italy over the last decades driven by the effective national policy of HBV burden control and increasing immigration from highly endemic areas. Tracing the dynamics of these changes will foster the most appropriate healthcare strategies for an effective control of HBV infection, higher adherence to general vaccination and timely antiviral treatment.

### PO-2366

#### Non-alcoholic fatty liver disease in chronic hepatitis B patients: patients' characterization and impact on disease progression

Yana Davidov<sup>1</sup>, Fadi Abu Baker<sup>1,2,3</sup>, Ilan Green<sup>3</sup>, Orna Mor<sup>4</sup>, Yael Gozlan<sup>4</sup>, Ziv Ben Ari<sup>1</sup>. <sup>1</sup>Sheba Medical Center, Hepatology, Ramat Gan, Israel; <sup>2</sup>Hillel Yaffe Medical Center, Hadera, Israel; <sup>3</sup>Leumit Health Care Services, Holon, Israel; <sup>4</sup>Sheba Medical Center, Virology Lab., Ramat Gan, Israel

Email: Fa\_fd@hotmail.com

**Background and aims:** Concomitant non-alcoholic fatty liver disease (NAFLD) is common in patients with chronic hepatitis B (CHB) infection, although its impact on liver-related outcomes remains controversial. We aimed to evaluate the effect of NAFLD on the course, phenotype, management and outcome of patients with CHB. **Method:** We performed a large retrospective cohort study utilizing the Leumit-Health-Service database in Israel. Electronic reports of 692106 members were reviewed between 2000 and 2019 and patients with CHB diagnosis based on ICD-9-CM codes and serology results were included. Patients with excessive alcohol consumption (>2 drinks per day) were excluded. CHB phase was determined in concordance with the EASL guidelines based on HBeAg status, ALT, HBV viral load and pathology results when available. Patients who had liver imaging during follow-up period were included for final analysis. Accordingly, patients diagnosed with NAFLD by imaging were included in the CHB-NAFLD group, while those with CHB but without NAFLD comprised the control group. We evaluated demographics, risk factors, habits, laboratory results, disease course and treatment. Outcome including cirrhosis and hepatocellular carcinoma (HCC) based on relevant ICD-9-CM as well as the rate of advanced fibrosis (FIB-4 >2.65 and/or APRI >1.5) based on laboratory

data at the end of the study period were compared between both groups.

**Results:** A total of 1166 patients with CHB were included. Of these, 179 (15.35%) had a diagnosis of NAFLD and were included in the CHB-NAFLD group. Patients in the CHB-NAFLD group were significantly older (44.6 ± 12.6 vs. 39 ± 14.2; P < 0.001) and had a more prominent male predominance (64.6% vs. 57.4%; P = 0.069). As expected, obesity (BMI > 30) (46.6% vs. 24.4%; P < 0.01) and diabetes mellitus (DM) (35.8% vs. 17.4%; P < 0.01) were significantly higher in CHB-NAFLD patients. CHB-NAFLD group was distinguished by higher levels of ferritin (165 ± 84 vs. 101 ± 19; P < 0.01) and triglycerides (150 ± 85 vs. 116 ± 71; P < 0.01). The HBeAg negative chronic infection phase was predominant in both groups. The vast majority of CHB-NAFLD patients (96.9%) were HBeAg negative at time of diagnosis. CHB-NAFLD patients had higher rates of HBeAg negative hepatitis (34.2% vs. 25%; P = 0.001). Moreover, HBeAg seroclearance rate was lower in these patients (1.7% vs. 4.4%; P = 0.029). Interestingly, patients with CHB-NAFLD had comparable outcome to the control group as the rate of cirrhosis (2.8% vs 1.9%; P = 0.003), advanced fibrosis (6.2% vs. 5.8%; P = 0.435) and HCC didn't differ significantly between the groups. In multivariate analysis, DM (HR 2.845, CI 1.146–7.061; P = 0.0024) but not NAFLD, was independently associated with cirrhosis and advanced fibrosis development.

**Conclusion:** Concomitant NAFLD and CHB is distinctive by features of the metabolic syndrome and HBeAg negativity but has similar outcome to CHB without NAFLD.

### PO-2484

#### Nomogram for predicting significant liver injury in chronic hepatitis B patients with immune tolerance

Chun-yan Wang<sup>1</sup>, Ya Deng<sup>2</sup>, Chang Guo<sup>1</sup>, Dong Ji<sup>1,2,3</sup>. <sup>1</sup>Fifth medical center of chinese PLA general hospital, Department of liver diseases, Beijing, China; <sup>2</sup>Southern Medical University, The Second School of Clinical Medicine, Guangzhou, China; <sup>3</sup>Peking University 302 Clinical Medical School, Beijing, China

Email: jidg302@126.com

**Background and aims:** While current guidelines advise against starting antiviral treatment for immune-tolerant CHB (IT-CHB) patients, some new data have shown that about 10% to 49% IT-CHB patients had significant liver injury (liver inflammation grade ≥G2 and/or liver fibrosis stage ≥S2) by liver biopsy (LB) proven. Whether IT-CHB patients should be treated with antiviral therapy still remains under debate. The aim of our study is to identify the high-risk factors of significant liver injury in IT-CHB patients and establish a nomogram prediction model.

**Methods:** IT-CHB patients who underwent LB at the Fifth Medical Center of the PLA General Hospital, from August 2002 to December 2017, were retrospectively enrolled. The criteria of IT-CHB met the definition of AASLD 2018 hepatitis B guidance. The eligible patients were assigned to two groups based on significant liver damage (≥G2/S2) or not. High-risk factors were identified by univariate and multivariate logistic regression, and then were incorporated into a nomogram model. The discrimination and calibration of the novel nomogram were assessed by concordance index (C-index) and calibration with 1000 bootstrap sampling.

**Results:** A total of 382 IT-CHB patients were enrolled, with an average age of 33.3 ± 10.2 years, males accounted for 68.3%, 57.9% had family history of hepatitis B, median HBV DNA was 8.4 log<sub>10</sub> IU/ml, and 21.5% had significant liver damage. Logistic regression analysis showed that age (OR = 1.074, 95%CI: 1.043 ~ 1.107, p < 0.001), HBV DNA load (OR = 0.442, 95%CI: 0.314 ~ 0.624, p < 0.001), AST (OR = 1.096, 95%CI: 1.051 ~ 1.142, p < 0.001) and PLT (OR = 0.992, 95%CI: 0.986 ~ 0.998, p = 0.006) were independent high-risk factors associated with significant liver injury. Based on the above factors, a nomogram model was established, which achieved good C-index of 0.845, and had well-fitted calibration curves. The area under ROC was 0.845 (95%CI: 0.795 ~ 0.895), which was significantly better than

Figure: (abstract: PO-2484)

APRI (0.781, 95%CI: 0.723 ~ 0.840) and FIB-4 (0.802, 95%CI: 0.746 ~ 0.859).

**Conclusions:** The proportion of IT-CHB patients with significant liver injury is not rare. Incorporating age, HBV DNA, AST, and PLT, the established nomogram model achieved good prediction accuracy, and can be used to predict significant liver damage in IT-CHB patients individually, reduce the need of LB, and provide a reference for precise antiviral treatment.

**Key words:** Hepatitis B; chronic; immune tolerance; IT-CHB; nomogram; significant liver injury

**PO-2575**

**Restoration of HBV-specific immune responses with therapeutic vaccine BRII-179 (VBI-2601) in chronic HBV patients in a phase 1b/2a study**

Haiyan Ma<sup>1</sup>, Tien Huey Lim<sup>2</sup>, Apinya Leerapun<sup>3</sup>, Martin Weltman<sup>4</sup>, Ji-Dong Jia<sup>5</sup>, Young-Suk Lim<sup>6,7</sup>, Pisit Tangkijvanich<sup>8</sup>, Wattana Sukeepaisarnjaroen<sup>9</sup>, Nina Le Bert<sup>1</sup>, Yun Ji<sup>10</sup>, Dong Li<sup>10</sup>, Yao Zhang<sup>10</sup>, Robert Hamatake<sup>10</sup>, Simone Strasser<sup>11</sup>, Chunming Li<sup>10</sup>, Huiquo Ding<sup>12</sup>, Jung-Hwan Yoon<sup>13</sup>, Stace Nigel<sup>14</sup>, David Anderson<sup>15</sup>, Li Yan<sup>10</sup>, Antonio Bertoletti<sup>1</sup>, Qing Zhu<sup>10</sup>, Man-Fung Yuen<sup>16</sup>. <sup>1</sup>Duke-NUS Medical School, Singapore; <sup>2</sup>Middlemore Hospital, New Zealand; <sup>3</sup>Maharaj Nakorn Chiang Mai Hospital, Thailand; <sup>4</sup>Nepean Hospital, Kingswood, Kingswood, Australia; <sup>5</sup>Beijing Friendship Hospital, Beijing, China; <sup>6</sup>Asan Medical Center, Seoul, Korea, Rep. of South; <sup>7</sup>Asan Medical Center, University of Ulsan College of Medicine, Korea, Rep. of South; <sup>8</sup>King Chulalongkorn Memorial Hospital, Bangkok, Thailand; <sup>9</sup>Srinagarind Hospital, Khon Kaen, Thailand; <sup>10</sup>Brii Biosciences, Durham, United States; <sup>11</sup>Royal Prince Alfred Hospital, Camperdown, Australia; <sup>12</sup>Beijing You 'an Hospital, Beijing, China; <sup>13</sup>Seoul National University Hospital, Seoul, Korea, Rep. of South; <sup>14</sup>Capital and Coast District Health Board, Wellington, New Zealand; <sup>15</sup>VBI Vaccines, Cambridge, United States; <sup>16</sup>The University of Hong Kong, Hong Kong, China  
Email: mfyuen@hku.hk

**Background and aims:** Functional cure of chronic HBV infection without life-long treatment requires a restoration of compromised HBV-specific T and B cell immunity. Therapeutic vaccines based on the major structural (core and S) and non-structural proteins (polymerase) have been tested in chronic HBV (CHB) patients but have shown scarce immunogenicity. BRII-179, also known as VBI-2601, is a virus-like particle-based therapeutic vaccine produced in CHO cells using the same manufacturing process as Sci-B-Vac®, a preventative vaccine. BRII-179 is a new formulation and higher dose of all three HBV envelope proteins (Pre-S1, Pre-S2, and S). Safety, immunogenicity, and early antiviral activity of BRII-179 admixed with IFN-alpha as co-adjuvant were assessed in a phase 1b/2a study in CHB patients.

**Method:** This randomized, open-label, controlled study included two dose levels, 20 mcg BRII-179 (Part 1; n = 25) and 40 mcg BRII-179 (Part 2 n = 24). Non-cirrhotic CHB patients, virally suppressed under nucleos (t)ide analog (Nrtl) therapy were randomized 1:2:2 into 3 cohorts in Part 1 and 1:1 to 2 cohorts in Part 2 to receive 4 monthly intramuscular injections of BRII-179 admixed with or without 3 MIU IFN-alpha. Antibody and cellular responses to surface antigens, as well as evolution of circulating HBsAg were monitored.

**Results:** Both dose levels of BRII-179 (20 mcg and 40 mcg) with/without IFN-alpha administered through intramuscular injection were safe and well-tolerated across all cohorts without severe adverse event. BRII-179 induced anti-HBs antibody response in >30% patients in all treated cohorts, however, moderate anti-PreS1 or anti-PreS2 antibody responses were only observed in patients receiving BRII-179 admixed with IFN-alpha. BRII-179 also restored and/or boosted S-, Pre-S1-, Pre-S2-specific IFN-gamma producing T cells in the majority of treated patients evaluated. Overall, no or minimal reduction of HBsAg was observed after 4 doses of BRII-179 treatment.

Figure:

**Conclusion:** In CHB patients under Nrtl therapy, BRII-179 with and without IFN-alpha co-adjuvant exhibited a good safety and tolerability profile. A limited number of doses of BRII-179 containing S, Pre-S1 and Pre-S2 antigens induced B and T cell responses in CHB patients. Restoration of HBV immune responses did not modify the HBsAg level during the study. These data support further clinical evaluation of BRII-179 as an immunomodulator in combination with other treatment modalities for functional cure.

## POSTER PRESENTATIONS

### PO-2637

#### In HBeAg-negative patients within grey zone, serum HBV-RNA levels are higher and more commonly detected, while intrahepatic markers are similar

Adriana Palom<sup>1</sup>, Mar Riveiro Barciela<sup>1,2</sup>, Sofía Pérez-del-Pulgar<sup>2,3</sup>, Luisa Roade<sup>1</sup>, David Tabernero<sup>2,4</sup>, Alison Kuchta<sup>2,3</sup>, Thais Leonel<sup>2,3</sup>, Mireia García-López<sup>2,3</sup>, Ariadna Rando<sup>2,4</sup>, Francisco Rodríguez-Frías<sup>2,4</sup>, Rafael Esteban<sup>1,2</sup>, Maria Buti<sup>1,2</sup>. <sup>1</sup>Hospital Universitari Vall Hebron, Universitat Autònoma de Barcelona, Barcelona, Spain, Liver Unit, Barcelona, Spain; <sup>2</sup>Instituto de Salud Carlos III, Centro de Investigación Biomédica en Red en el Área temática de Enfermedades Hepáticas, Madrid, Spain; <sup>3</sup>Hospital Clínic, University of Barcelona, IDIBAPS, Liver Unit, Barcelona, Spain; <sup>4</sup>Hospital Universitari Vall d'Hebron, Barcelona, Spain, Liver Pathology Unit (Biochemistry and Microbiology departments, Clinical Laboratories), Barcelona, Spain  
Email: mbuti@vhebron.net

**Background and aims:** Serum hepatitis B virus RNA (HBV-RNA) has been reported to be a surrogate marker of intrahepatic cccDNA in HBeAg-positive patients. However, there are scarce data on HBeAg negative subjects. The aim of the study was to evaluate the correlation between HBV-RNA and intrahepatic HBV markers in HBeAg negative patients within the grey zone (HBV-DNA >2000 IU/ml).

**Method:** Collaborative study that included 74 HBeAg negative patients in the grey zone (HBV-DNA >2000 IU/ml plus normal or slightly increased ALT) and were classified according to the EASL guidelines after the performance of a liver biopsy as CHB (N = 22) and IC (N = 52). HBV-RNA was determined by an automated standardized technique (Cobas<sup>®</sup> HBV-RNA test Roche; LLQ 10 cop/ml, LLD 6.6 cop/ml), as well as qHBsAg and HBcrAg. In a subgroup of patients (N = 22) intracellular markers were also quantified in fresh-frozen liver biopsies.

**Results:** 74 naïve HBeAg negative patients were included: 38 (51.5%) male, age 47 ± 14 years, 58% Caucasian, 30% African. HBV-RNA could be performed in 63 subjects. HBV-RNA was detected in all CHB and in 72% IC (p = 0.01), with higher median levels in the CHB group (2.3 vs 0.8 log<sub>10</sub> IU/ml, p < 0.001). Overall, CHB subjects had higher levels of liver stiffness (LS), ALT and HBV markers (HBV-DNA, qHBsAg, HBcrAg). The marker with the highest AUROC for CHB identification was HBV-RNA (0.868), followed by HBcrAg (0.774), HBV-DNA (0.754), APRI (0.700) and LS (0.663). 93% of subjects with HBV-RNA <1 log<sub>10</sub> IU/ml were ICs. A high correlation between HBV-RNA and HBcrAg (R = 0.815) and HBV-DNA (0.797) was observed. No correlation was found with qHBsAg (R = 0.264). In the 22-patient subgroup with a fresh liver biopsy (7 CHB and 15 ICs), no significant differences were observed in intracellular levels of HBV-RNA, HBV-DNA, cccDNA or cccDNA transcriptional activity between CHB and IC (table). Overall, there was a positive correlation between HBcrAg and intracellular HBV-DNA (R = 0.64, p = 0.003) and with intracellular HBV-RNA (R = 0.5, p = 0.03) but not with plasmatic HBV-RNA or other intracellular markers. In CHB subjects, a trend was observed between plasmatic HBV-RNA and cccDNA (R = 0.795), absent in ICs (R = -0.148).

	CHB (N = 7)	IC (N = 15)	p value
<i>Serum HBV markers</i>			
DNA (log IU/ml)	5.4 (4.9–5.8)	3.9 (3.8–4.1)	<0.001
qHBsAg (Log IU/ml)	4.3 (4.2–4.6)	3.5 (3.1–3.8)	0.004
HBcrAg (Log U/ml)	3.7 (2.6–4.4)	2.6 (2.3–2.8)	0.046
RNA (cop/ml)	2.4 (1.3–4.4)	1.3 (0.5–1.6)	0.019
<i>Intrahepatic HBV markers</i>			
DNA (cop/cell)	2.6 (0.0–12.2)	1.0 (0.7–2.2)	0.237
RNA (cop/25 ng total RNA)	79.0 (25.1–405.5)	56.2 (9.8–136.2)	0.400
cccDNA (cop/cell)	0.8 (0.4–2.4)	1.2 (0.5–1.5)	0.694
cccDNA transcriptional activity	104.1 (58.0–5682.0)	101.7 (6.3–214.1)	0.718

Median (IQR)

**Conclusion:** In HBeAg negative subjects within the grey zone, those with CHB present higher HBV-RNA and HBcrAg levels than ICs, while intrahepatic markers are similar.

### PO-2834

#### HBsAg protein composition differs across stages of hepatitis B and hepatitis Delta: a validation cohort study

Luisa Roade<sup>1,2</sup>, Sara Sopena Santistevé<sup>2,3</sup>, Maria Pfefferkorn<sup>4</sup>, Mar Riveiro Barciela<sup>1,2</sup>, Adriana Palom<sup>1</sup>, Marta Bes<sup>2,5</sup>, Rosario Casillas<sup>3</sup>, David Tabernero<sup>2,3</sup>, Francisco Rodríguez-Frías<sup>2,3</sup>, Thomas Berg<sup>4</sup>, Rafael Esteban<sup>1,2</sup>, Florian van Bömmel<sup>4</sup>, Maria Buti<sup>1,2</sup>. <sup>1</sup>Hospital Universitari Vall d'Hebron, Liver Unit, Barcelona, Spain; <sup>2</sup>Instituto de Salud Carlos III, Madrid, Spain, Centro de Investigación Biomédica en Red en el Área temática de Enfermedades Hepáticas, Spain; <sup>3</sup>Hospital Universitari Vall d'Hebron, Biochemistry and Microbiology Unit, Clinical Laboratories, Barcelona, Spain; <sup>4</sup>Leipzig University medical center, Division of Hepatology, Department of Medicine, Leipzig, Germany; <sup>5</sup>Banc de Sang i Teixits, Transfusion Safety Laboratory, Barcelona, Spain  
Email: mbuti@vhebron.net

**Background and aims:** The components of the hepatitis B virus (HBV) surface antigen (HBsAg) small, medium and large surface proteins (SHBs, MHBs and LHBs) were proposed as novel tool to differentiate stages of chronic hepatitis B (CHB), including chronic hepatitis delta virus co-infection (CHD). We aimed to validate these findings independently in a well-characterized cohort with CHB or CHD infection, and at assessing a possible impact of HBV genotypes (GT).

**Method:** We performed a retrospective analysis in serum samples of 216 patients from an academic hospital in Barcelona (Spain). This population included 160 treatment-naïve patients with HBeAg negative chronic HBV infections: 86 chronic HBV infection/inactive carriers (ICs), 39 low viremic-LV subjects (normal ALT, HBV DNA >2000 IU/ml and absence of fibrosis), 35 HBeAg negative CHB; as well as 56 CHD patients (47 with detectable HDV RNA). MHBs and LHBs proteins were measured by ELISA in serum samples stored at -20°C. The proportion of each component was calculated based on total HBsAg levels (log<sub>10</sub> ng/ml; Siemens Healthcare, Enzygnost HBsAg 6.0). Results of IC were compared with those obtained in CHB and LV subjects analyzed altogether.

**Results:** Patients with HBeAg negative CHB had higher total HBsAg levels than IC patients (3.9 vs 3.4 log<sub>10</sub> IU/ml, p = 0.002). No differences in HBsAg levels were observed between CHB and ICs with HBsAg ≥1,000 IU/ml (p = 0.555). However, IC patients with HBsAg ≥1,000 IU/ml had significantly lower LHBs proportions compared to CHB patients (p = 0.036), regardless of HBV DNA levels. In both CHB and ICs, proportions of LHBs differed according to HBV genotype (GT) (Figure). Thus, HBV GT D patients showed higher LHBs levels as compared to GT A. In CHD patients, HBsAg levels were higher in those with detectable HDV RNA (p = 0.011). These patients also had higher LHBs ratios than those with undetectable HDV RNA (median 6.2 vs 3.2, p = 0.047). The LHBs proportion was similar between CHD patients with undetectable HDV RNA and ICs (median 3.2% vs. 3.4%, p = 0.289). No differences in MHBs proportions were found across all patient groups (p = 0.086).

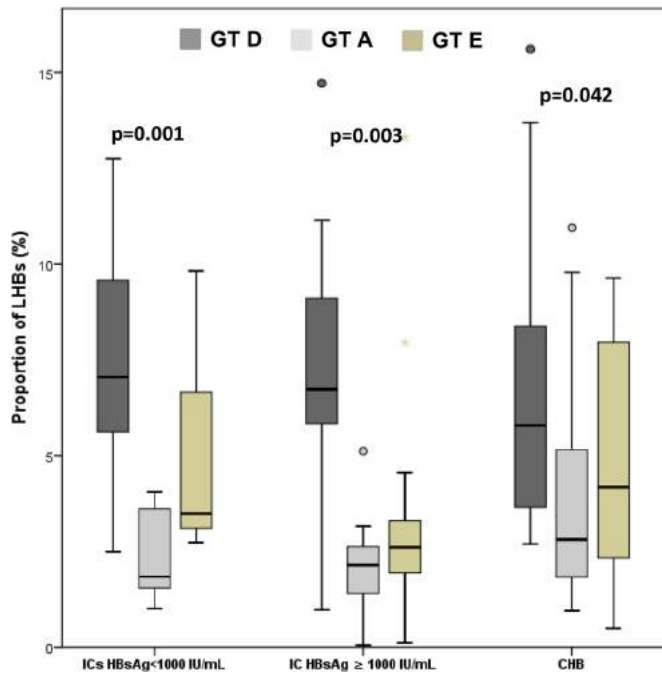

Figure:

**Conclusion:** Our results validated previous findings that ICs have lower LHBs ratios compared to patients with HBeAg negative CHB. They support the quantification of HBsAg components as a valuable clinical tool for CHB, and possibly also for CHD patients. HBV GT has a significant impact on LHBs proportion that needs to be further researched.

## Viral hepatitis B-D: therapy

### PO-43

#### Preliminary pharmacokinetics and safety in healthy volunteers of VIR-3434, a monoclonal antibody for the treatment of chronic hepatitis B infection

Sneha V. Gupta<sup>1</sup>, Andre Arizpe<sup>1</sup>, Marie C. Fanget<sup>1</sup>, Sanjay Dholakiya<sup>1</sup>, Ling Shen<sup>1</sup>, Phil Pang<sup>1</sup>, Chin Tay<sup>1</sup>, Daniel Cloutier<sup>1</sup>, Erik Mogalian<sup>1</sup>, Edward Gane<sup>2</sup>. <sup>1</sup>Vir Biotechnology, San Francisco, United States; <sup>2</sup>University of Auckland, Auckland Clinical Studies, Auckland, New Zealand

Email: sgupta@vir.bio

**Background and aims:** VIR-3434 is a fully human, monoclonal antibody in development for the treatment of chronic hepatitis B virus (HBV) infection with three distinct modes of action: 1) entry inhibition via neutralization of all 10 HBV genotypes in vitro, 2) reduction of circulating HBsAg-containing particles in vivo, and 3) potential therapeutic vaccination via Fc engineering. Preliminary blinded pharmacokinetic (PK) and safety data from a Phase 1 study evaluating VIR-3434 in healthy volunteers is presented herein

**Method:** This is an ongoing randomized, double-blind, placebo-controlled Phase 1 single ascending dose study evaluating VIR-3434 in healthy volunteers (Part A) and participants with chronic HBV infection who are receiving nucleos(t)ide reverse transcriptase inhibitor (NRTI) therapy (Parts B-C). In Part A, healthy adults were randomized 3:1 to receive a single dose of VIR-3434 or placebo. Doses of 90, 300, and 900 mg were administered subcutaneously (SC), and doses of 900 and 3,000 mg were administered intravenously (IV). Subjects were followed for safety, tolerability, PK, and immunogenicity for 24 weeks following study drug administration.

**Results:** Forty-one subjects (n = 8 per cohort, with 1 subject replaced for non-safety related reasons) were enrolled and received VIR-3434 or placebo. Preliminary PK data for the 90–900 mg SC cohorts (N = 18) and blinded safety data for all cohorts (N = 41) are reported here. VIR-3434 was absorbed after SC injection with a median T<sub>max</sub> of 7 days and has a half-life of approximately 28 days. Based on available data, exposure (C<sub>max</sub> and AUC) increased in a dose proportional manner across the range of 90–900 mg. Intersubject variability within each cohort was generally low (CV ~35%). VIR-3434 was well tolerated across doses of 90–3,000 mg. A total of 24/41 (59%) subjects experienced adverse events (AEs), which were predominantly Grade 1. No serious adverse events (SAEs) were reported, and no clinically significant effects on laboratory parameters or electrocardiograms were observed.

**Conclusion:** VIR-3434 was well tolerated in healthy volunteers following single doses of up to 3,000 mg. VIR-3434 demonstrated favorable PK properties in healthy volunteers supportive of SC dosing and continued development for the treatment of chronic HBV infection. Additional data from this ongoing study, including PK from IV doses, will be presented.

### PO-80

#### End-of-treatment HBsAg, HBcrAg and HBV RNA levels predict sustained response and HBsAg loss in chronic hepatitis B patients

Sylvia Brakenhoff<sup>1</sup>, Robert De Knecht<sup>1</sup>, Margo J.H. van Campenhout<sup>1</sup>, Annemiek Van der Eijk<sup>2</sup>, Willem Pieter Brouwer<sup>1</sup>, Florian van Bömmel<sup>3</sup>, Andre Boonstra<sup>1</sup>, Bettina Hansen<sup>4,5</sup>, Thomas Berg<sup>3</sup>, Harry Janssen<sup>4</sup>, Robert De Man<sup>1</sup>, Milan Sonneveld<sup>1</sup>. <sup>1</sup>Erasmus MC, University Medical Center, Gastroenterology and Hepatology, Rotterdam, Netherlands; <sup>2</sup>Erasmus MC, University Medical Center, Viroscience, Rotterdam, Netherlands; <sup>3</sup>Leipzig University Medical Center, Division of Hepatology, Department of Medicine II, Leipzig, Germany; <sup>4</sup>Toronto General Hospital, University Health Network, Toronto Center for Liver Disease, Toronto, Canada; <sup>5</sup>University of Toronto, Institute of Health Policy, Management and Evaluation, Toronto, Canada Email: s.brakenhoff@erasmusmc.nl

**Background and aims:** We recently demonstrated that high end-of-treatment (EOT) HBV RNA, HBsAg and HBcrAg levels are associated with an increased risk of off-treatment ALT flares. We aimed to assess the relationship between EOT serum hepatitis B biomarkers with sustained response and HBsAg loss.

**Method:** We studied chronic hepatitis B patients who participated in 3 global randomised controlled trials of peginterferon-based therapy (99-01 [PEG-IFN vs PEG-IFN + lamivudine], PARC [PEG-IFN vs PEG-IFN + ribavirin] and ARES [entecavir with PEG-IFN add-on]). Serum HBsAg, HBV RNA and HBcrAg were quantified at EOT. Associations between serum biomarkers and treatment response were assessed using continuous data and after categorisation (low vs high; <3/>3 log for HBsAg, undetectable/detectable for HBV RNA, and for HBcrAg <3/>3 log HBeAg-negative and <6/>6 log for HBeAg-positive patients). SCALE-B score (comprising HBsAg and HBcrAg) was calculated and categorised (<260, 260–320, ≥320). Treatment response was defined as sustained response (SR; HBV DNA levels <2,000 IU/ml 6 months after EOT) and HBsAg loss. We excluded patients who were HBsAg-negative at EOT.

**Results:** We included 344 patients with EOT data; 230 HBeAg-positive and 114 HBeAg-negative. Patients were predominantly Caucasian (77.0%) and had genotype A/B/C/D in 23/7/13/52%. SR was achieved in 57/311 (18.3%) and HBsAg loss in 6 (1.8%) patients. Lower HBsAg (OR 0.480, 95% CI 0.371–0.621, p < 0.001), HBV RNA (OR 0.119, 95% CI 0.017–0.807, p = 0.029) and HBcrAg (OR 0.658, 95% CI 0.565–0.767, p < 0.001) levels were associated with higher probability of SR (Figure) and HBsAg loss. Combinations of biomarkers improved prediction. Among 65 patients with both high HBV RNA and HBsAg levels, 2 (3.1%) achieved SR, compared to 23/36 patients (63.9%) with both low levels (p < 0.001; Figure). HBsAg loss was exclusively observed in patients with both low levels of HBsAg and HBV RNA

## POSTER PRESENTATIONS

(7.3% vs 0.0%,  $p = 0.004$ ). Findings were consistent when data was stratified based on HBeAg-status and in multivariate analysis adjusted for potential predictors including HBeAg-status and EOT response (HBV DNA  $< 200$  IU/ml).

Figure: Rates of sustained response (HBV DNA  $< 2,000$  IU/ml 6 months after treatment withdrawal), according to HBsAg, HBcrAg and HBV RNA levels at end-of-treatment.

**Conclusion:** Lower EOT HBsAg, HBcrAg and HBV RNA levels are associated with higher probability of sustained response and HBsAg loss after therapy cessation. Combinations of biomarkers improved response prediction, supporting the use of combined biomarkers as treatment end points in HBV trials.

### PO-111

#### One-year safety results of the Nuc-Stop Study, an open-label study on stopping antiviral therapy in HBeAg negative chronic hepatitis B

Asgeir Johannessen<sup>1</sup>, Dag Henrik Reikvam<sup>2</sup>, Soo Aleman<sup>3</sup>, Nega Berhe<sup>4</sup>, Nina Weis<sup>5</sup>, Lars Heggelund<sup>6</sup>, Lars Normann Karlsen<sup>7</sup>, Pascal Brugger-Synnes<sup>8</sup>, Hans Erling Simonsen<sup>9</sup>, Jan Svendsen<sup>10</sup>, Olav Dalgard<sup>11</sup>, <sup>1</sup>Sykehuset i Vestfold, Tønsberg, Norway; <sup>2</sup>Oslo University Hospital Ullevål, Oslo, Norway; <sup>3</sup>Huddinge Hospital, Sweden; <sup>4</sup>Addis Ababa University, Addis Ababa, Ethiopia; <sup>5</sup>Hvidovre Hospital, Hvidovre, Denmark; <sup>6</sup>Drammen sykehus, Norway; <sup>7</sup>Stavanger Universitetssjukehus-SUS, Norway; <sup>8</sup>Ålesund Sykehus, Norway; <sup>9</sup>Nordland Hospital, Bodø, Bodø, Norway; <sup>10</sup>Vestre Viken-Baerum Hospital, Norway; <sup>11</sup>Akershus University Hospital, Lørenskog, Norway  
Email: johannessen.asgeir@gmail.com

**Background and aims:** Antiviral therapy effectively reduces the risk of complications in chronic hepatitis B (CHB). However, treatment is indefinite as a functional cure, defined as loss of hepatitis B s-antigen (HBsAg), rarely occurs with antiviral therapy. Stopping antiviral therapy may trigger an immune response which induces HBsAg loss, but there is concern about the safety of this intervention. Here we present one-year safety results of the Nuc-Stop Study, a randomized, multicentre, open-label trial of stopping antiviral therapy in hepatitis B e-antigen (HBeAg) negative CHB patients.

**Method:** HBeAg negative CHB patients with at least 24 months of full viral suppression were eligible for inclusion. Patients with past or present evidence of cirrhosis were excluded. All study participants stopped antiviral therapy and were randomized to either low threshold (alanine aminotransferase [ALT]  $> 80$  U/L and viral load  $> 2000$  IU/ml) or high threshold (ALT  $> 100$  U/L for  $> 4$  months or ALT  $> 400$  U/L for  $> 2$  month) for re-start of therapy. Patients in both groups re-started therapy in case of a severe flare, defined as ALT  $> 800$  U/L or any ALT flare with INR  $\geq 1.4$  or bilirubin  $> 38$  mmol/L.

**Results:** A total of 127 patients were included at 11 centres in Norway, Sweden, Denmark and Ethiopia; 86 (67.7%) were men and median age was 43 years (range 25–66). Median duration of antiviral treatment prior to inclusion was 45 months (interquartile range 32–76), and most patients were receiving either tenofovir disoproxil fumarate (TDF;  $n = 90$ ; 70.9%) or entecavir ( $n = 30$ ; 23.6%). During the initial 12 months after treatment cessation, 108 patients (85.0%) experienced virological relapse (viral load  $> 2000$  IU/ml) and 44

(34.6%) had clinical relapse (ALT  $> 80$  U/L and viral load  $> 2000$  IU/ml). Nine patients (7.1%) had a severe flare (maximum ALT 2600 U/L), one of whom had bilirubin  $> 38$  mmol/L. The occurrence of a severe flare was neither associated with age, sex nor duration of previous antiviral treatment; however, all nine occurred among patients who stopped TDF therapy. No other serious adverse events related to treatment interruption were observed.

**Conclusion:** Stopping long-term nucleoside analogue therapy was safe among non-cirrhotic HBeAg negative CHB patients, although one in ten patients stopping TDF therapy experienced a severe flare.

### PO-247

#### On-treatment HBsAg kinetics can predict HBsAg loss after nucleos(t)ide analogues interruption in HBeAg negative patients

Teresa Broquetas<sup>1,2,3</sup>, Juan-Jose Hernandez<sup>4</sup>, Montserrat Garcia-Retortillo<sup>1,2,3</sup>, Lidia Canillas<sup>1,3</sup>, Marc Puigvehí<sup>1,2,3</sup>, Nuria Cañete Hidalgo<sup>1,2,3</sup>, Susana Coll<sup>1,2,3</sup>, Ana Viu<sup>1,3</sup>, Esther Garrido<sup>1,3</sup>, Judit Romero<sup>1,3</sup>, Xavier Bessa<sup>1,2,3</sup>, Jose A. Carrión<sup>1,2</sup>. <sup>1</sup>Hospital del Mar, Liver Section, Gastroenterology Department, Barcelona, Spain; <sup>2</sup>Universitat Autònoma de Barcelona, Medicina, Bellaterra, Spain; <sup>3</sup>IMIM, Barcelona, Spain; <sup>4</sup>Laboratori de Referència de Catalunya, Spain  
Email: 95565@parcdesalutmar.cat

**Background and aims:** Studies in Asian and Caucasian patients with HBeAg-negative chronic hepatitis B (CHB) have shown that nucleos(t)ide analogues (NA) withdrawal after a long-term viral suppression, can improve HBsAg loss rates. However, there are not well-established conditions during therapy to select patients who will benefit from this strategy. The aim of the study was to evaluate HBsAg kinetics before and after treatment interruption.

**Method:** Single centre, longitudinal, ambispective study in non-cirrhotic CHB HBeAg-negative patients analysing HBsAg levels before and after NA withdrawal. Patients were eligible if they had been under NA therapy for at least 3 years. HBsAg levels were evaluated before NA initiation, at 1 and 3 years of therapy, at end of treatment, and at weeks 12, 24, 36, 48, 72 and 96 post-treatment. We report the results 48 weeks after NA interruption.

**Results:** From December 2017 to October 2019, 75 patients were evaluated, 17 (23%) declined participation, and serum samples were suboptimal in 6. Therefore, HBsAg kinetics before and after NA interruption were evaluated in 52, 75% males, median age of 52 years, treatment duration of 8.2 years, 65% with TDF, and 56% infected by genotype D. During 48 weeks after NA interruption, 6 (11.5%) patients lost HBsAg. Multivariate analysis showed that on-treatment HBsAg decline was independently associated with HBsAg loss after NA interruption (OR = 0.10; 95%CI = 0.016–0.632;  $p = 0.014$ ). Patients with an HBsAg decline  $> 1 \log_{10}$  IU/ml ( $n = 10$ ) showed lower HBsAg levels before interruption (114 vs. 1277;  $p = 0.001$ ) despite before NA initiation were similar (3330 vs. 3891;  $p = ns$ ). Therefore, 50% of patients with HBsAg decline  $> 1 \log_{10}$  IU/ml or HBsAg  $< 100$  before NA interruption achieved HBsAg loss during the first year after treatment withdrawal ( $p = 0.001$ ).

**Conclusion:** Kinetics of HBsAg during antiviral treatment can predict the frequency of HBsAg loss after NA interruption. Half of the patients with a significant HBsAg decline ( $> 1 \log_{10}$  IU/ml) or HBsAg  $< 100$  IU/ml during therapy can eliminate HBsAg during the first year after NA withdrawal.

PO-397

**Novel hepatitis B virus gene expression inhibitor in clinical development**

Yixin Zhou<sup>1</sup>, Wenqiang Wu<sup>1</sup>, Shikui Chen<sup>1</sup>, Zhou Yu<sup>1</sup>, Neha Nagpal<sup>2</sup>, Suneet Agarwal<sup>2</sup>, Vadim Bichko<sup>1</sup>, John Mao<sup>1</sup>, Yanbin Hu<sup>3</sup>, Fei Sun<sup>3</sup>, Qiong Zhou<sup>3</sup>, Charles Z. Ding<sup>3</sup>, Shuhui Chen<sup>3</sup>. <sup>1</sup>Fujian Cosunter Pharmaceutical Co., Ltd., Fuzhou, China; <sup>2</sup>Boston Children's Hospital, Dana-Farber Cancer Institute, and Harvard Medical School, Boston, United States; <sup>3</sup>Domestic Discovery Service Unit, WuXi AppTec (Shanghai) Co., Ltd., Shanghai, China  
Email: vbichko@gmail.com

**Background and aims:** The currently used therapies for chronic hepatitis B virus (HBV) infection seldom achieve hepatitis B serum surface antigen (HBsAg) loss. However, HBsAg loss is considered one of the ultimate end points, leading to restoration of the immune function and achieving virus control. GST-HG131 is a small-molecule inhibitor of hepatitis B virus (HBV) gene expression that significantly reduces the levels of hepatitis B surface antigen (HBsAg) and HBV DNA in vitro and in HBV mouse models. Here we report preclinical characterization of GST-HG131, which is currently under phase I clinical evaluation.

**Methods:** Effects on HBsAg, hepatitis B e-antigen (HBeAg), HBV DNA and RNA were determined in HepG2.2.15 cells and in primary human hepatocytes (PHH), using ELISA, qPCR and northern blotting. Terminal nucleotidyl transferase 4B (TENT4B) binding and inhibition assays were done as previously described (Nagpal et al, Cell Stem Cell 2020 4;26 (6):896–909). The in vivo antiviral efficacy was assessed in the AAV-HBV mouse model.

**Results:** GST-HG131 potently inhibited secretion of HBsAg (EC<sub>50</sub> = 3.4 ± nM), HBeAg (EC<sub>50</sub> = 8 nM, and HBV DNA (EC<sub>50</sub> = 3.3 ± 1.7 nM) from HepG2 2.15 cells in the absence of cytotoxicity (CC<sub>50</sub> >100 microM), and was additive with Entecavir. The antiviral effects of GST-HG131 were not significantly affected (EC50 fold shift = 1.5) by 50% human serum. Secretion of both HBsAg and HBeAg by PHH was also strongly inhibited, with the EC<sub>50</sub> values of 18 and 19 nM, respectively). In cell culture experiments, GST-HG131 significantly reduced the level of HBV 2.4/2.1 kb RNAs, as well as 3.5 kb pre-genomic RNA, albeit to a lesser extent, in a concentration-dependent manner. It was shown that GST-HG131 binds recombinant TENT4B, and potently inhibits its enzymatic function in vitro, disrupting polyadenylation tail of mRNAs. No significant cytotoxicity was observed

in nine human cell lines and primary cells (CC<sub>50</sub> >10 microM). HBV inhibition by GST-HG131 was specific, as no other tested DNA and plus-/minus-strand RNA viruses were inhibited. In the AAV/HBV model, GST-HG131 demonstrated a robust dose-dependent reduction in serum HBsAg (~1 log<sub>10</sub>), following 28 days of dosing. Combination with Tenofovir resulted in additivity. GST-HG131 was well-tolerated, no significant effect on animal body weight was observed.

**Conclusions:** GST-HG131 is a novel, orally-bioavailable inhibitor of HBV gene expression. It has an excellent antiviral potency in vitro, efficacy in vivo, and is well-tolerated in rodents. The molecular mechanism of GST-HG131 antiviral action, including strong inhibition of HBsAg secretion, involves binding to and inhibition of TENT4B, leading to shortening of poly-adenylation tail of HBV mRNAs, and thus accelerating its degradation. Further development of GST-HG131 for chronic HBV infections is warranted. Currently GST-HG131 is undergoing phase I clinical evaluation.

PO-430

**High probability of reactive HBV-specific CD8 cells after stopping nucleos(t)ide analogue treatment forecast rapid HBsAg decrease in eAg (-) chronic hepatitis B**

Julia Peña Asensio<sup>1,2</sup>, Henar Calvo<sup>2,3</sup>, Joaquin Miquel<sup>2,3</sup>, Eduardo Sanz de Villalobos<sup>2,3</sup>, Alejandro González Praetorius<sup>2,4</sup>, Miguel Torralba<sup>2,5,6</sup>, Juan Ramón Larrubia<sup>2,3,6</sup>. <sup>1</sup>University of Alcalá, Departamento de Biología de Sistemas, Alcalá de Henares, Spain; <sup>2</sup>Guadalajara University Hospital, Translational Hepatology Unit, Guadalajara, Spain; <sup>3</sup>Guadalajara University Hospital, section of Gastroenterology and Hepatology, Guadalajara, Spain; <sup>4</sup>Guadalajara University Hospital, Section of Microbiology, Guadalajara, Spain; <sup>5</sup>Guadalajara University Hospital, Service of Internal Medicine, Guadalajara, Spain; <sup>6</sup>University of Alcalá, Department of Medicine and Medical Specialties, Alcalá de Henares, Spain  
Email: juan.larrubia@uah.es

**Background and aims:** Restoration of a reactive cytotoxic T cell response (RCTCR) during eAg (-) chronic hepatitis B (CHBeAg (-)) treatment with nucleos (t)ide analogue (NUC) could lead to functional cure. We developed a model to predict RCTCR with variables involved in T cell exhaustion. We tested the model as treatment stopping rule.

**Method:** In NUC treated CHBeAg (-), we checked for peripheral HBV-specific RCTCR detection. We performed a logistic regression model (LRM) to predict RCTCR probability, based on patients' age (infection

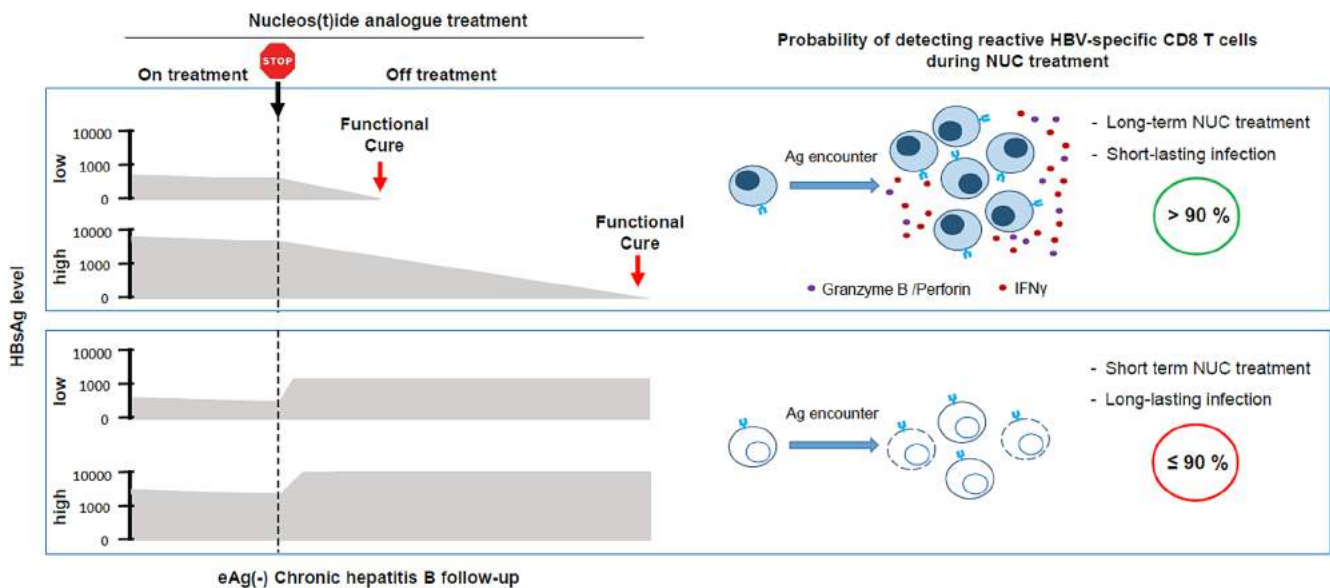

Figure: (abstract: PO-430)

## POSTER PRESENTATIONS

length), NUC treatment duration and HBsAg level (antigenic pressure). We stopped NUC treatment and assessed >50% HBsAg decline during follow-up, according to RCTCR probability.

**Results:** We observed a negative correlation between HBsAg and both treatment duration and patients' age. We found higher HBsAg level in short-term (ST) than in long-term (LT) treated cases. HBV-core18-27 and HBV-pol455-63 RCTCRs were more frequent, and interferon- $\gamma$  secreting cells were more prevalent in LT group. Peripheral HBV-env183-91-specific CD8 cells were deleted in both groups. LRM predicted HBV-core18-27 RCTCR presence which, correlated positively with treatment duration and negatively with age but not with HBsAg level. LRM explained 55% of the observed variability. After stopping treatment, HBsAg decline during 24-month median follow-up was faster in patients with RCTCR probability >90%, independently of HBsAg level at treatment stop, although HBsAg loss was higher in cases with HBsAg <1000 IU/ml.

**Conclusion:** Short-term Ag exposure rather than its level and long-lasting NUC treatment impact on RCTCR presence. High probability of RCTCR detection after NUC treatment withdrawal associates with rapid HBsAg reduction.

### PO-482

**Background and aims:** Vebicorvir (VBR) is a 1<sup>st</sup>-generation core inhibitor being developed for chronic HBV infection (CHBV). In Study 201, Nrtl-suppressed eAg pos or eAg neg CHBV patients (pts) with F0-F2 fibrosis were randomized to VBR or placebo +Nrtl for 24 wks. Eligible pts then received VBR+Nrtl in Study 211. VBR+Nrtl resulted in deep on-treatment viral suppression assessed by high sensitivity assays. VBR+Nrtl was discontinued if total HBV nucleic acid (DNA +pgRNA) was <20 U/ml and eAg negative or levels  $\leq$ 5 IU/ml for  $\geq$ 6 mths at Wk 52 or later. Here we report off-treatment (off-Rx) viral response and safety after VBR+Nrtl discontinuation (DC) in Study 211. **Method:** The primary end point in Study 211 was sustained virologic response (SVR; HBV DNA <20 IU/ml, COBAS TaqMan v2.0) 24 wks off-

treatment. eAg and sAg were measured by Abbott Architect (LLOQ = 0.11 IU/ml, 0.05 IU/ml, respectively) and crAg by Lumipulse G (LOD = 1 kU/ml). Safety was assessed by adverse events (AEs) and labs. Nrtl was restarted per protocol-specified criteria or investigator/pt preference.

**Results:** Of the pts in Study 211, 18 of 43 eAg pos and 23 of 26 eAg neg pts discontinued VBR+Nrtl. In these 41 pts, the mean age was 46 yrs, 71% male, 78% Asian, 80% on TFV and 20% on ETV. At time of DC, the mean duration of VBR treatment was 76 wks and Nrtl was 6 yrs; the eAg pos pts had mean eAg 1.1 IU/ml, crAg 247 kU/ml and sAg 6595 IU/ml and the eAg neg pts had mean crAg 7.0 kU/ml and sAg 2808 IU/ml. No pt achieved SVR. Of the 18 eAg pos pts, 17 (94%) relapsed early at off-treatment (off-Rx) Wk 4 and 1 pt (6%) relapsed at off-Rx Wk 12. Of the 23 eAg neg pts, 16 (70%) relapsed early at off-Rx Wk 4, and 3 (13%) and 4 (17%) pts relapsed later at off-Rx Wk 12 and 16, respectively. Univariate logistic regression identified ETV use ( $p < 0.001$ ) and lower crAg ( $p = 0.03$ ) as associated with later relapse after off-Rx Wk 4. The current mean time off-Rx was 19 wks with 29/41 (71%) pts restarting Nrtl with subsequent decline in HBV DNA. Off-Rx, 14/41 (34%) pts had AEs, most Grade 1 or 2. The most common AE was ALT elevation in 4/41 (10%) pts. No pt had confirmed ALT flare ( $\geq 10 \times$ ULN) or hepatic decompensation. Two unrelated SAEs were reported, hemorrhage following surgery and seizure.

**Conclusion:** While VBR+Nrtl DC was well-tolerated, SVR was not achieved. Data suggest crAg level may be important in future DC criteria. Other studies with VBR+Nrtl in multi-drug combinations will evaluate potential finite treatment regimens.

### PO-655

#### **Activation of inducible caspase 9 allows efficient depletion of adoptively transferred HBV-specific T cells**

Alexandre Klopp<sup>1</sup>, Martin Pule<sup>2</sup>, Ulrike Protzer<sup>3</sup>, Karin Wisskirchen<sup>3</sup>. <sup>1</sup>Institute of Virology, Helmholtz Zentrum München/Technical University Munich, School of Medicine, Munich, Germany; <sup>2</sup>Cancer Institute, University College London, London, United Kingdom; <sup>3</sup>Institute of Virology, Helmholtz Zentrum München/Technical University Munich, School of Medicine, Munich, Germany Email: alexandre.klopp@tum.de

**Background and aims:** Adoptive T-cell therapy with T cells that express either an HBV-specific chimeric antigen receptor (S-CAR) or T-cell receptor (TCR) represents a promising therapeutic strategy for treatment of chronic hepatitis B and HBV-associated cancer. However, side effects such as cytokine release syndrome or hepatotoxicity are not excluded. Inclusion of a safeguard mechanism, which allows depletion of transferred T cells on demand, would thus be an interesting means to increase safety of T-cell therapy.

**Method:** In this study, T cells were generated by retroviral transduction to co-express an HBV-specific receptor and in addition a safeguard molecule, namely inducible Caspase 9 (iCasp9), herpes simplex virus thymidine kinase (HSV-TK), or the CD20-based molecule RQR8. First, comparative experiments including the different safeguard molecules were performed and iCasp9 proved to be the most efficient and practical approach to deplete HBV-specific cells. It was further evaluated *in vitro* and *in vivo*.

**Results:** *In vitro*, co-expression of iCasp9, slightly reduced receptor expression but did not alter T cell functionality. HBV-specific T cells were specifically activated to secrete IFN $\gamma$  and kill HBV<sup>+</sup> target cells. Real-time cytotoxicity assays using HBV-replicating HepG2.2.15 hepatoma cells revealed that induction of iCasp9 by addition of an iCasp9 dimerizer to activate caspase 9 function halted cytotoxicity of HBV-specific T cells within less than one hour.

*In vivo*, iCasp9 expressing S-CAR T cells were injected into AAV-HBV-infected Rag2IL2rg<sup>-/-</sup> mice followed by the dimerizer at day four. By day seven, numbers of S-CAR<sup>+</sup> T cells in both liver and spleen were reduced by 3log<sub>10</sub> in comparison to mice in which depletion of HBV-specific T cells had not been induced. After iCasp9 induction, the remaining S-CAR T cells were mostly unfunctional as determined by

restimulation with HBsAg and intracellular cytokine staining. Depletion of transferred T cells halted hepatotoxicity but also reduced the antiviral effect of S-CAR T cells.

**Conclusion:** In conclusion, T cells co-expressing iCasp9 and HBV-specific receptors efficiently recognize and kill HBV-replicating cells. Induction of cell death via iCasp9 is efficient *in vitro* and *in vivo*, leading to a strong depletion of transduced T cells and prevention of cytotoxicity.

**PO-715**

 Email: gepapath@med.uoa.gr

**Background and aims:** In the registrational trials, TAF compared to tenofovir disoproxil fumarate (TDF) was shown to have similar efficacy and improved safety in renal function and bone mineral density (BMD) parameters, but CHB patients with significant renal and/or bone disorders were not included. In Greece, TAF has been reimbursed since 02/2018 for CHB patients with estimated glomerular filtration rate (eGFR) <60 ml/min, serum phosphate <2.5 mg/dl or osteoporosis (T-score <-2.5). This study assessed the safety and efficacy of one-year TAF therapy in CHB patients treated in Greek tertiary liver centers.

**Method:** Adult (≥18 years old) CHB patients who started TAF between 02/2018–10/2019 at 13 clinics participating in the HERACLIS-TAF registry were included. Main exclusion criteria were coinfection with HDV, active malignancy and bisphosphates use in the last 6 months. Clinical and laboratory characteristics were recorded at onset and 6 and 12 months of TAF. MDRD formula was used for eGFR (ml/min) estimation.

**Results:** TAF was initiated in 176 patients: age 64 ± 12 years, 71% males, 85% undetectable HBV DNA, 86% ALT<40, 45% eGFR<60, 94% nucleos(t)ide analogue (NA) experienced (91% directly switched to TAF from another NA–81% from TDF; 3% NA discontinuation >2 months). At month-12 of TAF, HBV DNA was undetectable (<15 IU/ml)

in 97% and ALT was <40 IU/L in 96% of cases. In cases switching to TAF from other NA, median ALT decreased from onset to month-12 of TAF (23 to 21 IU/L, P < 0.001). Mean eGFR had decreased from previous NA onset (74 ± 28) to TAF onset (65 ± 27, P < 0.001) and then increased at 6 (69 ± 26, P < 0.001) or 12 months of TAF (71 ± 29, P < 0.001). eGFR difference between 12 months and onset of TAF was ≥0 in 71% and ≥10 in 65% of cases; eGFR difference >0 was not associated with any patients' characteristic, while eGFR difference >10 was associated with BMI>25 [OR:2.4 (1.1–5.1), P=0.024] and no hemodialysis. In cases starting TAF with phosphate <2.5, mean phosphate levels increased from onset to month-12 (2.1 to 2.7, P < 0.001). Mean BMD did not change significantly from onset to month-12 of TAF (T-score: -2.1 to -1.9, P = 0.164).

**Conclusion:** In mostly NA experienced CHB patients with renal and/or bone disorders/risks, one year of TAF achieves maintenance of virological suppression and improvement of ALT, eGFR and serum phosphate levels. eGFR improvement >10 ml/min can be achieved in >2/3 of non-hemodialysis patients and seems to be associated with BMI >25 kg/m<sup>2</sup>.

**PO-774**

**A combination of gapmers and/or siRNA as potential gene therapy strategy against HBV infection: in vitro results.**

Maria Francesca Cortese<sup>1,2</sup>, Selene Garcia-Garcia<sup>1,2</sup>, Beatriz Pacín<sup>1,2</sup>, Rosario Casillas<sup>1,2</sup>, David Taberero<sup>1,3</sup>, Roser Maria Ferrer-Costa<sup>4</sup>, Mar Riveiro Barciela<sup>3,5</sup>, Maria Buti<sup>3,5</sup>, Francisco Rodríguez-Frías<sup>1,2,3</sup>.  
<sup>1</sup>Vall D'hebron University Hospital, Biochemistry and Microbiology/Liver Pathology Unit, Barcelona, Spain; <sup>2</sup>Vall D'hebron Research Institute, Liver Unit, Spain; <sup>3</sup>Instituto De Salud Carlos III, Centro De Investigación Biomédica En Red, Enfermedades Hepáticas y Digestivas (CIBERehd), Spain; <sup>4</sup>Vall D'hebron University Hospital, Department of Biochemistry, Spain; <sup>5</sup>Vall D'hebron University Hospital, Liver Unit, Internal Medicine Department, Barcelona, Spain  
 Email: maria.cortese@vhir.org

**Background and aims:** Hepatitis B virus (HBV) infection cannot be eradicated due to the persistence of its covalently closed circular DNA, which supports HBV proteins expression, contributing to hepatocellular carcinoma development. Gene silencing could be a valuable strategy and HBX gene, thanks to its co-terminal localization, an optimal target. Here we present a gene therapy strategy based on antisense locked nucleic acid (LNA) Gapmer (GP) and siRNA targeting HBX hyper-conserved regions.

**Method:** HepG2-NTCP cells were treated with DMSO 2.5% at least 14 days and later infected with HBV at 500 multiplicities of genome equivalents by centrifugation at 37°C for 1 h and incubating overnight. Infected cells were treated with GP (GP1 and/or GP4 at 50nM, Qiagen) and/or siRNA (50nM) using TransIT-X2 at 48 h or 5d post infection (pi). A scrambled control gapmer was used in each experiment. Cells and supernatants were collected after 72 h of treatment. Pregenomic RNA (pgRNA) was extracted from cells through RNAeasy Plus mini kit (Qiagen) and quantified by RT-qPCR using TaqMan probe (Roche, Lightcycler@480). HBsAg and HBeAg were quantified in supernatants by chemiluminescent enzyme assay (Roche, COBAS@8000).

**Results:** Early after infection (at 48hpi), GP1 treatment allowed an inhibition of more than 70% for both pgRNA, HBeAg and HBsAg (respectively 75.5 ± 9.9; 74.7 ± 6.4 72.4 ± 7.7%). Differently, GP4 showed an inhibition between 7.4 and 13 percentage points lower than GP1 (62 ± 17; 66.1 ± 11.2 and 64.7 ± 12% for respectively pgRNA, HBeAg and HBsAg). When GP were introduced at late timepoint (5 dpi), the inhibition of pgRNA decreased for both GP1 and GP4 (respectively 53.5 ± 29% and 58.5 ± 17%). The efficiency was lower if considering viral proteins expression (less than 48% for both GP). Of note, the combination of both GP or GP with a siRNA increased the inhibition efficiency of pgRNA (69.1 ± 16.5%; 66.7 ± 12.2%; 63.8 ± 21% for respectively GP1+GP4; GP1+siRNA; GP4+siRNA), just partially improving viral proteins inhibition.

## POSTER PRESENTATIONS

**Conclusion:** Gapmers seem to be valuable molecules to inhibit HBV expression *in vitro*. Their limited efficiency after the establishment of a productive infection (5 dpi) could be improved by combining GP with each other or with siRNA targeting the same hyper-conserved region. Further experiments are required to confirm these results and other delivery systems should be tested to improve treatment efficiency. Funding: Instituto de Salud Carlos III (grant PI18/01436), co-financed by the European Regional Development Fund (ERDF).

### PO-797

#### Tenofovir alafenamide in blocking mother-to-child transmission of hepatitis B virus: A multi-center, prospective clinical study

Guorong Han<sup>1</sup>, Guanlun Zhou<sup>1</sup>, Tong Sun<sup>2</sup>, Xiucui Luo<sup>3</sup>, Jinxia Xu<sup>4</sup>, Chao Chen<sup>1</sup>, Wen Xu<sup>3</sup>, Su'e Jiang<sup>4</sup>, Chenxu Wang<sup>1</sup>. <sup>1</sup>The Affiliated Nanjing Hospital of Nanjing University of Chinese Medicine; <sup>2</sup>The Fifth People's Hospital of Wuxi; <sup>3</sup>The Maternal and Child Health Hospital of Lianyungang; <sup>4</sup>The Maternal and Child Health Hospital of Huai'an  
Email: hgr518@163.com

**Background and aims:** Few data are available regarding the administration of tenofovir alafenamide (TAF) during pregnancy for the prevention of mother-to-child transmission (MTCT) of hepatitis B virus (HBV). This prospective study aimed to evaluate the efficacy and safety of TAF for preventing MTCT of HBV.

**Method:** In this ongoing, multi-center, prospective study, chronic HBV-infected pregnant women aged from 20 to 35 years old, positive for Hepatitis B e-antigen and with HBV DNA level at least  $1 \times 10^6$  IU/ml, received oral TAF (25 mg/day) from gestational weeks 24–28 until postpartum week 4. All infants received HBV immunoprophylaxis. The participants, including mothers and infants, were followed up until postpartum week 28. The primary measurement was MTCT rate. The key secondary measurement was the safety of TAF for mothers and infants. The other assessments were the dynamic changes of HBV DNA, liver and renal function of mothers.

**Results:** To date, 91 mothers were enrolled, 2 of them were unable to get TAF due to the COVID-19 outbreak and dropped out after enrollment. 84 mothers delivered, and 86 infants (two sets of twins) were born. 54 mothers (56 infants) were followed up to postpartum week 28. TAF therapy was initiated at a mean gestational age of 25.04 ( $\pm 0.96$ ) weeks with the mean treatment duration of 14.3 ( $\pm 1.2$ ) weeks before delivery. 96.4% (81/84) mothers discontinued the TAF treatment, the median [interquartile range, IQR] time was 5.9 [4.5, 9.8] weeks postpartum. The HBsAg positive rate was 0% at 7 months in 56 infants, among whom no growth retardation was detected at that time. No infant (0/86) had congenital defects. 84 mothers were tolerated during TAF treatment and had no drug-related serious adverse events. At delivery, 82.1% (69/84) mothers achieved an HBV DNA level  $< 200000$  IU/ml, and 20.2% (17/84) mothers achieved an HBV DNA level  $< 500$  IU/ml. There were no significant changes on the mean ( $\pm$  SD) serum phosphate between baseline ( $1.20 \pm 0.10$  mmol/L) and at delivery ( $1.22 \pm 0.13$  mmol/L,  $p = 0.85$ ). The serum creatinine at delivery ( $51.97 \pm 8.65$   $\mu$ mol/L) was higher than baseline ( $45.97 \pm 5.60$   $\mu$ mol/L,  $p < 0.05$ ), but all within the normal range. None of the mothers had ALT flares on TAF treatment during pregnancy, however, 9 of 81 mothers who stopped TAF treatment after delivery had mild ALT flare.

**Conclusion:** TAF therapy initiated during the second trimester for HBV-infected pregnant women with HBeAg positive and HBV DNA level  $> 1 \times 10^6$  IU/ml was effective in preventing MTCT, and there were no safety concerns for mothers and infants with 28 weeks of follow-up after delivery. (ClinicalTrials.gov number, NCT04065230).

### PO-811

#### Unreliable estimation of fibrosis regression during treatment by liver stiffness measurement in patients with chronic hepatitis B

Dong Ji<sup>1</sup>, Yan Chen<sup>1</sup>, Yongping Yang<sup>1</sup>. <sup>1</sup>5th Medical Center of Chinese PLA General Hospital, Department of Liver Diseases  
Email: yongpingyang@hotmail.com

**Background and aims:** Little reliable evidence has been reported regarding usefulness of liver stiffness measurement (LSM) for monitoring the hepatic fibrosis changes during treatment. We aimed to assess the association between changes in LSM and histological outcomes in patients with chronic hepatitis B (CHB).

**Method:** In this prospective multicenter study, 727 treatment-naïve patients receiving entecavir-based therapy, who underwent paired biopsies at treatment baseline and week 72, were analyzed. Changes in LSM were defined as  $\geq 30\%$  decrease, minor change and  $\geq 30\%$  increase. Multivariate logistic regression was used to estimate odd ratios (ORs) of changes in LSM on clinical outcomes accounting for regression to the mean (RtM). A new on-treatment LSM threshold was established by receiver operating curve.

**Results:** Overall regression of fibrosis, improvement of inflammation, significant histological response, virologic response, ALT normalization and HBeAg seroconversion were 51.2%, 74.4%, 22.0%, 86.0%, 83.5% and 7.6%, respectively. The association between changes in LSM and improvement of inflammation was non-linear ( $p = 0.012$ ). LSM decrease  $\geq 30\%$  was associated with regression of fibrosis (OR 1.501, 95% CI 1.073–2.099,  $P = 0.018$ ), significant histological response (OR 1.726, 95% CI 1.124–2.652,  $P = 0.013$ ) and ALT normalization (OR 2.149, 95% CI 1.229–3.757,  $P = 0.007$ ). After adjusting for RtM, LSM increase  $\geq 30\%$  became negatively associated with the above three outcomes. A new on-treatment LSM cutoff value of 5.4 kPa was established for indicating the significant histological response.

**Conclusion:** Changes in LSM is unreliable to estimate regression of fibrosis during treatment, the established cutoff value of on-treatment LSM can optimize monitoring strategy for histological outcomes in CHB patients.

### PO-824

#### Preliminary on-treatment data from a phase 2 study evaluating VIR-2218 in combination with pegylated interferon alfa-2a in participants with chronic hepatitis B infection

Man-Fung Yuen<sup>1</sup>, Young-Suk Lim<sup>2</sup>, Daniel Cloutier<sup>3</sup>, Ling Shen<sup>3</sup>, Andre Arizpe<sup>3</sup>, Phil Pang<sup>3</sup>, Chin Tay<sup>3</sup>, Vaidehi Thanawala<sup>3</sup>, Sneha V. Gupta<sup>3</sup>, Andrea Cathcart<sup>3</sup>, Edward Gane<sup>4</sup>. <sup>1</sup>Queen Mary Hospital, The University of Hong Kong, Hong Kong; <sup>2</sup>Asan Medical Center, University of Ulsan College of Medicine, Gastroenterology, Seoul, Korea, Rep. of South; <sup>3</sup>Vir Biotechnology, San Francisco, United States; <sup>4</sup>University of Auckland, Auckland Clinical Studies, Auckland, New Zealand  
Email: dcloutier@vir.bio

**Background and aims:** VIR-2218 is a novel synthetic small interfering ribonucleic acid (siRNA) therapeutic in development for functional cure of chronic hepatitis B virus infection (CHB). Pegylated interferon alfa-2a (Peg-IFN $\alpha$ ) is an approved immunomodulator for the treatment of CHB; however,  $< 10\%$  of patients achieve HBsAg loss after 48 weeks of treatment. We hypothesize that combining VIR-2218 with Peg-IFN $\alpha$  may increase the rates of HBsAg loss in CHB patients. We present here the preliminary on-treatment 12-week data.

**Method:** In this Phase 2 open-label study, noncirrhotic, virologically suppressed CHB participants were enrolled. Study treatment included 200 mg of subcutaneous (SC) VIR-2218 every 4 weeks for 6 doses, either alone (Cohort 1), in combination with 24 weeks of 180 mcg SC Peg-IFN $\alpha$  administered concurrently (Cohort 3), or in combination with 12 weeks of 180 mcg SC Peg-IFN $\alpha$  starting on week 12 of VIR-2218 treatment (Cohort 2). Through week 12, Cohort 2 participants have only received VIR-2218. Participants will be followed for at least 24 weeks after completing study treatment.

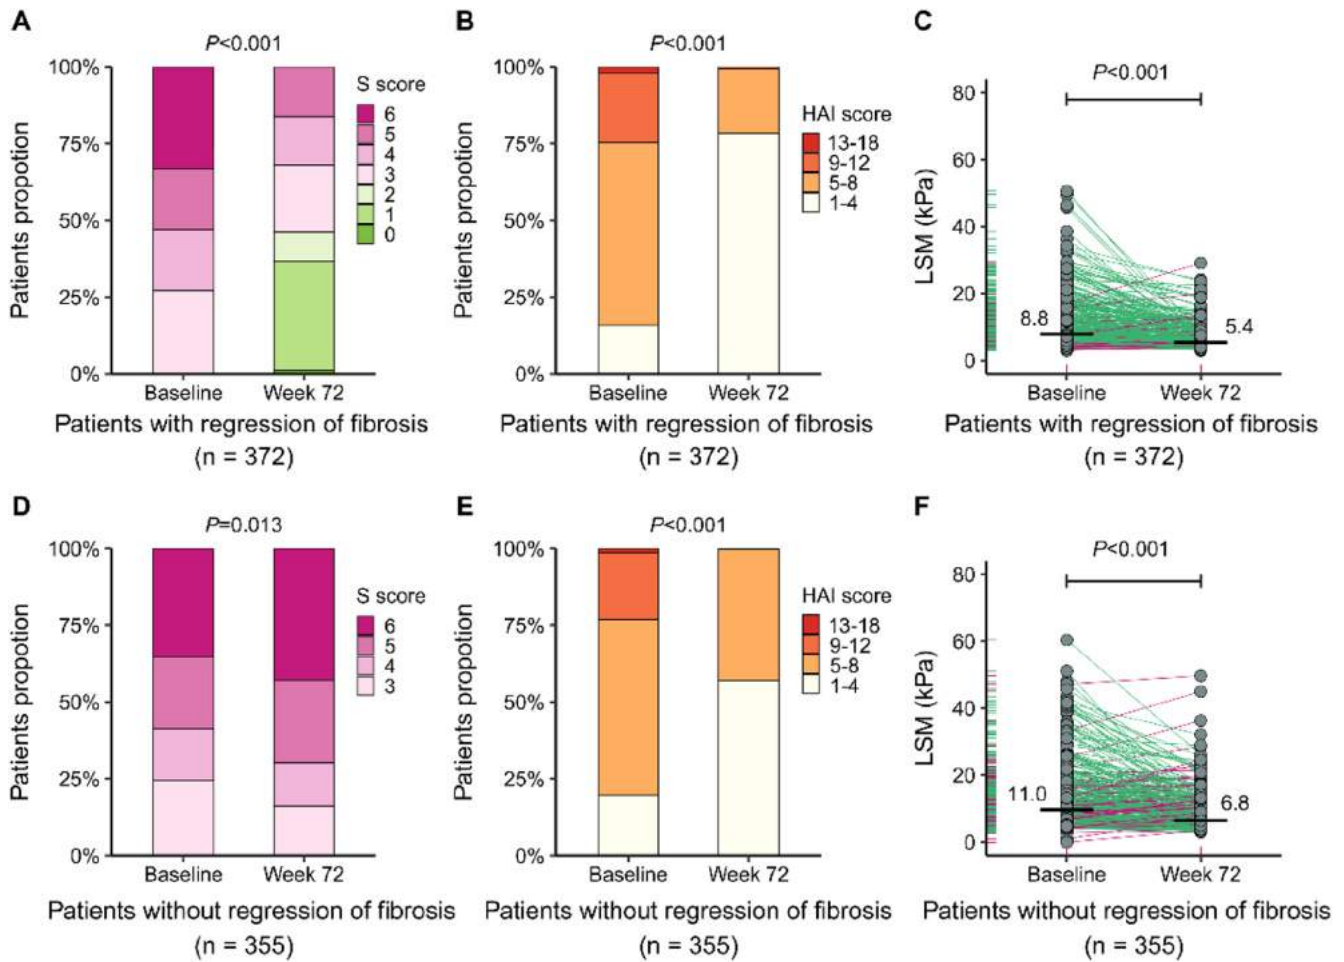

Figure: (abstract: PO-811)

**Results:** To date, 27 participants have been enrolled, of which 14 have completed at least 12 weeks of treatment. At week 12, the mean HBsAg decline for the 10 participants (3 HBeAg+, 7 HBeAg-) receiving VIR-2218 alone is 1.0 (Cohort 1) and 1.1 (Cohort 2) log<sub>10</sub> IU/ml, respectively, and 1.8 log<sub>10</sub> IU/ml for the 4 participants (1 HBeAg+, 3 HBeAg-) receiving VIR-2218 with Peg-IFNa (Cohort 3). Earlier and steeper HBsAg declines were observed in Cohort 3, with a mean reduction of ≥1 log<sub>10</sub> IU/ml by week 4. Some participants receiving Peg-IFNa and VIR-2218 combination experienced asymptomatic ALT elevations (grade 2–3) concurrent with HBsAg decline (≥1 log<sub>10</sub> IU/ml). ALT elevations were not associated with functional changes of the liver (bilirubin, PT or INR). No serious AEs have been reported.

**Conclusion:** The initial data from this ongoing study show that co-administration of VIR-2218 with Peg-IFNa results in a more rapid and substantial HBsAg decline compared to either VIR-2218 alone or what has been shown with Peg-IFNa alone. In other published studies, Peg-IFNa plus NRTI was associated with <0.5 log<sub>10</sub> IU/ml HBsAg declines, on average, over the first 12 weeks. This data supports the hypothesis that the antiviral activity of VIR-2218 can be potentiated by immunomodulators, such as Peg-IFNa. Additional data beyond 12 weeks, as available, will be presented at the congress.

**PO-853**

**A novel therapeutic vaccine achieves functional cure in a mouse model of chronic hepatitis B**

Rena Walsh<sup>1,2</sup>, Stephen Locarnini<sup>1,2</sup>, Rachel Hammond<sup>1,2</sup>, Michiko Hyakumura<sup>1,2</sup>, Chee Leng Lee<sup>1,2</sup>, Joan Ho<sup>1,2</sup>, Ronald Farquhar<sup>1</sup>, Aileen Rubio<sup>1</sup>, Hans Netter<sup>1,2</sup>, <sup>1</sup>ClearB Therapeutics, Concord, United States; <sup>2</sup>Victorian Infectious Diseases Reference Laboratory, Molecular Research and Development, Melbourne, Australia  
Email: rwalsh@clearbtherapeutics.com

**Background and aims:** We have previously reported hepatitis B virus (HBV) specific antibody responses in patients associated with HBsAg loss and functional cure [Walsh, Ret al 2019. Liver Int 39 (11) pp2066]. This ‘clearing’ anti-HBs antibody response is defined by an antibody clearance profile (CP) associated with the occupation of key loop 1 and 2 epitopes within the HBsAg ‘a’ determinant, which is distinct from the anti-HBs profile elicited following standard HBV prophylactic vaccination. We generated three bio-nano particles (BNPs) of

Figure:

## POSTER PRESENTATIONS

HBsAg modified with multiple repeats of these key CP epitopes (CP-BNPs). This study investigated whether CP-BNP vaccination cleared HBV infection in association with the generation of the clinically observed CP-specific antibody responses, in a chronic hepatitis B (CHB) murine model.

**Method:** CBA/CaJ mice (Jackson Laboratory, Maine, USA) were hydrodynamically injected (HDI) in the tail vein with an infectious HBV clone (genotype A2adw2), and CHB established [Chou H-H et al 2015. PNAS 112 (7) pp2175]. Animals were vaccinated by subcutaneous injection across three fortnightly doses with aluminium hydroxide-adjuvanted CP-BNPs. The effect of the therapeutic vaccine to influence functional cure, compared to placebo CHB-infected mice, was assessed by 1) serological HBsAg, anti-HBs antibody and HBV DNA load; and 2) immunohistochemistry anti-HBs and anti-HBc staining of liver sections.

**Results:** Therapeutic vaccination of persistently HBV infected mice with the CP-BNP vaccine formulation (CLB-101/401/501) resulted in >3 log IU/ml reduction in serum HBV DNA and HBsAg to undetectable levels, as well as the development of a vaccine-elicited 'clearing' anti-HBs response. Liver compartment analysis confirmed clearance of HBV positive cells following serum HBsAg clearance and seroconversion. In comparison, persistent CHB infection was maintained in placebo mice. Vaccination with the standard prophylactic vaccine (Engerix B) at an equivalent human dose did not result in significant virological effects.

**Conclusion:** A novel HBsAg therapeutic vaccine developed by targeting CP antibody epitopes identified from CHB functionally cured patients demonstrated viral control, HBsAg clearance from serum and liver compartments, and seroconversion, in a mouse CHB model. These findings support the clinical development of the CLB-101/401/501 trivalent vaccine for the treatment of CHB.

### PO-942

#### Discovery and characterization of EDP-721, a novel hepatitis B virus RNA destabilizer

Michael Vaine<sup>1</sup>, Tessa Cressey<sup>1</sup>, Anand Balakrishnan<sup>1</sup>, Victor Dellisola<sup>1</sup>, Joe Panarese<sup>1</sup>, Dexter Davis<sup>1</sup>, Nate Kenton<sup>1</sup>, Samuel Bartlett<sup>1</sup>, Yat Sun Or<sup>1</sup>, Bryan Goodwin<sup>1</sup>, Kai Lin<sup>1</sup>. <sup>1</sup>Enanta Pharmaceuticals, Inc, Watertown, United States  
Email: mvaine@enanta.com

**Background and aims:** Available therapies for chronic hepatitis B virus (HBV) infection are effective at reducing both the circulating viral load and the risk for developing hepatocellular carcinoma. However, these therapies rarely result in viral clearance and require lifelong treatment. One barrier to a functional cure for chronic HBV (CHB) is the abundance of circulating surface antigen (HBsAg) which is believed to play an immunosuppressive role. Here we report the discovery of EDP-721, a potent and selective inhibitor of the non-canonical poly (A) RNA polymerase-associated domain containing proteins 5 and 7 (PAPD5 and PAPD7). These host factors play a central role in the post-transcriptional stabilization of HBV RNA and their inhibition results in the destabilization of viral transcripts leading to reduced production of viral proteins, including HBsAg. We show that EDP-721 is effective at reducing HBV RNA and protein in both *in vitro* and *in vivo* models of HBV infection.

**Method:** The activity and selectivity of EDP-721 was determined biochemically against PAPD5, PAPD7, PAP $\alpha$ , PAPD1, and PAPD4. Antiviral activity was assessed in the 2.2.15 cell line, which stably expresses HBV, as well as in cells permissive to HBV infection including, HepG2-NTCP and primary human hepatocytes. *In vivo* efficacy studies were conducted in mice infected with an adeno-associated virus (AAV) vector delivering an HBV genome.

**Results:** EDP-721 inhibits the catalytic activity of PAPD5 and PAPD7 with a half-maximal inhibitory concentration (IC<sub>50</sub>) of 4 nM and 32 nM, respectively. No inhibition of the poly (A) polymerases PAP $\alpha$ , PAPD1, or PAPD4 was observed at concentrations up to 10 mM. *In vitro*, EDP-721 prevents production of HBsAg with EC<sub>50s</sub> of 160 pM,

223 pM, and 360 pM in 2.2.15 cells, HepG2-NTCP cells, and primary human hepatocytes, respectively. This antiviral activity results from a reduction in the length of HBV mRNA poly (A) tails and subsequent degradation of HBV RNAs. We demonstrate that EDP-721 is pan-genotypic and has additive to synergistic activity with nucleos (t)ide analogs and HBV core inhibitors. *In vivo*, EDP-721 reduces circulating HBsAg levels by up to 3 logs with 14 days of dosing in an AAV-HBV mouse model.

Figure:

**Conclusion:** EDP-721 is a potent and selective HBV RNA destabilizer that leads to robust reductions in viral proteins including, HBsAg, and has the potential to be a key component of a regimen enabling a functional cure for CHB.

### PO-990

#### Safety of tenofovir alafenamide administered before or in early phase of pregnancy in women with active chronic hepatitis B and the effectiveness in preventing perinatal hepatitis B virus infection: a multicenter prospective study

Qing-Lei Zeng<sup>1</sup>, Guangming Li<sup>2</sup>, Ying-Hua Feng<sup>3</sup>, Guofan Zhang<sup>4</sup>, Wei Li<sup>5</sup>, Jiang-Hai Xu<sup>6</sup>, Zhi-Qin Li<sup>1</sup>, Yi-Hua Zhou<sup>7</sup>, Zu-Jiang Yu<sup>1</sup>. <sup>1</sup>The First Affiliated Hospital of Zhengzhou University, Department of Infectious Diseases and Hepatology, Zhengzhou, China; <sup>2</sup>The Sixth People's Hospital of Zhengzhou City, Department of Hepatology, Zhengzhou, China; <sup>3</sup>The Sixth People's Hospital of Kaifeng City, Department of Hepatology, Kaifeng, China; <sup>4</sup>The First Affiliated Hospital of Nanyang Medical College, Department of Infectious Diseases, Nanyang, China; <sup>5</sup>Henan Provincial People's Hospital, Department of Infectious Diseases, Zhengzhou, China; <sup>6</sup>The Fifth People's Hospital of Anyang City, Department of Hepatology, Anyang, China; <sup>7</sup>Nanjing Drum Tower Hospital, Nanjing University Medical School, Department of Experimental Medicine and Jiangsu Key Laboratory for Molecular Medicine, Nanjing, China  
Email: zengqinglei2009@163.com

**Background and aims:** We previously demonstrated that tenofovir alafenamide (TAF) administered from gestational weeks 24–35 to delivery in inactive chronic hepatitis B virus (HBV)-infected pregnant women with HBV DNA >200,000 IU/ml is safe and can completely prevent mother-to-child transmission (MTCT) of HBV. Here we report the safety data of TAF administration initiated before gestation or from early phase of pregnancy in mothers with active chronic hepatitis B (CHB) and the effectiveness in preventing MTCT.

**Method:** In this multicenter prospective study, mothers and expectant mothers with newly diagnosed and previously diagnosed treatment-experiencing CHB who chose and switched to TAF therapy were enrolled and followed until postpartum months 12. Infants received standard immunoprophylaxis and were followed until 12 months of age.

**Results:** In total, 60 mothers were eligible, 51 of them were enrolled, and 19 (37%) mothers switched from non-TAF regimens to TAF. The mean TAF initiation time was 2.6 ( $\pm$  14) weeks of pregnancy, and 24 (47%) of them started TAF before pregnancy from a mean of  $-10$  ( $\pm$  7) weeks. The mean age, alanine aminotransferase, and HBV DNA levels at TAF initiation for mothers were 29.2 ( $\pm$  4.6) years, 113.3 ( $\pm$  93.8) U/L,

and  $5.1 (\pm 3) \log_{10}$  IU/ml, respectively. TAF was well tolerated for mothers during a mean treatment duration of  $79 (\pm 20)$  weeks, and the most common adverse event was nausea (21.6%). Notably, one (2%) mother who exposed to pesticide during early pregnancy and initiated TAF from gestational weeks 12 undergone induced abortion at gestational weeks 22 due to the diagnosis of cleft lip and palate for the fetus. A total of 50 living infants were born at a mean gestational age of  $39.2 (\pm 1.2)$  weeks, the prenatally potential TAF exposure duration were  $36 (\pm 14.7)$  weeks, no infants had birth defects at birth, and 35 (70%) infants received breast milk. Notably, 1 (2%) infant was diagnosed with hearing impairment at 1 week and was identified as conductive hearing impairment due to secretory otitis media at 3 months. Additionally, 1 (2%) infant was reported the cutaneous hemangioma (Figure) at 4 weeks. Hepatitis B e antigen seroconversion occurred in 2 (4%) mothers, however, viral breakthrough occurred in 2 (4%) other mothers after 6 months of switchover from previous entecavir to TAF. The infants' physical and neurological development at birth, 7 months, and 12 months were comparable with the China national and World Health Organization standards. None of 50 infants was infected with HBV at 7 months.

Figure: Infantile hemangioma (lower right, size:  $15 \times 25$  mm) on the left arm. The upper left one was the BCG vaccination site.

**Conclusion:** TAF administered before or in early phase of pregnancy in women with active CHB was generally safe for both mothers and infants, and reduced the MTCT rate to 0%, however, the abnormalities with ambiguous cause should be noticed and future large-scale studies are needed.

**PO-1004**

**Safety, tolerability and pharmacokinetics (pk) of single and multiple doses of alg-010133, an s-antigen transport inhibiting oligonucleotide polymer (stops) for the treatment of chronic hepatitis B**

Edward Gane<sup>1</sup>, Man-Fung Yuen<sup>2</sup>, Jeysen Yogaratnam<sup>3</sup>, Kha Le<sup>3</sup>, Jennifer Vuong<sup>3</sup>, Westland Christopher<sup>3</sup>, Vikrant Gohil<sup>3</sup>, Christian Schwabe<sup>4</sup>, Kosh Agarwal<sup>5</sup>, Alina Jucov<sup>6</sup>, JyanWei Liu<sup>3</sup>, Tse-i Lin<sup>3</sup>, Lawrence Blatt<sup>3</sup>, Sushmita Chanda<sup>3</sup>, Matthew McClure<sup>3</sup>, John Fry<sup>3</sup>. <sup>1</sup>University of Auckland, Faculty of medicine, Auckland, New Zealand; <sup>2</sup>Queen Mary Hospital, Hong Kong; <sup>3</sup>Aligos Therapeutics, South San Francisco, United States; <sup>4</sup>Auckland Clinical Studies, Auckland, New Zealand; <sup>5</sup>King's College Hospital, London, United Kingdom; <sup>6</sup>Arensia Exploratory Medicine, Chisinau, Moldova  
Email: jeysen.yogaratnam@hotmail.com

**Background and aims:** To evaluate the safety, PK and antiviral activity of ALG-010133, a STOP molecule designed to reduce hepatitis B surface antigen (HBsAg) in chronic hepatitis B (CHB) patients.

**Method:** This is a three-part, multicenter, double-blind, randomized, placebo-controlled study. In Parts 1 and 2, each cohort consisted of 8 healthy volunteers (HV) randomized to ALG-010133 or placebo in a 3:1 ratio. Each cohort in Parts 1 and 2 received a single or three-weekly subcutaneous (SC) doses, respectively. Part 3 is evaluating cohorts (N=10 each; 8 ALG-010133, 2 placebo) of virologically suppressed CHB patients who will receive study drug weekly for 12 weeks. Safety assessments (adverse events (AEs), vital signs, electrocardiogram (ECG) and laboratories), viral markers (Part 3) and plasma/urine PK samples (Parts 1 and 2) were collected throughout study conduct. Reported here are preliminary blinded results in Parts 1 and 2. Available Part 3 data will also be presented at the conference.

**Results:** In Part 1, 7 cohorts (N=56 HVs) received a single 20, 50, 75, 125, 160 or 200 mg (100 mg/ml and 200 mg/ml) SC dose of ALG-010133/placebo. In Part 2, 2 cohorts (N=16 HVs) received three weekly 120 or 180 mg SC doses. There were no serious AEs, premature discontinuations, or dose-limiting toxicities. All treatment emergent AEs (TEAEs) were mild (Grade 1) or moderate (Grade 2) except for one Grade 3 injection site reaction (ISR) that occurred in a subject in the 200 mg cohort. The most commonly occurring ( $\geq 3$  subjects) TEAEs in Part 1 were injection site bruising (n=11), ISRs (erythema/rash; n=7), headache (n=7), nausea (n=4) and diarrhea/loose stools (n=3) and, in Part 2, ISRs (n=3). There was no dose relationship to severity or frequency of AEs. All treatment-emergent laboratory abnormalities were Grade  $\leq 2$  with the exception of three (Grade 3, n=2; Grade 4, n=1) exercise-related creatine kinase elevations. No clinically significant PE, vital signs, or ECG abnormalities were reported. ALG-010133 exposures increased in a greater than dose-proportional manner with moderate variability after single doses. Median  $t_{max}$  was 2–10 hours. Plasma ALG-010133 achieved steady state and did not accumulate with weekly dosing over 3 weeks. Doses of 100–200 mg are projected to result in antiviral activity.

**Conclusion:** ALG-010133 was generally safe and well tolerated in HV as single and multiple SC doses up to 200 and 180 mg, respectively. The PK exposures achieved are expected to result in antiviral activity, supporting the ongoing evaluation in CHB patients.

#### Baseline serum exosome-derived miRNAs predict HBeAg seroconversion in chronic hepatitis B patients treated with peginterferon

Qiankun Hu<sup>1</sup>, Qianqian Wang<sup>1</sup>, Qiang Li<sup>1</sup>, Yi Zhang<sup>1</sup>, Shuai Tao<sup>1</sup>, Xueyun Zhang<sup>2</sup>, Xiaoqin Liu<sup>2</sup>, Xinyan Li<sup>1</sup>, Xuhua Jiang<sup>1</sup>, Chenlu Huang<sup>1</sup>, Wei Xu<sup>1</sup>, Xun Qi<sup>1</sup>, Liang Chen<sup>1</sup>, Yuxian Huang<sup>1,2</sup>.

<sup>1</sup>Shanghai Public Health Clinical Center, Fudan University, Department of Liver Diseases, Shanghai, China; <sup>2</sup>Huashan Hospital, Fudan University, Department of Infectious Diseases, Shanghai, China

**Background and aims:** Peginterferon (Peg-IFN) is one of the first-line treatment options for HBeAg-positive chronic hepatitis B (CHB) patients, whereas the clinical application is compromised by the limited serological response rates and frequent side effects. This study aimed to explore the predictive value of baseline serum exosome-derived miRNAs for HBeAg seroconversion in CHB patients treated with Peg-IFN.

**Method:** 120 treatment-naïve, HBeAg-positive CHB patients who received Peg-IFN therapy were enrolled. Serological response was defined as HBeAg seroconversion after 48 weeks of Peg-IFN treatment. Next-generation sequencing (NGS) was performed to screen the differentially expressed serum exosomal miRNAs, which were further validated by qRT-PCR in a confirmation cohort. The area under the receiver operating characteristic curve (AUROC) was used to evaluate the predictive efficacy of selected serum exosomal miRNAs.

**Results:** Thirty-three patients (27.5%) achieved HBeAg seroconversion after a 48-week course of Peg-IFN therapy. Forty serum exosome-derived miRNAs were differentially expressed in the identification cohort. Validation analysis revealed that the expression levels of serum exosomal miR-194-5p ( $p < 0.001$ ) and miR-22-3p ( $p < 0.001$ ) were significantly downregulated in the response group compared to the non-response group. Multivariate analysis identified baseline serum exosomal miR-194-5p ( $p = 0.019$ ), miR-22-3p ( $p = 0.023$ ), alanine aminotransferase (ALT) ( $p = 0.035$ ) and HBV DNA ( $p = 0.038$ ) as independent predictors for HBeAg seroconversion. The predictive performances of serum exosomal miR-194-5p (AUROC = 0.77) and miR-22-3p (AUROC = 0.75) were superior to ALT (AUROC = 0.70) and HBV DNA (AUROC = 0.69). The combined detection of serum exosomal miR-194-5p and miR-22-3p further improved the predictive performance to 0.82.

**Conclusion:** Pretreatment serum exosomal miR-194-5p and miR-22-3p may serve as novel biomarkers to predict HBeAg-positive CHB patients who are likely to experience HBeAg seroconversion after treatment with Peg-IFN.

### PO-1196

#### ALG-125755, a Small Interfering RNA (siRNA) Against Hepatitis B Virus (HBV) Effectively Inhibits Hepatitis B Surface Antigen (HBsAg) Secretion in HBV Cell Models and the AAV-HBV Mouse Model

Jin Hong<sup>1</sup>, Saul Martinez Montero<sup>1</sup>, Tilani De Costa<sup>1</sup>, Yuchun Nie<sup>1</sup>, Hua Tan<sup>1</sup>, Rajendra Pandey<sup>1</sup>, Vivek Rajwanshi<sup>1</sup>, Aneerban Bhattacharya<sup>1</sup>, Cheng Kao<sup>1</sup>, Kang Hyunsoon<sup>1</sup>, Elen Rosler<sup>1</sup>, Sucheta Mukherjee<sup>1</sup>, Kusum Gupta<sup>1</sup>, David Smith<sup>1</sup>, Lawrence Blatt<sup>1</sup>, Julian Symons<sup>1</sup>, Leonid Beigelman<sup>1</sup>. <sup>1</sup>Aligos Therapeutics, South San Francisco, United States

Email: jhong@aligos.com

**Background and aims:** The current standard of care for chronic hepatitis B (CHB) fails to reduce HBsAg needed to attain a “functional cure.” HBV siRNA therapies have been shown to be effective in reducing HBsAg in CHB patients. In this study, we applied multiple stabilization chemistries, including unique end capping, to distinct HBV siRNA sequences and achieved significant improvements in depth and duration of HBsAg knockdown over their parent compounds in the serum of AAV-HBV mouse model. ALG-125755, a

GalNAc conjugated form of the siRNA ALG-125903 that utilizes these chemistries was selected for further development.

**Method:** HBV siRNAs were profiled for HBsAg release in HepG2.2.15 cells, a commonly used genotype D HBV cell model, PLC/PRF/5 cells containing integrated partial HBV genome, and a primary human hepatocyte (PHH) live HBV infection model. Unconjugated siRNAs were transfected using Lipofectamine® RNAiMAX. For PHH cells, infection with HBV at 200 MOI ( $ge$ ) occurred 4 days prior to the transfection of siRNA. The secreted HBsAg was quantified by ELISA. In the AAV-HBV mouse model, HBV siRNAs conjugated with GalNAc were administered subcutaneously (SC) with blood collections every 5 days for HBsAg and ALT assessments.

**Results:** ALG-125755 targets a highly conserved region of the HBV genome in the Small HBsAg open reading frame and can cleave 4 HBV transcripts including both 2.4 kb and 2.1 kb transcripts encoding HBsAg. The sequence demonstrates  $\geq 99\%$  homology to HBV genotypes A-J. In HepG2.2.15, ALG-125903 showed an EC<sub>50</sub> of 24 pM in inhibiting HBsAg release. This sequence also demonstrated similar potency in HBV-infected PHH and PLC/PRF/5 cells. A single 5 mg/kg, SC dose of ALG-125755 reduced HBsAg by 1.5 log<sub>10</sub> IU/ml in the serum of AAV-HBV mice, 0.5 log<sub>10</sub> IU/ml greater than its unoptimized parent. ALG-125918, containing a novel end cap to the antisense strand of another HBV siRNA, improved maximum HBsAg reduction by 0.5 log<sub>10</sub> IU/ml from its parent following a single SC dose of 5 mg/kg. Importantly, this modification significantly improved the durability of HBsAg knockdown which was stable for 90 days in AAV-HBV mice after a single dose.

**Conclusion:** Multiple novel GalNAc conjugated HBV siRNA sequences containing unique optimized stabilization patterns and novel chemistries demonstrated significant and durable HBsAg knockdown in the AAV-HBV mouse model. Among these, ALG-125755 has been selected for further development.

### PO-1240

#### Pharmacokinetics of ATI-2173, a novel active site polymerase inhibitor nucleotide, in a Phase 1b clinical trial

Katherine Squires<sup>1</sup>, Lauren Ogilvie<sup>1</sup>, Jade Huguette<sup>2</sup>, Alina Jucov<sup>3</sup>, Igor Anastasiy<sup>4</sup>, Nelli Ghicavii<sup>5</sup>, Rebeca Melara<sup>2</sup>, Martin Constantineau<sup>2</sup>, Douglas Mayers<sup>1</sup>. <sup>1</sup>Antios Therapeutics, Inc, Atlanta, United States; <sup>2</sup>Altasciences Company, Inc., Laval, Quebec, Canada; <sup>3</sup>Nicolae Testemitanu State University of Medicine and Pharmacy of the Republic of Moldova, Chisinau, Moldova; <sup>4</sup>Arensia Exploratory Medicine, Kyiv, Ukraine; <sup>5</sup>Arensia Exploratory Medicine, Chisinau, Moldova

Email: logilvie@antiostherapeutics.com

**Background and aims:** ATI-2173 is a novel phosphoramidate liver-targeted prodrug of clevudine-5'-triphosphate that functions as an active site polymerase inhibitor nucleoside (ASPIN). Unlike nucleoside inhibitors, the triphosphate is a non-competitive, non-chain terminating inhibitor that distorts the active site of the HBV polymerase. ATI-2173 demonstrated improved pharmacokinetics in animal models as compared to its parent molecule, clevudine, and was assessed for safety, tolerability, pharmacokinetics, and antiviral activity in a phase 1b clinical trial.

**Method:** The phase 1b portion of the ANTT101 study, a randomized, double-blind, placebo-controlled trial of ATI-2173 in HBV-infected subjects, was conducted at clinical sites in Moldova and Ukraine. Seventeen HBV-infected subjects were given 10 mg, 25 mg, or 50 mg ATI-2173 once a day for 28 days. Pharmacokinetics visits were conducted on days 1, 2, 3, 7, 10, 14, 21 and 28 on treatment and days 2, 3, 4, 7, 10, and 14 off treatment. A validated UHPLC method with MS/MS detection was used to measure plasma concentrations of ATI-2173 and Clevudine (1–1000 ng/ml), intermediate metabolite M1 (1–500 ng/ml). PK analysis was performed using noncompartmental methods.

**Results:** ATI-2173 was rapidly absorbed, with median T<sub>max</sub> observed at 0.5–1.0 hours post-dose, after which plasma levels rapidly declined

and were quantifiable for up to 6 hours. ATI-2173 was generally dose proportional with no indication of accumulation. Clevudine was quantifiable in the plasma through 2 to 24 hours post-dose on Day 1 and through 312 hours post-dose in all subjects on Day 28, with total exposure (AUC) being higher on Day 28 versus Day 1. Clevudine AUC<sub>24</sub> following daily dosing of 10 mg, 25 mg, and 50 mg ATI-2173 for 28 days was 5%, 13%, and 34% of the plasma exposures historically seen with the 30 mg dose of clevudine, respectively. "M1," an intermediate metabolite, is also being evaluated for PK. The mean 28-day viral load reduction with all three dose levels was  $-2.7 \log_{10}$  IU/ml.

**Conclusion:** ATI-2173 is a novel ASPIN to treat chronic HBV infection. ATI-2173 at doses of 10 to 50 mg orally per day had potent antiviral activity against chronic HBV with greatly decreased systemic exposure to the active nucleoside clevudine. The 25 and 50 mg doses of ATI-2173 have been advanced into a phase 2a study in combination with tenofovir in both HBV mono-infected and HBV/HDV co-infected populations.

**PO-1251**

**Phase 1 results for ATI-2173, a novel active site polymerase inhibitor nucleotide, in HBV-infected subjects**

Douglas Mayers<sup>1</sup>, Alina Jucov<sup>2</sup>, Igor Anastasiy<sup>3</sup>, Nelli Ghicavii<sup>2</sup>, Lauren Ogilvie<sup>1</sup>, Katherine Squires<sup>1</sup>, Abel De La Rosa<sup>1</sup>. <sup>1</sup>Antios Therapeutics, Inc., Atlanta, United States; <sup>2</sup>Arensia Exploratory Medicine, Chisinau, Moldova; <sup>3</sup>Arensia Exploratory Medicine, Kyiv, Ukraine  
Email: logilvie@antiostherapeutics.com

**Background and aims:** ATI-2173 is a novel phosphoramidate liver-targeted prodrug of clevudine-5'-triphosphate that functions as an active site polymerase inhibitor nucleoside (ASPIN). ATI-2173 was designed to enhance the antiviral HBV activity and significantly reduce systemic exposure to the parent nucleoside, clevudine. ANTT101 included a phase 1b 28-day study of ATI-2173 in treatment-naïve subjects with chronic HBV-infection eligible for treatment under EASL guidelines.

**Method:** The phase 1b portion of the ANTT101 study was a randomized, double-blind, placebo-controlled trial of ATI-2173 in chronic HBV-infected subjects conducted at sites in Moldova and Ukraine. Predominantly HBeAg-negative, HBsAg-positive subjects (n = 25) were randomized 6:2 to doses of 10 mg, 25 mg, 50 mg ATI-2173 or placebo (PBO) orally once a day for 28 days. Safety labs and pharmacokinetics were evaluated on days 1, 2, 3, 7, 10, 14, 21, and 28 on-treatment and days 2, 3, 4, 7, 10, 14, and 28 off-treatment. Antiviral activity was measured at baseline and on days 7, 14, 21, and 28 on-treatment and days 4, 10, and months 1, 3 and 6 off-treatment. HBV DNA was measured using a Roche Cobas 6800 (LLOQ = 10 IU/ml). HBsAg was measured using a Roche Elecsys (LLOQ = 0.05 IU/ml).

**Results:** ATI-2173 was generally safe and well tolerated. There were no apparent dose-related adverse events (AE) or serious adverse events. The most common AE was headache. One subject withdrew on day 3 for personal reasons and was replaced. Viral load responses at day 28 for 10 mg (N = 6), 25 mg (N = 5), 50 mg (N = 6) or PBO (N = 7) doses of ATI-2173 were  $-2.7$ ,  $-2.7$ ,  $-2.7$  and  $+0.2 \log_{10}$  IU/ml, respectively. There was no change in HBsAg at day 28. After treatment, 3/6 subjects in the 10 mg cohort, 4/5 subjects in the 25 mg cohort, 5/6 subjects in the 50 mg cohort, and 0/7 in the PBO cohort were BLQ (<10 IU/ml). Of the subjects who were BLQ, 9/9 remain BLQ at 4 weeks, 4/9 remain BLQ at 12 weeks, and 1/4 remains BLQ at 12 weeks off-treatment.

**Conclusion:** ATI-2173 is a novel ASPIN with potent activity ( $-2.7 \log_{10}$  IU/ml) against HBV at 28 days of treatment. 65% of ATI-2173 treated subjects were BLQ at EOT. Sustained off-treatment responses were noted 1- to 6-months post ATI-2173 discontinuation. The 25 mg and 50 mg doses of ATI-2173 have been advanced into a phase 2a study in combination with tenofovir in both HBV mono-infected and HBV/HDV co-infected populations.

**PO-1270**

**Safety and efficacy of switching to besifovir dipivoxil maleate in virologically-suppressed chronic hepatitis B patients with tenofovir disoproxil fumarate: 24-week interim analysis**

Email: gudwns21@korea.ac.kr

**Background and aims:** Long-term viral suppression is needed for the management of chronic hepatitis B (CHB). Although tenofovir disoproxil fumarate (TDF) shows high antiviral efficacy, its extended use is associated with renal toxicity and bone mineral density reduction. Therefore, we aimed to evaluate the efficacy and safety of besifovir dipivoxil maleate (BSV) for 48 weeks in CHB patients after switching therapy from TDF to BSV.

**Method:** We are currently performing a randomized, active-controlled, open-label, multicenter study to evaluate safety and non-inferior efficacy of switching from TDF to BSV for 48 weeks compared to continuing TDF in virologically suppressed patients (HBV DNA <20 IU/ml). The primary end point was the proportion of patients who achieve a sustained undetectable HBV DNA level <20 IU/ml at 48 weeks. We evaluated renal and bone-related outcomes for safety analysis.

**Results:** A total of 153 patients were enrolled. An interim analysis was conducted on a subset of 142 patients (70 switched to BSV, 72 maintaining TDF) at week 24. Baseline characteristics were similar between the two groups. At 24 weeks, high rates of virologic response were maintained 98.6% and 100% in BSV and TDF groups, respectively (95% CI - 4.33 to 1.39; p = 0.493). None of the patients developed virologic breakthrough. The mean eGFR significantly improved by 4.20% in the BSV group (p = 0.003) whereas it changed only by 1.00% in the TDF group (p = 0.482). Patients who switched to BSV experienced improvements in bone turnover biomarkers while those who maintaining TDF worsened, and had increased T-score of bone mineral density at spine (p < 0.001). FIB-4 score declines in the BSV group was larger than in TDF group (p = 0.005).

## POSTER PRESENTATIONS

**Conclusion:** In this interim analysis, patients who switched from TDF to BSV maintained efficacy in viral suppression without virological breakthrough with significant improvements in bone safety at 24 weeks.

### PO-1286

#### No emergent core inhibitor resistance in patients with chronic hepatitis B virus infection treated with Vebicorvir in combination with a nucleoside reverse transcriptase inhibitor

Man-Fung Yuen<sup>1</sup>, Stephen Locarnini<sup>2</sup>, Peter Revill<sup>3</sup>, Ran Yan<sup>4</sup>, Lea Ouyang<sup>4</sup>, Dawei Cai<sup>4</sup>, William Delaney<sup>4</sup>, Katie Kitrinov<sup>4</sup>, Alexander Thompson<sup>5</sup>, Fabien Zoulim<sup>6</sup>, Mark Sulkowski<sup>7</sup>. <sup>1</sup>The University of Hong Kong, Department of Medicine, Hong Kong; <sup>2</sup>VIDRL Doherty Institute, Research and Molecular Development, Melbourne, Australia; <sup>3</sup>VIDRL, Royal Melbourne Hospital at the Peter Doherty Institute for Infection and Immunity, Melbourne, Australia; <sup>4</sup>Assembly Biosciences, South San Francisco, United States; <sup>5</sup>St. Vincent's Hospital and the University of Melbourne, Department of Gastroenterology, Fitzroy, Australia; <sup>6</sup>Viral Hepatitis Laboratory, Cancer Research Center of Lyon, Lyon, France; <sup>7</sup>Johns Hopkins University School of Medicine, Baltimore, United States  
Email: ryan@assemblybio.com

**Background and aims:** Vebicorvir (VBR, ABI-H0731) is a 1<sup>st</sup> generation hepatitis B virus core inhibitor in development for the treatment of chronic hepatitis B virus infection (cHBV). In the Phase 2 Study 201, virologically suppressed cHBV patients were randomized in a blinded manner to VBR or placebo with nucleoside reverse transcriptase inhibitor (NrtI) for 24 weeks after which eligible patients entered the open-label extension Study 211 to receive VBR+NrtI. On treatment, VBR+NrtI led to deeper virologic suppression as assessed by high sensitivity HBV DNA and pgRNA assays. The aim of this study was to investigate whether any treatment emergent core inhibitor or NrtI substitutions were observed after treatment discontinuation.

**Method:** 41 patients discontinued VBR+NrtI; all patients experienced virologic rebound and were included in the study. Sanger sequencing of RNA at HBV core and the pol/RT region was attempted for all patients at Study 201 baseline and DNA was sequenced for the first 2 consecutive off treatment visits with HBV DNA >20 IU/ml. Sequence evaluations were conducted across core and the pol/RT region, focusing on core inhibitor binding pocket substitutions and NrtI resistance mutations.

**Results:** 28 and 22 patients were successfully sequenced at all 3 timepoints for HBV core and pol/RT, respectively. There were 13 and 19 patients without baseline sequences for core and pol/RT, respectively, due to low viral loads. Overall, no core inhibitor substitutions were observed in 32/41 (78%) patients at all timepoints tested. Y38F and Y118F substitutions were each detected off treatment in 1 patient missing a baseline sequence; both substitutions remained stable between off treatment timepoints ( $\geq 4$  weeks) (Table 1). Seven patients had core inhibitor substitutions at baseline (Y38H/F, P25S, D29E and I105 T); no enrichment of these substitutions was observed off treatment. NrtI resistance mutations were detected off treatment in 4 patients missing baseline sequences. All NrtI mutations reverted towards wildtype off treatment, with no enrichment/development of NrtI mutations.

Table: Summary of core inhibitor Substitutions Observed

Subject	Baseline	Off Treatment 1	Off Treatment 2
1	no baseline	Y38F	Y38F
2	no baseline	Y118Y/F	Y118Y/F
3	Y38F	Y38F	Y38F
4	Y38H/Y	Y38Y/H	Y38
5	Y38Y/F	Y38F/Y	Y38F/Y
6	Y38Y/H	Y38Y/H	Y38
7	P25P/S	P25	P25
8	D29D/E	D29D/E	D29D/E
9	I105T	I105T	I105T

**Conclusion:** Overall, most patients (78%) had no core inhibitor substitutions detected by Sanger sequencing. For patients harboring a core inhibitor substitution (22%), no enrichment compared to baseline was observed after treatment was removed.

### PO-1386

#### Capsid assembly modulator ALG-000111 and its prodrug ALG-000286 display excellent in vitro and in vivo antiviral activity

Yannick Debing<sup>1</sup>, Dieudonné B. Kum<sup>1</sup>, Cheng Liu<sup>2</sup>, Jerome Deval<sup>2</sup>, Hannah Vanrusselt<sup>3</sup>, Abel Acosta Sanchez<sup>3</sup>, Qingling Zhang<sup>2</sup>, Sucheta Mukherjee<sup>2</sup>, Dinah Misner<sup>2</sup>, Sushmita Chanda<sup>2</sup>, Raymond F. Schinazi<sup>4</sup>, Julian Symons<sup>2</sup>, Lawrence Blatt<sup>2</sup>, Leonid Beigelman<sup>2</sup>, Pierre Raboisson<sup>1</sup>, Sandrine Vendeville<sup>1</sup>, David Smith<sup>2</sup>, Andreas Jekle<sup>2</sup>. <sup>1</sup>Aligos Belgium BV, Leuven, Belgium; <sup>2</sup>Aligos Therapeutics, Inc., South San Francisco, United States; <sup>3</sup>Novalix, Leuven, Belgium; <sup>4</sup>Emory University, Atlanta, United States  
Email: ydebing@aligos.com

**Background and aims:** Hepatitis B virus (HBV) capsid assembly is a promising target for the treatment of chronic hepatitis B. Class II capsid assembly modulators (CAMs) induce rapid HBV core protein (HBc) assembly into empty capsids, thus inhibiting HBV RNA encapsidation and formation of infectious HBV particles. CAMs can also block cccDNA establishment by blocking viral DNA release from the capsid after entry. As a part of our efforts to advance multiple structurally diverse CAMs, we report on ALG-000111, a novel Class II CAM with excellent antiviral activity and efficacy in the AAV-HBV mouse model.

**Method:** HBV DNA antiviral activity was determined in HepG2.117 cells using qPCR, with and without 40% human serum. Optimized assays were performed to assess inhibition over several logs and longevity of the antiviral effect after compound removal. Activity was also studied in HBV-infected primary human hepatocytes, both the primary effect on HBV DNA and the secondary effect on cccDNA establishment. Further characterization was performed using biochemical quenching assays, electron microscopy visualization, and immunofluorescent HBc staining. ADME properties were evaluated in vitro, whereas in vivo antiviral efficacy was assessed in the AAV-HBV mouse model.

**Results:** ALG-000111 and its prodrug ALG-000286 potently inhibited HBV DNA production in HepG2.117 cells with EC50/EC90 values of 0.88/4.34 nM and 2.06/9.23 nM respectively. An optimized protocol allowed the determination of EC99/EC99.9 values of 4.81/15.3 nM and 10.4/39.7 nM respectively. Inclusion of 40% human serum resulted in a modest 7-fold shift in antiviral activity. Rebound assays showed a significant retention of antiviral activity, with strong inhibition observable up to 10 days after compound removal. ALG-000111 also displayed significant antiviral activity in HBV-infected primary human hepatocytes with EC50/EC90 values of 0.98/3.22 nM on HBV DNA. Additionally, the formation of cccDNA was blocked, indicated by potent reductions in secreted HBsAg and intracellular HBV RNA (EC50/EC90 values of 41.7/651 nM and 34.0/189 nM respectively). ALG-000111 induced empty capsid formation in

biochemical quenching assays and by electron microscopy. Immunofluorescent imaging revealed a tendency for cytoplasmic HBc accumulation. ALG-000111 was stable in SGF/SIF and in liver microsomes and hepatocytes across species. The compound displayed low CYP450-mediated drug-drug interaction potential and high permeability across Caco-2 monolayers. Evaluation of the prodrug ALG-000286 in the AAV-HBV mouse model resulted in a strong reduction in HBV DNA with a mean maximum 3.7 log<sub>10</sub> IU/ml drop in HBV DNA following 4 weeks of PO dosing at 30 mg/kg BID.

**Conclusion:** With sub-nanomolar activity and deep knockdown of HBV DNA in cell-based assays and the AAV-HBV mouse model, ALG-000286 is a promising Class II CAM candidate for further development.

**PO-1416**

**Pharmacokinetics and safety of JNJ-73763989, an RNA interference therapy for hepatitis B virus, in moderately hepatically impaired participants**

Thomas Kakuda<sup>1</sup>, Atef Halabi<sup>2</sup>, Carine Guinard-Azadian<sup>3</sup>, Katja Nedoschinsky<sup>3</sup>, Julius Nangosyah<sup>3</sup>, Emmanuel Njumbe Ediage<sup>3</sup>, Peter Verboven<sup>3</sup>, Michael Biermer<sup>3</sup>. <sup>1</sup>Janssen BioPharma Inc., South San Francisco, United States; <sup>2</sup>Clinical Research Services Kiel GmbH, Kiel, Germany; <sup>3</sup>Janssen Pharmaceutica NV, Beerse, Belgium  
Email: tkakuda@its.jnj.com

**Background and aims:** JNJ-73763989 comprises hepatitis B virus (HBV)-specific, liver-targeted N-galactosamine-conjugated short interfering RNA (siRNA) triggers, JNJ-73763976 and JNJ-73763924, which silence HBV RNA transcripts from host-integrated HBV DNA and episomal DNA. JNJ-73763989 administered subcutaneously (SC) as 3 monthly doses 100–400 mg + a nucleos (t)ide analogue daily, demonstrated HBsAg decline ≥1 log<sub>10</sub> IU/ml in chronic HBV patients that was sustained in 39% of patients for up to 48 weeks off treatment (Gane EJ, et al. EASL 2020). Here, pharmacokinetics (PK), safety/tolerability of JNJ-73763989 in participants with moderate hepatic impairment (Child-Pugh B) for reasons other than HBV infection were evaluated and compared to healthy participants with normal liver function.

**Method:** 73763989HPB1002 (NCT04208386) was a Phase 1 single-dose, open-label, parallel study. Eight Child-Pugh B participants and 8 healthy participants matching for sex, age (± 10 years) and body weight (± 10 kg) were enrolled and received a single 200 mg SC dose of JNJ-73763989. Plasma and urine concentrations of JNJ-73763976 and JNJ-73763924 were collected over 72 hours and analyzed using liquid chromatography coupled to a fluorescence detector. PK parameters were estimated using non-compartmental analysis (WinNonlin, Certara, Princeton NJ). Safety/tolerability were assessed throughout.

**Results:** PK parameters are summarized (table). JNJ-73763976 geometric mean ratio for C<sub>max</sub> was 1.4- and AUC 1.3-fold higher in Child-Pugh B participants vs case controls; for JNJ-73763924, 2.2- and 2.0-fold higher. Half-life and amount of drug renally excreted were slightly higher for both analytes in Child-Pugh B participants. There were no deaths, serious adverse events (AEs) or discontinuations. Overall, 2 participants, 1 in each group, reported ≥1 treatment-emergent AE (TEAE). TEAEs were mild/moderate and not related to JNJ-73763989. All TE graded laboratory abnormalities were mild/moderate, except for transient platelet reductions from grade 2 at screening to grade 3 in 2 Child-Pugh B participants. There were no relevant cardiovascular findings.

Liver status	JNJ-73763976		JNJ-73763924	
	Child-Pugh B 8	Healthy participants 8	Child-Pugh B 8	Healthy participants 8
C <sub>max</sub> (ng/mL)	1,640 (1,087)	1,068 (565)	444 (355)	190 (75)
t <sub>max</sub> (h)	7.00 (0.25–12.00)	9.00 (4.00–12.00)	6.00 (0.25–12.00)	8.00 (0.50–12.00)

**First real-life experiences with 2 mg bulevirtide for the treatment of hepatitis delta-data from a tertiary reference centre in Germany**

Caroline Zöllner<sup>1</sup>, Katrin Lutz<sup>1</sup>, Münevver Demir<sup>1</sup>, Frank Tacke<sup>1</sup>. <sup>1</sup>Charité-University Medicine Berlin, Department of Hepatology and Gastroenterology, Campus Virchow Klinikum and Charité Campus Mitte, Berlin, Germany  
Email: caroline.zoellner@charite.de

**Background and aims:** Hepatitis B/D coinfection poses a high risk for the progression to severe liver disease. In July 2020, bulevirtide (2 mg/day) was approved in the European Union for the treatment of chronic hepatitis delta. The drug blocks the bile salt transporter Ntcp, which is also the entry receptor for Hepatitis B and D viruses. Here we describe the first sixteen weeks of therapy with bulevirtide in hepatitis delta patients who were included in an early access programme in a tertiary care centre in Germany.

**Method:** We included patients with active hepatitis B/D coinfection who were eligible for the early access programme. The main exclusion criteria were liver cirrhosis Child-Pugh Score B or C, thrombocytopenia below 50/nl, hepatocellular carcinoma or planned pregnancy. All included patients (n = 8) received detailed information and training for drug administration.

**Results:** All patients (n = 8) were under concomitant therapy with nucleoside/nucleotide analogues. None had a concomitant interferon treatment, mostly due to patients' reticence or contraindications. One patient dropped out shortly after inclusion because of a newly diagnosed hepatocellular carcinoma, and seven patients completed at least 16 weeks of therapy (table). Mean ALT values before treatment (baseline) were 78 U/l and declined to 39 U/l after 16 weeks. Mean HDV-RNA was 10, 902, 457 cop/ml at baseline and dropped to 3, 740, 569 cop/ml. One patient showed no significant biochemical or viral response and was discontinued. We observed no relevant side effects apart from asymptomatic elevation of bile acids.

Table: HDV-RNA in the first 16 weeks of therapy (cop/ml)

	Baseline	Week 4	Week 8	Week 12	Week 16
Pat. 1	13,200	non detectable	non detectable	<3,000	<3,000
Pat. 2	541,000	non detectable	non detectable	<3,000	5,380
Pat. 3	>24,50,000	6,240,000	>24,500,000	>24,500,000	>24,500,000
Pat. 4	>24,500,000	5,030,000	1,150,000	255,000	665,000*
Pat. 5	>24,500,000	>24,500,000	1,980,000	1,060,000	980,000
Pat. 6	2,260,000	24,9000	118,000	29,500	27,600
Pat. 7	<3,000	5,230	<3,000	NA	<3,000

\*HDV-RNA for this patient was not available at week 16 but at week 20  
The linear range in our laboratory is from 3,000 to 24,500,000 copies

## POSTER PRESENTATIONS

**Conclusion:** These are the first real life data on bulevirtide therapy in Germany. Overall, we observed a favorable safety profile as well as a marked biochemical and virological response in the majority of our patients. However, middle- and long-term data are needed to evaluate the impact of bulevirtide on clinical end points in hepatitis delta patients.

### PO-1448

#### Excellent virological and clinical responses maintained over 3 years of continuous Bulevirtide treatment in patients with HDV compensated cirrhosis and clinically significant portal hypertension

Email: ale.loglio@gmail.com

**Background and aims:** Treatment with Bulevirtide (BLV) for 48 weeks in compensated HDV cirrhotic patients is safe and effective, but its long-term effects in a real-life setting even after dose reduction/discontinuation have not been investigated yet.

**Method:** Three difficult-to-treat compensated HDV cirrhotic patients with clinically significant portal hypertension added BLV 10 mg/day (high dose) to ongoing TDF. Case 1: 69 years, female, HDV-RNA 23, 600 IU/ml, HBsAg 10 IU/ml, ALT 140 U/L; Case 2: 51 years, male, HDV-related autoimmune hepatitis, small esophageal varices, platelets 74, 000/mm<sup>3</sup>, HDV-RNA 392, 000 IU/ml, ALT 232 U/L; Case 3: 58 years, female, HDV-RNA 104, 803 IU/ml, ALT 244 U/L. HDV-RNA was quantified by RoboGene 2.0 (LLOQ 6 IU/ml). In first two patients, HDV/HBV-specific T cells were analyzed in blood by direct ex-vivo IFN- $\gamma$  ELISPOT methods, up to last follow-up

**Results:** In Case 1, HDV-RNA became undetectable by week 36 and ALT normalized by week 20. After BLV withdrawn (week 52), HDV-RNA became rapidly detectable, peaked at week 16 (13, 655 IU/ml), and then declined at week 32 (421 IU/ml), remaining stable <1, 000 IU/ml afterwards. ALT level increased from week 14 to 30 (41–333 U/L) and then declined to persistent normal values. At 101-weeks off therapy: HDV-RNA 87 IU/ml, ALT 26 U/L, HBsAg 0.49 IU/ml. Two patients were treated continuously for 3 years: undetectable HDV-RNA and normal ALT levels were achieved after 28 and 12 weeks in Case 2, and 52 and 28 weeks in Case 3. Virological and biochemical response were maintained through the following 2 years of therapy, even after BLV dose reduction to 5 and 2 mg/day. At last visit: both patients had undetectable HDV-RNA and ALT 22 U/L. In one patient, virological response was associated with an excellent clinical response: esophageal varices disappeared, histological/lab features of autoimmune hepatitis resolved, AFP normalized, platelets and albumin improved. Overall, no safety issues were recorded, as bile salt increase was asymptomatic. Circulating HDV/HBV-specific T cells were tested in 2 patients at baseline and every 2 months during and off-therapy: no changes were observed, neither after HDV reactivation (Case 1) nor in 2.5 years of BLV continuative treatment (Case 2).

**Conclusion:** Continuous administration of BLV for 3 years provides excellent virological and clinical response in HDV cirrhotic patients with clinically significant portal hypertension.

**Background and aims:** HIV-positive patients on Tenofovir (TDF)/FTC have a lower risk for COVID-19 and related hospitalization than those on other therapies (Ann Intern Med 2020;173:536). We hypothesize that TDF reduces the incidence and severity of COVID-19 in patients with chronic hepatitis B (CHB). Our aim was to analyze the incidence and severity of COVID-19 in patients with CHB on antiviral treatment, TDF or entecavir (ETV).

**Method:** Search of patients with COVID-19 infection between 1st February to 30th November in the database of adult (>18 yr) CHB patients on TDF or ETV from 28 Spanish hospitals. COVID-19 infection was defined by a positive polymerase chain reaction, and severe infection by bilateral severe pneumonia, acute respiratory distress syndrome, sepsis or septic shock (WHO criteria). The effect of antiviral treatment on the risk of severe COVID-19 was estimated by the inverse probability of treatment weighting propensity score (IPTW) method. Need for intensive care unit (ICU) and ventilatory support, and mortality were explored by bivariate analysis.

**Results:** The database search of 4736 CHB patients identified 117 with COVID-19 (2.5%, 95%CI 2.1–2.9%), 67 on TDF and 50 on ETV. Forty-one (35%), 5 (4.3%) and 6 (5.1%) out of the 117 patients with COVID-19 were hospitalized, admitted to ICU or died, respectively. Compared with patients on TDF, those on ETV had significantly ( $p < 0.05$ ) greater rates of obesity (22 vs. 9%), diabetes (32 vs. 12%), ischemic cardiopathy (14 vs. 3%) and arterial hypertension (44 vs. 18%). There was a trend for greater severity of advanced (F3–F4) fibrosis in the ETV groups (35 vs. 18%,  $p = 0.06$ ). The incidence of COVID-19 in patients on TDF or ETV was similar (0.023 vs. 0.026,  $p = 0.44$ ). Table shows that, compared with those on TDF, patients on ETV more often had severe COVID-19, required ICU, ventilatory support, had longer hospitalization or died. In multivariate logistic regression adjusted by age, sex, obesity, comorbidities and fibrosis stage, TDF reduced by 6-fold the risk of severe COVID-19 (adjusted-IPTW-OR 0.17, 95%CI 0.04–0.67,  $p = 0.01$ ).

Table: Characteristics of COVID-19 by treatment groups

	ETV (50)	TDF (67)	p
Severe COVID-19	18 (36%)	4 (6%)	<0.01
ICU admission	5 (10%)	0 (0%)	0.01
Ventilatory support	10 (20%)	2 (3%)	<0.01
Hospitalization days	10.8 ± 19	3.1 ± 7	<0.01
Death	5 (10%)	1 (1.5%)	0.08

**Conclusion:** Patients with CHB on TDF have a lower risk of severe COVID-19 infection than those on ETV. TDF seems to exert a protective effect in patients with CHB infected by COVID-19.

**PO-1628**

**Comparison of hepatitis B virus relapses between hepatitis B e antigen-negative chronic hepatitis B patients who discontinue tenofovir disoproxil fumarate with or without switching to alafenamide**

Chien-Hung Chen<sup>1</sup>, Rachel Wen-Juei Jeng<sup>2,3</sup>, Tsung-Hui Hu<sup>4</sup>, Yen-Chun Liu<sup>5</sup>, Jing-Houng Wang<sup>4</sup>, Chao-Hung Hung<sup>4</sup>, Sheng-Nan Lu<sup>4</sup>, Rong-Nan Chien<sup>2</sup>. <sup>1</sup>Chang Gung Memorial Hospital, Internal Medicine, Kaohsiung, Taiwan; <sup>2</sup>Linkou Chang Gung Memorial Hospital, Internal Medicine, Taoyuan, Taiwan; <sup>3</sup>Chang Gung University, College of Medicine, Taiwan; <sup>4</sup>Kaohsiung Chang Gung Memorial Hospital, Internal Medicine, Kaohsiung, Taiwan; <sup>5</sup>Linkou Chang Gung Memorial Hospital, Taoyuan, Taiwan  
Email: e580306@ms31.hinet.net

**Background and aims:** Previous studies showed that hepatitis B virus (HBV) relapse after the cessation of tenofovir disoproxil fumarate (TDF) occurs much earlier than that after the cessation of entecavir. Prior study showed the clinical relapse pattern goes along with the ended-up nucleos(t)ide analogues (Peng CW AASLD 2020 abstract). Tenofovir alafenamide (TAF) is a new prodrug of tenofovir, TAF was non-inferior to TDF in efficacy. However, the incidence of HBV relapse after the cessation of TAF therapy remains unclear. The aim of this study is to compare HBV relapse rates between hepatitis B e antigen (HBeAg)-negative chronic hepatitis B (CHB) patients who discontinued TDF with or without switching to TAF.

**Method:** A total of 442 HBeAg-negative patients who received TDF monotherapy and 31 HBeAg-negative patients who received TDF at the start treatment and switching to TAF at least 12 weeks (range 20–

69 weeks) were recruited. The patients all had post-treatment follow-up for at least 4 months. All patients fulfilled the stopping criteria of the Asia-Pacific Association for the Study of the Liver of 2012. The propensity score-matching method was used by creating a ratio of 1:3 to adjust age, sex, cirrhosis, HBV DNA at entry, treatment and consolidation duration and end-of-treatment (EOT) HBsAg. Thus, 31 and 93 patients who discontinued TDF with (Group I) and without (Group II) switching to TAF were included in this study.

**Results:** There were no significant differences in terms of clinical features or HBsAg levels between the two groups. In the Group I and Group II patients, the incidences of virological relapse at post-treatment 12 and 24 weeks were 50.5% versus 36.6% and 71.4% versus 59.1% ( $p = 0.211$ ), respectively, and the clinical relapse rates were 34.4% versus 30.1% and 62.1% versus 52.7% ( $p = 0.259$ ), respectively. There was no significant difference in virological and clinical relapse rates between the two groups. Multivariate analysis showed that old age, NA-naïve status and lower EOT HBsAg levels were independent predictors of virological and clinical relapse.

**Conclusion:** HBV relapse rate might be comparable between HBeAg-negative CHB patients who discontinued TDF with or without switching to TAF.

**PO-1661**

**Outcomes and characteristics of hepatocellular carcinomas (HCC) in Caucasian chronic hepatitis B (CHB) patients treated with long-term entecavir (ETV) or tenofovir disoproxil fumarate (TDF) therapy**

Email: gepapath@med.uoa.gr

**Background and aims:** HCC can develop in CHB patients under long-term oral antiviral therapy even in reduced rates, but the characteristics of this occurrence have not been adequately studied. This study aimed to assess patient and tumour characteristics as well as outcomes in adult Caucasian CHB patients, with or without compensated cirrhosis, who developed HCC during long-term therapy with ETV or TDF.

**Method:** In total, 1951 adult Caucasian CHB patients treated with ETV/TDF were included in the PAGE-B cohort (baseline age 53 ± 14 years, males 71%, HBeAg-positive 18%, cirrhosis 28%). Patients with

## POSTER PRESENTATIONS

decompensated cirrhosis or coinfections were excluded. HCC surveillance was based on ultrasonography  $\pm$  aFP at least every 6 or 12 months in patients with and without cirrhosis, respectively. During a median follow-up of 8.8 years after ETV/TDF onset, HCC was diagnosed in 155 (7.9%) patients at a median of 3.8 (0.1–13.5) years. Patient characteristics at baseline and at HCC diagnosis, HCC therapeutic interventions and outcomes were analysed.

**Results:** In the 155 patients with HCC, mean age was  $63 \pm 8$  years at ETV/TDF onset and  $67 \pm 9$  years at HCC diagnosis, whereas 87% were males, 10% were HBeAg-positive and 69% had cirrhosis at baseline. HCC was diagnosed within Milan criteria in 84% of cases, whereas 80%, 12% and 8% of cases were classified as BCLC stage 0-A, B and C, respectively. Potentially curative intervention was provided in 72% of patients. No patient or tumour characteristic or type of intervention differed in patients with HCC diagnosed in  $\leq 2$  and  $>2$  (or  $\leq 5$  and  $>5$ ) years after ETV/TDF onset, except for mean age at HCC diagnosis ( $61 \pm 9$  vs  $66 \pm 8$  vs  $71 \pm 7$  years in patients with HCC diagnosed in  $\leq 2$  vs  $>2$ – $5$  vs  $>5$  years after ETV/TDF onset,  $P < 0.001$ ). Cumulative rates of 1-, 3-, 5-year overall survival were 87%, 63%, 49% and liver transplantation free survival 81%, 55%, 43%, respectively. Overall survival was not associated with any of the patient characteristics, but it was better in patients treated with curative interventions (HR:3.2, 95%CI:1.8–5.7;  $P < 0.001$ ).

**Conclusion:** In treated Caucasian CHB patients, with or without compensated cirrhosis, who are under HCC surveillance, HCCs are usually diagnosed within Milan criteria and in early BCLC stage allowing potentially curative therapies in most cases. The probability of 5-year overall survival after HCC diagnosis is almost 50% and is affected only by curative intervention but not by patient characteristics.

### PO-1699

#### Discovery and preclinical profile of VNRX-9945, a potent, broadly active core protein inhibitor for the treatment of hepatitis B virus (HBV) infection

Glen Coburn<sup>1</sup>, Bin Liu<sup>1</sup>, Christopher Benetatos<sup>1</sup>, Jiangchao Yao<sup>1</sup>, Steve Boyd<sup>1</sup>, Tom Haimowitz<sup>1</sup>, Stephen Condon<sup>1</sup>, Tony Drager<sup>1</sup>, Susan Emeigh Hart<sup>1</sup>, Daniel Pevear<sup>1</sup>, Christopher Burns<sup>1</sup>. <sup>1</sup>Venatorx Pharmaceuticals, Inc., Malvern, United States  
Email: coburn@venatorx.com

**Background and aims:** A functional cure for chronic hepatitis B virus (HBV) infection remains the ultimate goal of HBV therapy. To achieve this objective, combinations of direct-acting antivirals, oligonucleotide agents that promote antigen knockdown and immune modulators, are likely required to further suppress viral replication and eliminate infected hepatocytes. Here we report on the discovery and preclinical profile of VNRX-9945, a potentially best-in-class core protein inhibitor for the treatment of chronic HBV infection.

**Method:** VNRX-9945 was identified through multiple iterative cycles of medicinal chemistry followed by rigorous profiling in a battery of antiviral, ADME, pharmacokinetic and *in vitro* safety assays. The *in vitro* antiviral properties of VNRX-9945 were evaluated in several HBV replication assays using quantitative polymerase chain reaction (qPCR) to measure extracellular HBV DNA. The pharmacokinetics, safety and tolerability of the compound were extensively studied in both rats and cynomolgus monkeys following single and repeat doses of VNRX-9945 for up to 28-days. Finally, the *in vivo* antiviral activity of VNRX-9945 was demonstrated in the AAV-HBV mouse model of HBV infection.

**Results:** VNRX-9945 binds to the dimer-dimer interface of the HBV core protein and accelerates the formation of normal sized capsids that are devoid of the HBV pgRNA and polymerase. The compound is a potent inhibitor of HBV replication with an  $EC_{50} = 2$  nM ( $EC_{90} = 12$  nM) in both HepG2.2.15 and HepAD38 cells with a modest shift ( $\sim 5$ -fold) in activity in the presence of human serum. VNRX-9945 demonstrates potent activity against genotypes A-H and is broadly active against the majority of amino acid polymorphisms localized to

the core inhibitor binding site. Addition of VNRX-9945 to primary human hepatocytes at the time of infection not only blocked normal capsid assembly but also inhibited *de novo* formation of covalently closed circular DNA (cccDNA) with an  $EC_{50} = 100$  nM. Oral administration of a solution of VNRX-9945 to mice, rats, dogs and monkeys resulted in linear exposures up to doses of 600 mg/kg. Administration of VNRX-9945 to rats and monkeys for up to 28 days resulted in no adverse effects or target organ toxicity. Finally, repeat dosing of VNRX-9945 (10–100 mg/kg bid) resulted in potent suppression of HBV DNA to below the lower limit of quantification in the AAV-HBV mouse model of infection.

**Conclusion:** VNRX-9945 is one of the most potent core inhibitors reported to date with demonstrated activity against both capsid assembly and *de novo* cccDNA formation in naive primary hepatocytes. The antiviral, pharmacokinetic and safety profile supports the inclusion of VNRX-9945 in future combination therapies that are optimized to achieve a functional cure for chronic HBV. VNRX-9945 is being advanced rapidly into clinical development as a potential best-in-class core protein inhibitor.

### PO-1775

#### GST-HG141, a novel clinical-stage hepatitis B virus capsid assembly modulator

Dong Zhang<sup>1</sup>, Wenqiang Wu<sup>1</sup>, Shikui Chen<sup>1</sup>, Zhou Yu<sup>1</sup>, Vadim Bichko<sup>1</sup>, John Mao<sup>1</sup>, Jiang Zhigan<sup>2</sup>, Haiying He<sup>2</sup>, Jian Li<sup>2</sup>, Shuhui Chen<sup>2</sup>. <sup>1</sup>Fujian Cosunter Pharmaceutical Co., Ltd., Fuzhou, China; <sup>2</sup>Domestic Discovery Service Unit, WuXi AppTec (Shanghai) Co., Ltd., Shanghai, China  
Email: vbichko@gmail.com

**Background and aims:** Capsid assembly process, a critical step in the hepatitis B virus (HBV) life cycle, has recently emerged as a key target for the treatment of chronic hepatitis B. The capsid assembly modulators (CAMs) have been validated in the clinic and have a potential for HBV cure. Here we report preclinical characterization of GST-HG141, a novel HBV CAM, including molecular mechanism (s) of its antiviral action and the resistance profile *in vitro*. Currently GST-HG141 is under phase I clinical evaluation.

**Methods:** A purified, recombinant, c-terminally truncated HBV core protein (aa 1–150) was used in the biochemical quenching assay, size-exclusion chromatography and transmission electron microscopy (TEM), to determine the effects on HBV capsid assembly *in vitro*. Effects on secreted HBV DNA were determined in HepG2.2.15 cells using qPCR. Western, southern and northern blots were performed to detect HBV capsids and HBV capsid-associated DNA and RNA, respectively. *In vivo* antiviral efficacy was assessed in the AAV-HBV mouse model.

**Results:** In the biochemical quenching assay, GST-HG141 induced HBV core protein assembly ( $EC_{50} = 0.93 \pm 0.11$   $\mu$ M). GST-HG141 also induced formation of intact capsids, demonstrated by the size-exclusion chromatography experiments. TEM studies confirmed that treatment with GST-HG141 did not affect the capsid morphology. In the GST-HG141-treated HepG2.2.15 cells, a dose-dependent reduction of capsid-associated HBV DNA was observed. However, a shift from T=4 towards T=3 capsid formation was not observed, in contrast to other class I CAMs. The HBV DNA secretion in HepG2.2.15 cells was potently inhibited ( $EC_{50} = 8.16 \pm 3.65$  nM). In the transient transfection assays, GST-HG141 retained potent antiviral activity against HBV genotypes A–D ( $EC_{50}$  of 26–228 nM), and against nucleos (t)ide- and CAM-resistant mutants. The resistance profile of this drug was different from that of other CAMs. No significant cytotoxicity was observed in human cell lines and primary cells ( $CC_{50} > 50$  microM). The antiviral effect of GST-HG141 was HBV-specific, no other tested viruses were inhibited. In the AAV/HBV model, GST-HG141 robustly and dose-dependently reduced serum ( $\sim 3.0$  log<sub>10</sub>) and liver (0.9 log<sub>10</sub>) HBV DNA. Combination with Tenofovir resulted in additivity. GST-HG141 was well-tolerated, no significant effect on animal body weight was observed.

**Conclusion:** GST-HG141 is a novel, orally-bioavailable HBV CAM. It accelerates HBV capsid assembly in vitro, leading to formation of “empty” capsids, devoided of genetic material. However, its mode of action and resistance profile appear to be distinct from other class I CAMs in development. GST-HG141 has an excellent antiviral potency in vitro, as well as efficacy in vivo, and is well-tolerated in rodents. Further development of GST-HG141 for chronic HBV infections is warranted. Currently it is undergoing phase I clinical evaluations.

**PO-1781**

**HCC incidence is low after HBsAg seroclearance in off-Nuc patients**

Rachel Wen-Juei Jeng<sup>1,2,3</sup>, Yen-Chun Liu<sup>1,2,3</sup>, Chien-Wei Peng<sup>1,2,3</sup>, Yi-Cheng Chen<sup>1,2,3</sup>, Rong-Nan Chien<sup>1,2,3</sup>, Yun-Fan Liaw<sup>2,3</sup>. <sup>1</sup>Linkou Chang Gung Memorial Hospital, Department of Gastroenterology and Hepatology, Taiwan; <sup>2</sup>Chang Gung University, College of Medicine, Taiwan; <sup>3</sup>Linkou Chang Gung Memorial Hospital, Liver Research Unit, Taiwan

Email: liveryfl@gmail.com

**Background and aims:** Hepatocellular carcinoma (HCC) incidence is low in chronic hepatitis B (CHB) patients with HBsAg seroclearance during natural history or antiviral therapy. Studies showed that 2.29% of CHB patients would develop HCC after HBsAg loss. However, the long-term outcome in patients with HBsAg loss after stopping nucleos (t)ide analogues (Nuc) therapy is unknown. **Aim:** To investigate the HCC incidence in CHB patients who had HBsAg loss after stopping Nuc

**Method:** Patients with finite Nuc therapy and had HBsAg loss after stopping Nuc were recruited. Age at treatment, end-of-treatment and HBsAg loss, as well as gender, cirrhosis, HBV genotype (GT), treatment duration were compared. Of a total of 1681 patients in the Chang Gung Memorial Hospital off-Nuc cohort, HBsAg loss was confirmed in 157 patients. Excluding patients with HBsAg loss during Nuc (N = 18), or HCC occurrence during (N = 8) or after stopping Nuc but before HBsAg loss (N = 5) and follow-up less than 6 months (N = 4), a total of 122 CHB patients were recruited.

**Results:** A total of 122 CHB patients with off-Nuc HBsAg loss were analysed. The median treatment duration was 2.7 (0.8–8.2) years, 90% were male, 41.8% were cirrhosis, GT-B: 68.9%, GT-C: 31.1%. Before HBsAg loss, 40 patients (32.8%) had clinical relapse without retreatment. The median time from end-of-treatment to HBsAg loss was 3.7 (0–16.7) years. During a median follow-up of 4.6 (0.5–18.6) years after HBsAg loss, 3 male patients developed HCC at month 10 (age 47, non-cirrhotic), 16 (age 61, cirrhotic), 52.5 (age 63, cirrhotic) after HBsAg loss. There’s no difference of HBV genotype, treatment duration, presence of clinical relapse between patients with and without HCC. The HCC occurrence was numerically higher in patients with cirrhosis (2/51, 3.9%) than non-cirrhosis (1/71, 1.4%) but the difference was non-significant statistically (p = 0.57).

**Conclusion:** This seemed to be the first report of HCC development after HBsAg loss in patients who had stopped finite Nuc therapy. The HCC rate of 3 (2.5%) in 122 patients is low, even in cirrhotic patients, and was similar to that reported in patients who lost HBsAg spontaneously or during antiviral therapy.

Email: grishma.hirode@gmail.com

**Background and aims:** Despite improvements in management of chronic hepatitis B (CHB), risk of progression to cirrhosis and HCC remains. There is discordance between guidelines regarding the safe discontinuation of nucleos (t)ide analogue (NA) therapy. We aim to analyze rates of liver-related complications (LRC) after NA cessation. **Method:** Cohort study of virologically suppressed, end-of-therapy HBeAg negative patients with CHB who stopped NAs between 2001 and 2020 from 12 participating centers across North America, Europe and Asia. Survival analysis techniques were used to analyze cumulative incidence of off-treatment LRC (hepatic decompensation and/or HCC) and differences by patient characteristics. LRC was considered related to treatment cessation if diagnosed off-treatment or within 6 months of starting retreatment. Patient was considered cirrhotic at cessation if cirrhosis was diagnosed at any time prior to NA cessation.

**Results:** Among 1528 included patients, 35 developed LRC after NA cessation: 18 hepatic decompensation and 17 HCC. Cumulative rate of LRC at 1- and 4-years of off-treatment follow-up was 1.4% and 3.5%. In the LRC group, mean age was 58 ± 11 years, most were male (77%), Asian (91%), Entecavir-treated prior to cessation (66%), infected with HBV genotype B (51%) (genotype C [17%], D [2.9%], A [0%]), and mean HBsAg level at cessation was 2.5 ± 0.7 log<sub>10</sub>IU/ml. Median off-treatment follow-up was 15 (IQR: 7–37) months. Patients with LRC (vs no LRC) were older at cessation (≥50 years: 80% vs 63%), more often cirrhotic at cessation (37% vs 11%) and had a higher proportion of start-of-therapy (SOT) HBeAg positive disease (29% vs 14%), resulting in higher cumulative incidence of LRC among these groups (Figure). Higher LRC incidence was mainly driven by decompensation for SOT HBeAg positive disease (vs SOT HBeAg negative: adjusted hazard ratio [aHR] 4.3, p=0.001) while it was driven by both decompensation and HCC for patients aged ≥50 years (vs <50 years: aHR 3.8, p=0.007) and cirrhotics at cessation (vs non-cirrhotics at cessation: aHR 4.7, p<0.001). There were no significant between-group differences for other patient characteristics. In the LRC group, 4/35 had off-treatment HBsAg loss, and 2/4 had HBsAg loss after the LRC had been diagnosed. Among those without LRC, 109/1493 had off-treatment HBsAg loss.

**Conclusion:** Regardless of off-treatment HBsAg loss, older, cirrhotic, and/or SOT HBeAg positive patients should be carefully assessed prior to stopping NAs to prevent deterioration to LRC.

## POSTER PRESENTATIONS

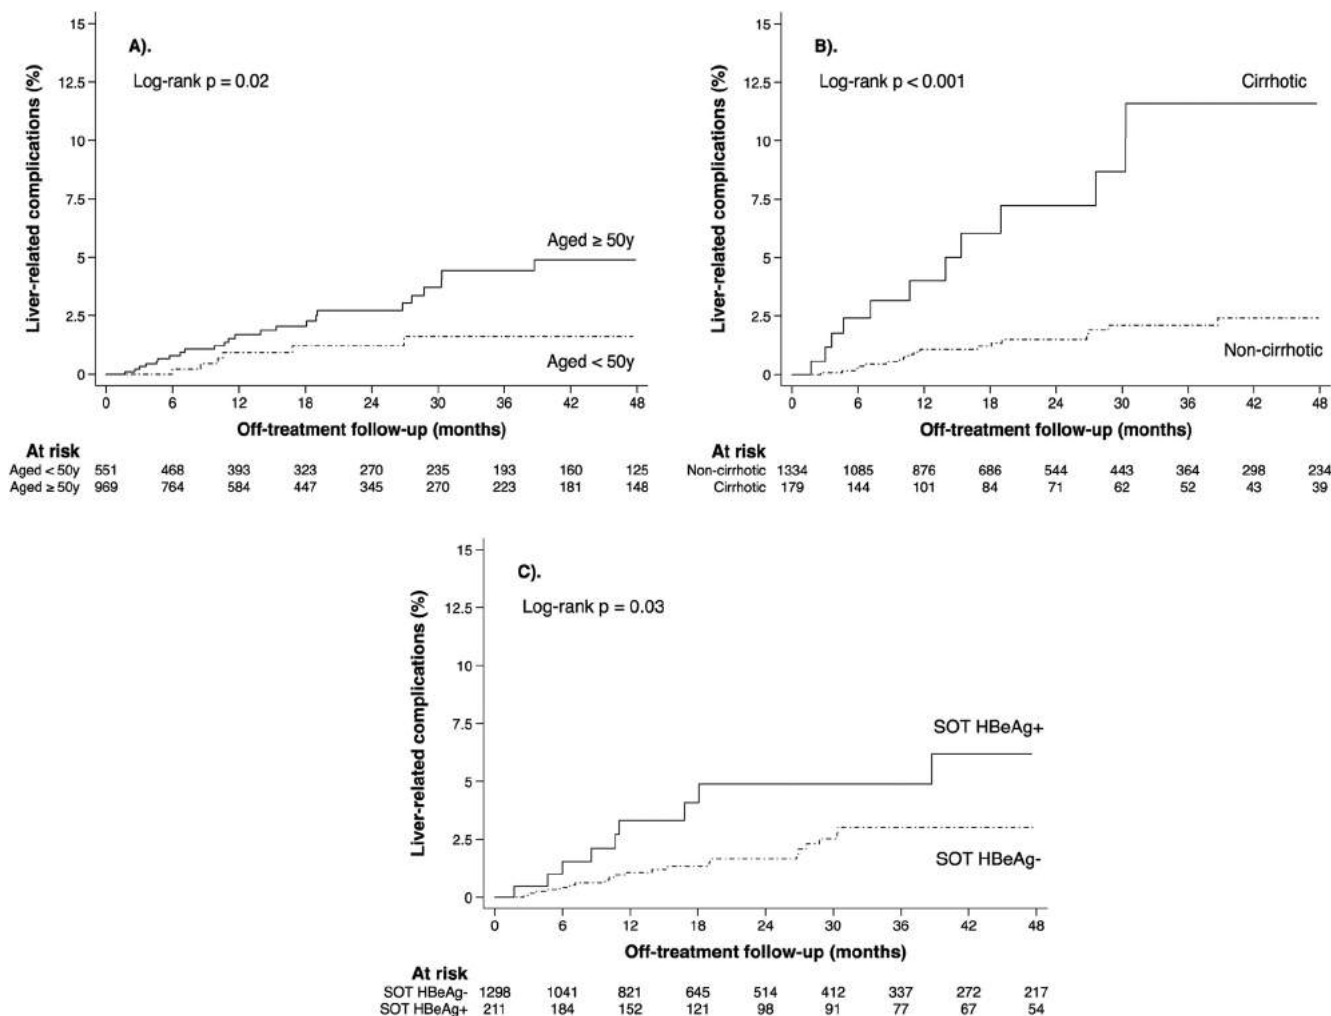

Figure: (abstract: PO-1791): Cumulative incidence of LRC by A) age at cessation, B) cirrhosis status at cessation and C) SOT HBeAg status. LRC, liver-related complications; SOT, start-of-therapy.

### PO-1837

#### HBsAg, anti-HBs and ALT kinetic characterization during NAP-based combination therapy of HBeAg negative chronic hepatitis B infection

Leeor Hershkovich<sup>1</sup>, Louis Shekhtman<sup>1,2</sup>, Michel Bazinet<sup>3</sup>, Victor Pântea<sup>4</sup>, Gheorge Placinta<sup>4</sup>, Iruie Moscalu<sup>5</sup>, Valentin Cebotarescu<sup>4</sup>, Lilia Cojuhari<sup>4</sup>, Pavlina Jimbei<sup>6</sup>, Liviu Iarovoi<sup>4</sup>, Valentina Smesnoi<sup>6</sup>, Tatiana Musteata<sup>6</sup>, Alina Jucov<sup>4,5</sup>, Scott Cotler<sup>1</sup>, Andrew Vaillant<sup>3</sup>, Harel Dahari<sup>1</sup>. <sup>1</sup>Loyola Univeristy Chicago, The Program for Experimental and Theoretical Modeling, Division of Hepatology, Department of Medicine, Stritch School of Medicine, Maywood, United States; <sup>2</sup>Northeastern, University, Network Science Institute, Boston, United States; <sup>3</sup>Replicor Inc., Montreal, Canada; <sup>4</sup>State University of Medicine and Pharmacy, Department of Infectious Diseases, Chişinău, Moldova; <sup>5</sup>Republican Clinical Hospital, ARENSIA Exploratory Medicine, Chişinău, Moldova; <sup>6</sup>Toma Ciorbă Infectious Clinical Hospital, Chişinău, Moldova  
Email: harel.dahari@gmail.com

**Background and aims:** The interplay among serum hepatitis B surface Antigen (HBsAg), anti-HBs, and alanine aminotransferase (ALT) during combination therapy with REP 2139-Mg or REP 2165-Mg, pegylated interferon alpha-2a (IFN) and tenofovir disoproxil fumarate (TDF) has not been analyzed in detail. Here we characterize HBsAg, anti-HBs and ALT kinetics during 48-week triple therapy.

**Method:** Serum samples of 20 chronic HBV-infected participants who received 48 weeks of triple therapy (following 24 weeks of TDF monotherapy) from the REP 401 study (Bazinet et al. Gastroenterology 2020; 158:2180–94) were analyzed for HBsAg (Abbott Architect, LLoQ 0.05 IU/ml), anti-HBs (Abbott Architect, seroconversion cutoff = 10 IU/ml) and ALT. HBV DNA was not analyzed since it became  $\leq 2.1$  log IU/ml in 19/20 participants during TDF monotherapy. Distinctions between HBsAg phases were defined as at least a 2-fold change in slope. A single-phase decline was defined as monophasic, and two-phase declines were defined as biphasic. Patients with an overall reduction from baseline in HBsAg  $< 1$  log at EOT were defined as non-responders (NR).

**Results:** Three HBsAg kinetic patterns were found: NR ( $n = 4$ , Fig. 1a), monophasic decline ( $n = 12$ , Fig. 1b) and biphasic decline ( $n = 4$ , Fig. 1c). HBsAg decline ( $9 \pm 2$  wk) was delayed in NR vs monophasic/biphasic decline ( $3 \pm 3$  wk,  $p = 0.001$ ). Rate of HBsAg decline in monophasic participants was  $0.52 \pm 0.22$  log IU/ml/week, all reaching  $< \text{LLOQ}$  by week  $18 \pm 8$ . The 1<sup>st</sup> phase decline in biphasic participants ( $0.25 \pm 0.15$  log IU/ml/week) was slower ( $p = 0.02$ ) versus monophasic participants followed by a slower phase decline of  $0.03 \pm 0.02$  log IU/week with only one patient reaching  $< \text{LLOQ}$  at EOT (Fig. 1c). Anti-HBs was not detected in 17/20 participants at baseline. Early ( $14 \pm 5$  wk, Fig. 1b) seroconversion ( $0.23 \pm 0.09$  log/mIU/wk) accompanied 11/12 HBsAg monophasic HBsAg declines. Only 1/4 HBsAg biphasic (Fig. 1c) and none of the NR participant (Fig. 1a) experienced

**Figure 1.** Representative patients based on HBsAg response kinetic patterns during 48-week combination therapy with TDF, IFN and REP. (a) non-responder, (b) monophasic, and (c) biphasic. Horizontal dashed line represents HBsAg LLoQ (log 0.1 IU/mL); horizontal dotted line represents anti-HBs seroconversion (log 10 IU/mL).

Figure: (abstract: PO-1837)

seroconversion by EOT (Fig. 1a). ALT kinetics were independent of HBsAg decline. Transient increases in ALT (baseline  $39 \pm 19$  U/ml) reached a  $12.0 \pm 10.4$ -fold peak above mean baseline ALT, followed by decline ( $2.9 \pm 2.4$ -fold from baseline) at EOT. ALT flares coincided with HBsAg decline in 19/20 participants and with anti-HBs seroconversion in monophasic decline. There was no difference in kinetic patterns between REP 2139-Mg and REP 2165-Mg.

**Conclusion:** Longer (>6 weeks) delay in HBsAg decline may predict non-responders to combination therapy. Concomitant ALT flare and anti-HBs seroconversion with a rapid decline in HBsAg suggest that NAP-based therapy leads to specific anti-HBV immune responses yet to be identified.

**PO-1841**

**Earlier and more frequent virological and clinical relapse after cessation of tenofovir disoproxil fumarate versus entecavir therapy: Results from a large, global, multi-ethnic cohort of chronic hepatitis B patients (RETRACT-B study)**

Hannah S.J. Choi<sup>1</sup>, Grishma Hirode<sup>1,2</sup>, Chien-Hung Chen<sup>3</sup>, Tung-Hung Su<sup>4</sup>, Grace Lai-Hung Wong<sup>5</sup>, Wai-Kay Seto<sup>6</sup>, Stijn Van Hees<sup>7</sup>, Margarita Papatheodoridis<sup>8</sup>, Sylvia Brakenhoff<sup>9</sup>, Sabela Lens<sup>10</sup>, Arif Sarowar<sup>1</sup>, Rong-Nan Chien<sup>11</sup>, Jordan Feld<sup>1</sup>, Xavier Forn<sup>10</sup>, Milan Sonneveld<sup>9</sup>, George Papatheodoridis<sup>8</sup>, Thomas Vanwolleghem<sup>7</sup>, Man-Fung Yuen<sup>6</sup>, Henry Chan<sup>5</sup>, Jia-Hong Kao<sup>4</sup>, Yao-Chun Hsu<sup>12</sup>, Markus Cornberg<sup>13</sup>, Bettina Hansen<sup>1</sup>, Rachel Wen-Juei Jeng<sup>11</sup>, Harry Janssen<sup>1</sup>. <sup>1</sup>University Health Network, Toronto Centre for Liver Disease, Toronto, Canada; <sup>2</sup>The Toronto Viral Hepatitis Care Network (VIRCAN), Toronto, Canada; <sup>3</sup>Kaohsiung Chang Gung Memorial Hospital, Kaohsiung, Taiwan; <sup>4</sup>National Taiwan University Hospital, Taipei, Taiwan; <sup>5</sup>The Chinese University of Hong Kong, Sha Tin, Hong Kong; <sup>6</sup>The University of Hong Kong, Pokfulam, Hong Kong; <sup>7</sup>Antwerp University Hospital, Edegem, Belgium; <sup>8</sup>Medical School of National and Kapodistrian University of Athens, Athens, Greece; <sup>9</sup>Erasmus MC, Department of Gastroenterology and Hepatology, Rotterdam, Netherlands; <sup>10</sup>Hospital Clínic Barcelona, IDIBAPS and CIBEREHD, Barcelona, Spain; <sup>11</sup>Chang Gung Memorial Hospital, Taoyuan, Taiwan; <sup>12</sup>Fu-Jen Catholic University Hospital/E-DA Hospital, New Taipei, Taiwan; <sup>13</sup>Hannover Medical School, Hanover, Ghana

Email: sjchoi0731@gmail.com

**Background and aims:** Whether tenofovir disoproxil fumarate (TDF) and entecavir (ETV) differentially affect relapse across different patient subpopulations following treatment discontinuation remains unclear. We aimed to study the association between drug type and relapse in a global multi-centre cohort of chronic hepatitis B (CHB) patients who discontinued either TDF or ETV therapy.

**Method:** We investigated outcomes in CHB patients who stopped either TDF or ETV therapy between 2001 and 2020 from 12

participating centres across North America, Europe, and Asia. All included patients were HBeAg-negative at discontinuation. Rates and risk of virological (VR; HBV DNA  $\geq 2000$  IU/ml) and clinical (CR; HBV DNA  $\geq 2000$  IU/ml and ALT  $\geq 2 \times$  ULN) relapse were analyzed using multivariable Cox regression stratified by site, adjusting for age, sex, race, total treatment duration, treatment history, HBeAg status at the start of therapy (SOT), and HBsAg level at the end of therapy (EOT).

**Results:** Of 1386 CHB patients included, 416 had been treated with TDF and 970 with ETV. No significant differences in age, sex, and EOT HBsAg levels and no proportional differences in cirrhosis and HBeAg status at SOT were observed between the two groups. The TDF group had fewer Asian patients (81% vs 94%), more patients previously treated with other NAs (27% vs 11%) or (peg-)interferon (10% vs 6%), and higher median ALT at EOT compared with the ETV group ( $0.7$  vs  $0.5 \times$  ULN); all  $p < 0.05$ . Overall, 995/1386 (72%) and 561/1386 (41%) patients experienced VR and CR, respectively, during a median off-treatment follow-up of 17 months; 838/995 (84%) VRs and 354/561 (63%) CRs occurred within 12 months of cessation. TDF vs ETV was associated with a higher rate of VR in the first 12 months overall (hazard ratio [HR]: 2.0,  $p < 0.01$ ) and across different races and HBeAg status at SOT; the difference became negligible over time (HR: 0.79,  $p = 0.37$ ) (Fig.). Among Asian patients, the risk of VR associated with TDF was further increased in males ( $p < 0.05$ ) and those with HBsAg  $\geq 1000$  IU/ml ( $p < 0.01$ ). TDF was also associated with consistently higher rates of CR compared with ETV throughout follow-up (Fig.). TDF was an independent predictor of CR (HR: 1.63,  $p < 0.01$ ), adjusting for the factors aforementioned.

**Conclusion:** VR was very frequent after ETV or TDF treatment discontinuation. VR and CR were observed earlier and more frequently in individuals treated with TDF vs ETV, adjusting for race, age, sex, treatment history, HBeAg status at SOT, and HBsAg levels at EOT. Only among TDF-treated Asian patients, the risk of VR was further increased with male sex and/or HBsAg  $\geq 1000$  IU/ml at EOT.

Email: t.riedl@dkfz.de

**Background and aims:** New therapeutic strategies against Hepatitis B virus (HBV) focus, among others, on the activation of the immune system to enable the infected host to eliminate HBV. Hypoxia inducible factor 1 alpha (HIF1 $\alpha$ ) stabilisation has been associated with impaired immune responses. HBV pathogenesis triggers chronic hepatitis-related scarring, leading *inter alia* to modulation of liver

Figure: (abstract: PO-2089)

oxygenation and transient immune activation, both factors playing a role in HIF1 $\alpha$  stabilisation. We addressed whether HIF1 $\alpha$  interferes with immune-mediated induction of the cytidine deaminase APOBEC3B and subsequent covalently closed circular DNA (cccDNA) decay.

**Method:** Liver biopsies of chronic HBV patients (CHB) were analysed by IHC, and *in situ* hybridization. The effect of HIF1 $\alpha$  induction/stabilisation on differentiated HepaRG or mice  $\pm$  HBV  $\pm$  LT $\beta$ R-agonist (BS1) was assessed *in vitro* and *in vivo*. Induction of A3B and subsequent effects were analysed by RT-qPCR, immunoblotting, ChIP, ICC, and mass-spectrometry.

**Results:** Analysing CHB highlighted that areas with high HIF1 $\alpha$  levels and low A3B expression correlated with high HBcAg, potentially representing a reservoir for HBV survival in immune-active patients. *In vitro*, HIF1 $\alpha$  stabilisation, strongly impaired A3B expression and anti-HBV effect. Interestingly, HIF1 $\alpha$  knock-down was sufficient to rescue the inhibition of A3B-upregulation and -mediated antiviral effects, whereas HIF2 $\alpha$  knock-down had no effect. HIF1 $\alpha$  stabilisation decreased the level of RelB protein but not its mRNA, which was confirmed *in vivo*. Noteworthy, this function of HIF1 $\alpha$  was independent of its partner ARNT.

**Conclusion:** In conclusion, inhibiting HIF1 $\alpha$  expression or stabilisation represents a novel anti-HBV strategy in the context of immune-mediated A3B induction. High HIF1 $\alpha$ , mediated by hypoxia or inflammation, offers a reservoir for HBV survival *in vivo*, and should be considered as a restricting factor in the development of novel immune therapies.

**PO-2106**

**T-cell engagers that bind HBV envelope proteins enable T cells to control the infection and to target hepatoma in mice**

Email: oliver.quitt@tum.de

**Background and aims:** Hepatitis B virus (HBV) infection is a global health problem responsible for 880,000 deaths per year. Current antiviral therapies control but rarely eliminate the virus, and leave chronic HBV carriers at risk to develop hepatocellular carcinoma (HCC). Lacking or dysfunctional virus-specific adaptive immune responses prevent immune control of HBV and allow the virus to persist. Therefore, alternative treatment strategies aim at restoring anti-viral T-cell immunity to achieve HBV elimination in chronically infected patients.

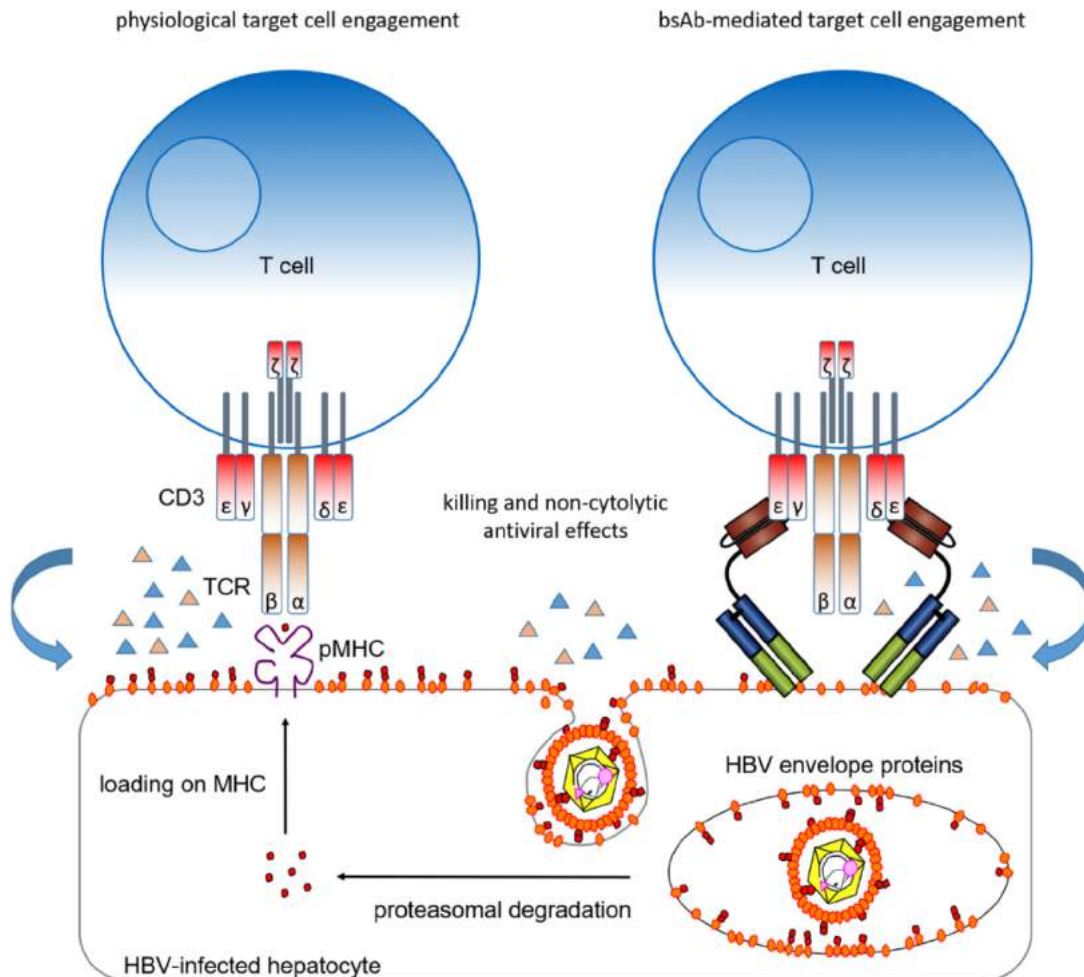

Figure: (abstract: PO-2106)

## POSTER PRESENTATIONS

**Method:** We constructed bispecific T-cell engager antibodies (bsAbs) that are designed to induce anti-viral immunity through simultaneous binding of HBV envelope proteins (HBVenv) on infected hepatocytes and CD3 and 28 on T cells. The constructs were employed in co-cultures with peripheral blood mononuclear cells (PBMC) and HBV-infected target cells and the redirected T-cell response was determined by detection of pro-inflammatory cytokines, viability of target cells and the quantification of viral DNAs. To study the efficacy of bsAbs *in vivo*, we established a tumor transplant model with human effector and HBVenv-positive hepatoma cells in immune-deficient Rag2<sup>-/-</sup>/IL2Ryc<sup>-/-</sup> mice.

**Results:** T-cell engager antibodies synergistically activated T cells to become polyfunctional effectors that in turn elicited potent anti-viral effects by killing infected cells and via non-cytolytic, cytokine-mediated antiviral mechanisms. In mice, the antibodies attracted T cells to tumors expressing HBVenv resulting in T-cell activation, infiltration into the tumor and reduction of tumor burden.

**Conclusion:** This study demonstrates that the administration of HBVenv-targeting bsAbs facilitates a robust T-cell redirection towards HBV-positive target cells and provides a feasible and promising approach for the treatment of chronic hepatitis B (CHB) and HBV-associated HCC.

Email: m.heikenwaelde@dkfz-heidelberg.de

**Background and aims:** Immune-mediated induction of cytidine deaminase APOBEC3B (A3B) expression leads to hepatitis B virus (HBV) covalently closed circular DNA (cccDNA) decay. Here, we aimed to decipher the signalling pathway (s) and regulatory mechanism (s) involved in A3B induction and related HBV control.

**Method:** Differentiated HepaRG (dHepaRG) knocked-down for NF- $\kappa$ B signalling components, transfected with siRNA or micro RNAs (miRNA), and primary human hepatocytes  $\pm$  HBV, were treated with

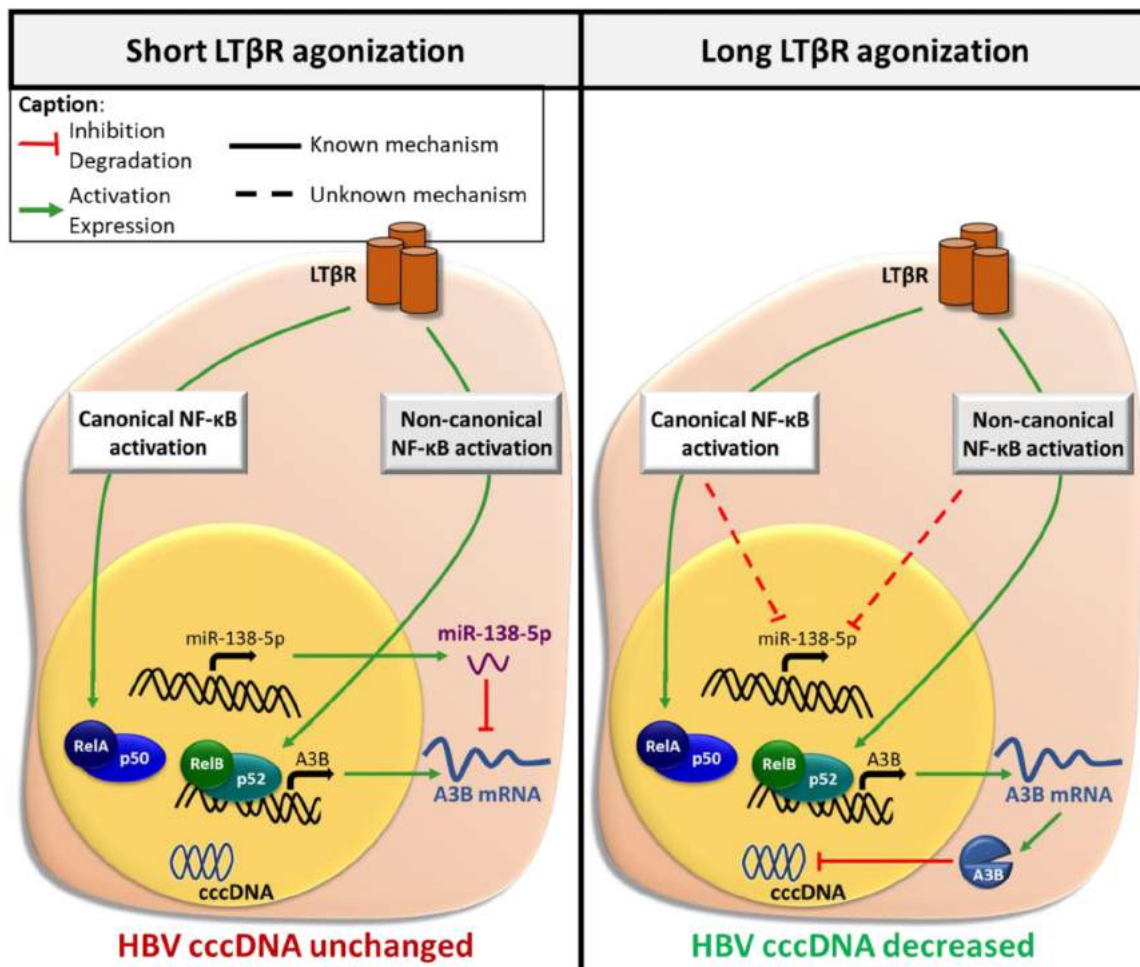

Figure: (abstract: PO-2243)

LT $\beta$ R-agonist (BS1). Induction of A3B and subsequent effects were assessed by RT-qPCR, immunoblotting, luciferase activity, ChIP, EMSA, targeted-bisulfite-, miRNA-, RNA-, genome-sequencing, and mass-spectrometry.

**Results:** We found that canonical and non-canonical NF- $\kappa$ B signalling pathways are mandatory for A3B induction and anti-HBV effects. The degree of immune-mediated A3B production is independent of A3B promoter demethylation but is controlled post-transcriptionally by the micro RNA 138-5p expression (hsa-miR-138-5p), promoting A3B mRNA decay. Hsa-miR-138-5p over-expression reduced A3B levels and its antiviral effects. Of note, established infection inhibited BS1-induced A3B expression through epigenetic modulation of A3B promoter. Twelve days of treatment with a lymphotoxin beta receptor-specific agonist BS1 is sufficient to reduce the cccDNA pool by 80% without inducing mutational load to the genomic DNA. Interestingly, the A3B-mediated effect on HBV is independent of the transcriptional activity of cccDNA as well as of rcDNA synthesis.

**Conclusion:** Altogether, A3B represents the only described enzyme to target both transcriptionally active and inactive cccDNA. Thus, inhibiting hsa-miR-138-5p expression should be considered in the combinatorial design of new therapies against HBV, especially in the context of immune-mediated A3B induction.

**HBsAg, HBcrAg, and HBV RNA in outcomes and after NA discontinuation in HBeAg negative patients with chronic hepatitis B: results from the Toronto STOP Study**

Arif Sarwar<sup>1</sup>, Scott Fung<sup>1</sup>, David Wong<sup>1</sup>, Colina Yim<sup>1</sup>, Seham Noureldin<sup>1</sup>, Jiayun Chen<sup>1</sup>, Karen Rother<sup>2</sup>, Mina Farag<sup>1</sup>, Thomas Berg<sup>2</sup>, Jordan Feld<sup>1,3</sup>, Florian van Bömmel<sup>2</sup>, Bettina Hansen<sup>1,4</sup>, Harry Janssen<sup>1</sup>, <sup>1</sup>University Health Network, Toronto Centre for Liver Disease, Toronto, Canada; <sup>2</sup>University Hospital Leipzig, Department of Gastroenterology and Rheumatology, Section of Hepatology, Leipzig, Germany; <sup>3</sup>McLaughlin-Rotman Centre for Global Health, Toronto, Canada; <sup>4</sup>University of Toronto, Institute of Health Policy, Management and Evaluation, Toronto, Canada  
Email: arif.sarwar@uhnresearch.ca

**Background and aims:** Novel biomarkers such as HBcrAg and HBV RNA have been shown to predict sustained response after NA discontinuation, however more understanding of these biomarkers during relapse and follow-up is needed. In this randomized controlled study, we studied the outcomes and kinetics of novel HBV biomarkers after NA discontinuation.

**Method:** HBV RNA, HBsAg, and HBcrAg levels were measured in 67 HBeAg negative patients, randomized into stop (n = 45) or continue (n = 22) NA therapy and followed for 72 weeks. HBV RNA was quantified using real time PCR (limit of detection: 160 cp/ml) and HBcrAg using CLEIA assay (limit of detection 3 log U/ml). Virological relapse (HBV DNA >2000 IU/ml), clinical relapse (HBV DNA >2000 and ALT >1.5x ULN), retreatment, and biomarker levels were assessed.

**Results:** For the 45 patients that discontinued NA, mean HBV RNA at end-of-treatment (EOT) was 1.92 log U/ml (1.8), with 32/45 (71%) patients undetectable. Mean HBcrAg was 3.36 log U/ml (0.83) with 22/45 (49%) patients undetectable at EOT. Virological relapse was observed in 39/45 (87%) stop patients, with clinical relapse occurring in 31/45 (69%) patients. In total 17/45 (38%) patients were retreated according to a standardized retreatment protocol, with 1/45 (2%) stop NA patients achieving HBsAg clearance. Presence of detectable HBcrAg at EOT (>3 log U/ml) was significantly associated with increased rates of retreatment. (p < 0.005, HR: 4.83), while no significant associations were found with HBV RNA and HBsAg at EOT. HBcrAg levels over time remain stable in patients not retreated, with retreated patients exhibiting a non-significant increase in HBcrAg levels by end of follow-up. No patients experienced adverse liver related outcomes or death.

Figure: Relapse and retreatment outcomes for stop patients (n = 45) based on HBcrAg, HBV RNA, and HBsAg levels at end of treatment. Limit of detection (LOD) for HBV RNA and HBcrAg was 160 cp/ml and 3 log U/ml, respectively

**Conclusion:** While HBsAg and HBV RNA show low predictive value in our randomized controlled study, HBcrAg shows potential predictive value for retreatment after NA discontinuation, with lower levels of HBcrAg associated with lower rates of retreatment. As 45% of our patients had undetectable levels at EOT, optimizing HBcrAg testing would improve sensitivity and further understanding of treatment management in future studies.

**Background and aims:** We have previously shown that in hepatically impaired (chronic hepatitis B) CHB patients, switching to tenofovir alafenamide (TAF) from tenofovir disoproxil fumarate (TDF) and/or other oral antivirals (OAVs) maintains high rates of viral suppression with stable bone and renal safety parameters through 48 weeks. Here we present our final 2-year (Week 96) results.

**Method:** In this Phase 2 study (NCT03180619), virally suppressed CHB patients (HBV DNA <LLOQ x  $\geq$  6 months and <20 IU/ml at screening) with Child-Turcotte-Pugh (CTP) scores  $\geq$  7 and  $\leq$  12 at screening (or previously documented to be  $\geq$  7) while receiving TDF and/or other OAVs for  $\geq$  48 weeks were enrolled and switched to TAF 25 mg QD for 96 weeks. Safety assessments including changes in bone (hip and spine BMD) and renal (CrCL by Cockcroft-Gault

## POSTER PRESENTATIONS

[eGFR<sub>CC</sub>], serum creatinine) parameters, viral suppression, and serological and biochemical responses were serially assessed.

**Results:** Of 31 patients enrolled, mean age was 55 y (29% ≥60 y), 68% male, 81% Asian, and 90% HBeAg-negative; median (Q1, Q3) CTP and MELD scores were 6 (5, 8) and 10 (7.5, 14.2), respectively, median eGFR<sub>CC</sub> 98.5 ml/min; 19% had osteoporosis on spine DXA. Twenty-five (81%) patients completed 96 weeks of TAF treatment (6 discontinued early: 2-withdrew consent, 1-adverse event [AE; Grade 2 creatinine increase], 1-investigator decision, and 2-death [respiratory failure and aspiration pneumonia-both not treatment-related]). Week 96 efficacy/safety results are summarized in the Table. 96% of patients on TAF treatment had HBV DNA <20 IU/ml with a high proportion having normal ALT levels. Bone and renal parameters remained stable. TAF was well tolerated with no patients having a Grade 3 or 4 AE or a serious AE related to treatment.

**Background and aims:** We have previously shown in renally impaired (RI) chronic hepatitis B (CHB) patients, including those with end-stage renal disease (ESRD) on hemodialysis (HD), that switching to tenofovir alafenamide (TAF) from tenofovir disoproxil fumarate (TDF) and/or other oral antivirals (OAVs) maintains high rates of viral suppression with stable bone and renal safety parameters at Week 48. Here we present the final Week 96 results. **Method:** In this Phase 2 study (NCT03180619), virally suppressed CHB patients (HBV DNA <LLOQ × ≥6 months and <20 IU/ml at screening while receiving TDF and/or other OAVs for ≥48 weeks were enrolled and switched to TAF 25 mg QD for 96 weeks. Safety assessments including adverse events (AEs) and changes in bone (hip and spine BMD) and renal (creatinine clearance by Cockcroft-Gault [eGFR<sub>CC</sub>], serum phosphorus, and serum creatinine -except in ESRD patients) parameters, viral suppression, and serological and biochemical responses were serially assessed.

**Table. Final Results at Week 96: Efficacy and Bone and Renal Parameters**

n/N (%), or median (Q1, Q3)	Moderate - Severe RI <sup>a</sup> (n=78)		ESRD on HD <sup>b</sup> (n=15)

<sup>a</sup>Moderate to severe renal impairment: eGFR<sub>CC</sub> 15 - <60 mL/min at screening;

<sup>b</sup>ESRD on HD: eGFR<sub>CC</sub> <15 mL/min maintained on chronic hemodialysis

<sup>c</sup>M=F, missing equal failure analysis; <sup>d</sup>M=E, missing equal excluded analysis (i.e. observed data)

<sup>e</sup>ALT value within normal range at Week 96 regardless of baseline ALT level; <sup>f</sup>ULN ≤35 U/L males and ≤25 U/L females

<sup>g</sup>ULN ≤43 U/L men and ≤35 U/L for men ≥65y, ≤34 U/L women and ≤32 for women ≥65y

<sup>h</sup>Only includes patients HBeAg positive at baseline; <sup>i</sup>Serum C-type collagen sequence (bone resorption marker); <sup>j</sup>Serum procollagen type 1 N-terminal propeptide (bone formation marker)

<sup>k</sup>Urine retinol binding protein/creatinine (renal tubular marker); <sup>l</sup>Urine beta-2 microglobulin/creatinine (renal tubular marker)

Abbreviations: eGFR<sub>CC</sub>, estimated creatinine clearance (Cockcroft-Gault method); ESRD, end-stage renal disease; BMD, bone mineral density by DXA scan; LLOD, lower limit of detection; NA, not applicable (hemodialysis patients)

**Results:** Of 93 patients (mod-severe RI 78; ESRD on HD 15) enrolled, most (74%) were male and Asian (77%), with 51% ≥65 y, 83% HBeAg-negative, 34% with cirrhosis, and median ALT 17 U/L. Up to 24% had osteoporosis at hip and/or spine, with most having comorbidities (HTN 60%, CV disease 22%, DM 25%). Twelve (13%; 11 mod-severe RI and 1 ESRD) patients discontinued the study early (5-withdrew consent, 3-deaths [none treatment-related], 2-AE, and 2-investigator decision). Key efficacy/safety results at Week 96 are summarized in the Table. Viral suppression (HBV DNA <20IU/ml) was maintained in all patients remaining on treatment (i.e. missing equals excluded); a

high proportion had target not detected. Overall, TAF was well tolerated with no Grade 3 or 4 AEs or serious AEs related to study treatment. Relative to baseline levels, switching to TAF resulted in small median % increases in hip/spine BMD in those with moderate to severe RI, and small median decreases in ESRD patients. 2 patients with mod-severe RI had a bone fracture (ankle, rib). Median eGFR<sub>CG</sub> increased while urinary markers of proximal tubular function progressively decreased in moderate to severe RI patients.

**Conclusion:** Renally-impaired CHB patients, including ESRD patients on HD, who were switched to TAF from TDF and/or other OAVs maintained high rates of viral suppression, and bone and renal parameters remained stable or slightly improved after 2 years of treatment.

Email: jenny.yang@gilead.com

**Background and aims:** IRIG, RIG-I agonist, has demonstrated antiviral activity in CHB patients. The MOA of IRIG suggests a direct antiviral and an immune modulatory pathway. This study evaluated safety, efficacy, and PD activity of IRIG ≤400 mg ± TAF in CHB pts.

**Method:** IA CHB pts were enrolled into 4 cohorts: 48WK TAF alone or TAF+IRIG 50, 200, and 400 mg QD for 12WK; and virally suppressed (VS) cohort of 12WK IRIG 100 mg. Safety included AEs and lab abnormalities. Primary obj: %pts with HBsAg ≥-0.5 log<sub>10</sub> IU/ml at WK12. Secondary obj: change from BL in immune PD biomarkers. Final WK48 data and immunological characterization of 400 mg cohort to be presented.

**Results:** 102 IA and 21 VS Asian CHB pts enrolled. Table shows BL and mean change at WK12 of viral markers. More TAF and IRIG 50 mg pts at BL had GT C (≥75%), higher HBV DNA and ALT vs IRIG 200 mg and 400 mg. No difference at WK12 in HBV DNA decline observed; TAF and IRIG 50 mg had numerically greater decline in HBsAg vs IRIG ≥200 mg. In VS pts, no change in HBsAg with IRIG 100 mg observed. Prelim WK12 safety showed, no G4 AEs; 3 IRIG and 1 TAF pts had G3 AEs. Majority of IRIG 400 mg pts had slight increase in ALT at WK16 (mean (SD) change in ALT=9 (65) U/L); similar trends were not observed at lower doses. AEs reported by 41% (46/111) IRIG and 58% (7/12) TAF pts. Frequent (>1 pt) AE related to study drug were: ALT increase (n = 5), constipation, dizziness, and headache (n = 2 each) all in IRIG pts. PD analysis demonstrates minimal changes to ISG expression with IRIG 50 mg and 200 mg. Peripheral cytokine and HBV-specific T cell response was similar between TAF and IRIG 50 mg.

**Conclusion:** No dose dependent changes in HBV DNA or HBsAg were observed with IRIG ≤400 mg+NUC. IRIG was generally safe and well tolerated at doses ≤400 mg for 12WK. IRIG development has been discontinued due to IRIG-related hepatotoxicity.

Table: (abstract: PO-2422):

	TAF (N = 12)	IRIG 50 mg (N = 30)	IRIG 200 mg (N = 30)	IRIG 400 mg (N = 30)	IRIG 100 mg VS Patients (N = 21)

**Background and aims:** Selgantolimod (GS-9688, SLGN) is an oral, Toll-like receptor 8 agonist in clinical development for the treatment of chronic hepatitis B (CHB). Here we present the results through week 48 on the safety and efficacy of 24 weeks of SLGN treatment in viremic CHB patients.

**Method:** In this multicenter, double-blind, phase 2 study, viremic CHB patients were randomized (2:2:1) to SLGN 3 mg, 1.5 mg, and placebo (PBO) once a week for 24 weeks in combination with tenofovir alafenamide. Safety assessments included monitoring of treatment emergent adverse events (TEAE) and laboratory abnormalities. The primary efficacy end point was the proportion of patients with ≥1 log<sub>10</sub>IU/ml decline in HBsAg levels from baseline at week 24. Exploratory end points include changes in pharmacodynamic (PD) markers (e.g. IL-12p40 and IL-1RA) and changes in peripheral T- cell, myeloid and NK-cell subsets.

**Results:** 67 patients (39 HBeAg-positive) were randomized. Baseline characteristics were similar across groups: majority were Asian (98.5%), male (58%) with a median (IQR) age of 47 (35–54) years, HBsAg level of 4.1 (3.5–4.7) log<sub>10</sub>IU/ml, and HBV DNA level of 7.5 (5.4–8.3) log<sub>10</sub>IU/ml. No patients achieved the primary end point of ≥1 log<sub>10</sub>IU/ml decline in HBsAg levels at week 24; however, 3 (6%) patients in the SLGN-treated achieved HBsAg decline ≥0.5 log<sub>10</sub>IU/ml compared to none in the placebo group. At week 48, 4 (7.4%) patients

## POSTER PRESENTATIONS

in the SLGN-treated group (including the 3 subjects at week 24) while none in the placebo group achieved HBsAg decline  $\geq 0.5$  log<sub>10</sub>IU/ml. Most frequent ( $\geq 10\%$  SLGN-treated) TEAE (SLGN v PBO) were: nausea (26% v 0%), headache (15% v 15%), vomiting (17% v 0%), fatigue (15% v 0%), and dizziness (11% v 0%). Grade  $\geq 3$  TEAE were observed in 0 (SLGN) v 7.7% (PBO) subjects; 1 subject (SLGN 3 mg) discontinued study due to TEAE of vomiting and abdominal pain. Most patients treated with SLGN showed decline of immune cell subsets in the circulation 4 h after dosing, concurrent with increases of circulating IL-12p40 and IL-1RA. Cell populations that decreased in the circulation included effector and memory T cell subsets. These parameters reverted to baseline values at 24 h post-dosing.

**Conclusion:** Oral SLGN up to 3 mg once weekly for 24 weeks is safe and well-tolerated. SLGN can induce sustained HBsAg declines of  $\geq 0.5$  log<sub>10</sub>IU/ml in some patients out to Week 48. Further evaluation of SLGN in combination with immunomodulatory and antiviral agents is planned.

### PO-2619

#### Effects of tenofovir alafenamide fumarate treatment in pregnant women on maternal viral load reduction and preventing mother-to-infant HBV transmission

Huey-Ling Chen<sup>1,2</sup>, Chien-Nan Lee<sup>3</sup>, Ming-Wei Lai<sup>4</sup>, Ming-Chieh Tsai<sup>5</sup>, Rong-Nan Chien<sup>6,7</sup>, Wan-Hsin Wen<sup>8,9</sup>, Kai-Chi Chang<sup>1</sup>, Chun-Jen Liu<sup>10</sup>, Yen-Hsuan Ni<sup>1</sup>, Mei-Hwei Chang<sup>1</sup>. <sup>1</sup>National Taiwan University College of Medicine and Hospital, Department of Pediatrics, Taipei, Taiwan; <sup>2</sup>College of Medicine, National Taiwan University, Department and Graduate Institute of Medical Education and Bioethics, Taipei, Taiwan; <sup>3</sup>National Taiwan University College of Medicine and Hospital, Department of Obstetrics and Gynecology, Taipei, Taiwan; <sup>4</sup>Chang Gung Memorial Hospital, Linkou Branch, Division of Pediatric Gastroenterology, Department of Pediatrics; Liver Research Center, Taiwan; <sup>5</sup>Hsinchu Cathay General Hospital, Department of Internal Medicine, Hsinchu City, Taiwan; <sup>6</sup>Chang Gung Memorial Hospital, Liver Research Center, Linkou, Taiwan; <sup>7</sup>Keelung Chang Gung Memorial Hospital, Liver Research Unit, Taiwan; <sup>8</sup>Cardinal Tien Hospital, Department of Pediatrics, New Taipei City, Taiwan; <sup>9</sup>College of Medicine, Fu-Jen Catholic University, School of Medicine, New Taipei City, Taiwan; <sup>10</sup>National Taiwan University College of Medicine and Hospital, Internal Medicine, Taipei, Taiwan  
Email: hueyling@ntu.edu.tw

**Background and aims:** Short-term antiviral therapy for pregnant women with chronic hepatitis B virus (HBV) infection and high viral load has been recommended to prevent maternal transmission. Data of using tenofovir alafenamide fumarate (TAF) treatment for such purpose is limited. This study is the interim analysis of a clinical trial using TAF for preventing mother-to-infant transmission of HBV, in comparison with mothers using tenofovir disoproxil fumarate (TDF) treatment.

**Method:** This prospective, multicenter clinical trial recruited 57 HBV-infected pregnant women seropositive for HBsAg and HBeAg, and with HBV viral load above 1,000,000 IU/ml. Enrolled subjects received TAF 25 mg daily since third trimester until 2 weeks postpartum in 2019–2021. Maternal and children outcomes were compared with 53 pregnant women received TDF 300 mg daily during 2016–2018.

**Results:** The maternal age of delivery in the TAF group was 35.56 ± 4.41 years and in the TDF group 34.56 ± 3.65 years ( $p = 0.20$ ). The HBV DNA levels decreased from 7.87 ± 0.57 Log<sub>10</sub>IU/ml at baseline, to 3.96 ± 1.10 Log<sub>10</sub>IU/ml at delivery in the TAF group; and from 8.30 ± 0.36 Log<sub>10</sub>IU/ml to 4.47 ± 0.86 Log<sub>10</sub>IU/ml in the TDF group. The mean reduction of HBV DNA levels was comparable between the TAF group (3.90 ± 0.90 Log<sub>10</sub>IU/ml) and TDF group (3.83 ± 0.83 Log<sub>10</sub>IU/ml,  $p = 0.67$ ). The percentage of the mothers to achieve HBV DNA level below 6.0 log<sub>10</sub>IU/ml at the time of delivery were 94.7% (54/57) in the TAF group versus 96.2% (51/53) in the TDF group ( $p = 1.00$ ). Of the mother in the TAF group, one experienced with nausea and one with dry eyes.

All symptoms subsided spontaneously. In the TDF group, two mothers experienced nausea, one with skin itching and one with mild diarrhea. Of the 62 newborns delivered in the TAF group, the average gestation age was 38.25 ± 1.83 weeks; and 38.66 ± 1.33 weeks of the 55 newborns in the TDF group ( $p = 0.17$ ). The mean body weight 2958 ± 519.9 gram in the TAF group and 3052 ± 431.3 g ( $p = 0.30$ ) in the TDF group. Of the 32 infants in the TAF group followed up to 12 months, none were HBsAg positive (0/32), versus 1.8% (1/55,  $p = 1.00$ ) in the TDF group. No major and minor congenital anomalies were identified in the infants.

Figure:

**Conclusion:** The effects of TAF treatment for highly viremic HBV-infected pregnant women were comparable with TDF treatment in terms of maternal HBV DNA reduction and in preventing mother-to-infant transmission.

### PO-2735

#### Durability of hepatitis B surface antigen seroclearance induced by peginterferon alpha-based regimens

Rui Lu<sup>1</sup>, Feng-ping Wu<sup>1</sup>, Yixin Liu<sup>1</sup>, Yikai Wang<sup>1</sup>, Yan Tian<sup>1</sup>, Yaping Li<sup>1</sup>, Mei Li<sup>1</sup>, Zicheng Jiang<sup>2</sup>, Xue Mei Li<sup>2</sup>, Juanjuan Shi<sup>1</sup>, Xin Zhang<sup>1</sup>, Xiaoli Jia<sup>1</sup>, Shuangso Dang<sup>1</sup>. <sup>1</sup>The Second Affiliated Hospital of Xi'an Jiaotong University, Department of Infectious Diseases, Xi'an, China; <sup>2</sup>The Ankang Central Hospital, Department of Infectious Diseases, Ankang, China  
Email: dang212@126.com

**Background and aims:** Durability of Hepatitis B surface antigen (HBsAg) seroclearance induced by Peginterferon -alpha (Peg-IFN alpha)-based regimens has not been well elucidated yet. The study was to observe the durability of HBsAg seroclearance induced by Peg-IFN alpha-based regimens.

**Method:** In this prospective, two-centre, observational study, 212 subjects with HBsAg seroclearance induced by Peg-IFN alpha-based regimens were enrolled from November 2015 to March 2021 at the Second Affiliated Hospital of Xi'an Jiaotong University and Ankang Central Hospital, China. From the date of cessation of Peg-IFN alpha-based regimens, all subjects were evaluated for hepatitis B virus (HBV) markers, HBV DNA, and liver functions every 1–3 months during the follow-up. The primary end point was HBV recurrence which was defined as the reappearance of either HBsAg, HBV DNA, or both at least 2 times in an interval of 4–8 weeks during the follow-up after treatment cessation. The second end points included the dynamics of HBsAb, alanine aminotransferase (ALT) flares, and the incidence of liver cirrhosis and hepatocellular carcinoma (HCC).

**Results:** After a median of 72 (42–120) weeks of follow-up, 2 subjects were lost of follow-up. A total of 28 subjects experienced HBsAg recurrence, while no subject experienced HBV DNA seroreversion. Intention-To-Treat analysis showed that the HBsAg recurrence rate was 13.6% (28/212). Among 119 patients with HBsAg seroconversion at the cessation, 20.4% (24/119) of the subjects experienced HBsAb disappearance. The median HBsAb level decreased from 1.76 log<sub>10</sub> mIU/ml at baseline to 1.33 log<sub>10</sub> mIU/ml at the end of follow-up. No

patient suffered from ALT flares, as well as developed into liver cirrhosis or HCC during the follow-up.

Characteristics	Patients in all (n = 212)
Age, years, mean ± SD	35.2 ± 11.3
Male, n (%)	124 (58.3)
<i>Characteristics before HBsAg clearance</i>	
Therapy regimens	
Peg-IFN alpha alone, n (%)	101 (43.8)
Adding on Peg-IFN alpha to NA, n (%)	93 (47.9)
NA de novo combination with Peg-IFN alpha, n (%)	18 (8.3)
Peg-IFN alpha types	
Peg-IFN alpha-2a, n (%)	88 (41.7)
Peg-IFN alpha-2b, n (%)	124 (58.3)
HBsAg levels at the initial of Peg-IFN alpha, log <sub>10</sub> IU/ml, mean ± SD	1.8 ± 1.3
HBsAb-negative, n (%)	199 (93.8)
HBsAb-positive, n (%)	13 (6.3)
HBV DNA negative, n (%)	137 (64.6)
HBeAg-positive, n (%)	42 (19.8)
ALT at the initial of Peg-IFN alpha, IU/ml, IQR	15.0 (23.0, 34.8)
AST at the initial of Peg-IFN alpha, IU/ml, IQR	24.0 (19.0, 30.0)
Treatment duration before HBsAg loss, weeks, IQR	24.0 (12.0, 48.0)
Consolidation treatment time after HBsAg loss, weeks, IQR	12.0 (6.0, 16.0)
<i>Characteristics at discontinuation of Peg-IFN alpha</i>	
Patients with HBsAg seroconversion, n (%)	119 (56.3)
HBsAb levels, log <sub>10</sub> mIU/ml, mean ± SD	1.2 ± 0.9

**Conclusion:** HBsAg seroclearance induced by Peg-IFN alpha-based treatment was durable during long-term follow-up.

**PO-2738**

**Functional cure based on pegylated interferon α in long-term nucleoside analog suppressed HBeAg negative chronic hepatitis B: A multicenter real-world study (everest project in china), a sequential report the predictors for HBsAg loss**

Email: gaozli@mail.sysu.edu.cn

**Background and aims:** Add-on or switch to pegylated interferon α (PegIFNα) in nucleoside analog (NA) suppressed chronic hepatitis B (CHB) patients are effective strategies to improve HBsAg loss. We sought to investigate efficacy of “add-on” or “switch to” strategy and predictors for HBsAg loss by pegIFNα.

**Method:** The Everest Project is a multicenter real-world study that focused on functional cure of CHB in China (NCT04035837). Patients who had experienced effective NA therapy for more than one year, presented as HBV DNA<100 IU/ml, HBeAg negative and HBsAg<1500 IU/ml were recruited. “Add-on” or “switch to” strategy for 48 weeks or up to 96 weeks was decided by patients. Interim data on those who have completed 48 weeks of treatment were analyzed. mITT population included 5055 patients and PP population included 3517 patients.

**Results:** In the PP analysis, 82% patients were male, the mean age was 41.1 years and the mean baseline of HBsAg was 386.7 IU/ml. The HBsAg loss rate were 10.3%, 23.0%, 28.9% and 32.8% at 12, 24, 36 and 48 weeks, respectively. Common clinical indicators as predictors for HBsAg loss were identified by subgroup analysis. HBsAg loss rate at 48 weeks were 55.3%, 31.2%, 22.8%, 16.8% and 8.4% for different baseline HBsAg stratification (0.05–100, 100–200, 200–500, 500–1000 and 1000–1500 IU/ml, respectively). HBsAg loss rate at 48 weeks of patients with HBsAg, 500 IU/ml at 24 weeks was significantly higher than those with HBsAg ≥500 IU/ml (36.7% vs. 1.2%, p <0.0001). For patients with HBsAg decline >1 log<sub>10</sub> IU/ml from baseline to 24 weeks, the HBsAg loss rate at 48 weeks was 57.5%, while 8.7% for those HBsAg decline ≤1 log<sub>10</sub> IU/ml (p <0.0001). According to different ALT stratification at 12 weeks (≥5 × ULN, 2–5 × ULN, 1–2 × ULN and, 1 × ULN), HBsAg loss rate at 48 weeks were 47.0%, 40.5%, 33.8% and 24.6%, respectively. It was worth noting that 66.6% (1146/1721) of the patients who did not achieved HBsAg loss at 48 weeks achieved HBsAg≤100 IU/ml, which may be the advantage patients for further functional cure. PegIFNα treatment was well-tolerated.

Figure: HBsAg loss rate at different time points in PP analysis.

**Conclusion:** Functional cure could be well achieved in NA-suppressed HBeAg negative chronic hepatitis B by pegIFNα strategy. Lower HBsAg at baseline, lower HBsAg at 24 weeks, a rapid decline of HBsAg and ALT elevations at 12 weeks are predictors for functional cure over the course of 48 weeks. There are still good chances of functional cure for more than half of the patients who had not achieved HBsAg loss by prolonged treatment or retreatment.

**PO-2759**

**Short-term peginterferon alpha re-treatment induced a high functional cure rate in patients with hepatitis B surface antigen recurrence after cessation of peginterferon alpha-based regimens**

Feng-ping Wu<sup>1</sup>, Rui Lu<sup>1</sup>, Yixin Liu<sup>1</sup>, Yikai Wang<sup>1</sup>, Yan Tian<sup>1</sup>, Yaping Li<sup>1</sup>, Mei Li<sup>1</sup>, Wenjun Wang<sup>1</sup>, Zicheng Jiang<sup>2</sup>, Xue Mei Li<sup>2</sup>, Song Zhai<sup>1</sup>, Xin Zhang<sup>1</sup>, Xiaoli Jia<sup>1</sup>, Shuangsoo Dang<sup>1</sup>. <sup>1</sup>The Second Affiliated Hospital of Xi'an Jiaotong University, Department of Infectious Diseases, Xi'an, China; <sup>2</sup>The Ankang Central Hospital, Department of Infectious Diseases, Ankang, China  
Email: dang212@126.com

**Background and aims:** Little is known about the efficacy of peginterferon alpha (peg-IFN- alpha) in the re-treatment of patients with hepatitis B surface antigen (HBsAg) recurrence after being clinically cured by peg-IFN alpha-based regimens. This study was aimed to evaluate the efficacy of peg-IFN α-2b in the re-treatment of

## POSTER PRESENTATIONS

Figure: (abstract: PO-2759)

patients with HBsAg recurrence after cessation of peg-IFN alpha -based regimens.

**Method:** In this real-world, two-center, observational study, a total of 21 patients with HBsAg recurrence after cessation of peg-IFN alpha -based regimens were prospectively enrolled. All patients received an individualized peg-IFN alpha -2b (PegBeron, 180 µg, subcutaneous injection, once weekly, Chinese-made) re-treatment. The hepatitis B virus (HBV) vaccine could be injected after HBsAg clearance. The primary end point was HBsAg clearance.

**Results:** All patients had HBsAg levels of <4 IU/ml and hepatitis B virus deoxyribonucleic acid (HBV DNA) levels of <20 IU/ml. The median (mean) baseline HBsAg levels were 0.88 (1.31) IU/ml. After a median (mean) of 24 (28) weeks of peg-IFN alpha-2b re-treatment, 17 patients (81.0%, 17/21) achieved HBsAg clearance again and 13 patients (61.9%, 13/21) achieved HBsAg seroconversion. Unfortunately, 2 patients experienced HBsAg recurrence again during a median (mean) of 28 (42.7) weeks of follow-up. Generally, the peg-IFN alpha-2b and HBV vaccine therapy were well tolerated.

**Conclusion:** High rate of HBsAg clearance can be achieved by short-course of peg-IFN alpha-2b re-treatment in patients with HBsAg recurrence after cessation of peg-IFN alpha-based regimens.

### PO-2822

**Inhibition of hepatitis B surface antigen by RNA interference therapeutic AB-729 in chronic hepatitis B patients correlates with suppression of all HBsAg isoforms and HBV RNA**

Emily P. Thi<sup>1</sup>, Man-Fung Yuen<sup>2</sup>, Edward Gane<sup>3</sup>, Heather Sevinsky<sup>1</sup>, Karen Sims<sup>1</sup>, Mark Anderson<sup>4</sup>, Angela M. Lam<sup>1</sup>, Michael J. Sofia<sup>1</sup>, Gavin Cloherty<sup>4</sup>, Gaston Picchio<sup>1</sup>. <sup>1</sup>Arbutus Biopharma Inc.,

Warminster, United States; <sup>2</sup>Queen Mary Hospital, Hong Kong; <sup>3</sup>Auckland Clinical Studies, New Zealand; <sup>4</sup>Abbott Diagnostics, Abbott Park, United States  
Email: ethi@arbutusbio.com

**Background and aims:** Therapeutic strategies to develop a cure for chronic hepatitis B (CHB) must address the high antigenemia that contributes to viral persistence and HBV immune tolerance. AB-729 is an N-Acetylgalactosamine-conjugated short interfering RNA (siRNA) therapeutic, currently in clinical development in combination with other agents for treatment of CHB. AB-729, a single trigger agent, blocks all HBV RNA transcripts including HBx, resulting in suppression of viral replication and all HBV antigens including hepatitis B surface antigen (HBsAg). Here we report the effect of AB-729 on novel HBV markers in nucleos (t)ide suppressed (HBV DNA-) or untreated (HBV DNA+) CHB subjects receiving single or repeat doses of AB-729. **Method:** Longitudinal plasma samples from CHB subjects receiving a single dose (60–180 mg, n = 22) or undergoing repeat dosing (60 mg every 4 weeks for 6 doses, n = 7 or 60 mg every 8 weeks for 3 doses, n = 7) were assessed for total HBV RNA and pregenomic RNA (pgRNA) by quantitative reverse-transcription polymerase chain reaction, and HBsAg isoforms and HBsAg immune complex by chemiluminescent immunoassays (Abbott Diagnostics).

**Results:** Following AB-729 single or repeat dosing, total HBsAg declines correlated significantly with reductions in total HBV RNA, pgRNA, Large (LHBs) and Middle (MHBs) HBsAg isoforms in HBV DNA- or HBV DNA+ subjects (p < 0.0001, two-tailed Pearson correlation). In HBV DNA- or HBV DNA+ “slow responders” (<0.3 log<sub>10</sub> HBsAg decline 4 weeks after AB-729 dose initiation), 0.46 to 1.44 log<sub>10</sub> reduction in total HBV RNA or pgRNA was observed in 4/5

subjects which was comparable to subjects with early HBsAg decline (0.02 to 0.99 log<sub>10</sub> HBV RNA decrease). Similar suppression of LHBS or MHBS was noted in all subjects undergoing AB-729 single or repeat dosing. No changes in immune complex levels were observed up to 24 weeks after AB-729 dosing initiation.

**Conclusion:** To our knowledge, this is the first assessment of HBsAg isoforms and immune complex in CHB subjects administered single or repeat doses of an HBV-targeting GalNAc-siRNA. Total HBsAg decline correlated with decreases in circulating HBV RNA species and both HBsAg isoforms. Early reduction in HBV RNA was observed in both "slow responders" who showed delayed HBsAg decline as well as in subjects who exhibited early HBsAg inhibition, confirming rapid target engagement by AB-729 in all CHB subjects. The significance of fast vs. slow HBsAg decline is currently being explored.

**PO-2823**

**Inhibition of hepatitis B surface antigen in chronic hepatitis B subjects by RNA interference therapeutic AB-729 is accompanied by upregulation of HBV-specific T cell activation markers**

Bhavna Paratala<sup>1</sup>, Jang-June Park<sup>1</sup>, Sharie C. Ganchua<sup>1</sup>, Edward Gane<sup>2</sup>, Man-Fung Yuen<sup>3</sup>, Amy C.H. Lee<sup>1</sup>, Chris Moore<sup>1</sup>, Angela M. Lam<sup>1</sup>, Heather Sevinsky<sup>1</sup>, Karen Sims<sup>1</sup>, Deana Antonello<sup>1</sup>, Michael J. Sofia<sup>1</sup>, Gaston Picchio<sup>1</sup>, Emily P. Thi<sup>1</sup>. <sup>1</sup>Arbutus Biopharma Inc., Warminster, United States; <sup>2</sup>Auckland Clinical Studies, New Zealand; <sup>3</sup>Queen Mary Hospital, Hong Kong

Email: ethi@arbutusbio.com

**Background and aims:** Therapeutic strategies aimed at reducing antigenemia, particularly hepatitis B surface antigen (HBsAg), may potentiate HBV-specific immune restoration in chronic hepatitis B (CHB). AB-729 is a single trigger N-Acetylgalactosamine (GalNAc)-conjugated siRNA targeting all HBV transcripts, currently in clinical development in combination with other agents for the treatment of CHB. Here we report immunological assessments in nucleos(t)ide analog-suppressed CHB subjects receiving single or repeat doses of AB-729.

**Method:** Longitudinal plasma samples from subjects receiving a single injection of AB-729 (60–180 mg, n = 16) were assessed for cytokines/chemokines using a multiplex Luminex assay. Longitudinal plasma or peripheral blood mononuclear cell samples from subjects (n = 6 or 5) undergoing repeat dosing of 60 mg AB-729 every 4 weeks (Q4W) for 6 doses were assessed using Luminex, interferon gamma (IFN $\gamma$ ) T-cell fluorospot, T-cell proliferation assay and flow cytometry.

**Results:** Following a single dose of AB-729, transient elevation of 2 to 6-fold over pre-dose baseline levels in plasma IFN $\gamma$ , IL-17a, CD163, CXCL9 and CXCL13 were observed in some subjects (60 mg, 90 mg n = 3/6 each). In one subject receiving AB-729 60 mg Q4W, a 1.7 log<sub>10</sub> reduction in HBsAg preceded a 9-fold elevation in IFN $\gamma$  at Week 28, which coincided with increase in IFN $\gamma$ -producing HBV-specific T-cells (Figure). This was preceded by mild elevations in serum alanine aminotransferase (ALT, Grade 1), which resolved by Week 28. In 3/5 subjects, elevated HBV-specific T-cell proliferation was observed by Week 8 and increases in IFN $\gamma$ -producing HBV-specific T-cells coincided with  $\geq 1.7$  log<sub>10</sub> HBsAg reduction. Mild to moderate ALT elevations (n = 2/5 Grade 1, 2/5 Grade 2) preceded or coincided with IFN $\gamma$ -producing HBV-specific T-cells. No changes were observed in any subjects for inflammatory cytokine IP-10, or other liver safety markers.

Figure:

**Conclusion:** We believe this represents the first immunological assessment of CHB subjects with prolonged HBsAg suppression following repeat doses of an HBV-targeting GalNAc-siRNA. Our findings suggest that AB-729-induced reductions in HBsAg results in increased HBV-specific immune responses in a subset of CHB subjects, accompanied by mild to moderate ALT elevations. These results strengthen the hypothesis that long-term HBV antigen suppression can promote immune reawakening in CHB and suggest AB-729 combinations with immunomodulatory agents may be beneficial.

**PO-2844**

**A phase 2 study testing FXR agonist Vofanefoxor in treatment naive patients with chronic hepatitis B (CHB): preliminary week 16 results**

Pietro Scalfaro<sup>1</sup>, Jeong Heo<sup>2</sup>, Chun-Jen Liu<sup>3</sup>, Chao-Wei Hsu<sup>4</sup>, Wan-Long Chuang<sup>5</sup>, Tsung-Hui Hu<sup>6</sup>, Wai-Kay Seto<sup>7</sup>, Virginie LE Meaux<sup>1</sup>, Jacky Vonderscher<sup>1</sup>, Raphaël Darteil<sup>1</sup>, Hugo Girma<sup>1</sup>, Marion Odoul<sup>1</sup>, Artin Karapet<sup>8</sup>. <sup>1</sup>ENYO Pharma SA, Clinical Operations, Lyon, France; <sup>2</sup>Pusan National University Hospital, BUSAN, Korea, Rep. of South; <sup>3</sup>National Taiwan University Hospital, Taipei, Taiwan; <sup>4</sup>Linkou Chang Gung Memorial Hospital, Taoyuan, Taiwan; <sup>5</sup>Kaohsiung Medical University Chung-Ho Memorial Hospital, Kaohsiung, Taiwan; <sup>6</sup>Kaohsiung Chang Gung Memorial Hospital, Kaohsiung, Taiwan; <sup>7</sup>Queen Mary Hospital, Hong Kong; <sup>8</sup>LyonaPharm Consulting, Lyon, France

Email: ps@enyopharma.com

**Background and aims:** The nuclear farnesoid X receptor (FXR) is a key factor regulating bile acid homeostasis and a target for metabolic liver diseases. FXR is also involved in hepatitis B virus (HBV) replication. The FXR agonist Vofanefoxor (V) impacted HBsAg levels in vitro and after a few weeks administration to CHB patients. We evaluate the safety and antiviral effect in CHB and report preliminary results after 16 weeks (W16) of treatment.

**Method:** In this ongoing multi-center, randomized, open-label Phase 2 trial (NCT04365933) treatment naive CHB patients with HBsAg  $\geq 300$  IU/ml and HBV DNA  $\geq 20'000$  IU/ml for HBeAg+ and  $\geq 2'000$  for HBeAg- were randomized to a combination of oral V 200 mg QD with sc pegylated interferon alpha2a (peg-IFN 180 mcg QW) to which entecavir (0.5 mg QD, ETV) was added (arm 1) or not (arm 2). Non-CHB or worsening liver disease were excluded. The experimental treatment to W16 is followed by an ongoing 24 week maintenance with ETV. Virology and safety assessments were collected every 2 weeks. The primary end point was the number of adverse events (AE) and the HBsAg decline from baseline (BL) to W16.

**Results:** Enrolled patients (n = 20) had a mean age of 48.3 years, 56% were male and 100% Asian. AE were mostly mild (47%) or moderate (37%), 11 patients had isolated ALT/AST flares (5–10x ULN) resolving with dosing interruptions. All (10/10) HBeAg- patients had a pronounced significant DNA and HBsAg decline, whereas HBeAg+ (n = 5) showed less response both for DNA and HBsAg:  $-3.7$  (0.4) log<sub>10</sub> IU/ml (mean, SE, p < 0.001) vs.  $-0.4$  (0.7, p = 0.53) and  $-0.9$  (0.1,

## POSTER PRESENTATIONS

Figure: (abstract: PO-2844)

$p < 0.001$ ) vs.  $-0.0$  ( $0.1$ ,  $p = 0.96$ ) resp. In addition and surprisingly HBsAg declines were more pronounced with dual (arm 2) over triple treatment (arm 1) Figure. Dosing interruptions with insufficient treatment duration explained HBsAg flares seen during follow-up in some patients.

**Conclusion:** Vofaxefor combined with peg-IFN induces a marked HBsAg decline in HBeAg- treatment naive CHB patients. No relationship between transaminase flares and viral response was found. Additional data is being collected during the ongoing follow-up period. The mechanism is investigated as to the cellular pathways involving FXR and the innate immunity.

### PO-2853

#### The incidence of hepatocellular carcinoma in patients with hepatitis B cirrhosis during long-term antiviral therapy: A real world cohort study

Ying Han<sup>1</sup>, Huiguo Ding<sup>2</sup>, BIN Xu<sup>1</sup>, Yanmin Liu<sup>1</sup>, Lei Li<sup>2</sup>. <sup>1</sup>Beijing You'an Hospital affiliated with Capital Medical University, Second Department of Liver Disease Center, Beijing, China; <sup>2</sup>Beijing You'an Hospital affiliated with Capital Medical University, Department of Gastroenterology and Hepatology, Beijing, China  
Email: gladyshanying@163.com

**Background and aims:** In the era of antiviral therapy, the incidence and risk factors of hepatocellular carcinoma (HCC) in patients with hepatitis B cirrhosis in different clinical stages need to be further clarified.

**Method:** This is a retrospective-prospective cohort study between June 2014 to June 2020. The enrolled hepatitis B cirrhotic patients received TDF or ETV monotherapy for more than 12 months from June 2014 to December 2018 at outpatient or inpatient department. The average follow-up time is 2 years The end point of follow-up: (1) occurrence of hepatocellular carcinoma, (2) death or liver transplantation.

**Results:** A total of 9601 hepatitis B cirrhotic patients were included, male/female 6593/3008,  $47.57 \pm 13.13$  years old. Of them, compensated (CC) and decompensated cirrhotic (DCC) patients were 2844 and 6757, respectively. Total 445 (6.6%: 445/6757) of enrolled patients were development to HCC during follow-up. Of them, 334 (4.9%: 334/6757) in DCC and 111 (3.9%: 111/2844) in CC patients respectively. The 6-year cumulative incidence of HCC were significantly difference between DCC (60.07%) and CC (43.70%). Interesting, the 2, 3, 4, 5, 6-year cumulative incidence of HCC in ETV vs TDF treatment cirrhotic patients were 4.35% vs 1.85%, 7.35% vs 3.82%, 11.62% vs 7.65% and 19.98% vs 15.66%, 55.99% vs 56.52%. The 2, 3, 4, 5, 6-year cumulative mortality of ETV combined/sequential TDF treatment were lower than ETV monotherapy (0.20% vs 0%, 0.58%

vs 0.15%, 0.90% vs 0.18%, 1.55% vs 0.25%, 2.81% vs 0.46%, 12.75% vs 2.50%),  $P = 0.040$ . The 6-year cumulative mortality were significantly difference between DCC (15.22%) and CC (2.91%),  $P = 0.028$ .

**Conclusion:** Whether it is CC or DCC patients, ETV or TDF antiviral treatment can significantly reduce the incidence of HCC. After antiviral treatment, the cumulative mortality rate has been reduced, especially in CC patients. Compared with ETV, ETV combined/sequential TDF treatment seems to reduce the cumulative mortality in patients with cirrhosis more significantly.

### PO-2879

#### A single dose of the GalNAc-siRNA, AB-729, results in prolonged reductions in HBsAg, HBcrAg, HBV DNA and HBV RNA in the absence of nucleos(t)ide analogue therapy in HBeAg negative subjects with chronic hepatitis B infection

Edward Gane<sup>1</sup>, Heather Sevinsky<sup>2</sup>, Man-Fung Yuen<sup>3</sup>, Mark Anderson<sup>4</sup>, Gavin Cloherty<sup>4</sup>, Emily P. Thi<sup>2</sup>, Tosh Wattamwar<sup>2</sup>, Michael J. Sofia<sup>2</sup>, Kevin Gray<sup>2</sup>, Deana Antonello<sup>2</sup>, Timothy Eley<sup>2</sup>, Gaston Picchio<sup>2</sup>, Karen Sims<sup>2</sup>. <sup>1</sup>University of Auckland, Auckland, New Zealand; <sup>2</sup>Arbutus Biopharma, United States; <sup>3</sup>Queen Mary Hospital, Hong Kong; <sup>4</sup>Abbott Laboratories, United States  
Email: hsevinsky@arbutusbio.com

**Background and aims:** AB-729 is an N-Acetylgalactosamine (GalNAc)-conjugated single trigger RNA interference therapeutic that blocks all HBV RNA transcripts, including HBx, resulting in suppression of viral replication and all viral antigens. AB-729 is currently in clinical development in combination with other antiviral agents for the treatment of chronic hepatitis B (CHB). Here we report additional pharmacodynamic (PD) results following a single dose of AB-729 in HBV DNA+ subjects with CHB.

**Method:** AB-729-001 is an on-going study examining AB-729 in healthy (Part 1) and CHB subjects (Parts 2/3). In Part 2 Cohort D, 6 non-cirrhotic, HBeAg negative CHB subjects with HBV DNA  $> 1,000$  IU/ml not on treatment received a single 90 mg subcutaneous dose of AB-729. Safety and PD assessments, including HBV DNA, HBsAg, HBV RNA and HBcrAg, were assessed.

**Results:** One subject was excluded as predose Day 1 results revealed a spontaneous HBV flare. To date, mean HBsAg and HBV DNA levels through Week 36 remained below baseline levels ( $-0.81 \log_{10}$  and  $-0.69 \Delta \log_{10}$  IU/ml, respectively). One subject's maximum HBV DNA decline of  $1.31 \log_{10}$  occurred at Week 32. In 2 subjects with apparent HBV DNA rebound at Weeks 24 and 28, a second decline of  $> 0.8 \log_{10}$  from baseline occurred without addition of any other therapy (Figure). HBV RNA became unquantifiable or undetectable post-dose in 5/5 subjects. 2/3 subjects with quantifiable HBcrAg at baseline reached unquantifiable levels post-dose. The remaining

subject achieved 1 log<sub>10</sub> decline in HBcAg that was maintained at Week 36. Amongst these 5 subjects there were no serious adverse events (AEs), discontinuations due to AEs, or Grade 2, 3 or 4 lab abnormalities. Ten TEAEs (9 mild, 1 moderate) were observed; only 1 was related to AB-729 (mild injection site bruising).

Figure: Individual  $\Delta\log_{10}$  HBV DNA, mean  $\Delta\log_{10}$  HBsAg and mean ALT over time in HBV DNA+ CHB subjects following a single dose of AB-729 90 mg

**Conclusion:** AB-729 90 mg single dose reduces all measured viral markers, including HBsAg, HBV DNA, HBV RNA and HBcAg, with suppression below baseline levels up to 36 weeks post-dose. Development of AB-729 continues, including repeat dosing at varying dosing intervals, in combination with other antiviral agents.

## Viral hepatitis C: Clinical aspects except therapy

### PO-68

#### Prospective independent confirmation of guideline defined hepatitis C screening strategies within the “Check-Up” examination in the primary care setting

David Petroff<sup>1</sup>, Ingmar Wolfram<sup>2</sup>, Olaf Bätz<sup>3</sup>, Katrin Jedrysiak<sup>3</sup>, Jan Kramer<sup>3</sup>, Thomas Berg<sup>4</sup>, Johannes Wiegand<sup>4</sup>. <sup>1</sup>University of Leipzig, Clinical Trial Centre, Leipzig, Germany; <sup>2</sup>Primary Care Physician, Paderborn, Germany; <sup>3</sup>LADR Laboratory Group Dr Kramer and Colleagues, Geesthacht, Germany; <sup>4</sup>Department of Medicine II, Leipzig University Medical Center, Division of Hepatology, Leipzig, Germany  
Email: johannes.wiegand@medizin.uni-leipzig.de

**Background and aims:** Adequate screening strategies for unknown infections are fundamental for hepatitis C virus (HCV) elimination. In 2015, we investigated HCV prevalence (anti-HCV 0.95%, HCV-RNA 0.43%) and screening strategies in 21 000 patients in an urban primary care setting based on a guideline adapted questionnaire for HCV risk scenarios. Presence of one of the risk factors iv drug abuse (IVDU), blood transfusion before 1992 (BT), immigration, or elevated ALT diagnosed 83% of unknown HCV-RNA positive cases by screening only 26% of the population (Wolfram, J Hepatol 2015). The aim of the present project was to perform a second independent screening and prospectively verify these results. In addition to a second urban area we included a rural region to analyse potential differences.

**Method:** Anti-HCV and ALT were included in a routine check-up (“Check-Up”) in the metropolitan area of Hamburg and rural area of Schleswig-Holstein together with a questionnaire covering 15 guideline adapted risk scenarios. HCV-RNA (PCR) was analysed in anti-HCV positive individuals. Risk factors were assessed by multivariate logistic regression.

**Results:** In Hamburg and Schleswig-Holstein, 4323 and 9321 individuals were recruited by 29 and 46 primary care practices, respectively. Baseline characteristics did not differ except for a slightly younger population in Hamburg (52.6 vs 56.6 years) and immigration being more prevalent (15.1% vs 5.9%). The anti-HCV prevalence was 0.56% and 0.49% and 0.1% of patients were HCV-RNA positive in both regions. In the total cohort (n = 13644), 52 of the 70 anti-HCV positive patients including eight HCV-RNA positive cases were so far unaware of the infection, which implies a number needed to screen of 262 to detect one unknown anti-HCV positive individual. At least one of the risk factors was present in 3000 patients (22% of the total cohort). This screening strategy identified 27 (52%) and 6 (75%) of the anti-HCV and HCV-RNA positive patients with unknown infections, reducing the number needed to screen to 111. The odds ratio (95% CI) for anti-HCV was 53.1 (27.9–96.5), 2.1 (0.8–4.4), 2.6 (1.4–4.6) and 1.4 (0.6–2.6) for IVDU, BT, immigration and elevated ALT, respectively.

**Conclusion:** Our second independent screening prospectively verifies the results of the first study. An anti-HCV screening in combination with a simply to capture risk questionnaire and ALT measurement should be included in the routine check up at the primary care level.

### PO-72

#### Hepatitis C in Connecticut Community Clinics: Measuring the Impact of the Project ECHO Model in Treatment in Primary Care

Aaron Smith<sup>1</sup>, Marwan Haddad<sup>2</sup>. <sup>1</sup>Quinnipiac University, Frank H. Netter MD School of Medicine, North Haven, United States; <sup>2</sup>Community Health Centers, Inc., Weitzman Institute, Middletown, United States

Email: aasmith@qu.edu

**Background and aims:** 3.5 million Americans are living with chronic hepatitis C virus (HCV), a viral infection of the liver which, prior to COVID-19, killed more people in the US than any other infectious disease. A significant barrier to treatment is a lack of training of primary care providers (PCPs). The Project Extension for Community Healthcare Outcomes (Project ECHO), a telemedicine model for training PCPs, has been used to address this barrier, with treatment outcomes comparable to those of gastroenterology (GI) specialists. Community Health Center, Inc. (CHC) in Connecticut has been operating a hepatitis C virus (HCV) ECHO program since 2012. This study aims to evaluate the program’s efficacy in changing provider behavior and increasing rates of treatment among HCV patients.

**Method:** This is a retrospective cohort study including the 2, 638 HCV patients in primary care at CHC from 2012 to 2019. A population analysis was conducted, comparing individuals in three treatment groups: patients treated in primary care, referred to GI, and neither. A multinomial logistic regression was used to create a predictive model for these groups. A Fisher’s exact test was used to compare patients treated in primary care who did and did not have an ECHO-trained PCP.

**Results:** Compared to the other two treatment groups, patients treated in primary care were more likely to have an ECHO-trained PCP, as well as be HIV-positive, and have opioid use disorder (OUD) and advanced fibrosis or cirrhosis. While 52.6% of patients treated in primary care had a PCP who was ECHO-trained, 81.3% of patients treated in primary care were prescribed medication by an ECHO-trained provider. Notably, having an ECHO-trained PCP was found to be a positive predictor of treatment in primary care (OR = 1.611; 95% CI = 1.332–1.949; p = <0.001), and a negative predictor for referral to a GI specialist (OR = 0.662; 95% CI = 0.526–0.832; p = <0.001).

## POSTER PRESENTATIONS

Additionally, advanced fibrosis or cirrhosis (OR = 4.048; 95% CI = 3.143–5.212;  $p < 0.001$ ), and OUD (OR = 2.45; 95% CI = 2.002–3;  $p < 0.001$ ) were found to be significant positive predictors of treatment in primary care.

**Conclusion:** Not only were patients of ECHO-trained providers more likely to be treated in primary care, but ECHO-trained-providers were responsible for the great majority of treatment in primary care. Moreover, patients who were the most medically complicated, based on the presence of advanced liver disease and HIV, were more likely to be treated in primary care, and more likely to be treated by an ECHO-trained PCP. The success of this program suggests that the ECHO model can be extremely effective in increasing access to care, by creating a significant change in provider behavior and increasing treatment in primary care. If the United States hopes to achieve its nation-wide goal of HCV elimination, the ECHO model should be an integral part of a multi-faceted approach.

### PO-131

#### From screening to therapy: Anti-HCV screening and linkage to care in a network of general practitioners and a private gastroenterology practice

David Petroff<sup>1</sup>, Olaf Bätz<sup>2</sup>, Katrin Jedrysiak<sup>2</sup>, Jan Kramer<sup>2</sup>, Hjördis Möller<sup>3</sup>, Renate Heyne<sup>3</sup>, Burkhard Jäger<sup>3</sup>, Thomas Berg<sup>4</sup>, Johannes Wiegand<sup>4</sup>. <sup>1</sup>University of Leipzig, Clinical Trial Centre, Leipzig, Germany; <sup>2</sup>LADR Laboratory Group Dr Kramer and Colleagues, Geesthacht, Germany; <sup>3</sup>Leberzentrum am Checkpoint, Berlin, Germany; <sup>4</sup>Department of Medicine II, Leipzig University Medical Center, Division of Hepatology, Leipzig, Germany  
Email: johannes.wiegand@medizin.uni-leipzig.de

**Background and aims:** Low rates of hepatitis C virus (HCV) diagnosis and sub-optimal linkage to care constitute barriers to eliminate HCV infection—a World Health Organisation goal for 2030. In 2012/13, we performed an HCV screening on top of a routine check-up in the primary care setting and observed an anti-HCV and HCV-RNA prevalence of 0.95% and 0.43%, respectively (Wolfram, J Hepatol 2015). However, anti-HCV positive patients may not receive further diagnostics and antiviral therapy, because they drop out during the referral pathway to the specialized care of gastroenterologists. Thus, clinical studies on linkage to care aspects are of major relevance to improve HCV elimination strategies: We used an existing network of primary care physicians and a specialized private practice of gastroenterology to investigate an ideal pathway from screening to referral of newly identified HCV patients with documentation of further diagnostic steps and initiation of therapy.

**Methods:** An anti-HCV and HCV-RNA screening was prospectively included in a routine check-up covered by statutory health care insurance in the primary care setting. Primary care physicians cooperated routinely with a private gastroenterology practice in Berlin. Anti-HCV positive patients were referred for further specialized diagnostics and treatment if indicated.

**Results:** Within 14 months, 17 primary care practices screened 1875 patients (46% male, age  $50 \pm 17$  years). 12 individuals were anti-HCV positive (0.6%), six of them reported previous antiviral HCV therapy, leaving six newly discovered cases, of whom one was HCV-RNA positive (0.05% of the population). The main risk factor for being anti-HCV positive was a history of iv drug abuse (5/12 (42%) vs. 12/1863 (0.6%);  $p < 0.001$ ). None of the 12 anti-HCV positive cases whom referral to secondary care was offered to showed up at the private gastroenterology practice. Thus, further clinical details of the pathway from screening to therapy could not be analyzed.

**Conclusions:** Although much effort was made to characterize linkage to care of newly diagnosed hepatitis C patients between primary and secondary care, the project failed its primary goals. The prevalence of anti-HCV and HCV-RNA positive patients was remarkably lower than in our primary screening project and did not allow detailed analysis of patient care pathways.

### PO-388

#### Increased screening, tailored access, linkage to care and treatment for PWUD through a patient centered program

Alessandra Mangia<sup>1,2</sup>, Rosa Cotugno<sup>1</sup>, Maria Franca<sup>3</sup>, Antonio Canosa<sup>4</sup>, Valeria Piazzolla<sup>1</sup>, Maria Squillante<sup>1</sup>, Ernesto Agostinacchio<sup>5</sup>, Giovanna Cocomazzi<sup>1</sup>, Loredana Ciaccia<sup>6</sup>, Egidio Visaggi<sup>7</sup>, Fausto Campanozzi<sup>8</sup>. <sup>1</sup>IRCCS “Casa Sollievo della Sofferenza”, San Giovanni Rotondo; <sup>2</sup>Liver Unit, Medical Sciences, San Giovanni Rotondo, Italy; <sup>3</sup>SUD Department, Policoro; <sup>4</sup>SUD Department, Termoli; <sup>5</sup>Internal Medicine, Bari; <sup>6</sup>IRCCS “Casa Sollievo della Sofferenza”, San Giovanni Rotondo; <sup>7</sup>Internal Medicine, Terlizzi; <sup>8</sup>SUD Department, Torremaggiore  
Email: a.mangia@tin.it

**Background and aims:** In Italy, rates of HCV testing and diagnosis are variable among PWUD. In Puglia in 2018, of 871 screened subjects, 38% had HCVAb\*. Despite DAAs are associated with 95% SVR rates, addition center (SERD) physicians are often located in remote areas and are not allowed to prescribe DAAs. Notably, during the last year, and in concomitance with COVID-19 pandemic, a reduction in DAAs prescriptions has been observed. To increase all the steps of HCV cascade, a dedicated program including “ad hoc” transportation service, fast track access to care and treatment was offered to PWUD in our geographical area.

**Method:** Over 12 months period, 1500 individuals seen at 15 SERDs underwent HCV screening by OraQuick. For patients testing HCVAb positive, a fast track baseline evaluation was performed at our Unit allowed to prescribe DAAs. Patients were transported to our center on a dedicated “ad hoc” shuttle and, after a 5 hours baseline evaluation, were taken to pharmacists close to their SERDs in order to receive medications. Treatment and adherence were supervised by SERDs physicians and SVR12 assessed at our center after the follow-up. Scalability of the process was assessed based on the number of patients screened in our region in 2018, and on the number of PWUD diagnosed and treated at our center during 06/2018–07/2019.

**Results:** Of the 1500 individuals screened, 634 (42.2%) tested HCVAb positive. Active HCV infection was observed in 231 ongoing PWUD, 54% of whom on OAT. Baseline characteristics of 634 patients and HCV RNA status are reported in Table 1. Higher rates were on OAT and had liver stiffness results compatible with cirrhosis among HCV RNA positive than negative. Median interval between HCV RNA assessment and treatment start was 22 days (0–300). Patients received pangenotypic treatment for 12 weeks without RBV. In 222 patients who completed treatment SVR rate was 98.6%. Among GT3 infected, SVR12 was 98%. Overall, 9 patients discontinued treatment or were lost to follow-up, 6 of them between week 4 and 8. No reinfection was observed.

	HCV Ab+ve N = 634
Median age (yrs) range	48.1 (22–71)
Male gender	562 (88.6)
Current IVDU	180 (28.4)
Heroin alone	56 (31.2)
Cocaina alone	23 (12.7)
Heroin combined with alcol/others	101 (56.1)
OAT	221 (34.8)
HCV RNA reactive	231 (36.4)
Past HCV treatment	278 (44.0)
HIV positive	14 (2.2)
Mental Disorders	56 (8.8)
Liver stiffness >12.5 Kpa	147 (23.1)

**Conclusion:** Among PWUD, a patient tailored service led to an increase in screening and diagnosis. A rapid treatment start occurred in the vast majority of cases. SVR12 was high regardless of HCV GT. In patients with history of drug addiction and social instability, dedicated treatment programs allow to increase the number of HCV infected patients identified, diagnosed and successfully treated.

Funding: this work was supported by Gilead for the study “The Puglia micro-elimination” NCT03923595.

**PO-453**

**The impact of unrestricted access to direct-acting antiviral among 1001 incarcerated hepatitis C virus-infected patients**

Yu Jun Wong<sup>1,2</sup>, Prem Harichander Thurairajah<sup>3</sup>, Rahul Kumar<sup>3</sup>, Ngai Moh Law<sup>1</sup>, Sin Yoong Chong<sup>1</sup>, Tiing Leong Ang<sup>1</sup>, Jessica Tan<sup>1</sup>, Eng Kiong Teo<sup>1</sup>. <sup>1</sup>Changi General Hospital, Gastroenterology and Hepatology, Singapore, Singapore; <sup>2</sup>Duke-NUS Medical School, Singapore; <sup>3</sup>National University Hospital, Gastroenterology and Hepatology, Singapore, Singapore  
Email: eugene.wong.y.j@singhealth.com.sg

**Background and aims:** Despite the disproportionately high prevalence of hepatitis C virus (HCV) amongst the incarcerated population, eradication remains challenging due to logistic and financial barriers. Although treatment prioritization based on disease severity is commonly practiced, the efficacy of such an approach remains uncertain. Recent modelling study showed that at least 630 HCV patients have to be treated annually in order for Singapore to achieved HCV elimination target by 2030 [1]. We aimed to compare the impact of unrestricted access to DAA among incarcerated HCV-infected patients in Singapore.

**Method:** In this retrospective study, we reviewed all incarcerated HCV-infected patients treated in our hospital during the restricted DAA era (2013–2018) and unrestricted DAA access era (2019). During restricted DAA era, DAA was reserved for patients with Genotype 1 HCV infection, HIV/HBV co-infection, cirrhosis, prior treatment experienced or contraindication to pegylated interferon. During unrestricted DAA era, all patients received DAA as first-line treatment. Study outcomes included the rate of SVR (both intention-to-treat (ITT) and per-protocol (PP) analysis), treatment completion and treatment default. Subgroup analysis was performed based on the presence of liver cirrhosis and HCV genotype.

**Results:** Total of 1001 HCV patients were treated during the study period. They were predominantly male (93%) with genotype-3 HCV infection (71%), and 38% were cirrhotic. More patients received DAA during unrestricted DAA era (95% vs 42%, p < 0.001). The overall SVR during the restricted DAA access era and unrestricted DAA access era were (ITT: 83.8%, PP: 92.1%) and (ITT: 92.1%, PP: 99.1%), respectively. Unrestricted access to DAA exponentially improved the treatment access among HCV-infected patients by 460% to 681 in the year 2019 alone, resulting in a higher SVR rate (99% vs 92%, p = 0.003), higher treatment completion rate (99% vs 93%, p < 0.001), lower treatment default rate (1% vs 9%, p < 0.001) and allowing more non-cirrhotic patients to be treated (non-cirrhotic: 74.4% vs 34.7%, p < 0.001). Our findings remained robust among subgroup analysis in patients with liver cirrhosis or genotype-3 HCV infection.

Figure: Exponential increase in non-cirrhotic HCV patients treated following unrestricted access to DAA.

**Conclusion:** In this large cohort of incarcerated HCV-infected patients, we demonstrated that unrestricted access to DAA is an

impactful strategy to allow rapid treatment up-scale in HCV micro-elimination.

**PO-525**

**Pooling plasma samples for hepatitis C RNA detection: a strategy to expand access to diagnostics**

A. Aguilera<sup>1</sup>, Sara Pereira<sup>1</sup>, Ana Fuentes<sup>2</sup>, Adolfo de Salazar<sup>3</sup>, Daniel Navarro<sup>1</sup>, Maria Cea<sup>1</sup>, Camila Picchio<sup>3</sup>, Jeffrey Lazarus<sup>3</sup>, Federico Garcia Garcia<sup>2</sup>. <sup>1</sup>Complejo Hospitalario Universitario de Santiago (CHUS). Universidad de Santiago de Compostela (USC). Instituto de Investigación Sanitaria de Santiago (IDIS), Departamento de Microbiología, Santiago de Compostela, Spain; <sup>2</sup>Hospital Universitario San Cecilio. Instituto de Investigación Ibs, Granada, Clinical Microbiology, Granada, Spain; <sup>3</sup>Barcelona Institute for Global Health (ISGlobal), Hospital Clínic, University of Barcelona  
Email: fe Garcia@ugr.es

**Background and aims:** Processing SARS-CoV-2 diagnostic tests has created an enormous workload for laboratories around the world, at the cost of processing many other tests. Yet the diagnosis of active hepatitis C virus (HCV) infection is the necessary first step for its elimination. In most countries, universal population screening and/or screening by age group have not been adopted due to cost and cost-effectiveness considerations. We propose a sample pooling diagnosis strategy to overcome this challenge, and to contribute to increasing the diagnostic capacity of clinical laboratories.

**Method:** A positive sample with known HCV RNA IU/ml was pooled 1/10, 1/100, 1/1000, 1/10 000, 1/1 00 000, and 1/10 00 000, and run by two commercially available diagnostic assays: CAP CTM v2 HCV and Cobas 6800 (Roche Diagnostics). The sensitivity of pooling was assessed as the last pool able to detect more than 15 IU/ml.

**Results:** As shown in Table 1, both tests were able to identify the positive sample when pooled in up to 10<sup>4</sup> samples. We observed a one log decrease per 10-fold pooling factor in the amount of HCV RNA that the commercial assays were able to detect.

Table: Pooling of a positive sample (U = unknown) by two commercially available HCV-RNA detection tests

Samples	Pool	CAP CTM v2 HCV		Cobas 6800	
		IU/ml	Log10	IU/ml	Log10
U		61 0311	5.78	1 15 000	5.06
U+9 negative	10	51 389	4.71	14 700	4.16
U+99 negative	100	4642	3.67	1730	3.23
U+999 negative	1000	604	2.78	231	2.36
U+9999negative	10 000	94	1.97	43	1.63
U+99999 negative	1 00 000	<15	<1.18	<15	<1.18
U+999999	10 00 000	TND	-	TND	-

TND: target not detected.

**Conclusion:** The strategy of pooling samples for the diagnosis of active HCV infection has great advantages that can and should be exploited with the aim of eliminating HCV as a public health threat. From our study, we believe that a plausible size for countries with a low prevalence of chronic hepatitis C would be 100 samples, very similar to the number used earlier by blood banks and transfusion centers. Given current prices on the market and for a pool size of 100 samples, the price of pooled testing for HCV-RNA would be reduced to EUR 0.30 per patient screened. We believe that by substantially improving cost-effectiveness, this strategy enables and provides the necessary sustainability for use in large-scale diagnosis of HCV.

## POSTER PRESENTATIONS

PO-637

### Achieving hepatitis C micro-elimination in prisons through High Intensive Test and Treat (HITT) interventions

Sean Cox<sup>1</sup>, Andrew Jones<sup>2</sup>, Lee Christensen<sup>1</sup>, Julia Sheehan<sup>1</sup>, Kate Dorrington<sup>3</sup>, Andrew Milner<sup>3</sup>, Phil Troke<sup>3</sup>, Iain Brew<sup>4</sup>, Rachel Halford<sup>1</sup>. <sup>1</sup>Hepatitis C Trust, London, United Kingdom; <sup>2</sup>Gilead Sciences Ltd, Medical Affairs, London, United Kingdom; <sup>3</sup>Gilead Sciences Ltd, London, United Kingdom; <sup>4</sup>Practice Plus Group Health and Rehabilitation, United Kingdom  
Email: andy.jones@gilead.com

**Background and aims:** National Health Service England plans to eliminate Hepatitis C in England by 2025, five years earlier than World Health Organisation goals. Achieving micro elimination in prisons is an essential component of this plan. Testing on prison admission has historically been low and, despite recent increases, there remains a large population who still require testing and treatment.

**Method:** Through a collaboration between The Hepatitis C Trust (HCT), Her Majesty's Prison and Probation Service, Prison Healthcare provider Practice Plus Group, Gilead Sciences and NHS England, we have developed a process to screen entire prisons over 1–5 days and rapidly initiate treatment. Prior to an intervention, HCT Peers engage with both staff and prisoners to raise awareness and reduce stigma. During the event, screening is performed using rapid point-of-care antibody tests followed by PCR-based assessment of positives. Testing acceptance is maximised by testing on the prison wings and provision of incentives: chocolate, toiletries, telephone credit. The aim is for treatment initiation to begin within 7 days (maximum 14 days) of PCR+ diagnosis.

\* COVID-19 impacted prisons following the national lockdown and this effected the initiation of treatment following 3 HITTs which took place in March 2020

Figure:

**Results:** During 2020, HITTs were performed at 9 prisons with 4, 724 prisoners tested out of a potential 4, 858 (97%; range 96–100%). HCV antibody prevalence varied greatly with the highest being female

closed (19%), and high turnover male remand (11%), prisons, compared to Young Offenders Prisons (0.2%). The initial prisons engaged were those with pre-existing reception testing and treatment pathways. As a result, over half of patients who tested positive for HCV antibody were already on treatment, previously treated or had naturally cleared the virus. COVID-19 significantly impacted these interventions but procedures were developed to safely deliver HITTs during the pandemic.

**Conclusion:** HITT interventions have proven effective in testing entire prison populations with all prisons achieving the NHSE target of over 95% of residents tested. HCT Peers with their lived experience of HCV have proven essential to engage prisoners who previously refused testing. Viraemia rates were low in comparison to antibody rates due to the successful testing and treatment pathways in these prisons. Future HITTs are planned for prisons with historically low HCV screening and treatment rates, with the aim of increasing identification of RNA+ individuals.

PO-649

### Impact of extending DAAs availability in France: a five-year overview (2015–2019) of data from French administrative healthcare databases (SNDS)

Stanislas Pol<sup>1</sup>, Fayssol Fouad<sup>2</sup>, Magali Lemaître<sup>2</sup>, Ingrid Rodriguez<sup>3</sup>, Olivier Lada<sup>3</sup>, Françoise Roudot-Thoraval<sup>4</sup>. <sup>1</sup>Cochin (AP-HP), Paris, France; <sup>2</sup>IQVIA, Courbevoie, France; <sup>3</sup>Gilead, Boulogne-Billancourt, France; <sup>4</sup>Henri-Mondor (AP-HP), Créteil, France  
Email: fayssol.fouad@iqvia.com

**Background and aims:** Direct antiviral agents (DAAs) first became available in France in 2014 for the treatment of chronic hepatitis C (CHC) in patients with severe fibrosis (prioritized access); then in 2017, DAAs became available to all CHC patients (universal access). Lastly, in May 2019, universal prescription was granted, allowing every physician, including GPs, to prescribe pangenotypic DAAs. This study evaluated the impact of DAA availability on CHC treatment access and HCV screening in general and at-risk populations.

**Method:** Adult patients affiliated with the French national health insurance system (SNDS databases) who were screened or treated for CHC between 2015 and 2019 were included. Different algorithms were developed to identify at-risk subpopulations: migrants, inmates, HIV+ patients, psychiatric patients and drug users.

**Results:** In the general population, the proportion of screened patients increased by 1% between 2015 and 2019 (from 4.6% to 5.6%). The median interval between the last screening test and treatment initiation decreased from 64 days in 2015 to 37 days in 2019.

During the study period, 71, 466 patients began CHC treatment (median age 55; [48–62]; 59% male). The proportion of patients starting treatment increased by 44% between 2015 and 2017 and decreased in 2019. The median age decreased from 56 to 54 years and the proportion of female increased from 36% to 39% during the study

Figure: (abstract: PO-649): Time trend of the proportions of at-risk subpopulations among treated patients, 2015–2019.

period. Among the study population, only 2, 212 (3%) patients were treated at least twice.

Among treated patients, 54% were not at-risk patients. The main nonexclusive risk factors for CHC were psychiatric conditions (27%), drug use (21%) and HIV positivity (11%). Among treated patients, the proportion of HIV+ patients decreased from 19% to 8%, while the proportions increased, or remained stable, in other at-risk subpopulations. Depending on the year, between 51% and 57% of psychiatric patients had additional risk factors, mainly drug use with a 38% to 52% overlap.

**Conclusion:** To our knowledge, this study is the first describing the HCV treatment management in France between 2015 and 2019 using the SNDS databases to assess the impact of extending DAA availability. It highlights that DAA availability was associated with a screening increase since 2015 and a decrease in the time to treatment initiation. It also emphasizes that universal access in 2017 led to a surge in treatment initiations in the general population. Finally, this study is the first to use algorithms to identify and describe at-risk subpopulations using the SNDS databases, which will help to improve the HCV cascade of care in these subpopulations.

**PO-690**

**Depist C pharma, an innovative outreach HCV screening project in pharmacy for drug users and general population**

André-Jean Remy<sup>1</sup>, Eric Puget<sup>1</sup>, Olivier Albert<sup>1</sup>. <sup>1</sup>Perpignan Hospital, Mobile Hepatitis Team, Perpignan, France  
Email: andre.remy@ch-perpignan.fr

**Background and aims:** Hepatitis C testing is still insufficient in France. Beyond defined groups with risk behaviors, hepatitis C testing should now be directed at the general population. The French pharmacies territorial coverage is excellent, and pharmacists are increasingly involved in public health actions (therapeutic education, vaccination against the flu). French Public Health Act on Innovation thank to the "Article 51" allow enables health care teams to propose experiments aimed at improving the diagnostic and/or therapeutic management of a disease. This funding methods and organization is unprecedented. Our aim was to screen for hepatitis C in pharmacies with POCT performed by pharmacists.

**Method:** Pharmacist recruitment was done on a voluntary basis from different pharmacies on a population pool of 600, 000 inhabitants. Pharmacists received training and education appropriate to the POC testing. At request of the health authorities, screening was only proposed for patients with one or more risk factors (national health agency list). There were planned 10 tests per week per pharmacy over 12 months for a total of 5, 000 tests. Expected prevalence was 10%. Patients with positive POCT were tested for HCV viral load real-time and for liver fibrosis assessment by FIBROSCAN. They could be treated with HCV antiviral direct agents.

**Results:** 37 pharmacists representing 25 pharmacies were trained to POCT use and announcement of results during 4 half days session. 9 pharmacies were located in agglomeration, including 5 in working-class areas, 7 in rural area, 7 in seaside area and 2 in middle mountain area. After 15 months of experimentation: 29 pharmacies have completed at least one POCT; we observed a decrease in the number of tests performed during the flu vaccination campaign; 656 tests were performed including 45 positives or a serological prevalence of 6, 9%. 33 patients had a negative viral load with 1 or 2 risk factors and a Fibroscan mean value at 4, 5 KPa (fibrosis stage F1); 13 patients had positive HCV viral load (prevalence 2%) and 3 to 9 HCV risk factors, mean Fibroscan value at 8.6 KPa (fibrosis stage F2). They all were effectively treated and cured by direct antiviral agents.

**Conclusion:** We have demonstrated the feasibility of hepatitis c screening by POCT performed by pharmacists regardless of geographic location. Targeting screening by risk factors does not identify all patients. Pharmacists represent very interesting local *healthcare professional* who could invest in COVID19 screening by POCT.

**Simulations of HCV vaccine trials reveal opportunities to re-evaluate vaccine efficacy**

Alexander Gutfraind<sup>1,2</sup>, Mary-Ellen Mackesy-Amiti<sup>3</sup>, Eric Tataru<sup>4,5</sup>, Nicholson Collier<sup>4,5</sup>, Scott Cotler<sup>1</sup>, Kimberly Page<sup>6</sup>, Jonathan Ozik<sup>4,5</sup>, Basmattee Boodram<sup>3</sup>, Marian Major<sup>7</sup>, Harel Dahari<sup>1</sup>. <sup>1</sup>Loyola University Chicago, The Program for Experimental and Theoretical Modeling, Division of Hepatology, Department of Medicine, Stritch School of Medicine, Maywood, United States; <sup>2</sup>University of Illinois at Chicago, Division of Epidemiology and Biostatistics, School of Public Health, Chicago, United States; <sup>3</sup>University of Illinois at Chicago, Division of Community Health Sciences, School of Public Health, Chicago, United States; <sup>4</sup>University of Chicago, Consortium for Advanced Science and Engineering, Chicago, United States; <sup>5</sup>Argonne National Laboratory, Decision and Infrastructure Sciences, Argonne, United States; <sup>6</sup>University of New Mexico Health Sciences Center, Division of Epidemiology, Biostatistics and Preventive Medicine, Department of Internal Medicine, Albuquerque, United States; <sup>7</sup>Food and Drug Administration, Division of Viral Products, Center for Biologics Evaluation and Research, Silver Spring, United States  
Email: harel.dahari@gmail.com

**Background and aims:** Agent-based models (ABM) can identify challenges and help to develop robust HCV vaccine trial designs to increase the chance of reaching end points. In this study we use an ABM to perform in-silico simulations of HCV vaccine randomized clinical trials (RCT).

**Method:** To forecast RCT outcomes, we designed an ABM simulation representing 32, 000 PWID in metropolitan Chicago, Illinois, USA accounting for their networks and infections with HCV. The in-silico simulation represents recruitment, follow-up, and statistical analysis of a two-dose vaccine based on a completed trial (NCT01436357 or NEJM in press). The vaccine was assumed to have vaccine efficacy (aVE) of 60% in preventing chronic HCV but no effect on acute infections. We ran 3 trial simulations with different random seeds, collecting daily HCV-infection status of each in silico PWID in the trial, which allowed us to examine the effect of HCV testing frequency (e.g., weekly vs. monthly) and various statistical approaches (SA) of calculating the estimated vaccine efficacy (eVE): (SA #1) incidence rate ratio (IRR) of chronic HCV, intention to treat, (SA #2) IRR of chronic HCV, per protocol sample, (SA #3) IRR of chronic HCV among acute infected, (SA #4) Cox proportional hazard (CPH) model for the risk of chronic HCV, (SA #5) adjusted CPH model for the risk of chronic HCV (Table 1).

Table 1: Prevented chronic HCV infection in simulated vaccine trial analysis with assumed vaccine efficacy of aVE=60%

	Trial A		Trial B		Trial C	
	Study	Placebo	Study	Placebo	Study	Placebo
N total	1604	1603	1604	1603	1604	1603
HCV acute cases	79	60	52	74	65	63
HCV chronic cases	34	41	20	50	30	44
<b>Statistical approaches (SA) of eVE (chronic HCV prevented)</b>						
(1) 1-IRR, ITT	.19	.60	.31			
(2) 1-IRR, per protocol	.25	.62	.33			
(3) 1-IRR, among acute	.38	.41	.36			
(4) 1-HR (Cox regression)	.19	.60	.32			
(5) 1-aHR (Cox regression) †	.27	.55	.25			

IRR: incidence rate ratio; ITT: intention to treat; HR: hazard ratio; aHR: adjusted HR; eVE: estimated efficacy based on in silico trial simulation results; † adjusted for age, gender, race/ethnicity, drug use degree, friend HCV prevalence, daily injection intensity, network mean age, fraction receptive sharing.

**Results:** The HCV incidence in each arm was found to have a significant effect on eVE. In trial A, a higher rate of acute infections in the vaccine arm compared to the placebo arm increased the number of chronic infections, and reduced the eVE calculated by the crude IRR (SA #1). Covariate adjustment (SA #5) only partially mitigated the effect of unequal infection rates. Conversely, in Trial B there were more acute cases in the placebo arm resulting in an overestimated eVE. Trial C showed eVE<60% despite a balanced incidence. An analysis of time to viral clearance among persons infected showed a strong vaccine effect in all trials, with clearance rates 3 to 5 times higher in the vaccine compared to placebo condition. The simple IRR

method (SA #1) appears to give similar eVE as the more complex (unadjusted) Cox method (SA #4) in all trials. The incidence rate ratio for chronic infection among acute cases (SA #3), as well as the time to clearance, were found to be robust measures of vaccine performance, and could provide secondary end points. Analysis of the choice of weekly vs. monthly blood testing did not find a systematic difference in results.

**Conclusion:** The statistical methodology and end point have a significant effect on the success of vaccine trials, with some analysis establishing a much lower eVE than aVE, which suggest a re-evaluation of how vaccine trials for HCV should be evaluated.

PO-908

**Diagnostic accuracy of dried blood spot and plasma separation card samples for testing hepatitis c virus rna**

Email: elena.ivanova@finddx.org

**Background and aims:** Dried blood spots (DBS) have the potential to improve access to diagnostic testing for hepatitis C virus. A number of studies have shown good performance of centralized HCV RNA assays with DBS specimens. However, there was no standard protocol for DBS collection, storage and processing and the use of DBS samples was limited to “off-label” use. Here, we evaluated the performance of three centralized HCV RNA assays from capillary blood collected on DBS and Plasma Separation Cards (PSC) using manufacturers’ protocols.

**Method:** Participants were enrolled at four sites located in Cameroon, Rwanda, Georgia, and Greece. Dried blood spot and Plasma Separation Card samples were prepared from capillary (fingerstick) and venous whole blood samples. Collected samples were tested locally and sent for further testing to the central laboratory facility at NRL Australia (Melbourne, Australia). The diagnostic accuracy of these sample types for detecting hepatitis C virus RNA was assessed using three platforms (Abbott m2000sp/rt, Roche cobas® 4800 and Roche cobas® 6800), with plasma tested using the respective plasma assays on each of the platforms, serving as the reference tests.

Table 1: Diagnostic accuracy of centralized HCV RNA assays using DBS and PSC samples

Index test and sample type	Sensitivity (%), (95% CI)	Specificity (%), (95% CI)
Abbott RealTime	95.2	95.6
DBS	(92.9–96.8)	(93.3–97.1)
Roche cobas® 4800	97.2	88.6
DBS	(95.2–98.3)	(85.4–91.2)
Roche cobas® 4800	95.2	99.6
PSC	(92.8–96.8)	(98.5–99.9)
Roche cobas® 6800	97.3	95.9
DBS	(95.4–98.5)	(93.7–97.3)
Roche cobas® 6800	96.9	99.8
PSC	(94.8–98.1)	(98.8–100)

Abbreviations: CI, confidence interval; DBS, dried blood spot; PSC, plasma separation card.

**Results:** A total of 946 participants were enrolled. The sensitivity and specificity of the Abbott RealTime assay was 95.2% and 95.6%, respectively, using capillary DBS samples. The sensitivity and

specificity of the Roche cobas® 6800 was 97.3% and 95.9%, respectively, on the DBS samples. Sensitivity and specificity were high on the Roche cobas® 4800 and 6800 assays using PSC samples. **Conclusion:** The diagnostic accuracy of DBS and PSC samples for detecting HCV RNA was high on all platforms evaluated, confirming that these sample types can be used as an alternative to plasma, to screen for HCV infection, thus facilitating access to testing.

**PO-951**

Email: a.mangia@tin.it

**Background and aims:** Given the millions of patients who remain unaware of their HCV infection and/or diagnosis, WHO solicits Countries to achieve elimination by 2030.

The Italian government started routine screening for HCV infection on January 2021 initially targeting subjects born between 1969 and 1989. In Italy, the most recent active HCV epidemiological estimate dates before the 2017 widespread DAA use and shows 1.7% prevalence with significant geographical differences. At the aim of achieving micro-elimination, we designed a hospital-wide project focusing on inpatients born from 1935 to 1985 to be conducted at our Institution.

**Method:** All inpatients aged up to 85, admitted from February 10, 2020 to February 9, 2021 underwent HCV screening. Patients were evaluated by III generation ELISA. Reflex HCV RNA test and genotyping were performed in HCVAb positive. Clinical history, diagnosis, laboratory data and concomitant medications were available for all.

**Results:** The HCV screening rate of inpatients was 100%. A total number of 11.146 were enrolled with a male prevalence of 54.5%. HCVAb positivity rate was 3.1% (95% CI, 3.06–3.10%) among the total population. The rate was significantly higher among male (3.4% vs 2.6%, p = 0.01). The HCVAb rate increased with age and was highest for patients born between 1944 and 1935 (5.2%). Overall, 81% of HCV RNA positive were 55 or older. The rate of HCV RNA positivity was 0.98%. Prevalence of HCVAb positivity by birth decades, and deaths by HCV RNA status are reported in the table. Overall, 18 patients died soon after diagnosis (1 due to COVID-19 infection). Among patients older

than 65, death rate was significantly higher than in those with active HCV infection. Although the proportion of HCV RNA positive patients was equal for Surgical and Medical departments, the rate of unaware patients with active HCV infection was higher among patients admitted to Orthopedic, Urologic, Abdominal, Cardiovascular, Thoracic, Maxillo-facial Surgery Units than among Medical Units (61% vs 55%).

Age cohorts	Number of subjects	HCV Abs positivity n, (%)	HCV RNA positivity n, (%)	Deaths among HCVAb n, (%)	Deaths among HCV RNA n, (%)
1975–1984	1432	24 (1.6)	6 (0.4)	0	0
1965–1974	1905	60 (3.1)	15 (0.8)	1	0
1955–1964	2546	64 (2.5)	16 (0.6)	1	0
1945–1954	2927	72 (2.4)	24 (0.8)	1	2
1935–1944	2341	124 (5.2)	46 (5.2)	3	10

**Conclusion:** The present study reveals a rate of active HCV infections among inpatients lower than that reported in the past in general population as a result of DAA use. The high rate of inpatients unaware of HCV infections, and the high number of deaths among subjects born from 1935 to 1965 suggest that –at least in Southern Italy– a targeted screening of these birth cohorts may be required to reduce the number of undiagnosed cases and hidden infections.

**PO-955**

**Cost and effectiveness of treatment at Day 1 (Rapid Start) for hepatitis C and screening intensification in high-risk populations (TandT strategy) in France**

Jean-Baptiste Trabut<sup>1</sup>, Marc Bourlière<sup>2</sup>, Ingrid Rodriguez<sup>3</sup>, Oliver Lada<sup>3</sup>, Martin Blachier<sup>4</sup>, Christophe Hezode<sup>3</sup>, Henri Leleu<sup>4</sup>. <sup>1</sup>Service d'addictologie, Hôpital Henri Mondor, France; <sup>2</sup>Service d'hépatogastroentérologie, hôpital Saint-Joseph, Marseille, France; <sup>3</sup>Gilead, Boulogne-Billancourt, France; <sup>4</sup>Public Health Expertise, Paris, France

Email: Ingrid.rodriguez@gilead.com

**Background and aims:** France is committed to improving prevention, diagnosis, and treatment of hepatitis C (HCV) in line with the WHO objective of eliminating HCV by 2030. However, despite increasing attention to HCV screening, half of the patients screened with a positive serology are lost to follow-up (LTFU) before initiating treatment. This study estimates the impact on patient care of a “test and treat” (TandT) strategy which combines a targeted screening effort on elderly (>55 y/o) with an early treatment on day 1 for all patients (Rapid Start).

**Method:** A decision tree combined with a Markov model stimulating HCV natural history was used. The model simulates HCV screening and treatment cascade, as well as HCV progression for untreated patients whether undiagnosed or LTFU. Four at-risk populations were included: intravenous drug users (IDU), men who have sex with men (MSM), immigrants and elderly over 55 years. Epidemiology and screening cascade parameters were specific for each risk group. A sustain virologic response (SVR) rate of 100% was assumed. Three screening strategies were compared: (1) the current screening strategy (2) Rapid Start (3) Rapid Start and a 300% increase in screening individuals over 55 years in the general population. A one-year cycle was used. Outcomes included epidemiological and economic results.

**Results:** Between 2020 and 2030, compared to the current strategy, implementing a TandT strategy (Rapid Start + increased screening) would decrease undiagnosed patients by 22, 608 and increase treated patients by 5, 602 (Table 1). This strategy would be associated with a decrease in HCV complications with 1, 873 decompensated cirrhosis and 3, 949 HCC avoided. Such a strategy would also lead to an

## POSTER PRESENTATIONS

increase of €348.75 m in treatment costs and of €0.49 m in screening costs. However, it would be compensated by a reduction in complication costs of €93.81 m and in indirect costs (absenteeism and presenteeism) of €516.06 m.

Table 1: Results of a TandT strategy in France

Versus current situation (2020–2030)	Rapid Start only (treatment on day 1 for all patients)	TandT: Rapid Start + increased screening targeted on individuals >55 y/o
<i>Main outcomes</i>		
Undiagnosed Reduction (2030)	13, 873	22, 608
Incident Cases Reduction	22, 124	22, 124
Treated Increase	-3, 958*	5, 602
<i>Avoided Complications</i>		
Decompensated Cirrhosis	736	1, 873
HCC	1, 513	3, 949
Liver Transplant	37	55
Liver-Related Deaths	851	1, 871
<i>Additional Costs (millions €)</i>		
Screening	-0.31	0.49
Treatment	111.18	348.57
<i>Avoided Costs</i>		
Complications	198.63	609.87
Indirect Costs	40.03	93.81
	158.60	516.06

**Conclusion:** A TandT strategy would reduce both the epidemiological and economic burden of HCC in France by 2030.

#### Concordance of SVR 4-12-24 timepoints in an era of reduced sustained virologic response (SVR) determination

Mark Sulkowski<sup>1</sup>, Jordan Feld<sup>2</sup>, Nancy S. Reau<sup>3</sup>, Liyun Ni<sup>4</sup>, Stacey Scherbakovsky<sup>5</sup>, Candido Hernández<sup>6</sup>, Kim Vanstraelen<sup>6</sup>, Kyle Hammond<sup>7</sup>, Bruce Kreter<sup>5</sup>, Vithika Suri<sup>8</sup>, Marc Bourliere<sup>9,10</sup>, Alessandra Mangia<sup>11</sup>. <sup>1</sup>Johns Hopkins University School of Medicine, Division of Infectious Diseases, Baltimore, United States; <sup>2</sup>Toronto General Hospital, Toronto Centre for Liver Disease, University Health Network, Toronto, Canada; <sup>3</sup>Rush University, Department of Internal Medicine, Division of Digestive Diseases and Nutrition, Rush Medical College, Chicago, United States; <sup>4</sup>Gilead Sciences, Biostatistics, Foster City, United States; <sup>5</sup>Gilead Sciences, Global Medical Affairs, Foster City, United States; <sup>6</sup>Gilead Sciences, Global Medical Affairs, Stockley Park, United Kingdom; <sup>7</sup>Gilead Sciences, Medical Affairs, Foster City, United States; <sup>8</sup>Gilead Sciences, Clinical Research, Foster City, United States; <sup>9</sup>Hopital Saint Joseph, Hepato-Gastro-Enterologie, Marseilles, France; <sup>10</sup>Aix Marseille Univ, INSERM, IRD, SESSTIM, Sciences Économiques and Sociales de la Santé and; <sup>11</sup>Fondazione “Casa Sollievo della Sofferenza” IRCCS, San Giovanni Rotondo, Italy  
Email: a.mangia@tin.it

**Background and aims:** Over the last 5 years the landscape of HCV treatment providers has evolved in response to the WHO call to action and simplified treatment algorithms. Non-specialist providers are seeing an increasing number of patients with mental health disorders, active injection drug use, and homelessness, many of whom have less severe liver disease. Often these patients are more difficult to engage, treat, and monitor, and more difficult to reach for confirmation of SVR. A high degree of concordance between SVR4, SVR12, and SVR24 helps validate the shift towards simplification, minimal monitoring, and acceptance of missing the traditional SVR12 timepoint. The most recent EASL guidance recognizes this shift with the statement that testing for SVR may be omitted in certain patients. Still, verifying effective cure reassures a health system that treating this vulnerable population is “worth” the effort.

**Method:** HCV RNA data from patients in the registrational ASTRAL-1, -2, and -3 clinical trials were evaluated. SVR was defined as patients

with HCV RNA less than the lower limit of quantification (15 IU/ml) at the aforementioned post-treatment visits, using the COBAS TaqMan HCV Test v2.0. Only patients with both SVR4 and SVR12 or SVR12 and SVR24 data were included in the concordance analysis.

**Results:** 1588 patients were evaluated in ASTRAL-1, -2, and -3. The overall SVR12 rate for all patients receiving 12 weeks of sofosbuvir/velpatasvir in ASTRAL 1–3 was 98% (n = 1015/1035; 13 relapses; 4 lost to follow-up; 1 discontinuation of drug; 1 withdrawal of consent; 1 death-unrelated). For the 13 relapses, 3 occurred between SVR4 and SVR12, while 10 occurred between treatment week 12 and SVR4. No relapses occurred between SVR12 and SVR24. Of the 1015 patients who had both SVR4 and SVR12 recorded, there was a 99.7% positive predictive value (PPV). For SVR12 and SVR24 concordance, the PPV was 100% for 993 patients. For both sets of concordance, the negative predictive value was 100%.

**Conclusion:** HCV treatment non-response with sofosbuvir/velpatasvir is infrequent and the absence of HCV RNA at SVR4 is highly predictive of HCV cure. This early time point to confirm HCV may be important when monitoring a vulnerable population at high risk to be lost to follow-up. These data support minimal monitoring of HCV treatment and follow-up, and the EASL guidance that testing for SVR can be omitted in certain patients without compromising the treatment paradigm.

### PO-1007

#### A comprehensive HBsAg-positive patient centered screening strategy targeting microelimination of Hepatitis C virus in Chongqing, China

Dachuan Cai<sup>1</sup>, Peng Hu<sup>1</sup>, Dazhi Zhang<sup>1</sup>, Hong Ren<sup>1</sup>. <sup>1</sup>The Second Affiliated Hospital of Chongqing Medical University, Department for Infectious Diseases, Chongqing, China  
Email: cqmucdc@cqmu.edu.cn

**Background and aims:** The exact prevalence of hepatitis B (HBV) and C viruses (HCV) coinfection is actually unknown. In regions where HBV is endemic, such as China with a HBsAg positive rate of 7.18%, the probability of coinfection increases due to a similar transmission route, especially in patients with high risk of HCV infection. The aim of the study was to explore the prevalence of HCV antibodies positive rate among HBsAg positive subjects, to investigate the HCV RNA positive rate in anti-HCV positive patients, and to evaluate HBV/HCV co-infection rate. All the patients with a positive HCV RNA have been informed about the possible sequelae of chronic HCV infection and available therapy in order to accelerate the micro-elimination of hepatitis C.

**Method:** 12, 500 HBsAg positive serum samples from the Second Affiliated Hospital of Chongqing Medical University between 2019.2–2020.1 have been collected. All samples were tested for anti-HCV. Furthermore, positive samples would be tested for HCV RNA. All patients with positive HCV RNA were followed up for suspicious transmission route of HCV and linkage to care. Chi-square accurate test and T-test were used for comparison.

**Results:** Forty four out of 10560 (0.4%) patients with positive HBsAg had detectable anti-HCV. There were 32 male (72.7%) and 12 females (27.3%), with statistical difference (p = 0.003). 17/44 (38.6%) were HCV RNA positive. 6/44 (13.6%) patients could not be contacted for investigation, suspected transmission routes of HCV for other 38 patients: surgical operation history [13/38 (34.2%)], intravenous drug use 10/38 [(26.3%), blood transfusion [8/38 (13.9%)], tooth extraction history [1/38 (2.6%)], paid blood donation [1/38 (2.6%)], hemodialysis [1/38 (2.6%)], sexual transmission [2/38 (5.3%)], dental treatment history [1/38 (2.6%)], others [11/38 (28.9%)]. Among 15 out of 38 patients with HCV RNA positive, 8 patients started anti-HCV treatment with DAA regimen, while the other 7 patients had not. The reason of not initiating treatment is 1 died, 4 for no awareness of the importance of anti-HCV treatment. After patient education, one patient started treatment and reached SVR12, 3 patients still refused anti-HCV treatment, 2 patients did not start HCV treatment for no

awareness of HCV infection, they agreed to start anti-HCV treatment after being informed of their condition and educated on prognosis of HCV infection and benefit of SVR.

**Conclusion:** HCV/HBV coinfection prevalence is lower compared with previous study result, and it is higher in male than female. Different from MTCT, HBV main transmission route, high risk behaviors in adults are the main transmission route of HCV in Chongqing, China, HBV and HCV didn't share the mutual transmission route, HBsAg positive population may not have high risk of HCV infection. It is possible to accelerate the micro-elimination of hepatitis C through patient education.

**PO-1029**

**Acute hepatitis C virus infection: A prospective ten years observational study of HCV-mono- and HCV/HIV-coinfected patients**

Christiana Graf<sup>1</sup>, Lutz Thomas<sup>2</sup>, Gaby Knecht<sup>2</sup>, Christoph Stephan<sup>3</sup>, Peter Gute<sup>2</sup>, Markus Bickel<sup>2</sup>, Kai-Henrik Peiffer<sup>1</sup>, Stefan Zeuzem<sup>1</sup>, Julia Dietz<sup>1</sup>, Christoph Sarrazin<sup>1,4</sup>. <sup>1</sup>Goethe University Hospital, Department of Internal Medicine I, Frankfurt, Germany; <sup>2</sup>Infektiologikum, Frankfurt, Germany; <sup>3</sup>Goethe University Hospital, Department of Infectious Diseases, Frankfurt, Germany; <sup>4</sup>St. Josefs-Hospital, Wiesbaden, Germany  
Email: christiana.graf@kgu.de

**Background and aims:** Hepatitis C virus (HCV) infection has emerged as a sexually transmitted infection among human immunodeficiency virus (HIV)-positive men who have sex with men (MSM) since several years in large urban centres worldwide. HIV coinfection is associated with lower rates of spontaneous clearance and HCV treatment response as well as with accelerated liver disease. This study evaluated epidemiological and clinical parameters of acute hepatitis C infection over time.

**Method:** This prospective, ongoing observational study has analysed clinical and epidemiological parameters of n = 161 patients with a proven acute HCV infection between 2009 and 2019, who were enrolled in three centres in Frankfurt. NS5B population-based sequencing was performed at the time of acute hepatitis C diagnosis (baseline) to re-evaluate the HCV genotype and for phylogenetic analyses.

**Results:** Overall, the majority of the patients were MSM (90%, 146/161) with a sexual HCV transmission route, of which n = 6 were HIV negative. In the remaining patients (n = 15/161), HCV transmission was attributable to infecting drug use, needle stick injuries or blood transfusions (non-MSM patients). In n = 155 patients with available baseline sequencing data, the prevalence of HCV genotypes was as follows: during the first five years of study, 80% (74/93) of the patients were infected with HCV GT1a, 4% each with GT1b or GT3a (4/93), 2% with GT2 (2/93) and 10% (9/93) had GT4d. However, in the last five years of study, HCV GT1a was detected in 74% (46/62) of patients, GT1b or GT3a in 1.5% of patients each and GT4d infection in 23% (14/62) of patients. Interestingly, MSM were mainly infected with HCV GT1a (82%, 115/140) or GT4d (16%, 23/140 with sequencing data available). In contrast, HCV genotypes were almost equally distributed in non-MSM patients. 42% (5/14 with sequencing data) were infected with HCV GT1a, 21% each (3/14) with GT1b or GT3a and 16% had GT2. Based on the comparison of HCV GT or NS5B sequences, 24 (15%) were diagnosed with a HCV reinfection, of which 14 patients had a genotype switch. The median time to reinfection was 3.2 years (range 0.6–10.3) and the overall HCV reinfection incidence rate was 2.2 per 100 person-years (PY). The incidence rate in MSM for a reinfection and for a first HCV infection declined in the period between 2017 and 2019 (1.2/100PY and 3.76/1000 PY) compared the DAA era between 2013 and 2016 (1.8/100 PY and 6.39/1000 PY) and to the interferon era (2008–2012; 1.6/100 PY and 6.5/1000 PY).

**Conclusion:** During the last 5 study years the prevalence of GT4 infections increased, while annual acute hepatitis C incidences decreased. Incidence of reinfections remains a frequent finding

among MSM in Germany, which may have implications for HCV elimination in MSM.

**PO-1186**

**Detection of active hepatitis C by two-step point-of-care based strategy and linkage to care among excluded people using a mobile unit in Madrid, Spain**

Pablo Ryan<sup>1,2,3</sup>, Jorge Valencia<sup>1</sup>, Guillermo Cuevas<sup>1</sup>, Juan Torres<sup>1,2</sup>, Jesús Troya<sup>1</sup>, Jeffrey Lazarus<sup>4</sup>, Maria Jose Muñoz-Gomez<sup>5</sup>, Sonia Vázquez-Morón<sup>5</sup>, Salvador Resino-García<sup>5</sup>. <sup>1</sup>Hospital Universitario Infanta Leonor, Madrid, Spain; <sup>2</sup>Complutense University of Madrid, Madrid, Spain; <sup>3</sup>Instituto de Investigación Sanitaria Gregorio Marañón (IISGM), Madrid, Spain; <sup>4</sup>Barcelona Institute for Global Health (ISGlobal), Barcelona, Spain; <sup>5</sup>Instituto de Salud Carlos III, Majadahonda, Spain  
Email: pabloryan@gmail.com

**Background and aims:** There is a considerable burden of hepatitis C virus (HCV) infection among people with social excluded, marginalized populations. We aimed to assess the effectiveness of a point-of-care (PoC) simplified model for screening of active HCV infection and its linkage to care among excluded people.

**Methods:** We carried out a prospective study in 2001 participants from Madrid, Spain. With a nurse and an educator, a mobile unit was used to screen active hepatitis C by a two-step PoC-based strategy (rapid HCV antibody test and an HCV RNA test for confirmation). Participants with active HCV were referred to the hospital the same day to evaluate and treat HCV with a navigator.

**Results:** Overall, 1621 (81%) participants were unexposed to HCV, 380 (18.9%) were positive for HCV antibodies, and 136 (6.8%) had active hepatitis C. Among the latter, 134 (98.5%) received the HCV screening results, 133 (97.8%) had an appointment at the hospital, 126 (92.8%) were attended at the hospital, and 105 (77.2%) started HCV treatment. People over 50 years and drug users, particularly people who inject drugs (PWID), were directly associated with active hepatitis C (p < 0.005). PWID were the only ones with HCV reinfections (4.3% in inactive PWID and 5.9% in active PWID). Furthermore, both having no economic resources and alcohol intake were also directly associated with active hepatitis C among PWID. Active PWID showed the lowest rates of attention in the hospital (91.8%) and those who started HCV treatment (70.4%).

**Conclusion:** HCV screening using a two-step PoC-based strategy and its linkage to care had excellent efficiency in identifying and treating excluded people with active hepatitis C. New approaches are needed to enhance rates of initiation of HCV treatment among PWID, particularly those who have problematic alcohol intake and who reported no economic resources.

**PO-1339**

**Impact of the COVID-19 pandemic on hepatitis C virus screening in drug treatment settings in England and implications for testing protocols**

Shayon Salehi<sup>1</sup>, Tracey Kemp<sup>2</sup>, Helen Hampton<sup>3</sup>, Stacey Smith<sup>4</sup>, Peter Smethurst<sup>5</sup>. <sup>1</sup>Gilead Sciences Ltd, Medical Affairs, London, United Kingdom; <sup>2</sup>C G L Change Grow Live, United Kingdom; <sup>3</sup>We Are With You, United Kingdom; <sup>4</sup>Humankind, United Kingdom; <sup>5</sup>Gilead Sciences Ltd, Patient Access to Care, United Kingdom  
Email: shayon.salehi@gilead.com

**Background and aims:** Individuals who have ever injected drugs are at risk of hepatitis C virus (HCV) infection and subsequent liver disease. Protocols developed by drug treatment services (DTS) allow at-risk individuals to be tested and linked to appropriate care. This analysis assessed the impact of the COVID-19 pandemic on HCV testing in DTS.

**Method:** The number of HCV tests conducted across three DTS providers in England was recorded (August 2019 and through October 2020).

## POSTER PRESENTATIONS

Figure: (abstract: PO-1339)

**Results:** During the period assessed, over 82,000 individuals accessed the services supported by the three providers. Of individuals accessing the service, 27–32% had a history of injecting drug use and 14.5–17% were current injectors. In the 7 months before the COVID-19 pandemic, the mean number of HCV tests conducted each month was 2418 (range: 2044–2915). A >88% reduction in HCV tests was observed (April–June 2020) following introduction of the U.K. COVID-19 restrictions in March 2020. By October 2020, the number of HCV tests/month had increased to 50% of the maximum pre-pandemic level following the adaptation of testing services including introducing postal tests.

**Conclusion:** Restrictions introduced in England to control the COVID-19 pandemic had a substantial negative impact on HCV testing. Rapid adaptation of services has increased the proportion of service users accessing tests, but more needs to be done to ensure those who need a test receives one. Continued adaptations should limit the impact future restrictions could have on HCV testing in this population.

### PO-1397

#### Community-based linkage to care program targeting HCV elimination-Establishment of a model towards HCV elimination in China

Ming Li<sup>1</sup>, Jingzhi Li<sup>2</sup>, Xiaojuan Shang<sup>1</sup>, Zhu Liu<sup>2</sup>, Kefeng Xin<sup>1</sup>, Ping Liu<sup>2</sup>, Kewei Wang<sup>2</sup>, Feng Wang<sup>2</sup>, Mei Wang<sup>2</sup>, Hui Zhao<sup>2</sup>, Jingjing Yu<sup>2</sup>. <sup>1</sup>No.2 People's Hospital of Fuyang City, The Second Infectious Department, Fuyang, China; <sup>2</sup>Jingjiu Chengzhuang Community Health Center, Community Health Center, Fuyang, China  
Email: 758529109@qq.com

**Background and aims:** Direct-Antiviral-Agents (DAAs) have been covered by Chinese Medical Insurance system currently. The barrier to eliminate Hepatitis C in China is to find out HCV patients and link to care. But for community doctors in rural areas and other under-developed places are hard to screen and treat HCV patients due to lacking of knowledge. An effective model is needed to screen, manage and follow-up with these populations.

**Method:** This program leads by Infectious doctors from No.2 people's hospital of Fuyang city and Community doctors from 6 communities of Jingjiu chengzhuang, from 2019 Jan, has been designed into 4 steps. First, infectious doctors provide education and online guidance for community doctors. Second, the residents be activated through materials advertisements, media, and community health classes which are conducted by community doctors in each community.

Those activities have been started earlier before screen and are continuing. Third, people be screened in communities and those with anti-HCV positive would be delivered to fixed doctors of No.2 people's hospital of Fuyang for further diagnose and treatment. Fourth, HCV patients on treatment or not both be followed up by community doctors. We planned to screen residents with age over 40 years old or with high risk (HCV family history, high risk behaviors) first, whom are from more than 40,000 rural and city communities' residents.

**Results:** by Jan 12th, 2020, 2679 residents had been screened. Age and gender information of 1851 had been collected. The mean age was 50 years old, 40% were male. 164/2679 (6.1%) subjects were seropositive for anti-HCV. 89/164 (54.3%) subjects detected HCV RNA, of which 67 subjects obtained HCV RNA detection through program team and 22 subjects obtained RNA detection by themselves. The HCV RNA positive rate was 42/89 (47.2%), of whom 40/42 (95.2%) patients initiated treatment. HCV GT1b was the most prevalent genotype (73.8%), followed by HCV GT2 (21.4%). 16.7% patients were diagnosed with cirrhosis. Up to now, 30 patients completed treatment, the SVR12 was 100% for those whom finished follow-up. The model with reinforced connection (Doctors education be held bi-monthly and team discussion be held monthly) between communities' doctors and fixed infectious doctors, to educate, screen and follow-up patients just in community which made none of the patients lost.

Figure:

**Conclusion:** It is the first large scale program to find out HCV patients and link to care in China mainland. It makes sense to screen patients with high risk. Community based program through reinforcing the connection of infectious doctors and community doctors improved screen rate and made most of those HCV patients linked to care, which is highly effective and necessary to large-scale applied towards HCV elimination in China.

**PO-1691**

**Feasibility and effectiveness of models of hepatitis C viraemia testing at harm reduction sites in Georgia: a prospective 3 arm study**

Sonjelle Shilton<sup>1</sup>, Jessica Markby<sup>1</sup>, Maia Japaridze<sup>2,3</sup>, Violet Chihota<sup>1</sup>, Shaun Shadaker<sup>4</sup>, Lia Gvinjilia<sup>5</sup>, Maia Tsereteli<sup>6</sup>, Maia Alkhazashvili<sup>6</sup>, Maia Butsashvili<sup>7</sup>, Ketevan Stvilia<sup>6</sup>, Alexander Asatiani<sup>6</sup>, Ekaterine Adamia<sup>8</sup>, Philippa Easterbrook<sup>9</sup>, Irma Khonelidze<sup>6</sup>, Amiran Gamkrelidze<sup>6</sup>. <sup>1</sup>Foundation for Innovative New Diagnostics; <sup>2</sup>Foundation for Innovative New Diagnostics, HCV, Tbilisi, Georgia; <sup>3</sup>Foundation for Innovative New Diagnostics, HCV, Tbilisi, Georgia; <sup>4</sup>Centers for Disease Control and Prevention, Division of Viral Hepatitis National Center for HIV, Hepatitis, STD and TB Prevention; <sup>5</sup>Task Force for Global Health; <sup>6</sup>National Center for Disease Control and Public Health, Georgia; <sup>7</sup>Health Research Union, Georgia; <sup>8</sup>Ministry of Health, Labour and Social Affairs of Georgia, Georgia; <sup>9</sup>Department of Global HIV, Hepatitis and STI Programmes, World Health Organization  
Email: lgi1@cdc.gov

**Background and aims:** In 2015, Georgia began a hepatitis C virus (HCV) elimination programme. Although screening programmes have largely been decentralised for high-risk groups, viraemia testing remains a limiting factor for people who inject drugs (PWID). As part of HEAD-Start (Hepatitis C Elimination through Access to Diagnostics) Georgia, Foundation for Innovative New Diagnostics (FIND) in partnership with Georgia's National Centers for Disease Control and Public Health conducted a cluster, non-randomized interventional study to describe two models of viraemia testing that aim to address this gap and compare them to the current standard of care (SOC).

**Method:** We assigned 8 harm reduction sites (HRS) to one of three arms. Arm 1: GeneXpert HCV viral load on-site testing, Arm 2: centralised viraemia testing with HCV core antigen (centralised HCVcAg), or Arm 3: SOC with all anti-HCV positive referred to treatment centres for HCV RNA testing.

**Results:** Between May 2018 and September 2019, 1671 HCV-seropositive participants were enrolled (Arm 1, 620; Arm 2, 486; Arm 3, 565). Participants were predominantly male (95.4%), with a median age of 43 years (interquartile range [IQR]): 37, 50), and 1290 (77.2%) were currently injecting drugs. Significantly higher proportions of participants in Arms 1 (100.0%) and 2 (99.8%) had viraemia testing performed compared with Arm 3 (91.3%) (Arm 1 vs Arm 3; P < 0.001, Arm 2 vs Arm 3; P < 0.001) (Figure). Among viraemic participants, treatment uptake was similar across all arms (Arm 1, 84.0%; Arm 2, 79.5%; Arm 3, 88.4%). The time between screening and sample collection for viraemia testing was significantly longer in Arm 3 (median 1 [0, 4] days) compared with both Arm 1 (p < 0.001) and Arm 2 (p < 0.001) (median 0 [0, 0] days for both), and the overall time between screening to treatment initiation was longer for Arm 3 (67 [45, 94] days) compared with Arm 1 (57 [39, 87] days; P < 0.001) and Arm 2 (50 [38, 80] days; P < 0.001).

Figure: Retention of patients in the hepatitis C care cascade by study arm. Abbreviations: HCV = hepatitis C virus; SVR = sustained virologic response

**Conclusion:** Point-of-care viraemia testing and blood drawn on-site for HCVcAg testing resulted in more HCV seropositive patients receiving viraemic testing within a shorter timeframe compared with referral for blood collection using SOC. However, proportions of viraemic patients who were referred to treatment centres and subsequently initiated treatment were similar across all arms. These findings underscore the benefits of fully decentralised HCV care.

**PO-1871**

**Screening, enhancement of access to care and prioritization of treatment of chronic hepatitis C infection in high-risk population in Hong Kong**

Lung Yi Loey Mak<sup>1,2</sup>, Cynthia Hui<sup>1</sup>, Wai Man Vivien Tsui<sup>1</sup>, Wai Pan To<sup>1</sup>, KL Ko<sup>1</sup>, Siu Yin Wong<sup>1</sup>, Kevin Liu<sup>1</sup>, Wai-Kay Seto<sup>1,2</sup>, Man-Fung Yuen<sup>1,2</sup>. <sup>1</sup>The University of Hong Kong, Medicine, Hong Kong, China; <sup>2</sup>State Key Laboratory of Liver Research, The University of Hong Kong, Hong Kong, China  
Email: loeymak@gmail.com

**Background and aims:** In the current era of highly effective direct acting antiviral (DAA) therapy, the one of the remaining obstacles to elimination of chronic HCV infection (CHC) is identification of high-risk groups for micro-elimination. In Hong Kong, people who inject drugs (PWIDs) are one of the targets. We aimed to provide linkage to care (LTC) for PWIDs with CHC who are undergoing drug rehabilitation.

**Method:** Since late 2019, we initiated the Conquering Hepatitis v/a Micro-Elimination (CHIME) program and performed a prospective study by forming an outreach team to conduct site visits to halfway house or drug rehabilitation centers run by non-governmental organizations. We performed point-of-care (POC) test for antibody to HCV (anti-HCV), and blood takings were performed for subjects with positive POC results to check for HCV RNA. Subjects with confirmed active CHC were contacted to attend the LTC clinic for counselling, risk stratification and evaluation for DAA.

**Results:** In this interim analysis, 9 site visits were conducted and 140 PWIDs were screened which identified 117 subjects with CHC (83.6% HCV RNA positive) and 52 already attended the LTC clinic (Figure 1A). Compared to subjects who received standard-of-care (non-CHIME, n = 275, 10.5% PWIDs), PWIDs under the CHIME program were younger (median 61 vs 52, p < 0.001), with more male (56.4% vs 49.2%, p < 0.001), lower chance to expose to previous CHC treatment (16.4% vs 3.8%, p0.017), higher RNA viral load ( $1.2 \times 10^6$  vs  $2.4 \times 10^7$  IU/ml, p = 0.006) and lower liver stiffness (11 vs 7.2 kPa, p < 0.001). CHIME patients had predominantly genotype 6 (63.5%) infection, with non-significantly higher prevalence of hepatitis B coinfection [7.8% vs 2.9% (non-CHIME patients), p=0.1]. The time from site visit to first LTC visit and to starting treatment were shorter for CHIME patients compared to non-CHIME patients (Figure 1A). The rates of sustained virological response (SVR) were 90.6% and 95.3 respectively (p=0.226). No significant differences in SVR were observed between different genotypes or PWIDs vs non-PWIDs. The treatment uptake rate was affected by COVID-19 (Figure 1B).

**Conclusion:** Micro-elimination is an effective strategy to identify subjects with CHC in places like Hong Kong where the overall prevalence of CHC in background population is low. The CHIME program successfully allowed PWIDs with CHC to be linked to care with significant shortening of waiting time and no compromise to treatment outcome.

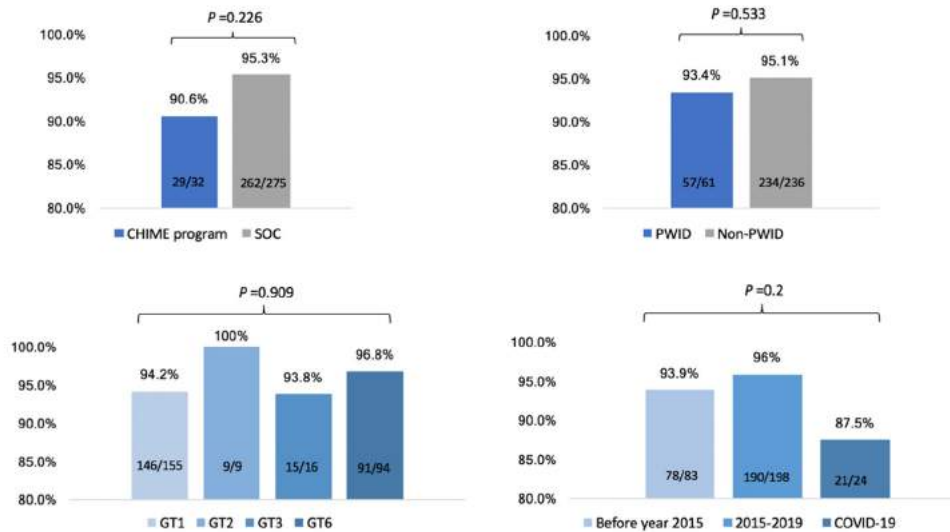

## POSTER PRESENTATIONS

**Figure 1A:** left panel: number of subjects at each step of CHIME program; right panel: number of days required between site visit or referral to 1<sup>st</sup> clinic visit, and number of days from 1<sup>st</sup> clinic visit to starting therapy

DAA: direct acting antiviral agents, LTC: Linkage-To-Care, POC: point-of-care, SOC: standard of care

### PO-1966

#### Hepatitis C Elimination in the Netherlands (CELINE): nationwide retrieval of lost to follow-up chronic hepatitis C patients

Marleen van Dijk<sup>1</sup>, Cas J. Isfordink<sup>2,3</sup>, Sylvia Brakenhoff<sup>4</sup>, Johannes E. Arends<sup>5</sup>, Robert De Knecht<sup>4</sup>, Marc van der Valk<sup>3</sup>, Joost Ph Drenth<sup>1</sup>. <sup>1</sup>Radboudumc, Gastroenterology and Hepatology, Nijmegen, Netherlands; <sup>2</sup>University Medical Centre Utrecht, Gastroenterology and Hepatology, Utrecht, Netherlands; <sup>3</sup>Amsterdam

Infection and Immunity Institute, Amsterdam University Medical Centre, Internal Medicine, Division of Infectious Diseases, Amsterdam, Netherlands; <sup>4</sup>Erasmus Medical Centre, Gastroenterology and Hepatology, Rotterdam, Netherlands; <sup>5</sup>University Medical Centre Utrecht, Infectious Diseases, Utrecht, Netherlands  
Email: marleen.vandijk@radboudumc.nl

**Background and aims:** Hepatitis C virus (HCV) prevalence in the Netherlands is estimated at 0.16%. Presumably, up to 30% of the diagnosed population has been lost to follow-up (LTFU) before being cured. Retrieval of LTFU patients has the potential to reduce the impact of the HCV epidemic. Therefore we initiated the nationwide

retrieval project CELINE, aiming to achieve HCV micro-elimination in previously diagnosed but LTFU HCV patients.

**Method:** LTFU patients were identified by consulting laboratory and patient records of up to 15 years old in hepatitis treatment centres and, when possible, public health or primary care laboratories and other hospitals. Subsequently, the Municipal Personal Records database was consulted to identify patients eligible for retrieval, defined as being alive and having a known Dutch residence. These patients were invited for a screening visit at their local hepatitis treatment centre. Primary end point was the number of LTFU patients successfully re-linked to care.

**Results:** So far, 29 centres have finished the identification phase and initiated the retrieval phase, whereas in a further 10 centres CELINE has been approved. Of 15, 558 potential ever chronically infected patients, 65% had already been cured or were still in care and only 8% (n = 1, 248) were LTFU and eligible for retrieval. Currently, 942 patients have been invited for re-evaluation: 24% of these had already been successfully treated elsewhere, 5% had either severe comorbidity, moved abroad or were deceased precluding treatment, 8% refused to be re-evaluated and in 45% contact has not (yet) been established. So far, 160 patients (17%) have been screened or have an outpatient care appointment scheduled. At their screening visit, patients were mostly male (69%), median 58 years old, LTFU for median 7 years (IQR 4–11) and intravenous drug use was the predominant HCV transmission route (68%). At re-evaluation, 86% tested HCV RNA positive and none HIV positive. Of those HCV RNA positive, 30% had a Fibroscan measurement indicating advanced fibrosis or cirrhosis ( $\geq 9.5$  kPa). So far, 79% of RNA-positive retrieved patients have commenced HCV treatment.

**Conclusion:** The majority of ever diagnosed HCV patients in the Netherlands has already been cured, while only 8% is LTFU and eligible for retrieval. So far, we have re-linked 160 patients (17%) to care, with 30% of HCV RNA positive patients showing signs of at least advanced fibrosis. This demonstrates that retrieval of LTFU HCV patients is feasible and worthwhile.

#### PO-2048

##### **Rapid point of care HCV testing allows high throughput HCV screening and rapid treatment uptake among PWID attending a medically supervised injecting room**

Michael MacIsaac<sup>1,2</sup>, Bradley Whitton<sup>1</sup>, Jenine Anderson<sup>3</sup>, Shelley Cogger<sup>3</sup>, Kasey Elmore<sup>3</sup>, David Pemberton<sup>3</sup>, Matthew Penn<sup>3</sup>, Jacinta Holmes<sup>1,2</sup>, Nico Clark<sup>4</sup>, Alexander Thompson<sup>1,2</sup>, <sup>1</sup>St Vincent's Hospital Melbourne, Gastroenterology, Fitzroy, Australia; <sup>2</sup>University of Melbourne, Department of medicine, Parkville, Australia; <sup>3</sup>North Richmond Community Health, Richmond, Australia; <sup>4</sup>North Richmond Community Health, Richmond, Australia  
Email: michael.macisaac@svha.org.au

**Background and aims:** In order to achieve the WHO HCV elimination targets, efforts must focus on developing novel models of care that engage people who inject drugs (PWID) in HCV screening and treatment. We aimed to assess the feasibility of a new model of care incorporating the Xpert<sup>®</sup> HCV fingerstick point of care (POC) test, which provides a HCV RNA result within 1 hour, in PWID attending a medically supervised injecting room (MSIR) in Melbourne, Australia.

**Method:** This was a prospective cohort study, recruiting PWID attending a high volume (>100 client visits/day) MSIR across a 9-week period (November 2020–January 2021). Clients were offered HCV screening using the rapid Xpert<sup>®</sup> fingerstick POC test, as well as venepuncture for HBV/HIV screening, and liver elastography for fibrosis assessment. HCV RNA results were returned the same day if clients were still present at the MSIR, or via phone or at their next MSIR visit if they had departed. HCV treatment was prescribed immediately upon return of a positive HCV test, and medication was dispensed within 30 minutes and couriered to the MSIR. Clients commencing treatment will be followed up 4 weekly during treatment, and at SVR12. Primary end points are i) number of

clients screened; ii) number of clients commenced on DAAs. Testing rates were compared to a historical control period of standard of care venepuncture testing led by a blood-borne virus nurse.

**Results:** 228 PWID consented to HCV screening with the Xpert<sup>®</sup> POC test, averaging >25/week. By comparison, 61 clients were screened using standard of care venepuncture testing during the same time period 12-months prior (274% increase with POC testing). Fingerstick testing was well received by participants and was preferred to venepuncture testing. Median age was 43 yrs (IQR 38–48), 78% were male. 9 (4%) had cirrhosis. HBV and HIV co-infection rates were 2% and 3%, respectively. 64 (28%) returned a positive HCV RNA result; 60 (94%) were informed of their positive result, with most (67%) receiving their result on the same day. 56/64 (88%) of HCV RNA positive clients commenced DAA therapy; 13 (23%) started treatment on the same day as POC testing. Median time to treatment initiation was 1 day (IQR 0.5–10). 31/35 clients who have reached the 4th week of treatment have remained engaged in care. Further treatment outcomes will be presented at the ILC.

**Conclusion:** Supervised injecting rooms service a high volume of marginalised clients with risk factors for HCV. Our streamlined, real world model of care using fingerstick POC testing rapidly engages large numbers of PWID in HCV screening. Further, almost all HCV RNA positive clients were successfully linked to treatment. Novel fingerstick POC testing in high prevalence settings is likely to play a critical role in achieving WHO elimination targets.

#### PO-2095

##### **Is elimination of hepatitis C across an entire prison network possible? A nurse-led test and treat model in 47 English prisons**

Hannah Alexander<sup>1</sup>, Andrew Jones<sup>2</sup>, Kate Dorrington<sup>3</sup>, Andrew Milner<sup>3</sup>, Sean Cox<sup>4</sup>, Rob Cheetham<sup>1</sup>, Phil Troke<sup>3</sup>, Iain Brew<sup>1</sup>. <sup>1</sup>Practice Plus Group, Health and Rehabilitation Services, Reading, United Kingdom; <sup>2</sup>Gilead Sciences Ltd, Medical Affairs, London, United Kingdom; <sup>3</sup>Gilead Sciences Ltd, London, United Kingdom; <sup>4</sup>Hepatitis C Trust, London, United Kingdom  
Email: andy.jones@gilead.com

**Background and aims:** With a prevalence of approximately 6% in male, and 12% in female prisons, secure environments are a critical part of the plan to eliminate HCV in England by 2025. In October 2014 a national prison policy for blood-borne viruses (BBV) opt-out testing upon entry was implemented, but despite this, testing rates remained low until the end of 2018.

**Method:** Practice Plus Group (PPG) is the provider of healthcare to 47 English prisons with approximately 30,000 residents. In 2019, PPG partnered with the Hepatitis C Trust (HCT) and Gilead Sciences with the aim of increasing BBV screening, linkage to care and achieving elimination of HCV across their entire network. Each prison faces unique challenges to creating an effective pathway, such as the prison's size, age/design, security level and duration of residents' stay. For this reason, each prison needs to be supported to adapt a pathway to suit their needs. PPG Regional BBV Lead Nurses, and Gilead medical colleagues, are leading multi-stakeholder pathway optimisation workshops to identify local issues, create individualised pathways and drive service improvements. Most prisons have also transitioned to point-of-care antibody testing to increase uptake. We have developed an accredited training course for healthcare staff, whilst HCT Peers with a personal experience of HCV are engaging in all prisons to educate and reduce stigma amongst prisoners and prison officers.

**Results:** As a result of staff and resident education, modified testing methods and improved pathways, the HCV screening rate upon prison entry increased 2.2-fold in 12 months from 25% in December 2018 to 56% by December 2019. COVID-19 significantly impacted pathways from March 2020, but testing continued to improve to 62% in December 2020. Despite the impact of COVID-19 lockdowns on all English prisons, regular adaptation of pathways meant that new

## POSTER PRESENTATIONS

admissions continued to be tested and treated throughout the entire of 2020.

Figure:

**Conclusion:** BBV care pathways individualised for each prison, in combination with education and the use of Peers, has proven to be successful in doubling the testing of new receptions for HCV. The key to success has been the role of dedicated Regional BBV Lead Nurses in driving the improvements through the on-site prison healthcare staff.

### PO-2193

#### Evaluation of hepatitis C virus (HCV) core antigen assay from venepuncture compared to HCV RNA in plasma: a cohort study from Pakistan

Saeed Sadiq Hamid<sup>1</sup>, Adeel Abid<sup>1</sup>, Muraduddin Gulab<sup>1</sup>, Sultan Sallahuddin<sup>1</sup>, Safia Awan<sup>1</sup>, Gavin Cloherty<sup>2</sup>. <sup>1</sup>Aga Khan University, Medicine, Karachi, Pakistan; <sup>2</sup>Abbott Laboratories, Abbott Park, United States

Email: saeed.hamid@aku.edu

**Background and aims:** Diagnosis of Hepatitis C virus (HCV) infection can be a challenge due to cost and lack of access to centralized testing. There is an urgent need to use simple and affordable HCV testing methods. The aim of this study was to evaluate the sensitivity and specificity of Hepatitis C core antigen (HCVcAg) assay in a resource-limited setting.

**Method:** This was an observational cohort study of people living in an underdeveloped union council of a highly endemic, peri-urban district of Karachi, Pakistan. Between October 2019 and July 2020, subjects aged 12 years and above who screened positive for HCV antibody underwent a phlebotomy procedure. 10 ml of venous blood was taken for both HCV RNA testing (GeneXpert® IV, Cepheid, France) and HCV core antigen testing (Abbott® Diagnostics) to confirm active HCV infection. Abbott ARCHITECT®-i2000R Immunoassay Analyser was set up in a local hospital as a point-of-care facility for HCVcAg testing while samples for HCV RNA testing were transported 40 km to a central lab. Sensitivity and specificity of the HCVcAg assay ( $\geq 10$  fmol/L) was evaluated at three different thresholds of HCV RNA, including  $\geq 12$ ,  $\geq 1000$  IU/ml and  $\geq 3000$  IU/ml. Kappa ( $\kappa$ ) statistic was calculated as a quantitative measure of agreement between the two diagnostic tests.

**Results:** 200 individuals (mean age  $46 \pm 14$  years, 71% females) who screened positive for HCV antibody were included in the study. HCV RNA was detected in 119 (59.5%) participants. Sensitivity and specificity of HCVcAg in plasma at different thresholds of HCV RNA was very high (Table 1). Similarly, there was a strong agreement between HCV core antigen assay ( $\geq 10$  fmol/L) with HCV RNA, resulting in  $\kappa$  values of 0.88, 0.93 and 0.96 for HCV RNA thresholds of  $\geq 12$  IU/ml,  $\geq 1000$  IU/ml and  $\geq 3000$  IU/ml respectively.

Table: Sensitivity and specificity of HCVcAg ( $\geq 10$  fmol/L) compared to different HCV RNA thresholds.

	Detected	Undetected	Sensitivity (95% CI)	Specificity (95% CI)
<b>HCV RNA Plasma (<math>\geq 12</math> IU/ml)</b>				
Detected	118	10	99.1% (95%–100%)	87.6% (78.4%–94%)
Undetected	1	71		
<b>HCV RNA Plasma (<math>\geq 1000</math> IU/ml)</b>				
Detected	118	5	99.1% (95%–100%)	93.8% (86%–98%)
Undetected	1	76		
<b>HCV RNA Plasma (<math>\geq 3000</math> IU/ml)</b>				
Detected	118	2	99.1% (95%–100%)	97.5% (91%–100%)
Undetected	1	79		

**Conclusion:** Sensitivity and specificity of HCVcAg assay came out to be very high in a highly endemic, resource-limited setting. The cheaper HCVcAg assay can therefore be as a confirmatory test in HCV elimination programs particularly for low-income countries.

### PO-2218

#### Cost-effectiveness of a novel point of care core antigen rapid diagnostic test for hepatitis C

Madeline Adee<sup>1</sup>, Huaiyang Zhong<sup>1,2</sup>, Elena Ivanova<sup>3</sup>, Yueran Zhuo<sup>1,2,4</sup>, Jagpreet Chhatwal<sup>1,2</sup>, Sonjelle Shilton<sup>3</sup>. <sup>1</sup>Massachusetts General Hospital Institute for Technology Assessment; <sup>2</sup>Harvard Medical School; <sup>3</sup>Foundation for Innovative New Diagnostics; <sup>4</sup>Mississippi State University College of Business

Email: madee@mgh.harvard.edu

**Background and aims:** Globally, fewer than 20% of the 71 million people living with hepatitis C virus (HCV) are aware of their status. Rapid diagnostic tests (RDT) at the point of care (POC) provide an opportunity to improve diagnosis rates by minimizing loss to follow-up and linking HCV positive individuals to treatment. An RDT that detects HCV core antigen (cAg) could be cheaper but also could have lower sensitivity compared to the molecular tests currently available. Our objective was to evaluate the performance and cost-effectiveness of using POC cAg RDT for HCV confirmation testing compared to lab-based RNA under different settings.

**Method:** We adapted a previously validated microsimulation model of the natural history of HCV to compare the outcomes of two HCV testing algorithms: (1) POC cAg RDT for confirmation (using a base-case sensitivity of 80%), followed by lab-based RNA confirmation for those with negative cAg tests, and (2) current standard of care algorithm with lab-based RNA confirmation only. Confirmed cases were treated with direct-acting antivirals after accounting for lost to follow-up in each algorithm. We simulated outcomes for 10,000 adults in Georgia and Malaysia, with an HCV prevalence of 5.4% and 1.5% respectively. The baseline characteristics of HCV patients in each country were determined based on different distributions of sex, HCV genotype, and METAVIR fibrosis stage. All costs were considered from a healthcare payers perspective.

**Results:** For Georgia, the diagnosis rate with the POC cAg algorithm was 95.4% vs 78.8% with the current standard. For Malaysia, the corresponding rates were 91.2% and 57.9%. Compared with the standard of care, the testing algorithm with POC cAg confirmation testing increased QALYs (207 for Georgia and 146 for Malaysia) and resulted in cost savings (\$232,000 for Georgia and \$504,000 for Malaysia) per 10,000 simulated people. POC cAg remained cost-saving over the wide range of values of model inputs. We also found that cost-savings begin to accrue for both countries after just the first year of treatment and continue to increase until eventually plateauing after 40 years. The majority of cost-savings come from averted HCV sequelae costs although testing costs are also saved (Figure).

Figure: (abstract: PO-2218)

**Conclusion:** HCV testing with cAg RDT, which allows the majority of HCV-infected individuals to initiate treatment the same day as testing, could increase HCV diagnosis rate and result in cost savings.

**PO-2352**  
**Beating Hepatitis C together in challenging times: an evaluation of a multi-disciplinary approach to testing and treating homeless people temporarily housed during the COVID-19 pandemic**

Rebecca Wilkinson<sup>1</sup>, Elizabeth Nother<sup>2</sup>, Tracey Stirrup<sup>2</sup>, Mark Aldersley<sup>2</sup>. <sup>1</sup>University of Southampton, School of Primary Care, Population Sciences and Medical Education, Southampton, United Kingdom; <sup>2</sup>Leeds Teaching Hospitals NHS Trust, Hepatology, Leeds, United Kingdom

Email: markaldersley@nhs.net

**Background and aims:** Homeless people are at particularly high risk of hepatitis C virus (HCV); a recent survey of people who inject drugs found that prevalence of chronic HCV was twice as high (35%) in those who reported homelessness in the previous year. The COVID-19 pandemic resulted in severe disruption to HCV testing and treating in the UK but the provision of temporary accommodation to rough sleepers provided a unique opportunity for HCV care providers and

partners to engage with this vulnerable group at a time when they were potentially more stable. This evaluation aims to establish the impact of one such multi-disciplinary intervention in Leeds, where outreach work was done in hotels, hostels and on the street using a healthcare bus. A further aim is to establish the enablers and barriers to successfully HCV outreach work with the housed homeless in order to inform future service delivery.

**Method:** Following the UK wide lockdown, resulting in a reduction of face to face clinics, HCV care providers in Leeds decided to work together and take testing and treatment directly to homeless clients being temporarily housed. The Hepatitis C Trust peer support workers performed some of the antibody testing and incentives were provided, ranging from £5 shop vouchers, to drinks, sweets and care packages. To evaluate this intervention, a mixed methods approach was used which combined descriptive analysis of routinely collected data with qualitative information from the HCV care providers.

**Results:** Between May-September 2020, 78 people (including 41 who were previously unknown to the HCV service) were tested either during street outreach or at four venues that were housing homeless people in Leeds. Of these, 21 (26.9%) were found to have chronic HCV infection. All were offered and subsequently started on treatment. At

## POSTER PRESENTATIONS

the time of analysis, 18 (85.7% of those starting) had completed treatment and 5 (23.8%) had confirmed SVR.

Figure: Hepatitis C testing at a hotel in Leeds housing homeless people.

Working with partners was found to facilitate access to this population group and also enabled a person-centered approach. The use of peers to maintain engagement with treatment was considered vital. Taking the service directly to the clients via the bus and offering immediate RNA testing were further facilitators.

**Conclusion:** Working together in a multi-disciplinary team has enabled progress towards HCV elimination by facilitating engagement with a particularly high-risk group at a time when services generally were severely disrupted.

#### Hepatitis B and C screening in hospitalized SARS-CoV-2 patients

Judith Gómez-Camarero<sup>1</sup>, Raisa Quiñones<sup>2</sup>, Rosa Sáiz Chumillas<sup>1</sup>, Laura Alcoba Vega<sup>2</sup>, Esther Badia-Aranda<sup>1</sup>, Sandra Díez Ruiz<sup>2</sup>, Noemi Gómez-Manero<sup>3</sup>, Raquel Vinuesa<sup>1</sup>, Francisco Jorquera<sup>2</sup>.

<sup>1</sup>Hospital Universitario de Burgos, Servicio de Aparato Digestivo, Burgos, Spain; <sup>2</sup>Complejo Asistencial Universitario de León, Servicio de Aparato Digestivo, León, Spain; <sup>3</sup>Hospital Universitario de Burgos, Servicio de Medicina Interna, Burgos, Spain

Email: jgomcam@hotmail.com

**Background and aims:** Hepatitis B and C remain a global health challenge, with great morbidity and mortality. The WHO has proposed the elimination of viral hepatitis as a public health threat by 2030. In 2020, the arrival of SARS-CoV-2 pandemic stopped the screening and treatment of viral hepatitis. However, hospital admissions due to SARS-CoV-2 infection can be an opportunity to screen patients for hepatitis B and C and thus move towards viral hepatitis elimination. The aim of this study is to evaluate the results of a screening program in hospitalized COVID-19 patients.

**Method:** This is a prospective cohort study conducted in two Spanish hospitals (Hospital Universitario de Burgos and Complejo Asistencial Universitario de León). All patients admitted to our centers from March 1st to December 31st 2020 with a diagnosis of COVID-19 were tested for markers of hepatitis B (HBsAg, anti-HBc) and C (anti-HCV, HCV RNA) infection.

**Results:** In the study period, 4513 patients with COVID-19 were admitted to our centers: 57.7% were male, median age was 74 years. Data regarding HBV infection was available in 3159 (70%) patients, of whom 303 (9.6%) were anti-HBc + and 11 (0.35%) HBsAg +. From these, only 4 (0.13%) patients did not have a previous diagnosis of hepatitis B (median age 80 years, all APRI <0.5). Seven HBsAg + patients received high dose corticosteroids; only one received prophylaxis and another one was treated with entecavir because a mild reactivation (DNA HBV 69 900 IU/ml). Anti-HCV were available in 3152 (69.8%) patients, of whom 24 (0.72%) were positive. From these, 13 patients had a previous hepatitis C diagnosis: 10 patients

had been treated and presented SVR, 2 achieved spontaneous cure and 1 did not receive treatment because of his age. From the 11 previously unknown anti-VHC + patients, 9 had a negative HCV RNA. Overall, only 3 (0.1%) patients tested RNA HCV positive. However, none received HCV treatment (2 older than 90 years, 1 died from COVID-19).

**Conclusion:** Screening of hepatitis B and C infection in hospitalized COVID-19 patients seems to be an unsuccessful tool in our region. The low prevalence of infection after antiviral treatments, the high age of our population and the difficulties for the application of the protocol in the context of the pandemic limit the detection of potential HCV candidates for treatment. HBV screening in this context should be aimed to prevent reactivation under immunosuppressive treatments.

## Viral Hepatitis C: Post SVR and long term follow up

Email: wedemeyer.heiner@mh-hannover.de

**Background and aims:** Direct acting antivirals against hepatitis C improve the short-term outcome of patients with chronic hepatitis C. The long-term clinical course after interferon-free treatment of chronic hepatitis C has rarely been studied in large real-world cohorts. We here present data on 10, 448 patients being followed for up to 7 years after DAA therapy in the German Hepatitis C-Registry.

**Method:** The DHC-R (German Hepatitis C-Registry) is a national multicentre real-world registry currently including about 17, 700 patients recruited by more than 250 centres. Data were analysed as of Jan 01, 2021. The present analysis is based on patients treated with DAAs against since February 2014.

**Results:** About 1/3 (32%) of the patients had liver cirrhosis at baseline. 26% (2, 712/10, 448) had a follow-up of at least three years after end of treatment. Antiviral treatment containing ribavirin (RBV) were given to 2, 359 patients, while 8, 089 patients received a regimen without RBV. The overall sustained virological response rates were 95% (9, 951/10, 448) and 97% (9, 824/10, 157) in intention-to-treat and per protocol analysis, respectively. During long-term follow-up, 181 patients died. Liver-related clinical events (liver transplantation, hepatocellular carcinoma (HCC), hepatic decompensation or increase in MELD score by  $\geq 3$  points) occurred in 416 (5.7%) patients. The time course of event-free survival is shown in the figure. The overall incidence for de novo HCC was 0.6%/year. In patients with liver cirrhosis the annual HCC risk was 1.2% in the first two years after

treatment and 0.8% from year 3–7. In multivariate analysis, parameters associated with the development of liver-related end points in SVR patients with high significance ( $p < 0.01$ ) were previous antiviral therapy, male sex, baseline hemoglobin, eGFR and alkaline phosphatase. Liver cirrhosis and treatment experience were the only factors being associated with de novo HCC development with high significance ( $p < 0.01$ ).

Figure: Kaplan-Meier curve analysis of liver related end point free survival of SVR patients with and without baseline liver cirrhosis during long-term follow-up.

**Conclusion:** This large real-world cohort confirmed that patients with chronic hepatitis C and liver cirrhosis are still at risk to develop complications of liver disease even beyond 3 years after HCV cure. We still strongly recommend a regular long-term monitoring in particular in treatment-experienced patients with liver cirrhosis.

**PO-404**

**12 weeks treatment of Sofosbuvir/Velpatasvir in HCV negative recipients receiving renal transplantation from HCV positive donors**

Ruoyang Chen<sup>1</sup>, Dawei Li<sup>1</sup>, Shaoyong Zhuang<sup>1</sup>, Ming Zhang<sup>1</sup>, Xiaodong Yuan<sup>1</sup>. <sup>1</sup>Affiliated Renji Hospital, School of Medicine, Shanghai Jiao Tong University, Urology, Shanghai, China  
Email:

**Background and aims:** To evaluate the efficacy and safety of Sofosbuvir/Velpatasvir prophylaxis in HCV negative recipients who received transplant kidney from HCV infected donors.

**Method:** This retrospective study included 26 consecutive HCV negative recipients between January 2019 and December 2020, who were treated with Sofosbuvir/Velpatasvir (400 mg/100 mg) once daily for 12 weeks after receiving transplant kidney from HCV infected donors (except for the first dose which was given 2 hours before renal transplant surgery). The primary end point was the proportion of patients with negative HCV RNA 12 weeks after the end of antiviral treatment.

**Results:** 16 patients completed 12 weeks of treatment and whole duration of follow-up. 7 patients completed Sofosbuvir/Velpatasvir treatment and are still under follow-up. The rest of 3 patients are still under 12 weeks of treatment. Among the 26 recipients, 22 recipients remained negative HCV Antibody (Ab) after transplantation. All patients had undetectable HCV RNA, including those who are still under treatment or follow-up, by the time we report. 3 patients experienced graft rejection, 6 patients experienced delayed graft function. However, none of them were related to study medication. The majority of adverse events reported in the study were mild and consistent with previous Sofosbuvir/Velpatasvir studies. Serious adverse events were reported in 6 patients, but none was considered

related to the drugs. Renal function remained stable during the whole study.

Table: Demographic and Clinical Characteristics of Recipient and Donor

Recipient Characteristics (n = 26)	
Median age (IQR), yr	42 (20–73)
Male, n (%)	19 (73.1%)
Cirrhosis, n (%)	0
Alanine aminotransferase level (U/L)	10.5 (3–70)
Serum creatinine level (μmol/L)	894 (373–1705)
Estimated glomerular filtration rate (ml/min)	7.715 (4–20.77)
Primary cause of renal failure, (n)	
IgA nephropathy	4
Polycystic kidney disease	3
Focal segmental glomerulosclerosis	3
Diabetic nephropathy	0
Hypertensive nephrosclerosis	1
Unknown	15
History of diabetes, (n)	2
Median time on dialysis before transplantation	330 (0–4340)
Median time on waitlist before transplantation	198 (29–865)
Donor Characteristics (n = 15)	
Male, n (%)	14 (93.3%)
Cause of death, (n)	
Donation after brain death	13
Donation after cardiac death	2
Median terminal serum creatine (μmol/L)	84.5 (24–194.5)

**Conclusion:** Sofosbuvir/Velpatasvir prophylaxis treatment was effective and safe in HCV uninfected recipients who received renal transplantation from HCV positive donors.

**PO-578**

**Long-term follow-up in patients with hepatitis C virus treated with direct-acting-antivirals agents**

Paula Fernandez Alvarez<sup>1</sup>, María Guerra Veloz<sup>1</sup>, Daniel Barranco Castro<sup>1</sup>, Patricia Cordero Ruiz<sup>1</sup>, Antonia Sáez Díaz<sup>2</sup>, Francisco Bellido Muñoz<sup>1</sup>, Angel Caunedo Alvarez<sup>1</sup>, Isabel Carmona Soria<sup>1</sup>. <sup>1</sup>Virgen Macarena University Hospital, Gastroenterology and Hepatology Department, Seville, Spain; <sup>2</sup>Virgen Macarena University Hospital, Statistics Department, Seville, Spain  
Email: paulafer7@gmail.com

**Background and aims:** The introduction of the new direct-acting antivirals agents (DAA) has revolutionized the natural history of chronic HCV. The aim of this study was to determine risk factors associated with the developing of liver related events (LRE) in patients with prior advanced fibrosis who achieved sustained virological response (SVR).

**Method:** Observational retrospective single center study which included patients with chronic hepatitis C and advanced fibrosis (Fibroscan >10 kPa, APRI >1.5 and/or FIB-4 >3.25) treated with DAA between 2014 and 2017 that achieved SVR.

**Results:** A total of 321 patients were included, 68.8% (221) were male with a median age of 57 years. The median follow-up was 52 months (IQR 41–63). 13.7% of patients developed LRE, 10% (32) portal hypertension decompensation and 3.7% (12) HCC.

Patients with portal hypertension decompensation had higher basal Child-Pugh score (B 46.9 vs 6.9%, C 3.1 vs 0.3%;  $p < 0.001$ ), basal MELD score (9.4 vs 7.8;  $p < 0.001$ ), basal fibroscan value (26.5 vs 20.1;  $p = 0.003$ ), basal APRI score (2.21 vs 1.13;  $p < 0.001$ ), basal FIB-4 score (6.12 vs 2.62;  $p < 0.001$ ) and more prior LRE (46.9 vs 5.9%;  $p < 0.001$ ) in comparison with patient who did not develop liver decompensation. Furthermore, APRI and FIB-4 scores at first and second year were also higher in decompensated patients. In the multivariable analysis only the basal fibroscan value (OR 1.09 (1.029–1.175)  $p = 0.005$ ) was associated with portal hypertension decompensation.

## POSTER PRESENTATIONS

Patients who developed hepatocellular carcinoma (HCC) were older (67.6 vs 58.5;  $p = 0.005$ ) and had higher rates of diabetes (50 vs 20.5%;  $p = 0.025$ ), basal Child Pugh score (B 33.3 vs 10%, C 8.3 vs 0.3%;  $p < 0.001$ ), genotype 3 (41.7 vs 12.6%;  $p = 0.032$ ) and basal FIB-4 score (5.4 vs 2.8;  $p < 0.011$ ) than those without HCC. During the follow-up patients who had higher APRI and FIB-4 scores at first and second year were more likely to develop HCC than those with low scores. In the multivariable analysis age (OR 1.13 (1.03–1.23)  $p = 0.007$ ), presence of diabetes (OR 8.54 (1.32–55.15)  $p = 0.024$ ) and the basal FIB-4 (OR 1.17 (1.04–1.32)  $p = 0.009$ ) were related with the development of HCC.

During this period death occur in 22 patients (6.85%).

**Conclusion:** Patient's age, presence of diabetes and the baseline fibroscan and FIB-4 values were associated with the developing of LRE in a long-term follow-up. FIB-4 and APRI score measured at first and second year after SVR were not associated with LRE.

### PO-602

#### Persistent perturbation of the circadian clock by chronic hepatitis C virus infection following cure with direct-acting antivirals

Email: thomas.baumert@unistra.fr

**Background and aims:** Chronic HCV infection is a major cause of HCC. While viral cure by direct-acting anti-viral (DAA) agents decreases the overall HCC risk, large cohort studies revealed that HCC risk persists following cure especially in advanced fibrosis. The absence of reliable biomarkers to robustly predict HCC risk is a challenge for patient management. Despite significant research efforts, the molecular basis of HCV-induced HCC is still incompletely understood. The circadian clock (CC) is a well-known regulator of liver physiology and disease biology, while its clinical impact for HCV infection and hepatocarcinogenesis is unknown. Here, we aimed to investigate the role of the circadian clock in HCV-associated HCC risk. **Method:** To study the perturbation of the CC in patients, we performed ChIP-seq and RNA-seq from liver tissue of patients with chronic HCV-infection, cured patients and non-infected control patients and measured gene expressions and transcription factor recruitments of CC components at different stages of disease and pre- and post-cure. In addition, we performed perturbation studies in a human liver chimeric mouse model, primary human hepatocytes and HCV-permissive differentiated human hepatocellular carcinoma cells to unravel the regulation of affected CC-components in detail.

**Results:** We show that chronic HCV infection, a major cause of chronic liver disease (CLD) and HCC, results in marked epigenetic and

transcriptional perturbations of CC-controlled pathways driving the progression of CLD and HCC in patients. Our data show that HCV-induced epigenetic and transcriptional perturbations of CC-controlled pathways persist upon viral cure in patients with advanced fibrosis. The downstream network of disturbed genes, including many oncogenes as well as tumor suppressor genes, are associated with the hallmarks of cancer, and correlate with the outcome and risk to develop HCC. Mechanistically, virus-induced cytokine signaling impairs the CC-function by altering the expression of key CC components and downstream signaling.

**Conclusion:** Our results demonstrate that a human virus targets the CC and thereby drives fibrosis, a chronic inflammation-related disease, which is strongly linked with the development of cancer in advanced stages. Our findings provide novel opportunities for the discovery of urgently needed biomarkers and strategies for HCC surveillance and chemoprevention, and for HCC risk assessment in HCV-infected and cured patients.

### PO-666

#### Characteristics and Survival Outcomes of Hepatocellular Carcinoma Developed After HCV SVR

Ming-Lun Yeh<sup>1,2</sup>, Po-Cheng Liang<sup>1</sup>, Pei-Chien Tsai<sup>1</sup>, Shu-Chi Wang<sup>3</sup>, Jennifer Leong<sup>4</sup>, Eiichi Ogawa<sup>5</sup>, Dae Won Jun<sup>6</sup>, Cheng-Hao Tseng<sup>7</sup>, Charles Landis<sup>8</sup>, Yasuhito Tanaka<sup>9</sup>, Chung-Feng Huang<sup>1,2</sup>, Jun Hayashi<sup>10</sup>, Yao-Chun Hsu<sup>7</sup>, Jee-Fu Huang<sup>1,2</sup>, Chia-Yen Dai<sup>1,2</sup>, Wan-Long Chuang<sup>1,2</sup>, Mindie Nguyen<sup>11,12</sup>, Ming-Lun Yu<sup>1,2</sup>. <sup>1</sup>Kaohsiung Medical University Hospital, Department of Internal Medicine and Hepatitis Center, Taiwan; <sup>2</sup>Kaohsiung Medical University, School of Medicine, Lipid Science and Aging Research Center, and Hepatitis Research Center, College of Medicine, and Center for Cancer Research and Center for Liquid Biopsy and Cohort Research, Taiwan; <sup>3</sup>Kaohsiung Medical University, Department of Medical Laboratory Science and Biotechnology, Taiwan; <sup>4</sup>Mt. Sinai Health System, Henry D. Email: minglunyeh@gmail.com

**Background and aims:** The clinical presentation and survival of hepatocellular carcinoma (HCC) developed in patients post hepatitis C virus (HCV) eradication as compared to HCC developed in patients of remained viremia are not well studied. We aimed to investigate the characteristics and survival between HCV viremic and non-viremic patients at HCC diagnosis.

**Method:** A total of 1,389 HCV-related HCC patients, including 301 with HCC post HCV eradication (post-SVR HCC) and 1,088 with remained HCV viremia (viremic HCC) were retrospectively analyzed overall survival outcomes. A propensity score-matching method was also used to evaluate overall survival in these two groups.

**Results:** Post-SVR HCC patients demonstrated an older age, less obese, less cirrhosis, better liver function, lower alpha-fetoprotein levels, earlier tumor stages, and higher surgical rate for HCC as compared to viremic HCC at HCC diagnosis. A higher median overall survival was observed in post-SVR HCC patients than viremic patients (153.3 vs 55.6 months,  $p < 0.01$ ), but post-SVR HCC was not independently associated with overall survival on multivariate analysis (adjusted HR: 1.05, 95% CI: 0.76–1.47). However, on sub-analysis, viremic HCC patients with subsequently HCV SVR by antiviral treatment showed a significantly higher median overall

survival than post-SVR HCC patients ( $p < 0.01$ ). Multivariate analysis further identified a significantly lower mortality of viremic HCC with subsequent HCV SVR as compared to post-SVR HCC (adjusted HR: 0.18, 95% CI: 0.11–0.29). Similar findings were also observed in the propensity score-matched cohorts.

**Conclusion:** The better overall survival of patients with post-SVR HCC was related to their advantages in clinical and tumor characters at HCC diagnosis. However, HCV eradication after HCC development improved survival, too.

**PO-689**

**Titer and breadth of anti-hepatitis C virus E2-glycoprotein antibodies in cirrhotic patients after direct antiviral agent therapy**

Email: danisecre@hotmail.com

**Background and aims:** Several lines of evidence point to the participation of antibodies to the hepatitis C virus (HCV) in protection against HCV infection. We aimed to compare the titers, dynamic, and breadth of plasma antibodies against the HCV E2 glycoprotein, the main target of neutralizing anti-HCV antibodies (HCV-Abs), in HCV-monoinfected and HIV/HCV-coinfected individuals before HCV therapy (baseline) and following HCV clearance after direct-acting antiviral (DAA) therapy.

**Method:** We performed a prospective study in 50 HIV/HCV-coinfected patients (HIV/HCV-group) and 12 HCV-monoinfected patients (HCV-group) with advanced cirrhosis who received DAA therapy. Patients were assessed at baseline and 48 weeks after HCV treatment completion. Antibody titers against four purified E2 glycoproteins from 1a (H77), 1b (J4), 3a (S52), and 4a (ED43) genotypes were determined in plasma by ELISA assays and computed by the area under the curve (AUC) using GraphPad Prism 7.0. Statistical analyses were performed using SPSS version 21.0.

**Results:** All HIV/HCV-coinfected individuals were on suppressive ART, the median of CD4<sup>+</sup> T-cells was 439 cells/mm<sup>3</sup>, the median of log<sub>10</sub> HCV-RNA was 6.2 IU/ml, and 18 of patients met acquired immune deficiency syndrome (AIDS) criteria at some point. Twenty-three HIV/HCV-coinfected patients were coinfecting with HCV genotype 1a, nine with genotype 1b, seven with genotype 3, and 10

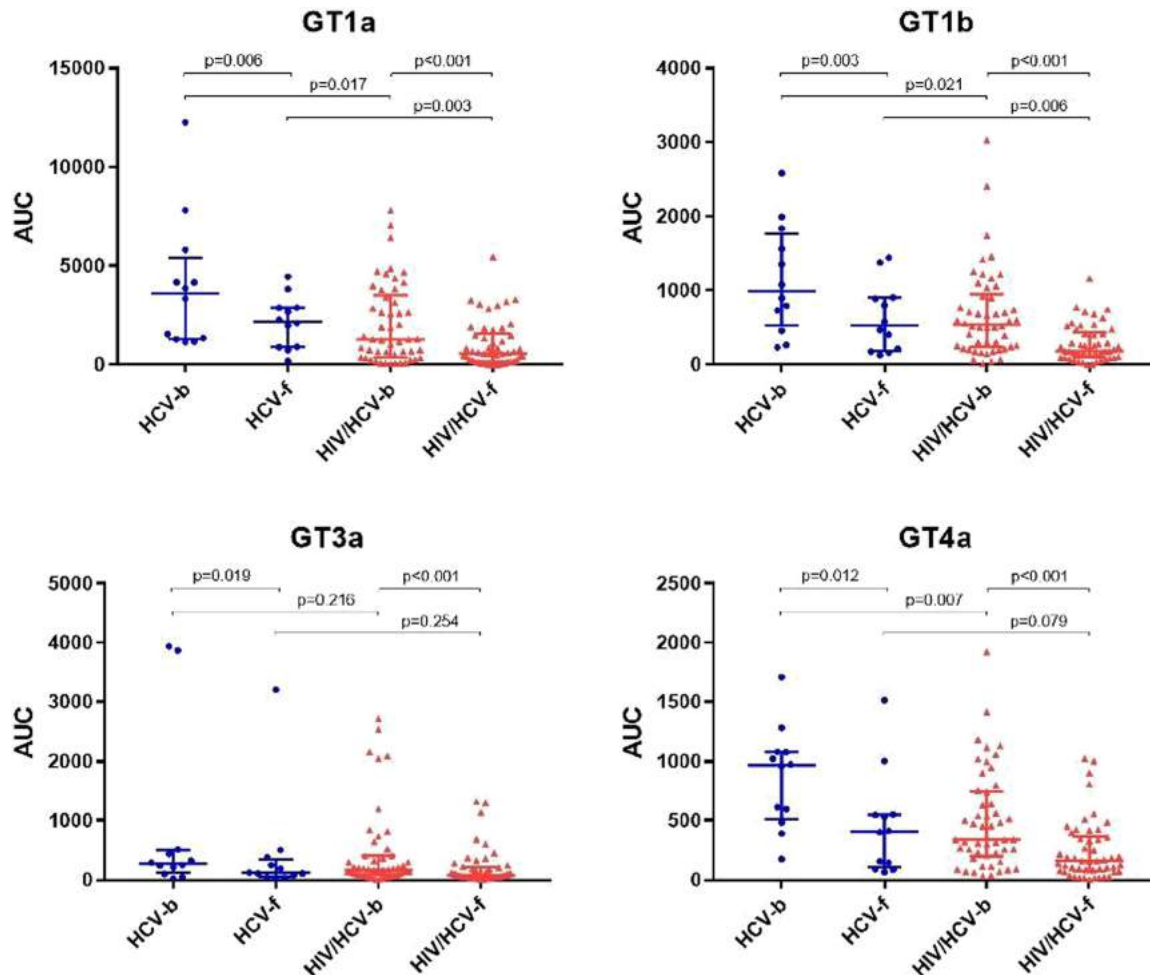

Figure: (abstract: PO-689)

## POSTER PRESENTATIONS

with genotype 4. HCV-monoinfected patients also had a median log<sub>10</sub> HCV-RNA of 6.2 IU/ml. Nine were infected with HCV genotype 1a, one with genotype 1b, and two with genotype 3. We found that AUC values decreased by around 50% in HIV/HCV-group and the HCV group after treatment. The decreasing order was: 1a (H77) >1b (J4) >4a (ED43) >3a (S52) ( $p < 0.05$ ; see Figure). The largest differences between independent groups (HIV/HCV-group vs. HCV-group) were found for 1a (H77), followed by 1b (J4), and 4a (ED43) at both baseline and the end of follow-up ( $p < 0.05$ ; see Figure). The antibody titers were around 1.5–4-fold higher in the HCV-group than in HIV/HCV-group for the four genotypes analyzed at baseline and week 48 after HCV treatment completion ( $p < 0.05$ ; see Figure).

**Conclusion:** The antibody response against HCV appears to be somewhat hampered by HIV coinfection. Furthermore, the decrease in antibody titers 48 weeks after completion of HCV treatment suggests that both mono and coinfecting patients may not be protected against HCV reinfection.

### PO-697

#### **Incidence of liver and non-liver related events and mortality in a large cohort of HCV cirrhotics with an SVR to DAA: a 5-year single center study**

Roberta D'Ambrosio<sup>1</sup>, Elisabetta Degaspero<sup>1</sup>, Maria Paola Anolli<sup>1</sup>, Ilaria Fanetti<sup>1</sup>, Marta Borghi<sup>1</sup>, Roberta Soffredini<sup>1</sup>, Massimo Iavarone<sup>1</sup>, Giulia Tosetti<sup>1</sup>, Riccardo Perbellini<sup>1</sup>, Angelo Sangiovanni<sup>1</sup>, Pietro Lampertico<sup>1,2</sup>. <sup>1</sup>Foundation IRCCS Ca' Granda Ospedale Maggiore Policlinico, Division of Gastroenterology and Hepatology, Milan, Italy; <sup>2</sup>CRC "A. M. and A. Migliavacca" Center for Liver Disease, University of Milan, Department of Pathophysiology and Transplantation, Milan, Italy  
Email: roberta.dambrosio@policlinico.mi.it

**Background and aims:** As the long-term benefits of a sustained virological response (SVR) in hepatitis C virus (HCV) cirrhosis following direct-acting antivirals (DAA) remain undefined, we assessed the SVR impact on liver-related (LRE), non-liver related events (NLRE) and mortality in cirrhotics successfully treated with DAA.

**Method:** Consecutive SVR cirrhotics were enrolled in a longitudinal, single-center study, and divided into *Cohort A* (CPT-A without previous LRE), *Cohort B* (previous non-HCC LRE), *Cohort C* (previous HCC). Study end points were incidence and predictors of LRE, NLRE and mortality.

**Results:** 647 cirrhotics (65 years-old, 58% males, 89% CPT-A) were followed for 51 (8–68) months. In *Cohort A* (n=486), LREs 5-year cumulative incidences (CumI) were 7.6% for HCC, 1.4% for ascites and 1.2% for bleeding. Corresponding figures in *Cohort B* (n=91) were 19.3% for HCC, 2.9% for ascites, 7.7% for bleeding, 2.5% for encephalopathy. Only HCC developed in 70 *Cohort C* patients (5-year CumI: 68.7%). Independent predictors of LREs were male gender (HR 2.93,  $p = 0.03$ ), diabetes (HR 2.49,  $p = 0.02$ ), anti-HBc positivity (HR 2.20,  $p = 0.04$ ) and pre-treatment liver stiffness (HR 1.05,  $p = 0.01$ ) in *Cohort A*; anti-HBc positivity (HR 3.34,  $p = 0.02$ ),  $\gamma$ GT (HR 1.01,  $p = 0.001$ ) and platelets (HR 0.98,  $p = 0.02$ ) in *Cohort B*. NLRE occurred in 70 (11%) patients (36 cerebro-cardiovascular, 33 non-HCC malignancies, 1 ESRD) across all cohorts, age being the only predictor. Overall, 50 patients died, (42% liver-related and 58% non-liver related causes), and 14 (2%) patients underwent liver transplantation (LT). HCC was the most frequent cause of liver-related death and LT. The 5-year CumI for the combined end point liver-related death and LT was 7.7%.

**Conclusion:** Despite HCV eradication, cirrhotics face a significant residual risk of HCC and non-liver-related complications.

### PO-717

#### **Non-invasive tests to predict liver-related events in a single-center cohort of 486 HCV cirrhotic patients treated with DAA**

Elisabetta Degaspero<sup>1</sup>, Roberta D'Ambrosio<sup>1</sup>, Ilaria Fanetti<sup>1</sup>, Riccardo Perbellini<sup>1</sup>, Maria Paola Anolli<sup>1</sup>, Marta Borghi<sup>1</sup>, Roberta Soffredini<sup>1</sup>, Pietro Lampertico<sup>1,2</sup>. <sup>1</sup>Foundation IRCCS Ca' Granda Ospedale Maggiore Policlinico, Division of Gastroenterology and Hepatology, Milan, Italy; <sup>2</sup>CRC "A. M. and A. Migliavacca" Center for Liver Disease, University of Milan, Department of Pathophysiology and Transplantation, Milan, Italy  
Email: elisabetta.degaspero@policlinico.mi.it

**Background and aims:** The association between non-invasive tests for fibrosis and liver-related events (LREs) after a sustained virological response (SVR) to direct-acting antivirals (DAA) in HCV cirrhotics remains undefined. We investigated their modifications following DAA and the association with LREs in a large cohort of cirrhotics.

**Method:** Consecutive compensated SVR cirrhotics treated between 2014 and 2019 in a single-Center were enrolled. LREs included hepatocellular carcinoma (HCC), ascites, variceal bleeding and encephalopathy; those occurring before SVR were excluded. LSM, Fibrosis-4 (FIB-4) and AST to Platelets Ratio index (APRI) were assessed at DAA start (baseline) and 12 months post-treatment (SVR48).

**Results:** Overall, 486 patients were analysed: median age 64 (24–92) years, 59% males, 19% diabetics. Compared to baseline, all tests significantly declined at SVR48: median LSM from 17.0 to 13.9 kPa, FIB-4 from 4.02 to 2.41, APRI from 1.7 to 0.49 ( $p < 0.0001$  for all comparisons). After 51 (8–68) months from baseline, 41 (8%) patients developed a LRE (32 HCC, 6 ascites, 3 bleedings), 5-year cumulative incidence being 10.2% (95% C.I. 7–13%). By multivariate analysis, neither baseline nor SVR48 APRI, FIB-4,  $\Delta$ APRI and  $\Delta$ FIB-4 were associated with LREs. Conversely, both baseline (HR 1.05,  $p = 0.01$ ) and SVR48 (HR 1.02,  $p = 0.003$ ) LSM, but not  $\Delta$ LSM, independently predicted LREs, together with diabetes, anti-HBc and male gender. By ROC curve analysis, baseline LSM >20.8 and SVR48 >16.1 kPa were the optimal cut-offs for LREs prediction: the 5-year cumulative incidence of LREs resulted 16.3% vs. 5.5% in patients with baseline LSM >or  $\leq$ 20.8 kPa ( $p = 0.01$ ); the corresponding figures were 21% vs. 3.7% for SVR48 LSM >or  $\leq$ 16.1 kPa ( $p = 0.003$ ).

**Conclusion:** In a large cohort of compensated HCV cirrhotics with an SVR to DAA, LSM but not FIB-4 or APRI score was associated with LREs.

### PO-862

#### **Mortality risk following HCV cure among people with HIV coinfection**

Naveed Janjua<sup>1,2</sup>, Stanley Wong<sup>1</sup>, Younathan Abdia<sup>1</sup>, Sofia Bartlett<sup>1</sup>, Hector Velasquez<sup>1</sup>, Makuza Jean Damascene<sup>2</sup>, Hasina Samji<sup>1</sup>, Dahn Jeong<sup>2</sup>, Prince Adu<sup>1</sup>, Margo Pearce<sup>2</sup>, James Wilton<sup>1</sup>, Maria Alvarez<sup>1</sup>, Mawuena Binka<sup>1</sup>, Terri Buller-Taylor<sup>1</sup>, Mel Krajden<sup>1</sup>. <sup>1</sup>BC Centre for Disease Control, Vancouver, Canada; <sup>2</sup>The University of British Columbia, Vancouver, Canada  
Email: naveed.janjua@bccdc.ca

**Background and aims:** Co-infection with Human Immunodeficiency Virus (HIV) is associated with higher morbidity and mortality compared to Hepatitis C Virus (HCV) mono-infection. Sustained virologic response (SVR) following HCV treatment is associated with reduced morbidity and mortality. We assessed all-cause, liver-, drug- and non-liver non-drug-related mortality following SVR among people with HIV co-infection (PWHI) compared to people with HCV mono-infection (PWHC) in a large population-based cohort in British Columbia (BC), Canada.

**Method:** We used data from the BC Hepatitis Testers Cohort, which includes ~1.3 million people tested for HCV since 1990, linked with data on medical visits, hospitalizations, prescription drugs and mortality. We followed PWHC and PWHI who achieved SVR following DAA treatment to death or December 31, 2019. We computed

mortality rates by HIV co-infection status and performed multi-variable proportional hazard modeling to assess the effect of HIV co-infection on all-cause, liver, drug-related and non-liver and non-drug-related mortality.

**Results:** There were 10, 101 people who achieved SVR following direct-acting antiviral treatment. PWHI: n = 811, person-years (PY) = 1, 774.2, deaths = 78; PWHC: n = 9, 290, PY = 19, 464.8, deaths = 474. Median follow-up time was 1.9 years (interquartile range 0.9–3.3; maximum = 5.4). The all-cause, liver, drug and non-liver and non-drug-related mortality rate among PWHI and PWHC was 44.0 vs. 24.4/1, 000PY, 5.1 vs. 9.1/1, 000PY, 20.9 vs. 4.5/1, 000PY, 18.0 vs. 11.9/1, 000PY, respectively. In the multivariable model, HIV co-infection was associated with higher all-cause (adjusted hazards ratio (AHR): 1.54, 95%CI: 1.18–2.00), drug-related (AHR: 1.86, 95%CI: 1.20–2.90) and non-liver and non-drug related mortality (AHR: 1.57, 95%CI: 1.05–2.35), while risk of liver-related mortality (AHR: 0.78, 95%CI: 0.39–1.54) was not significant different compared to HCV mono-infection.

**Conclusion:** After successful treatment, people with HIV co-infection have similar liver-related mortality as people with HCV mono-infection, but have higher all cause, drug- and non-liver, non-drug-related mortality. Higher drug-related and non-liver, non-drug related mortality indicate tailoring services based on syndemic conditions co-occurring with HIV and HCV infections, such as substance use and mental health support and care for chronic non-communicable conditions.

**PO-881**

**Gender differences in microRNAs profile in HIV patients after HCV eradication with DAAs: potential biased consequences**

Daniel Valle Millares<sup>1</sup>, Óscar Brochado Kith<sup>1</sup>, Alicia Gómez Sanz<sup>1</sup>, Luz Martín Carbonero<sup>2</sup>, Pablo Ryan<sup>3</sup>, Ignacio De los Santos<sup>4</sup>, Juan Miguel Castro Álvarez<sup>2</sup>, Jesús Troya<sup>3</sup>, Mario Mayoral Muñoz<sup>2</sup>, Guillermo Cuevas<sup>3</sup>, Paula Martínez<sup>1</sup>, Jesús Sanz Sanz<sup>4</sup>, María Muñoz Muñoz<sup>5</sup>, María Ángeles Jiménez Sousa<sup>1</sup>, Salvador Resino García<sup>1</sup>, Verónica Briz<sup>1</sup>, Amanda Fernández Rodríguez<sup>1,6</sup>. <sup>1</sup>ISCIII, Majadahonda, Spain; <sup>2</sup>IdiPAZ,

Madrid, Spain; <sup>3</sup>Hospital Universitario Infanta Leonor, Madrid, Spain; <sup>4</sup>Hospital de La Princesa, Madrid, Spain; <sup>5</sup>INA-Instituto Nacional de Investigación y Tecnología Agraria y Alimentaria, Madrid, Spain; <sup>6</sup>Alfonso X el Sabio, Villanueva de la Cañada, Spain  
Email: da.valle@isciii.es

**Background and aims:** Gender-specific consequences after HCV eradication are unexplored. MicroRNAs (miRNAs) play a crucial role in the immune response against viral infections. However, few have highlighted miRNA role in sex-biased disease or therapy response. This study aims to assess gender differences reflected in the miRNA expression of HIV/HCV-coinfected patients who achieve sustained virological response (SVR) with direct acting antivirals (DAAs).

**Method:** We conducted a prospective study of miRNA expression in PBMCs from 28 chronic HIV/HCV-coinfected patients (HIV/HCV group) at baseline and after achieving SVR with DAAs. Sixteen HIV-monoinfected patients were used as controls (HIV group). Identification of significant differentially expressed (SDE) miRNAs was performed with generalized linear model and mixed GLMs. We also explored putative dysregulated biological pathways.

**Results:** The HIV/HCV group at baseline showed differences in the miRNA profile concerning the HIV group (165 and 102 SDE miRNAs for males and females, respectively). Gender-stratified analysis of HIV/HCV group at baseline versus at SVR achievement showed higher differences in males (80 SDE miRNAs) than in females (55 SDE miRNAs). After SVR, HIV/HCV group showed similar values to HIV individuals, especially in females (1 SDE miRNA). However, ten miRNAs in males remained dysregulated, which were mainly involved in the cancer, fatty acid, and inflammatory pathways.

**Conclusion:** Our findings show gender-biased dysregulation in the miRNA expression profile of PBMCs after HCV eradication with DAA therapy. These differences were normalized in females, while miRNA profile and their target-related pathways of males remained different from HIV patients, which may be related to a high-risk of developing liver-related complications.

Figure: (abstract: PO-881)

## POSTER PRESENTATIONS

### PO-921

#### **PIVKA-II levels predict hepatocellular carcinoma development in caucasian HCV cirrhotic patients treated with DAAs**

Elisabetta Degasper<sup>1</sup>, Riccardo Perbellini<sup>1</sup>, Roberta D'Ambrosio<sup>1</sup>, Sara Colonia Uceda Renteria<sup>2</sup>, Ferruccio Ceriotti<sup>2</sup>, Alberto Perego<sup>3</sup>, Corinna Orsini<sup>3</sup>, Marta Borghi<sup>1</sup>, Massimo Iavarone<sup>1</sup>, Mariangela Bruccoleri<sup>1</sup>, Alessandro Rimondi<sup>1</sup>, Angelo Sangiovanni<sup>1</sup>, Pietro Lampertico<sup>1,4</sup>. <sup>1</sup>Foundation IRCCS Ca' Granda Ospedale Maggiore Policlinico, Division of Gastroenterology and Hepatology, Milan, Italy; <sup>2</sup>Foundation IRCCS Ca' Granda Ospedale Maggiore Policlinico, Clinical Laboratory, Milan, Italy; <sup>3</sup>Fujirebio, Sweden, <sup>4</sup>CRC "A. M. and A. Migliavacca" Center for Liver Disease, University of Milan, Department of Pathophysiology and Transplantation, Milan, Italy  
Email: elisabetta.degasper@policlinico.mi.it

**Background and aims:** Prothrombin induced by vitamin K absence or antagonist-II (PIVKA-II) has been associated with hepatocellular carcinoma (HCC), but its performance in HCV cirrhotics achieving a sustained virological response (SVR) to direct-acting antivirals (DAA) is unknown.

**Method:** In this single-center study, we tested a large cohort of HCV cirrhotics with an SVR for PIVKA-II and alpha-fetoprotein (AFP) (Fujirebio, Japan) at DAA start (baseline), end of treatment (EOT) and HCC diagnosis. PIVKA-II and AFP performances were evaluated at HCC diagnosis and as predictors of HCC.

**Results:** 400 patients (1,029 samples tested) were included: age 65 (24–92) years, 56% males, 91% Child-Pugh Turcotte (CPT) A, Liver Stiffness Measurement (LSM) 16.9 (12.0–75.0) kPa. During DAA, PIVKA-II did not change [35 (12–886) vs. 35 (16–867) mAU/ml,  $p = 0.43$ ] while AFP significantly decreased [12 (1–537) to 6 (1–347) ng/ml,  $p < 0.0001$ ]. After 52 (3–66) months from baseline, 34 (8.5%) patients developed *de-novo* HCC, the 5-year probability being 11.3% (95% CI 7–16%). At HCC diagnosis, 82% were BCLC 0-A, AFP was 9 (2–12, 868) ng/ml and PIVKA-II was 80 (22–1, 813) mAU/ml. The Youden cut-offs for HCC detection were PIVKA-II > 47 mAU/ml (76% Sn, 79% Sp, 25% PPV, 97% NPV) and AFP > 17 ng/ml (29% Sn, 97% Sp, 48% PPV, 97% NPV), with higher AUROC for PIVKA-II (0.82 vs. 0.6,  $p = 0.03$ ). HCC features (size, nodule number, BCLC stage) did not differ according to PIVKA-II or AFP levels.

At multivariate analysis, baseline predictors of HCC were PIVKA-II (HR 1.01,  $p < 0.001$ ), diabetes (HR 3.79,  $p = 0.002$ ), bilirubin (HR 1.79,  $p = 0.04$ ) and anti-HBc (HR 2.53,  $p = 0.03$ ). Among EOT variables, PIVKA-II (HR 1.01,  $p = 0.01$ ) and AFP (HR 1.01,  $p < 0.001$ ) independently predicted HCC together with diabetes (HR 3.68,  $p = 0.002$ ), GGT (HR 1.01,  $p = 0.001$ ) and albumin (HR 0.31,  $p = 0.01$ ). Optimal cut-offs for HCC prediction were calculated by ROC curve analysis. The 4-year cumulative probability of HCC was 24% vs. 2% in patients with EOT PIVKA-II > or £41 mAU/ml ( $p < 0.0001$ ), and 26% vs. 9% for EOT AFP > or £15 ng/ml ( $p = 0.02$ ). By combining the two markers at EOT, patients testing positive for both had a 38% 4-year estimated cumulative probability of HCC vs. 21% of patients with a single positive marker and 2% of patients with both negative markers ( $p < 0.0001$ ).

**Conclusion:** In DAA-treated HCV cirrhotics, PIVKA-II was superior to AFP and independently predicted HCC, while the combination of biomarkers improved risk stratification.

### PO-975

#### **Long-term effect of hcv eradication with direct acting antiviral (daas) therapy on egyptian patients with mixed cryoglobulinemias (mc)**

Mohamed Elnadry<sup>1</sup>, Sayed Farouk Mohamed<sup>1</sup>, Mohamed Mahmoud Abdelhalem<sup>1</sup>, Kareem Elnoomany<sup>2</sup>. <sup>1</sup>Al-Azhar University, Hepato-Gastroenterology and Infectious Diseases, Cairo, Egypt; <sup>2</sup>Sheben Elkoom Fever Hospital, Hepato-Gastroenterology and Infectious Diseases, Monof, Egypt  
Email: prof\_nadry@yahoo.com

**Background and aims:** The highest prevalence of HCV infection worldwide was present in Egypt. Mass HCV treatment program was

started using DAAs since 2015 aiming to eradicate HCV infection by 2030. HCV is usually associated with variable types of MCs. The long-term impact of DAAs on MCs associated to HCV is still being researched. The aim of this study is to evaluate the long-term effect of DAAs on Egyptian patients with HCV-associated MCs.

**Method:** This prospective observational study included 80 patients with HCV-associated MC, 30 patients with cutaneous lesions, 30 patients with musculoskeletal manifestations (was defined by circulating cryoglobulin associated with systemic vasculitis symptoms) and 20 patients with Renal involvement (was established by kidney biopsy). All patients fulfilled the inclusion criteria of the study and received DAAs from March to December 2017 in the form of a three-month course of Sofosbuvir/Daclatasvir ± Ribavirin regimen. Post-treatment follow-up ranged from 30 to 36 months.

**Results:** The mean age of the included HCV-MCs patients was 54.2 years ± 8.4 SD; 44 (55%) of them were females. Purpuric papules of the lower extremities was the most frequent cutaneous lesion 80% (24/30) while haemorrhagic crusts, and/or ulcers, lichen planus, and chronic urticaria were frequent in 10% (3/30), 3.33% (1/30), and 6.7% (2/30) of patients, respectively. Arthralgia was the most frequent in musculoskeletal manifestations 90% (27/30). Diffuse membranoproliferative glomerulonephritis was the most frequent lesion in patients with kidney involvement 90% (18/20). All patients reached SVR12. There were improvements in the presenting HCV-MCs clinical manifestations in variable degrees, ranging from complete response (clinical, and immunological) in 53.75% (43/80) patients and partial response (clinical, and immunological) in 33.75% (27/80) patients with no response (clinical and immunological) in 12.5% (10/80). Immunosuppressive therapies are required in 40% (12/30), 26.7% (8/30), 85% (17/20) of patients with cutaneous, musculoskeletal and kidney involvement, respectively. Cryoglobulins were detected (post treatment with DAAs) in 10% (3/30), 6.7% (2/30), and 25% (5/20) of HCV-patients with cutaneous, musculoskeletal and kidney involvement respectively.

**Conclusion:** Clearance of HCV led to resolution and improvement of most patients with cutaneous and musculoskeletal manifestation. In patients with HCV-induced MCs especially those with kidney involvement are still a difficult to treat group and most of them need immunosuppressive therapy.

### PO-1176

#### **Hepatitis C virus eradication improves cognition in patients with and without cirrhosis: results from a real-life prospective study**

Luis Ibañez<sup>1</sup>, Marta Rapado<sup>2</sup>, Lucía Cabrero<sup>3</sup>, Cristina Navarrete<sup>1</sup>, Seila García-Mulas<sup>1</sup>, Adriana Ahumada<sup>1</sup>, LAURA Marquez<sup>1</sup>, María Dolores Pérez<sup>1</sup>, Diego Rincón Rodríguez<sup>1</sup>, Rafael Bañares<sup>1</sup>, Rita Garcia Martinez<sup>1</sup>. <sup>1</sup>Gregorio Marañón Hospital, Madrid, Spain; <sup>2</sup>Instituto de Psiquiatria y Salud Mental Hospital Gregorio Marañón, Madrid, Spain; <sup>3</sup>Instituto de Investigación Sanitaria Gregorio Marañón, Madrid, Spain  
Email: lisamaniego@gmail.com

**Background and aims:** HCV infection is associated with neuropsychiatric disturbances that impact on functioning and health-related quality of life (HRQoL). The potential reversibility in different stages of the liver disease is not well-known. We aimed to evaluate cognitive function, functioning and HRQoL at different stages of liver disease following HCV eradication.

**Method:** A random selection of consecutive patients attending the viral hepatitis clinic (April'15–March'17) were assessed before initiating treatment, 12 and 48 weeks after end of direct-acting antiviral agents (DAAs). A comprehensive neuropsychological assessment, functioning and HRQoL questionnaires were applied.

**Results:** One-hundred and thirty-six HCV-infected patients completed the follow-up, of whom 45 had cirrhosis (12% decompensated). One cirrhotic patient did not achieve virological response and was excluded from the analysis. Twenty-one percent of patients (Figure) had cognitive impairment before starting DAAs (34%

cirrhotic vs 14% non-cirrhotic,  $p < 0.011$ ). Viral eradication was associated with improvement of cognitive performance and a decrease of cognitive impairment to 23% in cirrhotic and to 6% in non-cirrhotic patients ( $p < 0.05$ ). Interestingly, age ( $B = 0.11$  IC95% 0.03–0.19) and baseline cognitive impairment ( $B = 3.58$ , IC95% 1.54–5.62) were independently associated to higher cognitive benefit, regardless the stage of liver disease. Patients with cognitive impairment after eradication were more likely to be obese, with diabetes mellitus, arterial hypertension, cirrhosis, lower educational level and with higher anxiety and depression scores. Functioning and HRQoL also improved following HCV cure.

Figure:

**Conclusion:** HCV-infected patients develop cognitive impairment even with mild liver disease. Viral eradication improves cognitive performance independently of the degree of liver disease and is associated with improvement in functioning and HRQoL. Identification of HCV-patients through screening programs may reduce the burden of cognitive disturbances and improve HRQoL beyond the prevention of liver disease progression.

**PO-1247**

**New onset steatosis but not persistent steatosis prevents hepatic fibrosis improvement after viral eradication by direct-acting antiviral therapy (DAAs) in patients with chronic hepatitis C: evaluation by CAP and LSM**

Annalisa Cespiati<sup>1</sup>, Salvatore Petta<sup>2</sup>, Rosa Lombardi<sup>1</sup>, Vito Di Marco<sup>2</sup>, Vincenza Calvaruso<sup>2</sup>, Giordano Sigon<sup>1</sup>, Giovanna Oberti<sup>3</sup>, Cristina Bertelli<sup>3</sup>, Giuseppina Pisano<sup>3</sup>, Erika Fatta<sup>3</sup>, Federica Iuculano<sup>3</sup>, Luciano Crapanzano<sup>2</sup>, Gerlando Gibilaro<sup>2</sup>, Paolo Francione<sup>1</sup>, Antonio Craxi<sup>2</sup>, Silvia Fargion<sup>1</sup>, Anna Ludovica Fracanzani<sup>1</sup>. <sup>1</sup>Unit of Internal Medicine and Metabolic Disease, Fondazione Ca' Granda IRCCS Ospedale Maggiore Policlinico, Department of Pathophysiology and Transplantation, University of Milan, Milan, Italy; <sup>2</sup>Section of Gastroenterology and Hepatology, PROMISE, University of Palermo, Italy, Palermo, Italy; <sup>3</sup>Unit of Internal Medicine and Metabolic Disease, Fondazione Ca' Granda IRCCS Ospedale Maggiore Policlinico, Milan, Italy  
Email: annalisa.cespiati@unimi.it

**Background and aims:** In patients with chronic hepatitis C (CHC) presence of steatosis before and after sustained virological response (SVR) has been demonstrated. A multifaceted behavior of hepatic steatosis has been related with metabolic alterations. Aim: to define the impact of post SVR steatosis on fibrosis improvement evaluated with Fibroscan in CHC patients after viral eradication by DAAs.

**Method:** 794 patients with CHC who achieved SVR, referring to 2 Italian Liver Units were enrolled. Data were collected the day of DAAs starting and six months after SVR. Fibroscan defined the presence of steatosis (by controlled attenuation parameter (CAP)  $\geq 248$  dB/m) and fibrosis (by liver stiffness measurement LSM).

**Results:** Mean age was  $64 \pm 16$ , 50% males, genotype 1 in 73%, genotype 3 in 7%. Mean CAP and LSM values at baseline were  $244 \pm 60$  dB/m and  $10 \pm 7.6$  kPa. Patients with baseline steatosis 365 (46%) presented significantly higher baseline LSM values compared to their counterpart ( $10.6 \pm 7.8$  vs  $9.4 \pm 7.4$  kPa;  $p = 0.04$ ). New onset steatosis (CAP  $\geq 248$  dB/m) after SVR developed in 125 out of 429 (29%) without steatosis at enrollment, persistent steatosis in 243/365 (66%). LSM significantly reduced after SVR ( $10 \pm 7.6$  vs  $8.2 \pm 7.2$  kPa,  $p < 0.001$ ), even in presence of hepatic steatosis post SVR ( $10.3 \pm 7.3$  vs  $8.2 \pm 6.6$  kPa;  $p < 0.001$ ). However, when the analysis was differentiated between patients with persistence and new onset steatosis, a significant reduction of LSM in patients with persistence ( $10.8 \pm 7.8$  vs  $8.0 \pm 5.7$  kPa,  $p < 0.001$ ) but not in those with new onset steatosis ( $9.4 \pm 6.4$  vs  $8.7 \pm 8.0$  kPa,  $p = 0.12$ ) was confirmed.

**Conclusion:** New onset steatosis but not persistence of baseline steatosis prevents fibrosis improvement after SVR, possibly because of a combined action of acute inflammation and metabolic alterations. Our finding may suggest the presence of two different type of post SVR steatosis. Further studies are warranted to better elucidate differences between entities.

**PO-1404**

**Metabolomic changes in HIV/HCV coinfecting patients after DAAs therapy**

Óscar Brochado-Kith<sup>1</sup>, Ana Virseda<sup>1</sup>, Juan Berenguer<sup>2</sup>, David Rojo<sup>3</sup>, Juan Gonzalez<sup>4</sup>, Amanda Fernández Rodríguez<sup>1</sup>, Cristina Diez<sup>2</sup>, Victor Hontañón<sup>4</sup>, Teresa Aldámiz-Echevarría<sup>2</sup>, Rafael Micán<sup>2</sup>, Chiara Fanciulli<sup>2</sup>, Carmen Busca<sup>4</sup>, Coral Barbas<sup>3</sup>, Salvador Resino-García<sup>1</sup>, María Ángeles Jiménez Sousa<sup>1</sup>. <sup>1</sup>ISCIII, Majadahonda, Spain; <sup>2</sup>Gregorio Marañón Hospital, Madrid, Spain; <sup>3</sup>CEMBIO, Alcorcón, Spain; <sup>4</sup>Hospital Universitario La Paz, Madrid, Spain  
Email: brochado1993@gmail.com

**Background and aims:** Changes in the metabolomic profile have been described during the different stages of cirrhosis. However, there is little information about what happens in patients coinfecting with human immunodeficiency virus (HIV) and hepatitis C virus (HCV) after direct-acting antivirals (DAAs) therapy. Thus, we aimed to assess plasma metabolites changes and their association with liver cirrhosis markers before and after effective DAAs therapy in HIV/HCV coinfecting patients with advanced HCV-related cirrhosis.

**Method:** We performed a multicenter prospective study in 49 coinfecting patients with advanced cirrhosis assessed at baseline and 48 weeks after DAAs therapy completion. Metabolomics analysis was carried out by gas chromatography-mass spectrometry and liquid chromatography-mass spectrometry. Inflammatory plasma biomarkers were analyzed by ProcartaPlex Immunoassays. The statistical analysis was performed by partial least squares discriminant analysis and generalized linear mixed model correcting for multiple testing.

**Results:** At 48 weeks after HCV treatment completion, patients experienced significant reduction in taurocholic acid, 2, 3-butanediol, and lysoPC (18:0); while several phosphatidylcholines (lysoPC (16:1), lysoPC (18:1), lysoPC (20:4), and PC (16:0/9:0 (CHO))), 2-keto-n-caproic acid/2-keto-isocaproic acid and N-methylalanine increased, compared to baseline. We also found the decrease in plasma taurocholic acid was associated with a reduction in Child-Turcotte-Pugh (CTP) score (AMR = 3.39; q-value = 0.006) and liver stiffness measurement (LSM) (AMR = 1.06; q-value < 0.001), the increase in plasma levels of lysoPC (20:4) was related to a reduction in LSM (AMR = 0.98; q-value = 0.027), and the rise of plasma 2-keto-n-caproic acid/2-keto-isocaproic acid was associated with a reduction in CTP (AMR = 0.35; q-value = 0.004). Finally, changes in taurocholic acid were directly associated with inflammatory plasma biomarkers, while changes in lysoPC (20:4) were inversely associated (Figure 1).

## POSTER PRESENTATIONS

**Figure 1:** Association between changes in plasma metabolites and plasma markers related to inflammation from baseline to 48 weeks after DAA therapy.

Figure:

**Conclusion:** We found significant changes in plasma metabolites after HCV clearance with DAAs therapy in HIV/HCV coinfecting patients with advanced liver cirrhosis. A decrease in plasmatic levels of taurocholic acid and increases in levels of lysoPC (20:4) and 2-keto-n-caproic acid/2-keto-isocaproic acid were associated with decreases in CTP score and LSM. Additionally, plasma levels of taurocholic acid and lysoPC (20:4) could influence the inflammatory state.

Email: emartro@igtp.cat

**Background and aims:** We demonstrated that dried blood spot (DBS) samples are a reliable tool to diagnose viremic HCV infection among people who currently inject drugs (PWID) attending harm reduction services (HRS) in Catalonia. We aimed to assess the usefulness of DBS for HCV genotyping in HCV-RNA positive PWID after on-site treatment with pangenotypic antivirals in order to inform the retreatment regimen.

**Method:** Within the context of an ongoing micro-elimination study targeting current PWID in the largest HRS in Barcelona, PWID were followed up after treatment and HCV viral load was assessed in fingerstick capillary blood by GeneXpert®. DBS from HCV-RNA positive participants at follow-up (FU) weeks 12, 36, or 60 were compared with baseline DBS to assess reinfection vs. treatment failure by an in-house NS5B nested-PCR followed by Sanger sequencing. The epidemiological relationship between HCV-RNA positive participants was assessed by phylogenetic analysis. In those cases where sequencing failed, a commercial real-time PCR assay was used (Abbott Molecular), which identifies the following genotypes/subtypes: 1, 1a, 1b, 2, 3, 4, 5 and 6.

**Results:** Among the 45 FU DBS from RNA-positive patients after treatment (40 cases, including five with a subsequent re-treatment), two FU36 DBS samples with <500 IU/ml (the lower limit of detection) could not be genotyped. Among the rest, 25 DBS were successfully genotyped by sequencing and the other 18 were tested by the real-time PCR assay (in four of them no genotype was assigned due to relatively low viral loads). Genotyping results from FU vs baseline DBS samples evidenced the presence of reinfection in 37 cases (in four cases with the same HCV subtype); four of them also presented reinfection after re-treatment. Conversely, treatment failure was identified in three cases (one of them also failed to re-treatment). Most of the patients got reinfected with subtypes 1a or 3a and were often phylogenetically related to other viremic study participants.

**Conclusion:** HCV genotyping from DBS samples is useful to identify reinfections in PWID in cases with >1000 IU/ml and administer retreatment regimens accordingly. Phylogenetic analysis evidenced that reinfection often occurs from other HRS users. Therefore, reinforced harm reduction measures and strategies such as “treat your friends” should be considered in this setting (treating persons in the same injecting network at the same time) in order to minimize reinfection.

### PO-1542

#### Metabolic comorbidities reduce the improvement of procoagulant imbalance in non-cirrhotic patients with chronic hepatitis C (CHC) after viral eradication with direct-acting antiviral agents (DAAs)

Giordano Sigon<sup>1</sup>, Roberta D'Ambrosio<sup>2</sup>, Marigrazia Clerici<sup>3</sup>, Giuseppina Pisano<sup>4</sup>, Veena Chantarangkul<sup>3</sup>, Annalisa Cespiati<sup>1</sup>, Federica Iuculano<sup>1</sup>, Rosa Lombardi<sup>1</sup>, Flora Peyvandi<sup>5</sup>, Pietro Lampertico<sup>2</sup>, Silvia Fargion<sup>1</sup>, Armando Tripodi<sup>3</sup>, Anna Ludovica Fracanzani<sup>1</sup>. <sup>1</sup>Unit of Internal Medicine and Metabolic Disease, Fondazione Ca Granda IRCCS, Ospedale Maggiore Policlinico, Department of Pathophysiology and Transplantation, University of Milan, Milan, Italy; <sup>2</sup>CRC AM e a Migliavacca Center for Liver Diseases, Gastroenterology and Hepatology, Fondazione Ca' Granda IRCCS Ospedale Maggiore Policlinico, Department of Pathophysiology and Transplantation, University of Milan, Milan, Italy; <sup>3</sup>Angelo Bianchi Bonomi Hemophilia and Thrombosis Center and Fondazione Luigi Villa, IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy; <sup>4</sup>Unit of Internal Medicine and Metabolic Disease, Fondazione Ca Granda IRCCS, Ospedale Maggiore Policlinico, Milan, Italy; <sup>5</sup>Unit of Internal Medicine Hemostasis and Thrombosis, Fondazione Ca' Granda IRCCS Ospedale Maggiore Policlinico, Milan, Italy  
Email: gio.sigon@virgilio.it

**Background and aims:** A strong relationship between endothelial dysfunction, inflammation, procoagulant imbalance, liver damage, was described in non-cirrhotic CHC patients. An improvement in procoagulant imbalance was reported, after DAAs-sustained virologic response (SVR) in CHC patients with cirrhosis. Aims: 1) to assess procoagulant imbalance changes in CHC patients without advanced fibrosis after SVR, 2) to evaluate if metabolic alterations may interfere with coagulation improvement.

**Method:** We enrolled 104 non-cirrhotic patients with CHC and SVR. All patients were evaluated for clinical and biochemical parameters, procoagulant imbalance (endogenous thrombin potential (ETP) with/without thrombomodulin and protein C (PC) to factor VIII ratio), early atherosclerosis (carotid intima-media thickness (IMT)), liver damage (liver stiffness measurement (LSM) at enrolment, after 6 months and in a subgroup of 52 patients after 24 months. Controls for coagulation parameters were 188 healthy hospital employees.

**Results:** At baseline CHC patients show a procoagulant imbalance compared to controls (FVIII/PC  $1.76 \pm 0.76$  vs  $1.1 \pm 0.3$ ,  $p < 0.0001$ ). Pre-treatment indices of procoagulant imbalance were associated

with liver fibrosis (FVIII/PC ratio with NAFLD fibrosis score: coefficient 0.7 SE 0.1,  $p < 0.0001$ ). After SVR a reduction of procoagulant imbalance (FVIII/PC  $1.76 \pm 0.76$  vs  $1.32 \pm 0.54$ ,  $p < 0.0001$ ) was observed in 86% of patients and remained stable at 24 months. A decrease of liver damage compared to pre-treatment (LSM:  $5.1 + 1.7$  vs  $6.5 + 5.5$ ; FIB-4:  $2.1 + 2.8$  vs  $1.7 + 0.7$ ,  $p = 0.02$ ; ALT:  $49 [31-75]$  vs  $17 [14-22]$ ,  $p < 0.0001$ ) was observed in 69%. At multivariate analysis procoagulant imbalance remained independently related to ALT levels (Coeff 0.02, ES 0.001,  $p = 0.005$ ). The absence of coagulation improvement was independently related to baseline age (OR 0.9, IC95 0.8–0.97,  $p = 0.009$ ), diabetes (OR 18.7, IC95, 1.6–217,  $p = 0.02$ ) and dyslipidaemia (OR 222, IC95 10–5077,  $p = 0.001$ ).

**Conclusion:** Non-cirrhotic CHC patients show a procoagulant imbalance that may play a role in the increased severity of fibrosis and endothelial dysfunction.

After HCV eradication by DAAs, a very early improvement of both procoagulant imbalance and liver fibrosis occurs strengthening the direct link between HCV, liver damage and coagulation modifications. Metabolic diseases may account for the lack of improvement of procoagulant imbalance and endothelial dysfunction.

**PO-1561**

**Risk of hepatocellular carcinoma after HCV eradication: capturing the role of portal hypertension**

Elton Dajti<sup>1</sup>, Giovanni Marasco<sup>1</sup>, Federico Ravaioli<sup>1</sup>, Alberto Ferrarese<sup>2</sup>, Davide Festi<sup>1</sup>, Antonio Colecchia<sup>2</sup>. <sup>1</sup>University of Bologna, Bologna, Italy; <sup>2</sup>Borgo Trento University Hospital of Verona, Unit of Gastroenterology, Verona, Italy  
Email: e\_dajti17@hotmail.com

**Background and aims:** Hepatitis C virus (HCV) eradication with direct-acting antivirals (DAAs) reduces but does not eliminate the risk for hepatocellular carcinoma (HCC). The development of surveillance strategies for HCC after the sustained virologic response (SVR) is warranted. We aimed to evaluate the role of spleen stiffness measurement (SSM) in the prediction of HCC risk in a cohort of patients with advanced chronic liver disease (ACLD) treated with DAAs.

**Method:** This is a retrospective cohort study of 140 patients with HCV-related ACLD successfully treated with DAAs at our centre between 2015 and 2017. Patients with available liver stiffness (LSM) and SSM before and at six months (SVR24) after treatment were included. A Cox regression model investigated the association between SSM and HCC.

**Results:** During a median follow-up of 41.5 (interquartile range 32–49) months, 20 patients presented HCC. SSM at SVR24 predicted HCC development in univariate and adjusted multivariate analysis (Hazard Ratio: 1.025; 95%-Confidence-Interval: 1.001–1.050); the best cut-off for this purpose was 42 kPa. Only one out of the 45 (2.2%) patients with LSM-SVR24  $\leq 10$  kPa developed HCC, so this was the category at lowest risk of HCC (incidence rate of 0.65%/year). In patients with LSM-SVR24  $> 10$  kPa, HCC incidence was not further influenced by LSM values (10–20 kPa vs  $> 20$  kPa), but by SSM-SVR24 values ( $\leq 42$  vs  $> 42$  kPa) (Figure 1A). Based on these values, risk could be stratified as moderate (incidence rate 3.14%/year) in patients with LSM-SVR24 10–20 kPa and SSM-SVR24  $\leq 42$  kPa and high (incidence rate 9.71%/year) in patients with LSM-SVR24  $> 20$  kPa or SSM-SVR24  $> 42$  kPa (Figure 1B).

Figure: A new algorithm based on LSM and SSM values at SVR24 for the HCC risk assessment and the surveillance strategy after SVR achievement.

**Conclusion:** Portal hypertension, as evaluated by SSM, plays an essential role in liver carcinogenesis after DAA treatment. We proposed a new algorithm based on post-treatment values of LSM and SSM to stratify for the risk of HCC and to guide the surveillance strategy after SVR achievement.

**PO-1918**

**The impact of hepatitis C virus eradication on hepatocarcinogenesis in haemophiliacs**

Yosuke Inukai<sup>1</sup>, Norihiro Imai<sup>1</sup>, Kenta Yamamoto<sup>1</sup>, Takanori Ito<sup>1</sup>, Yoji Ishizu<sup>1</sup>, Takashi Honda<sup>1</sup>, Masatoshi Ishigami<sup>1</sup>, Mitsuhiro Fujishiro<sup>1</sup>. <sup>1</sup>Nagoya university graduate school of medicine, Gastroenterology and Hepatology, Aichi, Japan  
Email: yokmok@med.nagoya-u.ac.jp

**Background and aims:** Haemophiliacs infected with hepatitis C virus (HCV) are known to develop cirrhosis and hepatocellular carcinoma (HCC) at a relatively younger age than non-haemophilic patients. Although recent progress in direct-acting-antivirals allow high rate of sustained virological response (SVR) against HCV, the clinical impact of HCV eradication in haemophiliacs remains unclear. The aim of this study is to compare the clinical outcomes after SVR against HCV in haemophiliacs with non-haemophilic patients.

**Method:** 699 patients who achieved SVR after HCV antiviral treatment were enrolled. Patients were divided into two groups; 78 haemophiliacs (H-group) and 621 non-haemophilic patients (NH-group). We evaluated the patient characteristics, clinical outcome and cumulative incidence of HCC after SVR.

**Results:** Compared with NH-group, patients in H-group were significantly younger, had more human immunodeficiency virus or hepatitis B virus co-infection and lower hepatic fibrosis score. No difference was found in the incidence of liver disease-related and overall death between the two groups during a mean follow-up of 7 years.

Four patients (5%) in H-group and 36 patients (6%) in NH-group were diagnosed as HCC after SVR. Multivariate analysis showed that male, age and cirrhosis were significant risk factors for incidence of HCC. There was no significant difference in the cumulative incidence of HCC after propensity score matching, adjusting for risk factors for HCC between the two groups.

## POSTER PRESENTATIONS

**Conclusion:** Haemophilia is not a significant risk factor for hepatocarcinogenesis after SVR against HCV.

### PO-1919

#### Long term follow-up in HCV infected patients with end stage chronic kidney disease after DAA therapy

Email: mbuti@vhebron.net

**Background and aims:** Direct acting antivirals (DAA) based on the combination of an NS5 inhibitor and protease Inhibitor are highly effective and safe in patients with end-stage chronic kidney disease (ESCKD). Currently there is scarce data regarding the impact of HCV cure on the long-term follow-up of kidney function. We assessed the evolution of renal function and development of renal and liver events in a real-life cohort of patients with ESCKD who received DAAs and were followed for a mean of 3, 9 ( $\pm 1, 5$ ) years.

**Method:** Multicentric retrospective-prospective study including patients with chronic kidney disease stage 3b-5 and dialysis who had previously participated in Vie-KinD<sup>1</sup> study in which HCV GT 1 and 4 patients received OBV/PTV/r  $\pm$  DSV for 12–24 weeks. Data on long-term hepatic and renal function, clinical events and mortality were collected.

**Results:** 135 patients were included in Vie-KinD study. SVR was achieved in 93% of the cases. At the time of starting DAAs, mean age was 58 ( $\pm 11$ ) years, 70% had hypertension, 24% diabetes, 14% dyslipidemia and 64 (47%) had advanced fibrosis (F3/F4 by transient elastography). Fifteen (11%) patients had CKD stage 3b, 20 (15%) stage 4 and 100 (74%) stage 5. 105 were under renal replacement (78%). 52 (38%) had history of kidney transplant.

69 patients were followed mean of 3, 9 ( $\pm 1, 5$ ) years. At baseline, mean creatinine and estimated glomerular filtration rate (eGFR) were 5, 8 ( $\pm 3$ ) mg/dl and 13 ( $\pm 8, 6$ ) ml/min respectively. Three (4%) patients had CKD stage 3b, 11 (16%) stage 4 and 55 (80%) stage 5. During the follow-up, 21 patients (36, 2%) died (7 due to cardiovascular events, 10 other causes, 2 liver-related and 2 kidney-related cause), 3 (4.3%) developed liver decompensation and 2 (2.9%) hepatocarcinoma. 25 (36.2%) individuals (21 CKD stage 5, 4 stage 4; 19 on dialysis) received a kidney transplant within a mean of 1, 9 ( $\pm 1, 2$ ) years after HCV cure.

Among the 44 (63, 8%) patients who didn't require kidney transplant, 33 were on dialysis at baseline and 34 at last follow-up. There were no changes on the mean creatinine (5, 9  $\pm 2, 9$  mg/dl,  $p = 0, 4$ ) or eGFR values (15, 5  $\pm 14, 3$  ml/min,  $p = 0, 5$ ), though in 5 (8, 6%) there was an improvement in the CKD stage.

**Conclusion:** Long-term follow-up of CKD stage 3b-5 patients who achieved HCV cure after DAA shown a high mortality mainly due to cardiovascular events and a stabilization of renal function. A small proportion of patients (<10%) had an improvement on the renal function after HCV cure.

### PO-2008

#### Liver stiffness measurements for the prediction of liver-related outcomes in chronic hepatitis C patients after viral elimination

Yen-Chun Liu<sup>1,2</sup>, Rachel Wen-Juei Jeng<sup>1,2</sup>, Ya-Ting Cheng<sup>1,2</sup>, Yi-Chung Hsieh<sup>1,2</sup>, Yi-Cheng Chen<sup>1,2</sup>, Chun-yen Lin<sup>1,2</sup>, Rong-Nan Chien<sup>1,2</sup>, Tai Dar-In<sup>1,2</sup>, I-Shyan Sheen<sup>1,2</sup>. <sup>1</sup>Chang Gung University, Taoyuan, Taiwan; <sup>2</sup>Linkou Chang Gung Memorial Hospital, Gastroenterology and Hepatology, Taoyuan, Taiwan  
Email: rachel.jeng@gmail.com

**Background and aims:** The utility of liver stiffness measurements (LSM) before or after direct acting antiviral agents (DAA) were reported to be predictive of liver-related adverse outcomes including HCC and hepatic decompensation. However, there's no comparison of the LSM's predictability at pre-DAA and SVR-24. The aim of the study was to compare predictive performances of LSM at different assessment timepoint (pre-DAA versus SVR-24) for liver-related adverse outcomes.

**Method:** Chronic hepatitis C patients achieved HCV elimination by interferon-free DAAs, whose LSM report by transient elastography (TE, Fibroscan) available at baseline and SVR-24, in Chang Gung Memorial Hospital were enrolled. The predictions for HCC and hepatic decompensation between baseline and SVR-24 LSM were compared by testing accuracy and AUROC. The cumulative de-novo HCC and decompensation incidences were calculated by Kaplan-Meier method.

**Results:** Among 951 patients enrolled, 19% had liver cirrhosis and 40% were males. The median follow-up duration was 22 months. The area under ROC curve for HCC and hepatic decompensation prediction by pre-DAA vs. SVR 24 were 0.821, 0.919 vs. 0.804, 0.924, respectively, both  $p > 0.1$  (Figure). The optimal cut-off value for prediction of HCC and hepatic decompensation by Youden index was lower when adopting SVR-24 timepoint (10 and 16 kPa) than pre-DAA treatment (12 and 18 kPa). The 2-year cumulative incidence of HCC of patients with pre-DAA LSM  $> 12$  kPa was 8% vs. 0.7% (LSM  $< 12$  kPa),  $P < 0.001$ , similar to that using SVR 24 LSM  $> 10$  kPa (8.7% vs. 1%). The 2-year cumulative incidence of hepatic decompensation of patients with pre-DAA LSM  $> 18$  kPa was 10.8% vs. 0.3% (LSM  $< 18$  kPa),  $P < 0.001$ , while that using SVR 24 LSM  $> 16$  kPa was 13.6% vs. 0.4%.

Figure:

**Conclusion:** The predictive performance of LSM for HCC and hepatic decompensation event are comparable at pre-DAA treatment or SVR-24 timepoints. The optimal cut-off value shall be adjusted according to the assessment timepoint.

**PO-2418**

**Hepatitis C virus genotype 3 is associated with high risk of de novo portal vein thrombosis in cirrhotic patients after successful antiviral therapy: Russian long-term single center experience**

Ekaterina Nabatchikova<sup>1</sup>, Dzhamal Abdurakhmanov<sup>1</sup>, Teona Rozina<sup>1,2</sup>, Elena Nikulkina<sup>1</sup>, Elena Tanashchuk<sup>1</sup>, Sergey Moiseev<sup>1,2</sup>. <sup>1</sup>I.M. Sechenov First Moscow State Medical University (Sechenov University), The Department of Internal, Occupational Diseases and Rheumatology; <sup>2</sup>M.V. Lomonosov Moscow State University  
Email: e.nabat4ikova@gmail.com

**Background and aims:** Portal vein thrombosis (PVT) is one of the most serious complications of liver cirrhosis, leading to the clinical decompensation and high risk of mortality. Successful antiviral therapy with direct-acting antivirals (DAAs) is reported to improve clinical outcomes in cirrhotic patients. However, data of the PVT risk after hepatitis C virus (HCV) eradication is not enough. The aim of our study was to assess incidence and risk factors of PVT in patients with HCV-related cirrhosis treated by DAAs.

**Method:** The prospective single-center cohort study included patients with HCV-related cirrhosis treated by DAAs between July 2015 and January 2020. Exclusion criteria was previous and present PVT. Patients who achieved sustained virological response underwent clinical, laboratory and imaging assessment every 3–6 months after the end of therapy (EOT).

**Results:** A total of 229 cirrhotic patients were enrolled. The median age was 54 (25; 60, 5) years, 48% were males, diabetes was present in 20%, obesity-in 33%, HCV genotype 3-in 25% and 30% were treatment-experienced. Child-Pugh class B/C were found in 28.4%. Baseline median MELD score was 11 (9; 13), liver stiffness (n = 131)-22.7 (16.1; 28.2) kPa, platelet count  $100 \times 10^3/\text{ml}$  were in 52.8% of patients, albumin  $\leq 35 \text{ g/l}$ -35.4%, bilirubin  $\geq 34 \mu\text{mol/l}$ -18.3%, prothrombin time  $\leq 60\%$ -19.7%, aspartate aminotransferase-platelet ratio index  $>2$ -55.4%, fibrosis-4 score  $\geq 3.25$ -67.2%. Esophageal varices were in 61%, ascites-24.4%. The median follow-up time after EOT was 30 (18; 36) months. De novo PVT occurred in 8 (3, 5%) patients. The median time from EOT to PVT diagnosis was 24 (13.5; 30) months. The cumulative incidence of developing PVT was 0, 9% and 5, 9% at 1-, 3-years, respectively. At the univariate analysis, HCV genotype 3 (Hazard ratio (HR) 9.4;  $p=0.008$ ), prothrombin time  $\leq 60\%$  (HR 4.81;  $p=0.027$ ), ascites (HR 6.14;  $p=0.018$ ) and spleen size  $\geq 81 \text{ cm}^2$  (HR 8, 47;  $p=0, 046$ ) were significantly associated with the risk of PVT. At the multivariate analysis, only HCV genotype 3 (HR 7.19;  $p=0.021$ ) was independent risk factor for PVT. By Kaplan-Mayer analysis, patients infected HCV genotype 3 have higher cumulative risk of PVT compared to patients with non-3 genotype (Figure).

Number at risk:  
Group 1: 172 172 165(1) 148 119 93(1) 56 33 16 7 1  
Group 2: 57 57(1) 50 44(1) 34(2) 19(1) 8(1) 2 2  
Figure: Cumulative incidence of PVT in DAAs treated cirrhotic patients with SVR.

**Conclusion:** Cirrhotic patients infected HCV genotype 3 have considerable cumulative risk of PVT occurrence and need more careful monitoring after antiviral therapy in order to prevent clinical decompensation.

**Impact of direct-acting antiviral treatment on mortality related to extrahepatic manifestations: findings from a large population-based cohort in British Columbia, Canada**

Dahn Jeong<sup>1,2</sup>, Stanley Wong<sup>2</sup>, Mohammad Ehsanul Karim<sup>1,3</sup>, Sofia Bartlett<sup>2,4</sup>, James Wilton<sup>2</sup>, Makuza Jean Damascene<sup>1,2</sup>, Hector Velasquez<sup>2</sup>, Mawuena Binka<sup>2</sup>, Prince Adu<sup>1,2</sup>, Margo Pearce<sup>2</sup>, Amanda Yu<sup>2</sup>, Maria Alvarez<sup>2</sup>, Hasina Samji<sup>2,5</sup>, Younathan Abdia<sup>2</sup>, Mel Krajden<sup>2,4</sup>, Naveed Janjua<sup>1,2</sup>. <sup>1</sup>University of British Columbia, School of Population and Public Health, Vancouver, Canada; <sup>2</sup>British Columbia Centre for Disease Control, Vancouver, Canada; <sup>3</sup>Centre for Health Evaluation and Outcome Sciences, Vancouver, Canada; <sup>4</sup>University of British Columbia, Department of Pathology and Laboratory Medicine, Vancouver, Canada; <sup>5</sup>Simon Fraser University, Faculty of Health Sciences, Burnaby, Canada  
Email: dahn.jeong@bccdc.ca

**Background and aims:** Chronic hepatitis C virus (HCV) infection is associated with mortality due to extrahepatic manifestations (EHM). The sustained virologic response (SVR) following the highly effective direct-acting antivirals (DAA) has been linked to decreased all-cause and liver-related mortality. However, evidence on the impact of DAA on EHM-related mortality is lacking. This study assessed the impact of DAA treatment on reducing mortality related to EHM using a population-based linked administrative data.

**Method:** The British Columbia (BC) Hepatitis Testers Cohort includes ~1.3 million people tested for HCV since 1990 and is linked with administrative health data, including medical visits, hospitalizations and chronic disease registry. We compared three groups of individuals: treated and SVR, treated and no-SVR, and untreated. EHM mortality included deaths due to diabetes, rheumatoid arthritis, cardiovascular, cerebrovascular, renal and neurocognitive diseases. Individuals were followed from baseline to the earliest of 1) death due to EHM 2) other death or 3) end of study (2019/12/31). EHM mortality rates were computed, and incidence curves were generated for each group. To adjust for differences in baseline characteristics, we estimated the inverse probability of treatment weights (IPTW). We used IPTW-weighted multivariable subdistributional hazards model adjusting for competing risk and confounders.

**Results:** Study population included 10, 694 treated (10, 254 SVR, 440 no-SVR) and 10, 694 untreated individuals. People who never received treatment had the highest EHM mortality rate, with 29.4 per 1, 000 person-years of follow-up (PYFU) (95% confidence interval [CI] 27.2–31.8). Among those who received DAA treatment, those who didn't have SVR had an EHM mortality rate of 25.3 per 1, 000 PYFU (95% CI 16.7–38.5 per 1, 000 PYFU). Those who had SVR had the lowest EHM mortality rate, with 5.9 per 1, 000 PYFU (95% CI 5.0–6.9 per 1000 PYFU). Figures show the 5-year (A) survival probability and (B) cumulative incidence curves for deaths related to EHM. In the multivariable model, the treated and SVR group had the greatest reduction in EHM mortality (adjusted hazard ratio [aHR] 0.16, 95% CI 0.13–0.20), followed by the treated and no-SVR group (aHR 0.57, 95% CI 0.34–0.94) compared to the untreated group. Older age and history of other comorbid conditions including ischemic heart disease, heart failure, hypertension, end-stage renal disease, diabetes mellitus, cirrhosis were associated with increased risk of EHM-related mortality.

## POSTER PRESENTATIONS

Figure:

**Conclusion:** Virologic cure of HCV following DAA treatment was associated with a significant reduction in mortality due to extrahepatic manifestations, with a 85% reduction in EHM mortality associated with SVR. This highlights the crucial need of providing diagnosis and treatment for people living with HCV infection to reduce extrahepatic mortality.

### PO-2836

#### Higher all-cause mortality in individuals living with HIV cured of HCV by direct-acting antivirals compared to HIV mono-infection despite controlled HIV: Results from the ANRS-CO4 FHDH cohort

Maria Requena<sup>1</sup>, Sophie Grabar<sup>1,2,3</sup>, Dominique Costagliola<sup>1</sup>, Karine Lacombe<sup>1,4</sup>. <sup>1</sup>Sorbonne Université, INSERM, Institut Pierre Louis d'Épidémiologie et de Santé Publique (IPLSP), Paris, France; <sup>2</sup>Hôpital Cochin, Unité de Biostatistiques et Epidémiologie, Paris, France; <sup>3</sup>Université de Paris Descartes, Paris, France; <sup>4</sup>Hôpital Saint-Antoine, Service de maladies infectieuses et tropicales, Paris, France  
Email: maria.requena@iplsp.upmc.fr

**Background and aims:** Hepatitis coinfection contributes to the leading causes of mortality among people who live with HIV (PLWH). Since 2014, direct-antiviral agents (DAAs) have enabled a 95% cure rate and decreased hepatic complications in mono-infected patients with Hepatitis C virus (HCV). This study aimed to compare all-cause mortality in PLWH achieving HIV viral suppression (<200 copies/ml) cured of HCV by DAAs to all-cause mortality in virally suppressed HIV mono-infected individuals of the nationwide ANRS-CO4 French Hospital HIV Database (FHDH) cohort.

**Method:** Cured HCV PLWH with controlled HIV viral load who started DAAs between September 2013 and September 2018 were included. They were matched on age ( $\pm 5$  years), gender, HIV transmission route (men who have sex with men -MSM- intravenous drug user -IVDU- or other), AIDS status, and BMI ( $\pm 1$ ) to up to 10 HIV mono-infected patients with controlled HIV viral load, followed at the index date (date of HCV cure). Multivariable Cox proportional hazards models with robust variance estimates were used to compare mortality in

both groups accounting for age, gender, HIV transmission route, AIDS status, year of first HIV serology, CD4 nadir, and BMI.

**Results:** 3, 574 PLWH cured of HCV by DAAs and 28, 846 mono-infected PLWH were included. Median follow-up time was 2.0 years in DAA cured, interquartile range [1.1; 3.7], and 2.2 years [1.3; 2.9] in mono-infected PLWH. Median age was 52.6 years [47.2; 55.9] and 52.0 years [48.4; 56.3]; 2, 649 (74.1%) and 22, 085 (76.6%) were men, respectively. In DAA cured participants, 311 (8.7%) had cirrhosis. One hundred and ten deaths occurred in the DAA cured PLWH group and 384 in the HIV-mono-infected PLWH group, with respective three-year survival estimates of 96% (95% CI 95–97) and 98% (95% CI 98–98). HCV past coinfection was associated with a higher risk of all-cause death (hazard ratio HR = 1.72, 95% CI 1.04–2.84), as were IVDU (HR = 1.76, 95% CI 1.02–3.06) and CD4 nadir <200 cells/ml (HR = 2.83, 95% CI 1.40–5.71). The risk of death with cured HCV co-infection was higher after 18 months of follow-up (relative risk 0–18 months = 1.65, 95% CI 1.44–1.88, relative risk 18–36 months = 3.08, 95% CI 2.76–3.43).

**Conclusion:** Despite HCV cure and HIV viral suppression, HCV-coinfected PLWH cured by DAAs are at higher risk of all-cause mortality than mono-infected PLWH, even after controlling for CD4 nadir. The risk is increased after 18 months of follow-up.

### PO-2946

#### Patients with cirrhosis show an improvement in dynamic liver function following the eradication of hepatitis C virus with direct acting antivirals

Jibran Mecci<sup>1</sup>, Polychronis Kemos<sup>1</sup>, Graham Foster<sup>1</sup>. <sup>1</sup>Barts Health NHS Trust, Barts Liver Centre, London, United Kingdom  
Email: alij16@hotmail.com

**Background and aims:** The introduction of direct acting antiviral (DAA) therapy in the treatment of hepatitis C virus (HCV) has revolutionised care for those with cirrhosis. Fibrosis and portal hypertension improve post eradication however, functional improvement has yet to be determined with reports of MELD score not showing overall improvement. We used indocyanine green (ICG) excretion to resolve this uncertainty.

**Method:** This was a prospective, longitudinal, observational trial, looking at a single cohort of patients with hepatic C cirrhosis treated at Bart's Health NHS trust. We included adult patients with cirrhosis (Fibroscan >11.5 kPa or APRI score >2 or liver biopsy or imaging report of cirrhosis) who were starting DAA treatment. Those unable to consent, pregnant or allergic to ICG were excluded. ICG excretion is solely by the liver and was measured by near infra-red spectroscopy (LiMON, PULSION medical systems, Munich, Germany) and stated as ICG retention at 15 minutes (ICGR15), with lower values showing better function. Data was captured at baseline, 4 weeks ( $\pm 2$  weeks) post treatment and 1 calendar year ( $\pm 2$  weeks). Correlations were determined and then inserted into a repeated measures analysis to determine to adjust for subject variance. Area under the curve (AUROC) estimation determined a cut-off value. The Declaration of Helsinki was adhered to (NCT02782247).

**Results:** Of the 52 patients willing to be enrolled, 43 had 2 or more investigations. Median age was 54 years old and most were male (58.1%). A history of heavy alcohol intake was reported in 27.2% with 25.6% being diabetic. Most cases were genotype 3 (58.1%) and Childs-Pugh A (88.5%) at enrolment. Fixed effects modelling showed a similar pattern though less marked with 5.38% initial improvement and 6.95% overall ( $p < 0.001$ ,  $R^2$  94.3%). Fibroscan readings improved by 6.53 kPa at 1 year ( $p < 0.001$ ). We found an ICGR15 of 24.7% predicted an acceptable value of 15% at 1 year (AUROC: 0.88, 95% C.I: 0.68–1.00,  $p < 0.001$ , sensitivity = 83%, specificity = 93%).

Figure: A line graph for the median percentage of ICG remaining after 15 minutes (ICG15) for all subjects over the course of the year with 95% confidence intervals, displayed.

**Conclusion:** We have demonstrated an improvement in dynamic liver function in patients with cirrhosis following HCV eradication.

## Viral hepatitis C: Therapy and resistance

### PO-51

#### Aiming for HCV elimination-Optimizing DAA therapy by characterisation of patients lost to follow-up (LTFU) in a large real world setting-Data from the German Hepatitis C-Registry (DHC-R)

Figure: (abstract: PO-51): Baseline characteristics of interest and results with significant differences in regression analysis

## POSTER PRESENTATIONS

(DAA) leads to HCV-cure in more than 90% of patients chronically infected. Simplifying all aspects associated with DAA treatment may facilitate access in particular for vulnerable patient groups. To characterise patients who went lost-to-follow-up (LTFU) before end of treatment (EOT) might help to identify those in need for alternative access strategies to DAA therapy.

**Method:** The DHC-R (German Hepatitis C-Registry) is a national multicentre real-world registry currently including about 17,700 patients recruited by more than 250 centres. Data were analysed as of Jan 01, 2020. The present analysis of patients with LTFU before and after EOT in comparison to patients with data on sustained virological response (SVR) 12/24 weeks after EOT (modified Intention-to-treat population, mITT) is based on 7,898 patients (ITT) treated with GLE/PIB, SOF/LDV, SOF/VEL, SOF/VEL/VOX and GZR/EBR ( $\pm$  ribavirin). LTFU before EOT was defined as reported lost before treatment was ended as scheduled, LTFU after EOT as lost after a full course of therapy without SVR12/24 data.

**Results:** In total, 11.5% (908/7,898) of the patients were reported as lost: 432 patients were lost before and 476 patients were lost after EOT. Thus, 6,990 were included in the mITT analysis. Baseline characteristics of interest are given in Table 1. The overall SVR rates were 86% (6,823/7,898) and 98% (6,823/6,990) in the ITT and mITT analysis, respectively. In multivariate regression analysis (Figure), being male or of younger age and having a history of drug abuse and/or an opioid substitution therapy (OST) has been associated with a higher risk of LTFU before and after EOT, HIV/HCV co-infected and patients with psychiatric disorders do have a lower risk of LTFU.

**Conclusion:** It is known that patients lost after EOT have a high probability of achieving SVR. In this analysis, we identified patient groups with a higher risk of LTFU before end of treatment. In the setting of good tolerability and high effectiveness of DAA therapy, alternative treatment approaches tailored to the target group such as less intense monitoring or in contrast, directly observed treatment (DOT) should be considered.

### PO-81

#### Economic consequences of anti-HCV treatment of patients diagnosed through screening in Italy: a prospective modeling analysis.

Loreta Kondili<sup>1</sup>, Andrea Marcellusi<sup>2,3</sup>, Claudia Simonelli<sup>2</sup>, Francesco Saverio Mennini<sup>2,3</sup>. <sup>1</sup>*Istituto Superiore di Sanità, Center for Global Health, Rome, Italy;* <sup>2</sup>*Center for Economic and International Studies: Economic Evaluation and HTA (CEIS-EEHTA);* <sup>3</sup>*Institute of Leadership and Management in Health, Kingston Business School*  
Email: loreta.kondili@iss.it

**Background and aims:** The World Health Organization (WHO) defined prevention and treatment targets for the elimination of the hepatitis C virus (HCV) as a public health threat by 2030. In Italy, the European country with the highest disease burden, challenges remain to achieve this goal, considering the significant portion of HCV-infected patients that are undiagnosed. Our aim is to evaluate the cost-consequences of the investment in anti-HCV treatment by the Italian National Health System (NHS) for patients that will be newly diagnosed through active HCV screening, to be implemented in Italy starting from 2020.

**Method:** A previously published Markov model was used to estimate the disease complications avoided and the associated savings over 20 years to treat a standardized population of 1,000 HCV-infected patients diagnosed as a result of the approved screening. Fibrosis stage and genotype distributions, treatment effectiveness, disease progression probabilities were obtained from the literature. Real-life medical expenses for disease management were estimated starting from a representative cohort of HCV treated patients in Italy (Italian Platform for the Study of Viral Hepatitis Therapies -PITER). The breakeven point in time (BPT) was defined as the time in years required for the initial investment in treatment to be recovered in terms of cumulative costs saved.

**Results:** For 1,000 standardized treated patients diagnosed through an active HCV screening, over a 20-year time horizon there are 589 avoided events of progression which are associated to €68.31 million net savings accrued by the Italian NHS. The initial investment in treatment is recouped in the form of savings from disease complications avoided in 4.8 years.

**Conclusion:** Investment in treatment of newly diagnosed patients will bring a significant reduction in disease complications which is associated to great economic benefits. This type of action can reduce the infection rate and clinical and economic disease burden of HCV infection in Italy, necessary to achieve the WHO elimination goals.

### PO-153

#### Prevalence and origin of rare HCV Genotypes in DAA-naïve and DAA-experienced patients

Julia Dietz<sup>1</sup>, Christiana Graf<sup>1</sup>, Peter Buggisch<sup>2</sup>, Beat Müllhaupt<sup>3</sup>, Kerstin Port<sup>4</sup>, Kai-Henrik Peiffer<sup>1</sup>, Georg Dultz<sup>1</sup>, Christophe Moreno<sup>5</sup>, Thomas Berg<sup>6</sup>, Christoph Berg<sup>7</sup>, Stefan Zeuzem<sup>1</sup>, Christoph Sarrazin<sup>1,8</sup>. <sup>1</sup>*Goethe University Hospital, Department of Internal Medicine I, Frankfurt am Main, Germany;* <sup>2</sup>*Institute for Interdisciplinary Medicine IFI, Hamburg, Germany;* <sup>3</sup>*Swiss Hepato-Pancreato-Biliary Center and Department of Gastroenterology and Hepatology, University Hospital Zürich, Zürich, Switzerland;* <sup>4</sup>*Department of Gastroenterology, Hepatology and Endocrinology, Medizinische Hochschule Hannover, Hannover, Germany;* <sup>5</sup>*Department of Gastroenterology, Hepatopancreatology and Digestive Oncology, CUB Hôpital Erasme, Université Libre de Bruxelles, Brussels, Belgium;* <sup>6</sup>*Section of Hepatology, Department of Gastroenterology and Rheumatology, University Hospital Leipzig, Leipzig, Germany;* <sup>7</sup>*Department of Gastroenterology, Hepatology, and Infectiology, University Hospital Tübingen, Tübingen, Germany;* <sup>8</sup>*St. Josefs-Hospital, Wiesbaden*  
Email: julia.dietz@em.uni-frankfurt.de

**Background and aims:** Treatment of chronic hepatitis C virus (HCV) infection with direct acting antivirals (DAAs) is highly effective and high SVR (sustained virologic response) rates make global HCV eradication feasible. However, second generation DAAs are not available in all countries. Studies showed that rare HCV genotypes (GT) exist in certain countries and are associated with lower SVR rates. This study investigated the prevalence of rare HCV GT and resistance-associated substitutions (RASs) among European DAA-naïve and DAA-failure patients.

**Method:** The European resistance database contains samples from 7300 patients, 4499 of whom were DAA-naïve and 1258 had failed to an IFN-free DAA treatment. NS3, NS5A and NS5B population sequencing was conducted to determine the HCV GT and RASs conferring a >2-fold increased DAA susceptibility were analyzed.

**Results:** In total, rare HCV GT were detected in 2% (72/4499) of DAA-naïve patients and 5% (57/1258) of DAA failures. The frequencies of rare GT1 (1c, 1e, 1g, 1h, 1i, 1p) and GT6 (6a, 6e, 6f, 6m, 6n, 6r) were comparable in DAA-naïve (GT1, 17%; GT6, 15%) and DAA-experienced patients (GT1 and GT6, 11% each). In contrast, rare GT2 (2i, 2k, 2l, 2m) and GT5a were less common among DAA failures (4% each) compared to DAA naïve patients (15% each). Interestingly, the frequencies of rare GT3 (3b, 3g, 3h, 3i, 3k) and GT4 (4b, 4c, 4f, 4m, 4n, 4o, 4r, 4v) were higher in DAA failures (GT3, 25%; GT4, 47%) compared to DAA-naïve patients (GT3, 14%; GT4, 25%). Among DAA failures, rare HCV GT were more common after first generation DAA regimens (LDV/SOF, DCV/SOF, GZR/EBR, 3D) (79%, 45/57) compared to second generation pangenotypic regimens (VEL/SOF, G/P) (21%, 12/57). With regard to RASs, characteristic NS5A patterns were particularly evident in patients with rare GT4 (L28M, M31L/V) and rare GT3 (A30 K, L31M) and Y93H was rare in both GT. Patients with rare GT1, GT2 or GT4 mainly originated from sub-Saharan Africa, those with rare GT3 from India or Pakistan, those with GT5a from South Africa and patients with rare GT6 came from South-East Asia.

**Conclusion:** Rare HCV GT were detected in 2% of DAA-naïve and 5% of DAA failure patients. Rare HCV GT were more frequent after failure to

first generation DAA regimens compared to second generation regimens. Patients originated mainly from Africa or South Asia and the first-generation DAAs available in these countries may not be effective enough to achieve the goals of global HCV elimination.

**PO-377**

**Risk of multiple drug-drug interactions (DDIs) in HCV patients receiving pangenotypic DAAs (pDAAs): A complex drug interaction scenario first time evaluated in German patients**

Tim Umland<sup>1</sup>, Andreas Hintz<sup>1</sup>, Gero Niess<sup>2</sup>, Mehtap Guendogdu<sup>2</sup>, Frank Tacke<sup>3</sup>. <sup>1</sup>Alexander Apotheke, Hamburg, Germany; <sup>2</sup>Gilead Sciences GmbH, Planegg, Germany; <sup>3</sup>Charite-Campus Mitte Medizinische Klinik m.S. Hepatologie und Gastroenterologie, Berlin, Germany

Email: frank.tacke@charite.de

**Background and aims:** Previous studies have evaluated the risk of DDIs in HCV patients receiving pangenotypic DAAs (pDAAs), but all based on given drug pair interactions (DAA and one comedication). However, none has considered that HCV patients take multiple comedications and the presence of multiple DDIs can exist in the same patient involving more than one comedication. Our aim was to describe for the first time the prevalence of this situation and the linked risk of DDIs.

**Method:** Data were obtained using the German IMS LRx database (IQVIA) covering about 80% of statutory health insurance prescriptions. Patients (pts) with HCV therapy between Nov 2019 and Oct 2020 were included in the analysis. Comedication was evaluated and potential DDIs and contraindications regarding pangenotypic DAAs prescribed in HCV therapy (i. e. Sofosbuvir/Velpatasvir [SOF/VEL], and Glecaprevir/Pibrentasvir [GLE/PIB]) were assessed using the University of Liverpool Hep Drug Interactions database. This study focused on evaluating patients receiving more than one comedication linked to risk of DDIs and the pharmacokinetic outcome of the different identified DDIs, classified in: increase in comedication (linked to safety/tolerability issues), increase in DAA (potential safety/tolerability issue), and decrease in DAA level (potential efficacy issue).

**Results:** Comedication was analyzed for 4, 950 HCV patients, 3, 154 treated with GLE/PIB and 1, 796 with SOF/VEL. The proportion of males and median age were similar in both groups: 32% vs 31%, and 46 y vs 48 y, respectively. Overall, 173 (3.5%) patients treated with pDAAs received ≥2 comedications showing risk of DDIs, concretely: two (116), three (47), four (7), and five (3) comedications.

For GLE/PIB, 102 (3.2%) patients received ≥2 comedications with DDI risk: two (74), three (23), four (4), and five (1) comedications. For SOF/VEL, 71 (4%) patients received ≥2 comedications with DDI risk: two (42), three (24), four (3), and five (2) comedications. In terms of the outcome; for GLE/PIB, 39 (1.2%) patients resulted in a risk of DAA concentration decrease, 20 (0.6%) in an increase in comedications, and 2 (0.06%) in an increase in DAA concentration. There were 2 patients receiving each one 3 concomitant drugs linked to a decrease of DAA, but none contraindicated. For SOF/VEL, 18 (1.0%) patients resulted in a risk of DAA decrease, 11 (0.6%) in an increase in comedications, and none in an increase in DAA, and there were no patients receiving 3 or more concomitant drugs linked to a decrease in the DAA.

**Conclusion:** In Germany, the percentage of HCV patients treated with pDAAs and ≥2 comedications showing risk of DDIs is 3.5%. The most frequent outcome resulted from the multiple DDI context was a decrease in the DAA, having similar risk both pDAA.

**PO-468**

**Direct antivirals can achieve a cure in all patients with chronic hepatitis C due to genotype 5. A French multicentre study.**

Email: cnicolas@chu-clermontferrand.fr

**Background and aims:** Genotype 5 (GT5) is found mainly in South and East Africa and in restricted areas of Belgium, France, Spain, Greece, Canada, Brazil, Syria... Prevalence of HCV GT5 in France is 2% and 14% in our area from central France. Migration from Syria can increase the prevalence of this genotype in European countries. As there are few data published on the response to treatment of these patients with new drugs. Our study aimed to evaluate the sustained virological response (SVR) in patients infected with HCV GT5 treated with direct-acting antivirals (DAA).

**Methods:** A cohort of 139 patients with HCV GT5 from 13 hospitals (central France = 101, other hospitals = 38) received all-oral DAA for 8, 12 or 24 weeks from 2014 to 2020. These patients were treated either in clinical trials (n = 39) or according to international guidelines (n = 100). The SVR was defined as an HCV RNA below the lower limit of quantification (LLOQ) 12 weeks after the end of treatment (SVR12).

**Results:** Baseline characteristics were: mean age 66 years, sex ratio 0.7 (M/F), fibrosis score: 62% ≥F2 (86/139) including 24% F4 (33/139), pre-therapeutic viremia >800,000 UI/ml: 65% (90/139) and ALT higher than the upper limit of normal: 54% (75/141). The average treatment duration was 12 weeks. Distribution of patients according to drug combinations was: sofosbuvir (SOF)/ledipasvir (LDV) ± ribavirine (RBV) 67, SOF/VEL (velpatasvir) 35, glecaprevir (GLE)/pibrentasvir (PIB) 16, SOF/DCV (daclatasvir) ± RBV 13, SOF/VEL/VOX (voxilaprevir) 4, SOF/SMP (simeprevir) 1 and grazoprevir (GZR)/elbasvir (EBR)/RBV 1. Seventy patients out of 139 were treatment-naïve (50%) and 69 had been treated with interferon (IFN) therapy (50%) (48 relapsers and 21 non-responders). Thirty-nine patients out of 139 were included in clinical trials (28%). At the end of treatment, 99% (100/101) of patients had HCV RNA <LLOQ for those treated for 12 weeks (W), 100% (13/13) for 8 weeks and 100% (8/8) for 24 weeks. The overall SVR12 result was 98% (136/139). Relapse occurred in 2 patients (SOF/DCV, SOF/LDV). Their profiles were different but both patients had prior treatment with IFN. One patient had been successfully retreated with the same DAAs (SOF/LDV) plus RBV for 24 weeks (instead of 12 weeks) and another had refused a new treatment. One patient had on-treatment virologic failure (SOF/VEL/VOX) between W8 and end of treatment (W12). No resistance to the DAAs received had been found (hepatitis C national reference center). The patient was naïve and had a good DAA adherence. A second 12-week SOF/VEL/VOX treatment resulted in a cure.

## POSTER PRESENTATIONS

**Conclusion:** A high SVR12, 99% (138/139) in intention to treat and 100% (138/138) per protocol, was achieved in HCV GT5 patients treated with a DAA-regimen. This cohort shows that the combination treatments of SOF/LDV, SOF/VEL and GLE/PIB are very efficient in patients infected with HCV GT5.

### PO-773

#### Frequency and impact of potential multiple drug-drug interactions (DDIs) associated with pangenotypic direct-acting antivirals in patients receiving opioid substitution therapy

Tim Umland<sup>1</sup>, Andreas Hintz<sup>1</sup>, Gero Niess<sup>2</sup>, Mehtap Guendogdu<sup>2</sup>, Frank Tacke<sup>3</sup>. <sup>1</sup>Alexander Apotheke, Hamburg, Germany; <sup>2</sup>Gilead Sciences GmbH, Planegg, Germany; <sup>3</sup>Charite-Campus Mitte Medizinische Klinik m.S. Hepatologie und Gastroenterologie, Berlin, Germany  
Email: gero.niess@gilead.com

**Background and aims:** Pangenotypic direct-acting antivirals (pDAA) are an essential prerequisite in reaching the global goal of eliminating hepatitis C virus (HCV) infections by 2030. Treatment of HCV infections in current and former people who inject drugs (PWID) is a cornerstone of this effort. However, previous studies have shown that polypharmacy and potential drug-drug-interactions (DDI) are issues of concern in treating patients who receive opioid substitution therapy (OST pts). The aim of the present analysis was to evaluate the frequency, type and possible consequences of potential multiple DDI, i.e. more than 2 concurrent DDI, of pDAA with comedication in a large nationwide cohort of OST pts.

**Method:** Data were obtained using the German IMS LRx database (IQVIA) covering about 80% of statutory health insurance prescriptions. Anonymised prescription information was extracted for the time period from November 2019 to October 2020. In OST pts, the frequency of potential multiple DDI between prescribed comedications and Sofosbuvir/Velpatasvir (SOF/VEL) and Glecaprevir/Pibrentasvir (GLE/PIB), respectively, was evaluated on the basis of the University of Liverpool Hep Drug Interactions database. Comedication was analysed according to ATC classes and individual substance levels. Clinical outcomes related to potential multiple DDI were evaluated for each substance.

**Results:** In total, 95,243 OST pts were included in the analysis. In 52,889 patients, at least one comedication that could be evaluated for DDI was documented. For the majority of these patients, no potential DDI were observed with SOF/VEL (57.9%) or GLE/PIB (47.6%). About one third received comedication with only one potential DDI (SOF/VEL: 27.2%; GLE/PIB: 31.1%). The total number of patients with at least two potential DDI related to pDAA was lower for SOF/VEL (n = 7, 883; 14.9%) compared to GLE/PIB (n = 11, 242; 21.3%). Almost twice as many patients had three or more potential DDI related to GLE/PIB compared to SOF/VEL (8.0% vs. 4.4%). Possible consequences of DDI include a decreased antiviral efficacy or an increased risk of adverse drug reactions (ADRs).

**Conclusion:** Multiple DDI with pDAA are likely to occur in a subset of OST patients. Compared to SOF/VEL, GLE/PIB is more frequently associated with potential multiple DDI in this population. Since the relevance of clinical outcomes may differ, possible consequences of DDI should be evaluated carefully prior to initiation of pDAA treatment in OST pts.

### PO-815

#### Efficacy and safety of 8- or 12 weeks of glecaprevir/pibrentasvir in patients with signs of portal hypertension

Robert Brown<sup>1</sup>, Michelle Collins<sup>2</sup>, Amanda Emmett<sup>2</sup>, Andrew Topp<sup>2</sup>, Margaret Burroughs<sup>2</sup>, Rosa Ferreira<sup>2</sup>, Jordan Feld<sup>3</sup>. <sup>1</sup>Center for Liver Disease and Transplantation, Weill Cornell Medical College, New York, United States; <sup>2</sup>AbbVie Inc., North Chicago, United States; <sup>3</sup>Toronto Centre for Liver Disease, University Health Network, University of Toronto, Toronto, Canada  
Email: rsb2005@med.cornell.edu

**Background and aims:** High efficacy and safety of 8-week glecaprevir/pibrentasvir (G/P) therapy was seen in hepatitis C (HCV)-infected, treatment-naïve (TN), compensated cirrhosis (CC) patients in EXPEDITION-8. However, the efficacy and safety of 8- or 12 weeks of G/P in patients with signs of portal hypertension (PHT) continues to be an area of exploration.

**Method:** Data for TN, CC, HCV GT 1–6 patients were derived from ad-hoc subgroup analyses of the EXPEDITION-8 study and from 9 pooled, phase II/III studies for patients receiving 8- and 12 weeks of G/P, respectively. Signs of PHT included at least one of the following at baseline: FibroScan  $\geq 20$  kPa, platelets  $< 100 \times 10^9/L$ , or medical history consistent with PHT. The primary efficacy end point was SVR12; adverse events consistent with hepatic decompensation were assessed.

**Results:** Of 343 patients receiving 8 weeks of G/P, 208 were identified with signs of PHT; out of 392 patients in the 12-week group, 224 PHT patients were identified. Baseline characteristics and delineation of patients by inclusion criteria are provided in the Table. In 8- vs 12 weeks, SVR12 was 97.6% (203/208) vs 98.7% (221/224) in the intention-to-treat analysis. Eight patients did not achieve SVR12; 3 experienced virologic failures (one on 8-week therapy), 4 were lost to follow-up and 1 discontinued therapy. Three cases of hepatic decompensation were reported: 2 nonserious cases of ascites (1 each in 8- vs 12 weeks) and 1 serious case of esophageal variceal bleeding in the 12-week group; none were assessed as related to G/P or led to discontinuation of therapy.

Table: Baseline demographics and inclusion criteria in portal hypertension patients receiving 8- and 12-weeks of glecaprevir/pibrentasvir<sup>a</sup>

	8-Weeks N = 208 n (%)	12-Weeks N = 224 n (%)
Male	136 (65.4)	127 (56.7)
Age, years, median (range)	57 (32–84)	59 (28–88)
Genotype		
1a/1b	64 (30.8)/75 (36.1)	34 (15.2)/84 (37.5)
2	15 (7.2)	47 (21.0)
3	43 (20.7)	42 (18.8)
4-6	11 (5.3)	17 (7.6)
FibroScan	149 (43.4) <sup>b</sup>	159 (40.6) <sup>c</sup>
$\geq 20$ kPa		
Platelets $< 100 \times 10^9/L$	80 (23.3) <sup>b</sup>	102 (26.0) <sup>c</sup>
Medical history consistent with PHT	70 (20.4) <sup>b</sup>	53 (13.5) <sup>c</sup>

<sup>a</sup>ITT population

<sup>b</sup>N = 343

<sup>c</sup>N = 392

ITT, intention-to-treat; PHT, portal hypertension

**Conclusion:** Eight weeks of G/P was as effective as 12 weeks of therapy in HCV patients with signs of PHT. Adverse events related to hepatic decompensation were uncommon in both groups. Analysis is ongoing.

**Background and aims:** SH229 is a novel potent, pan-genotypic HCV NS5B polymerase inhibitor in development for the treatment of chronic HCV infection. Data from a phase 2 study showed that SH229 plus daclatasvir was well tolerated and highly effective for Chinese patients infected with HCV, with a SVR12 rate of 90.2%, 95.2%, and 100% in patients receiving daclatasvir at a standard dose of 60 mg daily plus SH229 at a dose of 400, 600, or 800 mg, respectively. Here, we performed a phase 3 study to confirm the efficacy and safety of SH229 in combination with daclatasvir in Chinese patients with HCV infection.

**Method:** This single-arm, open-label, phase 3 study was conducted at 35 study centers in China. All patients with chronic HCV infection received 600 mg SH229 tablets plus 60 mg daclatasvir tablets once daily for 12 weeks. Patients were followed up at post-treatment weeks 4 and 12, and those who achieved SVR12 were followed up at post-treatment week 24. Plasma samples were collected for HCV RNA quantification in a central laboratory using Roche COBAS® AmpliPrep®/COBAS® TaqMan® HCV v2.0 test, which has a reported

lower limit of quantification (LLOQ) of 15 IU/ml. The primary end point was SVR12.

**Results:** A total of 327 patients were enrolled in the study, and 326 patients received at least one dose of SH229 plus daclatasvir, including 169 (51.8%) with HCV genotype 1, 95 (29.1%) with HCV genotype 2, 22 (6.7%) with HCV genotype 3, and 40 (12.3%) with genotype 6. 12.6% of patients had compensated cirrhosis at baseline, 7.1% failed prior interferon-based therapy, and 83.1% had the IL28B CC allele. The median baseline HCV RNA was 6.2 log<sub>10</sub> IU/ml. 99.4% of patients had pre-existing NS5A and/or NS5B resistance-associated substitutions (RASs) at baseline. Of the 326 patients who received at least one dose of study drugs, 321 (98.5% [95% CI 96.5%-99.5%]) achieved SVR12, which was superior to a historical SVR rate of 88% (p < 0.0001). The SVR12 rates was 100% (3/3) among patients with HCV genotype 1a, 98.8% (164/166) with genotype 1b, 100% (95/95) with genotype 2a, 93.8% (15/16) with genotype 3a, 100% (6/6) with genotype 3b, 97.1% (33/34) with genotype 6a, and 83.3% (5/6) with genotype 6n. The SVR12 rates were similar regardless of most baseline characteristics, such as viral load, prior HCV treatment history, IL28B genotype, and the presence of pre-existing RASs. The most common adverse event (≥10%) was only hypercholesterolemia. Serious adverse events were reported in 25 (7.7%) patients, none of which was judged to be related to SH229 plus daclatasvir treatment. The majority of adverse events were mild to moderate in intensity.

**Conclusion:** Treatment with the pan-genotypic regimen of SH229 plus daclatasvir for 12 weeks was highly effective and safe in Chinese patients infected with HCV genotype 1, 2, 3, or 6, suggesting this regimen could be a promising option for HCV treatment in China irrespective of genotype.

PO-1307

**High rate of early HCV reinfection among PWID with high-risk practices and re-treatment efficacy**

Sabela Lens<sup>1,2</sup>, Anna Miralpeix<sup>1</sup>, Mont Gálvez<sup>1</sup>, Elisa Martró<sup>3,4,5</sup>, Noemi Gonzalez<sup>6</sup>, Sergio Rodriguez-Tajes<sup>1,2</sup>, Zoe Mariño<sup>1,2</sup>, Veronica Saludes<sup>3,4,7</sup>, Juliana Reyes<sup>4,7</sup>, Xavier Major<sup>8</sup>, Joan Colom<sup>8</sup>, Xavier Forns<sup>1,2</sup>. <sup>1</sup>Liver Unit, Hospital Clínic Barcelona, IDIBAPS, University of Barcelona, Spain; <sup>2</sup>Centro de Investigación Biomédica en Red de Enfermedades Hepáticas y Digestivas (CIBEREHD), Spain; <sup>3</sup>Institut d'Investigació Germans Trias i Pujol (IGTP), Microbiology Department, Badalona, Spain; <sup>4</sup>Center for Epidemiological Studies on HIV/AIDS and STIs of Catalonia (CEEISCAT), Spain; <sup>5</sup>Centro de Investigación Biomédica en Red de Epidemiología y Salud Pública, Spain; <sup>6</sup>REDAN La Mina. Parc de Salut Mar, Barcelona, Spain; <sup>7</sup>Centro de Investigación Biomédica en Red de Epidemiología y Salud Pública (CIBERESP), Spain; <sup>8</sup>Program on Substance Abuse. Public health Agency of Catalonia (ASPCAT). Government of Catalonia, Spain  
Email: slens@clinic.cat

**Background and aims:** Reported HCV reinfection rates in people who inject drugs (PWID) after antiviral therapy ranges between 2 and 10/100 persons/year. These differences mainly reflect heterogeneity in study populations with regards to risk behaviours. We analyzed the reinfection rate, associated factors and retreatment efficacy in PWID with ongoing high-risk practices in a harm reduction center (HRC) in Barcelona.

**Method:** HCV point-of-care screening for HCV-RNA (GeneXpert®), liver stiffness measurement (LSM), antiviral therapy delivery and sustained virological response (SVR) assessment were performed at the HRC. Dried blood spot was collected at baseline, FU12 and every 6 months in order to differentiate relapse vs reinfection by genotyping and phylogenetic analysis. Adherence was assessed by daily/weekly visits. The program included educative and harm-reduction interventions.

**Results:** 919 active drug injectors were prospectively enrolled. Of those accepting screening (386, 42%), 212 (55%) were HCV-RNA positive. Of the 168 (79%) individuals who already started treatment,

## POSTER PRESENTATIONS

median age was 42 years, 86% were male, 45% foreigners, 33% homeless, 73% unemployed, 20% HIV+ and 62% had been imprisoned before. Advanced fibrosis (LSM>9.5 kPa) was present in 12%. In regard to high-risk practices, 72% were daily injectors at enrolment, 30% reported either syringe or paraphernalia sharing and 38% unprotected sexual relationships. All patients received a pangenotypic regimen. ITT and per protocol SVR12 were 61% (89/146) and 70% (87/123), respectively; only 5 patients had a relapse. There were 39 (32%) reinfections after a median follow-up of 14 months with most cases 28/39 (72%) occurring as early as FU12. The most frequent genotypes at reinfection were 1a and 3a (44%). Patients with reinfection were more frequently homeless (38% vs 18%), HIV+ (41% vs 10%), shared syringes (29% vs 11%) or had been imprisoned during treatment (18% vs 4%); all  $p < 0.05$ . Of those re-treated (30/37), 83% received the same antiviral regimen. At FU12 after re-treatment, a new reinfection was documented in 4/17 patients (23%), while the rest achieved SVR (Figure).

Figure:

**Conclusion:** This patient-centered circuit demonstrates that HCV treatment can be successfully delivered to active PWID with high-risk practices. However, the early high reinfection rate emphasizes the role of harm reduction interventions and prompt re-treatment initiation. Preliminary results of this cohort supports re-treatment strategies with the same antiviral regimen.

### PO-1508

#### Injecting network structure determines the most efficient strategy to achieve Hepatitis C elimination in people who inject drugs

Chloe Brown<sup>1</sup>, Martin Siegle<sup>2</sup>, Mark Wright<sup>3</sup>, Salim Khakoo<sup>1</sup>, Julie Parkes<sup>1</sup>, Rachel Sacks-Davis<sup>4</sup>, Ryan Buchanan<sup>1</sup>. <sup>1</sup>University of Southampton, Southampton, United Kingdom; <sup>2</sup>University of Sussex, Brighton, United Kingdom; <sup>3</sup>University Hospital Southampton, Southampton, United Kingdom; <sup>4</sup>Burnet Institute, Australia  
Email: rmb1d14@soton.ac.uk

**Background and aims:** Transmission of Hepatitis C (HCV) continues via sharing of injection equipment between people who inject drugs (PWID). Network-based modelling studies have produced conflicting results as to whether random treatment is preferable to targeting treatment at PWID with multiple partners. We hypothesise that differences in the modelled injecting network structure produce this heterogeneity, and aim to test how changing network structure affects HCV transmission and treatment effects.

**Method:** We create three different dynamic injecting network structures connecting 689 PWID (UK-net, AUS-net and USA-net) based on published empirical data. HCV within the networks is

transmitted via a susceptible-infected-susceptible model. At 5 years we compare prevalence of HCV in the three networks in three scenarios: 1) with no treatment, 2) with randomly targeted treatment and 3) with treatment targeted at PWID with the most injecting partnerships.

**Results:** Median HCV prevalence at 5 years without treatment differed significantly between the three networks (UK-net 42.8%; AUS-net 38.2%,  $p < 0.0001$ ; USA-net 54.0%,  $p < 0.0001$ ). In the treatment scenarios UK-net showed a clear benefit of targeted treatment (median 5-year prevalence 1.0% vs. 9.6%  $p < 0.0001$ ), AUS-net showed a smaller benefit (0.15% vs. 0.44%,  $p < 0.0001$ ) and USA-net showed no significant difference (29.3% vs. 29.2% random,  $p = 0.0681$ ). In sensitivity analyses, targeted treatment was optimised in low prevalence, moderate treatment coverage conditions whereas random treatment was optimised in low treatment coverage, high baseline prevalence conditions.

Figure: Box plots showing the distribution of HCV prevalence at 5 years from 1000 simulations in each network structure. Random and degree-based targeted ('network') strategies are compared in each network model. The ends of the boxes are the upper and lower quartiles, a horizontal line inside each box marks the median value and the whiskers extend to extreme values at most 1.5 × the inter-quartile range. Outliers beyond this range are indicated by crosses.

**Conclusion:** Network structure determines the transmission rate of HCV in PWID and the most efficient treatment strategy to achieve elimination. In real-world injecting network structures, the benefit of targeting HCV treatment at individuals with multiple injecting partnerships may have been underestimated.

### PO-1533

#### Full dose Sofosbuvir-Velpatasvir in chronic Hepatitis C in patients with end stage renal disease.

Aadil Ashraf<sup>1</sup>, Altaf Shah<sup>1</sup>, Mushtaq Khan<sup>1</sup>, Muzafar Maqsood Wani<sup>2</sup>, Ghulam M. Gulzar<sup>1</sup>, Jaswinder Singh<sup>1</sup>, Shaheena Parveen<sup>1</sup>, Nadeem Ahmad<sup>1</sup>, Hilal Dar<sup>3</sup>, Riffat Abdul Aziz<sup>1</sup>, Neeraj Dhar<sup>1</sup>, Syed Mushfiq Shafi<sup>1</sup>, Avinash Tiwari<sup>1</sup>. <sup>1</sup>Skims Soura, Gastroenterology, Srinagar, India; <sup>2</sup>Skims Soura, Nephrology, Srinagar, India; <sup>3</sup>GMC Baramulla, Medicine, Baramulla, India  
Email: draadilgastro@gmail.com

**Background and aims:** Successful treatment of HCV infection is associated with improved outcome in different clinical domains. Use of Direct Acting Anti Virals (DAAs) has been largely limited to patients with estimated Glomerular Filtration Rate (eGFR)>30 ml/min. This is largely related to paucity of data on safety of safety of Sofosbuvir which has a predominant renal excretion. We conducted study (one

of the largest in country) on efficacy of fixed dose combination of Sofosbuvir-Velpatasvir in End Stage Renal disease patients.

**Method:** The study was conducted in our hospital, SKIMS Soura. Patients with HCV infection (detectable RNA levels) with eGFR <15 ml/min and on hemodialysis were included in the study. All the patients were evaluated for liver disease. Patients with prior exposure to a DAA, portal vein thrombosis or hepatocellular carcinoma were excluded from the study. All the patients received open label combination of sofosbuvir and velpatasvir (400 mg/100 mg). The primary end point was to assess sustained virological response [SVR12] and secondary end point was to assess side effect profile of the patients.

**Results:** A total of 162 patients were enrolled in the study. Mean age in our study population was 43.08 ± 12.08 years. Mean creatinine in our study population was 7.01 ± 2.61 mg/dl. 125 (78%) among them were on regular hemodialysis sessions. 24 (14.8%) had evidence of liver disease with 4 patients having evidence of decompensated liver disease. 142 (87.6%) achieved Viral clearance at 4 weeks of therapy. 160 (98.7%) of the patients achieved End of treatment viral clearance and same number of patients maintained viral clearance 12 weeks after stopping the treatment (SVR12) (Fig. 1). Remaining 2 patients expired (1 due to massive anterior wall myocardial infarction, another patient died of Sepsis secondary to pneumonia). Mean bilirubin before start of therapy was 1.25 ± 1.1 mg/dl and at 12 weeks after therapy was 0.97 ± 0.09 mg/dl (*p* value 0.003). Mean Alanine Transaminase (ALT) before start of therapy was 77.51 ± 99.7 U/L and at 12 weeks after therapy was 37.4 ± 5.77 U/L (*p* value ≤ 0.0001). No significant difference was found in pre- and post-treatment Sr albumin, Sr creatinine, MELD scoring (in liver disease patients) (Fig. 2). The most common adverse effects noticed were nausea (20%), vomiting (18%), head ache (10%), weakness (7%).

Parameter	Baseline	SVR 12	p Value
Bilirubin (mg/dl)	1.25 ± 1.1	0.97 ± 0.09	0.003
ALT (U/L)	77.51 ± 99.7	37.4 ± 5.77	≤ 0.0001
Creatinine (mg/dl)	7.01 ± 2.61	6.9 ± 2.9	0.71
Albumin (mg/dl)	3.19 ± 0.44	3.25 ± 0.37	0.18
MELD	13.88 ± 3.66	12.93 ± 4.46	0.42

Comparison between different parameters.

**Conclusion:** We conclude that treatment with sofosbuvir-velpatasvir is a safe and effective treatment option in HCV infection in end stage renal disease.

**PO-1553**

**Progress towards achieving hepatitis C elimination in the country of Georgia, April 2015-December 2020**

Email: tt@aidcenter.ge

**Background and aims:** In April 2015, with the technical assistance of U.S. CDC and commitment from Gilead Sciences to donate direct acting antivirals (DAAs), Georgia launched the world's first HCV elimination program. Key strategies include nationwide HCV screening, active case finding, linkage to care, decentralized care, provision of treatment for all HCV persons, and effective prevention interventions. The initial goal of the program was to achieve the following targets by 2020: a) diagnose 90% of HCV-infected persons, b) treat 95% of those diagnosed, and c) cure 95% of those treated. We report progress towards elimination targets 5 years into the elimination program.

**Method:** The program collects data on all persons registered with the treatment program. Treatment was provided with Sofosbuvir, Ledipasvir/Sofosbuvir or Velpatasvir/Sofosbuvir-based regimens. Data on persons tested for chronic HCV infection, and those deemed cured by sustained virologic response (SVR) were extracted as of December 2020.

**Results:** As of December 31, 2020 a total of 90,578 persons were diagnosed with chronic HCV infection, representing 60.4% of the estimated 150,000 adults living with HCV in Georgia. A total of 72,811 (80.4%) patients initiated treatment-56.8% of the estimated target population to be treated (128,250). Of the 51,208 patients who were evaluated for SVR, 50,644 (98.9%) tested negative for HCV by PCR, representing 41.6% of the estimated target population cured (121,837).

High cure rates were achieved for all HCV genotypes: 98.9% in genotype 1, 98.9% in genotype 2 and 98.3% in genotype 3, typically the most challenging to treat. Treatment effectiveness was comparable among persons with advanced fibrosis (F3 and F4) with 98.2% achieving SVR, and among patients with mild or no liver fibrosis (≤F2), SVR = 99.1%.

Figure: Hepatitis C care cascade as of December 31, 2020

**Conclusion:** Georgia has made substantial progress towards eliminating hepatitis C, with over 40% of persons with chronic HCV infection identified and cured. Efforts to identify and link to care persons with HCV infection, ensure SVR testing and implement prevention interventions are needed to achieve the elimination goals.

**PO-1872**

**A costing analysis of a state-wide, nurse-led hepatitis C treatment model in prison**

Anna Palmer<sup>1</sup>, Tim Papaluca<sup>2,3</sup>, Mark Stoope<sup>1,4</sup>, Rebecca Winter<sup>1,2</sup>, Alisa Pedrana<sup>1,4</sup>, Margaret Hellard<sup>1,4,5,6,7</sup>, David Wilson<sup>1</sup>, Alexander Thompson<sup>2,3</sup>, Nick Scott<sup>1,4</sup>. <sup>1</sup>Burnet Institute, Disease Elimination Program, Melbourne, Australia; <sup>2</sup>St Vincent's Hospital Melbourne, Department of Gastroenterology, Melbourne, Australia; <sup>3</sup>The University of Melbourne, Department of Medicine, Parkville, Australia; <sup>4</sup>Monash University, School of Population Health and Preventive Medicine, Melbourne, Australia; <sup>5</sup>The Alfred Hospital, Department of Infectious Diseases, Melbourne, Australia; <sup>6</sup>Peter Doherty Institute for Infection and Immunity, Parkville, Australia; <sup>7</sup>The University of Melbourne, School of Population and Global Health, Parkville, Australia  
Email: anna.palmer@burnet.edu.au

**Background and aims:** Hepatitis C is highly prevalent among prisoners. The simplicity of direct-acting antiviral (DAA) treatment

## POSTER PRESENTATIONS

for hepatitis C makes it possible to use novel models of care to increase treatment uptake within prisons. We estimate the average non-drug cost of initiating a prisoner on treatment using real world data from the State-wide Hepatitis Program (SHP) in Victoria, Australia—a coordinated nurse-led model of care.

**Method:** Data were considered from prisoners presenting to the SHP (following antibody-positive diagnosis) during the initial evaluation period, November 2015 to December 2016. All costs associated with the SHP were estimated, including staffing salaries, medical tests, pharmacy costs and overhead costs. DAA costs were excluded as in Australia an unlimited number of treatments are available with costs covered by a federal government risk-sharing agreement with pharmaceutical companies. The average non-drug cost of treatment initiation through the SHP was compared to equivalent costs from primary and hospital-based models of care in the community.

**Results:** The total non-drug cost accumulated by 803 prisoners engaged in the SHP was A\$749,470 (uncertainty range: A\$728,905–794,111). 659/803 were infected, 424/659 had sentences long enough to be eligible for treatment, and 416/424 were initiated on treatment, resulting in an average cost of A\$1,802 (95% CI: A\$1,799–1,841) per prisoner initiated. A protocol change allowing prisoners with short sentences to start treatment reduced the average cost to A\$1,263 (95% CI: A\$1,263–1,287) per prisoner initiating treatment—11% and 56% cheaper than estimated equivalent costs in primary (A\$1,647) and hospital-based (A\$2,840) models of care in the community, respectively.

Figure:

**Conclusion:** Delivering hepatitis C treatment in prison using a nurse-led model of care is cheaper than delivering treatment in the community. These findings provide an economic rationale for implementing coordinated prison-based hepatitis C treatment programs.

### PO-1962

#### Validation of a simple score to identify patients who can safely use protease inhibitor-based therapy for HCV infection

Lisette Krassenburg<sup>1,2</sup>, Joy Peter<sup>3</sup>, Lucy Akushevich<sup>4</sup>, Rael Maan<sup>1</sup>, Alnoor Ramji<sup>5</sup>, Heiner Wedemeyer<sup>6</sup>, Robert De Man<sup>1</sup>, Harry Janssen<sup>2</sup>, Bettina Hansen<sup>2,7</sup>, Adriaan Van der Meer<sup>1</sup>, David R. Nelson<sup>3</sup>, Michael W. Fried<sup>4</sup>, Jordan Feld<sup>2</sup>. <sup>1</sup>Erasmus MC University Medical Center Rotterdam, Department of Gastroenterology and Hepatology, Rotterdam, Netherlands; <sup>2</sup>Toronto General Hospital, University Health Network, Toronto Centre for Liver Disease, Toronto, Canada; <sup>3</sup>University of Florida, Department of Medicine, Gainesville, United States; <sup>4</sup>University of North Carolina at Chapel Hill, Division of Gastroenterology and Hepatology, Chapel Hill, United States; <sup>5</sup>University of British Columbia, Department of Medicine, Division of Gastroenterology, Vancouver, Canada; <sup>6</sup>Hannover Medical School, Department of Gastroenterology, Hepatology and Endocrinology, Hannover, Germany; <sup>7</sup>University of Toronto, Institute of Health Policy, Management and Evaluation, Toronto, Canada  
Email: l.krassenburg@erasmusmc.nl

**Background and aims:** Although highly effective as part of direct-acting antivirals (DAAs), protease inhibitors (PI) have been associated with decompensation in people with cirrhosis. A simple tool to identify patients who can safely take PIs with a very low or no risk of

decompensation would be useful, particularly as treatment expands to primary care. We validated our previously developed score using only baseline albumin and platelets (plt) in the large HCV-TARGET real-world cohort.

**Method:** All patients treated with PI-based therapy in the HCV-TARGET and PRIORITIZE studies were included. Incidence of decompensation (ascites, spontaneous bacterial peritonitis, variceal bleed or encephalopathy) from treatment start to SVR12 was determined in patients with normal baseline bilirubin. Patients were categorized by previously identified thresholds of baseline albumin $\geq$ 38 g/L and plt $\geq$ 130  $\times$  10<sup>9</sup>/L.

**Results:** A total of 2894 patients were included, 2136 without cirrhosis, 590 with compensated cirrhosis and 168 with history of decompensation. Median (IQR) age was 59 (51–64) years, 1689 (58.3%) were male, 108 (3.7%) had Genotype 3 and 126 (4.4%) had prior liver transplantation. In patients with available virological outcomes, SVR was attained in 93.2% (94.5% CI 92.5–96.4) with compensated cirrhosis, 86.5% (95% CI 81.0–91.9) with decompensated cirrhosis and in 95.7% (95% CI 94.8–96.6) non-cirrhotic patients. Overall, 17 (0.6%) patients experienced decompensation during treatment, all of whom had cirrhosis (17/758, 2.2%). The most frequent symptom of decompensation was hepatic encephalopathy in 12 (70.6%) patients. No treatment-emergent decompensation occurred in 2136 patients without cirrhosis. In patients with compensated cirrhosis, no decompensation events occurred in patients with albumin $\geq$ 38 and plt $\geq$ 130 (0/219). Among patients with a history of prior decompensation, 31/168 (18.5%) had an albumin $\geq$ 38 and plt $\geq$ 130 at baseline, of whom 2 (6.5%) decompensated during treatment (Figure).

Compensated Cirrhosis (n=590)				
	Alb<3.8	Alb $\geq$ 3.8	Total	
	0/0	0/1	0/7	
Plt<130	0/4	2/116 (1.7%)	1/150 (0.7%)	3/270 (1.1%)
Plt $\geq$ 130	0/1	2/93 (2.2%)	0/219	2/313 (0.6%)
<b>Total</b>	0/5	4/210 (1.9%)	1/375 (0.3%)	5/590 (0.8%)
Cirrhosis with prior history of decompensation (n=168)				
	Alb<3.8	Alb $\geq$ 3.8	Total	
	0/0	0/3	0/4	
Plt<130	0/0	9/65 (13.8%)	0/35	9/100 (9.0%)
Plt $\geq$ 130	0/2	1/31 (3.2%)	2/31 (6.5%)	3/64 (4.7%)
<b>Total</b>	0/2	10/99 (10.1%)	2/67 (3.0%)	12/168 (7.1%)

Figure: Risk of decompensation among patients with cirrhosis starting DAA therapy

**Conclusion:** These results confirm that patients with baseline albumin $\geq$ 38, plt count $\geq$ 130 and compensated cirrhosis or without cirrhosis can safely be treated with PI-based therapy. Even patients with a history of prior decompensation meeting these thresholds have a low risk of treatment-related decompensation but should still preferably use non-PI-based therapy. This simple approach allows for identification of patients who can safely use PI-based therapy, a key to expanding treatment outside of specialty care to help achieve the WHO elimination goals by 2030.

### PO-2020

#### Good practice hepatitis C screening and linkage to care initiatives at the SLTC Summit 2020: three out of four diagnosed patients able to start direct-acting antiviral treatment

Joaquín Cabezas<sup>1,2</sup>, Daniella Cohen<sup>3</sup>, Chris Fraser<sup>4</sup>, Dominique Larrey<sup>5</sup>, Andreas Maieron<sup>6</sup>, Anthony Martinez<sup>7</sup>, Lucy McDonald<sup>8,9</sup>, Candido Hernández<sup>10</sup>, Margaret O'Sullivan<sup>11</sup>, André-Jean Remy<sup>12</sup>, Jens Rosenau<sup>13</sup>, Pablo Ryan<sup>14</sup>, Tessa Windelinckx<sup>15</sup>, Ming-Lung Yu<sup>16</sup>. <sup>1</sup>Marqués de Valdecilla University Hospital, Santander, Spain; <sup>2</sup>Valdecilla Research Institute, Santander, Spain; <sup>3</sup>Maccabi Health Services, Tel Aviv-Yafo, Israel; <sup>4</sup>Victoria Cool Aid Society-Community Health Centre, Victoria, Canada; <sup>5</sup>University Hospital of Montpellier, Montpellier, France; <sup>6</sup>University Hospital St. Pölten, Sankt Pölten, Austria; <sup>7</sup>Erie County Medical Center, Buffalo, United States; <sup>8</sup>St. Vincent's Hospital Melbourne, Fitzroy, Australia; <sup>9</sup>University of Melbourne, Parkville, Australia; <sup>10</sup>Gilead

Sciences Europe Ltd, Hayes, United Kingdom; <sup>11</sup>Brighton And Sussex University Hospitals NHS Trust, Brighton, United Kingdom; <sup>12</sup>Hospital Centre of Perpignan, Perpignan, France; <sup>13</sup>University of Kentucky Medical Center, Lexington, United States; <sup>14</sup>Infanta Leonor Teaching Hospital, Madrid, Spain; <sup>15</sup>Free-Clinic, Antwerp, Belgium; <sup>16</sup>Kaohsiung Medical University, Kaohsiung City, Taiwan  
Email: candido.hernandez@gilead.com

**Background and aims:** The SLTC Summit is a Gilead-sponsored event initiated in 2017 and designed to facilitate the sharing of good practice examples of hepatitis C (HCV) screening and linkage to care (SLTC). We sought to evaluate patient cascade data derived from the 17 global examples of good practice presented in 2020.

**Method:** Key data from good practices initiatives presented during the SLTC Summit in 2020 were extracted and supplemented by additional data where possible. Six variables were analysed: prevalence of HCV Ab+ and HCV RNA+ from the screened population; proportion of HCV RNA+ among the HCV Ab+ population; proportion of HCV RNA+ patients able to start (direct-acting antiviral) DAA treatment; proportion of HCV RNA+ patients who were cured; proportion of patients who started treatment who were cured. Only initiatives that included these variables were included in the respective analyses. Some data included the period during the COVID-19 pandemic.

**Results:** Data from 13 initiatives in 10 countries (Australia, Austria, Belgium, Canada, France, Israel, Spain, Taiwan, UK and USA) were evaluable. Target populations included people who used drugs, people in prison, homeless people, sex workers, migrants, and the 'general population'. Complete care cascade data were not available for each initiative. Overall, 500, 353 people were screened for HCV and 7691 patients initiated DAA treatment. Of the programmes with evaluable datasets, an average of 76% (range 45%–100%) of people diagnosed as HCV RNA+ went on to start DAA treatment. See Table for detailed information.

Variable	Mean percentage across the initiatives (range)	Sample	Countries/cohorts
HCV Ab+ of those screened	29 (1–72)	7696/496,663	7/9
HCV RNA+ of those screened	21 (2–49)	1192/9753	7/9
HCV RNA+ among HCV Ab+	53 (30–82)	1164/2364	6/8
HCV RNA+ and starting DAA Tx	76 (45–100)	725/922	6/8
HCV RNA+ and achieving SVR	60 (31–85)	466/731	6/7
Starting DAA Tx and achieving SVR	75 (56–94)	705/1011	6/7

**Conclusion:** This analysis of good practice HCV screening and linkage to care initiatives from around the world, focused on high-risk populations, indicates that 3 out of 4 patients start DAA treatment after HCV RNA+ diagnosis. Despite the global impact of the COVID-19 pandemic it is important to maintain or even improve this ratio in order to achieve global HCV elimination goals.

**PO-2021**

**Deferred direct-acting antiviral treatment in kidney transplantation from HCV-viremic donors into HCV-negative recipients**

Giulia Pagano<sup>1</sup>, Eulàlia Solà<sup>2</sup>, Nuria Cañete<sup>1,3</sup>, Teresa Broquetas<sup>1,3</sup>, Jose A. Carrión<sup>1,4</sup>, Marc Puigvehí<sup>1,3</sup>, Susanna Coll<sup>1,3</sup>, Esther Garrido<sup>1,3</sup>, Ana Viu<sup>3</sup>, Judit Romero<sup>1</sup>, MARIA JOSE Pérez<sup>2</sup>, ANA Zapatero<sup>5</sup>, Xavier Bessa<sup>1,3</sup>, Marta Crespo Barrio<sup>2</sup>, Montserrat Garcia-Retortillo<sup>1,3</sup>.

<sup>1</sup>Hospital del Mar, Liver Section, Gastroenterology Department, Barcelona, Spain; <sup>2</sup>Hospital del Mar, Nephrology Department, Barcelona, Spain; <sup>3</sup>Hospital del Mar Medical Research Institute (IMIM), Barcelona, Spain; <sup>4</sup>Universitat Autònoma de Barcelona, Bellaterra, Spain; <sup>5</sup>Hospital del Mar, Transplant Coordination, Barcelona, Spain  
Email: 97235@parcdesalutmar.cat

**Background and aims:** Outcomes of kidney transplantation (KT) from HCV-viremic donors into HCV-negative recipients has shown excellent results when prophylactic or early antiviral treatment is initiated. However, oral tolerance and drug-drug interactions (DDIs) can limit this strategy. Aim: To analyze the efficacy and safety of deferred direct-acting antiviral therapy with glecaprevir/pibrentasvir (GLE/PIB) in KT recipients from HCV-viremic donors.

**Method:** KT candidates testing negative for HCV who received a kidney from a HCV-viremic donor at a tertiary care center were included prospectively. HCV-RNA was determined in kidney recipients pre-KT, at day 3, 7 and 14 post-KT, immediately before antiviral treatment, at the end of treatment and at 12, 24 and 48 weeks after the end of treatment. Antiviral therapy with GLE/PIB had to be initiated per protocol within the 2<sup>nd</sup> and 4<sup>th</sup> week post- KT after achieving a correct oral tolerance and stability of immunosuppressant levels. Levels of immunosuppressants were registered at day 3, 7, 14 and 28 post-KT and monthly thereafter

**Results:** Eight KT recipients were included from 1/2020 to 9/2020, 7 of them were men with a median age of 56 years (range 48–62) and a follow-up period of 156 days (IQR: 50–277). The immunosuppressant regimens consisted in the combination of steroids plus tacrolimus and mycophenolate (n=4) or everolimus (n=4). HCV-RNA was detected 3 days after KT in 6 out of 8 patients (75%) and in 100% of patients one week after KT. Moderate and asymptomatic elevation in transaminases appeared in 7 out of 8 patients (87, 5%) and reached the maximum peak between the 11<sup>th</sup> and 27<sup>th</sup> day after KT. GLE/PIB was initiated the 19<sup>th</sup> day post-KT (range: 12–33 days). Tacrolimus levels after 2 and 4 weeks post-antiviral treatment initiation increased a 99% and 52% respectively and were associated with dose reduction of 22% and 13% at the same time points. Four patients have reached week 12 after the end of treatment and all of them achieved the SVR. There were no adverse events related to antiviral therapy in any recipient

**Conclusion:** Deferred antiviral therapy with GLE/PIB after KT from HCV-viremic donors into HCV-negative recipients is a safe and effective strategy and avoids the higher risk period for DDIs. However, a close monitoring of tacrolimus levels is required for an appropriate dose adjustment.

**PO-2138**

**Safety and efficacy of direct acting antiviral therapy for chronic HCV infection in elderly people**

Adriano De Santis<sup>1</sup>, Daniela Maggi<sup>1</sup>. <sup>1</sup>Università La Sapienza, Policlinico Umberto I, Gastroenterologia, Rome, Italy  
Email: daniela.maggi2@gmail.com

**Background and aims:** The mean age of patients with chronic HCV infection and the number of elderly patients with advanced liver disease is gradually increasing in many countries. Screening strategies concerning high-risk groups and leaving out the elderly population risk to be unsuccessful in a global eradication perspective. The elderly should be considered a Special Population to screen and treat like other subjects considered at high risk. This study aim is to evaluate the safety and efficacy of direct antiviral therapy in the elderly patient with chronic HCV infection.

**Method:** We retrospectively analyzed the efficacy and safety of DAAs in 137 HCV patients of 70 years or older treated in our center between 2015 and 2020. Eligibility for treatment was assessed according to current clinical practices. We evaluated personal and anamnestic data, Cumulative Illness Rating Scale (CIRS), ultrasound, elastometry and laboratory parameters. The pre-therapy data were compared with the data collected 6 months after the end of therapy.

## POSTER PRESENTATIONS

**Results:** The mean age was 77 years. The CIRS severity scale is moderate-severe in 65% of patients and 40% of them have compensated cirrhosis. 73% of patients were taking two or more drugs. In 38% of cases, we had to change chronic therapy to avoid potentially serious drug interactions. One serious adverse event occurred (diverticular bleeding due to interaction with DOAC). Mild side effects occurred in 37% of patients. HCV RNA undetectability EOT was achieved in 97% of patients, while SVR 12 and SVR24 in 98% of patients. After treatment, we saw a reduction in the incidence of episodes of liver decompensation in cirrhotic patients. In all patients, we find a significant improvement in all ultrasound variables and a significant reduction in the elastographic measurements. No significant differences in outcomes were observed dividing the population into patients aged  $\geq 80$  and  $< 80$  years.

**Conclusion:** The benefit of DAA therapy in the elderly patient mainly concerns liver disease and is strongly indicated in the cirrhotic patients. For non-cirrhotic patients, the therapy does not affect extrahepatic comorbidities but allows to end follow-up in 40% of patients with consequent savings in terms of resources. It also plays an important role in reducing the risk of hepatocellular cancer and all-cause mortality, if compared to untreated patients. Age should not be an a priori exclusion factor if the patient has a good performance status.

### PO-2191

#### Directly observed therapy for hepatitis C alongside opioid agonist therapy as an effective microelimination strategy for PWIDs with a high risk for non-adherence in Vienna, Austria

Michael Schwarz<sup>1,2,3</sup>, Angelika Schütz<sup>4</sup>, Cornelia Schwanke<sup>4</sup>, Caroline Schmidbauer<sup>1,2,3</sup>, Eva Krabb<sup>4</sup>, Raphael Schubert<sup>4</sup>, Enisa Gutic<sup>1</sup>, Roxana Pirker<sup>1</sup>, Tobias Lang<sup>1</sup>, Thomas Reiberger<sup>2,3</sup>, Hans Haltmayer<sup>4</sup>, Michael Gschwantler<sup>1,5</sup>. <sup>1</sup>Klinik Ottakring, Department of Internal Medicine IV, Division of Gastroenterology and Hepatology, Vienna, Austria; <sup>2</sup>Medical University of Vienna, Department of Internal Medicine III, Division of Gastroenterology and Hepatology, Vienna, Austria; <sup>3</sup>Vienna HIV and Liver Study Group; <sup>4</sup>Suchthilfe Wien gGmbH, Vienna, Austria; <sup>5</sup>Sigmund Freud University Vienna, Vienna, Austria

Email: michael.gschwantler@gesundheitsverbund.at

**Background and aims:** Despite highly effective direct acting antivirals (DAAs), people who inject drugs (PWIDs) still show high hepatitis C virus (HCV) prevalence. Austria offers a national opioid agonist therapy (OAT) program for PWIDs with recent or ongoing intravenous drug use (IDU). However, a considerable subgroup of PWIDs on OAT, especially those with ongoing IDU, have a high risk of non-adherence to therapy with DAAs. Thus, the innovative Viennese concept of directly observed therapy (DOT) combines DAA therapy with OAT to improve adherence to antiviral treatment.

**Method:** From September 2014 until January 2021 PWIDs with a high risk for non-adherence to DAA therapy were included in the Viennese HCV elimination project using DOT. DAA regimens were selected according to genotype (GT), fibrosis stage, comedication, and reimbursement policy of insurances. PWIDs received HCV treatment

alongside their OAT under supervision of healthcare workers in a pharmacy or low-threshold facility.

**Results:** 523 PWIDs were included. 400 patients were male (76.5%), median age at baseline was 39.6 years. Coinfection with HIV or HBV was found in 23 (4.4%) and 7 (1.3%) patients, respectively. 52 (9.9%) had received prior HCV treatment. 259/414 patients (62.6%) reported ongoing IDU. Most common GTs were GT-1 (291, 55.6%) and GT-3 (197, 37.7%). Most frequently used DAA combinations were sofosbuvir/velpatasvir (201, 40.2%), glecaprevir/pibrentasvir (188, 36.0%) and sofosbuvir/ledipasvir (63, 12.1%). Stages of fibrosis measured through transient elastography were: F0/F1 207 (39.6%), F2 137 (26.2%), F3 71 (13.6%), F4 106 (20.3%).

Following the concept of DOT adherence to DAA treatment was excellent with only 98/25.864 (0.4%) scheduled visits missed by the patients. Sustained virologic response 12 weeks after treatment completion (SVR12) was achieved in 400/404 (99.0%; CI: 97.5–99.7%) patients according to modified intention to treat analysis (mITT), while 4/404 (1.0%) patients showed treatment failure (or reinfection before confirmed SVR12). 57 patients were lost to follow-up, 2 patients died due to reasons not related to DAA treatment before SVR12 was documented. By the time of submission, 60 patients remain on treatment or SVR12 surveillance. Over a median follow-up of 28 weeks (IQR 22) 21 (5.3%) reinfections were observed.

**Conclusion:** HCV treatment according to the concept of DOT achieved excellent SVR12 rates of 99% in PWIDs at high risk for non-adherence to DAA therapy.

### PO-2205

#### Delivering elimination: rapid scale-up of hepatitis c virus treatment among people who inject drugs in Tayside, Scotland

Christopher Byrne<sup>1,2</sup>, Lewis Beer<sup>2</sup>, Sarah Inglis<sup>2</sup>, Emma Robinson<sup>1,3</sup>, Andrew Radley<sup>1,4</sup>, Sharon Hutchinson<sup>5</sup>, David Goldberg<sup>5</sup>, Matthew Hickman<sup>6</sup>, John Dillon<sup>1,3</sup>. <sup>1</sup>University of Dundee, Molecular and Clinical Medicine, Dundee, United Kingdom; <sup>2</sup>University of Dundee, Tayside Clinical Trials Unit, Dundee, United Kingdom; <sup>3</sup>NHS Tayside, Ninewells Hospital and Medical School, Dundee, United Kingdom; <sup>4</sup>NHS Tayside, Public Health, Dundee, United Kingdom; <sup>5</sup>Glasgow Caledonian University, School of Health and Life Sciences, Glasgow, United Kingdom; <sup>6</sup>University of Bristol, Population Health Sciences, Bristol, United Kingdom

Email: c.x.byrne@dundee.ac.uk

**Background and aims:** Tayside, in the North East of Scotland, had high levels of injection drug use and hepatitis c virus (HCV) infection. In 2017, rapid scale-up of HCV treatment for People Who Inject Drugs (PWID) commenced to achieve a substantial reduction of chronic HCV, thereby achieving elimination. Novel HCV care pathways in community settings were implemented. This study analyses outcomes for the treated cohort during the scale-up against programme targets. It also aims to: determine the most efficacious pathways and assess if any routinely collected data predict Sustained Virologic Response (SVR).

**Method:** All treatments were with Direct Acting Antivirals (DAA). Treatment was delivered through five novel pathways in addition to standard care: nurse-led outreach clinics, drug treatment centres;

Table 1: (abstract: PO-2205): Treatment initiations, sustained virologic response, by pathway: Tayside 2017–20

Treatment Pathway	Standard care	Drug treatment centres <sup>a</sup>	Community pharmacies <sup>a</sup>	Needle exchanges <sup>a</sup>	Nurse-led community clinics <sup>a</sup>	Prisons <sup>a</sup>	Total
Treatments initiated-n (%)	91 (12.8)	46 (6.4)	144 (20.2)	205 (28.8)	124 (17.4)	103 (14.4)	713 (100)
SVR-n (%)	74 (81.3)	34 (73.9)	129 (89.6)	156 (76.1)	101 (81.5)	79 (76.7)	573 (80.4)

Abbreviations: SVR, sustained virologic response; exc., excluding.

<sup>a</sup>Novel care pathway.

<sup>b</sup>Excluding those without an SVR test, n = 624.

needle exchanges; community pharmacies; and prisons. Demographic and treatment outcomes were summarised using descriptive statistics. Multivariate analysis was by binary logistic regression.

**Results:** Treatment was initiated 713 times for 662 PWID, resulting in 573 SVRs. 74.2% were male, 51.9% self-reported injecting in twelve months prior to treatment. Overall and adjusted SVR rates are reported in table 1. Needle exchanges and community pharmacies treated 49% of patients. Community pharmacies had highest SVR rate. Completing treatment (OR, 6.21 [95% CI, 3.78 – 10.20],  $p < .001$ ) and receiving treatment via a clinical trial of a novel pathway (OR, 2.13 [95% CI, 1.38–3.31],  $p = .001$ ) were significant predictors of SVR.

**Conclusion:** Tayside exceeded its targets for the elimination scale-up programme. Needle exchanges and pharmacies delivered most PWID into care. Completing DAA treatment and receiving treatment through a pragmatic trial of a novel pathway increased odds of achieving SVR. Delivering HCV care in community settings is effective in reducing the population level burden of infection.

**Real-time utility of response-guided DAA therapy for hepatitis C based on a mathematical modeling approach: database formation and machine learning methods**

Stephanie Kriss<sup>1</sup>, Alex Churkin<sup>2</sup>, Asher Uziel<sup>1</sup>, Jay Srinivas<sup>1</sup>, Scott Cotler<sup>1</sup>, Ohad Etzion<sup>3</sup>, Amir Shlomai<sup>4,5</sup>, Danny Barash<sup>6</sup>, Harel Dahari<sup>1</sup>. <sup>1</sup>Loyola University Chicago, Program for Experimental and Theoretical Modeling, Division of Hepatology, Department of Medicine, Stritch School of Medicine, Maywood, United States; <sup>2</sup>Sami Shamoon College of Engineering, Department of Software Engineering, Beer Sheva, Israel; <sup>3</sup>Soroka University Medical Center, Beer Sheva, Israel; <sup>4</sup>Rabin Medical Center, Petah-Tikva, Israel; <sup>5</sup>Tel Aviv University, Tel Aviv, Israel; <sup>6</sup>Ben-Gurion University of the Negev, Department of Computer Science, Beer Sheva, Israel  
Email: harel.dahari@gmail.com

**Background and aims:** We recently reported (Sci Rep.2020;10 (1):17820) the first proof-of-concept clinical trial assessing in real-time the utility of response-guided therapy (RGT) with direct-acting antivirals (DAA) in chronic hepatitis C (CHCV), based on a mathematical modeling approach. Several retrospective studies have shown that mathematical modeling of viral kinetics predicts time to cure (TTC) of less than 12 weeks in the majority of individuals treated with sofosbuvir-based as well as other DAA regimens (Table 1). The aims of this study are to build a database of these studies and to evaluate machine learning (ML) methods for estimating missing datapoints to facilitate real-time modeling studies.

**Method:** Data from six studies exploring mathematical modeling of early HCV kinetics under DAA in CHCV-infected patients were gathered and analyzed (Table 1). Statistical analysis was conducted to examine associations between patient demographics (such as age, gender, liver disease severity) and estimated HCV kinetic parameters that are used to predict the individualized TTC. A linear-regression ML model was trained on part of our dataset ('train' set), to predict missing data-points on the untrained part ('test' set).

**Results:** Overall, 266 patients from the retrospective studies had a mean age of  $66 \pm 12$  years, 133 (50%) were male, 113 patients (42%) had measured IL28B genotypes, 145 (55%) had cirrhosis, 52 (20%) had decompensated cirrhosis, 213 (80%) had HCV genotype-1, and 96 (36%) were treatment naïve (Table 1). Among the 266 patents, there was a significant ( $p < 0.001$ ) difference in the mean serum viral clearance rate between patients with cirrhosis ( $7.4 \pm 3.4$ ) and patients without cirrhosis ( $10.0 \pm 4.5$ ). In the real-time study, patients had a mean age of  $49 \pm 15$  years, all patients were non-cirrhotic, and all but one were treatment naïve. The gender, HCV genotype-1, and mean baseline HCV baseline viral load were comparable to patients baseline characteristics of the retrospective studies. Patients in the real-time study had a significantly ( $p \leq 0.03$ ) lower viral clearance rate and lower infected cell death/loss rate compared to the patient in the retrospective studies (Table 1), which may partially be related to the difference in HCV quantification assay used in the real-time study (Cepheid, GeneXpert) compared to all retrospective studies (Roche

## POSTER PRESENTATIONS

CobasTaqMan). Preliminary ML efforts suggest that it is possible to predict missing data points in the dataset, such as “day 14” or “day 28,” with a very high accuracy (relative error around 0.04%).

**Conclusion:** ML provides a means to estimate missing dataset parameters to establish an accurate TTC prediction that will support the implementation of our individualized treatment approach on a world-wide scale.

### PO-2275

#### Prevalence of resistance associated substitutions in hepatitis C virus NS5A against direct acting antivirals

Zain Ul Abideen<sup>1</sup>, Shafiq Siddique<sup>2</sup>, Azeem Butt<sup>3</sup>. <sup>1</sup>COMSATS University Islamabad, Biosciences, Islamabad, Pakistan; <sup>2</sup>National University Of Medical Sciences (NUMS), Armed Forces Institute of Pathology (AFIP), Rawalpindi, Pakistan; <sup>3</sup>COMSATS University Islamabad (CUI), Biosciences, Islamabad, Pakistan

**Background and aims:** The introduction of direct-acting antivirals (DAAs) has significantly increased the sustained virological response (SVR) rate in hepatitis C (HCV) patients however, resistance-associated substitutions (RASs) are reported to emerge and impair the DAAs' effectiveness against HCV particularly in cases such as cirrhosis. Identification and functional analysis of such RASs is therefore important in clinical settings to optimize treatment regimens thereby, increasing the SVR rates. We performed a meta-analysis to provide an update on prevalence of RASs in the HCV NS5A gene across all genotypes.

Figure: Prevalence of NS5A RASs across genotypes. (A) Prevalence of RASs in genotype 1a (B) Prevalence of RASs in genotype 1b. (C) Prevalence of RASs in genotype 2. (D) Prevalence of RASs in genotype 3. (E) Prevalence of RASs in genotype 6

**Method:** The current study was conducted as per PRISMA guidelines. Different databases were searched for studies reporting RASs in the HCV NS5A gene till July 2020. After the screening of 288 research publications, 67 studies were included in the meta-analysis. For modest heterogeneity fixed-effect model was used; otherwise, a random effect model was applied. The odds ratio (OR) and 95% confidence interval (CI) were calculated by comparing the prevalence of RASs between the different groups for the potential association.

**Results:** Overall, 9377 individuals (GT 1a, n = 2347; GT 1b, n = 4712; GT 2, n = 203; GT 3a, n = 1371; GT 3 others, n = 94; GT 4, n = 554; GT 6, n = 96), treatment naïve and treatment-experienced were included. M28V, Y93H, L31M, H58P, L28M, and P32S were the most observed RAS in HCV genotype 1a, 1b, 2, 3a, 4, and 6a, respectively. Significantly higher prevalence of Q30H, Q30R, and L31M were observed in genotype 1a treatment-experienced group while Y93H, L31M, and L28V were significantly higher in genotype 1b and 4 treatment-experienced groups respectively.

**Conclusion:** The presence of baseline mutation significantly hinders the efficacy of DAAs, indicating that it could be beneficial to offer resistance testing before initiating the DAA treatment regime in HCV patients.

### PO-2295

#### Amino acid substitutions associated with treatment failure of hepatitis C virus infection

Carlos García-Crespo<sup>1</sup>, Maria Eugenia Soria<sup>1</sup>, Brenda Martínez-González<sup>1</sup>, Lucía Vázquez-Sirvent<sup>1</sup>, Rebeca Lobo-Vega<sup>1</sup>, Ana Isabel de Ávila<sup>1</sup>, Isabel Gallego<sup>1</sup>, Qian Chen<sup>2</sup>, Damir García-Cehic<sup>2</sup>, Meritxell Llorens-Revull<sup>2</sup>, Carlos Briones<sup>3</sup>, Jordi Gómez<sup>4</sup>, Cristina Ferrer-Orta<sup>5</sup>, Nuria Verdaguer<sup>5</sup>, Josep Gregori<sup>2</sup>, Francisco Rodríguez-Frías<sup>6</sup>, Maria Buti<sup>2</sup>, Juan Ignacio Esteban<sup>2</sup>, Esteban Domingo<sup>1,7</sup>, Josep Quer<sup>2</sup>, Celia Perales<sup>1,2,8</sup>. <sup>1</sup>Centro de Biología Molecular Severo Ochoa, Department of Interactions with the environment, Madrid, Spain; <sup>2</sup>VHIR-Vall d'Hebron Institut de Recerca, Liver Unit, Internal Medicine Hospital Universitari Vall d'Hebron, Barcelona, Spain; <sup>3</sup>Astrobiology Center, Department of Molecular Evolution, Torrejón de Ardoz, Spain; <sup>4</sup>Instituto de Parasitología y Biomedicina López Neyra-CSIC, Department of Molecular Biology, Spain; <sup>5</sup>Institute for Molecular Biology of Barcelona, Structural Biology Department, Barcelona, Spain; <sup>6</sup>VHIR-Vall d'Hebron Institut de Recerca, Biochemistry and Microbiology Departments, Barcelona, Spain; <sup>7</sup>Centro de Investigación Biomédica en Red de Enfermedades Hepáticas y Digestivas, Madrid, Spain; <sup>8</sup>IS-Fundación Jiménez Díaz, Department of Clinical Microbiology, Madrid, Spain  
Email: carlos.garciac@cbm.csic.es

**Background and aims:** Despite the high sustained virological response rates achieved with current directly-acting antiviral agents (DAAs) against hepatitis C virus (HCV), around 2% to 5% of patients do not achieve such a response. Identification of amino acid substitutions associated with treatment failure requires analytical designs, such as subtype-specific ultra-deep sequencing (UDS) methods for HCV characterization and patient management.

**Method:** By deep sequencing analysis of 220 subtyped HCV samples from infected patients who failed therapy, collected from 39 Spanish hospitals, we determined amino acid sequences of the DAA-target proteins NS3, NS5A and NS5B, by UDS of HCV patient samples, in search of resistance-associated substitutions (RAS).

**Results:** Using this procedure, we have identified six highly represented amino acid substitutions (HRSs) in NS5A and NS5B of HCV, which are not bona fide RAS. They were present frequently in basal and post-treatment virus of patients who failed therapy to different DAA-based therapies. Contrary to several RAS, HRSs belong to the acceptable subset of substitutions according to the PAM250

replacement matrix. Coherently, their mutant frequency, measured by the number of deep sequencing reads within the HCV quasispecies that encode the relevant substitutions, ranged between 90% and 100% in most cases. Also, they have limited predicted disruptive effects on the three-dimensional structures of the proteins harboring them.

Figure:

**Conclusion:** The information on HRSs that will be gathered during sequencing should be relevant not only to help predict treatment outcomes but also to further understand HCV population dynamics, which appears much more complex than thought prior to the introduction of deep sequencing.

Email: m\_elkassas@hq.helwan.edu.eg

**Background and aims:** Despite several antiviral drugs have been evaluated as possible treatments for the COVID-19 pandemic, none of these drugs has proved to be effective against the SARS-CoV-2 virus. The journey to find a curative therapy for HCV is successful and

inspiring. We evaluated the possibility of repositioning for Sofosbuvir/Ledipasvir (SOF/LED) and Nitazoxanide (NTZ) as a possible treatment for COVID-19 infection.

**Method:** This multicenter open-label randomized controlled trial recruited patients with mild and moderate COVID-19 infection. Patients were randomly assigned in a 1:1:1 ratio to receive either the fixed combination of SOF/LED (400 mg and 90 mg, orally) once daily for 14 days, plus the standard of care therapy (SCT) for COVID-19 patients according to Egyptian Ministry of Health protocol (group 1), or NTZ (500 mg, orally) four times per day for 14 days plus the SCT (group 2), or to receive the SCT alone (group 3) for 14 days. NTZ was used in a dose of 500 mg q.id. as this dose was found to be able to present in both the plasma and the lung and can be maintained above the in vitro EC90 for the majority of the dosing period. Patients were excluded if they were less than 12 years old, had severe or critical COVID-19 infection, pregnant, had renal impairment with creatinine clearance <30 ml/min, with evidence of malignancies, and patients using favipiravir or lopinavir-ritonavir, as the co-administration of these drugs with sofosbuvir/ledipasvir has not been well studied. Follow-up by PCR was done at 5, 8, 11, and 14 days interval. The primary end point was the viral clearance.

**Results:** One-hundred and ninety patients were included. Viral clearance was significantly higher in the SOF/LED and NTZ groups compared to the standard of care group in all follow-up intervals (p <0.001). In the SOF/LED, 36.9% showed early viral clearance by day 5. By the end of the follow-up at 14 days, 83.1% of the SOF/LED group, 39.7% of the NTZ group, and 19.4% of the SCT groups developed negative PCR (Figure 1). Although there was a significant difference between the groups regarding age and sex, the Cox regression analysis showed that SOF/LED and NTZ were the only significant factors with the highest OR (17.88, 95% CI: 6.66–47.98 and 2.59, 95% CI: 1.11–6.07, respectively). No mortality or progression to severe COVID-19, ICU admission, or severe side effects were recorded.

Figure: The cumulative incidence of negative RT-PCR following treatment at each follow follow-up time interval. P1; P value between Sofosbuvir/Ledipasvir plus SCT and SCT alone, P2; P value between Sofosbuvir/Ledipasvir plus SCT and Nitazoxanide plus SCT, P3; P value between Nitazoxanide plus SCT and SCT alone.

**Conclusion:** The addition of sofosbuvir/ledipasvir or nitazoxanide to the standard therapy resulted in an early and high viral clearance rate in mild and moderate COVID-19. These drugs appear to be promising and safe treatment in COVID-19 management.

## Reviewers list

We express our deepest appreciation to the following people, who have given us generous and invaluable help as abstract reviewers for the ILC 2021.

Alazawi William	Gill Upkar	Raggi Chiara
Aleman Soo	Gonzales Emmanuel	Ramachandran Prakash
Alisi Anna	Gracia-Sancho Jordi	Ratziu Vlad
Andersson Emma	Graupera Isabel	Rautou Pierre-Emmanuel
Armstrong Matthew	Grebely Jason	Reiberger Thomas
Asselah Tarik	Gual Philippe	Reig María
Bansal Ruchi	Gustot Thierry	Rimassa Lorenza
Behrendt Patrick	Hagström Hannes	Ripoll Cristina
Berg Thomas	Hatzakis Angelos	Roman Eva
Bernal William	Hoener zu Siederdisen Christoph	Romeo Stefano
Berzigotti Annalisa	Hofmann Maïke	Romero Gomez Manuel
Beuers Ulrich	Housset Chantal	Ronot Maxime
Björnsson Einar S.	Huch Meritxell	Sällberg Chen Margaret
Boni Carolina	Hydes Theresa	Sarobe Pablo
Böttler Tobias	Iavarone Massimo	Schulze zur Wiesch Julian
Buti Maria	Jack Kathryn	Schwabl Philipp
Cabezas Joaquin	Jeng Rachel Wen-Juei	Scorletti Eleonora
Cabibbo Giuseppe	Komuta Mina	Seehofer Daniel
Calderaro Julien	Kuenzler Patrizia	Semmler Georg
Calvaruso Vincenza	Lachenmayer Anja	Serfaty Lawrence
Childs Kate	Laleman Wim	Shiri-Sverdlov Ronit
Ciesek Sandra	Lammers Twan	Solà Elsa
Clayton Michelle	Lemoine Maud	Spaan Michelle
Coll Mar	Lemoïne Sara	Spee Bart
Conti Filomena	Line Pål Dag	Spengler Ulrich
Corpechot Christophe	Leo Ana	Sperl Jan
D'Ambrosio Roberta	Long Michelle	Sposito Carlo
Dao Thi Viet Loan	Longerich Thomas	Stal Per
de Lédinghen Victor	Louvet Alexandre	Steinmann Eike
De Martin Eleonora	Makara Michael	Stickel Felix
Deuffic-Burban Sylvie	Manolakopoulos Spilios	Strick-Marchand Helene
Devisscher Lindsey	Marschall Hanns-Ulrich	Strnad Pavel
Dietz Julia	Marzioni Marco	Taubert Richard
Durand François	Mas Valeria	Thomsen Karen Louise
Elkrief Laure	Maticic Mojca	Thorburn Douglas
Engelmann Cornelius	Mauss Stefan	Tomasiewicz Krzysztof
Faivre Sandrine	McPhail Mark J W	Tonitutto Pierluigi
Ferraioli Giovanna	Merle Uta	Trebicka Jonel
Fischler Björn	Meuleman Philip	Trepo Eric
Flisiak Robert	Minguez Beatriz	Triantos Christos
Floreani Annarosa	Montagnese Sara	Tsochatzis Emmanuel
Forner Alejandro	Moreau Richard	Vacca Michele
Forrest Ewan	Moschetta Antonio	Valenti Luca
Fraga Christinet Montserrat	Negro Francesco	van de Graaf Stan
Franca Maria Manuela	Newsome Philip N	van Mil Saskia
Francoz Claire	Oude Elferink Ronald	Vesterhus Mette
Friedman Scott	Papatheodoridis George	Vonghia Luisa
Fuchs Claudia	Pérez-del-Pulgar Sofia	Wagner Martin
Galle Peter	Petta Salvatore	Waidmann Oliver
Gastaldelli Amalia	Piano Salvatore	Webb Glynn
Gastaminza Pablo	Pietrangelo Antonello	Weiland Ola
Gerbes Alexander	Pons Monica	Weiss Emmanuel
Gilgenkrantz Hélène	Ponziani Francesca	Yki-Järvinen Hannele
