decision-project

### The objective of the **DECISION** project

is to enhance the understanding of the pathophysiology of decompensation of cirrhosis leading to acute-on-chronic liver failure (ACLF) or death. This consortium will take advantage of already existing large and clinically well characterized cohorts to ultimately develop prognostic and response tests and combinatorial therapies tailored to the needs of individual patients to decrease the risk of short-term death.

- Systems level elucidation of the pathophysiology of acute decompensation of cirrhosis at multiple levels (genetic, epigenetic, transcriptomic, metabolomics, lipidomics, miR, and extracellular vesicles)
- Integration of existing clinical data and new multi-omics data from 2,200 patients with more than 8,600 measurements
- Development of new combinatorial therapies
- Optimization of therapies using existing and newly developed animal models
- Development of new tests for prediction of outcome and response to new therapies
- Phase II clinical trial to test the new combinatorial therapies
- Creation of new guidelines for prediction and treatment of acute decompensation of cirrhosis to prevent ACLF and death

This project has received funding from the European Union's Horizon 2020 research and innovation programme under grant agreement No 847949.

**Registration of Clinical Trials**

The *Journal of Hepatology* endorses the policy of the WHO and the International Committee of Medical Journal Editors (ICMJE) on the registration of clinical trials. Therefore, any trial that starts recruiting on or after July 1, 2005 should be registered in a publicly owned, publicly accessible registry and should satisfy a minimal standard dataset. Trials that started recruiting before that date will be considered for publication if registered before September 13, 2005.

More detailed information regarding clinical trials and registration can be found in *New Engl J Med* 2004; 351:1250–1251 and *New Engl J Med* 2005; 352:2437–2438.

# The A-TANGO project - featuring G-TAK, a novel combinatorial therapy for acute-on-chronic liver failure (ACLF)

## Expected Impact

- More than **10 million people** suffer from **decompensated cirrhosis** worldwide.
- Effective treatment of ACLF is an urgent and unmet need.
- A-TANGO performs **Phase II clinical studies of G-TAK**, a novel and innovative therapeutic strategy that aims to **reduce inflammation and improve hepatocyte proliferation**.
- A-TANGO also strives to identify **reliable biomarkers** for better patient stratification and increased survival.

project duration	grant amount	8 countries	kick-off

 MICROB-PREDICT

Grant amount  
15 million €

10 Countries  
22 Partners

[www.microb-predict.eu](http://www.microb-predict.eu)

will investigate

the human microbiome to identify predictors and mechanisms associated with the development of decompensation of cirrhosis and progression to **acute-on-chronic liver failure (ACLF) and death.**

- New microbiome-based tests for better stratification of cirrhosis patients
- Personalized prediction and prevention of decompensation and ACLF
- Clinical trial to predict response to treatment
- Modern, effective nanobiosensors as clinical tools with improved specificity
- More personalized treatment
- Increased survival times
- Decreased costs for the health systems

This project has received funding from the European Union's Horizon 2020 research and innovation programme under grant agreement No 825694.

# LIVER SCREEN

## Screening for liver fibrosis population-based study across European Countries

A project that will change the paradigm  
of diagnosis of chronic liver diseases

### AIM:

To assess the prevalence of liver fibrosis in the general population  
using Transient Elastography, with the objective of establishing  
criteria for screening for liver fibrosis in the population.

---

## General session I

---

**GS-1065****External validation of LCR1-LCR2, a multivariate HCC risk calculator, in patients with chronic hepatitis C**

Thierry Poynard<sup>1,2</sup>, Jean-Marc Lacombe<sup>3</sup>, Olivier Deckmyn<sup>4</sup>, Valentina Peta<sup>4</sup>, Sepideh Akhavan<sup>2</sup>, Victor de Lédighen<sup>5</sup>, Fabien Zoulim<sup>6</sup>, Didier Samuel<sup>1</sup>, Philippe Mathurin<sup>7</sup>, Vlad Ratziu<sup>1</sup>, Dominique Thabut<sup>1</sup>, Chantal Housset<sup>8</sup>, Helene Fontaine<sup>1</sup>, Stanislas Pol<sup>1</sup>, Fabrice Carrat<sup>3</sup>. <sup>1</sup>Assistance Publique-Hôpitaux de Paris, Hepatology, Paris, France; <sup>2</sup>Sorbonne Université, INSERM, Hepatology, Paris, France; <sup>3</sup>Institut Pierre Louis d'Épidémiologie et de Santé Publique; <sup>4</sup>Biopredictive, Research, Pars, France; <sup>5</sup>Hôpital Haut-Lévêque, Hepatology; <sup>6</sup>Hospices civils de Lyon, Hôpital Croix Rousse, INSERM, Hepatology; <sup>7</sup>CHRU Claude Huriez, Lille; <sup>8</sup>Sorbonne Université, INSERM, Centre de Recherche Saint-Antoine (CRSA), Institute of Cardiometabolism and Nutrition (ICAN), Paris  
Email: thierry@poynard.com

**Background and aims:** Liver cancer risk test algorithm (LCR1-LCR2) is a multi-analyte blood test combining proteins involved in liver cell repair (apolipoprotein A1, haptoglobin), known HCC risk factors (gender, age, GGT), a marker of fibrosis (alpha2-macroglobulin) and AFP a specific marker of HCC. The aim of the present study was to externally validate LCR1-LCR2 in patients with chronic hepatitis C, treated or not with antivirals agent.

**Method:** Pre-included Patients were from the Hepather cohort, a prospective study in adult patients with chronic HCV infection enrolled from 32 hepatology centers in France. LCR1-LCR2 was assessed retrospectively in the patients with the components and AFP, available at baseline. The co-primary study outcome was the NPV of LCR1-LCR2 at 5-years for the occurrence HCC and survival without HCC according to the predetermined LCR1-LCR2 cutoffs, adjusted for risk covariables and for the response to HCV treatment, quantified using time-dependent Cox proportional hazards models.

**Results:** A total of 4, 903 patients, 1, 026 (21.9%) with baseline cirrhosis, were included in the study. For a median of 5.7 (IQR 4.2–11.3) years, 3, 788 (77.3%) patients had a sustained virological response, 137 HCC occurred at 5 years and 214 at the end of followup. Twenty-four occurred at 5 years in 3, 755 patients with a low-risk LCR1-LCR2 vs. 113 in 1, 148 with a high-risk LCR1-LCR2. The NPV was 99.4% (95%CI 99.1–99.6). Similar findings (Cox hazard-ratio = 10.8; 8.1–14.3;  $p < 0.001$ ) were obtained after adjustment for exposure to antivirals, age, gender, geographical origin, HCV genotype-3, previous alcohol consumption, and type 2-diabetes.

**Conclusion:** The performance of LCR1-LCR2 for identifying patients with chronic hepatitis C at very low risk of HCC at 5 years, was externally validated. **NCT01953458.**

**GS-1072****Food Insecurity is Associated with All-Cause Mortality in U.S. Adults with Non-alcoholic Fatty Liver Disease and Advanced Fibrosis**

**Background and aims:** Autoimmune hepatitis (AIH) frequently recurs after liver transplantation (LT). We evaluated risk factors associated with the recurrence of AIH and its effects on patient and graft survival in a multicentre, international cohort from the International AIH study group.

**Method:** We included 736 patients (77% female, mean age, 42 ± 1 years) with AIH who underwent LT from January 1987 through June 2020, among 33 centers in North America, South America, Europe and Asia. Patients with overlap syndrome were excluded. Clinical data before and after LT, biochemical data within the first 12 months after LT, and immunosuppression after LT were analyzed to identify patients with a higher risk of recurrence of AIH based on a histological diagnosis. Cumulative probabilities of graft and overall survival after LT were calculated using semi-Markov models.

**Results:** AIH recurred in 20% of patients after 5 years and 31% after 10 years. Age at LT ≤42 years (HR, 3.01; 95% CI, 1.15–7.89; p = 0.03), use of mycophenolate mofetil post-LT (HR, 3.22; 95% CI, 1.40–7.41; p = 0.006), donor and recipient gender mismatch (HR, 2.68; 95% CI, 1.42–5.06; p = 0.002) and higher IgG pre-LT (HR, 1.03; 95% CI, 1.01–1.06; p = 0.008) were associated with a higher risk of AIH recurrence after adjusting for age at diagnosis, concomitant autoimmune disease, use of tacrolimus, cyclosporine, azathioprine, rejection episodes, living related-LT, Roux-en-Y bile duct anastomosis, bilirubin at 6-month, ALT at 6- and 12- month. In multivariate Cox regression with time-dependent covariate, recurrent AIH significantly associated with graft loss (HR, 9.63, 95% CI 4.73–19.61, p < 0.001) and death (HR, 2.09, 95% CI 1.09–3.99, p = 0.03) after adjusting for confounders. The 5-, 10-, 15- and 20-year probability of graft survival was 78%, 65%, 53% and 53% in patients with recurrent AIH and 96%, 93%, 93%, and 87% in patients without recurrence (Log rank, p < 0.001, Figure 1a). For the overall survival, probability was 81%, 73%, 55%, and 44% in patients with recurrence and 93%, 81%, 75%, and 61% in patients without recurrence (p < 0.001, Figure 1b).

**Conclusion:** In the largest global cohort study to date we demonstrate that recurrent AIH following liver transplantation is clinically meaningful and associates with younger age at LT, use of mycophenolate mofetil post-LT, gender mismatch and higher IgG pre-LT. Recurrent disease impacts graft and overall survival, highlighting the need for improved management strategies.

 Email: vincent.mallet@cch.aphp.fr

**Background and aims:** There are uncertainties on the risk of dying after coronavirus disease 2019 (Covid-19) for patients with chronic liver disease. We measured the contribution of chronic liver disease and of alcohol use disorders to the burden of Covid-19 in France in 2020.

**Method:** The data source was the French National Hospital Discharge database (Programme de Médicalisation des Systèmes d'Information), which contains all public and private claims for acute inpatients. We selected all patients (N = 187,283; mean [SD] age 66 [22] years; 25% men) aged 18 years and older who were discharged in the year 2020 with a diagnosis code for Covid-19 and captured all, 2011–2020, corresponding, standardized discharge summaries, including demographics (sex, age at entry, and postal code of residency); primary and associated discharge diagnosis codes according to the WHO International Classification of Diseases, tenth revision (ICD-10); medical procedures received; length of stay; and discharge modes (including in-hospital death). The primary exposures were chronic liver disease, compensated or advanced (defined as chronic liver disease with a previous liver-related event), and alcohol use disorders, before Covid-19. The outcome was mortality, including death after a liver-related complication, and overall death. The risk of dying at hospital after Covid-19 was estimated with Cox proportional hazards models stratified on age categories, sex, obesity, hypertension, and on the Charlson comorbidity index. Attributable risks (AR) combine information about prevalence and adjusted hazard ratios estimates and denote the fraction of mortality that would have been prevented in 2020 if a risk factor (here chronic liver disease and alcohol use disorders) was absent.

**Results:** Overall, 16,338 (8.7%) patients diagnosed with chronic liver disease were admitted for Covid-19 in France in 2020 and 3943 (24.1%) of them died, including 2518 (63.9%) after a liver-related complication. The plot of the Kaplan Meyer estimates for patients with and without chronic liver disease diagnosed is presented in the Figure. Of 10,652 (5.7%) patients diagnosed with alcohol use

disorders, 872 (8.1%) died (p < 0.001), including 472 (54.1%) after a liver-related complication. The adjusted mortality hazard ratios for chronic liver disease and alcohol use disorders were 1.23 (95% confidence interval [CI] 1.10–1.38, p < 0.001) and 1.12 (95% CI 1.07–1.17, p < 0.001), respectively. The population attributable fractions of Covid-19 mortality were 2.5% and 0.8% for chronic liver disease and alcohol use disorders, respectively.

**Conclusion:** Chronic liver disease and alcohol use disorders were independent risk factors of Covid-19 mortality and contributed to disease burden in 2020.

**Background and aims:** Treatment of ACLF is an unmet need. DIALIVE is a novel liver dialysis device, that replaces dysfunctional albumin and removes pathogen and damage associated molecular patterns. This randomised study tests the hypothesis that DIALIVE will significantly improve the prognosis of ACLF patients. The primary end point was safety; device performance; clinical and pathophysiologic effects.

**Method:** EUH2020 funded the ALIVER study. Patients with ACLF Grades 1-3a were randomized and the main end points were evaluated at Day 10. A minimum of 3 DIALIVE sessions (max 5) were needed for the patient to be evaluable. No specific hypothesis was to be statistically assessed. 2-populations were defined: *Safety population:* Patients having at least 1 DIALIVE treatment. *Modified-safety (MS) set:* Evaluable patients. A post-hoc inferential Mixed Models for Repeated Measurements analysis was performed to evaluate the statistically significant differences between groups at Days 5 and Day 10. Log-rank tests and Wald test were performed to assess resolution of ACLF.

**Results:** Study: 32-ACLF patients with alcoholic cirrhosis were randomised either to DIALIVE (N = 17; 13M; age: 49 (12.4); CLIF-OFs: 10.3 (1.6); CLIF-C ACLFs: 48.6 (7.3)) or SOC (n = 15; 13M; age: 49.1 (10.2); CLIF-OFs: 9.9 (1.2); CLIF-C ACLFs: 47 (6.5)). 30 patients (n = 15) comprised the MS set. DIALIVE therapy was administered for a median of 3 sessions (range 1–5) in first 3-days (range 1–6) for a median of 8 hours (hours 7–12) each. Safety: 5-patients died in the DIALIVE group; 4 in SOC group. Serious AEs were seen in 64.7% in DIALIVE and 53.3% in the SOC group. Efficacy: *CLIF-OF score:* Significant improvement in the Liver (p = 0.045) and Brain (p < 0.001) subscores in DIALIVE; and deterioration of Lung subscore (p = 0.002) in the SOC group (Day 10). This resulted in a significant overall treatment effect in CLIF-OFs (p = 0.043). *ACLF Grade:* Significantly more cases reached ACLF 0 (33.3% vs 66.7%) favoring DIALIVE (logrank p = 0.0357) and a 2.8x faster time to ACLF 0 (Wald test p = 0.059) (Fig). *CLIF-C ACLF score:* Difference of means (standard error) between DIALIVE and SOC at Day 10 was -5.4 (2.9) in favour of the DIALIVE group (p = 0.064). *MELD score:* Significantly lower in DIALIVE at both Days 5 (p = 0.049) and 10 (p = 0.028) vs SOC.

**Conclusion:** DIALIVE is safe and significantly increases proportion of patients resolving ACLF whilst reducing time to resolution. The data justify start of late phase clinical trials.

## GS-2069

### Claudin-1 is a target for treatment of advanced liver fibrosis and cancer prevention

Email: thomas.baumert@unistra.fr

**Background:** Tissue fibrosis is the key driver of end-stage organ failure, accounting for up to 45% of death in developed countries. Advanced liver fibrosis is the main risk factor for hepatocellular carcinoma (HCC). Despite the urgent medical need, approved antifibrotic therapies are absent and compounds in clinical development have limited anti-fibrotic efficacy. Claudin-1 (CLDN1) is a cell membrane protein mediating cell adhesion, signaling and epithelial-mesenchymal differentiation (EMT). Furthermore, CLDN1 is a cell entry factor and signal transducer of hepatitis C virus, a major cause of liver fibrosis and HCC worldwide.

**Aims and Method:** Using highly specific humanized monoclonal antibodies (mAbs) targeting non-junctional CLDN1 and a large series of patient-derived cell-based and mouse models combined with loss-of-function studies, we aimed to investigate the role CLDN1 as a therapeutic target for liver fibrosis.

**Results:** CLDN1 was overexpressed in liver tissues derived from patients with NASH, liver fibrosis and HCC. Targeting non-junctional CLDN1 on the hepatocyte basolateral membrane by highly specific mAbs markedly and significantly inhibited fibrosis and suppressed tumorigenesis *in vivo* in two state-of-the-art NASH fibrosis mouse models including humanized liver chimeric mice. Antifibrotic effects were further confirmed in NASH F3/F4 patient-derived precision-cut liver slices, 3D bioprinted liver tissues and NASH patient-derived liver spheroids. Perturbation studies revealed that CLDN1-targeting mAbs suppress pro-fibrogenic differentiation of liver myofibroblasts and Kupffer cells as well as EMT of hepatocytes by interfering with host cell signaling. Treatment with humanized anti-CLDN1 antibodies is considered to be safe, as administration in non-human primates and mouse models did not reveal any major toxicity even when high doses largely exceeding the therapeutic need were repeatedly applied.

**Conclusion:** Our results provide robust preclinical proof-of-concept for CLDN1-specific mAbs for treatment of advanced liver fibrosis and prevention of HCC. A key differentiator of CLDN1-targeting approach is the combination of a robust direct anti-fibrotic and HCC preventive effect complementing compounds in clinical development mostly targeting metabolism.

**Background and aims:** The benefit of long-term anticoagulation on the risk of recurrence of thrombosis in patients with non-cirrhotic chronic portal venous system thrombosis (PVT) is unknown. We aimed to assess the effects of rivaroxaban, compared to no anticoagulation, on thrombosis-free survival in PVT patients without high risk factor for thrombosis.

**Method:** In this French multicentre, investigator-driven, controlled study, patients with chronic PVT without high-risk factor for thrombosis were randomly assigned to receive either rivaroxaban 15 mg/day or no anticoagulation for a minimum of 2 years planned follow-up. Primary end point was survival free of new occurrence of a venous thromboembolic event in any territory or death.

**Results:** We included 111 patients: 56 in rivaroxaban arm and 55 in no-anticoagulation arm. An interim analysis was requested by the independent safety monitoring board, which led to discontinuation of enrolment, 28 months after study start and 11.8 months (95% CI [8.8–13.2]) of median follow-up, due to an increased occurrence of thromboses in the no-anticoagulation group. Incidence rate of thrombosis recurrence was 0/100 person-years in rivaroxaban arm and 19.71/100 person-years (95% CI [7.49/100–31.92/100]) in no-anticoagulation arm (3 deep venous phlebitis, 3 pulmonary embolisms, and 4 splanchnic thrombosis in 10 control patients). Recurrent thrombosis-free survival was significantly different between study arms (p = 0.0008) (Figure).

Patients of the no-anticoagulation group were then switched to rivaroxaban 15 mg/d. Monitoring of bleeding and thrombosis events was pursued until the last included patient reached 2 years of follow-up. At the end of the study, after a median follow-up of 30.3 months (95%CI [29.8–35.9]), 3 patients have experienced severe hemorrhage related to portal hypertension, two in patients treated with rivaroxaban and one in a patient without anticoagulant. Three patients were lost to follow-up; and there were no deaths.

**Conclusion:** In patients with chronic PVT without high-risk factor for thrombosis, rivaroxaban reduces the risk of recurrent venous thrombosis without increasing the risk of severe bleeding.

Figure: (abstract: GS-613): Recurrent thrombosis-free survival.

#### Radiological and pathological response to neoadjuvant Nivolumab in patients with BCLC A HCC treated by curative percutaneous irreversible electroporation: preliminary report from the NIVOLEP trial (NCT03630640)

Pierre Nahon<sup>1</sup>, Olivier Seror<sup>1</sup>, Frédéric Oberti<sup>2</sup>, Solohaja Faniha Dimby<sup>3,4</sup>, Christophe Aubé<sup>2</sup>, Jean-Frédéric Blanc<sup>5</sup>, Hervé Trillaud<sup>5</sup>, Philippe Merle<sup>6</sup>, Agnès Rode<sup>6</sup>, Eric Assenat<sup>7</sup>, Boris Guiu<sup>7</sup>, Mohamed Bouattour<sup>8</sup>, Zohra Talib<sup>3</sup>, Annick Tibi<sup>9</sup>, Julien Calderaro<sup>10</sup>, Marianne Ziou<sup>1</sup>, Eric Vicaut<sup>3</sup>. <sup>1</sup>APHP Avicenne, Bobigny, France; <sup>2</sup>CHU Angers; <sup>3</sup>APHP Fernand Vidal; <sup>4</sup>SAMM (EA 4543), Université Paris 1 Panthéon Sorbonne, Paris, France; <sup>5</sup>CHU Bordeaux; <sup>6</sup>CHU Lyon; <sup>7</sup>CHU Montpellier; <sup>8</sup>APHP Beaujon; <sup>9</sup>APHP Ageps; <sup>10</sup>APHP Henri Mondor  
Email: pierre.nahon@aphp.fr

**Background and aims:** Irreversible electroporation (IRE) is a percutaneous ablation which induces tumour cells apoptosis. It has been shown to be safe and effective for curative ablation of HCC located near vascular or biliary trunks. The preservation of the tumour microvasculature and extracellular matrix favours infiltration by anti-tumoral immune cells. Given these immunomodulatory changes, neoadjuvant and adjuvant immunotherapy might act in synergy with this non-thermal ablative technique to improve HCC curative management.

**Method:** The NIVOLEP trial is a French multicentre (n = 6) phase 2 trial aimed at recruiting 50 patients with BCLC A HCC eligible for IRE and high-risk of recurrence (single lesion >3 cm or multiple). Patients consecutively received: (1) 2 neoadjuvant Nivolumab infusions (every 15 days); (2) curative IRE procedure; (3) 12 adjuvant Nivolumab infusions (every 30 days) during one year. All HCC nodules were biopsied at inclusion then during IRE procedure to assess neoadjuvant Nivolumab impact on tumour biology. The present data report preliminary results of the neoadjuvant phase in the first 20 included patients as assessed by sequential radiological and pathological examination before and after 2 Nivolumab infusions.

**Results:** 37 HCC nodules (uni-nodular 9, bi-nodular 5 and tri-nodular 6 patients, mean size: 31.4 mm) in 20 patients (mean age 69 yrs, males 90%, cirrhosis: 70%, baseline AFP: 56 ng/ml, AFP >50 ng/ml: 10%) were considered. No Grade 3 or 4 adverse events related to

Nivolumab infusions were reported. Following neoadjuvant Nivolumab, radiological response defined by an objective reduction in nodule (s) size (s) was observed in 11 (29%) (complete response in 0 nodules). One patient experienced progression and was ineligible for IRE. The 19 other patients underwent successful curative IRE procedure. Among these 37 nodules, 17 paired pre- and post neoadjuvant Nivolumab HCC biopsies from 15 patients were analyzed. Pathological response pattern was observed in 3/17 nodules (17%), characterized by tumor regression, replaced by fibrosis with mixed inflammatory infiltrate including foamy macrophages and heavy peritumoral and intratumoral lymphocyte infiltration. These 3 nodules also had radiological response. Additionally, significant increase of peritumoral and intratumoral infiltrating lymphocytes, without evidence of tumor regression zone were observed in 4 other nodules. Overall, 9/17 (53%) had either radiological or pathological modification following Nivolumab infusion.

**Conclusion:** Neoadjuvant Nivolumab in BCLC A HCC patients eligible for IRE was safe and did not delay ablation procedure. Induced radiological and pathological changes were reported in a substantial number of patients suggesting antitumoral and/or immunomodulation effect of neoadjuvant immunotherapy for liver cancer. **NCT03630640.**

### GS-1645

#### SZN-043, a hepatocyte-targeted R-spondin mimetic, promotes robust hepatocyte proliferation and zonal gene expression changes in mice

Russell Fletcher<sup>1</sup>, Helene Baribault<sup>2</sup>, Mehaben Patel<sup>2</sup>, Jacqueline Phipps<sup>2</sup>, Shalaka Deshmukh<sup>2</sup>, Darshini Shah<sup>2</sup>, Asmiti Sura<sup>2</sup>, Suhani Gupta<sup>2</sup>, Hui Chen<sup>2</sup>, Jay Ye<sup>2</sup>, Jay Tibbitts<sup>2</sup>, Trudy Vanhove<sup>2</sup>, Wen-Chen Yeh<sup>2</sup>, Yang Li<sup>2</sup>, Chenggang Lu<sup>2</sup>. <sup>1</sup>Surrozen, Inc., South San Francisco; <sup>2</sup>Surrozen, Inc., South San Francisco, United States  
Email: russell@surrozen.com

**Background and aims:** Wnt signaling is critical for hepatocyte development and for regeneration after liver injury, and it contributes to the region-specific expression of metabolic genes. R-spondins enhance Wnt signaling via stabilization of Wnt receptors. We tested the effect of repeated dosing of our hepatocyte-targeted

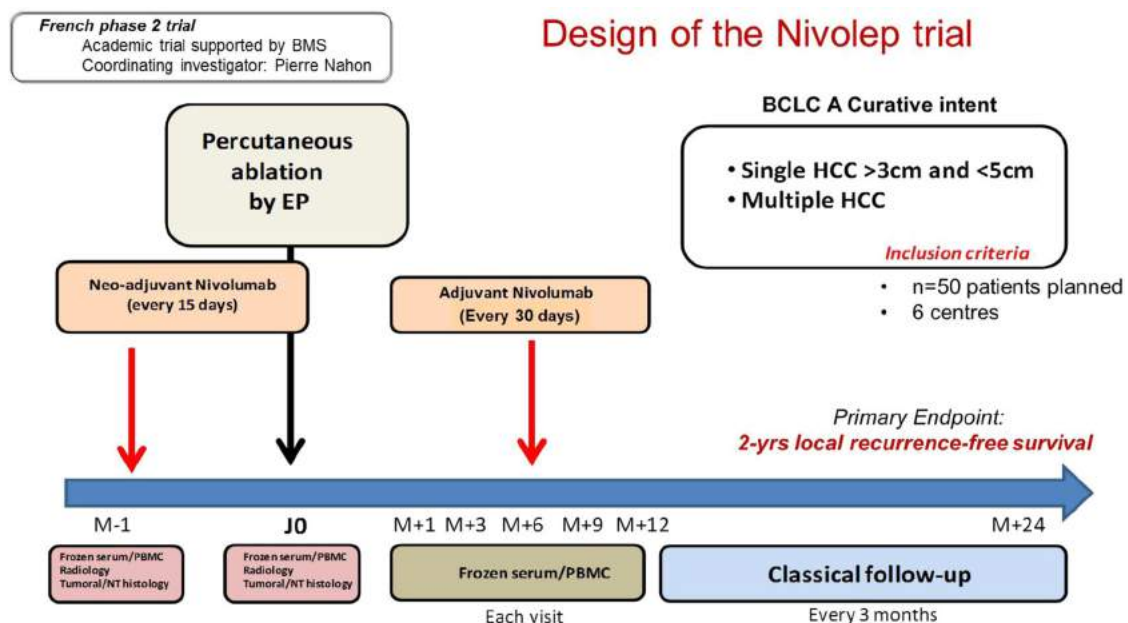

Figure: (abstract: GS-945)

R-spondin mimetic, SZN-043, in mice to understand how SZN-043 impacts hepatocytes and all other cell types and to understand how the liver normalizes upon washout.

**Method:** C57Bl/6 mice were dosed with either a control antibody (anti-GFP) twice weekly or with SZN-043 at 10 mg/kg intraperitoneally (IP) daily for two weeks. Liver samples were collected at 24 hours after the first dose, 24 hours after the last dose, and at a range of washout timepoints (Day 7, 14, 28, and 56 after the last dose). We perfused livers and performed single cell RNA seq (scRNA-seq) at 24 hours after the first and last dose and 56 days after the last dose. We also examined tissue by immunohistochemistry, RNA in situ hybridization, and/or RT-qPCR at all timepoints.

**Results:** We detected all known cell types in the liver in our scRNA-seq data, and SZN-043 induced Wnt target gene expression in hepatocytes and promoted hepatocyte proliferation. At 24 hours after the first dose, minimal pharmacologic effects were observed. At Day 14, the expression of central vein-associated metabolic genes was expanded and the expression of periportal vein-associated metabolic genes reduced. In addition, a significantly higher number of proliferating hepatocytes (Ki67+/HNF4 $\alpha$ +) were observed in mice treated with SZN-043 compared to mice administered anti-GFP. The proliferating hepatocytes were located primarily in the periportal area, colocalizing with periportal markers. Both hepatocyte proliferation and changes in zonal-specific gene expression normalized upon 7 days of washout. We did not detect any direct effects of SZN-043 on non-hepatocytes in the liver although we did observe an increase in *Chil3* expression, a gene associated with an anti-inflammatory macrophage state, in a subset of Kupffer cells.

**Conclusion:** SZN-043 induces a transient increase in the number of proliferating hepatocytes and a transient shift in zonal metabolic gene expression, and both changes normalize within 7 days of dosing cessation. The ability of SZN-043 to target hepatocytes and promote their proliferation suggests its utility as a regenerative therapy for liver diseases.

### GS-2283

#### Long-term Efficacy and Safety of Tenofovir Disoproxil Fumarate (TDF) in Children with Chronic Hepatitis B (CHB): Final Results from a Placebo-Controlled Trial

Mei-Hwei Chang<sup>1</sup>, Jorge Bezerra<sup>2</sup>, Byung-Ho Choe<sup>3</sup>, Daniela Pacurar<sup>4</sup>, Sandeep Nijhawan<sup>5</sup>, Jae Hong Park<sup>6</sup>, Rajiv Mehta<sup>7</sup>, Yon Ho Choe<sup>8</sup>, John F. Flaherty<sup>9</sup>, Anh-Hoa Nguyen<sup>9</sup>, Yang Liu<sup>9</sup>, Alexandrina Constantinescu<sup>10</sup>, Philip Rosenthal<sup>11</sup>, Kyung Mo Kim<sup>12</sup>, Daniel Hao Bin Leung<sup>13</sup>. <sup>1</sup>National Taiwan University Hospital, Taipei City, Taiwan; <sup>2</sup>Cincinnati Children's Hospital, Cincinnati, United States; <sup>3</sup>Kyungpook National University; <sup>4</sup>Grigore Alexandrescu Emergency Clinical Hospital for Children, Institute of Medicine and Pharmacy Bucharest; <sup>5</sup>Sawai Man Singh Hospital, SMS Medical College; <sup>6</sup>Pusan National University Children's Hospital; <sup>7</sup>Surat Institute of Medical Sciences (SIDS); <sup>8</sup>Sungkyunkwan University School of Medicine; <sup>9</sup>Gilead Sciences Inc.; <sup>10</sup>Fundeni Clinical Institute; <sup>11</sup>University of California, San Francisco; <sup>12</sup>Asan Medical Center Children's Hospital, Ulsan College of Medicine; <sup>13</sup>Texas Children's Hospital, Baylor College of Medicine  
Email: john.flaherty@gilead.com

**Background and aims:** TDF was approved in 2018 for treatment of CHB in children  $\geq 2$  years (y) weighing  $\geq 10$  kg based on 48-week results from GS-US-174-0144 (NCT01651403); here we report long-term efficacy and safety findings for TDF treatment through 4 years (192 weeks).

**Method:** Pediatric CHB patients aged 2 to  $<12$  y,  $\geq 10$  kg body wt. with HBV DNA  $\geq 4$  log<sub>10</sub> IU/ml, ALT  $\geq 1.5 \times$  ULN ( $\leq 30$  U/L), and creatinine clearance (eGFR)  $\geq 80$  ml/min/1.73 m<sup>2</sup> were randomized (1:1) to TDF 8 mg/kg or matching placebo (PBO) once daily in a double-blind (DB) fashion for 48 weeks (primary end point: % with HBV DNA  $<69$  IU/ml) or 72 weeks, and then eligible for open-label (OL) TDF through Week 192. Viral suppression, serologic and biochemical responses

were serially determined, viral resistance (pol/RT sequencing/phenotyping) was performed yearly (HBV DNA  $\geq 69$  IU/ml), and safety, including changes in renal and bone parameters was assessed.

**Results:** 89 patients (TDF 60; PBO 29) were randomized and treated, of which 81 (91%; TDF 56; PBO 25) and 77 (87%; TDF 55; PBO-TDF 22) completed both DB and OL phases. At baseline: mean (range) age and weight were 6 (2–12) y and 24 (10.5–55) kg, with 56% male, 65% Asian, 96% HBeAg-positive; mean (SD) HBV DNA and ALT were 8.1 (0.9) log<sub>10</sub> IU/ml and 123 (92) U/L, respectively. Week 192 efficacy (TDF vs PBO-TDF by missing = failure analysis): HBV DNA  $<29$  IU/ml 82% vs 62%; ALT normalization 72% vs 50%; HBeAg loss 54% vs 34%, and HBsAg loss 10% vs 0%. Most adverse events (AEs) during the OL phase were mild-moderate (most common were URIs and GI disorders); no patient had a Grade 3/4 AE or serious AE related to study treatment and none discontinued OL treatment due to an AE. 3 patients (2 TDF; 1 PBO-TDF) had confirmed eGFR  $<70$  but  $\geq 50$  ml/min/1.73 m<sup>2</sup>. Mean % (SD) BMD increased from baseline which was slightly less in TDF vs PBO-TDF patients: spine: +19.2% [12.28] vs +26.1% [14.26]; whole body: +23.7% [9.82] vs. +27.7% [11.14]. No HBV amino acid substitutions associated with tenofovir resistance were detected through Week 192.

**Conclusion:** Long-term TDF treatment of CHB in children was associated with a high rate of viral suppression without resistance, while also being safe and well tolerated. Biochemical and serologic responses were comparable to those seen in adults and no patient experienced clinically significant bone or renal toxicity.

**Background and aims:** Latin-America has substantial socio-economic disparities between countries. Although alcohol consumption

## ORAL PRESENTATIONS

health effects are well-known in Latin-America, alcohol policies' impact are unknown. Therefore, we aimed to assess the association between alcohol policies, alcohol consumption, and cirrhosis in Latin-American countries.

**Method:** An Ecological multi-national Study including 20 countries in Latin America. We obtained country-level socio-demographic information from the World Bank Open Data source. Alcohol policies data for countries in Latin America were obtained from the World Health Organization (WHO) Global Information System of Alcohol and Health (GISAH). Data analysis included a fixed-effects model to estimate proportions and multiple linear regression models.

**Results:** We included 20 countries (628, 466, 088 inhabitants). The average  $\pm$  SD GINI index in 2016 was  $45.9 \pm 3.9$ , and the mean  $\pm$  SD gross domestic product per capita was US\$ 14, 723  $\pm$  7, 555. The estimated alcohol per capita consumption (APC) among the population 15 years old was 6.84 liters of pure alcohol (5.62 recorded and 1.23 unrecorded). The countries that lead APC were Uruguay (10.8 liters), Argentina (9.8 liters), and Chile (9.3 liters). The prevalence of alcohol use disorder (AUD) was 4.89%. A total of 19 (95%) countries have alcohol-related public health policies. The most frequent alcohol policies were: limiting drinking age and youth focus (90%), alcohol and driving (90%), and government monitoring systems (90%). The presence of alcohol policies in the country was associated with a lower risk of AUD (OR 0.83, 95%CI 0.73–0.94;  $p = 0.004$ ), lower deaths due to traffic injuries (OR 0.84, 95% CI 0.71–0.98;  $p = 0.028$ ), and alcohol-associated cirrhosis (OR 0.18, 95%CI 0.07–0.46,  $p < 0.001$ ).

**Conclusion:** The current ecological study demonstrates that countries with more alcohol policies have lower alcohol per capita consumption, deaths due to traffic injuries, and alcohol-associated cirrhosis. These results encourage the introduction of alcohol control policies in all countries.

#### OS-1293

#### Neutrophil extracellular traps formation induced by alcohol generates a unique neutrophil subset with defective neutrophil functions causing liver damage in alcoholic hepatitis

Yeonhee Cho<sup>1,2</sup>, Terence Bukong<sup>3</sup>, David Tornai<sup>4</sup>, Gyongyi Szabo<sup>2,5</sup>.  
<sup>1</sup>University of Massachusetts Medical School, Medicine, Worcester, United States; <sup>2</sup>Beth Israel Deaconess Medical Center (BIDMC), Gastroenterology, Boston, United States; <sup>3</sup>Armand-Frappier Santé Biotechnologie, Laval, Canada; <sup>4</sup>University of Debrecen Medical School, Internal Medicine, Debrecen, Hungary; <sup>5</sup>Harvard Medical School, Boston, United States

Email: ycho3@bidmc.harvard.edu

**Background and aims:** In alcoholic hepatitis (AH), neutrophil count correlates with poor clinical outcomes. However, it is yet to be

explored why neutrophil count increases and whether increased neutrophils induce inflammation and liver damage in AH. Here, we aimed to explore whether neutrophils contribute to alcohol-induced liver damage through increased neutrophil extracellular traps (NET) formation. We identified a unique neutrophil subset (low-density neutrophils, LDNs) and studied mechanisms and consequences of LDNs increase in AH.

**Method:** NETs were assessed by NET assays, co-immunofluorescence staining and microscopic analysis with liver specimen from AH patients and mice. LDNs and high-density neutrophils (HDNs) were isolated from AH patients and controls for RNA sequencing. The NIAAA AH model or 4-week chronic alcohol feeding was utilized for in vivo studies in mice.

**Results:** NET components, including citrullinated histone H3, were significantly elevated in the serum from AH patients, and NET formation was detected in the liver from AH patients and mouse models. Neutrophil depletion in vivo with anti-Ly6G antibody prevented NET formation and reduced alcohol-induced liver damage in mice, supporting the role of NET-mediated liver damage in AH. In patients with AH, we identified low-density neutrophils (LDNs), a unique neutrophil subset, during density separation of blood mononuclear cells. LDNs were present only in AH patients and

## ORAL PRESENTATIONS

not in healthy subjects or NASH patients. AH-specific LDNs expressed markers of mature neutrophils with exhaustive phenotypes based on flow cytometry and transcriptomic profile. We discovered that LDNs are generated from HDNs after alcohol-induced NET formation. Moreover, transcriptomic analysis identified significant reduction of the neutrophil homing receptor, CXCR4, expression and increased transpondin-1 (don't eat me signal) in AH HDNs and to a greater extent in LDNs compared healthy subjects suggesting that LDNs are defective in homing back to the bone marrow or clearance by phagocytes such as macrophages.

**Conclusion:** Alcohol-induced NET formation contributes to prolonged liver damage and generates a novel LDN neutrophil subset that has defects in functions and clearance from circulation and/or liver.

### OS-1619

#### Lung infection impacts short-term survival in severe alcoholic hepatitis treated with steroids: results of a prospective monocenter study

Line Carolle Ntandja Wandji<sup>1</sup>, Elise Lemaître<sup>1</sup>, Khaldi Marion<sup>1</sup>, Massih Ningharhari<sup>1</sup>, Pierre Saffers<sup>1</sup>, Julien Lollivier<sup>1</sup>, Lassailly Guillaume<sup>1</sup>, Sebastien Dharancy<sup>1</sup>, Philippe Mathurin<sup>1</sup>, Alexandre Louvet<sup>1</sup>. <sup>1</sup>CHU de Lille, Lille, France  
Email: alexandre.louvet@chru-lille.fr

**Background and aims:** Severe alcoholic hepatitis (AH) is associated with an increased risk of infection but the impact of lung infection has not been specifically analyzed in a dedicated cohort.

**Method:** All patients admitted for severe AH (Maddrey score  $\geq 32$ ) between 2002 and 2020 in our unit were prospectively included. AH was confirmed by liver biopsy. Systematic screening for infection was performed at admission and renewed in case of clinical suspicion during follow-up. If present, infection was treated before steroid initiation and response to steroids was defined using the Lille model.

**Results:** We included 614 patients with severe AH (males in 60.4% of cases, mean age 49.9 years, median MELD 25.2, bilirubin 18.1 mg/dl), of whom 202 (32.9%) were infected at admission (73 lung infections). In multivariate analysis, encephalopathy (OR 3.9, 95%CI 1.48–10.24,  $p=0.006$ ), MELD score (OR 1.1, 95%CI 1.046–1.155,  $p=0.0002$ ) and tobacco exposure (past: OR 4.29, 95%CI 1.726–10.691,  $p=0.002$  or active: OR 3.424, 95%CI 1.462–8.02,  $p=0.005$ ) were independently associated with lung infection at admission. Factors associated independently with death before steroid initiation were encephalopathy (OR, 5.1, 95%CI 1.734–15.044,  $p=0.003$ ), MELD score (OR 1.056, 95%CI 1–1.15,  $p=0.05$ ) and especially lung infection compared to other infections (OR 14.285, 95%CI 3.959–51.541,  $p<0.0001$ ). Thus, patients with lung infection at admission had a lower probability of receiving steroids as compared to those with other infections and those non-infected: 54.8 vs. 88.4 vs. 98.1% ( $p<0.0001$ ). Among the 558 patients who received corticosteroids, 146 developed infection, including 57 (39.04%) lung infections. The risk of lung infection was higher in non-responders to steroids (Lille score  $\geq 0.45$ ) than in responders: 13% vs. 7.6%,  $p=0.03$ . The risk of non-respiratory infection was also higher in non-responders: 27.9% vs. 10.6%,  $p<0.001$ . Variables independently associated with 2-month death were lung infection (RR 1.76, 95%CI 1.05–2.96,  $p<0.0001$ ), non-response to steroids (RR 10.41, 95% CI 5.33–20.33,  $p<0.0001$ ), MELD score at steroid initiation (RR 1.096, 95%CI 0.53–1.14,  $p<0.0001$ ) while non-respiratory infection was not independently predictive of 2-month death (RR 1.11, 95%CI 0.680–1.81,  $p=0.67$ ).

**Conclusion:** Lung infection is frequent during severe AH and impacts mortality at admission and after steroid initiation. These results question the need for a systematic chest CT-scan during AH course.

### OS-1663

#### Extracellular inflammasome components perpetuate inflammation in alcoholic hepatitis

Marcelle de Carvalho Ribeiro<sup>1</sup>, Mrigya Babuta<sup>1</sup>, Charles D. Calenda<sup>1</sup>, Christopher Copeland<sup>1</sup>, Donna Catalano<sup>2</sup>, Yeonhee Cho<sup>1,2</sup>, Gyongyi Szabo<sup>1</sup>. <sup>1</sup>Beth Israel Deaconess Medical Center (BIDMC), Department of Medicine, Boston, United States; <sup>2</sup>University of Massachusetts Medical School, Department of Medicine, Worcester, United States  
Email: mribeir1@bidmc.harvard.edu

**Background and aims:** Nucleotide-binding oligomerization domain-like receptor family, pyrin domain containing 3 (NLRP3) inflammasome is activated in Alcoholic Liver Disease (ALD). Upon stimulation, NLRP3 recruits the adaptor protein apoptosis-associated speck-like protein containing CARD (ASC) to oligomerize into specks intracellularly for interleukin (IL)-1 beta release. ASC specks released from pyroptotic cells remain bioactive extracellularly and can activate inflammasomes in neighboring cells. In alcoholic hepatitis (AH), the mechanism for maintaining inflammation even after cessation of alcohol use is yet to be understood. We hypothesized that alcohol induces ASC specks in macrophages (MØs) and hepatocytes, and that these ASC specks propagate inflammation in ALD. Our aim was to investigate how extracellular ASC specks perpetuate inflammation in AH.

**Method:** Liver and plasma samples from patients with AH and healthy controls were analyzed for ASC aggregates or ASC specks. Transgenic mice expressing fluorescent ASC (ASC-Citrine/Cre+ mice) were evaluated for ASC specks in plasma, liver tissue, MØs, and hepatocytes. The extracellular effect of ASC specks was assessed in HepG2 and THP-1 cell lines. MCC950 was used *in vivo* and *in vitro* to inhibit NLRP3 inflammasome.

**Results:** Circulating ASC specks and hepatic ASC aggregates were elevated in AH patients compared to healthy controls. Additionally, EtOH binge increased circulating and hepatic ASC specks levels, and induced Kupffer cells pyroptosis and hepatocyte damage in mice. We found that EtOH-treated MØ and hepatocytes released ASC specks via pyroptosis and GSDMD KO mice were protected from EtOH-induced increases in ALT and ASC release in plasma. ASC specks derived from EtOH/LPS-stimulated MØs or hepatocytes triggered significant IL-1 beta release in monocytes, and this was prevented by the NLRP3 inhibitor, MCC950. *In vivo*, MCC950 administration reduced liver ASC specks formation, caspase-1 activation, IL-1 beta production, and steatohepatitis in AH mice.

**Conclusion:** ASC specks in the circulation and in the liver perpetuate inflammation in AH. Alcohol binge induces the release of ASC specks involving pyroptosis both in hepatocytes and MØs and sustains inflammation. NLRP3 activation, eliciting liver ASC specks formation is responsible for progression of AH, identifying NLRP3 as a potential therapeutic target in ALD.

OS-1726

**Natural history of alcohol-related liver disease according to biopsy-proven fibrosis in a prospective study of 422 patients and 1,419 patient years**

Ditlev Rasmussen<sup>1</sup>, Maria Kjærsgaard<sup>1</sup>, Katrine Prier Lindvig<sup>1</sup>, Mads Israelsen<sup>1</sup>, Kathrine Thorhauge<sup>1</sup>, Nikkolaj Christian Torp<sup>1</sup>, Stine Johansen<sup>1</sup>, Sönke Detlefsen<sup>2</sup>, Aleksander Krag<sup>1</sup>, Maja Thiele<sup>1</sup>.  
<sup>1</sup>Odense University Hospital, Department of Gastroenterology and Hepatology; <sup>2</sup>Odense University Hospital, Department of Pathology  
 Email: ditlev.nytoft.rasmussen@regionh.dk

**Background and aims:** Alcohol-related cirrhosis is associated with high risk of complications and death, but the natural history of different stages of liver fibrosis in asymptomatic, alcohol-overusing patients is unknown. We aimed to describe the natural history of alcohol-related liver disease according to fibrosis stage determined by liver biopsy, and alcohol status at baseline and during follow-up.

**Method:** We included patients with a history of alcohol overuse but without decompensated liver disease. Based on transient elastography and liver biopsies scored according to Kleiner, we compared liver healthy patients who had a biopsy with F0-F1 fibrosis or transient elastography <6 kPa, patients with significant fibrosis (F2), and advanced fibrosis (F3-4). Ongoing alcohol consumption was an additional predictor. We manually assessed the patients' medical charts for mortality and decompensating events defined as development of overt hepatic encephalopathy, ascites, hepatorenal syndrome, variceal bleeding, or jaundice.

**Results:** We followed 422 patients for a total of 1,419 patient-years. The median age at baseline was 57 years (IQR 50–64) and 75% were men. During a median follow-up of 43 months (IQR 20–59), 53 patients died. Fifty-one patients experienced a decompensating event, 27 of whom also died. Decompensation-free survival significantly followed disease stage: 13/225 (5.8%) liver-healthy patients died and/or decompensated, compared to 22/104 (21%) with significant fibrosis (hazard ratio, HR 3.8, 1.9–7.5,  $p < 0.01$ ), and 42/93 (45%) with advanced fibrosis (HR 9.6, 5.2–18.0,  $p < 0.01$ ), see figure. At three years, the overall mortality was 3% for liver healthy patients, 12% for patients with significant fibrosis and 22% for patients with advanced fibrosis. Ascites and overt hepatic encephalopathy were the most common decompensating events, followed by variceal bleeding. Periods of excessive drinking during follow-up resulted in poorer decompensation-free survival (HR 1.6, 1.02–2.6), mainly due to decompensation or death in patients with significant or advanced fibrosis. Hospitalizations occurred more frequently in the group of advanced fibrosis, but were comparable for the two remaining groups.

**Conclusion:** Patients with alcohol-related significant or advanced fibrosis are at high risk of short-term decompensation and death. This

suggests that also patients with moderate fibrosis should be offered combined alcohol rehabilitation and monitoring in liver specialist care.

OS-2028

**CXCL12-CXCR4 pathway drives hepatocyte reprogramming in alcoholic hepatitis**

Beatriz Aguilar-Bravo<sup>1</sup>, Silvia Ariño Mons<sup>1</sup>, Elisa Pose<sup>2</sup>, Juanjo Lozano<sup>3</sup>, Philippe Mathurin<sup>4</sup>, Pere Ginès<sup>2</sup>, Pau Sancho-Bru<sup>1</sup>.  
<sup>1</sup>Institut d'Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS), Cell plasticity and tissue repair, Barcelona, Spain; <sup>2</sup>Hospital Clínic de Barcelona, Liver Unit, Barcelona, Spain; <sup>3</sup>Centro de Investigación Biomédica en Red de Enfermedades Hepáticas y Digestivas (CIBERehd), Barcelona, Spain; <sup>4</sup>Hospital Claude Huriez, Service des Maladies de l'Appareil Digestif, Lille, France  
 Email: aguilar@clinic.cat

**Background and aims:** Hepatocyte reprogramming leading to a loss of cell identity has been previously shown to take place in alcoholic hepatitis (AH) patients. However, the mechanisms and the impact on liver function are poorly understood. The aim of this study was to evaluate the impact of hepatocyte reprogramming and the presence of intermediate hepatobiliary (IHB) cells on the progression of alcohol-related liver disease (ALD) and to dissect the molecular mechanisms regulating this process.

**Method:** KRT7<sup>+</sup> hepatocytes (IHB cells) were quantified in liver biopsies from an ALD cohort (n=34). IHB cells, KRT7<sup>+</sup> ductular reaction (DR) cells and KRT7<sup>-</sup> hepatocytes were isolated by laser capture microdissection from AH liver sections and used for RNAseq analysis. Transcriptomic analysis was confirmed by immunofluorescence. The protein network interaction of CXCR4 pathway was evaluated by String. CXCR4 and CXCL12 expression was assessed in AH liver sections, and mechanistic studies were performed with primary hepatocytes.

**Results:** Both IHB and DR cells were increased in AH and decompensated cirrhotic patients, but only IHB cells correlated with poor liver function and reduced synthetic capacity. Transcriptomic profile of IHB cells revealed a transitional phenotype between hepatocyte and biliary cells. Interestingly, hepatocyte transcription factors (TF) and functional markers were reduced in IHB cells suggesting a loss of hepatocyte identity. Functional analysis identified well known pathways involved in hepatocyte reprogramming such as TGFβ, but also novel pathways such as CXCR4 or JAK-STAT. Histologically, CXCR4 protein expression was increased in IHB and DR cells, but it was absent in KRT7<sup>-</sup> hepatocytes. Importantly, CXCR4 expression was found to negatively correlate with the expression of mature hepatocyte TF and albumin and positively with disease severity in a cohort of AH patients. Mechanistically, primary hepatocytes showed expression of CXCR4 in response to TGFβ, and recombinant CXCL12 promoted hepatocyte reprogramming.

**Conclusion:** This study shows the association of the loss of hepatocyte identity with ALD progression and poor liver function. Moreover, we identify the CXCL12/CXCR4 pathway as a new driver of hepatocyte reprogramming in AH. Overall, this study suggests that strategies limiting hepatocyte reprogramming and enhancing differentiation may be of interest to improve liver function in advanced ALD.

Email: s.chokshi@researchinliver.org.uk

**Background and aims:** Advanced alcohol-related liver disease (ALD) is associated with defective antibacterial immunity. Consequently, patients face an increased vulnerability to bacterial infection, which may worsen organ failure and increase the risk of death. The interferon lambda family (IFN- $\lambda$ 1/ $\lambda$ 2/ $\lambda$ 3/ $\lambda$ 4) are important mediators of anti-pathogen immunity, but their role in ALD remains unexplored.

**Method:** Genetic variants in IFN- $\lambda$ 1/ $\lambda$ 2/ $\lambda$ 3/ $\lambda$ 4 and their associations with infection were explored in 814 STOPAH participants with severe alcoholic hepatitis (SAH) and >11000 disease and healthy controls. Liver and colon expression of IFN- $\lambda$ 4 was measured in a public ALD liver microarray dataset and in ALD colonic biopsies. Systemic plasma IFN- $\lambda$ 4 levels and production of IFN- $\lambda$ 4 during in vitro bacterial challenge of peripheral blood mononuclear cells (PBMC) in ALD patients and healthy controls (HC) were measured by ELISA. IFN- $\lambda$ 4 gene expression was assessed in a large PBMC transcriptomics dataset from patients with ALD (30 alcohol-related cirrhosis, ARC; 15 SAH; 12 HC). Finally, the impact of recombinant IFN- $\lambda$ 4 on antibacterial immune responses in *E. coli* stimulated PBMC cultures from ALD patients and HC was measured by flow cytometry and Luminex.

**Results:** The only variant associated with bacterial infection in SAH patients at presentation ( $p=0.03$ ) was the loss-of-function rs117648444 in IFNL4. Based on this, we focussed the mechanistic arm of this study on IFN- $\lambda$ 4 alone. IFN- $\lambda$ 4 was not expressed in the liver or colon of ALD patients but plasma IFN- $\lambda$ 4 was lower in these patients compared to HC. PBMC IFN- $\lambda$ 4 production was lower in ARC patients and undetectable in SAH, compared to HC, and was completely abolished following *E. coli* challenge. In the PBMC transcriptomics dataset, IFN- $\lambda$ 4 gene expression was lower in ARC and SAH patients compared to HC ( $p=0.005$ ), and in vitro treatment of ALD and HC PBMC with recombinant IFN- $\lambda$ 4 modulated the antibacterial immunity.

**Conclusion:** IFN- $\lambda$ 4 is involved in the immunopathogenesis of ALD and may be a novel attractive target for immunomodulation of antibacterial responses in patients with advanced disease.

##### PD-L1 expression of monocytes relates to severity, infection and mortality in acute-on-chronic liver failure

Evangelos Triantafyllou<sup>1</sup>, Francesca Trovato<sup>2</sup>, Hannah Husbyn<sup>1</sup>, Xiaohong Huang<sup>2</sup>, Sujit Mukherjee<sup>1</sup>, Christine Bernsmeier<sup>3</sup>, Robert D. Goldin<sup>1</sup>, Julia Wendon<sup>2</sup>, Lucia Possamai<sup>1</sup>, Wafa Khamri<sup>1</sup>, Mark Thursz<sup>1</sup>, Mark J.W. McPhail<sup>2</sup>. <sup>1</sup>Imperial College London,

Metabolism, Digestion and Reproduction, London, United Kingdom; <sup>2</sup>King's College London, Inflammation Biology, School of Immunity and Microbial Sciences, London, United Kingdom; <sup>3</sup>University of Basel and University Centre for Gastrointestinal and Liver Diseases, Department of Biomedicine, Basel, Switzerland  
Email: e.triantafyllou@imperial.ac.uk

**Background and aims:** Monocyte dysfunction and bacterial infections are common in cirrhosis and acute-on-chronic liver failure (ACLF) and substantially contribute to the high mortality. We recently identified the importance of the PD-1/PD-L1 checkpoint pathway in regulating macrophage antimicrobial responses in acute liver failure. Here, we sought to explore PD-1/PD-L1 axis in chronic liver failure.

**Method:** Flow cytometry was used to determine the phenotype of lymphocytes (CD3<sup>+</sup>CD4<sup>+</sup>, CD3<sup>+</sup>CD8<sup>+</sup> T cells and CD3<sup>+</sup>CD4<sup>+</sup>CD25<sup>high</sup>CD127<sup>low</sup> Tregs) and monocytes (CD14<sup>+</sup>HLA-DR<sup>+</sup>) in blood of 10 healthy controls (HC) and patients with stable cirrhosis (SC, n=6), decompensated cirrhosis (DC, n=8) and ACLF (n=24). Plasma cytokine concentrations were measured by Meso-Scale-Discovery (MSD) kit. PD-L1 expression was examined by immunohistochemistry (IHC) in tissue derived from cirrhotic patients and pathological controls. Monocyte *E. coli* phagocytosis was assessed in PBMCs (HC and ACLF, n=5 each) pre-treated with or without anti-PD-1 blocking antibody (10  $\mu$ g/ml).

**Results:** Compared to healthy and disease controls, monocytes in ACLF patients displayed decreased HLA-DR expression (A), as previously established, and significantly increased PD-L1 expression (both % and MFI) (B). Of note, PD-1 expression of CD4<sup>+</sup>, CD8<sup>+</sup> and Treg cells was not altered among study groups. Importantly, monocyte PD-L1 expression was significantly higher in patients who developed infectious complications or had poor outcome (day 90 mortality) (C). PD-L1 levels correlated with other monocyte anti-inflammatory/pro-restorative markers (CD163 and MerTK), systemic inflammation (e.g., plasma IL-10, IL-8 and IL-6) and disease severity (e.g., MELD, CLIF-SOFA, CLIF-ACLF) (D). Increased hepatic PD-L1 expression was detected in liver tissue from cirrhotic patients, compared to pathological controls. Finally, compared to HC, ACLF patients had decreased monocyte *E. coli* phagocytosis capacity [34663 vs 22722 (MFI);  $p=0.0281$ ] which was improved with in vitro PD-1/PD-L1 blockade (22722 vs 26160 MFI;  $p=0.0312$ ).

**Conclusion:** We have identified the expansion of an immune-suppressive PD-L1<sup>+</sup> monocyte population that correlates with disease severity and risk of infections in ACLF. Thus, monocyte PD-L1 may serve as prognostic marker and deserves further evaluation as immunotherapeutic target aimed to prevent the high morbidity and mortality associated with infections in this condition.

#### OS-845

##### Treatment of hepatorenal syndrome type 1 with terlipressin reduces need for renal replacement therapy post-liver transplantation

Juan Carlos Q. Velez<sup>1</sup>, Seth Sclair<sup>2</sup>, Antonio Sanchez<sup>3</sup>, Stephen Caldwell<sup>4</sup>, Samuel Sigal<sup>5</sup>, Paul J. Thuluvath<sup>6</sup>, Rohit S. Satoskar<sup>7</sup>, S. Chris Pappas<sup>8</sup>, Khurram Jamil<sup>9</sup>. <sup>1</sup>Ochsner Health System, Department of Nephrology; <sup>2</sup>University Hospitals Cleveland Medical Center, Division of Gastroenterology and Liver Disease, Cleveland; <sup>3</sup>University of Iowa Hospitals and Clinics, Division of Gastroenterology and Hepatology, Iowa City; <sup>4</sup>University of Virginia, Gastroenterology and Hepatology; <sup>5</sup>Montefiore Medical Center, Department of Medicine; <sup>6</sup>Mercy Medical Center and University of Maryland School of Medicine, Division of Gastroenterology; <sup>7</sup>MedStar Georgetown University Hospital, Liver Transplantation; <sup>8</sup>Orphan Therapeutics, Scientific Affairs; <sup>9</sup>Mallinckrodt Pharmaceuticals, Department of Scientific Affairs  
Email: juancarlos.velez@ochsner.org

**Background and aims:** Hepatorenal syndrome type 1 (HRS-1) is a severe but reversible acute kidney injury in patients with cirrhosis. The need for renal replacement therapy (RRT) posttransplant is

Figure: (abstract: OS-638)

associated with prolonged intensive care unit stays and decreased survival. Recently, a randomized placebo (PBO)-controlled trial (CONFIRM, NCT02770716) demonstrated the efficacy of terlipressin (TERLI) for inducing reversal of HRS-1 and reducing the cumulative need for RRT. This study assessed whether TERLI reduces the rate of RRT following liver transplantation (LT).

**Method:** CONFIRM was a North American trial (N=300) that compared HRS-1 reversal rates between patients treated 2:1 with albumin plus TERLI (n = 199) or albumin plus PBO (n = 101). In a post hoc analysis, we assessed the rate of RRT post-LT by intention-to-treat analysis through 90 days of follow-up. We also conducted a pooled analysis of the 3 TERLI RCTs in HRS-1 (OT-0401 [NCT00089570], REVERSE [NCT01143246], and CONFIRM) to examine 90-day overall and RRT-free survival rates in patients who received LT.

**Results:** In CONFIRM, 23.1% (46/199) of patients in the TERLI group and 28.7% (29/101) of patients in the PBO group underwent LT. Following LT, the rate of post-LT RRT in patients who received TERLI was significantly lower than that in those who received PBO (19.6% [9/46] vs 44.8% [13/29], respectively; p = 0.036). The overall 90-day survival rate for those transplanted in the TERLI group was 100% (46/46) compared with 93.1% (27/29) in the PBO group (p = not significant). Further, in the pooled analysis of the 3 phase 3 studies, the 90-day survival rates were 98.9% (93/94) and 91.0% (71/78), respectively (p = 0.014). In the pooled analysis of REVERSE and CONFIRM, for transplant-listed patients, 50.0% (46/92) of patients in the TERLI group were alive without RRT at Day 90 compared with 32.2% (19/59) in the PBO group (p = 0.032).

**Conclusion:** Treatment with TERLI added to albumin for patients with HRS-1 significantly decreases the need for RRT following LT.

Email: rbanares@ucm.es

**Background and aims:** In ACLF, systemic inflammation (SI) due to pathogen and damage associated molecular patterns (PAMPs and DAMPs), albumin and endothelial dysfunction results in organ failure. DIALIVE, a liver dialysis device replaces dysfunctional albumin and removes PAMPs and DAMPs. In a randomised controlled trial, DIALIVE resolved ACLF faster and in a greater proportion of patients compared with standard of care (SOC). This substudy aimed to evaluate the effect of DIALIVE on pathophysiological processes that are thought to be causally associated with ACLF.

**Method:** The study included patients with ACLF 1-3a, randomized either to DIALIVE or SOC. End points were evaluated at Day 10. The DIALIVE group received treatments in the first 3-days (range 1-6). Plasma samples were obtained on Days 0, 5 and 10. A post-hoc inferential Mixed Models for Repeated Measurements analysis was performed to evaluate the statistically significant differences

## ORAL PRESENTATIONS

Figure: (abstract: OS-2060): Impact of DIALIVE on the pathophysiological processes deranged in ACLF-change from baseline at Days 5 and 10 for DIALIVE (green) and SOC (red) group.

between groups at the Day 10. Changes in variables from baseline in the groups is shown in the Fig.SAS system v.9.4 used.

**Results:** 32 ACLF patients were randomised to DIALIVE (N = 17; CLIF-Ofs: 10.3 (1.6)) or SOC (n = 15; CLIF-Ofs: 9.9 (1.2)). 30-evaluable patients (n = 15 each group) comprised this substudy. **PAMPs:** *Endotoxin activity assay:* The patient-level pre-defined reduction goals were 20%. Marked advantage seen for DIALIVE (80%) vs SOC (36.4%) at Day 5. **LAL assay.** Significant reduction in DIALIVE group (p = 0.001). **Albumin Function:** DIALIVE increased human mercaptalbumin (p = 0.001) and reduced human nonmercaptalbumins 1 and 2 (p = 0.005 and p = 0.017); improved binding capacity (p = 0.016; using EPR spectroscopy) and reduced ischemia modified albumin ratio (p = 0.009) vs SOC. **DAMPs:** M30 and M65 components of cytokeratin 18 (p = 0.005; p = 0.029) and RIPK3 (marker of necroptosis) (p = 0.486) were reduced in the DIALIVE group. **SI:** IL-8, IL-18 and TNF $\alpha$  were reduced in the DIALIVE compared with SOC group (p = 0.006; p = 0.636; p = 0.053). **Endothelial function:** ADMA and Factor VIII were markedly reduced in the DIALIVE patients (p = 0.002; p = 0.195). **TLR4 and Inflammasome ligands:** Incubation of patient's plasma with a 1L1b/IL18 Inflammasome cell line and TLR4 reporter cell line reduced signalling significantly (p = 0.002 and p = 0.030).

**Conclusion:** IALIVE impacts significantly on DAMPs, PAMPs, albumin and endothelial function, markers of SI and, reduces TLR4 and inflammasome ligands that collectively contribute to its ability to resolve ACLF.

### OS-2142

#### Comparison of 20% albumin versus crystalloid plasmalyte for fluid resuscitation in cirrhotics with sepsis induced hypotension an open label randomized controlled trial

Abhinav Verma, Dr<sup>1</sup>, Rakhi Maiwall<sup>1</sup>, Amrish Sahney<sup>1</sup>, Lalita Mitra<sup>2</sup>, Shiv Kumar Sarin<sup>1</sup>. <sup>1</sup>ILBS, Hepatology, New Delhi, India; <sup>2</sup>ILBS, Critical Care, NEW DELHI, India  
Email: shivsarin@gmail.com

**Background and aims:** Sepsis is an inflammatory response to severe infection characterized by hypovolemia and vasodilation requiring treatment with early antibiotics and fluid resuscitation. The choice of fluid to be used in a cirrhotic presenting with sepsis induced hypotension (SIH) is still unclear. We compared the efficacy and

safety of 20% albumin (ALB) versus plasmalyte (PLA) in reversing SIH in critically ill patients with cirrhosis (CICs).

**Method:** Cirrhotics with septic shock underwent open label randomization to receive either 20% albumin [0.5–1.0 gm/kg over 3 hours; n = 50] or plasmalyte (30 ml/kg over 3 hours, n = 50). Primary outcome was reversal of hypotension. Secondary outcomes included lactate clearance, need for dialysis, length of stay in the intensive care unit (ICU), 28-day mortality and adverse effects of therapy.

**Results:** The baseline characteristics were comparable between the two groups. The mean baseline arterial lactate (mmol/L) [9.16  $\pm$  3.18 vs 9.38  $\pm$  4.77, p = 0.78], mean arterial pressure [MAP] (mm of Hg) [51.4  $\pm$  6.51 vs. 49.8  $\pm$  4.45, P = 0.17] and SOFA scores [10.8  $\pm$  2.96 vs. 11.1  $\pm$  4.2; p = 0.68] were comparable in ALB vs. PLA groups, respectively. The most common etiology of cirrhosis was alcohol (39%) and commonest type of sepsis was pneumonia (40%). At 3 hours, there was no difference in the MAP, however a trend towards reduction in norepinephrine dose was noted in ALB vs. the PLA group [p = 0.05]. The lactate clearance was noted in both the groups at 3 hours, significantly higher in ALB than PLA (p = 0.012). There was no difference in the 28-day mortality in both the groups [ALB (42% vs. PLA 58%, p = 0.16) and length of ICU stay [p = 0.6]. Patients in the PLA group more frequently required dialysis [58% vs. 44.8%; p = 0.07], however, there was no difference in time to initiation of dialysis in both groups [99.67  $\pm$  71.2 vs. 82.12  $\pm$  48.3 hours; p = 0.26]. Patients in the ALB group showed significant worsening of lung functions [PaO<sub>2</sub>/FiO<sub>2</sub>] requiring discontinuation of therapy within 3 hours in 6 (12%) patients.

**Conclusion:** In cirrhotics with sepsis induced hypotension, Plasmalyte is as effective as 20% albumin in reversing hypotension, restoring the impaired microcirculation and is safe and well-tolerated. Albumin even though achieves rapid lactate clearance, cautious and judicious use of 20% ALB in cirrhotics with hypotension is recommended. **NCT02721238.**

OS-2779

**Targeted albumin therapy increases serum sodium in hospitalized cirrhosis patients with hyponatremia at baseline, but has no effect on short term outcome; a sub study from the ATTIRE Trial**

Louise China<sup>1</sup>, Nicholas Freemantle<sup>2</sup>, Ewan Forrest<sup>3</sup>, Gavin Wright<sup>4</sup>, Yiannis Kallis<sup>5</sup>, Alastair O'Brien<sup>6</sup>. <sup>1</sup>UCL Institute for Liver and Digestive Health, London, United Kingdom; <sup>2</sup>University College London Comprehensive Clinical Trials Unit, University College London, London, United Kingdom; <sup>3</sup>Glasgow Royal Infirmary, Glasgow, United Kingdom; <sup>4</sup>Mid and South Essex NHS Foundation Trust, Basildon and Thurrock University Hospitals NHS Foundation Trust, United Kingdom; <sup>5</sup>Barts and the London School of Medicine and Dentistry Queen Mary University of London, United Kingdom; <sup>6</sup>UCL Institute for Liver and Digestive Health, London, United Kingdom  
Email: alastair.o'brien@nhs.net

**Background and aims:** Hyponatremia is negatively associated with outcome in decompensated cirrhosis. Though there is little evidence-based guidance on treatment, data from a large retrospective cohort study indicated that patients treated with intravenous human albumin solution (HAS) saw greater resolution of hyponatremia associated with improved survival. We investigated data from ATTIRE (Albumin to Prevent Infection in Chronic Liver Failure) to determine whether albumin treatment benefited hospitalised decompensated cirrhosis patients with hyponatremia.

**Method:** ATTIRE was a randomized, multicenter, open-label, parallel-group trial in 777 patients. Patients received targeted 20% HAS infusions for up to 14 days or discharge, to raise albumin >30 g/L, or standard care. Albumin was permitted for paracentesis, spontaneous bacterial peritonitis, or hepatorenal syndrome in standard care. The composite primary end point was new infection, kidney dysfunction,

or death on days 3–15. We examined the interaction between targeted albumin and standard care for the primary end point stratifying by baseline sodium  $\geq$ / $<$ 130 mmol/L. Differences in sodium at day 5 between groups were analysed as a mixed model with sodium as response variable.

**Results:** 568/777 had a sodium  $\geq$ 130 and 206 <130 mmol/L at baseline. For <130 mmol/L patients, targeted albumin patients received 239.4 g (SD 129.1) of albumin and standard care 123.2 g (SD 138.4) ( $p < 0.0001$ ). For the composite primary end point, there was a non-linear response according to sodium at baseline with odds ratio rising for low and elevated values (Fig.1A and B). Randomisation to albumin was associated with an overall 1.77 mmol/L increase in sodium, (95% CI 1.04–2.51;  $p < 0.0001$ ) at day 5 which was greater in the hyponatremic group (mean 2.84 mmol/L, CI 1.10–4.57 compared to 1.46, CI 0.67–2.25). There was no interaction between sodium category (hypo or hypernatremia) and treatment group (albumin or standard care) for the composite primary end point, ( $p = 0.1002$ ; Fig. 1C), nor renal dysfunction and death individually ( $p = 0.532$  and  $0.528$ ). There was a significant interaction for development of new infection ( $p = 0.021$ ).

**Conclusion:** These prospective data from a randomised trial demonstrate the efficacy of targeted intravenous HAS to raise serum sodium in hospitalized decompensated cirrhosis with hyponatremia at baseline compared to standard care, however, this does *not* improve short-term outcome. There was a significant interaction for new infection but was a combination of improved outcome in targeted albumin hyponatremic patients compared to standard care and improvement in standard care in sodium  $\geq$ 130 mmol/L.

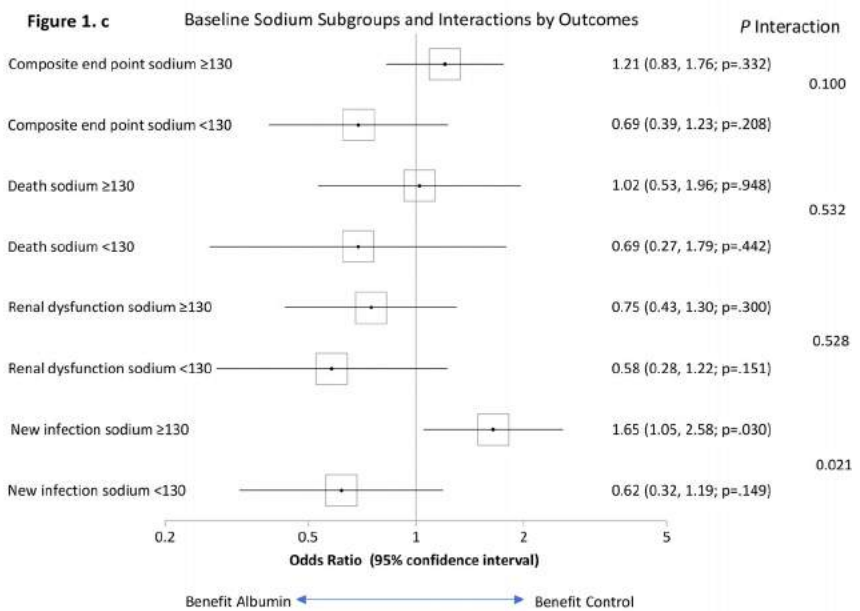

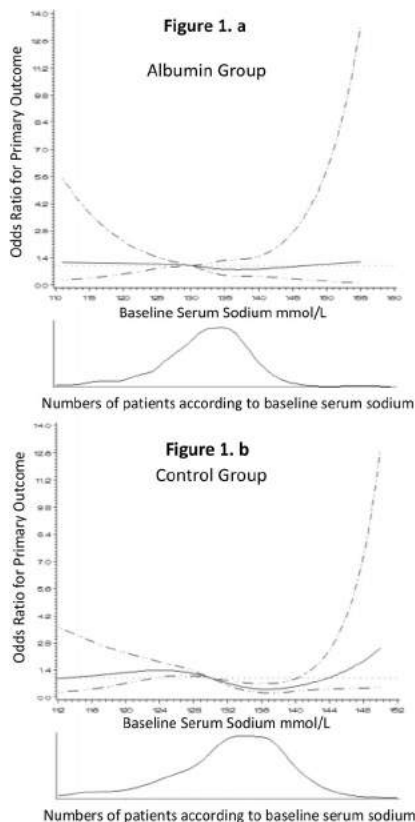

Figure: (abstract: OS-2779): Odds ratio for primary composite outcome according to baseline serum sodium in (a) Albumin and (b) Standard Care treatment groups. (c) Baseline Sodium subgroups and interactions by outcomes.

Tanabe<sup>2</sup>, Nathalie Pochet<sup>4,5</sup>, Yujin Hoshida<sup>3</sup>, Bryan C. Fuchs<sup>2,6</sup>, Thomas Baumert<sup>1,7</sup>. <sup>1</sup>Inserm U1110, Institute of Viral and Liver Disease, University of Strasbourg, Strasbourg, France; <sup>2</sup>Division of Surgical Oncology, Massachusetts General Hospital Cancer Center, Harvard Medical School, Boston, United States; <sup>3</sup>Liver Tumor Translational Research Program, Simmons Comprehensive Cancer Center, Division of Digestive and Liver Diseases, University of Texas Southwestern Medical Center, Department of Internal Medicine, Dallas, United States; <sup>4</sup>Broad Institute of Harvard and Massachusetts Institute of Technology, Cambridge, United States; <sup>5</sup>Program in Translational NeuroPsychiatric Genomics, Brigham and Women's Hospital, Harvard Medical School, Boston, United States; <sup>6</sup>Ferring Research Institute, San Diego, United States; <sup>7</sup>Institut Hospitalo-Universitaire, Pôle Hépatodigestif, Nouvel Hôpital Civil, Strasbourg, France  
Email: thomas.baumert@unistra.fr

**Background and aims:** Hepatocellular carcinoma (HCC) is a leading cause of death among cirrhotic patients. While new modalities for HCC treatment have been recently approved, HCC chemopreventive strategies for advanced fibrosis are lacking. Identification of candidate compounds for HCC chemoprevention has been hampered by the absence of tractable model systems and the complex cell circuitry driving disease progression. To address these roadblocks, we have recently developed a simple human cell-based system modeling a clinical prognostic liver signature (PLS) predicting liver disease progression and HCC risk (Crouchet et al. ILC 2020). Applying our cell-based discovery system combined with computational screening we identified captopril, an approved angiotensin converting enzyme (ACE) inhibitor, as a candidate compound for HCC chemoprevention. Here we aimed to explore ACE as a therapeutic target for HCC chemoprevention in state-of-the-art preclinical models of advanced fibrosis.

**Methods:** HCC chemoprevention was investigated in the DEN rat cirrhosis model and a diet-based rat model for NASH-induced hepatocarcinogenesis. The mechanism of action was explored using perturbation studies in cellular and patient-derived models combined with integrative RNA-Seq analyses and proteomics. To investigate the clinical translatability, we studied the impact of captopril on the liver cell circuits predicting fibrosis progression to HCC in cirrhotic patients.

**Results:** In both animal models Captopril markedly and significantly improved liver function, reduced liver fibrosis, and had a pronounced HCC chemopreventive effect as shown by a robust and significant decrease of tumor nodules and burden in the fibrotic or cirrhotic livers. RNA-Seq analysis in cirrhotic rat liver tissues showed that captopril significantly suppressed the expression of pathways mediating fibrogenesis, inflammation and carcinogenesis including

epidermal growth factor receptor (EGFR) signaling. Mechanistic data using gain- and loss-of function studies in cell-based liver disease models uncovered a cross-activation of the EGFR pathway by angiotensin in hepatic cells. Corroborating the clinical translatability, captopril markedly reversed the HCC high risk status of a well-established prognostic liver signature predicting HCC risk in liver tissues of patients with advanced fibrosis.

**Conclusion:** Captopril prevents fibrotic liver disease progression towards HCC development by targeting the angiotensin converting enzyme and EGFR transactivation. Our study identified the ACE inhibitor captopril as a generic and safe candidate drug ready for clinical assessment and HCC chemoprevention.

## Cirrhosis and its complications: Other clinical complications except ACLF and critical illness

### Branched chain amino acids do not improve muscle mass in patients of cirrhosis with sarcopenia: A double blind randomized placebo controlled trial

Srikant Mohta<sup>1</sup>, Sumaira Qamar<sup>1</sup>, Abhinav Anand<sup>1</sup>, Deepak Gunjan<sup>1</sup>, Namrata Singh<sup>1</sup>, Sanchit Sharma<sup>1</sup>, Samagra Agarwal<sup>1</sup>, Anoop Saraya<sup>1</sup>. <sup>1</sup>All India Institute of Medical Sciences, Department of Gastroenterology and human nutrition, New Delhi, India  
Email: ansaraya@yahoo.com

**Background and aims:** The role of branched-chain amino acids (BCAA) in alleviating sarcopenia in patients with cirrhosis is presently undefined. We aimed to evaluate the role of BCAA in improving the muscle mass in a randomised controlled trial.

**Method:** Consecutive patients of cirrhosis with Child Pugh score <10 and sarcopenia were randomized to receive either 12 g/day of BCAA or a placebo for 6 months in addition to a structured home-based exercise program (30 minutes/day) and diet counselling (1–1.2 g/kg/day, daily protein intake). Sarcopenia was defined according to gender specific axial skeletal muscle index (SMI) cut-offs. The primary end point was change in muscle mass based on computed tomography (CT) scan at the 6 months.

**Results:** Sixty patients [median age:43.5 (IQR = 19.3) years; males (66.6%) of predominantly alcohol related (40%) and viral (31.7%) etiologies] were randomised. Baseline clinical and demographic characters were similar except model for end-stage liver disease (MELD) score (10.2 ± 2.8 vs. 12.2 ± 3.5, p = 0.02) and calorie intake (1838.1 kcal ± 631.5 vs. 2217.5 kcal ± 707.3, p = 0.03), both being higher in the placebo arm. After adjusting for both baseline confounders and protein intake, the change in SMI was similar in both groups [mean adjusted difference (MAD) +0.84, CI –2.9; +1.2, p = 0.42]. The secondary outcomes including change in hand grip strength (MAD +0.49, CI –1.68; +2.67, p = 0.65), 6-meter gait speed (MAD –0.07, CI –0.17; +0.04, p = 0.20), 6-minute walk distance (MAD –11.0, CI –36.4; 14.4, p = 0.39) were similar in both groups. The change in quality of life (chronic liver disease questionnaire) (p = 0.55), plasma ammonia (p = 0.73) and serum myostatin (p = 0.77) levels were also similar. No difference was noted on gender, etiology and severity of liver disease specific subgroup analysis. Four patients had minor adverse events in each group.

Table 1: Outcome measures in both groups at baseline and 6 months of follow-up (unadjusted)

	Baseline			At 6 months		
	BCAA	Placebo	p	BCAA	Placebo	p
Skeletal muscle index (cm <sup>2</sup> /m <sup>2</sup> )	37.92 ± 5.94	35.23 ± 6.54	0.10	38.93 ± 5.97	37.97 ± 6.43	0.55
Hand grip strength (kg)	22.2 ± 7.3	22.8 ± 7.4	0.73	23.4 ± 7.1	24.0 ± 7.7	0.72
6 m gait speed (m/sec)	0.96 ± 0.20	1.04 ± 0.26	0.14	1.03 ± 0.21	1.15 ± 0.20	0.03
6 minute walk distance (m)	307.3 ± 40.6	326.2 ± 55.0	0.14	342.3 ± 58.0	344.1 ± 64.4	0.21

\*values represented as mean ± SD or median (Interquartile range)

**Conclusion:** Addition of BCAA to standard exercise and dietary counselling does not improve muscle mass in patients with cirrhosis and sarcopenia. (CTRI/2019/05/019269).

**OS-513**

**Algorithm combining fat-free muscle index and total spontaneous portosystemic shunt area identifies high-risk cirrhotic patients**

Michael Praktiknjo<sup>1</sup>, Jasmin Abu-Omar<sup>1</sup>, Anton Faron<sup>2</sup>, Nina Böbling<sup>1</sup>, Alois Martin Sprinkart<sup>2</sup>, Ulrike Attenberger<sup>2</sup>, Christian Strassburg<sup>1</sup>, Johannes Chang<sup>1</sup>, Christian Jansen<sup>1</sup>, Jonel Trebicka<sup>3</sup>, Luetkens Julian<sup>2</sup>.  
<sup>1</sup>University Hospital Bonn, Center for Cirrhosis and Portal Hypertension Bonn (CCB), Department of Internal Medicine I, Bonn, Germany;  
<sup>2</sup>University Hospital Bonn, Department of Radiology, Bonn, Germany;  
<sup>3</sup>University Hospital Frankfurt, Department of Internal Medicine 1, Frankfurt, Germany  
 Email: michael.praktiknjo@ukbonn.de

**Background and aims:** Sarcopenia and spontaneous portosystemic shunts (SPSS) are common complications of liver cirrhosis and both are associated with higher rates of hepatic encephalopathy (HE) development in these patients. This study aimed to evaluate the simultaneous impact of skeletal muscle mass and spontaneous portosystemic shunting, measured from routine diagnostic computed tomography (CT), on outcome in patients with liver cirrhosis. **Method:** Retrospective analysis of cirrhotic patients. Skeletal muscle mass (including fat-free muscle index (FFMI) as surrogate for sarcopenia) and total cross-sectional spontaneous portosystemic shunt area (TSA) were quantified from CT scans. Primary end point was development of HE, secondary end point was all-cause mortality within 1-year follow-up.

**Results:** Among 301 evaluations, 156 patients with liver cirrhosis were included. Patients with low (L-) FFMI and large (L-)TSA showed higher rates of HE development. In multivariable analysis, L-FFMI and L-TSA were independent predictors of HE development (L-FFMI HR = 2.69, CI 1.22–5.93; L-TSA HR = 2.50 CI = 1.24–4.72) and 1-year mortality (L-FFMI, HR = 7.68, CI 1.75–33.74; L-TSA, HR = 3.05, CI 1.32–7.04). Simultaneous presence of L-FFMI and L-TSA exponentially increased the risk of HE development (HR 12.79, CI 2.93–55.86) and 1-year mortality (HR 13.66, CI 1.75–106.50). An easy sequential algorithm including FFMI and TSA identified patients with good, intermediate and poor prognosis.

**Conclusion:** This study is the first to indicate a potential synergy between low skeletal muscle mass and large TSA to predict

exponentially increased risk of HE development and mortality in liver cirrhosis. Simultaneous screening for sarcopenia and TSA from routine diagnostic CT may help to improve identification of high-risk patients using an easy-to-apply algorithm. ClinicalTrials.gov Identifier: NCT03584204.

 Email: thomas.reiberger@meduniwien.ac.at

**Background and aims:** Guidelines suggest implantation of a transjugular intrahepatic portosystemic shunt (TIPS) in patients with recurrent/refractory ascites—a population at risk for hepatorenal syndrome (HRS). However, data on the course and risk of HRS after TIPS are limited.

**Methods:** Patients with cirrhosis and ascites undergoing covered TIPS implantation for ascites were included. Serum creatinine (sCr) and blood urea nitrogen (BUN) were recorded prior to TIPS (baseline, BL), within 2–7 days after TIPS, and at 1, 3, 6 and 12 months (M1/M3/M6/M12) after TIPS.

**Results:** 165 patients were included: male: 75.2%, mean age: 58.4 ± 9.2 years, Child-C cirrhosis: 18.8%, median MELD: 13 (range: 6–30). BUN improved consistently and significantly from median BL 26.9 mg/dL (IQR: 18.0–39.2) to 16.0 (12.2–22.6) mg/dL at M12 (p < 0.0001). Overall, sCr changed from median 1.19 (IQR: 0.91–1.60) mg/dL at BL to 0.92 (0.79–1.20) mg/dL at M12 (p = 0.0048). sCr improved mostly in patients with HRS (i.e. sCr > 1.5 mg/dL; n = 35) from 1.82 (1.52–2.15) mg/dL at BL to 1.22 mg/dL (0.95–1.54) at M3 (p = 0.009) and in patients with BL-sCr of 1.2–1.5 mg/dL to 0.95 (0.85–1.06) mg/dL at M6 (p = 0.024), but remained stable in patients with <1.2 mg/dL at BL (p = 0.424). Overall, renal function improved (sCr decrease by >0.3 mg/dL) in 83.3% of patients with HRS and in 61.8% of patients with a BL-sCr of 1.2–1.5 mg/dL. Diuretic treatment was reduced in 44.8% (60.0% of HRS) at the next clinical visit after TIPS, while 25.5% (32.4% of HRS patients) still required multiple paracenteses. Post-TIPS acute kidney injury was uncommon, and in many cases, non-TIPS related triggers were identified (11/20). BL-sCr and BL-BUN did NOT impact on transplant-free survival (p > 0.05 for both), but TFS was significantly longer in patients who resolved HRS than in those who did not (median 1014 (154–3788) days vs 41 (30–660) days, respectively; p = 0.039).

**Conclusion:** TIPS implantation significantly improves renal function and ascites control in patients with recurrent/refractory ascites and HRS. Pre-TIPS renal function parameters did not influence transplant-free mortality after TIPS. Acute kidney injury after TIPS was mostly precipitated by non-TIPS related complications.

### Changes in gas-exchange abnormalities over time in patients with moderate to severe hepatopulmonary syndrome

Xun Zhao<sup>1</sup>, Sreelakshmi Kotha<sup>2</sup>, Dhruv Nayyar<sup>3</sup>, Eric Lui<sup>4</sup>, Xiayi Ma<sup>4</sup>, H el ene Castel<sup>5</sup>, Samir Gupta<sup>4</sup>. <sup>1</sup>Universit e de Montr eal, Medicine, Montreal, Canada; <sup>2</sup>Guy's and St Thomas' NHS Foundation Trust, Department of Hepatology, London, United Kingdom; <sup>3</sup>University of Toronto, Medicine, Toronto, Canada; <sup>4</sup>St. Michael's Hospital, Li Ka Shing Knowledge Institute, Toronto, Canada; <sup>5</sup>Centre Hospitalier de l'Universit e de Montr eal (CHUM), Department of Hepatology and Liver Transplantation, Montreal, Canada  
Email: xun.zhao@mail.mcgill.ca

**Background and aims:** Hepatopulmonary syndrome (HPS) is a complication of cirrhosis defined by abnormal oxygenation and intrapulmonary vascular dilatation (IPVD). It carries a poor prognosis but can be treated with liver transplant. Small studies suggest that most patients with HPS experience a progressive decline in oxygenation, however little is known about the rate of this decline and corresponding changes in physiological measures.

We sought to measure rates of change in oxygenation (PaO<sub>2</sub>), diffusion capacity (DLCO), and 6-minute walk distance (6MWD) in patients with HPS, both before/without, and after liver transplant.

**Methods:** This was a prospective cohort study of Canadian HPS Program patients. We included patients with moderate to very severe HPS, defined as (1) liver dysfunction and/or portal hypertension; (2) IPVDs on contrast echocardiography; and (3) Alveolar-arterial oxygen gradient ≥15 mm and paO<sub>2</sub> <80 mmHg. We used linear mixed-effects models with both random intercept and random slope terms to determine rates of change in PaO<sub>2</sub>, DLCO, and 6MWD over time, and a Bootstrap method to compare rates in the first year after transplant to the last year before transplant.

**Results:** We included 105 patients and 869 clinical visits. PaO<sub>2</sub> declined at a rate of 3.7 mm Hg/year (n = 102) in the first year after diagnosis and increased at a rate of 6.5 mmHg/month (n = 43) in the first year after transplant. The difference in rate of change in the first

year after transplant compared to the last year before transplant was 6.8 mm Hg/month (6.1, 7.5). The 6MWD declined at a rate of 26 m/year after diagnosis (n = 62) and increased at a rate of 190 m/year after transplant (n = 38), with a post- to pre-transplant rate change of 198 m/year (174, 220). The DLCO declined at a rate of 3.3% predicted/year after diagnosis (n = 86) and increased at a rate of 11.0% predicted/year after transplant (n = 34), with a post- to pre-transplant rate change of 11.6% predicted/year (7.6, 15.5).

### PaO<sub>2</sub> - 1 year pre- and post-transplant

**Conclusion:** This is the largest and longest longitudinal follow-up study in HPS. We describe the natural history of physiological decline in this disease and the rate of expected improvement in key variables

after liver transplantation. These data enhance our understanding of the physiological effects of HPS and can aid in prognostication both before and after transplant.

**OS-1864**

**Sex is a major effect modifier on the association between body composition and mortality in patients with cirrhosis assessed for liver transplantation**

Amine Benmassaoud<sup>1,2</sup>, Davide Roccarina<sup>2</sup>, Francesco Arico<sup>2</sup>, Marta Cilla<sup>2</sup>, Rossella Donghia<sup>3</sup>, Gioacchino Leandro<sup>3</sup>, Laura Iogna Prat<sup>2</sup>, Mohamed Zuhair<sup>2</sup>, Matthew North<sup>2</sup>, Orla Kearney<sup>2</sup>, John Ryan<sup>4</sup>, Emmanuel Tsochatzis<sup>2,5</sup>. <sup>1</sup>Division of Gastroenterology and Hepatology, McGill University Health Centre; <sup>2</sup>Royal Free Sheila Sherlock Liver Center, Royal Free Hospital, London, United Kingdom; <sup>3</sup>National Institute of Gastroenterology, S. de Bellis Research Hospital, Castellana Grotte, Italy; <sup>4</sup>Translational Gastroenterology Unit, University of Oxford, Oxford, United Kingdom; <sup>5</sup>UCL Institute for Liver and Digestive Health, University College of London, London, United Kingdom  
Email: amine.benmassaoud@mcgill.ca

**Background and aims:** Body composition predicts increased mortality in patients with cirrhosis. The impact of sex on this association is largely unknown. We studied the impact of sarcopenia, malnutrition and adipose tissue mass on mortality in patients with cirrhosis assessed for liver transplantation (LT) stratified by sex.

**Method:** We included 628 consecutive patients assessed for elective LT. Nutritional status was assessed using the validated Royal Free Hospital-Global Assessment (RFH-GA). Radiology software was used to calculate muscle and adipose tissue mass data at third lumbar vertebrae, including psoas muscle index (PMI), total (TATI), visceral (VATI) and subcutaneous adipose tissue index (SATI). Sarcopenia PMI was defined as sex-based PMI below 25<sup>th</sup> percentile.

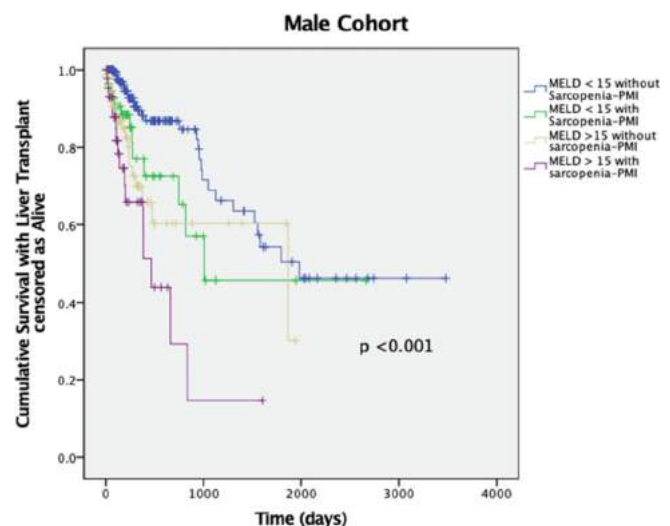

Figure 1: Cumulative survival of male patients with cirrhosis assessed for liver transplantation.

**Results:** 628 patients were included, of which 429 were males. Median age was 54.5 years, duration of follow-up was 192 days, alcohol misuse was the most common etiology of cirrhosis (30%) and median MELD was 14. Males had more commonly sarcopenia by SMI (male: SMI below 50 cm<sup>2</sup>/m<sup>2</sup>; female: SMI below 39 cm<sup>2</sup>/m<sup>2</sup> when compared to females (41.3% vs 26.6%, p < 0.001). In the entire cohort, multivariate analysis showed that when adjusted for age and MELD, both RFH-GA (aHR1.39, 95%CI 1.08–1.79) and Sarcopenia PMI

(aHR1.49, 95%CI 1.01–2.21) were independent predictors of mortality. In males, multivariate analysis showed that when adjusted for age and MELD, sarcopenia PMI (aHR 1.74, 95%CI 1.08–2.80) and RFH-GA (aHR1.40, 95%CI 1.03–1.90) remained independent predictors of mortality. Kaplan Meier survival analysis showed that sarcopenic male patients with MELD < 15 did worse than non-sarcopenic male patients with MELD < 15 (p = 0.024), and as poorly as non-sarcopenic male patients with MELD > 15 (p = 0.53) (Figure 1). Sarcopenic male patients with MELD ≥ 15 did worse than sarcopenic male patients with MELD < 15 (p = 0.021), and tended to do worse than non-sarcopenic male patients with MELD ≥ 15 (p = 0.084) (Figure 1). Adipose tissue had no impact on outcomes in males. In females, muscle or adipose tissue parameters did not predict mortality.

**Conclusion:** This study demonstrates that sex is an important effect modifier on the relationship between body composition and mortality in cirrhosis. Future research in this patient population should minimize sex-related bias, and present data for both groups separately.

**Cirrhosis and its complications: Portal Hypertension**

**Relationship between genotype and severe hepatic phenotype in compound heterozygous Cystic Fibrosis patients with one F508del CFTR mutation**

Suzan Duursma<sup>1</sup>, Henkjan Verkade<sup>1</sup>, Frank Bowedes<sup>1</sup>. <sup>1</sup>University Medical Center Groningen, Pediatric Gastroenterology/Hepatology, Groningen, Netherlands  
Email: s.duursma@umcg.nl

**Background and aims:** Cirrhosis with portal hypertension (CFCPH) is the most severe hepatic manifestation of CF. Due to the relatively low incidence of CFCPH, it has remained unclear if the cystic fibrosis transmembrane conductance regulator (CFTR) genotype is associated with the risk of developing CFCPH. F508del is the most prevalent disease-causing CFTR gene mutation in Europe. F508del can occur as a homozygous mutation or in a compound heterozygous combination with a different CFTR mutation. We aimed to study the contribution of the second mutation on the prevalence and mortality of CFCPH in CF patients with one F508del mutation, using the European Cystic Fibrosis Society Patient Registry (ECFSPR).

**Method:** We assessed 37,642 CF patients with at least one F508del mutation with regards to severe liver disease and mortality in the period 2008–2016. We identified 1486 CFCPH patients of which 942 were homozygous for F508del and 544 were compound heterozygous. We stratified the second mutation of compound heterozygous patients based on the functional defect class of the mutation of the CFTR protein (class I–V; TIPS 2007; 8:334–41) and compared.

**Results:** The prevalence of CFCPH in compound heterozygous patients with one F508del mutation decreased along the class of the second mutation (Fig. 1; p < 0.001). In the study period, CFCPH was associated with increased mortality compared to non-CFCPH patients (11% vs. 5%, p < 0.001). The mortality rate of CFCPH between the different compound heterozygous F508del patients and homozygous F508del did not significantly differ (10% vs. 12%, resp., NS). However, the difference in mortality between CFCPH and non-CFCPH patients within each class stepwise increased from class I (11% vs. 5%, p < 0.001) to class IV (18% vs. 2%, p < 0.001).

Fig. 1. Prevalence of CFCPH in patients with one F508del mutation (▲) in relation to the functional defect classes of the second mutation

**Conclusion:** The risk of developing CFCPH in compound heterozygous F508del patients is negatively related to the functional defect class of the second mutation. Independent from the functional defect class, CFCPH is associated with increased mortality risk. The characterization of the present genotype-phenotype relationships allows for an early and improved prognostication towards a severe hepatic phenotype in CF patients and may contribute to a more patient-tailored follow-up and treatment.

**Acknowledgments:** We thank the people with CF, and their families, for consenting to their data being included in the ECFSPR.

**Background and aims:** The use of anticoagulation in patients with cirrhosis and portal vein thrombosis (PVT) is controversial. Observational series and aggregate-data meta-analysis have proven the safety and efficacy of anticoagulation to yield portal vein recanalization, but it is unknown whether this benefit translates into a survival improvement. Existing aggregated data meta-analysis are limited by the difficulties to adjust by confounders and by their cross-sectional nature. We conducted an individual patient data (IPD) meta-analysis to assess the efficacy of anticoagulation on overall survival and portal vein recanalization in patients with cirrhosis and PVT.

**Method:** Two review authors performed the literature search up to 1st June 2020. We included studies that compared the efficacy of anticoagulation [low molecular-weight heparin (LWMH)/Warfarin] vs. no treatment in cirrhosis with PVT. We used a one-stage meta-analysis for overall survival and thrombus recanalization. Mortality was analyzed as a time-to-event variable with Hazard Ratios (HR) calculated by a multilevel mixed-effects model with random-intercepts for studies. Thrombus recanalization was analyzed by mixed-effects logistic regression. All analysis were adjusted for age, Child-Pugh, etiology, and PVT location and extension. Survival was described with Kaplan-Meier curves (PROSPERO registration #CRD42020140026).

**Results:** Five studies with a total of 500 patients assessed the effect of anticoagulants (n = 205) vs. no treatment (n = 295). During a median follow-up of 25.0 months (95%CI 15–52), 115 patients (39%) died in the no treatment group and 53 (25.8%) in the anticoagulant group. Anticoagulation increased overall survival (HR: 0.68, 95%CI 0.48–0.95, p = 0.026) (Figure). Recanalization, partial or complete, was more frequent in patients on anticoagulants (61.4 vs. 37.2%; OR 3.2, 95%CI 2.12–4.88, p = 0.000). Recanalization was independent of the anticoagulation type (LWMH: OR 2.7, 95%CI 1.53–4.77, p = 0.001 and VKA: OR 2.8, 95%CI 1.24–6.34, p = 0.013). The effect of anticoagulation on survival was primarily due to recanalization, as shown by the mediation analysis (recanalization HR: 0.55, 95%CI 0.37–0.81, p = 0.003).

**Conclusion:** Treatment with anticoagulants increases overall survival in patients with cirrhosis and PVT. The beneficial effect of anticoagulation is largely dependent on portal vein recanalization.

## Fibrosis

### OS-874

**A fully agonistic anti-MET antibody protects hepatocytes against acute and chronic injury, promotes fibrosis regression and restores liver function in cirrhotic mice**

Virginia Morello<sup>1</sup>, Manuela Cazzanti<sup>1</sup>, Luca Rossi<sup>1,2</sup>, Damiana Sattanino<sup>1,2</sup>, Torsten Dreier<sup>1</sup>, Philippe Wiesel<sup>1</sup>, Paolo Michieli<sup>1,2</sup>. <sup>1</sup>AgomAb Therapeutics, Gent, Belgium; <sup>2</sup>University of Torino Medical School, Molecular Biotechnology Center, Torino, Italy  
Email: paolo.michieli@agomab.com

**Background and aims:** Restoring liver function in cirrhotic patients is a high unmet medical need. We have developed a panel of agonistic monoclonal antibodies directed against MET, the high affinity receptor for Hepatocyte Growth Factor (HGF), that mimic the biological activities of the natural ligand. Here we show that 71D6, a fully agonistic anti-MET antibody, displays hepato-protective, anti-inflammatory and anti-fibrotic activity in mouse models of both acute and chronic liver disease.

**Method:** The hepato-protective activity of 71D6 was tested in BALB-c mice using 3 different models of tetracarbon chloride (CCl<sub>4</sub>)-induced liver injury: (1) Acute liver failure: A single CCl<sub>4</sub> administration was followed by a single bolus of antibody. Mice were sacrificed 72 hours post-injection. (2) Chronic liver failure, preventive setting: CCl<sub>4</sub> and antibody were administered 2 times per week for 6 weeks. Mice were sacrificed on week 7. (3) Chronic liver failure, regression setting: Mice were exposed to CCl<sub>4</sub> for 6 weeks and antibody treatment started on week 7 with the same regimen as above. Mice were sacrificed after 2 or 4 weeks of antibody treatment. In all models, liver injury was determined by histology (hematoxylin and eosin) and

immunohistochemistry (picro Sirius red, alpha-smooth muscle cell actin, F4/80). Plasma levels of liver markers was also determined, including aspartate aminotransferase (AST), alanine transaminase (ALT) and bilirubin.

**Results:** In the acute model, 71D6 inhibited CCl<sub>4</sub>-induced AST, ALT and bilirubin increase by 66%, 66% and 57%, respectively. In the chronic preventive model, 71D6 inhibited CCl<sub>4</sub>-induced AST, ALT and bilirubin increase by 108%, 76% and 97%, respectively. Collagen deposition was reduced by 87%, myofibroblast activation by 94%, and macrophage infiltration by 77%. In the chronic regression model, 71D6 effectively promoted fibrosis regression already after 2 weeks of treatment. Collagen deposition was regressed by 87%, myofibroblast activation by 78%, and macrophage infiltration by 87%. AST, ALT and bilirubin normalized spontaneously in both arms 2 weeks after CCl<sub>4</sub> discontinuation. In all models, the therapeutic benefits of 71D6 were associated with active hepatocyte regeneration.

**Conclusion:** These results suggest that 71D6 possesses pro-regenerative, anti-fibrotic and anti-inflammatory activity in mouse models of hepatic injury, and provide proof-of-concept for further 71D6 development.

### OS-888

**CtsD deficient macrophages display altered proteolytic profile and dysregulated collagen recycling, resulting in increased liver fibrosis**

Valeria Pistorio<sup>1,2</sup>, Paloma Ruiz-Blázquez<sup>1</sup>, Maria Fernández-Fernández<sup>1</sup>, Susana Núñez<sup>3</sup>, Carmen García-Ruiz<sup>1,3,4,5</sup>, Luigi M. Pavone<sup>2</sup>, José Fernández-Checa<sup>1,3,4,5</sup>, Anna Moles<sup>1,3,4</sup>. <sup>1</sup>Institute of Biomedical Research of Barcelona, Spanish Research Council (IIBB-CSIC), Barcelona, Spain; <sup>2</sup>University of Naples Federico II, Napoli, Italy; <sup>3</sup>CiberEHD, Spain; <sup>4</sup>IDIBAPS, Barcelona, Spain; <sup>5</sup>USC Research Center for ALPD, Los Angeles, United States

Email: anna.moles.fernandez@gmail.com

**Background and aims:** Changes in proteolytic activity are essential to liver fibrosis development. Previous reports suggest that macrophages are important effectors for extracellular matrix (ECM)

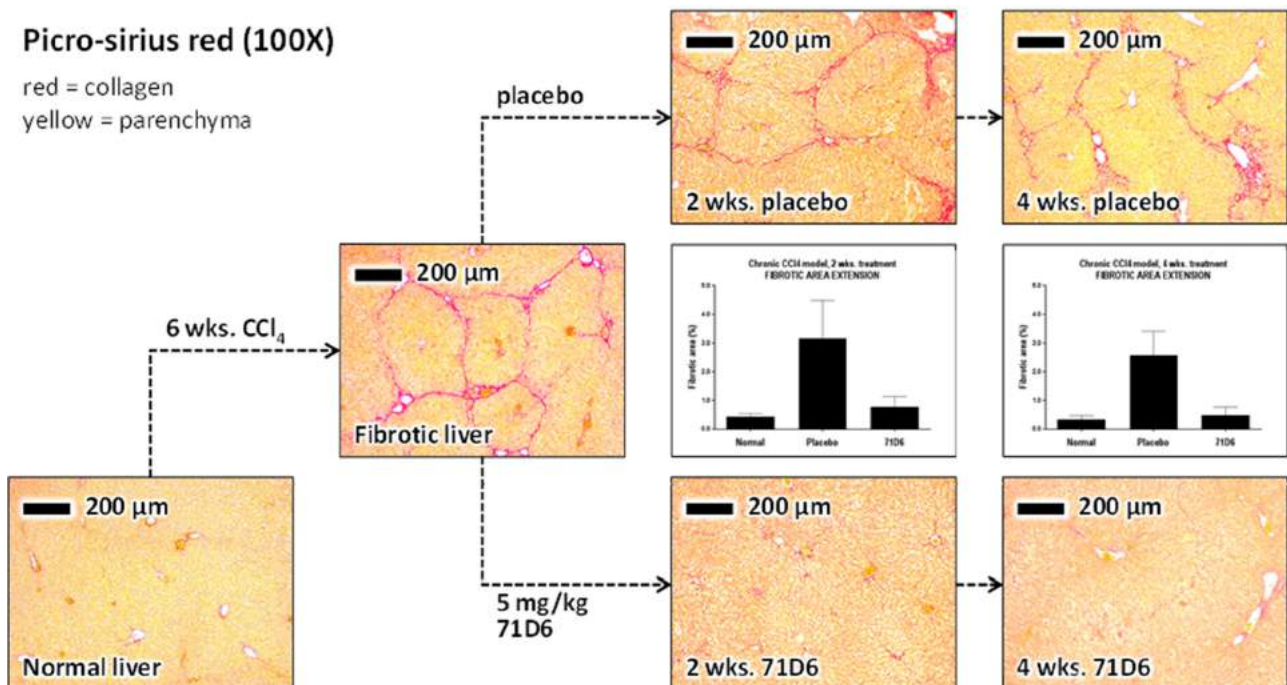

Figure: (abstract: OS-874)

## ORAL PRESENTATIONS

remodelling via its phagocytosis and processing within acidic compartments. However, the role of macrophages in ECM remodelling during liver fibrosis is unknown. Thus, the aim of this study was to investigate the proteolytic and degradative pathways associated to macrophages during liver fibrosis.

**Method:** To study the degradative signals contributing to fibrosis in macrophages we focused our attention on the lysosomal protease cathepsin D (CtsD). We generated and validated a novel macrophage-CtsD knock-out mouse by breeding LysMCre (macrophages) with CtsD floxed mice. Peritoneal macrophage polarization from CtsD<sup>ΔMyel+/+</sup> or CtsD<sup>ΔMyel-/-</sup> mice was achieved with LPS for M1 or IL4/IL13 for M2 stimulation. Polarization markers and MMP profile were assessed by RT-PCR. Collagen degradation and endocytosis was studied using DQ<sup>TM</sup> Collagen, type I and 10 kDa Dextran probes respectively, and WB for Endo180 and UPAR. Lysosomal colocalization was determined using LAMP2. Fibrosis was established chronically by CCl<sub>4</sub> (0.5μl/g) in CtsD<sup>ΔMyel+/+</sup> or CtsD<sup>ΔMyel-/-</sup> mice and determined by SR staining, α-SMA IHP and Col1 WB as well as RT-PCR.

**Results:** First, CtsD deletion in macrophages from CtsD<sup>ΔMyel-/-</sup> mouse was confirmed by WB, CtsD activity in macrophages and dual IHP (F4/80-CtsD) in liver tissue. M1 and M2 polarization of CtsD<sup>ΔMyel+/+</sup> and CtsD<sup>ΔMyel-/-</sup> macrophages using LPS (10 and 50 ng/ml) or IL4/IL13 (20 and 50 ng/ml) resulted in similar and significant induction of iNOS (M1) and CD206 (M2) gene expression respectively. However, while M1 downstream effector CCL2 was similarly induced between CtsD<sup>ΔMyel+/+</sup> and CtsD<sup>ΔMyel-/-</sup> macrophages after LPS stimulation, IL10 was defectively induced in M2-primed CtsD<sup>ΔMyel-/-</sup> macrophages. In addition, both, M1 and M2 CtsD<sup>ΔMyel-/-</sup> macrophages displayed defective induction of MMP-2, -3 and -7 gene expression. CtsD<sup>ΔMyel-/-</sup> macrophages showed a significant decrease in DQ<sup>TM</sup> Collagen, type I degradation versus CtsD<sup>ΔMyel+/+</sup> macrophages at 37C. As expected, no degradation was detected at 4C. Collagen degradative profile colocalized partially with LAMP2, indicating that collagen was degraded within the lysosome. Furthermore, Dextran endocytosis in both CtsD<sup>ΔMyel+/+</sup> and CtsD<sup>ΔMyel-/-</sup> macrophages remained unaffected. CtsD<sup>ΔMyel-/-</sup> mice presented enhanced liver fibrosis as shown by an increase in Sirius red staining, alpha-SMA and Col1A1 gene and protein expression with no affectation of the Endo180/UPAR collagen internalization receptors (WB).

**Conclusion:** Lysosomal cathepsin D is essential for a correct collagenolytic activity displayed by macrophages during liver fibrosis.

### OS-1478

#### HSC-targeted plasmonic hyperthermia treatment reduces liver fibrosis in mice

Jordi Ribera<sup>1,2</sup>, Clara Vilches<sup>3</sup>, Vanesa Sanz<sup>3</sup>, Ignacio de Miguel<sup>3</sup>, Irene Portolés<sup>1,2</sup>, Bernat Cordoba-Jover<sup>1,2</sup>, Wladimiro Jiménez<sup>1,2,4,5</sup>, Romain Quidant<sup>3,6</sup>, Manuel Morales-Ruiz<sup>1,2,4,5</sup>. <sup>1</sup>CIBERehd; <sup>2</sup>IDIBAPS, Barcelona, Spain; <sup>3</sup>ICFO-Institut de Ciències Fotòniques, The Barcelona Institute of Science and Technology, Castelldefels, Spain; <sup>4</sup>University of Barcelona, Biomedicine Department, Barcelona, Spain; <sup>5</sup>Hospital Clínic de Barcelona, Biochemistry and Molecular Genetics Department, Barcelona, Spain; <sup>6</sup>Nanophotonic Systems Laboratory, Department of Mechanical and Process Engineering, Zurich, Switzerland  
Email: mmoralesruiz@ub.edu

**Background and aims:** Hepatic stellate cells (HSC) are the main responsible cells for fibrosis formation, and PDGF and its receptor (PDGFRb) play a major role in HSC activation. Gold nanorods (GNR) have unique photothermal properties that can be exploited to induce localized near-infrared light-mediated thermal ablation. Therefore, this study aimed to induce thermal ablation of activated-HSC in fibrotic livers of mice using GNR conjugated with PDGFRb antibody (GNR-PDGFRb) and plasmonic photothermal therapy (PPTT).

**Method:** Fibrosis was induced in mice by intraperitoneal injection of CCl<sub>4</sub>. Tissue gold distribution was analyzed by mass spectrometry, and the subcellular location of GNR in the liver was assessed using transmission electron microscopy (TEM). PPTT was performed after 10 days of GNR-PDGFRb treatment (n=15). Liver fibrosis was quantified by Sirius-Red staining, and hepatic macrophage infiltration by immunofluorescence using F4/80 antibody.

**Results:** Liver and spleen were still the major reservoirs of gold, accounting for the 12–15% and <3% of injected dose, respectively. TEM revealed that GNR-PDGFRb was present in the cytosol of HSC in CCl<sub>4</sub>-treated mice. In contrast, GNR-PDGFRb abundance was significantly lower in healthy livers of the control group and accumulated in Kupffer cells. After 5 days from the PPTT, GNR-PDGFRb CCl<sub>4</sub>-treated mice showed a significant decrease in hepatic collagen content compared to those who did not receive GNR (2.3 ± 0.2 vs. 4.1 ± 0.5% of fibrotic area per field; p < 0.01). This reduction correlated with a significant decrease in the hepatic macrophage infiltration (p < 0.01) and in the serum concentration of AST and ALT (83.7 ± 8.9 vs. 207.7 ± 61.44 U/L for AST, 22.4 ± 0.9 vs. 28.8 ± 2.6 U/L for ALT; p < 0.05). We also studied the in vivo elimination routes of the GNR and their potential toxic effect in healthy mice. After two months of GNR treatment, the percentage of nanoparticles in the liver decreased using the fecal excretion route preferentially. During this period,

Figure: (abstract: OS-1478)

animals showed no signs of physical discomfort or presence of increased circulating biomarkers for inflammation or tissue injury.

**Conclusion:** GNR-PDGFRb-mediated photothermal therapy decreases fibrosis, hepatic inflammation, and hepatocyte injury in mice with liver fibrosis, with an optimal biosafety profile without long-term toxicity. This is the first evidence demonstrating the feasibility of applying HSC-targeted PPTT therapy in fibrotic livers.

**Liver progenitor cells regulate ductular reaction and induce fibrosis upon severe liver injury via RAGE signaling**

Wai Ling Macrina Lam<sup>1,2</sup>, Dr. Amruta Damle Vartak<sup>1</sup>, Simone Jörs<sup>3</sup>, Nachiket Vartak<sup>4</sup>, Gisela Gabernet<sup>5</sup>, Tanja Poth<sup>6</sup>, Doris Schneller<sup>1</sup>, Melanie Sator-Schmitt<sup>1</sup>, Georgia Günther<sup>4</sup>, Aurora De Ponti<sup>1</sup>, Mathias Heikenwälder<sup>7</sup>, Sven Nahnsen<sup>5</sup>, Jan G. Hengstler<sup>4</sup>, Fabian Geisler<sup>3</sup>, Peter Angel<sup>1</sup>. <sup>1</sup>German cancer research center, Signal transduction and growth control, Heidelberg, Germany; <sup>2</sup>Ruprecht Karl University of Heidelberg, Heidelberg, Germany; <sup>3</sup>Technical University of Munich, Clinic and Polyclinic for Internal Medicine II, Germany; <sup>4</sup>Leibnitz Research Centre for Working Environment and Human Factors, System toxicology, Germany; <sup>5</sup>Eberhard Karls University of Tübingen, Quantitative Biology Center, Germany; <sup>6</sup>University Hospital Heidelberg, The center for model system and comparative pathology, Germany; <sup>7</sup>German cancer research center, Chronic Inflammation and Cancer, Germany

Email: m.lam@dkfz-heidelberg.de

**Background and aims:** Liver fibrosis is characterized by hepatic stellate cell (HSC) activation and extracellular matrix (ECM) deposition upon persistent injury and inflammation, which can impair hepatic function and its ability to regenerate. Ductular reaction is a clinical manifestation observed in response to acute and chronic liver

injury, which involves the proliferation of biliary-like liver progenitor cells (LPCs). The receptor for advanced glycation end products (RAGE) signaling is often associated with chronic inflammation-associated tissue damage and plays an essential role in modulating the tissue microenvironment. Our previous data showed that global deletion of RAGE results in strong reduction in LPC expansion, onset of liver fibrosis and HCC formation (Pusterla et al. Hepatology. 2013). In this study, we seek to delineate the LPC-specific functional and mechanistic role of RAGE activity in response to liver injury.

**Method:** R26-tdTomato Hnf1b-CreER reporter mouse was utilized as a biliary lineage tracing model, and were crossed with Rage flox/flox mice to generate tamoxifen-inducible LPC-specific RAGE knockout mice. Mice were exposed to a choline-deficient ethionine-supplemented (CDE) diet for three weeks to induce chronic liver damage. RNA-seq of isolated LPCs from CDE-challenged mice, was combined with standard histology analyses and multi-modal 3D architectural staining to investigate the role of RAGE on LPCs and fibrosis formation. *In vitro* co-culture assays combined with live cell imaging were employed to delineate RAGE-dependent crosstalk between LPCs and stellate cells.

**Results:** Deletion of RAGE in LPCs strongly impairs ductular reaction during chronic liver damage, accompanied by reduction of activated HSCs and bridging fibrosis. RNA-seq data revealed the mechanistic role of LPCs in modulating ECM organization and HSC activation in a RAGE-dependent manner. Classical fibrotic mediators (*Tgfb1*, *Timp1*) and ECM genes (*Col4a1*, *Col16a1*, *Col18a1*) were differentially expressed in the enriched hepatic fibrosis pathways. Indirect co-culture assay showed that *Acta2* and *Col1a1* gene expression in HSC is affected *in trans* by soluble factors from LPCs expressed in a RAGE-dependent manner.

**Conclusion:** RAGE on LPCs is required for ductular reaction and crosstalk with HSCs in supporting fibrogenesis. Our study provides a

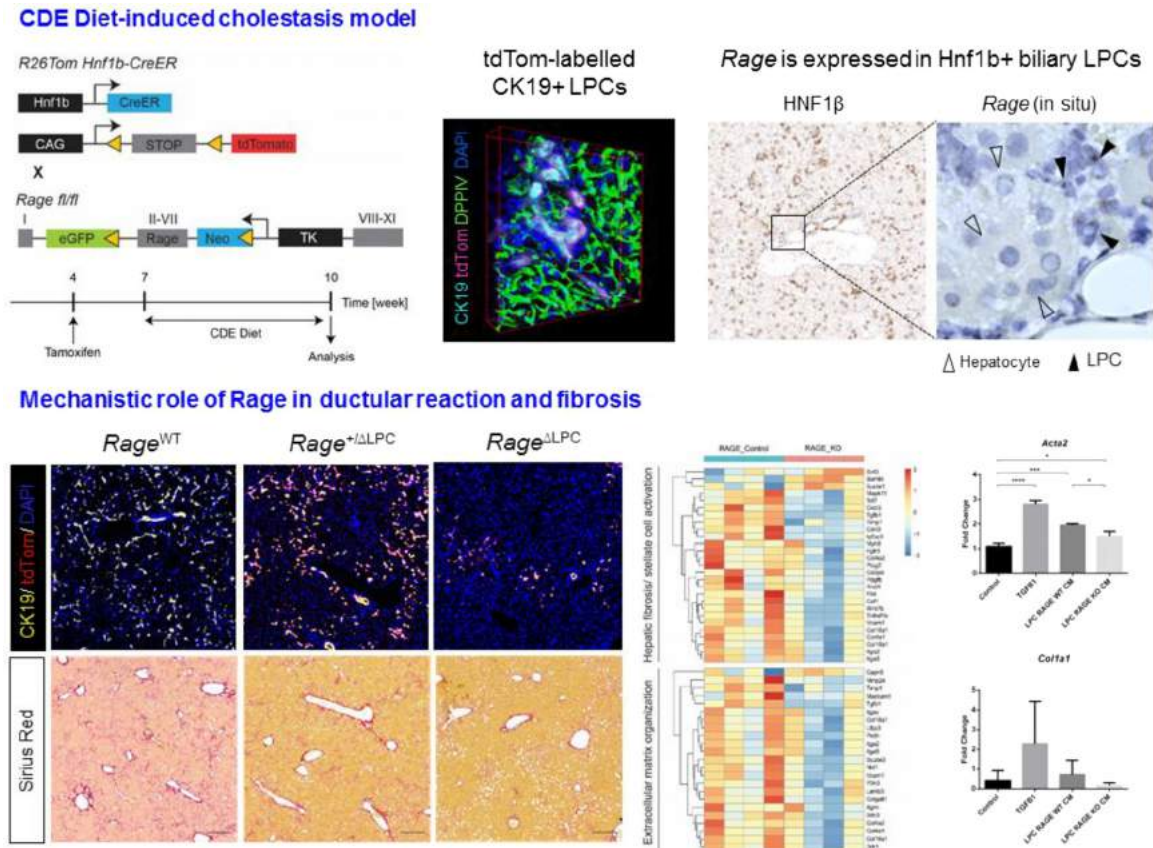

Figure: (abstract: OS-2754)

## ORAL PRESENTATIONS

novel insight of RAGE on LPC in shifting the dynamic of ductular reaction to a pro-fibrotic microenvironment upon chronic injury.

### OS-2854

#### Elderly with advanced liver fibrosis had lower response to Pfizer's SARS-CoV-2 vaccine response

David Hakimian<sup>1</sup>, Asher Shafir<sup>1</sup>, Yael Milgrom<sup>1</sup>, Mohammad Masarwa<sup>1</sup>, Wadi Hazou<sup>1</sup>, Johnny Amer<sup>1</sup>, Rifaat Safadi<sup>1</sup>.  
<sup>1</sup>Hadassah-Hebrew University Hospital, Liver Unit, Jerusalem, Israel  
Email: johnnyamer@hotmail.com

**Background and aims:** Pfizer's and Moderna's mRNA SARS-CoV-2 vaccines show high efficacy in clinical and real-world data. In Israel, more than 90% of ≥60 years population received both vaccine doses. The risk factors for vaccine failure following the recommended doses are unclear. We aimed to assess impact of advanced chronic liver disease on the efficacy of Pfizer's SARS-CoV-2 vaccines, as reported responses for other historical vaccines decreased.

**Method:** Hepatic fibrosis correlated with vaccine responses in subjects who received both doses of BNT162b2 vaccine and tested for serum SARS-CoV-2 spike immunoglobulins (S IgG) at least 7 days later (Liaison assay). In the current pilot, CRN fibrosis score in 88 NAFLD patients underwent liver biopsy correlated to post vaccine S IGG levels.

**Results:** The mean age of the 88-study group was 57.1 ± 12.2 years (51.1% males) with mean S IgG levels 291.1 ± 124.7 AU/ml. Except of one case (1.1%) found vaccine failure (S IGG levels <12 AU/ml), all 87 (98.9%) achieved a good response (S IgG levels ≥19 AU/ml). S IgG cutoff of 200 AU/ml considered to differentiate excellent vs. good responses among the 87 responders. The excellent responses (S IgG titers ≥200 AU/ml) observed in 64/88 (72.7%) with mean age 55.3 ± 12.5 years (48.4% males) and mean S IgG levels 358 ± 60.6 AU/ml. The good responders (S IgG titers <200 AU/ml) observed in 23/88 (26.1%) with older (P = 0.01) age 62 ± 10.1 years (60.9% males) and mean S IgG levels 117.4 ± 51.4 AU/ml. Both excellent and good response groups had a similar BMI and gender distribution. However, histologic NAS grading and CRN fibrosis scoring showed significant changes. Mean NAS scoring found was 3.6 ± 1.9 in the excellent responders as compared with 2.9 ± 1.2 in the good responders (p = 0.045), that is mainly derived from significant steatosis changes of 1.6 ± 0.9 vs. 1.2 ± 0.7, repeatedly (p = 0.02). Hepatocyte ballooning and lobular inflammation were similar. Importantly, advanced fibrosis correlated with weaker vaccine responses. Mean Fibrosis scoring was 1.7 ± 1.1 vs. 2.2 ± 1.5, percentage of advanced fibrosis (F3-F4) were 23% vs. 48% of each group, respectively (p = 0.05). Findings confirmed also by significant changes in blood tests.

	T Bili (micromol/L)	±STD	GGT	±STD	AST	±STD	PLT	±STD
IgG≥200	7.7	7.6	68.1	74.1	36.3	16.3	231.8	84.1
IgG<200	14.0	7.9	189.5	289.2	65.8	61.7	165.9	98.4
P	0.010		0.019		0.003		0.005	

Figure:

**Conclusion:** Older age, advanced fibrosis with decreased steatosis are risk factors for lower vaccine response for Pfizer's BNT162b2 vaccine. A third dose vaccine booster in those risk factor populations should be evaluated in future trials.

## Gut microbiota and liver disease

### OS-119

#### Virulence factors in gut metagenomics worsen with disease progression and predict outcomes in cirrhosis

Jasmohan S. Bajaj<sup>1</sup>, Amirhossein Shamsaddini<sup>2</sup>, Andrew Fagan<sup>1</sup>, Edith Gavis<sup>1</sup>, Masoumeh Sikaroodi<sup>2</sup>, Patrick Gillevet<sup>2</sup>.  
<sup>1</sup>Virginia Commonwealth University and Richmond VAMC, Richmond, United States; <sup>2</sup>George Mason University  
Email: jasmohan.bajaj@vcuhealth.org

**Background and aims:** Cirrhosis is linked with altered gut microbiota and higher pathobionts, which can carry several virulence factors (VFs). However, the role of metagenomic VFs in prognosis on patients with cirrhosis is unclear.

**Aim:** Define change in metagenomic VF abundance with cirrhosis progression and their role in prediction of death and hospitalizations.

**Methods:** Cirrhotic outpts [±hepatic encephalopathy (HE)] and controls underwent fecal collection. Cirrhotics were followed for 1 year for death/hospitalizations. Microbial metagenomics was performed for VF-containing bacteria using the virulence factor database. Comparisons between controls vs cirrhosis, cirrhosis with/without HE were performed. Multi-variable analysis using MAAsLin2 using VF-containing bacteria and clinical factors were performed for death and hospitalizations.

**Results:** 40 controls and 163 cirrhotics (63 no-HE and 100 HE, Table 1) were enrolled. 44 pts were hospitalized at 90 days and 14 died at 1 year. Cirrhotics had fold change for VFs belonging to *Klebsiella*, *Streptococcus* and *Escherichia* (Fig. A). This burden was even higher in those with HE vs no-HE (Fig. B) with additionally higher *Enterococcus*, *Pseudomonas*, and *Legionella* VF-producing spp. Death: On MaAsLin2, *C.difficile* strains and MELD were linked with death (Table 2).

Hospitalizations: HE, lactulose and MELD and multiple *E.coli* strains that produce VFs were associated with higher hospitalizations (Table 2).

**Conclusion:** Virulence factors that increase the pathogenicity of *Escherichia*, *Streptococcus*, *C.difficile* and *Klebsiella* are higher in gut microbiome of cirrhosis compared to controls and worsens with cirrhosis progression. VF-containing taxa from *E.coli* and *C.difficile* are linked with hospitalizations and death in independent of MELD, lactulose and HE. Treatments aimed at VF reduction in gut microbiota are needed in cirrhosis.

### OS-1167

Figure: (abstract: OS-119)

innate immune dysfunction, which predisposes to infection, and multi-organ failure. We hypothesised that modifying the gut microbiota with faecal microbiota transplant (FMT) may reduce the progression of chronic liver failure. We previously reported FMT reduces the burden of enteric pathogens, known to cause epithelial gut barrier disruption in cirrhosis. Here we investigate further the effects of FMT on intestinal barrier restoration and local luminal mucosal immunity in patients with cirrhosis.

**Method:** The prospective, randomised, single-blinded, feasibility trial evaluating FMT (n=15) against placebo (n=6) [PROFIT NCT02862249] was completed in late 2019. Patients were administered FMT/placebo into the jejunum within 7 days of baseline. To assess the efficacy in modulating the patient's own microbiome, disease and inflammatory status: stool was collected at days 0, 7, 30 and 90 post-FMT administration. Stool was assessed for cytokine production and barrier integrity markers (electrochemiluminescence/ELISA) and metabolite profile (<sup>1</sup>H-NMR).

**Results:** FMT treatment removed enteric pathogens including *E. faecalis*. Coinciding with a temporary reduction in luminal proinflammatory cytokine IL-17A at day7 (mean -68%, p=0.0037) in contrast with placebo, which increased 30 days post treatment (mean +36%). High levels of IL-17A are known to induce intestinal inflammation via intestinal epithelial cell tight junction permeability; suggestive that FMT initially modulates inflammation towards gut-barrier repair. However, subsequent increases in IL-17A correlated with improved MELD scores 30 days post FMT (p = 0.034) corresponding to levels of endotoxin (p=0.033); indicating restoration to mucosal antimicrobial responses. Similar modulations in cytokines IL-17E/F and IL-21 were observed. Improvement in gut-barrier function and increased butyrate production (p=0.014) were observed post FMT.

**Conclusion:** These data support FMT as playing an important role in inflammatory restoration at the mucosal barrier and enteric pathogen reduction, promoted by butyrate-induced β-oxidation. Collectively, it may be possible to alter the gut-microbiota to promote barrier repair and to restore immune tolerance in cirrhosis and other systemic inflammatory diseases where the gut-barrier is compromised.

Paneth cells regulate lymphangiogenesis in normal physiology and experimental portal hypertension

Mohsin Hassan Bhat<sup>1</sup>, Oriol Juanola<sup>2</sup>, Andrea de Gottardi<sup>2,3</sup>, Sheida Moghadamrad<sup>2</sup>. <sup>1</sup>Charité-Universitätsmedizin Berlin, Department of Hepatology and Gastroenterology, Germany; <sup>2</sup>Università della Svizzera Italiana, Translational Research Laboratory, Switzerland; <sup>3</sup>Ente Ospedaliero Cantonale, Department of Gastroenterology and Hepatology, Switzerland  
Email: sheida.moghadamrad@usi.ch

**Background and aims:** The mesenteric lymphatic network contributes to the transport of fluid and intestinal mucosal associated immune cells along the gut-liver axis. We hypothesized that Paneth cells (PCs), as part of the intestinal innate immune system, regulate the development of lymphatic vessels and affect portal pressure in response to microbial-derived products.

**Method:** Math1<sup>lox/lox</sup> VilCreER<sup>T2</sup> or control mice were injected three doses of tamoxifen to induce depletion of PCs in the intestine. Portal hypertension was induced by partial portal vein ligation (PPVL). After 14 days, portal pressure was measured. Intestinal and mesenteric lymphatic vessels were identified by immunohistochemistry and quantified using Metamorph. The intestinal expression of specific genes involved in lymphangiogenesis was quantified using qPCR. Furthermore, intestinal crypts were isolated to culture organoids from mice with or without PCs. The organoids were then challenged with different microbial-derived products. Then human lymphatic microvascular endothelial cells (LECs) were cultured in the presence of conditioned media (CM). The lymphangiogenic activity of LECs was assessed using the tube formation and wound healing assays. Additionally, we quantified differentially expressed proteins in the CM collected from all different conditions with mass spectrometry-based proteomics and data were analyzed using MaxQuant.

**Results:** Depletion of PCs resulted in a significantly reduced portal pressure associated with lower density of lymphatic vessels in the intestine and mesentery as compared to PPVL mice with PCs. Several lymphangiogenic genes were significantly downregulated in the

Restoration to mucosal immunity

Enhanced Butyrate ( $\beta$ -oxidation)

Reduction in pathogenic species

Figure: (abstract: OS-1167)

group of mice without PCs when compared to the control mice with PCs. Tube formation and wound healing responses were significantly decreased in LECs treated with CM from organoids without PC. In the absence of PCs, proteomic analyses revealed a significant down-regulation of several proteins involved in lymphatic vessel development and morphogenesis, as well as in processes of lipid metabolism and transport.

**Conclusion:** In the absence of PCs, intestinal and mesenteric lymphangiogenesis was significantly decreased, and this was associated with an attenuation in portal hypertension. These findings suggest that PCs secrete lymphangiogenic signaling molecules in response to microbial-derived products, thereby regulating intestinal-mesenteric lymphatic vessels proliferation and portal pressure.

Patel<sup>3,5,8</sup>. <sup>1</sup>King's College London-Guy's Campus, Centre for Host Microbial Interactions, London, United Kingdom; <sup>2</sup>Institute of Hepatology, Foundation For Liver Research, London, United Kingdom;

<sup>3</sup>King's College Hospital, Institute of Liver Studies, United Kingdom; <sup>4</sup>King's College Hospital NHS Foundation Trust, Department of Critical Care, London, United Kingdom; <sup>5</sup>King's College London, School of Immunology and Microbial Sciences, London, United Kingdom; <sup>6</sup>In Memoriam; <sup>7</sup>Science for Life Laboratory (SciLifeLab), KTH-Royal Institute of Technology, Sweden; <sup>8</sup>Institute of Hepatology (Foundation for Liver Research), London, United Kingdom  
Email: vishal.patel@nhs.net

**Background and aims:** Alterations in the gut microbiome in decompensated cirrhosis (DC) and acute on chronic liver failure (ACLF) are recognised as being critical in influencing clinical outcomes (Trebicka *et al.*, Nat Rev Gastroenterol Hepatol, 2020). Knowledge of the oral microbiome is evolving and recognised as important in predisposing to hepatic decompensation (Acharya *et al.*, JCI Insight, 2017). Our aims were to interrogate the gut and oral microbiome by shotgun metagenomic sequencing of faecal and saliva samples, respectively, in well phenotyped cohorts of cirrhosis patients, with healthy and positive disease controls.

**Method:** 18 healthy controls (HC), 20 compensated cirrhotics (CC), 50 DC, 18 ACLF and 15 with non-liver sepsis (NLS) i.e. severe infection but without underlying CLD were prospectively recruited at a tertiary liver centre in London. DNA extractions were undertaken from faecal samples utilising optimised SOPs, and sequenced on an Illumina NovaSeq 6000 platform to a minimum depth of 20 million reads.

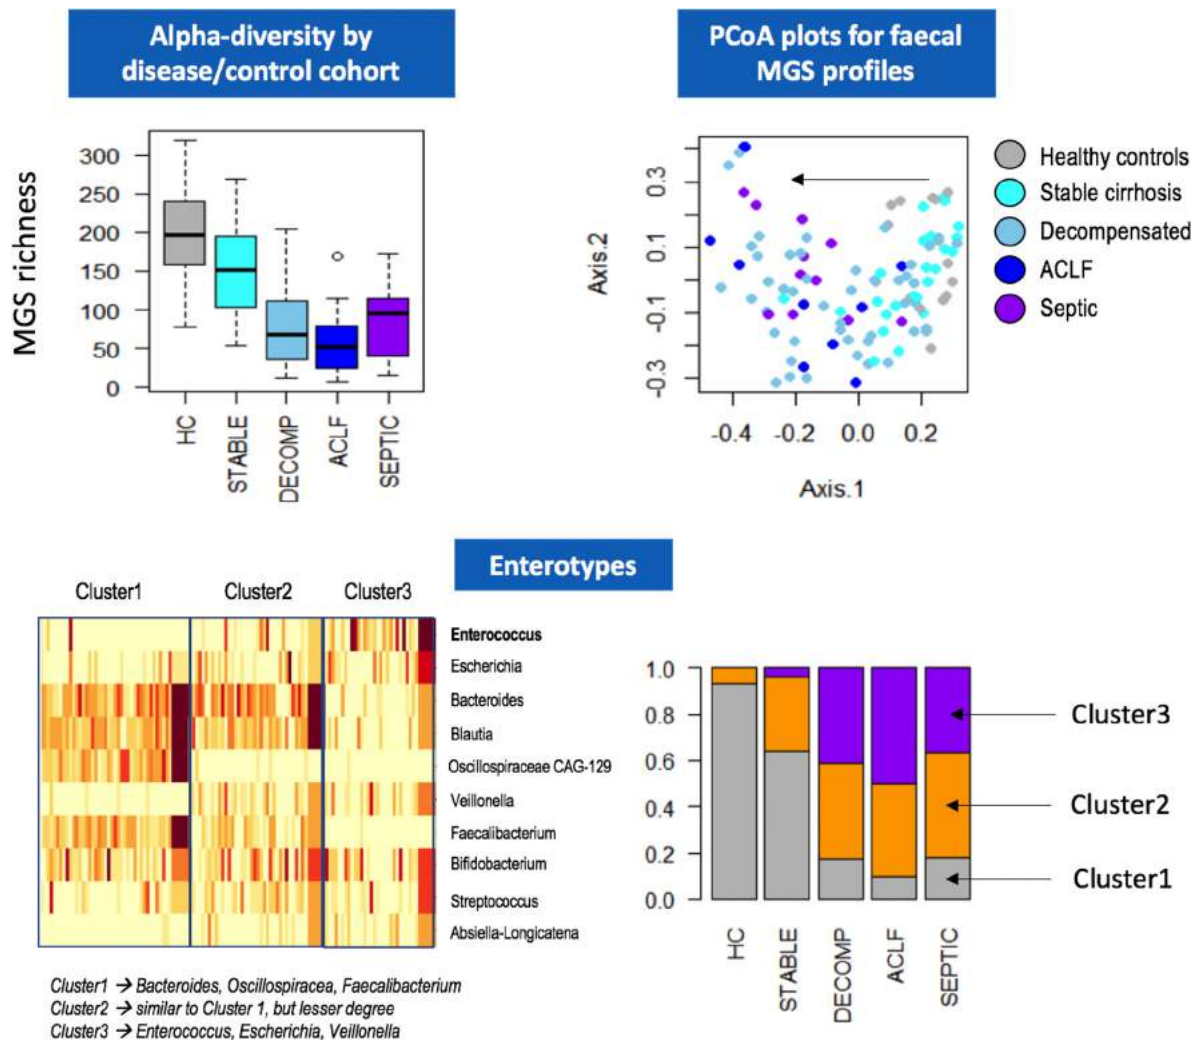

Figure: (abstract: OS-2044)

Filtered and trimmed reads were aligned to a human gut microbiome integrated gene catalogue. Abundance of metagenomic species pan-genomes (MSP) were quantified based on median abundances of 25 markers representing the centroid of gene clusters of MSPs. Enterotypes were calculated by scaling genus profile abundance and clustering by Dirichlet multinomial mixture models.

**Results:** Faecal DNA was of sufficient quality and quantity in 15 HC, 15 CC, 46 DC, 14 ACLF and 12 NLS. There was a striking decrement in alpha-diversity the sicker the patient cohort vs healthy controls and NLS. Principal coordinate analysis (PCoA) showed discrimination between the groups, with clear shifts from control to sicker patients along the first axis. NLS as a positive disease control group had higher alpha-diversity than DC and ACLF patients, even though all 3 groups received broad-spectrum antimicrobials. Three specific enterotypes were identified based on clustering of genera; Cluster 1 consisted of autochthonous genera, cluster 2 similar to 1 and cluster 3 pathogenic, with significant variation in clusters by disease cohort and control groups.

**Conclusion:** Gut microbiome profiles differ significantly according to severity and stage of cirrhosis, with specific enterotype clusters reflecting pathogenic potential. DC and ACLF have significantly worse microbial diversity than NLS, despite similar antimicrobial exposure, supporting an additive patho-biological effect of cirrhosis. Comparisons between gut and oral profiles to evaluate the degree of microbiome 'tropism' are underway, with integrations of these data and immuno-metabolic profiles in relation to clinically relevant outcomes.

## Immune-mediated and cholestatic: Experimental and pathophysiology

### OS-1847

#### A3907, a novel orally bioavailable inhibitor of the apical sodium-dependent bile acid transporter, improves liver injury in a mouse model of cholestatic liver disease

Peter Akerblad<sup>1</sup>, Erik Lindström<sup>1</sup>, Jan Mattsson<sup>1</sup>, Pal Lundin<sup>1</sup>, Sara Straniero<sup>2</sup>, Bo Angelin<sup>2</sup>, Magnus Soholt Larsen<sup>3</sup>, Thomas Secher<sup>3</sup>, Michael Feigh<sup>3</sup>, Jesus Maria Banales<sup>4</sup>. <sup>1</sup>Albireo Pharma, Inc.;

<sup>2</sup>Karolinska Institutet at Karolinska University Hospital Huddinge;

<sup>3</sup>Gubra Aps; <sup>4</sup>Donostia University Hospital

Email: peter.akerblad@albiroepharma.com

**Background and aims:** Cholestasis is characterised by the intrahepatic accumulation of toxic bile acids (BAs). The apical sodium-dependent bile salt transporter (ASBT) plays an important role in regulation of BA homeostasis by promoting their reuptake in the ileum, bile ducts, and kidney. Thus, ASBT inhibition may block the enterohepatic circulation of BAs and enhance their excretion, leading to beneficial effects on cholestasis and cholangitis. A3907 is a selective ASBT inhibitor with high oral bioavailability and systemic exposure that has potential to modulate BA transport in intestine,

## ORAL PRESENTATIONS

kidney, and bile ducts. The objective of this study is to investigate the effect of A3907 on characteristic cholestasis and sclerosing cholangitis developed by *Mdr2* knockout mouse over time.

**Method:** Male *Mdr2*<sup>-/-</sup> mice (7–8 weeks old) were treated with A3907 (1–30 mg/kg) or vehicle by oral gavage once daily for 4 weeks. Plasma and liver biochemistry and histology were assessed after sacrifice.

**Results:** After 4 weeks of A3907 treatment, the concentration of total BAs in plasma was reduced compared with vehicle. Liver transaminases (all A3907 doses  $P \leq 0.01$ ) and alkaline phosphatase (A3907 3–30 mg/kg  $P \leq 0.01$ ) were also reduced. A3907 was associated with dose-dependent reductions in liver and spleen weight vs vehicle (all  $P \leq 0.05$ ), as well as reduced biliary tree volume compared with vehicle (all  $P \leq 0.05$ ). Moreover, A3907 reduced liver inflammation (galectin-3, monocyte chemoattractant protein-1), fibrosis (hydroxyproline and alpha-smooth muscle actin), and expression of the biliary marker cytokeratin 7 compared with vehicle. Pharmacokinetic studies in wild-type mice demonstrated that A3907 can selectively target ASBT in the intestine as well as the bile ducts and kidney.

**Conclusion:** A3907 improves cholestatic liver injury and the characteristic sclerosing cholangitis of *Mdr2*<sup>-/-</sup> mice and is a promising new therapeutic tool for cholestatic liver diseases.

### OS-1946

#### CCR2<sup>+</sup> monocytes induce hepatic accumulation and activation of tissue destructive CD8<sup>+</sup> T cells in a murine model of checkpoint inhibitor-induced hepatitis

Cathrin L.C. Gudd<sup>1,2</sup>, Charalambos G. Antoniadis<sup>1</sup>, Samra Turajlic<sup>3</sup>, Martin Gore<sup>3</sup>, James Larkin<sup>3</sup>, Mark R. Thursz<sup>1</sup>, Wafa Khamri<sup>1</sup>, Robert D. Goldin<sup>1</sup>, Kevin J. Woollard<sup>2</sup>, Evangelos Triantafyllou<sup>1,2</sup>, Lucia A. Possamai<sup>1,2</sup>. <sup>1</sup>Imperial College London, Department of

Metabolism, Digestion and Reproduction, London, United Kingdom; <sup>2</sup>Imperial College London, Division of Immunology and Inflammation, London, United Kingdom; <sup>3</sup>The Royal Marsden Hospital National Health Service Foundation Trust, Renal and Skin Units, London, United Kingdom  
Email: cathrin.gudd@gmail.com

**Background and aims:** Checkpoint inhibitor-induced hepatitis (CPI-Hep) is a growing clinical challenge with the expanding use of checkpoint inhibitors (CPIs) in cancer immunotherapy. We aimed to better understand the mechanisms underlying CPI-Hep by developing and interrogating a murine model of this condition.

**Method:** Wild-type (WT) C57BL/6J male mice, 8–12 weeks-old, were dosed with TLR9 agonist (TLR9-L), in combination with anti-CTLA-4/PD-1 (CPI) or PBS for up to 7 days (n=4–8/treatment group). Flow cytometry, histology, immunofluorescence and RT-PCR were used to characterise liver myeloid/lymphoid cell subsets and inflammation. Hepatocyte damage was assessed by measuring plasma cytokeratin-18 (CK-18) and alanine transaminase (ALT) levels. *In vivo* investigations of CPI-Hep were carried out in *Rag2*<sup>-/-</sup> and *Ccr2*<sup>trfp/trfp</sup> transgenic mice.

**Results:** In WT mice, hepatic immune profiling revealed an increased infiltration and formation of inflammatory aggregates of granzyme B<sup>+</sup>perforin<sup>+</sup>CD8<sup>+</sup> T cells and CCR2<sup>+</sup> monocytes 7 days post TLR9-L/CPI treatment, compared to TLR9-L/PBS treated or baseline mice. This was accompanied by apoptotic hepatocytes surrounding immune aggregates and elevated CK-18 levels at day 4 and 7 post TLR9-L/CPI treatment and ALT levels at day 4 (Fig.). Increased liver tissue mRNA levels of monocyte/T cell recruitment and inflammation related markers (*Ccl2*, *Cxcl9*, *Cxcl10*, *iNos*, *Tnfa*) were detected. In contrast, TLR9-L/CPI treated *Rag2*<sup>-/-</sup> mice, lacking mature lymphocytes, were protected from hepatocyte damage and showed significantly reduced CK-18 and ALT levels compared to TLR9-L/CPI treated WT (Fig.).

**Figure:** Representative H&E stained liver sections of CPI treated WT, *Ccr2*<sup>trfp/trfp</sup> and *Rag2*<sup>-/-</sup> mice at day 7 of experimental CPI-Hep. Magnification: 100X. Measurement of CK-18 in plasma of WT, *Ccr2*<sup>trfp/trfp</sup> and *Rag2*<sup>-/-</sup> mice throughout the time course. Each symbol represents an individual mouse. \* represents comparison between groups; # shows comparisons with D1 in the same group. \*\*  $p < 0.01$ , \*\*\*\*  $p < 0.0001$ . D: day.

Figure: (abstract: OS-1946)

CCR2<sup>flp/rfp</sup> mice, lacking CCR2<sup>+</sup> monocytes, when treated with TLR9-L/CPI showed a reduced number of granzyme B<sup>+</sup>perforin<sup>+</sup>CD8<sup>+</sup> T cells compared to TLR9-L/CPI treated WT mice, normal liver histology and significantly reduced CK-18 and ALT levels (Fig.).

**Conclusion:** Our newly established TLR9-L CPI murine model, which closely resembles human pathology with CD8/macrophage inflammatory aggregates and hepatocyte injury, provides a new platform for *in vivo* mechanistic studies on CPI-Hep. We show that liver infiltration of CCR2<sup>+</sup> monocytes and their interaction with CD8<sup>+</sup> T cells are necessary to the pathogenesis of CPI-Hep and hepatocyte injury. This work highlights a potential pathway for therapeutic intervention. Further studies are underway to elucidate the mechanisms of CD8<sup>+</sup> T cell and monocyte cross talk in driving CPI-induced liver pathology.

OS-2274

**Farnesoid X Receptor agonists block macrophage derived IL1beta production, disrupt Th1/Th17 polarization of effector lymphocytes, and ameliorates disease progression in murine sclerosing cholangitis**

Astha Malik<sup>1</sup>, Annika Yang vom Hofe<sup>1</sup>, Brandee Wagner<sup>2</sup>, Alexander Miethke<sup>1</sup>. <sup>1</sup>Cincinnati Children's Hospital Medical Center, Division of Gastroenterology, Hepatology and Nutrition, Cincinnati, United States; <sup>2</sup>Metacrine, Inc., San Diego, United States  
Email: alexander.miethke@cchmc.org

**Background and aims:** Hepatic monocytes from PSC patients were shown to produce high levels of IL1b upon stimulation with microbes and microbial products (LPS) and to drive pathogenic Th17 responses. We aimed to elucidate the role of FXR in controlling the monocyte-IL1b- Th1/Th17 axis in sclerosing cholangitis (SC).

**Method:** Wild type (WT), IL1r knockout mice (IL1r<sup>-/-</sup>) and transgenic mice lacking FXR expression in myeloid cells (FXRdMC) were fed a diet containing 0.1% of the xenobiotic diethoxycarbonyl-1, 4-dihydrocollidine (DDC) to induce cholangiopathy and liver inflammation. M044 was administered at 10 mg/kg by oral gavage following initiation of DDC diet. Liver mononuclear cells (LMNC) were isolated after 7 days of DDC challenge and subjected to treatment with LPS for 16 hours prior to intracellular flow cytometry.

**Results:** LMNCs isolated from DDC-fed WT mice were treated with 40 ng/ml of IL1Ra antagonist which reduced Ifng expression on macrophages (MP), CD4, and CD8 lymphocytes following LPS stimulation. LMNCs from DDC-fed IL1r<sup>-/-</sup> mice exhibited decreased IL17a expression in MP, CD4 and CD8 T cells compared with WT mice upon LPS stimulation. End of DDC treatment serum total bilirubin (TB), ALT, and ALP levels were significantly lower in these knockout mice compared with controls. LMNCs from DDC-fed FXRdMC displayed higher levels of Ifng and IL17a expression in MP, CD4, and CD8 cells, higher serum ALT and TB levels, and worse bile duct proliferation by CK19 immunohistochemistry compared with WT controls. To elucidate the role of MP in mediating treatment effects of the FXR agonist M044 in SC, DDC-fed WT and FXRdMC mice were subjected to treatment with M044 or vehicle. Reduction of Th1 and

Th17 responses upon M044 treatment was far less in FXRdMC compared with WT mice (Figure 1). While M044 treatment significantly reduced serum ALT, ALP, and TB levels by 42, 42, and 83%, respectively, in WT mice, no significant reduction of liver biochemistries was observed in identically treated FXRdMC mice. Reduction of %CK19+ area on liver sections was observed in WT mice following administration of an FXR agonist.

**Conclusion:** Monocyte derived IL1b licenses Ifng and IL17a production by hepatic effector lymphocytes in xenobiotic induced SC. This pathway is critically controlled by FXR in hepatic myeloid cells which mediate the therapeutic effects of FXR agonist therapy in this model of PSC.

**Immune-mediated and cholestatic disease: Clinical aspects**

OS-706

**Blue-collar work increases the risk of developing IgG4-RD of the biliary tract and pancreas**

Lowiek Hubers<sup>1</sup>, Alex Schuurman<sup>1</sup>, Jorie Buijs<sup>2</sup>, Nahid Mostafavi<sup>1</sup>, Marco Bruno<sup>2</sup>, Roel Vermeulen<sup>3</sup>, Anke Huss<sup>3</sup>, Henk Van Buuren<sup>2</sup>, Ulrich Beuers<sup>1</sup>. <sup>1</sup>Amsterdam UMC, Locatie AMC, Department of Gastroenterology and Hepatology, Tytgat Institute for Liver and Intestinal Research, Amsterdam, Netherlands; <sup>2</sup>Erasmus MC, Department of Gastroenterology and Hepatology, Rotterdam, Netherlands; <sup>3</sup>Utrecht University, Institute for Risk Assessment Sciences, Utrecht, Netherlands  
Email: l.m.hubers@amc.uva.nl

**Background and aims:** IgG4-related disease (IgG4-RD) of the biliary tract and pancreas typically affects men above 50 years of age. The reason for male predominance (~85%) is unclear. Here, we tested our working hypothesis (Hepatology 2014;60:1453) that 'blue-collar work' and occupational exposure to industrial contaminants are risk factors for IgG4-RD of the biliary tract and pancreas.

**Method:** An age- and sex-matched case-control study was performed in the two largest academic medical centers in the Netherlands. Disease controls were matched 3:1 to cases and consisted of six equally-sized groups with digestive diseases unrelated to occupational risk. The occupational history was surveyed using questionnaires. Jobs were classified by the International Standard Classification of Occupations (ISCO88). The number of years patients were exposed to a selection of industrial compounds were determined using Job Exposure Matrices ALOHA and DOM. Conditional logistic regression was used to assess effects of blue-collar work and exposure to occupational contaminants on developing IgG4-RD of biliary tract and pancreas.

**Results:** A total of 303 disease controls were matched to 101 patients with IgG4-RD of biliary tract and pancreas. Overall, patients with

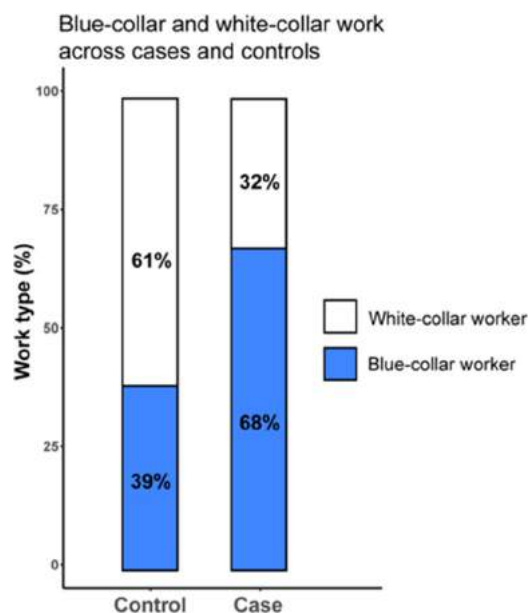

Figure 1: (abstract: OS-2274): **Genetic deletion of FXR from myeloid cells renders immune cells unresponsive to *in vivo* FXR agonist treatment.** WT and FXRdMC were challenged with 0.1% DDC and treated with M044 or vehicle for 7 days. LMNCs were exposed to LPS prior to PMA/Ionomycin restimulation and intracellular flow cytometry Percent reduction was plotted by comparing each of the treated controls to the average of the vehicle treated mice in each group (n = 4 mice/group).

## ORAL PRESENTATIONS

IgG4-RD had a lower education level ( $p = 0.001$ ). 68% of patients with IgG4-RD ( $n = 69$ ) had a history of blue-collar work compared to 39% of controls ( $n = 117$ , Figure). The odds of developing IgG4-RD among blue-collar workers was 3.66 times higher than among white-collar workers (95% CI 2.18–6.13;  $p < 0.001$ ). Also, long-term exposure ( $>1$  year) to ALOHA (e.g. mineral dust; vapors-dust-gases-fumes) and DOM compounds (e.g. asbestos) increased the odds of developing IgG4-RD (OR = 2.14 (CI 1.26–3.16,  $p < 0.001$ ) and OR = 2.95 (CI 1.78–4.90,  $p < 0.001$ ), respectively).

**Conclusion:** Blue-collar work increases the risk of developing IgG4-RD of biliary tract and pancreas, presumably through long-term exposure to specific industrial compounds and may explain the striking male predominance among patients.

Email: christophe.corpechot@aphp.fr

**Background and aims:** Liver stiffness measurement (LSM) assessed by vibration-controlled transient elastography (Fibroscan) has been shown to predict clinical outcomes in primary biliary cholangitis (PBC), but this finding is based on still very limited single-center data. This study aimed to assess the prognostic value of LSM in a large, multicenter, international cohort of patients with PBC.

**Method:** Patients with PBC with at least one LSM (Fibroscan) available and a subsequent follow-up  $\geq 1$  year were included in a multicenter retrospective cohort study. Patients with overlap syndrome were excluded. LSMs with an interquartile/median ratio  $\leq 0.3$  were considered reliable. All repeated LSMs and associated serum liver function tests were collected. The primary outcome was all-cause mortality or liver transplantation (LT). The secondary outcome was all-cause mortality or liver complication (LC). These outcomes were assessed using a time-dependent, multivariable-adjusted Cox proportional hazards model. The C-statistic was used to assess the predictive performance of LSM. The relationship between the hazard ratio (HR) and LSM was assessed using a cubic spline function.

**Results:** A total of 5323 reliable LSMs (median value at baseline: 6.8 kPa, IQR 5.3–10.0) was collected in 2736 UDCA-treated patients with PBC (mean age 58; 91% female; 11% cirrhosis; median time between UDCA start and baseline LSM 3.0 years) from 18 centers and 10 countries. The median follow-up from baseline LSM was 4.1 years (range 1.0–16.4). A total of 145 deaths (62 liver-related), 51 LT, and 85 LC with no subsequent death or LT until the last visit was registered. In a time-dependent multivariable analysis adjusted for age, sex, total bilirubin, albumin, ALP, AST, and platelet count, LSM was significantly associated with all-cause mortality or LT (adjusted HR: 1.046 per kPa increase, 95% CI 1.033–1.060) and all-cause mortality or LC (adjusted HR: 1.041, 95% CI 1.028–1.054). Its performance at baseline to predict these outcomes was 0.85 and 0.83, respectively. Within the 5–30 kPa range, the log-HR for all-cause death or LT increased as a linear function of LSM (Figure 1). LSM predicted outcomes independently of the biochemical response to UDCA (regardless of the definition used) and the Globe, UK-PBC, and MELD scores.

Figure 1: The hazard of all-cause death or LT as a function of LSM at baseline

**Conclusion:** LSM assessed by Fibroscan can predict clinical outcomes of patients with PBC and might be used as a surrogate end point in clinical trials.

**OS-1088**

**Hepatobiliary malignancy surveillance strategies in primary sclerosing cholangitis associate with reduced mortality**

**Background and aims:** Patients with primary sclerosing cholangitis (PSC) are at increased risk for hepatobiliary malignancies, especially cholangiocarcinoma. Although many recommend surveillance for malignancy in PSC, different strategies are used by various centers and countries. We aimed to evaluate different surveillance strategies and their effectiveness in PSC with the hypothesis that surveillance imaging improves survival.

**Method:** We queried centers about surveillance practices and retrospectively collected imaging surveillance data for hepatobiliary cancer in 2, 975 patients with PSC from 28 centers within the International PSC Study Group (IPSCSG). Surveillance strategies were grouped in (i) non-surveillance (no imaging in asymptomatic patients), (ii) magnetic resonance imaging (MRI) and/or ultrasound (US) surveillance (regular imaging regardless of symptoms/labs) and (iii) surveillance including endoscopic retrograde cholangiopancreatography (ERCP)-based (imaging and/or ERCP regardless of symptoms/labs). The primary end point was all-cause mortality. Cox-proportional hazard regression models were used to estimate hazard ratios (HRs).

**Results:** 65.6% (1953/2975) of patients were male, mean age (SD) at diagnosis of PSC was 35.6 (14.2) years, with concomitant IBD in 71.5% (2127/2973). Hepatobiliary malignancy was found in 175 (5.9%) patients at 7.9 years of follow-up (Figure). Surveillance strategies differed significantly between centers. Of patients undergoing surveillance, 83% were subjected to MRI/MRCP, 49% to US and 28% to ERCP. Deaths were more frequent in the non-surveillance group 23.4% (82/350) than in the surveillance group 8.3% (218/2625). Mortality rate (95% CI) per 1000 person-years was 23.1 (18.1–28.1) in the non-surveillance group (n=350), 12.5 (10.6–14.5) in imaging surveillance with MRI and/or US (n=1897) and 8.4 (6.3–10.5) in surveillance that included ERCP (n=728). The risk of dying was reduced in patients undergoing any type of surveillance (HR 0.53;

# ORAL PRESENTATIONS

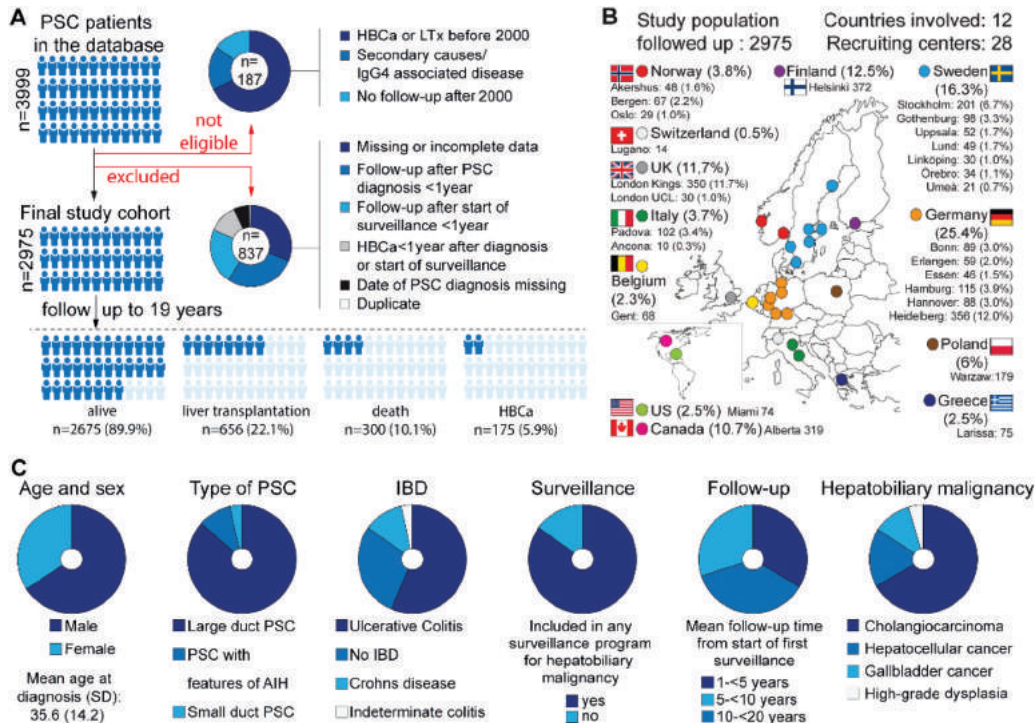

Figure: (abstract: OS-1088)

95% CI: 0.41–0.68) and the reduced risk remained after adjusting for sex, age and start year of follow-up (HR 0.61; 95% CI: 0.47–0.80). **Conclusion:** A broad variety of surveillance strategies across centers are used. Regular surveillance for hepatobiliary malignancy in patients with PSC is associated with improved survival.

**Background and aims:** Sufficiency of UDCA response is dynamic in PBC, with varied patterns over time. We describe patterns of response and their association with liver transplant-free survival.

**Method:** Patients with >1 year of UDCA therapy from 8 Canadian sites were assessed; those with a clinical event within 6-mo of diagnosis or

without labs at 1-year ( $\pm 6$ mo) were excluded. We defined UDCA response as alkaline phosphatase (ALP) < 1.67 $\times$ ULN and total bilirubin (TB)  $\leq 1 \times$ ULN. Multistate models estimated dynamic transition through biochemical response states over time, and from each state to transplantation or death (LTx/Death). We adjusted for sex, age, ALP, TB, and FIB-4  $\geq 4.03$  at 1-year.

**Results:** Of 823 patients, median age at UDCA initiation was 53.6 years, 91.0% were female and 86.8% AMA positive. Median follow-up was 6.5 years and 7.0%/11.4%/13.5% had LTx/Death by 5/10/15 years. At 1-year, 67.4% of patients were responders. By 5-years, an estimated 6.4% never responded, 53.6% retained response, and 8.3% had LTx/Death. An estimated 31.8% fluctuated between response states: (i) 15.5% lost response and were non-responders at 5-years; (ii) 14.8% lost but then regained response and were responders at 5-years; (iii) 1.5% had at least five state changes (Figure, dotted line). At any point, patients retaining initial response had significantly lower rates of LTx/Death than those who never responded (0.074-fold, 95% CI 0.015–0.359) or lost response (0.045-fold, 95% CI 0.009–0.219). At any point, regaining response was protective against LTx/Death (transition rates: <0.001 vs 0.037; 0.005 vs 0.064).

Older age at UDCA initiation was associated with increased hazard of responding (HR 1.03/year, 95% CI 1.01–1.04) and of regaining response after loss of initial response (HR 1.04/year 95% CI 1.03–1.05). Response patterns of patients  $\leq 40$  years at UDCA initiation indicated high risk compared to patients aged 40–60 years: at 1-year, 56.2%/66.3% were responders. By 5-years an estimated 14.8%/6.7% never responded, 53.0%/57.8% retained response, and 4.2%/3.3% had LTx/Death. An estimated 28.0%/32.2% fluctuated between states: 17.9%/15.3% lost response by 5-years while 10.1%/17.0% lost then regained response. Age comparisons are for females, FIB-4 < 4.03, mean ALP and TB at 1-year.

**Conclusion:** Achievement of response at any time improves liver transplant-free survival regardless of prior non-response. New therapies will be important in improving response patterns, especially for younger patients.

##### Frequency, clinical features and outcomes of COVID-19 in patients with IgG4-related hepato-pancreato-biliary disease: a collaborative European multi-centre study

Giuseppe A. Ramirez<sup>1,2</sup>, Marco Lanzillotta<sup>1,2</sup>, Mikael Ebbö<sup>3,4</sup>, Andreu Fernandez-Codina<sup>5,6,7</sup>, Gaia Mancuso<sup>1</sup>, Fernando Martínez-Valle<sup>8,9</sup>, Olimpia Orozco-Galvez<sup>8,9</sup>, Loren Smith<sup>10,11</sup>, Nicolas Schleinitz<sup>3,4</sup>, Lorenzo Dagna<sup>1</sup>, Emanuel Della Torre<sup>1,2</sup>, Emma Culver<sup>10,11</sup>, <sup>1</sup>IRCCS Ospedale San Raffaele, Unit of Immunology, Milan, Italy; <sup>2</sup>Università Vita-Salute San Raffaele, Immunology, Milan, Italy; <sup>3</sup>CHU de Marseille-Hôpital de la Timone, Département de Médecine Interne, Marseille, France; <sup>4</sup>Aix-Marseille University, Internal Medicine, Marseille, France; <sup>5</sup>Windsor Regional Hospital, General Internal Medicine, Windsor, Canada; <sup>6</sup>University of Western Ontario, Rheumatology, London, Canada; <sup>7</sup>Hospital Clinic i Provincial, Emergency Department, Barcelona, Spain; <sup>8</sup>Universitat Autònoma de Barcelona, Autoimmune Diseases Research Lab, Barcelona, Spain; <sup>9</sup>Vall d'Hebrón Hospital, Systemic Diseases Unit and Internal Medicine Service, Barcelona, Spain; <sup>10</sup>John Radcliffe Hospital, Oxford Liver Unit, Oxford, United Kingdom; <sup>11</sup>University of Oxford, Nuffield Department of Medicine, Oxford, United Kingdom

Email: emmaculver@yahoo.co.uk

**Background and aims:** The incidence of coronavirus disease 2019 (COVID-19) and of its complications in patients with immune-mediated liver and biliary disease remains unclear. We aimed to assess the frequency and impact of COVID-19 on patients with IgG4-related hepato-pancreato-biliary disease (IgG4-HBD), many of whom are on concurrent immunosuppression.

**Method:** A European multi-centre retrospective observational study from France, Italy, Spain and the United Kingdom was conducted between February 2020 to January 2021. Phone or in-person interviews were used to evaluate the frequency of COVID-19 infection, clinical presentation, disease course and outcomes in patients with IgG4-HBD. Demographics, comorbidities, organ involvement, current and past treatment, presumed COVID-19 (based on clinical, serological or imaging features: pCOVID) and confirmed COVID-19 (reverse-transcriptase polymerase chain reaction-confirmed: cCOVID). Total pCOVID and cCOVID (totCOVID) were pooled and compared to patients who were not diagnosed with COVID-19. Inter-group comparison of categorical and quantitative variables was performed using chi-square test with Fisher's correction and the Mann-Whitney's test, respectively.

**Results:** Data were collected for 119 patients [81% males, median age 68 (56–76) years] with IgG4-HBD. The majority (90%) had pancreatic involvement and 50 (42%) had coexisting diabetes mellitus. Fifty-four (45%) were taking corticosteroids (17% >10 mg daily prednisolone for active disease), 32 (27%) were on conventional immunosuppressants (azathioprine n = 17; mycophenolate n = 9; methotrexate n = 3; other n = 2) and 15 were on biological agents (rituximab n = 13). Thirty (25%) were on two or more immunosuppressive drugs for disease

control. Nine totCOVID cases (7 cCOVID, 2 pCOVID) were identified: 5 were hospitalised, 1 in intensive care and 2 died. Having one or more infected family members was a risk factor for COVID-19 in IgG4-HBD (OR = 15.4; p = 0.028). There was no association between adverse outcomes with COVID-19 and higher doses of steroids (>10 mg prednisolone), dual immunosuppression or rituximab.

**Conclusion:** The prevalence and course of COVID-19 in IgG4-HPB patients are similar to those of the general population of the same age, despite immunosuppressive treatment. There was no evident impact of disease- or treatment-related factors to the basal infectious risk. Effective public health countermeasures should be advocated for patients with IgG4-HBD.

#### OS-2096

##### Surrogate markers for bile duct disease progression assessed by sequential ERCP examinations in primary sclerosing cholangitis

Martti Färkkilä<sup>1</sup>, Henrik Alftan<sup>2</sup>, Andrea Tenca<sup>3</sup>, Kalle Jokelainen<sup>3</sup>, Johanna Arola<sup>4</sup>, Hannu Kautiainen<sup>5</sup>. <sup>1</sup>University of Helsinki, Faculty of Medicine, Helsinki, Finland; <sup>2</sup>Helsinki University Hospital, HUSLab, Helsinki, Finland; <sup>3</sup>Helsinki University Hospital, Clinic of Gastroenterology, Helsinki, Finland; <sup>4</sup>Helsinki University Hospital, Department of Pathology, Helsinki, Finland; <sup>5</sup>University of Eastern Finland, Primary Health Care Unit, Kuopio, Finland

Email: martti.farkkila@hus.fi

**Background and aims:** Primary sclerosing cholangitis [PSC] is a chronic inflammatory disease of biliary epithelium leading to strictures and eventually to cholestasis and secondary cirrhosis. Several surrogate markers have been developed to predict the disease progression, such as decrease of ALP, IL-8, and ELF and bile calprotectin, using liver cirrhosis, transplantation free survival or death as end points. In recent study, ALP did not associate with disease progression assessed by cirrhosis. Biliary IL8, collected at different stages of PSC demonstrated that it is elevated compared to controls, suggesting an ongoing inflammation driving IL8 production. However, liver cirrhosis, transplantation free survival or death are very late end points and not suitable for monitoring progression of bile duct disease and development of dominant strictures needing dilatations. We evaluated the role of clinical parameters, serum and biliary markers to predict the bile duct disease progression assessed by sequential ERC examinations to find better surrogate markers for PSC progression and drug development.

**Method:** Patients with suspicion or documented PSC referred for ERC examination to confirm the diagnosis, follow-up of disease progression or dysplasia surveillance were included. ERC findings were scored according to modified Amsterdam score. Based on ERC-score the patients were divided into (1) No progression (n = 259) or (2) Progression  $\pm$  need for dilatation (n = 381). Time weight AUC was calculated based on ERC score. Brush cytology was collected from both extra- and intrahepatic ducts. Biliary calprotectin were analysed using ELISA method and IL8 was measured by immune-chemiluminometrics. Optimal cut points, AUC, sensitivity, specificity, positive likelihood ratio (LR+) and PPV were calculated. The study protocol was accepted by HUS Ethical Committee HUS/1566/2020.

**Results:** 76% had a concomitant IBD, but it had no impact on disease progression, neither did colectomy done before or after diagnosis of PSC, age or sex. None of the liver enzymes levels (P-ALP, P-GT, P-AST, P-ALT) or P-bil demonstrated significant impact on disease progression (AUC 0.55–0.58). Only biliary (Bi-) calprotectin (AUC 0.77 [95% CI 0.73–0.82]), Bi-IL8 (0.81 [0.75–0.86]) or their combination (0.80 [0.75–0.85]) and to less extent S-IL8 (0.60 [0.53 to 0.68]) could significantly predict bile duct disease progression and/or need for dilatation. The LR+ were respectively 2.79 (2.16–3.60), 2.84 (2.07–3.89) and for the combination 3.30 (2.29–4.76).

**Conclusion:** In this large PSC patient cohort with sequential ERCP regardless of symptoms, liver enzymes or patient demography could not predict bile duct disease progression or need for dilatation. The most sensitive markers with highest LR were Bi-calprotectin and Bi-

## ORAL PRESENTATIONS

IL8. The value of serum liver enzymes in assessing bile duct disease progression in PSC seemed to be limited.

### OS-2782

#### Bacterial and fungal colonisation of bile ducts associates with the prognosis of Primary Sclerosing Cholangitis

Ehud Zigmond<sup>1,2</sup>, Britta Zecher<sup>3</sup>, Anna-Lena Bartels<sup>3</sup>, Tomer Ziv<sup>2</sup>, Thomas Rösch<sup>4</sup>, Ansgar Lohse<sup>3</sup>, Hanno Ehlken<sup>3,4</sup>, Christoph Schramm<sup>3,5,6</sup>. <sup>1</sup>Tel Aviv Sourasky Medical Center, Department of Gastroenterology, Tel Aviv, Israel; <sup>2</sup>Tel Aviv University, Sackler Faculty of Medicine, Tel Aviv, Israel; <sup>3</sup>University Medical Center Hamburg-Eppendorf, Ist Department of Medicine, Germany; <sup>4</sup>Dept. for Interdisciplinary Endoscopy, Germany; <sup>5</sup>University Medical Center Hamburg-Eppendorf, Martin Zeitz Center for Rare Diseases, Germany; <sup>6</sup>University Medical Center Hamburg-Eppendorf, Hamburg Center for Translational Immunology (HCTI), Germany  
Email: zigmondu@gmail.com

**Background and aims:** Primary Sclerosing Cholangitis (PSC) is a rare immune mediated chronic and progressive liver disease characterized by inflammation and fibrosis of bile ducts. Bile ducts in PSC are frequently colonised with bacteria and we have recently described an altered biliary microbiota composition in PSC with a high abundance of *Enterococcus sp.* However, little is known about the impact of these findings on the clinical course of disease.

**Method:** We here investigated the association of bile fluid culture results obtained routinely during ERCP on major clinical end points in a large single center cohort of PSC patients. Peri-interventional i.v. antibiotics were given as standard after the sampling of bile fluid in our center. Procedures with overt bacterial cholangitis and receiving antibiotic treatment prior to ERCP were excluded.

**Results:** Microbiological culture results from 591 ERCP were included. Culture results were not associated with the occurrence of cholangiocarcinoma (CCA), which was therefore not included as an end point for further analyses. Positive bile cultures were significantly associated with development of cirrhosis and its complications and survival free of liver transplantation. Bacteria grew in 75% of biliary cultures and in 32% of first time ERCP procedures. Interestingly, amongst the bacterial species, the presence of *Enterococcus faecalis* and/or *faecium* in bile fluid conferred risk of disease progression independent of the presence of fungi in bile with a HR of 2.28 (95% CI 1.32–3.92,  $p < 0.005$ ) for achieving clinical end points and HR of 1.9 (95% CI 1.05–3.41,  $p < 0.05$ ) for survival free of liver transplantation. Fungobilia, present in 20% of cases, was found to strongly associate with disease progression with a HR of 2.39 (95% CI 1.37–4.17,  $p < 0.001$ ) for achieving clinical end points.

**Conclusion:** Our peri-interventional standard antibiotic regimen and exclusion of patients with overt bacterial cholangitis enabled us to analyze the association of bile duct colonisation with disease course in a large cohort of PSC patients. The strong association of *Enterococcus sp.* and fungi with disease progression highlights the importance of microbiota-mucosal interplay for the pathogenesis of PSC. These results should stimulate further mechanistic studies on the role of microbiota for biliary inflammation in PSC.

#### Non-autonomous induction of endothelial RelA underpins immune-mediated surveillance of premalignant hepatocytes

Kelvin Yin<sup>1,2</sup>, Daniel Patten<sup>3</sup>, Aaron Lun<sup>2</sup>, Martijn Schuijjs<sup>2</sup>, Adelyne Chan<sup>2</sup>, Andrew Young<sup>2</sup>, Tim Halim<sup>2</sup>, Shishir Shetty<sup>3</sup>, Masashi Narita<sup>2</sup>, Matthew Hoare<sup>2,4</sup>. <sup>1</sup>Helmholtz Pioneer Campus, Helmholtz Zentrum München, Munich, Germany, <sup>2</sup>CRUK Cambridge Institute, Cancer Research UK, Cambridge, United Kingdom, <sup>3</sup>Institute of Immunology and Immunotherapy, University of Birmingham, Birmingham, United Kingdom, <sup>4</sup>University of Cambridge, Department of Medicine, Cambridge, United Kingdom  
Email: chuan-hsin.yin@helmholtz-muenchen.de

**Background and aims:** Oncogene-induced senescence (OIS) is a tumour suppressor mechanism, with profound effects on the microenvironment (ME) through the senescence-associated secretory phenotype (SASP). Previous studies have shown that OIS hepatocytes are progressively cleared by a SASP-driven CD4+ T-lymphocyte-dependent immune response, termed senescence surveillance; failure of this clearance leads to tumorigenesis. The mechanisms underpinning this surveillance of pre-malignant cells are not well understood. We hypothesised that OIS hepatocytes would regulate immunomodulatory endothelial behaviour, controlling immunocyte recruitment and behaviour in the liver ME.

**Method:** Using hydrodynamic tail vein injection (HDTV) of NRAS<sup>G12V</sup>-containing transposons, we generate OIS in murine hepatocytes. To test our hypothesis, we use pharmacological blockade of NF- $\kappa$ B signalling, as well as inducible endothelial-specific knock-out transgenic mouse model following OIS. LSECs were isolated from dissociated murine livers for characterization by quantitative-PCR. Our observations were validated in two

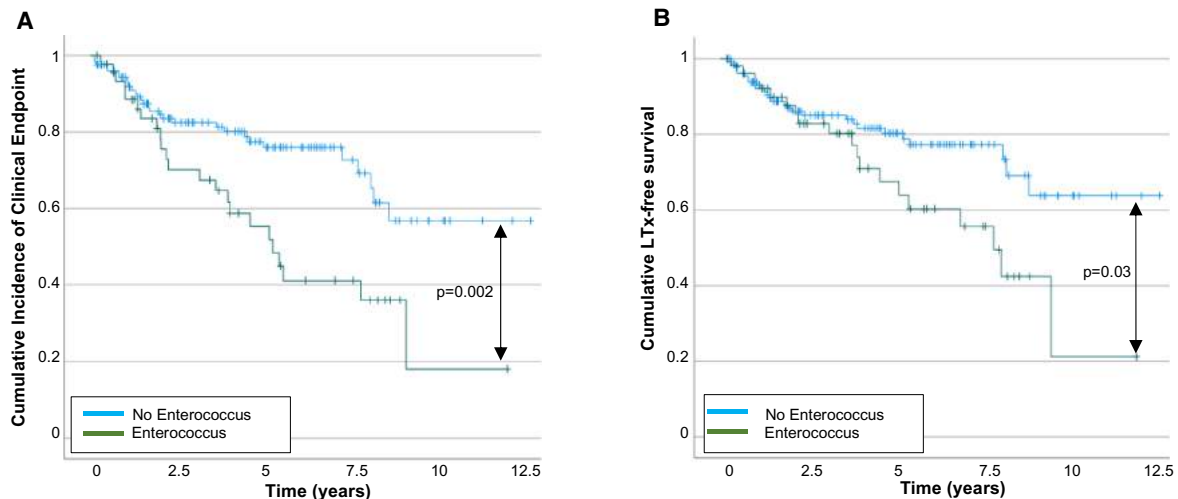

Figure: (abstract: OS-2782)

independent human endothelial cell lines, and in trans-endothelial migration *in vitro* assays using SASP-primed human primary LSECs and lymphocytes. scRNAseq and mass cytometry were used to characterize the hepatic immune landscape in response to OIS.

**Results:** Using an *in vitro* model of OIS, we have demonstrated a SASP-driven non-autonomous upregulation of NF- $\kappa$ B-target genes in primary human liver sinusoidal endothelial cells (LSECs). Genetic or pharmacological blockade of NF- $\kappa$ B signaling in SASP-primed LSECs abrogated lymphocyte trapping and trans-endothelial migration *in vitro*. In the context of *in vivo* studies, we show hepatocyte OIS non-autonomously upregulates multiple NF- $\kappa$ B-target genes in LSECs, including *Cxcl1* and *Icosl*. Transgenic mouse model of *Cdh5*<sup>CreERT2</sup>; *Rela*<sup>fl/fl</sup> provided evidence that endothelial NF- $\kappa$ B signalling is crucial to senescence surveillance, where loss of endothelial *Rela* leads to persistence of OIS hepatocytes. scRNA-seq suggests that loss of endothelial *Rela* leads to a complete loss of a *Stat1*-expressing CD4+ lymphocyte subset from the liver ME.

**Conclusion:** Endothelial cells are a target of non-autonomous signalling from senescent cells *in vitro* and *in vivo*. We found that immunomodulatory endothelial behaviour, through non-autonomous induction of endothelial NF- $\kappa$ B signalling, forms a crucial part of the immune surveillance of premalignant hepatocytes.

**Selective depletion of HBsAg-specific B cells in paediatric HBV infection**

Sabela Lens<sup>1,2</sup>, Ida Heiberg<sup>3</sup>, Thilde Nordmann Winther<sup>3</sup>, Anna Jeffery-Smith<sup>1</sup>, Nikolai Novikov<sup>4</sup>, Simon Fletcher<sup>4</sup>, Birthe Hogh<sup>3</sup>, Alice Burton<sup>1</sup>, Mala Maini<sup>1</sup>. <sup>1</sup>Division of Infection and Immunity, UCL, London, United Kingdom, <sup>2</sup>Liver Unit, Hospital Clínic Barcelona, IDIBAPS, CIBERehd, University of Barcelona, Barcelona, Spain, <sup>3</sup>Department of Paediatrics, Hvidovre Hospital, University of Copenhagen, Copenhagen, Denmark, <sup>4</sup>Gilead Sciences, United States  
Email: m.maini@ucl.ac.uk

**Background and aims:** Exposure to HBV during vertical transmission or in infancy is associated with a high rate of chronicity, but the immunological mechanisms accounting for this remain unclear. Recent data have highlighted a contribution of B cells to ongoing control of chronic hepatitis B (CHB) and direct *ex vivo* analysis has revealed defects of HBsAg-specific B cells in adults. We therefore characterized the HBV-specific and global B cell compartment (and the T follicular helper cell (Tfh) response that supports it) in children with CHB, comparing with uninfected children or adults with CHB.

**Method:** 16-colour flow cytometry was used to characterise the composition and phenotype of circulating HBsAg- and HBcAg-

specific B cells (detected using dual fluorochrome-labelled antigen baits), global B cells and circulating Tfh in a cohort of children with CHB (n = 25; age range 5–17 yrs), compared to uninfected children (n = 24) and CHB adults matched by disease phase (n = 35).

**Results:** HBsAg-specific B cells were strikingly reduced in children compared to adults with CHB. By contrast HBcAg-specific B cells and tetanus-specific B cells were detectable at higher frequencies, comparable in children and adults. These data pointed to a selective depletion of HBsAg-specific B cells in children with CHB, regardless of HBV phase, HBV-DNA level or HBeAg status. HBsAg-specific B cells in children were enriched for the atypical memory phenotype recently described to be a feature associated with the dysfunction of this specificity in adults (atMBC: CD21<sup>-</sup>CD27<sup>-</sup>). AtMBC were also more enriched within global B cells in children with CHB than in adults with CHB or in uninfected children. AtMBC upregulated inhibitory markers (CD22, PD-1) and downregulated homing and signaling molecules (CXCR5, CD80, CD40) compared to their classical memory counterparts. In addition to these defects, we postulated HBsAg-specific B cells received inadequate T cell help; in line with this, HBsAg-specific B cells correlated with frequencies of circulating Tfh, but the latter had reduced CD40L in children with CHB compared to controls.

**Conclusion:** Children with CHB have a profound and selective depletion of HBsAg-specific B cells compared to adults. Residual HBsAg-specific B cells have a phenotype indicative of dysfunction and may have defective T-B cell interactions. These findings are consistent with the low rate of anti-HBs seroconversion in children and point to pathways for therapeutic intervention.

**Background and aims:** Small for size syndrome (SFSS) is a common complication following partial liver transplantation or extended hepatectomy. SFSS is characterized by postoperative liver dysfunction caused by insufficient regenerative capacity and portal hyperperfusion, and is more frequent in patients with pre-existing liver disease. Hepatocyte growth factor (HGF) possesses potent anti-inflammatory, anti-fibrotic, and regenerative properties, but its very short plasmatic half-life precludes its clinical use. We explored the efficacy of the MET-agonistic antibody 71D6, which mimics the biological activities of HGF, in mice undergoing carbon tetrachloride (CCl4) exposure followed by 70% partial hepatectomy (PHx).

**Method:** 8-week-old mice were administered CCl4 subcutaneously twice a week for 10 weeks, then randomly assigned to receive 71D6 (3 mg/kg) or control IgG, starting 2 weeks before PHx. Livers were

## ORAL PRESENTATIONS

harvested at different time points following PHx. The survival rate, body and liver weights, serum albumin, and expression of fibrosis-related and inflammation-related genes were analyzed.

**Results:** Compared to control IgG, 71D6-treatment in mice undergoing CCL4 and PHx resulted in robust hepatocellular regeneration via activation of extracellular signal regulated kinase (ERK) 1/2 signaling, leading to accelerated recovery of liver function and improved survival 28-day post PHx ( $p=0.027$ ). 71D6 reduced myofibroblast activation and collagen deposition, as shown by reduced alpha smooth muscle cell actin ( $p < 0.01$ ) and picro Sirius red staining ( $p < 0.05$ ), by inhibiting multiple fibrogenic pathways including platelet-derived growth factor, tissue matrix metalloproteinase inhibitor-3, and transforming growth factor- $\beta$ 1 ( $p < 0.01$  for gene expression levels 28 days post-PHx). 71D6 also prevented the development of severe inflammation, as shown by a statistically significant reduction in macrophage infiltration and chemokine/cytokine expression.

**Conclusion:** Our results demonstrate that mimicking HGF with the MET-agonistic antibody 71D6 promotes liver regeneration, inhibits fibrosis and attenuates immune cell infiltration after PHx in mice with pre-existing liver injury. These results suggest that activating the MET pathway via an HGF-mimetic antibody may be beneficial in patients with SFFS and possibly other types of acute and chronic liver disorders.

**Background and aims:** Liver is the largest solid organ, consisting of predominantly parenchymal hepatocytes, which are interspersed in an ordered matrix to provide 'cross-talk' with less common cell types, including liver sinusoidal endothelial cells (LSECs), Kupffer cells (KCs)

Figure: (abstract: OS-943)

and immune cells. Traditional single-cell RNA-sequencing methodologies require a two-step enzymatic digestion to dissociate liver tissues, leading to the downregulation of liver-specific transcription factors, including *Hnf4a* and *Cebpa*, as well as their downstream target genes. In this context, we have developed a novel single-nucleus RNA-sequencing 2 method (snRNA-seq2) which allows deep characterization of isolated nuclei from frozen samples.

**Method:** Using flash frozen archived liver samples from 3 months old male C57BL/6J mice, we demonstrate the efficiency of snRNA-seq2, which consists of a modified lysis buffer that efficiently lyses the nuclear membrane. Importantly, snRNA-seq2 utilizes unbiased sorting of single-nuclei, allowing the analysis of differential transcriptional variability between different ploidy levels in hepatocytes. Using pseudotemporal ordering and markers of liver zonation, revealed a functional crosstalk between liver zonation and ploidy. Our observations were validated by immunofluorescence/RNAScope co-detection approach in paraffin embedded liver tissues and in a mouse model of liver fibrosis in which zonation is affected.

**Results:** SnRNA-seq2 is a highly sensitive method for frozen liver tissue, capable of detecting on average more than 4000 genes per nucleus compared with other single-cell genomic approaches, including MARS-seq, 10x, Smart-seq2 and CELL-seq. SnRNA-seq2 allowed comprehensive characterization of all hepatic cell types, including upstream transcriptional regulators and key metabolic genes. Additionally, tetraploid hepatocytes show extensive co-expression of liver stem cell markers and high capacity for adaptation and regeneration. Importantly, we found that gene expression in hepatocytes is determined by its hepatic metabolic zonation and independent of their ploidy status.

**Conclusion:** SnRNA-seq2 is a robust and reliable method to investigate the impact of cellular heterogeneity in the development and progression of liver disease using frozen archived samples. We anticipate that changes in the number of 2n and 4n hepatocytes in the overall liver cell composition might lead to the development of chronic liver diseases.

**Integrin Alpha FG-GAP Repeat Containing 1 (ITFG1) knockdown enhances liver regeneration and attenuates chronic liver damage related liver fibrosis**

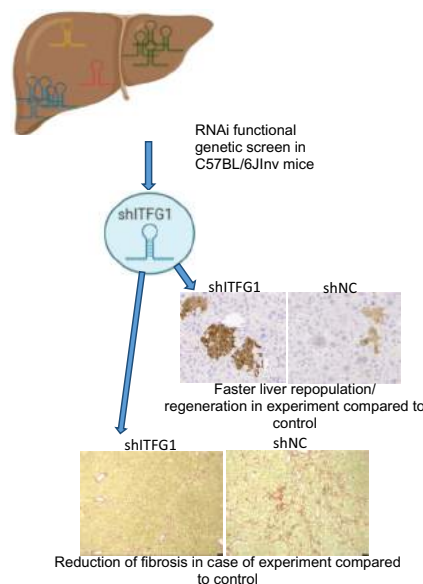

Viktoriia Iakovleva<sup>1,2</sup>, Anna Potapova<sup>1</sup>, Agnes Bee Leng Ong<sup>1</sup>, Yock Young Dan<sup>2</sup>, Torsten Wuestefeld<sup>1,3,4</sup>. <sup>1</sup>Genome Institute of Singapore, Singapore; <sup>2</sup>National University of Singapore, Medicine, Singapore; <sup>3</sup>National Cancer Centre, Singapore; <sup>4</sup>Nanyang Technological University, Singapore  
Email: iakovlevav@gis.a-star.edu.sg

**Background and aims:** Chronic liver diseases are one of the major leading causes of death. Moreover, the only current curative treatment for end-stage liver disease is liver transplantation. However, donor organs are limited. Therefore, it is crucial to find alternative strategies to treat such patients. In our research, we established RNAi based *in vivo* functional genetic screens to identify endogenous agents that reverse and hold off end-stage liver disease.

**Method:** We conducted an RNAi based *in vivo* functional genetic screen in 'wild-type' mice (C57BL/6JInv). We delivered a focused shRNA pool into mouse livers by hydrodynamic tail vein injections (HDTV) together with transposase sleeping beauty 13 (SB13). Then, we applied thioacetamide (TAA) treatment 3 times per week for 8 weeks intraperitoneally to simulate chronic damage of the livers. After that, the abundance of each shRNA was compared to the starting shRNA pool by Illumina based deep sequencing. We followed up enriched candidates. We identified Integrin Alpha FG-GAP Repeat Containing 1 (ITFG1) as a potential regulator of liver regeneration and disease.

We further validated ITFG1, performed *in vitro* and *in vivo* assays. For *in vitro* assays, we generated stable cell lines with ITFG1 knockdown. We tested knockdown efficiency by qPCR. We validated 2

independent shRNAs against ITFG1 to avoid the off-target effect. Stable cell lines with ITFG1 knockdown were used for wound healing assay. For *in vivo* assays, we investigated liver repopulation in FAH<sup>-/-</sup> mouse model, fibrosis score in chronic liver damage model by using TAA, and fibrosis score in NASH condition by using "Western-Diet" model.

**Results:** Efficient ITFG1 knockdown accelerated wound healing *in vitro*. Furthermore, faster clonal expansion was observed in the case of ITFG1 knockdown compare to control *in vivo*, using FAH knockout mice. In two chronic liver disease models (TAA and NASH), a significant reduction of fibrosis was observed in the experimental group with ITFG1 knockdown compared to the non-targeting control. **Conclusion:** ITFG1 knockdown accelerates wound healing and liver repopulation, attenuates chronic liver damage related liver fibrosis, protects against NASH related fibrosis.

## ORAL PRESENTATIONS

**Background and aims:** Although organoid technology holds great promise for regenerative medicine, it has not yet been applied to humans. We address this challenge in the context of cholangiocyte organoids and cholangiopathies, which are a leading indication for liver transplantation. We demonstrate that cholangiocytes are plastic and small changes in their transcriptional profile, induced by organoid culture, are reversed when the cells are re-exposed to their natural niche. We exploit this property to inject cholangiocyte organoids in the bile ducts of mice with toxin-induced cholangiopathy and in a novel model for cell transplantation using human organ donor livers perfused *ex situ* and show that organoid transplantation can rescue cholangiopathy in mouse and human.

**Method:** Primary cholangiocytes were cultured as organoids using published methods. Primary cells and organoids were characterized using droplet encapsulation single-cell RNA sequencing (scRNAseq). Cholangiopathy was induced in immunocompromised mice with 4,4'-methylene-dianiline (MDA). The *metra* (OrganOx) normothermic liver perfusion device was used for *ex situ* perfusion of human livers not used for transplantation and organoids were injected in bile duct branches under radiological guidance.

**Results:** We first demonstrate that different regions of the human biliary tree contain cells with distinct transcriptional profiles. We then show that cholangiocytes lose these differences in organoid culture and become interchangeable, but their *in vivo* identity can be restored using environmental stimuli in culture, suggesting that these cells are plastic. We subsequently transplant human organoids from different regions of the biliary tree in the intrahepatic ducts of mice with MDA-induced cholangiopathy and demonstrate that the cells engraft, they assume an intrahepatic identity and rescue the animals, with resolution of cholestasis in serum samples and resolution of cholangiopathy in histology and MRCP. We repeat this experiment using human livers undergoing *ex situ* normothermic perfusion and show that organoids engraft, rescue cholangiopathy and restore bile parameters (e.g. pH).

**Conclusion:** Our study validates that cholangiocytes are plastic and interchangeable in organoid culture. Therefore, cholangiocyte organoids derived from any region can repair the entirety of the biliary tree. Moreover, we provide the first proof-of-principle for the efficacy of cell-based therapy using organoids in human organs.

### Liver transplantation and hepatobiliary surgery: Clinical aspects

Email: margherita.saracco@gmail.com

**Background and aims:** The COVID-19 pandemic affected every aspect of healthcare and threatened the availability of liver donors. To limit this phenomenon, the Italian National Transplant Center allowed liver transplantation (LT) from SARS-CoV-2 positive donors to patients with severe liver disease who are SARS-CoV-2 positive or with a previous history of COVID-19. We aimed to ascertain the

prevalence of neutralizing antibodies against SARS-CoV-2 in all our cirrhotic patients on LT waiting list.

**Method:** From the 25<sup>th</sup> of November 2020 to the 22<sup>nd</sup> of January 2021, each patient on the LT waiting list was tested for SARS-CoV-2 neutralizing antibodies (with LIAISON® SARS-CoV-2 S1/S2 IgG test, a quantitative assay for the detection of IgG antibodies against S1/S2 antigens of SARS-CoV-2:  $\geq 15$  UA/ml positive) and detailed medical history was collected. IgG antibodies were retested 1 month after the first evaluation. COVID-19 asymptomatic patients with positive IgG test underwent immediate SARS-CoV-2 molecular testing using nasopharyngeal swab (NPS, with Simplexa® COVID-19 Direct, DiaSorin Molecular).

**Results:** At the beginning and at the end of the enrollment period 61 and 73 patients, respectively, were actively on the LT waiting list. During the study period, 17 first adult LTs were consecutively performed in our Center. 80 patients underwent SARS-CoV-2 IgG test, and 17 (21.3%) of them tested positive. 7 out of 17 (41.2%) had a previous documented history of COVID-19; the remaining 10 (58.8%) were asymptomatic and tested negative at NPS. 4 out of those 17 IgG-positive cirrhotics (23.5%) received a graft from a positive SARS-CoV-2 RNA donor. After a median post-LT follow-up of 6.5 weeks: no SARS-CoV-2-related complications occurred. Patient N.8 showed negative SARS-CoV-2 IgG at 1 month, and Patient N.10 showed sole intermittent NPS positivity (Table 1).

**Conclusion:** In our cohort, 21.3% of cirrhotic patients on the LT waiting list tested positive for SARS-CoV-2 neutralizing antibodies and 58.8% of them did not show a clinical history. This screening allowed a precious expansion of the donor pool by allocating 4 SARS-CoV-2 RNA positive donors to 4 IgG-positive recipients.

##### Radiology-histopathology discordance in Hepatocellular cancer and its impact on post-transplant outcome

Islam Mohamed<sup>1,2</sup>, Mohamed Ismail<sup>1,2</sup>, Efstathia Polychronopoulou<sup>3</sup>, Mahmoud Hashim<sup>1</sup>, Ahmed Elkheshen<sup>1</sup>, Manal Hassan<sup>1,4</sup>, Prasun Jalal<sup>1</sup>. <sup>1</sup>Baylor College of Medicine, Hepatology, Houston, Texas, United States; <sup>2</sup>Ain Shams university Faculty of Medicine, Internal Medicine, Division of Gastroenterology and Hepatology, Cairo, Egypt; <sup>3</sup>UTMB Health, Biostatistics, Galveston, United States; <sup>4</sup>The University of Texas MD Anderson Cancer Center, Epidemiology, Houston, Texas, United States

Email: islam.mohamed@bcm.edu

**Background and aims:** Multiphasic contrast enhanced cross-sectional imaging is standard in the diagnosis and management of HCC in Society guidelines, replacing the need for histopathology. Milan criteria based radiology is used for selection of HCC patients to liver transplantation (LT). However, radiology-histopathology discordance may lead to improper staging of HCC affecting post-LT outcome. This study aims to assess radiology-histopathology discordance at transplantation in patients with HCC and its impact in the post-LT outcome.

**Method:** Using OPTN/UNOS database, all adult patients with deceased donor liver-only transplants between April 1, 2012 and December 31, 2017 with HCC exception points based on radiology were analyzed retrospectively. Correctly-staged patients were defined as within Milan by both pre-LT radiology and explant. Under-staged patients were defined as within Milan by radiology and outside Milan by explant. Kaplan-Meier methods and Cox regression analysis were used to evaluate the impact of under-staging on 3-yrs HCC recurrence and post-LT patient survival.

**Results:** A total of 6842 patients were included in the cohort, of whom 67.7% (n = 4564) were correctly-staged and 32.3% (n = 2278) were under-staged. Post-LT HCC recurrence and death were significantly higher in under-staged patients (p < 0.0001). In adjusted analysis, under-staging is an independent predictor of HCC recurrence (HR 1.88; 95% CI 1.37–2.59) and death (HR 1.31; 95% CI 1.04–1.65).

Figure 1: 3-yrs recurrence free rate post-LT.

Figure 2: 3-yrs survival rates post-LT based on Milan criteria by explant.

**Conclusion:** Current practice of pre-LT staging of HCC based on radiology is inadequate and accounts significantly for post-LT HCC recurrence and survival. Improvement in radiological assessment is needed to optimize patient selection to decrease post-LT recurrence and improve survival.

Email: julien.vionnet@chuv.ch

**Background and aims:** Management of long-term immunosuppression (IS) following liver transplantation (LT) remains empirical. Surveillance liver biopsies in combination with transcriptional profiling has the potential to overcome this challenge by identifying recipients with ongoing alloimmune-mediated liver damage despite normal liver function tests (LFT), but has low applicability. Our aim was to investigate the utility of non-invasive tools in stratifying stable long-term surviving LT recipients according to their immunological risk and need for IS.

**Method:** We conducted a cross-sectional study of 191 long-term adult LT recipients in whom a liver biopsy was performed between October 2015 and May 2019 as part of the baseline assessment of a multinational immunosuppression withdrawal (ISW) trial (NCT02498977). Participants had normal LFT and had been transplanted for non-autoimmune non-replicative viral liver disease >3 years before inclusion. We conducted histological, immunogenetic and serological studies and assessed the intrahepatic transcript levels of a 11-gene classifier highly specific for T cell-mediated rejection (TCMR). We used logistic regression and classification and regression tree analysis to develop models to predict silent alloimmune damage.

**Results:** 68/191 recipients (36%) harbored silent fibro-inflammatory liver lesions, which were scored as moderate-to-severe in 42 (22%). The severity of this histological damage was positively associated with TCMR-related transcripts, class II donor-specific antibodies (DSA), ALT and liver stiffness measurements (LSM), and negatively correlated with serum creatinine and tacrolimus trough levels. To assess for the presence of clinically-significant underlying alloimmunity, we stratified the study biopsies according to their TCMR transcript levels using a cut-off derived from liver biopsies with clinically-apparent TCMR. A risk prediction model including ALT and LSM had high discrimination in classifying patients with or without alloimmune damage. A simplified model was developed with classification and regression tree analysis (Figure). Another model with ALT and class II DSA respectively had also good discrimination. This latter model was externally validated in an independent cohort of 156 liver biopsies from pediatric LT recipients with similar

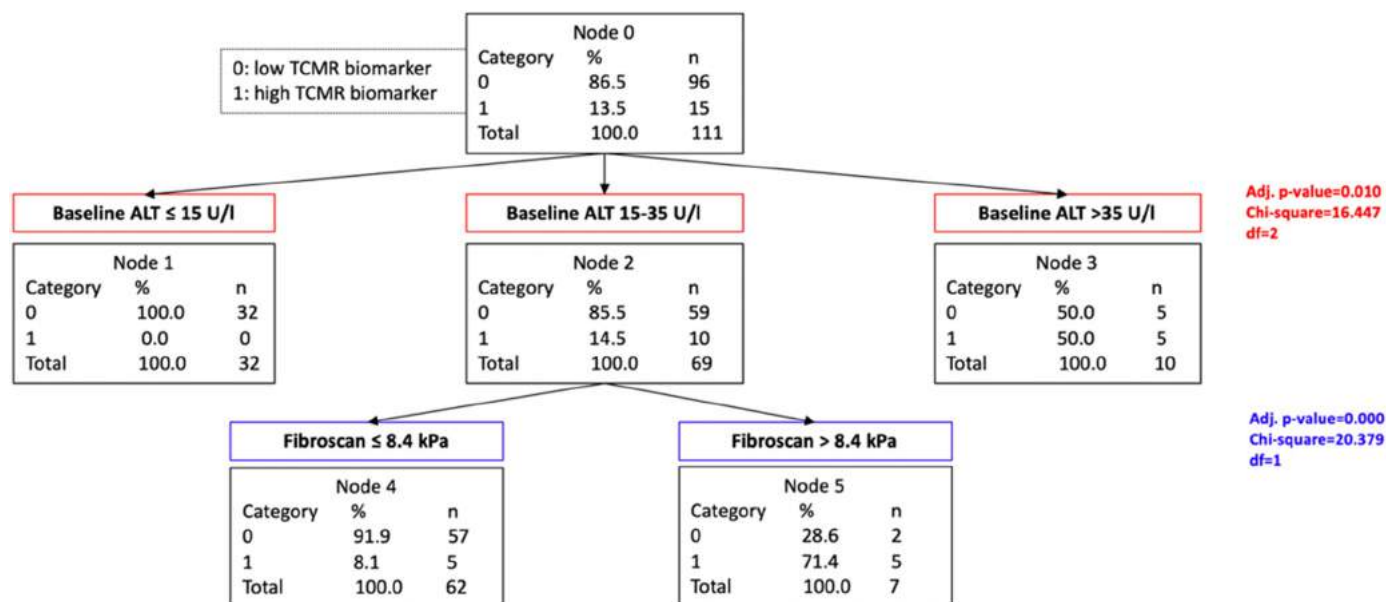

Figure: (abstract: OS-213)

inclusion/exclusion criteria (but without LSM), showing good discrimination (c-statistic 0.72) and excellent calibration.

**Conclusion:** ALT, class II DSA and LSM are valuable tools to non-invasively identify stable LT recipients without significant underlying alloimmunity, who could benefit from IS minimization.

## OS-2792

### HLA-A mismatching is associated with an increased risk of hepatic artery thrombosis, sepsis, graft loss and reduced survival following liver transplant

Christopher Bricogne<sup>1</sup>, Neil Halliday<sup>1,2</sup>, Raymond Fernando<sup>3</sup>, Emmanuel Tsochatzis<sup>1,2</sup>, Mark Harber<sup>4</sup>, Rachel Westbrook<sup>1</sup>. <sup>1</sup>Royal Free London NHS Foundation Trust, Sheila Sherlock Liver Unit, London, United Kingdom; <sup>2</sup>University College London, Institute of Liver and Digestive Health, London, United Kingdom; <sup>3</sup>Royal Free London NHS Foundation Trust, The Anthony Nolan Research Institute, London, United Kingdom; <sup>4</sup>Royal Free London NHS Foundation Trust, Kidney Unit, London, United Kingdom

Email: christopher.bricogne@nhs.net

**Background and aims:** Human leukocyte antigen (HLA) mismatching has an adverse impact on heart, lung and kidney transplant outcomes, however the impact on liver transplant (LT) outcomes is uncertain. As no consistent benefit for HLA matching in LT has been observed it is not routinely performed. Due to this uncertainty, we analysed the impact of HLA mismatches upon LT outcomes.

**Method:** Historically, donors and recipients at our centre have undergone HLA-A, -B, -C, -DQ and -DR typing at the time of LT, but the results did not influence organ allocation or immunosuppression used. We identified 1165 transplants performed between October 1999 and December 2016 from the hospital transplant registry. 123 were excluded due to missing HLA data. We analysed the influence of mismatching at each HLA locus on graft and patient survival over time and on cause of graft loss.

**Results:** 1042 LT were included and followed up for a median of 9.16 years. Log rank analysis demonstrated that 1 or 2 HLA-A mismatches were associated with reduced graft (p = 0.004 and 0.012) and patient (p = 0.009 and 0.004) survival, although no consistent effect of mismatches at HLA-B, -C, -DR and -DQ were observed (see figure). One and two HLA-A mismatches were associated with hazard ratios for graft failure of 1.93 (p = 0.004) and 1.77 (p = 0.014), respectively, in

univariate and 1.90 (0.005) and 1.74 (p = 0.018) in multivariate Cox regression analyses. Specific HLA-A mismatches were associated with worse graft survival, including HLA-A2 (p = 0.014), HLA-A1 (p = 0.003) and HLA-A24 (p = 0.014), but no significant differences were seen with HLA-A3 and HLA-A11 mismatch.

Excess graft loss with HLA-A mismatched LT occurred in the 1<sup>st</sup> 12 months following transplantation; graft loss within 12 months was seen in 6/102 (5.9%) of HLA-A matched LT and 138/940 (14.7%) of those with HLA-A mismatches (OR 2.75, p = 0.015). Analysis of the causes of graft loss revealed that all graft losses due to hepatic arterial thrombosis (n = 31) and sepsis (n = 35) occurred in patients with HLA-A mismatches.

**Conclusion:** In this large cohort, with long follow up, donor-recipient HLA-A mismatching was associated with a significant reduction in graft and patient survival, and this may be specific to certain HLA-A alleles. We have demonstrated a significant association with the risk of hepatic arterial thrombosis and sepsis, suggesting HLA-A mismatching may influence the risk of these important complications.

**Background and aims:** Immunotherapy with atezolizumab plus bevacizumab represents the new standard of care in systemic front-line treatment of hepatocellular carcinoma (HCC). Biomarkers to predict treatment success are an unmet need.

**Method:** Patients with HCC treated with PD- (L)1-based immunotherapy between July 2015 and May 2020 in 6 European centers (training set; n = 104) and between August 2015 and February 2020 in 7 European centers (validation set; n=73) were included. We investigated the prognostic value of baseline variables by using a Cox regression model in the training set and developed the CRAFTITY (CRP and AFP in ImmunoTherapy) score. The score was validated in the independent, external cohort.

**Results:** Baseline serum alpha-fetoprotein (AFP)  $\geq$  200 ng/ml (HR, 2.0; p=0.009) and C-reactive protein (CRP)  $\geq$  1 mg/dl (HR, 2.0; p=0.016) were identified as independent negative prognostic factors in multivariable analysis and were used to develop the CRAFTITY score. Patients who fulfilled none or only one criterion (0–1 point; CRAFTITY-low) had a significantly longer median overall survival (21.8 (95%CI, 13.4–30.2) months) than patients meeting both criteria (2 points; CRAFTITY-high; 5.3 (95%CI, 1.9–8.6) months; p < 0.001). Additionally, they had a significantly better disease control rate (70% vs. 32%; p = 0.001). These results were confirmed in the independent validation set (OS: 14.2 (95%CI, 9.7–18.7) months for CRAFTITY low (n = 52) vs. 8.6 (95%CI, 6.1–11.2) months for CRAFTITY high (n = 21, p = 0.011);

## ORAL PRESENTATIONS

DCR: 75% in CRAFITY low patients compared to 41% in CRAFITY high patients ( $p=0.013$ ) and remained significant irrespective of Child-Pugh stage and treatment line.

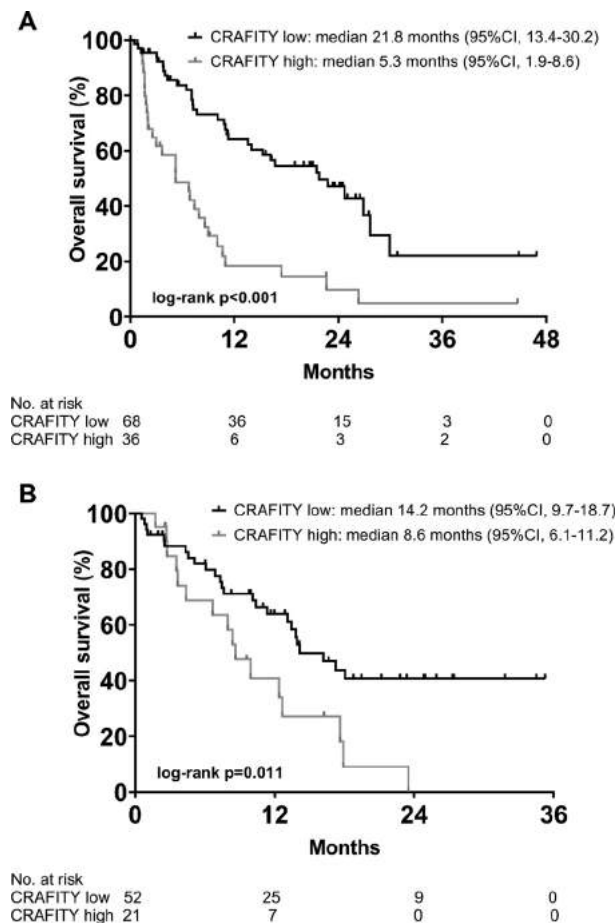

Figure: Kaplan-Meier curves comparing overall survival (OS) between patients with (A) CRAFITY low (0–1 point) versus high (2 points) in the training cohort and (B) according to CRAFITY low (0–1 point) versus high (2 points) in the validation cohort.

**Conclusion:** The CRAFITY score identifies patients with favorable disease control and survival. The score may help to guide treatment decisions and patient counseling.

### OS-1101

#### Glucose variability and risk of hepatocellular carcinoma in diabetic patients: A nationwide population-based study

Jeong-Ju Yoo<sup>1</sup>, Sang Gyune Kim<sup>1</sup>, Young Seok Kim<sup>1</sup>. <sup>1</sup>SoonChunHyang University School of Medicine, Internal Medicine, Bucheon, Korea, Rep. of South

Email: puby17@naver.com

**Background and aims:** Although diabetes is a well-known risk factor for hepatocellular carcinoma (HCC), exactly which metabolic parameters of diabetes are associated with HCC remains unexplored. In this study, we investigated the relationship between glucose variability (GV) and HCC in diabetic patients through a nationwide population-based study.

**Method:** A population-based cohort study including 674,178 diabetic subjects participating in more than 3 health examinations within 5 years from the index year (2009–2010) were followed until the end of 2017. The coefficient of variation, standard deviation, variability independent of the mean, and average real variability were calculated as GV indices.

**Results:** During a median follow-up of 6.7 years, there were 5,494 cases of HCC. When classified groups according to glucose level, the highest risk for HCC was observed when the basal blood glucose level was 180 mg/dL or greater [adjusted hazard ratio (aHR) 1.19, 95% confidence interval (CI), 1.08–1.31]. We observed increasing trends for the relationship between GV and HCC in multivariable Cox proportional analyses. The risk of HCC increased by 27% (aHR 1.27, 95% CI, 1.17–1.38) for the highest quartile of GV relative to the lowest quartile. These findings were consistent regardless of the presence of chronic viral hepatitis or cirrhosis, alcohol consumption, or body mass index.

**Conclusion:** GV is an independent predictor of HCC, even after adjusting for confounding factors. There was a linear relationship between increase in GV and prevalence of HCC. Visit-to-visit GV might be helpful for identifying diabetic patients at high risk of HCC.

### OS-1704

#### Is alcohol only-related hepatocellular carcinoma so frequent? A cluster analysis of 12,841 hepatocellular carcinomas

Charlotte Costentin<sup>1</sup>, Mélanie Minoves<sup>2</sup>, Sylvain Kotski<sup>2</sup>, Olivier Farges<sup>3</sup>, Nathalie Goutte<sup>4</sup>, Thomas Decaens<sup>1</sup>, Sébastien Bailly<sup>2</sup>. <sup>1</sup>Grenoble Alpes University Hospital, Hepatology, Gastro-Enterology and Digestive Oncology, Grenoble, France; <sup>2</sup>HP2 Laboratory, INSERM U1042, Grenoble Alpes University, Grenoble, France; <sup>3</sup>Beaujon Hospital, Hepato-Biliary Surgery Department, Clichy, France; <sup>4</sup>Paul-Brousse Hospital, Assistance Publique-Hôpitaux de Paris Villejuif, Paris XI University, INSERM UMRS-1193, DHU Hépatinov and centre hépatobiliaire, Villejuif, France

Email: charlotte.costentin.pro@gmail.com

**Background and aims:** Alcohol-associated hepatocellular carcinoma (AL-HCC) poor prognosis has been mostly attributed to diagnosis at a later stage. However, host factors and specific health trajectories have been associated with severe outcomes in alcohol-associated liver disease. We hypothesize AL-HCC is not an homogeneous condition but encompasses subgroups yielding different outcomes. Our aim was to provide a first attempt at a clinical phenotyping of AL-HCC including host factors, comorbidities and the dynamic course of the underlying liver.

**Method:** We analyzed data for the calendar years 2007–2013 from the French nationwide administrative hospital database. We selected patients with HCC AL-HCC only, excluding patients with mixed etiologies. Clustering of AL-HCC phenotypes was performed by latent class analysis (LCA).

**Results:** The study included 12,841 patients with AL-HCC, mainly male (89%), median age 67 years [IQR: 61; 74] of which 68.3% had at least one metabolic comorbidity. Five phenotypes were identified. Only one seemed to be solely related to alcohol (phenotype 1) while others displayed high rates of metabolic comorbidities (diabetes in 40.3% to 53.3% of patients) with history of and/or current complicated underlying liver disease. Phenotype 1 represented only 13% of all AL-HCC and was the youngest group (median age 57 years [IQR: 52; 61]).

	Cluster 1 N=1 632 (12.8%)	Cluster 2 N=6 226 (48.5%)	Cluster 3 N=1 601 (12.5%)	Cluster 4 N=1 389 (10.8%)	Cluster 5 N=1 993 (15.5%)
Age at diagnosis	57	71	62	65	67
Diabetes	1.9	44.8	40.3	53.3	48.8
Arterial hypertension	1.8	65.4	39.8	53.5	61.9
Hist. Anemia	1.2	6.6	28.5	22.2	4
Hist. Ascite	3.4	1.3	85.5	5	11.7
Hist. Liver failure	3.1	1.3	53.8	17.1	7.1
Hist. Portal HT	8.5	2.5	84.3	100	6.5
Co. Ascite	18.1	8.5	78.7	14.4	82.6
Co. Liver failure	10.6	4.2	54.8	18.5	58
Co. Portal HT	18.4	10.6	62.9	77.8	57.8

Figure: (abstract: OS-1704)

In multivariable logistic regression, compared to phenotype 1, probability of death after HCC diagnosis was significantly different for all of the other four phenotypes.

**Conclusion:** LCA identified five phenotypes of AL-HCC associated with specific survival outcomes. Only one minority phenotype seemed to be solely related to alcohol. Our results provide new perspectives into determinants of HCC prognosis in the setting of alcohol-associated HCC.

Email: g\_shiha@hotmail.com

**Background and aims:** We recently reported the ability of our novel simple predictive model (GES) score for the development of hepatocellular carcinoma (HCC) after direct-acting antivirals (DAAs) [1]. However, our results were restricted to Egyptian patients with HCV-genotype 4. To evaluate the predictive accuracy of our score in mixed populations with various HCV genotypes we aimed at validating our early findings in an independent large sample of multi-ethnic population through our international collaborative activity.

**Method:** GES score can identify three patients' categories; low risk of HCC ( $\leq 6/12.5$ ), intermediate risk ( $>6-7.5/12.5$ ), and high risk ( $>7.5/12.5$ ) using readily available predictors and thus can be easily calculated in clinical practice, namely, age  $>54$  yrs., male gender, albumin  $<3.8$ , AFP levels  $>20$  ng/ml and fibrosis stage at baseline. We included 11202 patients with chronic HCV from 54 centers from the following countries (France; Japan; India; USA; and Spain). Additional 836 patients were included from Gilead-sponsored RCT cohort from USA, Europe, Canada, and Australia. Total of 12038 chronic HCV patients were analyzed in this study. Descriptive statistics and survival analysis were performed using Kaplan-Meier and Log-rank test. The performance of the GES score was evaluated using Harrell's C-index (HCI).

**Results:** GES score displayed significant prediction for HCC development in all participants ( $p < .0001$ ), with Harrel C Index range from 0.55 to 0.76 among all cohorts after adjusting for HCV genotyping and ethnicity. GES score was able to stratify all patients successfully into three risk groups, low, intermediate, and high groups (Table 1).

Table 1: GES Risk Scarification by participating site (Validation Assessment)

Countries	N	Low risk	Intermediate risk	High risk	P value	Harrell's C statistic
France	7752	1.23%/5 years	7.39%/5 years	17.69%/5 years	<0.001	0.7688
Japan	2231	2.31%/3 years	4.08%/3 years	6.68%/3 years	<0.001	0.622
India	662	1.50%/5 years	3.06%/5 years	6.35%/5 years	<0.001	0.643
USA	276	1.07%/5 years	0.91%/5 years	5.17%/5 years	0.046	0.666
Spain	181	0.51%/4 years	1.14%/4 years	1.56%/4 years	0.509	0.615
RCT (Gilead)	836	7.46%/3 years	5.88%/3 years	19.61%/3 years	0.0055	0.55
Total	12038					

## ORAL PRESENTATIONS

**Conclusion:** GES score can be used to stratify HCV patients into three HCC risk categories; low, intermediate, and high irrespective of ethnicities or HCV genotypes. This international multicenter validation of a simple, easy to use score based on readily available parameters may pave the way to its use in individualized HCC-risk based surveillance.

Email: lea.duwe@bric.ku.dk

**Background and aims:** Cholangiocarcinoma (CCA) is a clinically and molecularly heterogeneous disease. The ability of microRNAs (miRs) to target multiple signaling pathways links them to tumor heterogeneity. Here, we analyzed the miR landscape in normal livers and tumors in the biliary tree to define their role in orchestrating gene regulation and involvement in CCA development.

**Method:** We performed miR sequencing (miRseq) of 213 human samples (99 iCCAs, 28 eCCAs, 63 matched adjacent livers and 23 normal livers), including the matched transcriptomes from 196 samples, to study miRs and regulation of target genes in CCA. High throughput screening (HTS) using a library of 2,700 miR mimics was analyzed for their proliferative role in 3 primary normal human cholangiocyte (NHC) cultures. After miRseq-HTS data integration, we performed target prediction and pathway overrepresentation analyses. The main target was confirmed by luciferase reporter assay and characterized by qPCR, immunoblotting and *in situ* hybridization (ISH) in tissue microarrays. To identify the biological role, we generated miR-CRISPR knockout (KO) lines and performed proliferation and wound-healing assays. The oncogenic phenotype *in vivo* was assessed by xenograft experiments in mice.

**Results:** MiRseq revealed 398 differentially expressed miRs (388 upregulated, 10 downregulated) in CCA compared to controls. Unsupervised hierarchical clustering identified three subgroups, differing significantly based on tumor location, overall survival, tumor microenvironment (i.e., macrophage, hepatic stellate and endothelial cell content) and immune infiltrates (dendritic cells, CD4+ and CD8+ T cells). In HTS, overexpression of 224 miRs increased the NHC proliferation rate, of which 35 miRs were upregulated in CCA. Pathway overrepresentation analysis showed FoxO signaling as the major affected pathway. Further, miR-27a-3p and FoxO1 interaction revealed a strong negative correlation in the CCA cohort, which was independently validated in TCGA-CHOL. This interaction was confirmed *in vitro* by luciferase reporter assay. ISH showed that miR-27a-

3p is highly expressed in tumor cells and vascular smooth muscle. MiR-27a-3p KO CCA cells showed decreased proliferation and migration, highlighting miR-27a-3p as an oncogenic vulnerability in CCA.

**Conclusion:** MiRs are highly deregulated in CCA. MiR-27a-3p seems to promote CCA, targeting FoxO1 and deregulating FoxO signaling, thus inducing tumor phenotypes.

### OS-615

#### Identification of IGF2 as genomic driver and actionable therapeutic target in hepatoblastoma

Email: jmllovet@clinic.cat

**Background and aims:** Hepatoblastoma (HB), the most frequent pediatric liver cancer, has limited therapeutic options for patients whose tumors are refractory to standard perioperative platin-based regimens, commonly cisplatin. Here, we aimed to identify actionable targets in human HB and assess their response to molecular therapies in experimental models.

**Method:** Tumor and paired non-tumor (NT) tissues from 32 HB patients were analyzed at the transcriptomic, genomic and epigenomic level using RNAseq, SNP and methylation arrays. The main targetable driver in HB was identified by gene co-expression network analysis (GCN) and its overexpression was confirmed by qRT-PCR. The antitumor potential of inhibiting actionable drivers was assessed *in vitro* (cell lines and PDX-derived organoid model) and *in vivo*.

**Results:** RNAseq and GCN identified IGF signaling as the top targetable deregulated pathway in HB, and IGF2 was overexpressed in 71% of samples (fold change >4 vs NT), whereas CTNNB1 was the most prevalent non-actionable mutation (~70%). IGF2-high tumors were enriched in progenitor and proliferative gene signatures and CTNNB1 mutations, while IGF2-low tumors were enriched in inflammatory signaling and TGF-beta overexpression. IGF2-high tumors correlated with shorter recurrence-free survival after resection (median 34 months vs not reached for IGF2-low; p = 0.02). Overall, we identified a mechanism of IGF2 overexpression in 86% of IGF2-high tumors: a) overexpression of the fetal IGF2 isoform due to promoter hypomethylation (50%), b) loss of heterozygosity (LOH) in the 11p15 chromosomal region containing IGF2 (57%) and c) overexpression of miR483 (55%), an enhancer of IGF2 transcription. Xentuzumab, a monoclonal antibody against IGF2, significantly reduced proliferation and clonogenic capacity in IGF2-high HB cell lines, whereas in combination with cisplatin in an IGF2-high organoid model was able to increase cisplatin efficacy by 25-fold

and promote apoptosis. *In vivo*, xentuzumab + cisplatin reduced viable tumor volume and extended time to sacrifice (1500 mm<sup>3</sup>) compared to cisplatin alone (p = 0.04).

**Conclusion:** IGF2 overexpression associated with promoter hypomethylation, LOH and miR483 overexpression is the main actionable alteration in human HB. In experimental models, IGF2 inhibition with xentuzumab + cisplatin led to a remarkable antitumoral effect, thus providing the rationale for exploring this combination in early trials in patients with IGF2-high HB.

**Background and aims:** Oncogenic mechanisms shape inflamed/non-inflamed microenvironments associated with immune response or immune evasion/resistance, respectively. We aimed to further refine the immune profiles of hepatocellular carcinoma (HCC) by assessing novel molecular features.

**Method:** We assessed the presence of immune infiltration, performed multiplex immuno-phenotyping for checkpoint molecules, TCR sequencing, RNA and whole-exome sequencing in a new cohort of 240 HCCs balanced according to etiology.

**Results:** We further characterized the previously described Immune class of HCC (22% of the cohort) (Sia et al. Gastroenterology 2017), which presented higher immune infiltration (52 vs 32%, p=0.05), higher expression of checkpoint molecules (CTLA-4: 58 vs. 29%, p = 0.03; PD-L1: 31 vs 4%, p=0.047) and a more diverse T cell repertoire when compared with the non-inflamed profiles. We identified an Immune-like class (15% of the cohort), that similarly presented high immune infiltration, interferon signaling, cytolytic activity and effector cytokine expression (Figure), but with more CTNNB1 mutations (64 vs 20%, p=0.003) and Wnt-beta catenin activation (54 vs 3%, p<0.001). In order to group all the immune-related subtypes (including active, exhausted and immune-like) in the newly defined inflamed class, we generated a 20-gene signature able to capture >90% of these tumors. In parallel, we characterized the non-inflamed Intermediate and Excluded classes. The Intermediate class was enriched in TP53 mutations (49 vs 29%, p = 0.035), higher broad chromosomal aberrations and deletions in subcytobands harboring immune-related genes (i.e 4q21.1: CXCL9, CXCL10, CXCL11). The Excluded class defined by Wnt-beta catenin activation was enriched in CTNNB1 mutations (93 vs rest 27%, p < 0.001). These Excluded-CTNNB1 mutations induced very high activation of Wnt signaling and were significantly distinct from the immune CTNNB1 mutations that induced weak activation of this cascade. In addition,

Figure: (abstract: OS-699)

## ORAL PRESENTATIONS

tumors with inflamed-*CTNNB1* mutations were associated to over-expression/demethylation of type I antigen presentation genes.

**Conclusion:** We have defined an inflamed HCC class involving ~35% of tumors and characterized the non-inflamed tumors. In addition, two distinct *CTNNB1* mutation patterns associated with differential pathway activation might explain the role of this oncogene in immune evasion. These features may help to predict response/resistance to immunotherapy in HCC.

### OS-906

#### Molecular plasticity underlies cisplatin resistance and tumor recurrence in hepatoblastoma

Theo Hirsch<sup>1</sup>, Jill Pilet<sup>1</sup>, Guillaume Morcrette<sup>1,2</sup>, Amélie Roehrig<sup>1</sup>, Benedict Monteiro<sup>1</sup>, Laura Molina<sup>1</sup>, Quentin Bayard<sup>1</sup>, Eric Trépo<sup>1</sup>, Lea Meunier<sup>1</sup>, Stefano Caruso<sup>1</sup>, Victor Renault<sup>3</sup>, Jean-François Deleuze<sup>3</sup>, Brice Fresneau<sup>4</sup>, Christophe Chardot<sup>5</sup>, Emmanuel Gonzales<sup>6</sup>, Emmanuel Jacquemin<sup>6</sup>, Florent Guerin<sup>6</sup>, Monique Fabre<sup>5,7</sup>, Isabelle Aerts<sup>8</sup>, Sophie Taque<sup>9</sup>, Véronique Laithier<sup>10</sup>, Sophie Branchereau<sup>6</sup>, Catherine Guettier<sup>6</sup>, Laurence Brugières<sup>4</sup>, Sandra Rebouissou<sup>1</sup>, Eric Letouze<sup>1</sup>, Jessica Zucman-Rossi<sup>1</sup>. <sup>1</sup>Centre de Recherche des Cordeliers, INSERM, Paris, France; <sup>2</sup>Hôpital Robert Debré, Paris, France; <sup>3</sup>Foundation Jean Dausset, Paris, France; <sup>4</sup>Gustave Roussy, Villejuif, France; <sup>5</sup>Hôpital Necker, Paris, France; <sup>6</sup>Bicêtre Hospital AP-HP, Le Kremlin-Bicêtre, France; <sup>7</sup>University Hospital Necker Enfants Malades, Department of Pathology, Paris, France; <sup>8</sup>Institut Curie Hospital, Paris, France; <sup>9</sup>CHU Fontenay, Rennes, France; <sup>10</sup>Centre hospitalier régional universitaire de Besançon, Besançon, France  
Email: theo.hirsch@polytechnique.org

**Background and aims:** Hepatoblastomas, the most frequent pediatric liver cancers, are characterized by high histological heterogeneity. Cisplatin-based neo-adjuvant chemotherapy and surgery lead to

>80% long-term survival, however resistance to chemotherapy can occur during the initial treatment or after tumor recurrence, and the molecular determinants of cisplatin resistance are yet to be discovered.

**Method:** We performed an integrated genomic analysis of 104 hepatoblastoma samples from 65 patients, including 24 patients with multiple samples (pre/post-chemotherapy primary tumors, relapses and metastases), through whole-genome or whole-exome sequencing, RNAseq and methylation analysis. We screened 8 hepatoblastoma cell lines to identify new therapeutic targets and tested one drug in mouse xenograft experiments.

**Results:** Most hepatoblastomas share driver alterations of *CTNNB1* and the 11p15.5 imprinted locus, but we also identified rare recurrent driver mechanisms, including new targetable genes. Transcriptomic and methylation analysis of spatial and longitudinal heterogeneity showed an important plasticity between 'Hepatocytic', 'Liver Progenitor' and 'Mesenchymal' molecular subgroups. Mutational signature analysis revealed that 'Liver Progenitor' cells specifically accumulate massive loads of cisplatin-induced mutations during chemotherapy, and can later give rise to heavily mutated relapses and metastases (Figure). Among genes overexpressed in 'Liver Progenitor' hepatoblastomas, we selected 3 key targetable genes (*PLK1*, *CHEK1* and *BIRC5*) and showed that hepatoblastoma cell lines are sensitive to their inhibitors even though most are resistant to cisplatin. Finally, we performed mouse xenograft experiments as a proof of concept and showed that the *PLK1* inhibitor BI-2536 can reduce tumor growth *in vivo* compared to cisplatin treatment.

**Conclusion:** Hepatoblastomas are deadly when they resist to chemotherapy, with limited alternative treatment options. Here, we identified the cellular phenotype at the origin of cisplatin resistance and validated new treatments targeting these molecular features in cell lines and xenografts.

Figure: (abstract: OS-906): Phylogenetic trees reconstructed for 4 patients with primary and recurrent hepatoblastoma analyzed by whole genome sequencing. Driver alterations are indicated. Branch lengths are proportional to the number of clonal mutations, with a color code indicating the contribution of each mutational signature. The cisplatin-related SBS35 signature is already present subclonally in primary tumors with 'Liver Progenitor' phenotype, and SBS35 clonal mutations accumulate in relapse/metastasis.

Email: mlmartinez@cicbiogune.es

**Conclusion:** Reduced MCJ levels, also visible in HCC patients, increase oxidative respiration and drive a metabolic reprogramming that enables immune evasion, through PD-1/PDL-1 axis. As elevated NAD<sup>+</sup> and PDL-1 are known to increase sensitivity to anti-PDL-1 treatment, tumor MCJ expression may serve as a predictive biomarker for HCC immunotherapy efficacy.

**Background and aims:** Recent evidence supporting the need of a mitochondria-based metabolism for tumor growth prompted us to study the role of MCJ, an endogenous negative regulator of mitochondrial complex I, in the context of hepatocellular carcinoma (HCC). The tumor microenvironment imposes various metabolic regulations to hamper the antitumor immunity of infiltrating immune cells, therefore, modulating the metabolic rewiring may help recover the antitumor immune potential. This work aims to study the metabolic reprogramming of cancer cells at different stages, to prove increased malignancy in mitochondria-based tumors, and to analyze the differential immune response driven by metabolic changes.

**Method:** Wt and *Mcj*<sup>-/-</sup> mice were injected intraperitoneally with 25 mg/kg body weight of diethylnitrosamine (DENA) at 14 days of age and they were monthly monitored, tumor growth was followed by ultrasound analysis and blood samples were extracted. DENA-treated mice, and the corresponding controls, were sacrificed at 5, 8, and 12 months post injection (a minimum of 5 mice per group). Mortality, tumor number and size, liver metabolism, mitochondrial activity and tumor infiltrating immune cell analysis were then assessed.

**Results:** The initial *in silico* approach using UALCAN revealed reduced *Mcj* expression in stage IV HCC patients. *In vivo*, lack of MCJ increased both the presence of liver tumors and mortality rate after DENA treatment. Fluxomics analysis using [<sup>U-13</sup>C]glucose or [<sup>U-13</sup>C]glutamine will provide information about the metabolic reprogramming during tumorigenesis. A highly oxidative phenotype was confirmed in *Mcj*<sup>-/-</sup> tumors, as mitochondrial respiration was significantly higher, along with elevated intracellular ATP, NAD<sup>+</sup> and NADPH levels. We then studied tumor infiltrating immune cells, observing a reduction in effector CD4<sup>+</sup> T lymphocytes (CD44<sup>+</sup> CD62L<sup>-</sup>) and neutrophils (GRI1<sup>+</sup>CD11b<sup>+</sup>) in *Mcj*<sup>-/-</sup> mice 5 months after DENA injection; similar results were also visible at 12 months, including significantly reduced PD-1. Analysis of PDL-1 revealed significantly increased hepatic protein levels in *Mcj*<sup>-/-</sup> mice, hinting a possible immune evasion. Serum analysis of cytokines highlighted reduced levels of inflammatory IFN-γ and TNF in *Mcj*<sup>-/-</sup> mice. Besides, highly ROS producing neutrophils were found in DENA-treated Wt mice. Analysis of hepatic cytokines showed increased levels of MCP-1 in Wt mice, a chemoattractant and NETosis facilitator.

Email: anamatillapena@gmail.com

**Background and aims:** Patients with Child-Pugh B (CPB) advanced hepatocellular carcinoma (aHCC) have a poor prognosis and are often excluded from clinical trials. In sorafenib-treated patients with CPB, overall survival (OS) is as low as ~4 months. Nivolumab received accelerated approval in the United States for sorafenib-treated patients with aHCC based on the phase 1/2 open-label CheckMate 040 trial (NCT01658878). In patients with CPB (cohort 5), at a median follow-up of 16.3 months, investigator-assessed objective response rate (ORR) was 12%; median OS was 7.6 months (95% CI 4.4–10.5). We report long-term efficacy and safety and new biomarker analyses for

## ORAL PRESENTATIONS

this CPB cohort, the first prospective immunotherapy trial in this population.

**Method:** Patients with CPB 7 or 8 aHCC (sorafenib naive n=25; sorafenib treated n=24) received nivolumab 240 mg intravenously for 30 minutes every 2 weeks until disease progression or unacceptable toxicity. OS was a secondary end point. Baseline tumor samples were assessed for inflammation biomarkers by immunohistochemistry (including CD3, CD4, CD8, PD-1, FOXP3, CD68, CD163). Neutrophil:lymphocyte ratio (NLR) and albumin-bilirubin (ALBI) score were derived from laboratory assessments. Associations between biomarkers and best overall response (BOR), OS, and viral etiology were evaluated. Multivariate analysis was done for each biomarker separately and estimated HR determined for 1 standard deviation difference of each biomarker.

**Results:** At a minimum follow-up of 33.8 months, median OS was 7.9 months (95% CI 4.4–10.5) for all treated patients; 8.9 months (4.1–13.4) and 7.4 months (1.6–10.5), respectively, in CPB subgroups B7 (n=37) and B8 (n=11); and 8.4 months (4.4–13.3) and 1.6 months (1.4–10.5), respectively, for ALBI score 2 (n=44) and 3 (n=5). 12-month OS rate was 34.7%, and 24-month OS rate was 10.2%. Lower tumor expression of PD-1 and CD163 was associated with longer OS (Fig); however, baseline expression of inflammation biomarkers was not associated with BOR ( $p > 0.05$ ). Baseline NLR of 3 or less vs more than 3 was associated with longer OS ( $p = 0.03$ ). NLR was not associated with response ( $p > 0.05$ ). Safety outcomes were consistent with the primary analysis.

### Multivariate analysis: association between biomarker and OS<sup>a</sup>

<sup>a</sup>Cox proportional-hazards regression models with each biomarker as a continuous variable and OS in multivariate models adjusting for gender, age, viral etiology, prior sorafenib, and Eastern Cooperative Oncology Group performance status as covariates. <sup>b</sup>Biomarkers associated with OS. CD, cluster of differentiation; FOXP3, forkhead box protein P3; OS, overall survival; PD-1, programmed death-1.

**Conclusion:** In patients with CPB aHCC, nivolumab efficacy and safety were maintained at long-term follow-up. PD-1, CD163, and NLR were not associated with BOR. Lower baseline tumor PD-1 and CD163 and lower NLR were associated with longer OS.

### OS-777

#### Real-world outcomes of patients with hepatocellular carcinoma treated with transarterial radioembolization: results from CIRT, a large European prospective observational study

Frank Kolligs<sup>1</sup>, Dirk Arnold<sup>2</sup>, Thomas Helmberger<sup>3</sup>, Geert Maleux<sup>4</sup>, Bora Peynircioglu<sup>5</sup>, Niklaus Schaefer<sup>6</sup>, Rita Golfieri<sup>7</sup>, Thomas Pfammatter<sup>8</sup>, Maxime Ronot<sup>9</sup>, Niels de Jong<sup>10</sup>, Bruno Sangro<sup>11</sup>. <sup>1</sup>Helios Klinikum Berlin-Buch, Internal Medicine and Gastroenterology, Berlin, Germany; <sup>2</sup>Asklepios Tumorzentrum Hamburg, AK Altona, Oncology and Hematology, Hamburg, Germany; <sup>3</sup>Klinikum Bogenhausen, Department of Radiology, Neuroradiology and Minimal-Invasive Therapy, Munich, Germany; <sup>4</sup>Universitair Ziekenhuis Leuven, Radiology, Leuven, Belgium; <sup>5</sup>Hacettepe University, Department of Radiology, School of Medicine, Ankara, Turkey; <sup>6</sup>Inselspital Hospital Lausanne, Service de médecine nucléaire et imagerie moléculaire, Lausanne, Switzerland; <sup>7</sup>Sant'Orsola Hospital, University of Bologna, Radiology Unit, Department of Experimental, Diagnostic and Speciality Medicine, Bologna, Italy; <sup>8</sup>Universitätsspital Zürich, Institut für Diagnostische und Interventionelle Radiologie, Zuerich, Switzerland; <sup>9</sup>APHP Beaujon, Department of Radiology, Clichy, France; <sup>10</sup>CIRSE-Cardiovascular and Interventional Radiological Society of Europe, Clinical Research, Vienna, Austria; <sup>11</sup>Clínica Universidad de Navarra, IDISNA and CIBEREHD, Liver Unit, Pamplona, Spain  
Email: dejong@cirse.org

**Background and aims:** Transarterial radioembolization (TARE) is a treatment option for patients with hepatocellular carcinoma (HCC). The CIRSE Registry for SIR-Spheres Therapy (CIRT, NCT02305459) was designed to evaluate the clinical outcomes of patients treated with TARE with SIR-Spheres Y-90 resin microspheres in primary and metastatic malignant liver tumours in the multi-institutional real-life clinical setting. The study, which included a large HCC cohort, was conducted by the Cardiovascular and Interventional Radiological Society of Europe (CIRSE).

**Method:** CIRT was a European-wide prospective multi-centre observational study which enrolled patients between Jan 2015 and Dec 2017. Eligible patients were adults treated with TARE with Y-90 resin microspheres for primary and metastatic malignant liver tumours. This analysis looks at a subset of the larger cohort-HCC patients. Baseline characteristics and treatment-related data were collected with follow-up data every 3 months for 24 months including overall survival (OS), progression-free survival (PFS), hepatic progression free survival (hPFS) and safety data.

**Results:** 422 patients with HCC were prospectively included from 25 sites in 8 European countries. Median age was 68 (range 22–92) and 80.8% were male. The Barcelona Clinic Liver Cancer (BCLC) staging was A (14.0%), B (51.4%), C (33.4%) or D (1.2%). Portal vein thrombosis (PVT) occurred in 33.1% (segmental 19.4%, lobar 9.0% and main thrombosis 4.7%). 50.2% of the patients received TARE as first-line treatment, 44.8% received locoregional treatments prior to TARE (primarily surgery 17.1%, ablation 14.7% and/or transarterial chemoembolization (TACE) 23.0%). 10.7% received prior systemic treatment. The investigator-assessed treatment intent was predominantly palliative (57.3%) or tumour downsizing (32.5%). Median OS was 16.5 months (95% CI 14.2–19.3), median PFS was 6.1 months (95% CI 5.7–7.0) and median hPFS was 6.7 months (95% CI 5.9–7.6). 36.7% of the patients experience 311 adverse events, with 9.7% of the patients having 41 (13.2%) grade 3 or higher adverse events: abdominal pain 2.1%, fatigue 1.4%, fever 0.5% nausea 0.7%, vomiting 0.5%,

gastrointestinal ulceration 0.2%, radioembolization-induced liver disease 0.7% and other 3.6%. Detailed subgroup analyses are currently being performed. Updated data describing OS, PFS and hPFS for BCLC and PVT, as well as other prognostic factors for OS, PFS and hPFS will be shown.

**Conclusion:** The results from this large prospective multi-centre observational study show that in the real-world setting, patients with HCC receive TARE as first-line treatment or after alternative locoregional treatments. TARE is well tolerated with low occurrences of severe adverse events.

#### OS-972

##### Safety and efficacy of holmium-166 radioembolisation in hepatocellular carcinoma: preliminary results from the HEPAR Primary study

Margot Reinders-Hut<sup>1</sup>, Karel J. van Erpecum<sup>2</sup>, Maarten Smits<sup>1</sup>, Arthur Braat<sup>1</sup>, Joep de Bruijne<sup>2</sup>, Rutger Bruijnen<sup>1</sup>, Dave Sprengers<sup>3</sup>, Robert De Man<sup>3</sup>, Erik Vegt<sup>4</sup>, Jan Ijzermans<sup>5</sup>, Adriaan Moelker<sup>4</sup>, Marnix Lam<sup>1</sup>. <sup>1</sup>University Medical Centre Utrecht, Radiology and Nuclear Medicine, Utrecht, Netherlands; <sup>2</sup>University Medical Centre Utrecht, Gastroenterology and Hepatology, Utrecht, Netherlands; <sup>3</sup>Erasmus Medical Centre, Gastroenterology and Hepatology, Rotterdam, Netherlands; <sup>4</sup>Erasmus Medical Centre, Radiology and Nuclear Medicine, Rotterdam, Netherlands, <sup>5</sup>Erasmus Medical Centre, Surgery, Rotterdam, Netherlands

Email: m.t.m.reinders@umcutrecht.nl

**Background and aims:** In contrast to Yttrium-90, Holmium-166 (166Ho) is a combined beta and gamma emitter, thus allowing quantitative nuclear imaging with perspective of individualized treatment planning (differentiating between tumour and liver parenchyma). Although transarterial radioembolisation with 166Ho-microspheres has shown promising results in hepatic metastases, no data are available for hepatocellular carcinoma (HCC). Considering their enhanced risk of hepatic decompensation, 166Ho-microspheres are expected to be particularly relevant in this patient group. The primary aim of this prospective clinical phase I/II study was to establish the toxicity profile of 166Ho-radioembolisation in patients with HCC.

**Method:** Inclusion criteria: HCC without curative options, Child-Pugh (CP)  $\leq$  B7 and performance state ECOG  $\leq$  1. Follow-up occurred at 3 and 6 weeks, and (including imaging) 3 and 6 months. The primary end point was the rate of unacceptable toxicity (i.e. total bilirubin increase grade  $\geq$  3 with ascites and low albumin) or any serious adverse event (SAE) that was related to study treatment. Tumour response was scored according to mRECIST.

**Results:** Thirty-one HCC patients with BCLC stage B (71%) or C (29%) were included, of whom 87% had multifocal disease and 71% had a CP score of A5. Median diameter of the largest tumour was 56 (range 15–195) mm. Patients were treated with an average absorbed dose of 60 Gy. Unacceptable treatment-related toxicity occurred in 3 patients with 4 SAEs (in 2 patients spontaneous bacterial peritonitis occurred and in one patient cholecystitis, bile duct stenosis and biliary fistula). Toxicity included fatigue (71%), back pain (55%), ascites (32%), dyspnoea (23%), nausea (23%) and abdominal pain (23%), mostly grade 1. CP score of 13 patients deteriorated after treatment by 1–4 points, of whom 3 recovered to baseline. At 3 months follow-up, target liver lesions showed complete response (CR) in 16% of the patients, partial response (PR) in 29%, stable disease (SD) in 35% and progressive disease (PD) in 3%, 17% was not evaluable (NE). At 6 months follow-up response was as follows: 23% CR, 29% PR, 10% SD, no PD, 38% NE. Median AFP levels declined with 67% (nadir). Median overall survival is 14.9 months (95% confidence interval 10.4 months-not reached). No significant decline in quality of life was observed.

**Conclusion:** <sup>166</sup>Ho-radioembolisation toxicity in this study for a selected group of patients with HCC was within the pre-defined limits. Response data support further evaluation. Future individualized treatment planning should allow a reduction of the risk of hepatic decompensation.

#### OS-1145

Email: david.pinato@imperial.ac.uk

**Background and aims:** The efficacy of TACE is secondary to its dual ischaemic and cytotoxic effect, which promotes immunogenic tumour cell death. We hypothesized that TACE will prime adaptive immunity and enhance pembrolizumab efficacy (pembro; anti-PD-1). The aim of this phase Ib study was to evaluate safety, preliminary activity of combination therapy and explore mechanisms of efficacy.

**Method:** Up to 32 patients (pts) with intermediate-stage HCC were planned to receive up to 2 rounds of TACE followed by pembro 200 mg q3w 30-days post-TACE until disease progression or unacceptable toxicity for up to 1-year. Primary end point was safety with dose-limiting toxicities (DLT) emerging from the combination being evaluated over a 21-day window from commencement of pembro. Secondary end points included progression-free survival (PFS) and evaluation of tumour and host determinants of response in tissue, blood and stool samples.

**Results:** Of 11 eligible pts, 82% were males, 18% HCV-positive, 55% ECOG PS 0 with a median age of 68 years. Child-Pugh (CP) class was A in 10 pts and B7 in 1 pt. Median tumour size was 4 cm, and median number of tumour nodules was 2. Six pts received pembro after 1 TACE, 5 pts after 2. Pembro yielded no synergistic toxicity with TACE and no DLTs were reported. All-grade adverse events potentially related to treatment (tx) occurred in 90% of pts most commonly skin rash (45%) and fatigue (45%). Median PFS was 9.7 months (95%CI 4.9–14.4) from TACE and 6.1 months (95%CI 3.8–8.3) from pembro initiation. Cause of withdrawal included disease progression (n = 7), adverse events (n = 1) worsening liver failure in the CP B7 pt, non tx-related (n = 1) and withdrawal due to Covid-19 pandemic (n = 2). We document dynamic changes in peripheral T-cell subsets throughout treatment, with significantly higher proportions of Mucosal-associated invariant T (MAIT) cells post-pembro in responding patients. Serum metabolic profiling revealed that TACE plus pembro globally altered the lipid profile of patients, causing significant changes in phosphatidylcholines, acylcarnitines and sphingomyelins. Treatment responders had higher levels of saturated and mono/di-unsaturated

## ORAL PRESENTATIONS

phosphatidylcholines, highlighting potential immune-metabolic mechanisms of efficacy.

**Conclusion:** The TACE plus pembro combination had a tolerable safety profile with no evidence of synergistic toxicity. Alongside emerging efficacy data, this encourages the clinical development of the combination in CP A pts.

### OS-1399

**Background and aims:** Hepatocellular carcinoma (HCC) is the third leading cause of death from cancer globally with an extremely variable 5-year survival rate. Immunotherapy strategies for HCC may represent a key therapeutic tool to improve clinical outcome in HCC patients. HepaVac-101 (EudraCT Number: 2015-003389-10; NCT03203005), is a single-arm, first-in-man Phase I/II clinical trial evaluating a therapeutic cancer vaccine in patients affected by HCC. It is a highly innovative, novel approach based on a multi-peptide vaccine (IMA970A) combined with the TLR7/8/RIG I agonist CV8102 as an adjuvant.

**Method:** The IMA970A off-the-shelf vaccine includes 5 HLA-A\*24 and 7 HLA-A\*02 as well as 4 HLA-DR restricted peptides identified and selected from native human HCC tumor tissue by applying the XPRESIDENT® discovery platform. CV8102 is a novel ribonucleic acid (RNA) based immunostimulatory agent inducing a balanced Th1/Th2 immune response.

HLA-A\*02 and/or A\*24-positive patients with very early, early and intermediate stage HCCs have been enrolled to be treated with 9 intradermal vaccinations consisting of IMA970A plus CV8102 following a single pre-vaccination infusion of low-dose cyclophosphamide acting as an immunomodulator. Patients have completed standard of care treatments at time of enrolment and received study drugs without concomitant anti-tumor therapy with no evidence of disease reactivation. The primary end points of the HepaVac-101 clinical trial are safety, tolerability, and antigen specific T cell response. Secondary/exploratory end points are additional immunological parameters in blood, infiltrating T-lymphocytes in tumor tissue, biomarkers in blood and tissue, disease-free survival/progression-free survival and overall survival.

**Results:** Patients were enrolled in 6 centers located in 5 European countries i.e. Italy (Naples and Negrar/Varese), Germany (Tübingen), UK (Birmingham), Spain (Pamplona) and Belgium (Antwerp). The end of trial (EOT) was reached on last December 20, 2019. 82 HCC patients have been screened for suitable HLA haplotypes, 22 patients were put on study treatment (i.e. received at least the pre-treatment with cyclophosphamide). The vaccination showed a good safety profile with no major SAE nor AESI reported during the protocol. Immunogenicity data show immune response against at least 1 vaccine class I TAA and 1 vaccine class II TAA in about 70% and 50% of

the vaccinees, respectively. More detailed immunological evaluations will be available at time of the meeting.

**Conclusion:** The HEPAVAC-101 clinical trial is safe and elicits immune response in HCC patients. This is the achievement of the HEPAVAC Consortium supported by the European Commission's 7th framework program with contract No. 602893 (www.hepavac.eu).

### OS-1674

#### IMbrave150: exploratory efficacy and safety results of atezolizumab + bevacizumab vs sorafenib in patients with unresectable hepatocellular carcinoma (HCC) who had prior locoregional therapy (LRT)

Riad Salem<sup>1</sup>, Peter Galle<sup>2</sup>, Richard Finn<sup>3</sup>, Michel Ducreux<sup>4</sup>, Amit Singal<sup>5</sup>, Alan Nicholas<sup>6</sup>, Sairy Hernandez<sup>6</sup>, Wendy Verret<sup>6</sup>, Philippe Merle<sup>7</sup>, Andrew Zhu<sup>8,9</sup>. <sup>1</sup>Northwestern University, Chicago, United States; <sup>2</sup>University Medical Center Mainz, Mainz, Germany; <sup>3</sup>Geffen School of Medicine at UCLA, Jonsson Comprehensive Cancer Center, Los Angeles, United States; <sup>4</sup>Gustave Roussy Cancer Center, Villejuif, France; <sup>5</sup>UT Southwestern Medical Center, Dallas, United States; <sup>6</sup>Genentech, Inc., South San Francisco, United States; <sup>7</sup>University Hospital La Croix-Rousse, Lyon, France; <sup>8</sup>Harvard Medical School, Massachusetts General Hospital Cancer Center, Boston, United States; <sup>9</sup>Jiahui Health, Jiahui International Cancer Center, Shanghai, China  
Email: r-salem@northwestern.edu

**Background and aims:** Atezolizumab (atezo) + bevacizumab (bev) has been approved in > 70 countries for systemic treatment (tx)-naive patients (pts) with unresectable HCC, based on IMbrave150 (NCT03434379; Finn RS NEJM 2020). Here, we report post hoc exploratory results of atezo + bev vs sorafenib (sor) in pts who had prior LRT using updated IMbrave150 data with 12 mo of further follow-up from primary analysis (Finn RS ASCO GI 2021).

**Method:** Pts were randomised 2:1 to atezo 1200 mg IV q3w + bev 15 mg/kg IV q3w or sor 400 mg bid until unacceptable toxicity or loss of clinical benefit per investigator. IMbrave150 enrolled 501 systemic tx-naive pts with unresectable HCC, ≥ 1 measurable untreated lesion (RECIST 1.1), Child-Pugh class A liver function and ECOG PS ≤ 1, including pts with prior LRT.

**Results:** 175, 84 and 77 atezo + bev pts and 80, 44 and 41 sor pts had 0, 1–2 and ≥ 3 prior lines of LRT, respectively. Compared with sor pts, atezo + bev pts had median overall survival (mOS) of 19.4 vs 13.1 mo (HR, 0.61; 95% CI: 0.44, 0.86) in pts without prior LRT, 22.8 vs 10.2 mo (HR, 0.60; 95% CI: 0.36, 1.00) in pts with 1–2 LRTs and 17.4 vs 16.6 mo (HR, 0.83; 95% CI: 0.51, 1.37) in pts with ≥ 3 LRTs. See table for more efficacy data. Grade 3–4 treatment-related adverse events were seen in 79 (46%), 33 (39%) and 31 (41%) atezo + bev pts and 30 (39%), 20 (49%) and 22 (58%) sor pts who had 0, 1–2 and ≥ 3 LRTs, respectively.

Table: Efficacy by no. of prior LRTs

	Atezo + bev			Sor		
	No prior LRT	1–2 LRTs	≥ 3 LRTs	No prior LRT	1–2 LRTs	≥ 3 LRTs
N	175	84	77	80	44	41
mOS (95% CI), mo	19.4 (16.7, 23.7)	22.8 (15.5, NE)	17.4 (14.0, 25.8)	13.1 (7.4, 16.1)	10.2 (7.0, 26.4)	16.6 (12.6, 21.9)
Median progression-free survival (95% CI), mo <sup>a</sup>	6.7 (5.5, 8.3)	9.4 (5.6, 12.9)	6.7 (5.5, 9.7)	4.8 (4.0, 6.7)	4.0 (2.6, 5.5)	4.4 (3.9, 8.6)
Objective response rate, n/N (%) <sup>a</sup>	50/172 (29)	28/79 (35)	19/75 (25)	12/78 (15)	2/41 (5)	4/40 (10)
Complete response	8 (5)	11 (14)	6 (8)	1 (1)	0	0
Stable disease	76 (44)	31 (39)	37 (49)	33 (42)	15 (37)	21 (53)
NE	3 (2)	4 (5)	1 (1)	7 (9)	4 (10)	3 (8)
Missing	9 (5)	1 (1)	4 (5)	7 (9)	8 (20)	3 (8)

Clinical cutoff: 31 Aug 2020. Median follow-up: 15.6 mo. N, no. of pts with measurable disease at baseline; NE, not estimable.

<sup>a</sup>Independently-assessed RECIST 1.1.

**Conclusion:** Survival benefit with atezo + bev over sor was seen in pts regardless of the number of prior LRTs. Atezo + bev seemed to have more benefit in pts with 1–2 vs  $\geq 3$  prior LRTs, suggesting an optimal time for switching from LRT to systemic tx.

Email: thomas.baumert@unistra.fr

**Background:** Hepatocellular carcinoma (HCC) is the fastest rising and third leading cause of cancer death. While new therapeutic modalities have been recently approved, treatment response and survival in patients remain poor. Claudin-1 (CLDN1) is a cell membrane protein mediating cell-cell adhesion, fate and differentiation. Functionality of CLDN1 in solid tumors including HCC has been demonstrated by gain- and loss-of-function studies, yet its impact as a therapeutic target is unexplored.

**Aims and Method:** Using humanized monoclonal antibodies (mAbs) targeting specifically the extracellular loop of human non-junctional CLDN1 and a large series of patient-derived cell-based and animal model systems we aimed to investigate the role of CLDN1 as therapeutic target for treatment of HCC.

**Results:** Here we show that humanized monoclonal anti-CLDN1 mAbs robustly and significantly inhibit growth, migration and invasion of tumor cells in cell line-based models of HCC and patient-derived HCC spheroids. Moreover, the robust effect on tumor growth was confirmed *in vivo* in a large series of cell line derived xenograft (CDX) and patient-derived xenograft (PDX) mouse models. Functional studies in patient-derived and cell line-based tumor spheroids revealed that the mAbs perturbed the 3D tumor architecture. Furthermore, CLDN1 mAbs markedly and significantly suppressed epithelial-mesenchymal transition (EMT) and matrix metalloproteinase synthesis in tumor cells. Good treatment response in PDX models correlated with expression of genes that are associated with a fibrotic tumor environment, whereas presence of the angiogenic factor VEGFB predicted low treatment efficacy. Treatment with humanized anti-CLDN1 mAbs is considered to be safe, as administration in non-human primates and mouse models did not reveal any major toxicity even when high doses largely exceeding the therapeutic need were repeatedly applied.

**Conclusion:** These results provide robust pre-clinical proof-of-concept for humanized CLDN1-specific mAbs for treatment of HCC and pave the way for clinical development of CLDN1-targeting therapies using monoclonal antibodies. The unique and different mechanism of action provides opportunities to break the plateau of limited response and survival offered by currently approved therapies.

#### Rifaximin regulates nitrogen detoxification in a PXR-independent manner in human small intestinal organoids

Koos de Wit<sup>1</sup>, Ulrich Beuers<sup>1</sup>, Saskia van Mil<sup>2</sup>, Bart Takkenberg<sup>1</sup>.

<sup>1</sup>Amsterdam Umc, location AMC, Gastroenterology and Hepatology, Amsterdam, Netherlands; <sup>2</sup>UMC Utrecht, Center for Molecular Medicine, Utrecht, Netherlands

Email: k.dewit1@amsterdamumc.nl

**Background and aims:** The poorly absorbed antibiotic rifaximin-a Pregnane X Receptor (PXR) agonist-prevents recurrent hepatic encephalopathy (HE). Although the pathophysiology of HE is only partly unravelled, ammonia accumulation, systemic inflammation and oxidative stress appear to play a central role. Ammonia is detoxified by formation of glutamine and urea. Due to its poor absorption, rifaximin is considered to exert beneficial effect on HE by acting on the gut microbiome, thereby decreasing bacterial ammonia production. Direct effects of rifaximin on intestinal epithelium have barely been studied. We tested our hypothesis that rifaximin is effective in HE by strengthening the human intestinal mucosal detoxification capacity.

**Method:** Using lentiviral delivery of short hairpins, we generated a PXR knockdown human small intestinal organoid line and a control line in which a non-target shRNA was introduced. Organoids were cultured for 24 hours with either rifaximin, rifampicin (100 uM each), or DMSO. RNA-sequencing and AccQ-Tag mass spectrometry were performed to investigate effects on gene expression and glutamine metabolism. Rifaximin uptake and secretion were studied by bright field microscopy.

**Results:** Uptake and apical secretion of rifaximin in human small intestinal organoids was documented using microscopy. In total, 31% of the differentially expressed genes upregulated by rifaximin were overlapping in the PXR knockdown and control organoids. Notably, PXR-independent upregulation of Asparagine Synthetase (Log2FC 2.3,  $p < 0.001$ ) and downregulation of Glutaminase 2 (Log2FC -0.8,  $p < 0.001$ ) are suggestive of increased ammonia detoxification whereas PXR-independent induction of Glutamate-Cysteine Ligase Modifier (Log2FC 1.7,  $p < 0.001$ ) and Glutamate-Cysteine Ligase Catalytic subunit (Log2FC 0.3,  $p < 0.001$ ) are in line with increased glutathione production. Indeed, intracellular concentrations of asparagine and glutathione were increased by rifaximin from 3.6 to 4.0 uM, ( $n = 3$ ,  $p = 0.017$ ) and from 33.3 to 44.6 uM ( $n = 3$ ,  $p = 0.047$ ) while no such effects were seen by rifampicin.

**Conclusion:** Our findings suggest that rifaximin-after uptake into human small intestinal cells-stimulates nitrogen detoxification and decreases ammonia production in a PXR-independent manner. Luminal intestinal rifaximin excretion may explain the lack of systemic effects of rifaximin.

#### A context-dependent role of c-myc in liver regeneration and hepatocarcinogenesis in chronic liver injury

Silke Marhenke<sup>1</sup>, Tiago De Castro<sup>2</sup>, Simon Peter<sup>1</sup>, Jan G. Hengstler<sup>3</sup>, Wei He<sup>4</sup>, Karsten Hiller<sup>4</sup>, Michael Saborowski<sup>2</sup>, Anna Saborowski<sup>2</sup>, Arndt Vogel<sup>2</sup>. <sup>1</sup>Medical School Hannover, Gastroenterology, Hepatology and Endocrinology, Hannover, Germany; <sup>2</sup>Medical School Hannover, Gastroenterology, Hepatology and Endocrinology, Hannover; <sup>3</sup>Leibniz Research Centre for Working Environment and Human Factors, Toxikologie, Dortmund; <sup>4</sup>BRICS-Braunschweig Integrated Centre of Systems Biology, Department of Bioinformatics and Biochemistry, Braunschweig

Email: marhenke.silke@mh-hannover.de

**Background and aims:** c-MYC is frequently dysregulated in human hepatocellular carcinoma (HCC), and is considered to be a driver of

malignant transformation. Despite its well established impact on HCC, the physiological role of c-MYC during acute and chronic liver injury remains enigmatic. We employed two murine liver injury models to explore the consequences of loss of c-MYC on liver damage, regeneration and carcinogenesis.

**Method:** To investigate the effect of c-Myc in distinct liver disease settings, we crossed conditional c-Myc<sup>fl/fl</sup> to *Mdr2*<sup>-/-</sup> and *Fah*<sup>-/-</sup> mice, respectively, and excised c-Myc by liver-specific Cre recombinase. Mice were monitored longitudinally for biochemical and metabolic parameters and tumor development. Partial hepatectomies (PH) were performed to assess the regenerative response, and bile duct ligations (BDL) to delineate the effects of acute biliary injury.

**Results:** In line with its role as a driver of hepatocarcinogenesis, loss of c-Myc delayed tumor development in the *Fah*<sup>-/-</sup> mice. In contrast, tumor development was markedly accelerated in the *Mdr2*<sup>-/-</sup> model. Biochemical parameters of liver damage were elevated in *Mdr2*/*cmcy*<sup>Δ/Δ</sup> mice, accompanied by an accelerated fibrosis. The increased liver injury coincided with an impaired regenerative response, likely a direct effect of loss of c-MYC, as indicated by a reduction in Ki67 positive cells in *cmcy*<sup>Δ/Δ</sup> mice after PH. In contrast, liver regeneration was not impaired in *Fah/cmcy*<sup>Δ/Δ</sup> mice suggesting a context specific role of c-MYC for liver regeneration. *Mdr2/cmcy*<sup>Δ/Δ</sup> displayed an altered energy metabolism reflected by decreased basal ATP-levels, and imbalances in the metabolite profile of the TCA cycle. Moreover, the bile acid composition was severely altered in *Mdr2/cmcy*<sup>Δ/Δ</sup> mice, and transcriptome analysis revealed a strong downregulation of the bile acid transporter *Slco1a1*. Of note, an increased sensitivity to cholestatic injury has been reported for a transgenic *Slco1a1*<sup>-/-</sup> model. In line with the observation in the *Mdr2*<sup>-/-</sup> mice, liver injury was markedly increased in *cmcy*<sup>Δ/Δ</sup> mice following BDL, suggesting c-MYC -regulated *Slco1a1* protects mice from bile acid induced liver injury.

**Conclusion:** Our results unveil a context-dependent role of c-myc during liver injury and injury-induced tumorigenesis and add a note of caution to the development of MYC-directed therapeutic strategies.

### OS-387

#### Loss of cholangiocyte primary cilia drives reorganisation of the biliary tree and accelerates tumorigenesis

Scott Waddell<sup>1</sup>, Yuelin Yao<sup>1</sup>, Stephanie Macmaster<sup>1</sup>, Kostas Gournopoulos<sup>1</sup>, Ava Khamseh<sup>1</sup>, Pleasantine Mill<sup>1</sup>, Luke Boulter<sup>1</sup>. <sup>1</sup>MRC Human Genetics Unit, Edinburgh, United Kingdom  
Email: scott.waddell@ed.ac.uk

**Background and aims:** Primary cilia (PC) are signalling organelles that protrude from most cells to sense the extracellular environment. Cholangiocytes project PC into the bile duct lumen to sense and regulate bile composition. Mutations in genes that result in PC dysfunction have been associated with ductal plate malformations and polycystic liver diseases, though whether loss of cilia function is causative in these pathologies is not entirely clear. In both cholangiopathies and cholangiocarcinoma, the bile duct must mechanically reorganise its structure to form a cyst or cancerous duct, respectively. In this study, we sought to define whether PC loss in bile ducts is sufficient to induce structural reorganisation of the biliary tree and define whether PC loss promotes oncogenesis.

**Method:** We generated a novel model whereby we can specifically delete PC from cholangiocytes using a *K19Cre;Wdr35*<sup>loxP/loxP</sup> transgenic mouse in health and in a model of cholangiocarcinoma. We used a combination of approaches including scRNAseq and lineage tracing to characterise the pathological and physical alterations that arise due to PC loss in cholangiocytes.

**Results:** PC deletion in the healthy adult liver results in the formation of extensive biliary cysts, which have a remarkably low proliferative rate. We found that extensive remodelling of the cholangiocyte cytoskeleton is associated with cystic liver disease. Moreover, when we delete PC in a novel transgenic model of cholangiocarcinoma we

observe increased tumour size and number, suggesting that in patient cholangiocarcinoma PC are lost to promote tumour growth. To understand the molecular changes that are regulated by the PC, we used scRNAseq and whole transcriptome sequencing to identify downstream signals that are deregulated upon PC loss, and immunohistochemistry to characterise physical rearrangements in the cytoskeleton that drive biliary tree reorganisation to generate cysts and promote tumour growth.

**Conclusion:** Our results show that PC are required to maintain cholangiocyte homeostasis and constrain dynamic reorganisation of the cytoskeleton in the bile duct. Deregulation of actin mediate gross rearrangements of the biliary tract to form extensive cysts in the adult liver, and this process contributes to tumour development. This work highlights the importance of PC in biliary pathophysiology and identifies a potential benefit of targeting actin processing in patients with polycystic liver disease and CCA.

**OS-901**

**A murine model of FGFR2 fusion driven intrahepatic cholangiocarcinoma to delineate mechanism of therapeutic response and resistance to FGFR inhibitors**

Gajanan Kendre<sup>1</sup>, Silke Marhenke<sup>1</sup>, Georgina Lorz<sup>1</sup>, Michael Saborowski<sup>1</sup>, Arndt Vogel<sup>1</sup>, Anna Saborowski<sup>1</sup>. <sup>1</sup>Hannover Medical School, Department of Gastroenterology and Hepatology, Hannover, Germany  
Email: saborowski.anna@mh-hannover.de

**Background and aims:** Intrahepatic cholangiocarcinoma (iCC) is an aggressive malignancy with a mOS below 12 months in the palliative setting. Gene fusions involving the *fibroblast growth factor receptor 2* (FGFR2) occur in up to 15% of iCCs, and their therapeutic relevance was confirmed in clinical phase II studies. Despite thus far unparalleled ORRs of up to 35% in second line, several FGFR2 fusion patients do not reach deep responses. Here, we describe a *in vivo* model system for the functional annotation of fusion genes, and delineate how the co-mutational spectrum influences therapy response.

**Method:** We utilized an *in vivo* electroporation approach to introduce six different FGFR2 fusion cDNAs (or control) into the livers of mice harbouring the latent mutant *Kras* allele (*Kras*<sup>G12D</sup>), or wildtype (wt) mice, in conjunction with a CRISPR/Cas9 plasmid targeting *Trp53*. The efficacy of FGFR inhibitors was probed both *in vitro* and *in vivo*, and we employ a combination of drug treatment and RNAi technology to

delineate the effect of co-treatment strategies on the sensitivity to FGFR inhibitors.

**Results:** Following electroporation with a FGFR2-fusion encoding cDNA, tumors developed rapidly in *Kras* mutant, and (with longer latency) in *Kras* WT mice. No tumor development was observed in the controls, indicating that FGFR2 fusions drive malignant transformation. Despite the pre-requisite of the fusion for tumor development, cell lines derived from FGFR2-fusion tumors that harboured a mutant *Kras* allele exhibited an unexpected resistance to FGFR-inhibitors, as determined by dose response assays. A combination of pharmacologic and genetic approaches revealed that, while KRAS knockdown (KD) did not affect the growth of the tumor-derived cell lines, KRAS KD or pharmacologic MAPK/ERK inhibition re-sensitized the cells to FGFR inhibition. Similarly, resistance was also observed following introduction of other MAPK activating mutations (ERBB2, NRAS, BRAF) in *Kras* WT cells.

**Conclusion:** We present an autochthonous *in vivo* model for FGFR2-fusion driven iCC. Due to its genetic flexibility, this model is highly suited to address mechanisms of primary resistance to clinically relevant FGFR inhibitors, caused by the co-mutational spectrum. Our data suggest that iCC patients with FGFR2 fusions and co-mutations that activate the MAPK-signaling may not benefit from monotherapy with FGFR inhibitors, but that resistance may be overcome by co-treatment strategies.

**OS-1355**

**Hepatic o-glcNacetylated-p53 as a hub integrating the glucose counter regulatory response and insulin-suppressed gluconeogenesis**

González Rellán<sup>1</sup>, Marcos Fernandez Fondevila<sup>1</sup>, Uxia Fernández Paz<sup>1</sup>, Amaia Rodriguez<sup>2</sup>, Marta Varela Rey<sup>3</sup>, Christelle Veyrat Durebex<sup>4</sup>, Samuel Seoane<sup>1</sup>, Ganeko Bernardo<sup>3</sup>, Fernando Lopitz Otsoa<sup>3</sup>, David Fernandez Ramos<sup>3</sup>, Jon Bilbao<sup>3</sup>, Cristina Iglesias<sup>1</sup>, Eva Novoa<sup>1</sup>, Natalia Lima<sup>1</sup>, Begoña Porteiro<sup>1</sup>, Timo d Müller<sup>5</sup>, Stephan Herzig<sup>5</sup>, Maria Luz Martinez Chantar<sup>3</sup>, Roman Perez Fernandez<sup>1</sup>, Miguel Lopez Perez<sup>1</sup>, Carlos Dieguez<sup>1</sup>, Jose Maria Mato<sup>3</sup>, Oscar Millet<sup>3</sup>, Roberto Copara<sup>4</sup>, Ashwin Woodhoo<sup>3</sup>, Gema Frugbeck<sup>2</sup>, Ruben Nogueiras Pozo<sup>1</sup>. <sup>1</sup>CIMUS, Physiology, Santiago de Compostela, Spain; <sup>2</sup>clinica universidad de navarra; <sup>3</sup>cic Biogune, Bilbao, Spain; <sup>4</sup>University of Geneva, Geneva, Switzerland; <sup>5</sup>Helmholtz Zentrum München, München, Germany  
Email: chusa.gz.z.rellan@gmail.com

**Background and aims:** Glucose homeostasis is essential for life. The liver is among the key tissues for maintaining an adequate metabolic homeostasis and its alterations are at the root of the pathogenesis of many disease states. A perfect balance between glucose production, mainly at the liver, and glucose consumption in different tissues, is provided by the action of insulin and counterregulatory hormones as glucagon, cortisol or catecholamines. p53 is an intensively studied protein primarily as a tumor suppressor. There is nowadays growing evidence demonstrating that cell cycle regulators have important actions in the metabolic control. In cancer cells, p53 regulates glucose metabolism, opposing the Warburg effect. Nevertheless, the relevance of endogenous hepatic p53 in the physiological fluctuation of gluconeogenesis, as well as the molecular pathways mediating these effects, remains totally unknown.

**Method:** Either *wild type* (WT) mice or hepatic p53-deficient littermates were subjected to different nutritional conditions to evaluate p53 expression and function. These experiments were also performed *in vitro*, in both THLE-2 cells and HEP3B cells (a hepatic KOP53 cell line). PTT, Gly, GTT and ITT were performed to study glucose homeostasis in WT mice and p53-deficient mice, as well as a clamp to further test their gluconeogenic capacity. Gain-of-function experiments were also performed, over-expressing p53 in the liver. *In vitro* and *in vivo* models were treated with gluconeogenic hormones and insulin, to study the role and function of p53 mediating their hepatic actions. Mutagenesis experiments were also performed to evaluate the relevance of O-GlcNAcylation on p53 gluconeogenic actions.

Figure: (abstract: OS-1355)

**Results:** We show that upon starvation hepatic p53 is stabilized by O-GlcNAcylation, and plays an essential role in the physiological regulation of glucose homeostasis. p53 binds to PCK1 promoter and regulates its transcriptional activation, thereby controlling hepatic glucose production. Mutant p53 that cannot be O-GlcNAcylated is unable to promote PCK1 activity gluconeogenesis. Mice lacking p53 in the liver show a reduced gluconeogenic response during calorie restriction. Glucagon, adrenaline and glucocorticoids augmented protein levels of p53, and administration of these hormones to human hepatocytes and to liver-specific p53 deficient mice fails to increase glucose levels. Moreover, insulin decreases p53 levels, and over-expression of p53 impairs insulin sensitivity. Finally, protein levels of p53, as well as genes responsible of O-GlcNAcylation are elevated in the liver of T2D patients, and positively correlate with glucose and HOMA-IR.

**Conclusion:** Our results indicate that O-GlcNAcylation of p53 plays an unsuspected key role regulating in vivo glucose homeostasis, with a potential therapeutic target interest.

IIBm (CSIC-UAM), Department of Pathophysiology Endocrine and Nervous System, Madrid, Spain  
Email: avalverde@iib.uam.es

**Background and aims:** Schizophrenia is a chronic and severe mental disorder which is treated with second generation antipsychotics (SGA). Patients under SGAs treatment, including olanzapine (OLA), have higher risk for abnormal weight gain, hyperglycemia and dyslipidemia. Our aim was to understand the molecular mechanisms by which OLA alters insulin sensitivity and hepatic metabolism either directly or mediated through the central nervous system (CNS).

**Method:** Wild-type (WT) and protein tyrosine phosphatase-1B deficient (PTP1B-KO) mice with hepatic insulin hypersensitivity and protection against obesity, were injected (i.p.) 10 mg/kg/day OLA or vehicle for 8 weeks. Glucose, insulin and pyruvate tolerance tests and tissue insulin signaling analysis were conducted. Body weight and metabolic parameters were monitored. Nuclear magnetic resonance (NMR) was used for metabolomic analysis of hypothalamus. Hypothalamus-liver-axis was corroborated by intracerebroventricular (ICV) OLA injections.

**Results:** WT mice receiving OLA showed decreased body weight, but insulin and pyruvate intolerance together with insulin resistance in liver and skeletal muscle, key tissue targets of PTP1B. Insulin resistance in OLA-treated WT mice concurred with proinflammatory signals and increased fatty acid synthase in liver. The latter effect paralleled to hypothalamic JNK phosphorylation. By contrast, PTP1B-KO mice were protected against these alterations. OLA ICV injections in WT mice corroborated peripheral molecular alterations in both liver and adipose tissues. OLA-treated WT mice showed lower hepatic ATP levels associated with increased AMPK and acetyl-CoA carboxylase phosphorylation,  $\beta$ -oxidation readouts. As result of these metabolic changes, a futile cycle might occur in the liver of male animals since steatosis was not detected. Analysis of the hypothalamus revealed a decrease of antioxidant metabolites which likely increases reactive oxygen species that are related with JNK activation. These alterations are independent of body weight gain. By contrast, gender differences were found since females were protected against the central effects of OLA regarding the hepatic cross-talk.

**Conclusion:** We show a hypothalamus-liver crosstalk responsible for OLA hepatic side effects, emphasizing an impact in the CNS and sexual dimorphisms. These results suggest that i.p. administration together with a PTP1B inhibitor might have less metabolic alterations in schizophrenic patients.

**OS-2934**

**Identifying patient relevant tumour suppressors that interact with oncogenic KrasG12D in intrahepatic cholangiocarcinoma**

Mollie Wilson<sup>1</sup>, Luke Boulter<sup>1</sup>, Nicholas Younger<sup>1</sup>, Alison Meynert<sup>1</sup>, Kostas Gournopoulos<sup>1</sup>. <sup>1</sup>The Institute of Genetics and Cancer, United Kingdom  
Email: s1217700@ed.ac.uk

**Background and aims:** Intrahepatic cholangiocarcinoma (iCCA), a malignancy arising from the bile ducts, presents with highly

Figure: (abstract: OS-1414)

genetically heterogeneous tumours. The lack of understanding surrounding the genetics of this disease has hampered therapeutic approaches. To address the gap in our understanding of the functional genetics of iCCA we developed a computational screen of patient exome sequencing data to comprehensively identify driver mutations in iCCA, and found that in addition to known drivers of iCCA a large number of infrequently mutated genes typifies iCCAs. Here, we aimed to address whether these infrequently mutated genes are capable of initiating iCCA formation and determine whether rare iCCA mutations are sufficient to enhance, or modify, iCCA growth.

**Method:** A CRISPR-Cas9 library of loss of function mutations in iCCA was generated using data from patients, which was hydrodynamically injected into immune competent mice to delete iCCA-genes, along with expression of oncogenic Kras<sup>G12D</sup>. Whole exome and RNA sequencing as well as proteomic approaches were combined to analyse the resulting tumours, to identify mutations that synergise with oncogenic Kras, define the transcriptional signatures that result from these mutations and uncover novel candidate therapeutic pathways.

**Results:** Computational screening of patient exomes identified a list of mutations in iCCA driver genes. Using this approach, we re-identified canonical mutations in iCCA and >90 mutations in novel genes. To determine which mutations are functional *in vivo*, we performed a CRISPR screen targeting genes found in patient iCCA. Tumours formed that histologically represented human iCCA when the CRISPR-library was co-expressed with Kras<sup>G12D</sup>. Whole exome sequencing of these tumours identified a number of novel CRISPR-induced mutations that interact with KRas<sup>G12D</sup> to drive iCCA formation and we identified mutations in neurofibromin 2 (Nf2), a cytoskeletal protein whose encoded protein Merlin is at the apex of many important signaling pathways as a gene of interest. Deletion of Nf2 cooperates with Kras<sup>G12D</sup> to initiate iCCA formation; moreover, Nf2-loss cooperates with Trp53-loss leading to cancer with a significantly accelerated phenotype and increased lethality. Proteomic analysis of tumour tissue from this aggressive model demonstrated that co-activation of Wnt and PI3K signaling typify these tumours and can be targeted therapeutically to reduce tumour progression.

**Conclusion:** Our study demonstrates that Nf2 is a rare driver gene of iCCA that acts in a cooperative manner with oncogenic Kras<sup>G12D</sup> to accelerate tumorigenesis. Using a combination of *in silico* and *in vivo* modelling holds a great deal of promise in unveiling the contribution

of different mutations to iCCA progression and also providing a platform to identify novel therapeutic vulnerabilities.

## NAFLD – Clinical aspects except therapy

#### Life expectancy and risk of cardiovascular disease in non-alcoholic fatty liver disease: a population-based cohort study

Ying Shang<sup>1</sup>, Patrik Nasr<sup>2</sup>, Linnea Widman<sup>3</sup>, Hannes Hagström<sup>4,5,6</sup>.

<sup>1</sup>Karolinska Institutet, Neurobiology, Care Sciences and Society, Stockholm, Sweden; <sup>2</sup>Linköping University, Department of Gastroenterology and Hepatology, Department of Health, Medicine and Caring Sciences, Linköping, Sweden; <sup>3</sup>Karolinska Institutet, Division of Biostatistics, Institute of Environmental Medicine, Stockholm, Sweden; <sup>4</sup>Karolinska University Hospital, Division of Hepatology, Department of Upper GI, Stockholm, Sweden; <sup>5</sup>Karolinska Institutet, Department of Medicine, Huddinge, Stockholm, Sweden; <sup>6</sup>Karolinska Institutet, Clinical Epidemiology Unit, Department of Medicine, Stockholm, Sweden  
Email: ying.shang@ki.se

**Background and aims:** Patients with non-alcoholic fatty liver disease (NAFLD) have a high risk for cardiovascular disease (CVD), but selection bias is common in many previous studies, and there is little data comparing this risk to the general population. It is further unclear if the risk is higher in patients with cirrhosis, differs for fatal and non-fatal events and if patients with NAFLD in general have lower life expectancy compared to the general population. We investigated these questions in a population-based study.

**Method:** We identified all patients diagnosed with NAFLD from 1970 to 2016 through the Swedish National Patient Register. For each person with NAFLD, up to 10 controls were randomly selected from the general population matched for age, sex, and municipality. The cohort consisted of 9,039 patients with NAFLD, and 91,495 controls with follow-up until 2016. Outcomes on all fatal, non-fatal CVD events and overall mortality were derived from national registers. Cox regression models with cause-specific hazards were used to estimate the risk of NAFLD with these outcomes, accounting for the competing risk of death. Observed and expected life expectancy by age at diagnosis were estimated with relative survival analysis.

## ORAL PRESENTATIONS

**Results:** Over a median follow-up period of 6 years (range 0–46), 1,041 (11.5%) patients with NAFLD and 3,807 (4.2%) controls developed CVD ( $p < 0.01$ ). Patients with NAFLD had a higher risk for all CVD outcomes (aHR = 2.9, 95%CI = 2.6–3.1), primarily for non-fatal CVD (aHR = 3.6, 95%CI = 3.3–4.0) but also for fatal CVD (aHR = 1.3, 95%CI = 1.1–1.5). However, there was no difference in overall mortality after a non-fatal CVD event between patients with NAFLD and controls (aHR = 0.8, 95%CI = 0.5–1.2). In patients with NAFLD, those with cirrhosis had a higher risk for CVD (aHR = 1.6, 95%CI = 1.1–2.3). Moreover, life expectancy was on average 2.5 years for men, and 1.7 years for women, lower than that of controls. Men had 3.2 years and women had 2.1 years lower life expectancy than that of controls when diagnosed in middle age (40–60 years).

Figure:

**Conclusion:** In this study of all patients with a diagnosis of NAFLD in Sweden, the risk of fatal and non-fatal CVD was higher than in the general population, and the presence of cirrhosis amplified this risk. Age at diagnosis appears to play a role in survival, which can have implications for when to consider a diagnosis of this common disease.

Email: vihernandez@clinic.cat

**Background and aims:** Portal hypertension is a key determinant of hepatic decompensation and death in patients with cirrhosis. The hepatic vein catheterization with hepatic vein pressure gradient (HVPG) measurement is the gold standard technique to measure portal vein pressure in patients with cirrhosis. Concerns have been raised about the accuracy of HVPG for determining the portal pressure gradient in patients with non-alcoholic fatty liver disease (NAFLD). We aimed to evaluate the relationship between HVPG and portal hypertension related decompensation in patients with advanced NAFLD (aNAFLD).

**Method:** We designed a multicenter cross-sectional study including 548 patients with advanced NAFLD and 444 with hepatitis C (HCV-RNA-positive; aHCV) who had detailed portal hypertension evaluation (HVPG measurement, gastroscopy and abdominal imaging). We examined the relationship between etiology, HVPG, and decompensation by logistic regression models. We also compared the proportions of compensated/decompensated patients at different HVPG levels.

**Results:** Both cohorts, aNAFLD and aHCV, had similar baseline age, gender, Child-Pugh score, and MELD. Median HVPG was lower in the aNAFLD cohort (13 vs 15 mmHg). However, rates of clinical decompensation and high-risk varices were higher in aNAFLD group (32% vs 25%,  $p = 0.019$ ; and 32% vs 27%,  $p = 0.103$ ) than in the aHCV group. Decompensated aNAFLD patients had lower median HVPG (17 mmHg vs 19 mmHg,  $p = 0.001$ ) than aHCV patients. Moreover, the prevalence of decompensation was higher than in the aHCV group for any HVPG threshold.

Figure:

**Conclusion:** Patients with aNAFLD have higher rate of portal hypertension related decompensation at any value of HVPG as compared to aHCV patients. Longitudinal studies aiming to identify HVPG thresholds able to predict decompensation and longterm outcomes in aNAFLD population are strongly needed.

**Background and aims:** While obesity is a major risk factor, non-alcoholic fatty liver disease (NAFLD) has also been reported in lean subjects. In this clinical setting, severity of liver injury and clinical outcomes are debated and few studies have been conducted at a general population level. This study aimed to assess prevalence, characteristics and mortality outcomes of lean NAFLD in the French adult population.

**Method:** The study population consisted of 127, 291 participants from the nationwide CONSTANCES cohort. After exclusion of subjects with excessive alcohol consumption, viral hepatitis or other liver diseases, 110, 120 were analyzed. Non-invasive diagnosis of NAFLD and advanced fibrosis was performed using the combination of Fatty Liver Index and Forns Index. Outcomes analyzed were liver-related events, hepatocellular carcinoma (HCC), cardiovascular disease (CVD), extrahepatic cancer (EHC), chronic kidney disease (CKD), liver transplantation and overall mortality. The median follow-up was 30 months.

**Results:** The prevalence of NAFLD was 18.1% in overall population and 5.3% in lean subjects, while 16.3% of NAFLD subjects were lean. Compared to non-lean, lean NAFLD were significantly younger and more frequently women, had fewer metabolic risk factors, were more frequently tobacco user and moderate alcohol consumer (all P value <0.001). Prevalence rates of elevated ALT and advanced fibrosis were significantly higher in lean compared to non-lean NAFLD (34.4% vs 20.9%, P<0.001 and 3.6% vs 1.7%, P<0.001, respectively). When adjustment for usual risk factors, NAFLD in lean subjects was associated with increased risk of liver-related events (aHR = 5.48, 95%CI 3.43–8.75), HCC (aHR = 3.35, 1.72–6.55), CVD (aHR = 1.72, 1.25–2.37), EHC (aHR = 2.90, 2.27–3.71), CKD (aHR = 2.11, 1.43–3.11) and overall mortality (aHR = 2.26, 1.76–2.91). Among NAFLD subjects, lean status was associated with increased risk of hepatic events (aHR = 9.10, 95%CI 4.48–18.48), HCC (aHR = 3.86, 1.35–11.03), EHC (aHR = 2.46, 1.78–3.38) and overall mortality (aHR = 3.76, 2.41–5.85), irrespective of usual risk factors.

**Conclusion:** From a large French community-based cohort, this study confirms the significant prevalence of lean NAFLD and suggests that NAFLD is more severe in terms of advanced fibrosis, liver disease progression and overall mortality in lean compared to non-lean subjects, despite fewer metabolic risk factors. Differences in lifestyle, genetics and microbiota may explain those results.

**OS-635**

**Increased serum ferritin levels predict long-term mortality in patients with NAFLD**

Email: angelo.armandi@unito.it

**Background and aims:** Hyperferritinemia is common in patients with Non-Alcoholic Fatty Liver Disease (NAFLD) and correlates with the severity of liver fibrosis. Our aim was to assess the impact of ferritin on long-term outcomes and survival in a large cohort of NAFLD patients.

**Method:** We included 1247 patients with biopsy-proved NAFLD from tertiary centers in Italy (Turin, Milan, Rome, Palermo), Australia (Sydney), UK (Newcastle) and Spain (Seville). Clinical and biochemical data were collected at the time of liver biopsy. Ferritin levels of 300 ug/L for men and 200 ug/L for women were considered as the upper limit of normal (ULN). Clinical outcomes, including liver-related events (ascites, encephalopathy, variceal bleeding), hepatocellular carcinoma (HCC) and survival, were collected after a median follow-up of 90 months.

**Results:** The median age of the study cohort was 48 [IQR 38–57] years and 814 (65.3%) patients were male. The overall prevalence of obesity and type 2 diabetes was 45.0% and 28.1%. Overall, hyperferritinemia

## ORAL PRESENTATIONS

was found in 373 (29.9%) patients; severe fibrosis (F3-4) was found at liver biopsy in 272 (21.8%) patients. NASH was diagnosed in 756 (60.6%) cases and was similarly distributed between those with normal and high ferritin levels. Serum ferritin  $>2 \times$  ULN (32.2% of the total population with hyperferritinemia), significantly associated with F3-4 (OR = 2.10 [95% CI 1.40–3.14],  $p < 0.001$ ). After a median follow-up of 90 months, 24 patients (2.3%) died, while 57 (4.8%) and 18 (1.5%) developed liver-related events and HCC. At univariate analysis, the incidence of liver-related events and mortality varied significantly according to serum ferritin values  $>2 \times$  ULN (log-rank test:  $p = 0.004$  and  $p = 0.001$ , respectively). However, at multivariate Cox regression analysis adjusted for age, body mass index, diabetes and fibrosis, ferritin levels  $>2 \times$  ULN independently predicted mortality (HR = 3.04 [95% CI 1.16–7.93],  $p = 0.023$ ) but not liver-related events (HR = 1.67 [95% CI 0.90–3.11],  $p = 0.105$ ).

**Conclusion:** Ferritin levels higher than  $2 \times$  ULN are associated with severe liver fibrosis in NAFLD patients and are able to predict long-term mortality.

Email: katy.wack@pathai.com

**Background and aims:** Limitations of manual pathology may confound results of NASH clinical trials. Our aim was to develop an AI-based drug development tool (AIM-NASH) that reproducibly calculates NASH Clinical Research Network (CRN) scores.

**Method:** AIM-NASH machine learning (ML) models were developed using 5923 biopsies from six phase 2b or 3 trials in NASH subjects with F1-F4 fibrosis. Models were trained to identify NASH histologic features and predict ordinal CRN scores using  $>100k$  annotations from expert pathologists. Analytic performance was tested in a held-out dataset of 639 HandE- and 633 trichrome-stained biopsy images (NCT02784444; EMINENCE). Agreement between AIM-NASH scores and the consensus of 3 expert hepatopathologists was evaluated using linearly-weighted Kappa ( $\kappa$ ) statistics. Histologic end points were retrospectively assessed by AIM-NASH and central reader scores from a separate phase 2b trial (NCT03449446; ATLAS). Comparisons of treatment responses between groups were made using the Mantel-Haenszel test, stratified by diabetes and cirrhosis status.

**Results:** Agreement between AIM-NASH and consensus reads was higher than that among pathologists [AIM-NASH steatosis  $\kappa = 0.71$  (95% CI 0.67–0.74) vs mean pairwise inter-pathologist steatosis  $\kappa = 0.60$  (0.56–0.63); lobular inflammation  $\kappa = 0.50$  (0.45–0.55) vs 0.33 (0.29–0.37); ballooning  $\kappa = 0.58$  (0.53–0.63) vs 0.48 (0.44–0.52); fibrosis  $\kappa = 0.58$  (0.54–0.62) vs 0.50 (0.47–0.53)]. In ATLAS, AIM-NASH identified more responders vs the central reader in subjects treated with cilofexor and firsocostat for  $\geq 1$ -stage fibrosis improvement

without NASH worsening (26% vs 21%), NASH resolution without fibrosis worsening (16% vs 5%), and  $\geq 2$ -point reduction in NAS (68% vs 38%), and greater improvements in treated subjects vs placebo (Table).

Table: AIM-NASH and Central Reader Assessments of Treatment Response in ATLAS (F3-F4).

End points*	AIM-NASH		P value	Central Reader		P value
	CILO+FIR	Placebo		CILO+FIR	Placebo	
Fibrosis improvement without NASH worsening	26% (16/61)	13% (4/32)	0.142	21% (13/63)	11% (4/38)	0.190
NASH resolution without fibrosis worsening	16% (9/55)	7% (2/27)	0.212	5% (3/63)	0% (0/38)	0.332
$\geq 2$ -pt reduction in NAS	68% (40/59)	27% (8/30)	<b>&lt;0.001</b>	38% (24/64)	11% (4/38)	<b>0.001</b>

\* Sample size for each end point varies due to data availability. CILO, cilofexor; FIR, firsocostat; NAS, NAFLD Activity Score.

**Conclusion:** AIM-NASH enables automated, and sensitive ML-based CRN scoring, and generates reproducible assessments of disease activity from biopsy samples. AIM-NASH may potentially support standardized evaluation of histologic end points in NASH clinical trials.

### OS-1780

#### Incidence rates of select outcomes among patients with non-alcoholic steatohepatitis (NASH) and evidence of fibrosis or cirrhosis

Monica Bertoia<sup>1</sup>, Erik Ness<sup>2</sup>, Thomas Capozza<sup>2</sup>, Lina Titievsky<sup>2</sup>, John D. Seeger<sup>1</sup>. <sup>1</sup>Optum Life Sciences, United States; <sup>2</sup>Intercept Pharmaceuticals, Inc., New York, United States  
Email: monica.bertoia@optum.com

**Background and aims:** There are limited epidemiologic data available characterizing patients with NASH using longitudinal data, and rates of rare events require a large patient sample. Electronic health record (EHR) databases represent useful real-world data sources for studying the epidemiology of NASH. This study aimed to systematically estimate incidence rates (IRs) of over 40 a priori outcomes within a cohort of patients with NASH.

**Method:** Patients with NASH were identified between 2016 and 2019 within Optum's EHR Research Database by structured (diagnosis codes, procedure codes, labs) and natural language processing (NLP) data. Patients with NASH were classified as having cirrhosis or fibrosis using information from the baseline period (the year prior to and including cohort entry). Outcomes were identified in the time following cohort entry using International Classification of Diseases, 10<sup>th</sup> revision diagnosis codes and lab values. Outcome IRs were estimated among the subset of patients at risk for that particular outcome at the beginning of follow-up (after excluding those with a prior history).

**Results:** Among 93, 204 patients identified as having NASH, 44, 685 (48%) had evidence of fibrosis and 29, 770 (32%) had evidence of cirrhosis. Patients with NASH were an average of 58 years old, 60% were female, and 81% were white. Estimated IRs of select outcomes are summarized in Table. IRs were highest for NASH patients with cirrhosis. IRs of kidney and cardiovascular outcomes were up to ~2-fold higher for patients with cirrhosis compared to those with fibrosis, and IRs of liver outcomes were several-fold higher.

Table: Incidence rates (95% CIs) per 1, 000 person-years of select outcomes among patients with NASH

	NASH with Fibrosis N = 44, 685	NASH with Cirrhosis N = 29, 770
Chronic kidney disease	98.31 (95.57–102.28)	215.46 (209.41–224.2)
Cerebrovascular accident	15.81 (14.84–17.26)	23.83 (22.3–26.11)
Myocardial infarction	12.08 (11.24–13.34)	26.65 (25.03–29.05)
Liver transplant	0.09 (0.03–0.25)	2.70 (2.22–3.5)
Hepatocellular carcinoma	0.91 (0.69–1.29)	7.31 (6.49–8.58)

**Conclusion:** This large EHR-based cohort of patients with NASH provides estimated IRs with narrow CIs even for rare outcomes such as liver transplant and hepatocellular carcinoma. These results showing a higher risk of various outcomes with more advanced fibrosis add to the evolving body of literature on the impact of hepatic fibrosis in patients with NASH.

Email: jesusriveraest@gmail.com

**Background and aims:** Metabolic associated fatty liver disease (MAFLD) has become a major public health problem, but the prevalence in the general population of fibrosis associated to non-alcoholic steatohepatitis (NASH) is largely unknown. The aim of this study was to provide an updated estimation of the prevalence of NASH fibrosis in Spain.

**Method:** This is an observational, retrospective, cross-sectional, population-based study. For the prevalence estimations, data was merged from 2 Spanish datasets: a large (N = 12246) population-based cohort (ETHON cohort), including transient elastography (TE) data, and a contemporary multi-centric biopsy-proven NASH cohort with paired TE data from tertiary centers (N = 501).

**Results:** From the ETHON dataset of patients with valid TE, 5.61% (95% Confidence Interval –95CI- 2.53–11.97) had a liver stiffness measurement (LSM) ≥8 kPa. The proportion attributable to MAFLD (using clinical variables and Controlled Attenuation Parameter data) was 57.3%. The estimated prevalence attributable to MAFLD in the population with LSM ≥8 kPa was 3.21% (95CI 1.13–8.75). In the cohort of patients with biopsy-proven NASH, 389 had LSM ≥8 kPa and among these, 36% did not have significant fibrosis (F2-4). Even at the highest interval (LSM ≥20 kPa), there was a substantial proportion of patients without cirrhosis (39%) in this biopsy-proven cohort. Prevalence for each NASH fibrosis stage in Spain was estimated by crossing TE data from ETHON with histology data from the biopsy-proven cohort and detailed in the table. The estimated prevalence of NASH F2-3 and cirrhosis in Spain's adult population were 1.33% (95CI 0.29–5.98) and 0.70% (95CI 0.10–4.95), respectively.

**Conclusion:** These estimations provide an accurate picture of the current prevalence of NASH in Spain and can serve as reference point for European populations for dimensioning the therapeutic efforts that will be required as NASH therapies become available.

Figure: Liver fibrosis distribution per LSM threshold and NASH prevalence per fibrosis stages in Spain's general population:

FIBROSIS STAGES	NASH FIBROSIS PREVALENCE (%)				
	LSM ≥8 kPa (%)	LSM ≥8 kPa (95%CI)	SIGNIFICANT FIBROSIS (F2-F4)	TREATABLE STAGES (F2-F3)	CIRRHOSIS (F4)
F0	13.37	0.43 (0.04–4.49)			
F1	23.39	0.75 (0.11–5.04)			
F2	17.99	0.58 (0.07–4.75)	2.03	1.33	
F3	23.39	0.75 (0.11–5.04)	(0.56–7.05)	(0.29–5.98)	
F4	21.85	0.70 (0.10–4.95)			0.70 (0.10–4.95)
TOTAL	100	3.21 (1.13–8.75)

**Background and aims:** Accurate staging of fibrosis in NAFLD is essential for clinical care delivery and trial recruitment. There is a pressing need for robust, comparative analysis on performance of non-invasive tests (NITs). The LITMUS project independently validated NITs that, singly or in combination, enable detection of high-risk NAFLD patients.

**Method:** Comparative diagnostic accuracy study in the LITMUS Metacohort, including biopsy-proven NAFLD patients in Europe, recruited 2010–18. Fibrosis was staged by the NASH CRN score. Biopsies were locally read. Sixteen NITs, including single markers and

## ORAL PRESENTATIONS

combinations were evaluated against liver biopsy for three target conditions: significant fibrosis ( $F \geq 2$ ), advanced fibrosis ( $F \geq 3$ ), and cirrhosis (F4). The area under the receiver operating curve (AUC)  $\pm$  95% confidence interval were calculated for each NIT in comparison to FIB-4 in the same patients.

**Results:** Data from 686 participants (nine centers) were included. Mean age 50 yrs; 57% male; 36% T2DM; mean BMI 35. Fibrosis: 44%  $F \geq 2$ , 26%  $F \geq 3$ , and 7% F4. Most combination panels (ELF, MACK-3, FIB3, ABC3D, NFS) had comparable accuracy to FIB-4, while single markers (PRO-C3, CK18, etc.) performed significantly worse. AUCs for  $F \geq 2$  ranged from 0.54 to 0.86 with only the SomaScan™ model significantly outperforming FIB-4. For  $F \geq 3$  (AUC: 0.53–0.85) SomaScan and ADAPT had significantly better AUC compared to FIB-4. The AUCs for several NITs exceeded 0.80 in detecting F4 (AUC: 0.53–0.90), most of which were combinations (Table 1).

Table 1: Accuracy of NITs in detecting fibrosis compared to FIB-4

NIT.	n.	AUC (95% CI).					
		$F \geq 2$ .		$F \geq 3$ .		F4.	
		NIT.	FIB-4.	NIT.	FIB-4.	NIT.	FIB-4.
SomaScan	278	0.86 (0.82–0.90)	0.69 (0.63–0.75)	0.89 (0.85–0.93)	0.74 (0.69–0.80)	0.88 (0.80–0.96)	0.81 (0.75–0.88)
ADAPT	417	0.78 (0.74–0.83)	0.74 (0.70–0.79)	0.85 (0.81–0.89)	0.76 (0.71–0.82)	0.90 (0.85–0.95)	0.83 (0.76–0.91)
MACK-3	391	0.79 (0.74–0.84)	0.73 (0.68–0.78)	0.80 (0.75–0.85)	0.77 (0.72–0.83)	0.71 (0.59–0.82)	0.84 (0.76–0.92)
ELF	673	0.69 (0.65–0.73)	0.74 (0.70–0.77)	0.78 (0.74–0.82)	0.78 (0.74–0.82)	0.83 (0.76–0.90)	0.85 (0.79–0.91)
PRO-C3	431	0.67 (0.62–0.72)	0.75 (0.70–0.79)	0.75 (0.69–0.80)	0.77 (0.72–0.82)	0.80 (0.72–0.88)	0.83 (0.76–0.91)

**Conclusion:** NITs performed well, especially for detecting cirrhosis (F4). For intermediate fibrosis stages ( $F \geq 2$ ,  $F \geq 3$ ), combination panels exhibited the highest AUCs. SomaScan and ADAPT had greater sensitivity than FIB-4 for intermediate stages, while the ELF test offered no advantage over FIB-4. Validation in an expanded cohort is underway.

**Background and aims:** Non-alcoholic fatty liver disease (NAFLD) is a spectrum of chronic liver diseases intertwined with the metabolic disorders. The prevalence of NAFLD is rapidly increasing worldwide, while the pathology and the underlying mechanism driving NAFLD is not fully understood. In NAFLD, a series of metabolic changes takes place in the liver. However, the alteration of the metabolic pathways in the human liver along the progression of NAFLD, *i.e.*, transition from non-alcoholic steatosis (NAFL) to steatohepatitis (NASH) through cirrhosis remains to be discovered. Here, we sought to examine the metabolic pathways of the human liver across the full histological spectrum of NAFLD.

**Method:** We analyzed the whole liver tissue transcriptomic (RNA-Seq)<sup>1</sup> and serum metabolomics data obtained from a large cohort of histologically characterized patients derived from the European NAFLD Registry (n = 206), and developed genome-scale metabolic models (GEMs) of human hepatocytes at different stages of NAFLD. The integrative approach employed in this study has enabled us to understand the regulation of the metabolic pathways of human liver in NAFL, and with progressive NASH-associated fibrosis (F0–F4).

**Results:** Our study identified several metabolic signatures in the liver and blood of these patients, specifically highlighting the alteration of vitamins (A, E) and glycosphingolipids, and their link with complex glycosaminoglycans in advanced fibrosis. Furthermore, by applying genome-scale metabolic modeling, we were able to identify the metabolic differences among carriers of widely validated genetic variants associated with NAFLD/NASH disease severity in three genes (PNPLA3, TM6SF2 and HSD17B13).

**Conclusion:** The study provides insights into the underlying pathways of the progressive-fibrosing steatohepatitis. Of note, there is a marked dysregulation of the glycosphingolipid metabolism in the liver of the patients with advanced fibrosis.

Email: wongv@cuhk.edu.hk

**Background and aims:** FibroScan<sup>®</sup> liver stiffness measurement (LSM) and controlled attenuation parameter (CAP) combined with aspartate aminotransferase (AST)-known as FibroScan-AST (FAST)-is a non-invasive method to identify patients with non-alcoholic steatohepatitis (NASH) at risk of progressive disease. Here, we evaluate whether changes in FAST correlate with histological changes in placebo and semaglutide-treated patients with NASH.

**Method:** In a 72-week phase 2 trial (NCT02970942), 320 patients with NASH and F1-F3 fibrosis were randomised to semaglutide (0.1, 0.2 or 0.4 mg) or placebo. Treatment with semaglutide 0.4 mg showed significant NASH resolution and a non-significant trend for fibrosis improvement vs placebo. This *post-hoc* analysis compared changes in FAST score from baseline to week 72 with histological change in non-alcoholic fatty liver disease activity score (NAS, using

analysis of covariance) and other clinical parameters (Kendall Tau-b correlations) in all randomised patients during the on-treatment period. Biopsies were performed at baseline and at week 72 to determine NAS and fibrosis stage.

**Results:** In total, 161 patients had FAST scores assessed at baseline and at week 72. Treatment with semaglutide for 72 weeks led to reductions in FAST score and the individual components (LSM, CAP and AST) in a dose-dependent manner. At week 72, mean reductions in FAST score (estimated treatment ratio vs placebo) were 0.7, 0.5 and 0.4 with semaglutide 0.1, 0.2 and 0.4 mg, respectively. Reductions in FAST scores for both placebo and semaglutide 0.4 mg were associated with resolution of NASH without worsening in fibrosis (primary end point), and improvements in NAS, steatosis and ballooning, but not lobular inflammation or improvement in fibrosis without worsening in NASH (Figure). A reduction in FAST score of  $\geq 0.2$  was identified as the cut-off point for improvement of  $\geq 1$  point in NAS (Youden's index; odds ratio (95% confidence interval): 25.3 [6.7; 166.9]). A decrease in FAST score of  $\geq 0.2$  from baseline to week 72 correlated with changes in NASH activity biomarkers (ALT, microRNA-122, interleukin-1 receptor antagonist, cytokeratin [CK] 18 M65, CK18 M30 antigen) and fibrosis biomarkers (Fibrosis-4, AST to platelet ratio index) (range: 0.30–0.64).

**Conclusion:** FAST score is associated with histological improvement of NASH activity, and may have potential as a non-invasive surrogate end point to monitor disease progression in patients with NASH.

Data are from all randomized patients during the on-treatment period. Response was defined by histology. \*p-value for comparisons between responders vs non-responders; CI, confidence interval; FAST, FibroScan-aspartate aminotransferase; N, number of patients; NA, not applicable; NAS, non-alcoholic fatty liver disease activity score; NASH, non-alcoholic steatohepatitis.

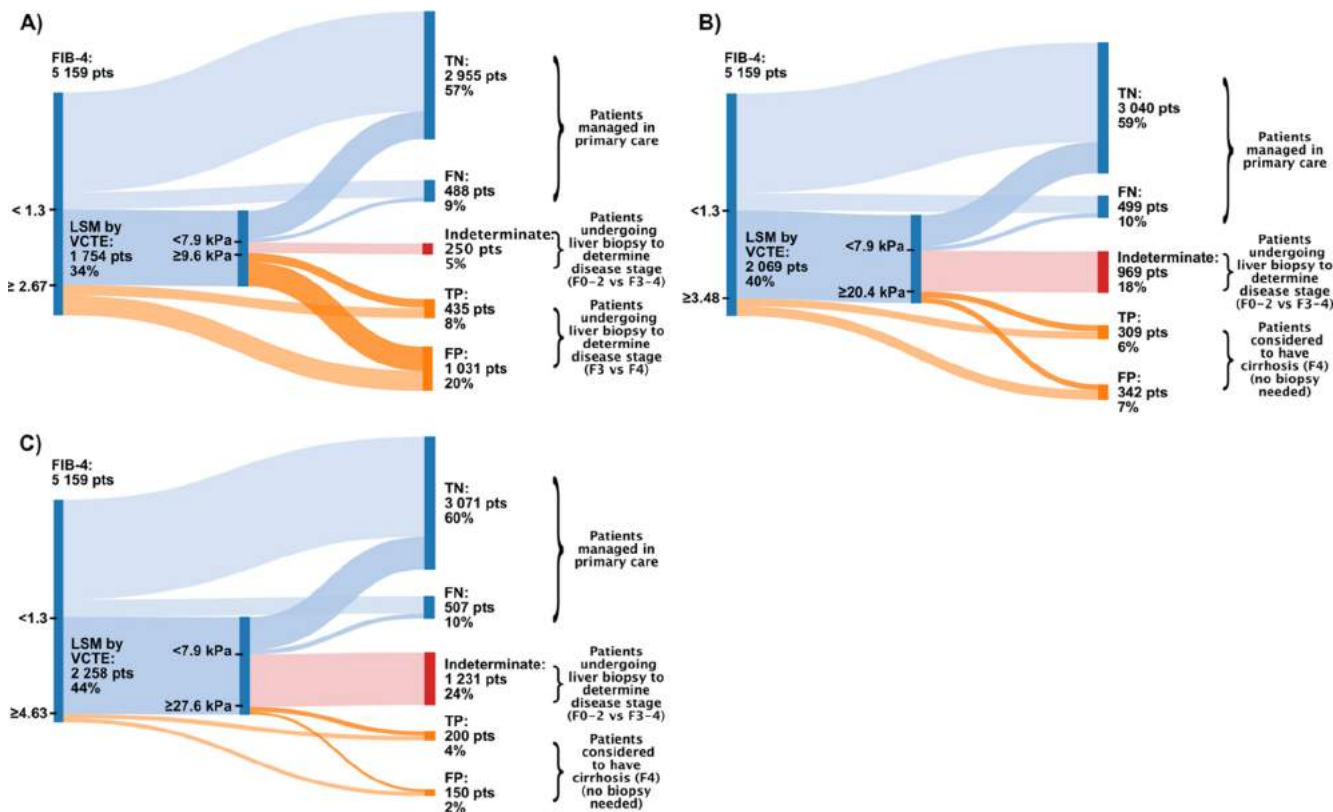

Figure 1: The distribution of the patients in true positive, true negative, false positive, false negative and indeterminate groups for a sequential combination of FIB-4 and LSM by VCTE. The lower cut-offs ruled out advanced fibrosis. The upper cut-off ruled in advanced fibrosis (A) or ruled in cirrhosis with 95% (B) and 98% (C) specificity.

## ORAL PRESENTATIONS

**Background and aims:** Non-invasive tests (NITs) can be used to identify patients with NAFLD at low risk of advanced fibrosis (AF) who can be managed in primary care. However, liver biopsy is still needed in patients where NITs are indeterminate or indicate high risk, to risk stratify and diagnose AF/cirrhosis respectively. Our aim was to perform an individual patient data meta-analysis to evaluate the performance of liver stiffness measurements by vibration controlled transient elastography (LSM-VCTE) and Fibrosis-4 index (FIB-4), and to propose algorithms that reduce the number of liver biopsies.

**Method:** After a systematic literature search for studies evaluating LSM-VCTE against liver histology, we contacted authors and collected data for LSM-VCTE, demographics, histology and lab parameters. FIB-4 was computed where possible. Diagnostic accuracy of NITs for AF was assessed using the area under the receiver operating curve (AUROC). Cut-offs were selected for 90% sensitivity (Se) and 90% specificity (Sp). Cut-offs from the literature were also evaluated. A strategy of using sequential application of NITs with lower cut-offs to rule out AF and upper cut-offs to rule in cirrhosis with 95% and 98% specificity were also tested.

**Results:** We included 5735 individual patient data from 37 primary studies (45% female, median age 54 years, median BMI 30 kg/m<sup>2</sup>; 33% type 2 diabetes; 30% AF, 11% cirrhosis). AUROCs for AF were 0.85 for LSM-VCTE and 0.76 for FIB-4 ( $p < 0.001$ ) and for cirrhosis 0.90 vs 0.80 ( $p < 0.001$ ). Cut-offs to diagnose AF for 90% Se and 90% Sp were respectively, 7.4 kPa (Sp 60%) and 12.1 kPa (Se 55%) for VCTE; 0.88 (Sp 39%) and 2.31 (Se 38%) for FIB-4. Cut-offs for cirrhosis at 95% and 98% Sp were respectively 20.4 kPa and 27.6 kPa for LSM-VCTE and 3.48 and 4.63 for FIB-4. The predefined literature cut-offs for LSM-VCTE (7.9 kPa; 9.6 kPa) and FIB-4 (1.3; 2.67) had Se 84% and Sp 78%, and Se 54% and Sp 91% respectively. Serial combinations of lower literature cut-offs to rule out advanced fibrosis and upper cut-offs to rule in cirrhosis led to a reduction in the number of cases needing liver biopsy from 33% to 18% (Figure 1).

**Conclusion:** Our results confirm the value of NITs as screening biomarkers to rule out AF. In addition, using upper cut-offs to rule in cirrhosis in sequential test combinations could reduce the number of patients undergoing biopsy in secondary care.

### OS-2362

#### Fibrosis biomarker performance in NAFLD is markedly improved by BMI-specific cut-offs

Email: sami.qadri@helsinki.fi

**Background and aims:** Guidelines recommend the use of FIB-4 or NFS for screening of advanced liver fibrosis in NAFLD. Age is known to influence diagnostic cut-offs, but whether obesity affects test performance is unknown. There are no data on the applicability of PRO-C3 derived direct biomarkers of fibrogenesis (ADAPT, FIBC3) in patients with obesity.

**Method:** We studied the impact of obesity on FIB-4 and NFS in 1256 patients with liver biopsy who were eligible for weight-loss surgery or referred to a hepatologist due to NAFLD (378 Finnish, 232 Italian, 646 Swedish, mean age 51 ± 12 years, mean BMI 32.3 ± 7.5 kg/m<sup>2</sup>). Additionally, we compared the performance of FIB-4, NFS, ADAPT, and FIBC3 to diagnose advanced fibrosis in the Finnish cohort (mean age 50 ± 9 years, mean BMI 40.3 ± 7.5 kg/m<sup>2</sup>).

**Results:** The AUC of FIB-4 (0.89) and NFS (0.77) for advanced fibrosis were unaffected by BMI. The specificity of NFS, but not FIB-4, deteriorated with higher BMI, decreasing from 83% in lean individuals to 9% in those with BMI over 40 kg/m<sup>2</sup> (Fig., left panel). We

Figure: (abstract: OS-2362)

developed and validated BMI-specific cut-offs for NFS to either rule in ( $\geq 95\%$  specificity) or rule out ( $\geq 85\%$  sensitivity) advanced fibrosis (Fig., middle panel). New cut-offs significantly improved the performance of NFS, with consistent sensitivity and specificity over the entire BMI range (Fig., right panel). ADAPT (AUC 0.89, sensitivity 79%, specificity 87%) and FIBC3 (AUC 0.86, sensitivity 61%, specificity 84%) performed similarly. They were overall more accurate than NFS and more specific than FIB-4 ( $p < 0.05$ ).

**Conclusion:** Obesity markedly influences the diagnostic performance of NFS, but not FIB-4. Thus, if using NFS to screen for advanced fibrosis in obese individuals, we recommend applying BMI-specific cut-offs. ADAPT and FIBC3 were marginally superior to FIB-4 in patients with obesity.

## NAFLD – Experimental and pathophysiology

**Background and aims:** Non-alcoholic fatty liver disease (NAFLD) is a leading cause of chronic liver disease and liver-related comorbidity and mortality. NAFLD has a strong inheritable component. The identification of genetic determinants leads to improvements in risk stratification and identification of therapeutic target. The aim of this study was to identify new genes involved in NAFLD pathogenesis.

**Method:** We performed whole-exome sequencing in 301 patients with NAFLD and severe fibrosis or hepatocellular carcinoma (EPIDEMIC and Perspective cohorts), followed by variant prioritization based on in silico predictors. We replicated the results in the European Liver Biopsy Cohort (LBC, n = 2, 268) and the UK BioBank (UKBB) and we investigated the molecular mechanisms in a Liver Transcriptomic Cohort (LTC) of 125 obese patients.

**Results:** In the EPIDEMIC cohort vs. the general population, we detected an enrichment of the p.P426L variant (OR = 7.2, 95% c.i. 2–17; p < 0.001) of Autophagy Related Gene 7 (ATG7), a gene involved in lipo-autophagy and steatohepatitis development in mice. We further observed a higher burden of rare (OR = 13.9, 95% c.i. 1.9–611; p = 0.002) and unselected protein-coding mutations (p = 0.027) in the conserved C-terminal ATG7 domain, and an increased frequency of the p.V471A variant (MAF = 0.06 vs. 0.04, OR = 1.7, 95% c.i. 1.2–2.5; p = 0.003). In the UKBB cohort, p.V471A was associated with NAFLD (p = 0.009) and liver disorders (p = 0.004). In the LBC, we confirmed p.V471A association with severe fibrosis, particularly in patients with S3 steatosis (p = 0.002), and those carrying the PNL3A3 p.I148M variant (p = 0.03); p.V471A was an independent predictor of hepatocellular ballooning (p = 0.007). In the LTC ATG7 correlated with suppression of the TNF- $\alpha$  pathway, which conversely was upregulated in carriers of p.V471A. ATG7 protein was expressed in Kupffer cells and predominantly periportal hepatocytes, where the staining was marked around lipid droplets, and more intense in the presence of ballooning.

**Conclusion:** We identified a novel association of ATG7 variants with severe NAFLD. The mechanism may involve impairment of autophagy and facilitation of hepatocellular ballooning degeneration for the p.V471A variant.

Email: michael.dudek@tum.de

**Background and aims:** Non-alcoholic steatohepatitis (NASH) is a manifestation of systemic obesity-related metabolic disease, characterized by chronic sterile inflammation that causes liver disease. Although it is known that the adaptive immunity drives liver pathology in chronic infectious inflammation, the mechanisms of immune-mediated liver damage in NASH remain incompletely understood. The liver microenvironment is a source of factors as cytokines, nutrients and cell stress molecules that can affect transcriptional networks to balance effector functions in tissue-resident T cells. Here, we identify murine and human Foxo1<sup>low</sup>CXCR6<sup>+</sup>CD8<sup>+</sup> T cells as critical tissue-resident T cells causing liver damage in NASH after sequential IL-15 and metabolic activation.

**Method:** A murine model of NASH (choline-deficient high-fat diet) with antibody intervention studies was used to explore mechanisms of T cell immunopathology *in vivo*. Single-cell and bulk RNA-seq, flow cytometry and cytotoxicity assays were performed to study immunity of murine and human CXCR6<sup>+</sup>CD8<sup>+</sup> T cells and its dependence on Foxo1 *in vitro* and *ex vivo* studies.

**Results:** In livers of NASH mice, CD8 T cells accumulated with a phenotype that combined tissue-residency (CXCR6) with effector (Granzymes) and exhaustion (PD-1) characteristics. Liver CXCR6<sup>+</sup>CD8 T cells were characterized by low Foxo1 transcription factor activity and were abundant in mouse and human NASH. Mechanistically, IL-15 induced Foxo1 down- and CXCR6 up-regulation, which rendered CXCR6<sup>+</sup>CD8 T cells tissue-resident and susceptible to local metabolic stimuli in NASH livers, including acetate and extracellular ATP. This collectively triggered MHC-independent CD8 T cell auto-aggression killing hepatocytes through TNF and FasL. Antibodies blocking the activity of TNF, FasL or IL-15 significantly ameliorated liver damage in NASH mice. Importantly, CXCR6<sup>+</sup>CD8 T cells from mouse and human NASH livers had similar transcriptional signatures and showed auto-aggressive killing of cells in an MHC-class-I-independent fashion after signaling through P2X7 purinergic receptors.

Figure:

**Conclusion:** We identify a novel pathway of T cell activation and T-cell mediated tissue-pathology that we termed auto-aggression. Distinguishing auto-aggressive from protective T cell immunity will help to design targeted immune intervention therapies for NASH while preserving immune surveillance against infection and cancer.

**OS-768**

**A first-in-class small molecule targeting 17-beta-hydroxysteroid dehydrogenase 13 for the treatment of non-alcoholic steatohepatitis**

Ji Won Choi<sup>1</sup>, Jin Woo Jung<sup>1</sup>, Chanwoo Park<sup>1</sup>, Jiyeon Park<sup>1</sup>, Hyeim Jo<sup>1</sup>, Seong Il Choi<sup>1</sup>, Somlee Park<sup>1</sup>, Seung-chul Lee<sup>1</sup>, Dong-hyun Ko<sup>1</sup>, Dong-Kyu Kim<sup>1</sup>. <sup>1</sup>HK inno.N Corporation, RandD Center, Icheon-si, Korea, Rep. of South  
Email: dongkyu.kim@kolmar.co.kr

**Background and aims:** Human genetic studies identified an association of single nucleotide polymorphisms in the hydroxysteroid 17-beta dehydrogenase 13 (HSD17B13) gene with non-alcoholic fatty liver disease (NAFLD) and HCC development. Recently, the study of human liver lipidome and transcriptome revealed that a loss-of-function variant in HSD17B13 increase hepatic phospholipids, especially phosphatidylcholines and phosphatidylethanolamines, and decrease fibrosis. Thus, we tried to approach to make a HSD17B13 protein (17-beta-hydroxysteroid dehydrogenase 13, 17beta-HSD13) inhibitor, as a first-in-class small molecule, and identified a potent 17beta-HSD13 inhibitor, Compound A.

**Method:** To determine the in vitro enzyme potency, Compound A was assessed using NAD/NADH-Glo™ assay. In vitro cell efficacy of Compound A were determined by measuring mRNA expression of alpha-smooth muscle actin (alpha-SMA) after treatment with tumor growth factor-beta (TGF-beta) in both normal and HSD17B13-overexpressed LX-2 hepatic stellate cells. C57BL/6 were given either a normal diet or choline-deficient, L-amino acid-defined high-fat diet (CDAHFD) for 14 weeks. After 7 weeks of being fed CDAHFD, mice were administered orally with Compound A for 7 weeks. Mice plasma were analyzed by Biochemistry Analyzer and NAFLD activity score (NAS) and liver fibrosis stage were graded by pathologist.

**Results:** Compound A inhibits the 17beta-HSD13 and significantly decreased mRNA level of alpha-SMA in normal and HSD17B13-overexpressed LX-2 cells. In CDAHFD model, Compound A improved lipid profiling, decreased alanine aminotransferase, lactate dehydrogenase, and liver to body weight ratio. Especially, administration of Compound A dramatically recovered liver morphology and significantly decreased NAS in CDAHFD-fed mice.

◆ CDAHFD model

Figure:

**Conclusion:** Compound A, a first-in-class oral small molecule targeting 17beta-HSD13, decreased the NAS and recovered liver function in CDAHFD model. It is suggested that Compound A could be a potent therapeutic agent for the treatment of non-alcoholic steatohepatitis.

**OS-1028**

**Background and aims:** Non-alcoholic fatty liver disease (NAFLD) is a silent pandemic associated with obesity and the metabolic syndrome, and is linked to increased cardiovascular- and cirrhosis-related morbidity and mortality. It remains debated whether activation of Sterol Regulatory Element-Binding Proteins (SREBPs) act as a pathogenic drivers of lipotoxicity in non-alcoholic steatohepatitis (NASH), or promote the biosynthesis of protective lipids that buffer excessive lipid accumulation, thus preventing inflammation and fibrosis. We aimed to better understand these adaptive compensatory metabolic programs that modulate NAFLD pathophysiology and NASH progression.

**Method:** To understand the role of lipid/cholesterol synthesis/remodelling pathways in NASH progression, we employed

## ORAL PRESENTATIONS

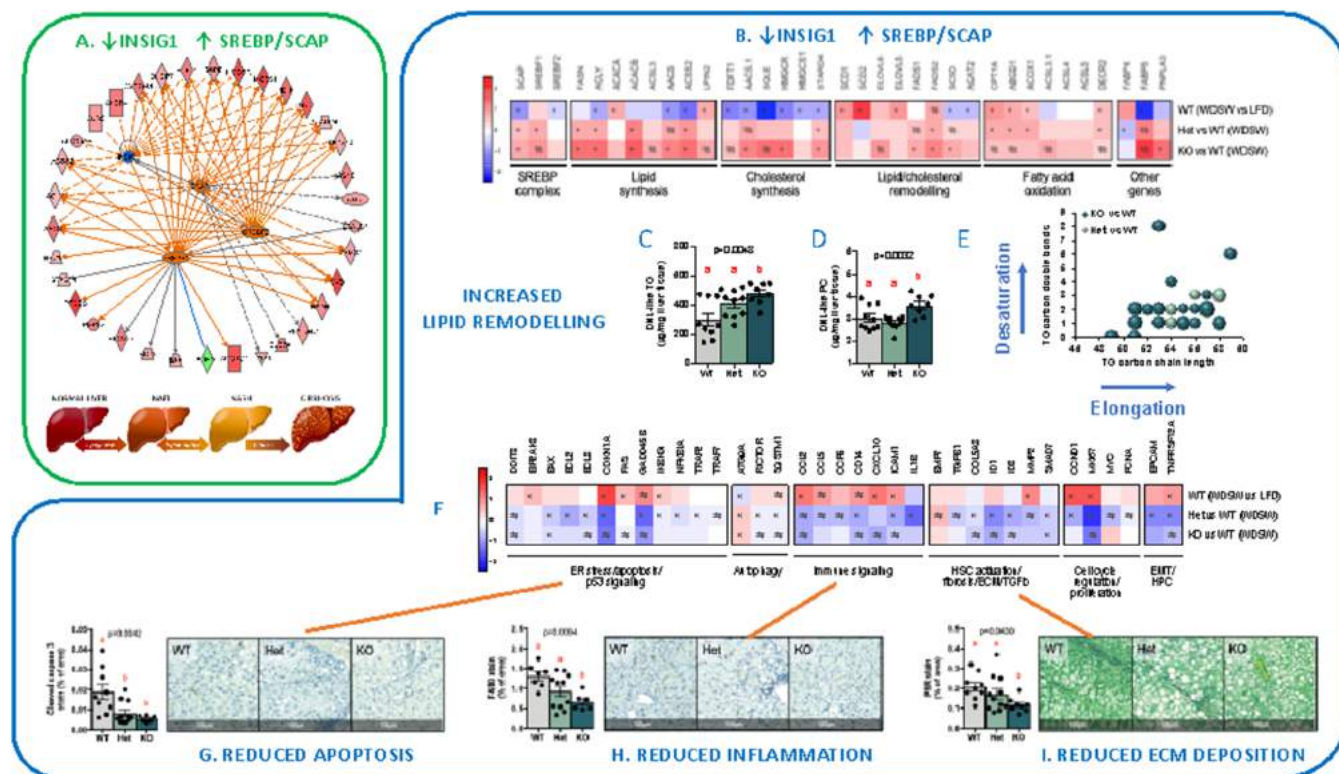

Figure: (abstract: OS-1028): **Upregulation of SREBP metabolic pathways is seen in patients with advanced NASH and mediates hepatic protection from diet induced NASH in mice.** (A) Network-like representation of IPA Upstream Regulator Analysis of human liver transcriptome shows strong SREBP/SCAP pathway upregulation that is associated with predicted INSIG1 downregulation in advancing NASH. (B–H) Mice treated with WDSW: *Insig1* ablation results in upregulation of lipid/cholesterol synthesis (B), shown by *Fasn*-mediated increase in DNL-TG (C) and DNL-PC (D), as well as lipid remodelling shown by desaturation and elongation of carbon chains (E). These lipidome changes correlate with reduced ER stress, apoptosis, inflammation and HSC activation/collagen deposition (F: NGS; G–H: IHC; I: PSR).

transcriptomic analysis of NAFLD patients' liver biopsies coupled with reverse translation in *INSIG1* deficient mice (which display hyperefficient SREBPs activation) challenged with a preclinical murine model of mild NASH (Western Diet Sugar Water, WDSW-12 weeks). Mice were phenotyped with a multiomics systems biology approach.

**Results:** Clustering the data against NASH progression, Ingenuity Pathway Analysis of hepatic transcriptome showed substantial rewiring of metabolic pathways: SREBPs transcriptional networks and *de novo* lipid/cholesterol synthesis and remodelling were predicted to be activated (Fig. 1A). In WDSW, *Insig1* KO mice had similar systemic metabolism and insulin sensitivity to Het/WT littermates; however, the hyperefficient SREBPs activity in KO mice led to enhanced lipid/cholesterol biosynthesis (Fig. 1B–D) and remodelling (Fig. 1B, E) and restrained NASH progression as a result of decreased apoptotic hepatocellular damage and inflammation, resulting in decreased extracellular matrix deposition (Fig. 1F–I).

**Conclusion:** Our results suggest that the SCAP/SREBP/INSIG1 trio governs transcriptional programs aimed at protecting the liver from lipotoxic insults in NASH and provides knowledge about NAFLD pathogenesis that may prove useful for the development of new therapeutic strategies.

### OS-1524

#### Acetyl-CoA metabolism drives epigenome change in liver steatosis leading to widespread abnormal transcription, DNA damage and promotion of hepatocarcinogenetic pathways

Gabriella Assante<sup>1,2</sup>, Aikaterini Tournia<sup>1,2</sup>, Shilpa Chokshi<sup>1,2</sup>, Nigel Turner<sup>3</sup>, J.W.O Ballard<sup>3</sup>, Margaret Morris<sup>3</sup>, Neil Youngson<sup>1,2,3</sup>.  
<sup>1</sup>Institute of Hepatology, Foundation for Liver Research, London, United Kingdom; <sup>2</sup>Kings College London, London, United Kingdom; <sup>3</sup>UNSW Sydney, Australia

Email: n.youngson@researchinliver.org.uk

**Background and aims:** Pathology-associated epigenetic and transcriptional changes in steatotic hepatocytes are currently thought to be caused by programmed cellular responses to lipotoxic processes such as oxidative stress and endoplasmic reticulum stress. However, due to the strong mechanistic links between energy metabolism and epigenetics, we investigated whether genome-wide epigenetic change could be considered an independent pathological process, and thus a novel driver of steatosis-associated transcriptional change and DNA damage.

**Method:** Genome-wide transcription and epigenetic state was examined in two rodent models of diet-induced fatty liver. To dissect the relationship between metabolism, epigenetics and transcription, steatosis was induced in immortalized human hepatocytes by supplementation with oleic acid. The hepatocytes were also treated with inhibitors of enzymes that produce acetyl-CoA from acetate, pyruvate and beta-oxidation. Imaging of whole genome chromatin state was performed with a DNaseI sensitivity assay, and DNA damage was visualised by gamma H2AX immunofluorescence. Chromatin immunoprecipitation and next-generation sequencing (ChIP-seq) was performed to identify regions of the genome which

are prone to steatosis-associated H4K16 acetylation and gamma H2AX.

**Results:** Liver triglyceride levels were more than double those of control animals after 6 months of high-fat diet in rats and 8 weeks of high-fructose diet in mice. Transcriptome and histone analysis in livers of rodent models of MAFLD confirmed that steatosis is associated with genome-wide loss of transcriptional repression and increased histone acetylation. *In vitro*, steatosis was associated with relaxed chromatin across the genome and increased gamma H2AX. ChIP-seq revealed that steatosis-associated gamma H2AX was enriched at highly expressed genes in pathways such as fat metabolism, histone acetylation and oxidative stress. Furthermore, known HCC tumour suppressor genes had increases in H4K16 acetylation and gamma H2AX. Finally, steatosis-associated gamma H2AX was reversed through inhibition of acetyl-CoA anabolism.

**Conclusion:** Our data point to metabolism-driven genome-wide epigenetic change being a new pathological mechanism in liver steatosis which promotes cellular dysfunction and carcinogenesis.

OS-1746

**Cilofexor and firsocostat treatment is associated with widespread changes in the hepatic transcriptome in NASH patients with advanced fibrosis**

Yevgeniy Gindin<sup>1</sup>, Jay Chuang<sup>1</sup>, Ling Han<sup>1</sup>, Catherine Jia<sup>1</sup>, Ryan Huss<sup>1</sup>, Chuhan Chung<sup>1</sup>, Robert Myers<sup>1</sup>, Simone Strasser<sup>2</sup>, Vincent Wai-Sun Wong<sup>3</sup>, Naim Alkhoury<sup>4</sup>, Kris Kowdley<sup>5</sup>, Mazen Nouredin<sup>6</sup>, Rohit Loomba<sup>7</sup>. <sup>1</sup>Gilead Sciences, Foster City, United States; <sup>2</sup>Royal Prince Alfred Hospital and The University of Sydney, Australia; <sup>3</sup>Department of Medicine and Therapeutics, The Chinese University of Hong Kong, Department of Medicine and Therapeutics, China; <sup>4</sup>Arizona Liver Health, Chandler, United States; <sup>5</sup>Liver Institute Northwest, Seattle, United States; <sup>6</sup>Cedars-Sinai Medical Center, Fatty Liver Program, Los Angeles, United States; <sup>7</sup>University of California at San Diego, NAFLD Research Center, United States  
Email: yevgeniy.gindin@gilead.com

**Background and aims:** In the phase 2b ATLAS study, the combination of the ACC inhibitor firsocostat (FIR) and the FXR agonist cilofexor (CILO) led to histologic improvement in patients with advanced fibrosis (F3-F4) due to NASH. We investigated hepatic transcriptomic changes with treatment and associations with histologic responses and serum biomarkers.

**Method:** FFPE tissue blocks of liver biopsies were obtained from NASH patients with F3-F4 fibrosis in the ATLAS trial (NCT03449446). Fibrosis stage and the NAFLD Activity Score (NAS) were assessed at baseline (BL) and Week 48 (W48) by a central pathologist. Extracted RNA was used to quantify gene expression by RNA-seq. We evaluated gene expression and transcriptome pathway activity (ssGSEA score) at BL and summarized longitudinal changes by treatment group at W48. Transcriptomic pathways were from the Hallmark collection (Broad Institute). Pearson correlations between changes in transcriptome pathways and serum biomarkers were calculated. p values were adjusted using the Benjamini-Hochberg procedure to control the FDR at 0.1.

**Results:** Compared to BL, CILO+FIR treatment (n=41) for 48 weeks was associated with significant up-regulation of 1015 genes and down-regulation of 320 genes, whereas no changes were observed with placebo (n=20). Placebo-adjusted transcriptome pathway analysis demonstrated 20 significantly affected pathways with CILO+FIR, of which 8 were influenced by CILO treatment, 6 with FIR, and 3 were shared across treatment groups (Figure). The most up-regulated genomic pathway associated with CILO+FIR treatment was related to oxidative phosphorylation, whereas statistically significant changes in pathways or individual genes related to fibrosis (e.g., *COL1A1*, *COL1A2*, *TIMP1*, *ACTA2*, *TGFB*, and *PDGF*) were not observed. Integration of pathway analysis and serum biomarkers revealed significant inverse associations between changes in the bile acid metabolism pathway and serum total bile acids (r= -0.42),

chenodeoxycholic acid (r= -0.41), and primary bile acids (r= -0.41) (all p < 0.05). Changes in the TNF- $\alpha$  signaling pathway, which was reduced by the combination of CILO+FIR, were associated with changes in the NAS (r= 0.39; p < 0.05) and fibrosis stage (r= 0.35; p= 0.1).

Figure: Each bar, representing log-fold- change (FC) for the pathway activity score, is divided to show the log-FC observed in each group. All depicted pathways are significantly affected by CILO+FIR treatment. Pathways that are also affected by the monotherapies are indicated with C (CILO) and/or F (FIR).

**Conclusion:** In NASH patients with advanced fibrosis, the combination of CILO+FIR led to widespread changes in hepatic gene expression and transcriptomic pathways. Significant associations were observed between changes in gene expression pathways and bile acid metabolism and inflammation with serum bile acids and changes in the NAS score, respectively.

OS-2450

**First in class, orally active Toll-like receptor signaling inhibitor mosedipimod (PLAG) attenuates molecular, biochemical and histological features of non-alcoholic steatohepatitis (NASH) in vitro and in vivo**

Jinseon Jeong<sup>1</sup>, Young Eun Ko<sup>2</sup>, Su-Hyun Shin<sup>3</sup>, Kaapjoo Park<sup>3</sup>, Ki -Young Sohn<sup>3</sup>, Sun Young Yoon<sup>1</sup>, Jae Wha Kim<sup>2</sup>, Michael Charlton<sup>4</sup>. <sup>1</sup>Enzychem Lifesciences, Korea, Rep. of South; <sup>2</sup>Korea Research Institute of Bioscience and Biotechnology, Korea, Rep. of South; <sup>3</sup>Enzychem Lifesciences; <sup>4</sup>University of Chicaco, Center for Liver Diseases, Chicaco, United States  
Email: mcharlton@medicine.bsd.uchicago.edu

**Background and aims:** There are no currently approved pharmacotherapies for non-alcoholic steatohepatitis (NASH). There is increasing evidence of an important role of the Toll-like receptors (TLRs) in initiation of the fibro-inflammatory cascade in NASH. Attenuating TLR signaling represents an attractive pharmacological strategy to prevent and reverse hepatic fibrosis. The acetylated diacylglycerol 1-palmitoyl-2-linoleoyl-3-acetyl-rac-glycerol (PLAG, chemical name mosedipimod), is an orally active synthetic mono-acetyl-diglyceride that has been shown to attenuate TLR signaling.

**Method:** We studied the effects of mosedipimod on molecular, metabolic and histologic facets of NASH in two nutrient-based murine models: a high-fat, high-fructose (HFHF) model of steatosis and inflammation, and the STAM™ model of fibrosing NASH. Effects

## ORAL PRESENTATIONS

of PLAG on palmitic acid-induced TLR4 signaling were also studied *in vitro*. In the STAM™ model, effects of PLAG were compared to two agents in advanced clinical trials, obeticholic acid (OCA) and resmetirom (MGL-3196).

**Results:** Mosedipimod significantly mitigated HFHF diet-induced hepatic steatosis, reducing lipogenesis-associated signaling, as measured by mRNA expression levels of ChREBP, SREBP-1c and FAS ( $p < 0.05$ – $0.001$ ), indicating attenuation of *de novo* lipogenesis by mosedipimod. Mosedipimod also reduced surface level expression of TLR4 and decreased TNF- $\alpha$ , IL-6 and MIP-2 levels ( $p < 0.05$ – $0.001$ ). Mosedipimod treatment significantly decreased hepatic inflammation (as measured by F4/80), NAFLD activity score (NAS) and fibrosis (Sirius red surface area %, see figure) on end of treatment liver biopsies ( $p < 0.05$ – $0.001$ ). PLAG demonstrated similar effects to OCA and resmetirom in reducing hepatic steatosis, inflammation, NAS and fibrosis compared with the vehicle group.

Figure:

**Conclusion:** Mosedipimod/PLAG mitigates the HFHF diet-induced hepatic injury and inflammatory cytokine production by modulating TLR4-dependent signaling pathways. Mosedipimod also prevents the histological and metabolic effects of NASH to a degree comparable to OCA and resmetirom in a widely utilized preclinical model. Taken together these data identify mosedipimod/PLAG, through a TLR4 signaling dependent mechanism, as a potential therapy for NASH that merits clinical investigation.

### OS-2831

**Background and aims:** Activation of hepatic progenitor cells (HPCs), observed as ductular reaction, in response to parenchymal tissue damage has been associated with advanced non-alcoholic fatty liver disease (NAFLD) and portal infiltrating immune cells. Yet, the role of HPCs in the progression of NAFLD is still unclear. This study aims to investigate the biological relevance and prognostic value of HPCs in steatohepatitis (NASH) development and fibrosis progression.

**Method:** A total of 279 patients were included in this study. HPCs and matching hepatocytes were isolated from end-stage NAFLD using laser microdissection and processed for RNA sequencing (RNAseq). Gene signature clustering was performed on a RNAseq cohort of 206 NAFLD patients representing the entire NAFLD spectrum. Cell of origin was determined using publicly available single cell RNAseq and targets were validated using cyclic multiplex immunofluorescence and functionally assessed using ex-vivo human liver slices. In a subgroup of NASH F2/F3 patients with a baseline and a follow-up biopsy at least one year apart, HPC immunophenotype was correlated with clinico-pathological prognostic features. The histological semi-quantitative NASH CRN system was used to score NAFLD biopsies.

**Results:** High-throughput RNAseq of the HPC niche in end-stage NASH F4 identified 3, 282 differentially expressed genes correlating to a strong pro-inflammatory immune response and tissue remodelling (genes such as *CCR2*, *CCL2*, *CD44*, *SPP1*, *CXCL6*, *S100A6*). Interestingly, this HPC signature stratified the 206 NAFLD patients into distinct clusters characterised by a gradual increase in the presence of NASH, disease activity score (ballooning and inflammation), fibrosis stage and AST levels. Integrated single cell RNAseq analysis and protein level validation showed that HPCs themselves express pro-inflammatory cytokines such as *CCL2* and *SPP1*. Moreover, ex-vivo HPC expansion in human liver slices resulted in an increased release of *CCL2* and *SPP1*. Moreover, comparing baseline and follow-up liver biopsies, the presence of HPCs in the parenchyma at baseline was significantly associated with progression of at least 1 fibrosis stage.

**Conclusion:** Pro-inflammatory HPCs are associated with disease activity and inflammation, and predict fibrosis progression in NAFLD patients. Further assessment of the HPC phenotype may prove important for both stratifying patients at risk at baseline and for the design of targeted therapies to patients with high likelihood of disease progression.

**OS-427**

**Human proof-of-concept in non-alcoholic liver disease (NAFLD) patients with PXL770, a novel first-in-class direct AMP-kinase activator – STAMP-NAFLD Phase 2a trial**

Kenneth Cusi<sup>1</sup>, Julie Dubourg<sup>2</sup>, David Moller<sup>2</sup>, Sébastien Bolze<sup>2</sup>, Sophie Bozec<sup>2</sup>, Pascale Fouqueray<sup>2</sup>, Stephen Harrison<sup>3</sup>, Vlad Ratziu<sup>4</sup>.  
<sup>1</sup>University of Florida, Division of Endocrinology, Diabetes and Metabolism, Gainesville, United States; <sup>2</sup>Poxel SA, Lyon, France; <sup>3</sup>Summit Clinical Research, San Antonio, United States; <sup>4</sup>Institute for Cardiometabolism and Nutrition, Paris, France  
 Email: kenneth.cusi@medicine.ufl.edu

**Background and aims:** AMPK activation enhances lipid catabolism, insulin sensitization, and inhibits inflammation and fibrosis. PXL770 is a potent direct allosteric AMPK activator. In rodent models of NASH and type 2 diabetes (T2D) it reduces: steatosis, ballooning, inflammation and fibrogenesis, and improves insulin sensitivity (euglycemic clamp) and normalizes HbA1c. Importantly, endogenous AMPK activity is suppressed in the setting of nutrient overload (including hyperglycaemia); therefore, increased response to an AMPK activator may be predicted to occur in patients with greater metabolic dysfunction. Our aim was to assess the efficacy and safety of PXL770 in a Ph2a study with presumed NASH patients.

**Method:** This was a 12-week randomized, double-blind, placebo-controlled trial to assess the efficacy and safety of PXL770 in patients with NAFLD. Adults with hepatic fat fraction of at least 10% at baseline (BL) when assessed by MRI-proton density fat fraction (MRI-PDFF) were eligible. Patients were randomly assigned 1:1:1 to receive PXL770 250 mg once-daily (QD), 250 mg twice-daily (BID), 500 mg QD or matching placebo (Pcb). The primary end point was relative change in hepatic fat by MRI-PDFF at week 12. Secondary end points included liver enzymes, glycemic parameters and safety.

**Results:** 387 patients were screened, and 121 patients were randomized. PXL770 produced a significant mean relative decrease of -18% in liver fat content (LFC, primary end point) from BL in the 500 mg QD dose group (p = 0.0036 vs. -0.7% change in Pcb). A greater proportion of patients who received PXL770 also achieved a >30% relative reduction in LFC compared to Pcb. PXL770 500 mg QD produced significant reductions in mean ALT (BL values 37–41 U/L). In patients with T2D (41–47% of each group), PXL770 treatment resulted in greater mean relative reductions in LFC (-27%; p = 0.004 vs. BL), ALT (-14.9 UI/L; p = 0.02 vs. Pcb) and AST (-9.9 UI/L; p = 0.02 vs. Pcb). In these well-controlled T2DM patients, significant placebo-adjusted decreases were observed in fasting glucose (-21.3 mg/dL) and HbA1c

(-0.64%) along with trends towards improved indices of insulin sensitivity. Adverse events were mostly mild or moderate and were balanced between groups. Safety in T2DM patients appeared similar to the whole trial population.

**Conclusion:** PXL770 is the first direct AMPK activator to be studied in patients with metabolic or liver disorders. These results support the potential utility of PXL770 in NASH-in particular for the large (~45–50%) subpopulation with coexisting T2DM where the severity and progression of disease is also associated with disproportionately high unmet medical need.

 Email: nakajima-tky@umin.ac.jp

**Background and aims:** Pemafibrate, a novel selective peroxisome proliferator-activated receptor alpha modulator (SPPARM alpha), has been approved in Japan for dyslipidemia. Pemafibrate reportedly improved non-alcoholic steatohepatitis (NASH) in model mice and serum liver parameters in patients with dyslipidemia. Thus, we aimed to assess the efficacy and safety of pemafibrate in patients with non-alcoholic fatty disease (NAFLD).

**Method:** This study was a randomized, double-blind, placebo-controlled, multicenter, 72-week, phase 2 clinical trial. The key inclusion criteria were liver fat content of ≥10%, by magnetic resonance imaging-estimated proton density fat fraction (MRI-PDFF); liver stiffness of ≥2.5 kPa, by magnetic resonance elastography (MRE); and elevated alanine aminotransferase (ALT) level. The patients were randomized to either pemafibrate (0.4 mg/day, BID) or placebo. The primary end point was percent change in liver fat content from baseline to week 24, and the key secondary end points were percent changes in liver stiffness and ALT level from baseline to week 72 and 24, respectively.

**Results:** Pemafibrate did not significantly alter liver fat content, however, liver stiffness and ALT level significantly decreased in

Table: (abstract: OS-681)

	Placebo (n = 60)			Pemafibrate (n = 58)		
	Week 24	Week 48	Week 72	Week 24	Week 48	Week 72
Liver fat content by MRI-PDFF	-4.2 (-11.6, 3.1)	-0.5 (-7.5, 6.5)	0.2 (-7.2, 7.7)	-5.3 (-12.8, 2.2)	0.5 (-6.7, 7.7)	-4.9 (-12.5, 2.8)

Data shows LS mean (95%CI) for % changes from baseline.

\*vs. placebo.

## ORAL PRESENTATIONS

pemafibrate compared to placebo (Table). Additionally, pemafibrate significantly improved lipid parameters (e.g., triglycerides, LDL-C). Pemafibrate showed no significant safety issues and it did not affect renal functions (e.g., serum creatinine).

**Conclusion:** In this proof-of-concept trial, pemafibrate improved liver stiffness by MRE and serum liver and lipid parameters despite not decreasing liver fat content. These results suggest that pemafibrate is a promising therapeutic agent for NAFLD/NASH.

### OS-931

#### Angiotensin-converting enzyme inhibitors/angiotensin receptor blockers is associated with lower risk of hepatocellular carcinoma and cirrhotic complications in patients with non-alcoholic fatty liver disease

Xinrong Zhang<sup>1</sup>, Vincent Wai-Sun Wong<sup>1</sup>, Terry Cheuk-Fung Yip<sup>1</sup>, Yee-Kit Tse<sup>1</sup>, Yan Liang<sup>1</sup>, Vicki Wing-Ki Hui<sup>1</sup>, Guanlin Li<sup>1</sup>, Huapeng Lin<sup>1</sup>, Henry Chan<sup>1</sup>, Grace Lai-Hung Wong<sup>1</sup>. <sup>1</sup>The Chinese University of Hong Kong, Department of medicine and therapeutics, Hong Kong  
Email: wonglaihung@cuhk.edu.hk

**Background and aims:** Angiotensin-converting enzyme inhibitors (ACEI) and angiotensin receptor blockers (ARBs) have been shown to inhibit hepatic stellate cells and liver fibrosis in animal studies. However, data from clinical studies are limited and inconclusive. This study aimed to evaluate the impact of ACEI/ARB use on the risk of hepatocellular carcinoma (HCC) and cirrhotic complications in a territory-wide cohort of NAFLD patients.

**Method:** We conducted a retrospective cohort study of NAFLD patients aged 18 years or above between January 1, 2000 and December 31, 2014. A propensity score-weighted Cox proportional hazards model was used to balance the clinical characteristics between ACEI/ARB users and non-users. Fine-Gray model was used to adjust for competing risk of death.

**Results:** We analysed data from 12,494 NAFLD patients (mean age, 54.4 ± 14.5 years; 6,301 men [50.4%]); 7,428 (59.5%) received ACEI/ARB and 5,066 (40.5%) did not. Compared to non-users, ACEI/ARB users were older, more likely to have type 2 diabetes, hypertension and cirrhosis, and had worse renal function. At a median (interquartile range) follow-up of 9.9 (5.4–14.2) years, 268 (3.6%) ACEI/ARB users and 173 (3.4%) non-users developed liver-related events (a composite end point of HCC and cirrhotic complications). After propensity score weighting, ACEI/ARB treatment was associated with a lower risk of liver-related events (weighted subdistribution hazard ratio (SHR) 0.44, 95% confidence interval (CI) 0.33–0.59,  $p < 0.001$ ), HCC (weighted SHR 0.46; 95% CI 0.30–0.72;  $p < 0.001$ ), and cirrhotic complications (weighted SHR 0.42; 95% CI 0.29–0.61;  $p < 0.001$ ).

**Conclusion:** In this retrospective territory-wide cohort study, ACEI/ARB treatment was associated with a lower risk of liver-related events, HCC and cirrhotic complications in NAFLD patients.

Table 1: Summary of the results of propensity score weighting on the subdistribution hazard ratio (SHR) of liver-related events, HCC and cirrhotic complications in NAFLD patients with or without ACEI/ARB use

	Weighted SHR (95% CI)	P value
Liver-related events	0.44 (0.33–0.59)	<0.001
HCC	0.46 (0.30–0.72)	<0.001
Cirrhotic complications	0.42 (0.29–0.61)	<0.001

### OS-1034

#### The pan-PPAR agonist lanifibranor significantly improves cardiovascular risk biomarkers in patients with NASH

Sven Francque<sup>1,2</sup>, Michael Cooreman<sup>3</sup>, Martine Baudin<sup>3</sup>, Philippe Huot-Marchand<sup>3</sup>, Lucile Dzen<sup>3</sup>, Junien Jean Louis<sup>3</sup>, Pierre Broqua<sup>3</sup>, Manal Abdelmalek<sup>4</sup>. <sup>1</sup>Antwerp University Hospital,

Gastroenterology and Hepatology, Edegem, Belgium; <sup>2</sup>University of Antwerp, Laboratory of Experimental Medicine and Paediatrics, Wilrijk, Belgium; <sup>3</sup>Inventiva, Daix, France; <sup>4</sup>Duke University, Gastroenterology and Hepatology, Durham, United States  
Email: sven.francque@uza.be

**Background and aims:** Cardiovascular disease (CVD) is a major cause of morbidity and mortality in patients with NASH. The panPPAR lanifibranor has shown efficacy on NASH resolution and improvement of fibrosis in non-cirrhotic NASH patients in the phase 2b NATIVE study (Francque et al, AASLD2020). PPAR alpha, delta and gamma signalling improve key mechanisms of atherosclerosis: lipid and carbohydrate metabolism, inflammation and high blood pressure (BP). The aim of this analysis is to assess changes in CVD risk profile in patients with NASH treated with Lanifibranor.

**Method:** The NATIVE study enrolled 247 patients with SAF activity score 3–4, fibrosis F0–F3, in three arms: Lanifibranor 800 mg/d, 1200 mg/d and placebo for a treatment duration of 24 weeks; 228 patients completed the trial and were included in the analyses. Serum biomarkers that infer increased CVD risk, specifically biomarkers of lipid metabolism (APO-A1 and APO-B (components of HDL and LDL/VLDL particles); APO-C3), insulin resistance (IR) and inflammation were measured at baseline and at end of treatment (EOT). Selected markers were also measured at weeks 4 and 14.

**Results:** Of the 247, 179 (72%) patients had features of metabolic syndrome (MS): high waist circumference (95%), high triglycerides (TG) (63%), low HDL-cholesterol (47%), type 2 diabetes (T2D) or pre-diabetes (62%), high BP (62%). HDL-cholesterol (HDL-c) significantly increased in both Lanifibranor arms from week 4 to EOT, while values did not change with placebo. APO-A1 and LDL-cholesterol (LDL-c) did not change in any treatment arm. TG, APO-B, APO-C3 and APO-B/APO-A1 (a risk factor for atherosclerosis), mean hs-CRP, fasting glucose and insulin all significantly declined from baseline to EOT with Lanifibranor 800 and 1200 mg/d but not with placebo, independent of diabetes status. Lanifibranor significantly decreased mean systolic and diastolic BP during therapy compared to placebo. Most of the improvements were already observed at week 4 and maintained throughout the treatment period.

**Conclusion:** Lanifibranor has significant beneficial effects on biomarkers of CVD risk in NASH patients, including dyslipidaemia, IR, inflammation and BP. These data confirm the promising profile of lanifibranor for the treatment of NASH as a manifestation of the broader MS. These effects will be further evaluated in the planned phase 3 study in NASH patients with fibrosis F2/F3.

### OS-1044

#### Lanifibranor therapy improves markers of lipid metabolism, insulin resistance, liver injury and fibrosis in patients with NASH and F2 and F3 fibrosis stages: a subgroup analysis of the phase 2b NATIVE study

Sven Francque<sup>1,2</sup>, Michael Cooreman<sup>3</sup>, Martine Baudin<sup>3</sup>, Philippe Huot-Marchand<sup>3</sup>, Lucile Dzen<sup>3</sup>, Junien Jean Louis<sup>3</sup>, Pierre Broqua<sup>3</sup>, Manal Abdelmalek<sup>4</sup>. <sup>1</sup>Antwerp University Hospital, Gastroenterology and Hepatology, Edegem, Belgium; <sup>2</sup>University of Antwerp, Laboratory of Experimental Medicine and Paediatrics, Wilrijk, Belgium; <sup>3</sup>Inventiva, Daix, France; <sup>4</sup>Duke University, Gastroenterology and Hepatology, Durham, United States  
Email: sven.francque@uza.be

**Background and aims:** In the NATIVE study, Lanifibranor, a pan-PPAR agonist, met the composite efficacy end point of NASH resolution and fibrosis regression in patients with non-cirrhotic NASH. Fibrosis progression is the main predictor of outcomes in NASH. Patients with NASH and significant (F2/F3) fibrosis are expected to have improved outcomes from pharmacological therapy that affects fibrosis and upstream metabolic and inflammatory pathways. We evaluated the effect of Lanifibranor on biomarkers of disease activity and associated risks in the subgroup of patients with F2/F3 fibrosis.

**Method:** A total of 247 patients were enrolled and randomized, stratified for type 2 diabetes (T2D), to placebo, lanifibranor 800 mg/d or 1200 mg/d for 24 weeks. Primary efficacy end point was a  $\geq 2$  points reduction of the SAF score (inflammation and ballooning) with no worsening of fibrosis; secondary end points included NASH resolution and fibrosis improvement. Serum markers of lipids, insulin resistance (IR), inflammation, liver injury and fibrosis were assessed at baseline and at end of therapy (EOT); selected markers were also measured at weeks 4 and 14. Data for the patient subgroup with F2/F3 fibrosis were analysed.

**Results:** Of the 247 patients enrolled, 188 (76%) had fibrosis [F2 (n = 102); F3 (n = 86)]. At baseline, the prevalence of T2D in the placebo (n = 57), lanifibranor 800 mg/d (n = 68) and 1200 mg/d (n = 63) was 47%, 40%, and 46%, respectively; the proportion of patients achieving the composite end point NASH resolution and fibrosis improvement was 7%, 24% (p = 0.012) and 33% (p < 0.001), respectively. Liver tests (ALT, AST, GGT), HbA1c and fasting glucose (FBG) declined significantly by week 4 or 14 in the lanifibranor arms and were maintained or further declined at EOT. Triglycerides (TG) also lowered by week 4, with a continued effect throughout therapy; LDL-C levels remained unchanged; there was a significant increase in HDL-C at week 4 and throughout therapy. Lanifibranor reduced APOB/APO-A1, hsCRP and fibrosis markers MACK-3 and TIMP1/MMP2 at EOT compared to baseline. No significant changes were observed in the placebo arm.

**Conclusion:** In patients with NASH and F2/F3 fibrosis, lanifibranor improved markers of lipid metabolism, IR, liver injury, inflammation and fibrosis at EOT compared to placebo, supporting previously reported histological efficacy. These findings support the planned phase 3 study of lanifibranor for patients with NASH and F2-F3 fibrosis.

OS-1627

**Treatment of NAFLD with intermittent calorie restriction, low-carb high-fat diet or standard dietary advice-a randomized controlled trial**

Magnus Holmer<sup>1</sup>, Catarina Lindqvist<sup>1</sup>, Sven Petersson<sup>2</sup>, John Moshtaghi-Svensson<sup>3</sup>, Veronika Tillander<sup>4</sup>, Torkel Brismar<sup>2</sup>, Hannes Hagström<sup>1</sup>, Per Stal<sup>1,5</sup>. <sup>1</sup>Karolinska Institutet, Department of Medicine Huddinge, Stockholm, Sweden; <sup>2</sup>Karolinska Institutet, Department of Clinical Science, Intervention and Technology, Stockholm, Sweden; <sup>3</sup>Godjy AB, Stockholm, Sweden; <sup>4</sup>Karolinska Institutet, Department of Laboratory medicine, Stockholm, Sweden; <sup>5</sup>Karolinska Institutet, Dept of Gastroenterology and Hepatology, Stockholm, Sweden  
Email: magnus.holmer@ki.se

**Background and aims:** A reduced caloric intake is central to achieve weight loss and reduced liver fat in non-alcoholic fatty liver disease (NAFLD). Several high-fat diets, such as the Low-Carb High-Fat diet (LCHF), are popular in the public, but the effect on liver steatosis is inconclusive. Diets based on intermittent calorie restriction, such as the 5:2-diet, are popular for weight loss purposes but has not yet been tested specifically as treatment for NAFLD. This trial compared the effects of the LCHF and 5:2 diets compared to standard dietary advice as treatment for NAFLD.

**Method:** We conducted an open-label randomized controlled trial including 74 patients with NAFLD. Participants were randomized 1:1:1 to a 12-week treatment with either LCHF diet, 5:2 diet or standard of care (SoC). The LCHF diet consisted of a carbohydrate intake of <10% of total energy intake (E%) and fat intake to 50–80 E%. In the 5:2 diet, energy intake was restricted to <500/600 kcal (women/men) on two non-consecutive days per week alternated with days with an intake of 2000/2400 kcal (women/men). The 5:2 and LCHF diets were isocaloric. SoC consisted of advice on a healthy diet with a balanced intake of macronutrients, to eat regular meals and reduce the size of servings. The main outcome was reduction of hepatic steatosis as measured with Magnetic Resonance Spectroscopy.

**Results:** The LCHF and 5:2 diets were superior to SoC in reducing steatosis (Figure). The LCHF and 5:2 diets were also more effective in

reducing body weight (LCHF -7.3 kg [95%CI = -9.6 to -5.0], 5:2 -7.4 kg [95%CI = -8.7 to -6.0] and SoC -2.5 kg [95%CI = -3.5 to -1.5]). There was no difference between the 5:2 and LCHF arms in reduction of steatosis (p = 0.41) or body weight (p = 0.78). Liver stiffness improved in the 5:2 (-1.8 kPa, p < 0.001) and SoC (-1.5 kPa, p = 0.005) but not in the LCHF group (-0.3 kPa, p = 0.52). In the 5:2 group a significant reduction of LDL-levels was observed (-0.4 mmol/L, p < 0.001). A trend towards higher LDL was seen in the LCHF-group (+0.2 mmol/L, p = 0.075).

Figure:

**Conclusion:** The LCHF and 5:2 diets were more effective than SoC in reducing steatosis and body weight in patients with NAFLD. Our findings suggest that dietary advice can be adjusted according to individual preferences. However, coexisting cardiovascular risk factors should be considered since the long-term effect of different diets on blood cholesterol is uncertain.

OS-1769

**Interim analysis from a 72 week, double-blind, placebo-controlled, multicenter, paired liver biopsy study of endoscopic sleeve gastroplasty in patients with non-alcoholic steatohepatitis (NASH)**

Javier Abad Guerra<sup>1</sup>, María Teresa Arias Lose<sup>2</sup>, Diego Burgos Santamaria<sup>3</sup>, Javier Ampuero<sup>4</sup>, José Luis Martínez Porras<sup>1</sup>, Paula Iruzubieta<sup>2</sup>, Rosa Martín-Mateos<sup>3</sup>, Belén Ruiz Antoran<sup>5</sup>, Álvaro Santos-Laso<sup>2</sup>, Javier Graus<sup>3</sup>, Adalberto Rincon<sup>4</sup>, Elba Llop<sup>1</sup>, Manuel Romero Gomez<sup>4</sup>, Agustín Albillos<sup>3,6</sup>, Javier Crespo<sup>2</sup>, José Luis Calleja Panero<sup>1</sup>. <sup>1</sup>Puerta de Hierro Hospital, Gastroenterology and Hepatology, Madrid, Spain; <sup>2</sup>Marques de Valdecilla Hospital, Gastroenterology and Hepatology, Santander, Spain; <sup>3</sup>Ramon y Cajal Hospital, Gastroenterology and Hepatology, Madrid, Spain; <sup>4</sup>Virgen del Rocío Hospital, Gastroenterology and Hepatology, Sevilla, Spain; <sup>5</sup>Puerta de Hierro Hospital, Pharmacology, Madrid, Spain; <sup>6</sup>Hospital Ramon y Cajal, IRYCIS, CIBEREHD, Universidad de Alcalá, Madrid, Spain  
Email: javiabad83@gmail.com

**Background and aims:** Life-style intervention losing weight more than 10% promoted NASH resolution in 90% of patients and fibrosis regression, at least one stage, in 80%. However, less than 25% of the subjects achieve this goal with diet and exercise. In recent years endoscopic sleeve gastroplasty with Overstitch® system has emerged as safe and effective option to promote weight loss in patients with obesity. We report the preliminary results of a multicenter,

## ORAL PRESENTATIONS

randomized, controlled and double-blind study to evaluate efficacy and safety of endoscopic sleeve gastroplasty in patients with NASH.

**Method:** This interim analysis was conducted when 21 out of 40 planned subjects included reached in week 72. Inclusion criteria included biopsy proven NASH with NAS $\geq$ 3 and fibrosis stage from F1 to F3. Patients were randomized 1:1 to endoscopic sleeve gastroplasty (ESG) (n = 11) with OverStitch® system (Apollo Endosurgery, Austin, TX, USA) plus lifestyle modification versus endoscopic simulated intervention (ESI) (n = 10) with a diagnostic upper endoscopy plus lifestyle modification. We evaluated changes from baseline in body weight, liver test, Fibroscan and histological features (baseline biopsy and week 72 biopsy).

**Results:** A significant reduction in body weight were observed in 9 out of 11 ESG group with an average of 9.7% weight reduction vs 4 out of 11 in ESI group with an average of 4% (p < 0.05). Only patients in the ESG group achieved more than 20% of their body weight.

ALT, AST and ferritin levels improved significantly in ESG group vs ESI group (-42.7 vs 1.6 p < 0.017; -32.4 vs 1.3 p < 0.045; -39.8 vs 57.7 p < 0.032). We observed a reduction in Fibroscan values of -5.80 (8.3) Kpa in ESG group vs +2.01 (7.3) Kpa in ESI group (p < 0.05).

Patients that achieved weight loss showed a significant improvement in the NAS score (p < 0.001). 70% of them were from the ESG group. The magnitude of the improvement was significantly higher in those patients with a weight reduction >10% (p < 0.001). ESG was well-tolerated and just mild adverse events were reported in 5% in ESG group vs 1% in ESI.

Table 1:

HISTOLOGICAL BY WEIGHT CHANGES (n)	No weight loss (8)	Weight loss (13)	p
NAS score (SD)	0.00 (1.07)	-3.00 (1.96)	0.001
Steatosis (SD)	-0.13 (0.64)	-1.38 (0.77)	0.001
Lobulillar inflammation (SD)	0.13 (0.83)	-0.54 (0.78)	0.080
Ballooning (SD)	0.00 (0.53)	-1.08 (0.86)	0.005

HISTOLOGICAL BY WEIGHT CHANGES (n)	Weight loss <10% (14)	Weight loss >10% (7)	p
NAS score (SD)	-0.57 (1.45)	-4.43 (0.53)	<0.001
Steatosis (SD)	-0.43 (0.65)	-1.86 (0.69)	<0.001
Lobulillar inflammation (SD)	0.07 (0.83)	-1.00 (0.00)	0.003
Ballooning (SD)	-0.21 (0.70)	-1.57 (0.53)	<0.001

**Conclusion:** Endoscopic sleeve gastroplasty is an effective and safe method to promote weight reduction associated with significant improvement in liver function test, stiffness and histological parameters compared to life-style intervention alone.

## Non-invasive assessment of liver disease except NAFLD

### OS-507

#### Von Willebrand factor for outcome prediction within different clinical stages of advanced chronic liver disease

Bernhard Scheiner<sup>1,2</sup>, Lorenz Balcar<sup>1,2</sup>, Rafael Paternostro<sup>1,2</sup>, Benedikt Simbrunner<sup>1,2</sup>, Lukas Hartl<sup>1,2</sup>, Mathias Jachs<sup>1,2</sup>, David J.M. Bauer<sup>1,2</sup>, Georg Semmler<sup>1,2</sup>, Albert Stättermayer<sup>1,2</sup>, Matthias Pinter<sup>1</sup>, Prof. Peter Quehenberger MD<sup>3</sup>, Michael Trauner<sup>1</sup>, Thomas Reiberger<sup>1,2</sup>, Mattias Mandorfer<sup>1,2</sup>. <sup>1</sup>Medical University of Vienna, Division of Gastroenterology and Hepatology, Department of Internal Medicine III, Vienna, Austria; <sup>2</sup>Medical University of Vienna, Vienna Hepatic Hemodynamic Laboratory, Vienna, Austria; <sup>3</sup>Medical

University of Vienna, Department of Laboratory Medicine, Vienna, Austria

Email: mattias.mandorfer@meduniwien.ac.at

**Background and aims:** Although von Willebrand factor (VWF) levels have been reported to predict hepatic decompensation and mortality, the specific prognostic value of VWF in distinct clinical stages (CS) has not been systematically assessed. We (i) compared changes in prognostic biomarkers throughout the clinical spectrum of ACLD and (ii) established CS-specific VWF cut-offs for risk prediction.

**Method:** Patients undergoing HVPG-measurement at the Vienna Hepatic Hemodynamic Lab with evidence of ACLD were considered. CS were defined as follows: **Probable compensated ACLD (cACLD):** LSM  $\geq$  10kPa and HVPG < 6 mmHg; **0:** cACLD and 6-9 mmHg; **1:** cACLD and HVPG  $\geq$  10 mmHg; **2:** decompensated ACLD (dACLD) with bleeding; **3:** dACLD with non-bleeding decompensation; **4:**  $\geq$  2 decompensations.

**Results:** 923 patients were included. As illustrated in the Figure, we observed a steady step-wise increase of VWF with CS progression. In contrast, HVPG levelled off in dACLD with only modest numerical differences between CS 2-4, whereas MELD showed only minor changes in early CS and CRP did not increase until CS 3, i.e., non-bleeding decompensation.

cACLD patients with VWF levels above the stage-specific 75<sup>th</sup> percentile ( $\geq$ 342%) had a more than four times increased risk of decompensation/death (HR: 4.17 (95%CI: 2.20-7.90), p < 0.001). In dACLD patients, VWF levels above the 75<sup>th</sup> percentile ( $\geq$ 418%) were associated with a 67%-increased risk (HR: 1.67 (95%CI: 1.28-2.19), p < 0.001), while having values below the 25<sup>th</sup> percentile (<268%) nearly halved the risk (HR: 0.57 (95%CI: 0.42-0.78), p < 0.001) of decompensation/death.

Importantly, even in a fully adjusted model (age, etiology, HVPG, MELD, albumin, and CRP), VWF was independently associated with hepatic decompensation/death in cACLD. In dACLD, VWF remained independently predictive after adjusting for MELD, but not when adjusting for additional variables.

N for VWF	302	418
75 <sup>th</sup> VWF percentile	342	418
Hazard ratio (HR)	4.17	1.67
95%CI	2.20-7.90	1.28-2.19
p-value	<0.001	<0.001
Median	259	348
25 <sup>th</sup> VWF percentile	-	268
Hazard ratio (HR)	-	0.57
95%CI	-	0.42-0.78
p-value	-	<0.001

Figure:

**Conclusion:** Among the investigated parameters, VWF was the only prognostic indicator that steadily increased throughout all CS of

ACLD. Its prognostic implications are particularly pronounced in cACLD patients, in whom VWF  $\geq 342\%$  identify those who are at a 4-fold increased risk of hepatic decompensation/death. In dACLD, VWF cut-offs  $<268\%$  and  $\geq 418\%$  identify low- and high-risk populations. The proposed stage-dependent VWF cut-offs are easily applicable in clinical routine and may help to broaden the use of VWF—a highly versatile and readily available biomarker—for risk stratification and treatment individualization.

#### OS-1954

##### Real-world assessment of the non-invasive ratio of exchangeable copper (REC) as a marker of Wilson's disease in a multicentric cohort of pediatric and adult patients.

Email: cmolera@sjdhospitalbarcelona.org

**Background and aims:** Wilson's disease (WD) is a rare disease with high diagnostic and follow-up challenges, due to high phenotypic variability and biomarkers drawbacks. Exchangeable copper and relative exchangeable copper ratio (REC) have shown to be promising diagnostic tools but its use in clinical practice is limited. Our aim was to assess the usefulness of REC in a real-world multicentric cohort of patients with WD.

**Methods:** This is a cross-sectional study where pediatric and adult patients with confirmed WD (by genetic diagnosis and/or Leipzig score  $\geq 4$ ) were included. Serum samples were obtained at diagnosis or follow-up. Exchangeable copper and REC were measured by Inductively plasma coupled to mass spectrometry (ICP-MS). Demographic, clinical and laboratory data were collected. A control group of non-WD individuals was included. Quantitative/categorical variables were expressed as median-IQR<sub>25-75</sub>/n (%); comparisons between groups were done by Chi-Square or U-Mann Whitney/Kruskal-Wallis, as appropriate; correlations were assessed by Spearman test.

**Results:** Forty-two WD patients were included (33 adults, 9 children): 52.4% male, mean age at sample extraction 28.5 years (IQR: 19–42); 88% were in the follow-up phase [median time from diagnosis: 13 years (IQR: 5–23)]; 71.4% compound heterozygosis; 61.9% with chronic liver phenotype; 50% under zinc salts and 52.4% classified as adherents. The control group consisted in 34 non-WD individuals with significantly lower age at sample extraction ( $p < 0.001$ ). REC was significantly higher in WD patients compared to controls (33.5% vs 3.9%,  $p < 0.001$ ), confirming its accuracy to detect

high values even during the follow-up phase. REC negatively correlated with ceruloplasmin levels ( $\rho = -0.51$ ,  $p = 0.002$ ) and positively with ALT ( $\rho = 0.35$ ,  $p = 0.021$ ) but no correlation with age was found. No significant differences of REC were found between time of evaluation (diagnosis vs follow-up), genotype, phenotype, time of follow-up or treatment adherence. REC was significantly higher in patients with abnormal ALT levels compared to those with normal ALT (40.3% vs 23%,  $p = 0.002$ ).

**Conclusion:** REC showed to be promising tool for WD diagnosis in this real-world cohort of adults and children, even during the follow-up phase. Despite REC was statistically associated with ceruloplasmin and ALT levels, its utility for follow-up monitoring and adherence deserves further evaluation.

#### OS-686

##### Suffering from the unpredictable illness in liver cirrhosis

Maria Hjorth<sup>1,2</sup>, Ann Karin Svanberg<sup>3</sup>, Daniel Sjöberg<sup>2</sup>, Fredrik Rorsman<sup>1</sup>, Elenor Kaminsky<sup>4</sup>. <sup>1</sup>Uppsala University, Department of Medical Sciences, Uppsala, Sweden; <sup>2</sup>Dalarna County Council, Center of Clinical Research in Dalarna, Sweden; <sup>3</sup>Dalarna University, School of Education, Health and Social Studies, Sweden; <sup>4</sup>Uppsala University, Department of Public Health and Caring Sciences, Uppsala, Sweden  
Email: maria.hjorth@regiondalarna.se

**Background and aims:** Mental reactions following chronic illnesses may be explained by suffering. According to Morse's theory suffering, the first phase, *enduring*, means suppressing emotions to preserve energy (Figure). When suffering proceeds to *emotional suffering*, there is a demand of energy due to overwhelming emotions. Gradually, one may experience *acceptance* or *hope*. The expression of feelings during the suffering process may fluctuate. The end of suffering, *self-reformulation*, means new insights about life arise. The lack of knowledge of suffering in liver cirrhosis (LC) hampers feasible nursing interventions to improve patients' health. Hence, Morse theory of suffering was used in this study to characterise suffering in LC.

**Method:** Purposive sampling of 20 informants (men = 10, age 25–71) with confirmed LC (range 0.5–10 years) resulted in twenty semi-structured interviews from 2016 to 2017. Inductive qualitative content analysis was performed of interview transcripts. Morse theory of suffering was used to discuss the study results.

**Results:** Coherent to Morse (Figure), all informants confirmed suffering. To avoid distress, informants *endured* by (I) remaining silent, (II) focus on anything but the illness or (III) constantly monitoring the illness, anxious that complications may arise (Figure, Box 1). In this phase, informants were uninterested of knowledge about the disease and preferred to be left alone. When *emotional suffering*, informants experienced sadness and grief (Figure, Box 7). Having someone to entrust then gave comfort and relief. Fluctuating between *enduring* and *emotional suffering* occurred. After suppression of anxiety, informants could suddenly broke out in tears or scream (Figure, Box 4–6). Sometimes acceptance of changes in life emerged (Figure, Box 8). *Hope* was expressed as a desire of improved health, or to be fortunate enough to be liver transplanted (Figure, Box 9). *Self-reformulation* was rare. One informant considered life with LC to be an educative process (Figure, Box 10).

**Conclusion:** Morse theory of suffering, facilitated the understanding of how suffering in LC may be experienced. The absence of self-reformulation, may be explained by the threat of unexpected and serious complications. Future interventions may target how nursing may relieve and support persons through different stages of suffering in LC.

Figure: (abstract: OS-686): Morse's suffering process with informant's citations, describing experiences of suffering due to liver cirrhosis.

## OS-798

### The impact of intervention by dedicated nurse upon the treatment of patients post DAA treatment for HCV

Evelin Oxtrud<sup>1</sup>, Yael Harif<sup>1</sup>, Orly Sneh Arbib<sup>1</sup>, Michal Cohen-Naftaly<sup>1</sup>, Erika Waiss<sup>1</sup>, Amir Shlomai<sup>1</sup>, Marius Braun<sup>1</sup>, Assaf Issachar<sup>1</sup>. <sup>1</sup>Rabin Medical Center, Liver Institute, Petah Tikva, Israel  
Email: assafissa@gmail.com

**Background and aims:** Chronic HCV infection may lead to cirrhosis, liver failure and hepatocellular carcinoma (HCC). The most important risk factor for disease progression is the degree of liver fibrosis. Treatment with DAA eradicates HCV infection in more than 98% of the patients. Cure is defined as SVR (sustained virological response, e.g., undetectable viral RNA 12 weeks after therapy). Despite achieving SVR, patients with advanced fibrosis remain at risk of liver deterioration and HCC, therefore follow-up and screening for HCC is recommended. We observed significant non-compliance with follow-up.

**Aims of the study:** To evaluate whether a phone call by a dedicated hepatology nurse providing detailed instructions might increase follow-up compliance to a greater degree than scheduling appointments only by mail, regarding attendance and performance of necessary tests.

To evaluate the patient perception regarding the value of instruction by dedicated nurses.

**Method:** 200 HCV patients treated with DAA between 2014–2019 in Rabin Medical Center who did not attend follow-up visits were randomly divided to two groups: group A-patients received a letter with a scheduled appointment and a request for blood tests and abdominal US and group B- patients received a phone call by nurse to explain the importance of the appointment and an appointment by mail. The patients who showed up were asked to complete a questionnaire about the added value of nurse instruction.

**Results:** There were no differences between the groups regarding age and gender. 140 patients (70%) showed up. The attendance was significantly higher in the phone intervention group (79 vs 61

respectively,  $p < 0.005$ ). There was no difference in compliance with having the tests done in time. 119 had complete results and 16 partial. During the appointment 5 patients were found to have significant lesions (3 liver lesions, 1 suspicious pancreatic cyst and 1 RCC). 74/140 patient (52.8%) completed the questionnaire about the value of the dedicated nurse intervention. All patients were satisfied with the professionalism of the team. 90% of the patients thought that the phone call contributed to their adherence with follow-up and 85% of the patients felt that the explanation provided by the nurse during the appointment contributed to their understanding of their medical situation.

**Conclusion:** Explanation by dedicated nurse by phone call in addition to scheduling appointments by mail can increase the compliance of patients post HCV treatment with follow-up. Clinically significant findings were diagnosed. The patients pointed the added value of nurse explanations and instructions for better understanding of the disease and the importance of follow-up. Intervention by dedicated nurses improves the communication and compliance.

## OS-1756

### Increased hospital presentations with alcohol-related disorders during the COVID-19 crisis in the United Kingdom

Michelle Layton<sup>1</sup>, Michael Luciw<sup>1</sup>, Nasima Ali<sup>1</sup>, Jeremy Cobbold<sup>1</sup>, Francesca Saffioti<sup>1</sup>. <sup>1</sup>Oxford Liver Unit, Oxford University Hospitals NHS Foundation Trust, Oxford, United Kingdom  
Email: fsaffioti.83@gmail.com

**Background and aims:** The social restrictions and increased psychological distress triggered by the COVID-19 pandemic have led to a change of the individual alcohol consumption patterns in the UK. General population survey data show variable behavioural changes in alcohol intake; increased alcohol misuse has also been documented. There are concerns about reduced visibility of an increased alcohol-related harm due to a general reduction of the healthcare utilisation during the COVID-19 crisis. Data on admission episodes for alcohol-

related conditions during the pandemic are lacking. We aimed to analyse the pattern of hospital presentations with alcohol-related disorders in the COVID-19 era.

**Method:** The number of presentations with “alcohol-related liver disease” [ALD], “drug overdose with alcohol intoxication” and “mental and behavioural disorders due to use of alcohol” [MBDA] (including acute intoxication and alcohol withdrawal seizures with and without delirium) at the Oxford University Hospitals NHS Foundation Trust was retrieved using the diagnosis codes for the periods April-August 2019 (pre-COVID era) and April-August 2020 (COVID era). The comparison of figures between the two periods was performed by Chi-square test.

**Results:** Compared with the pre-COVID era, in the COVID era there was a 48.7% increase in the presentations with drug overdose with alcohol intoxication (80 vs 119,  $p = 0.005$ ) and a 32.6% increase in the number of presentations with MBDA (1838 vs 2438,  $p < 0.0001$ ). In particular, the number of presentations with alcohol withdrawal seizures with (22 vs 64,  $p < 0.0001$ ) and without delirium (221 vs 411,  $p < 0.0001$ ) increased by 191% and 86%, respectively.

There was a 47.5% increase in the presentations with ALD (781 vs 1152,  $p < 0.0001$ ). Notably, there was a 77% increase of presentations with alcoholic hepatic failure (96 vs 170,  $p < 0.0001$ ) and a 34% increase of presentations with alcohol-related cirrhosis (444 vs 595,  $p < 0.0001$ ). There was also a remarkable 207% increase in diagnoses of alcoholic hepatitis between the two periods (68 vs 209,  $p < 0.0001$ ).

**Conclusion:** Our local data demonstrate a significant increase of hospital presentations with alcohol-related disorders, in particular acute alcoholic hepatitis and withdrawal syndrome, in the context of the COVID-19 crisis. Close integration and reinforcement of clinical and alcohol services both in the community and in hospital are urgently needed, including an improvement of alcohol counselling services and psychological support.

### Hospital presentations with alcohol-related liver disease

#### Exploring the relationship between maternal pre-pregnancy BMI and outcomes of NAFLD in young adulthood: a parental negative control study

Kushala Abeysekera<sup>1,2</sup>, James Orr<sup>2</sup>, Gwen Fernandes<sup>1</sup>, Paul Madley-Dowd<sup>1</sup>, Luisa Zucculo<sup>1,3</sup>, Fiona Gordon<sup>2</sup>, Deborah Lawlor<sup>1,3,4</sup>, Jon Heron<sup>1</sup>, Matthew Hickman<sup>1,3</sup>. <sup>1</sup>University of

Bristol, Population Health Sciences, United Kingdom; <sup>2</sup>Bristol Royal Infirmary, Department of Liver Medicine, Bristol, United Kingdom; <sup>3</sup>University of Bristol, MRC Integrative Epidemiology Unit, Bristol, United Kingdom; <sup>4</sup>University of Bristol, Bristol NIHR Biomedical Research Centre, Bristol, United Kingdom  
Email: k.abeysekera@bristol.ac.uk

**Background and aims:** The importance of the maternal-infant dyad in the genesis of non-alcoholic fatty liver disease (NAFLD) is of increasing interest. Murine models suggest an obesogenic in utero environment can “prime” the liver to develop NAFLD. The Avon Longitudinal Study of Parents and Children (ALSPAC) showed that at age 24, 1 in 5 had NAFLD measured by controlled attenuation parameter (CAP) during transient elastography. Our aim was to investigate the association between maternal pre-pregnancy BMI and offspring NAFLD in young adulthood, building on previous analyses from the Raine birth cohort which found maternal pre-pregnancy obesity more than doubled odds of NAFLD in adolescent offspring.

**Method:** 4021 offspring participants attended clinic for FibroScan and CAP measurement using the Echosens 502 Touch®. 440 participants with Alcohol Use Disorders were excluded. Offspring of 100 non-singleton pregnancies were excluded. 2961 valid CAP measurements for NAFLD were analysed. The exposure of interest was maternal pre-pregnancy BMI, categorized into BMI < 25 kg/m<sup>2</sup>, overweight (25 to < 30 kg/m<sup>2</sup>) and obese (≥ 30 kg/m<sup>2</sup>). Multivariable logistic regression models estimated the odds of NAFLD at 24 years by level of the exposures. Confounders included maternal age, smoking in pregnancy and social class. A paternal negative control test was used to explore the potential for residual shared confounding in the analyses of pre-pregnancy BMI. Paternal and maternal BMI were mutually adjusted for to account for bias secondary to assortative mating.

**Results:** Maternal and paternal pre-pregnancy BMI was available for 2869 and 2316 participants respectively. Offspring of mothers with obesity had three times higher odds of NAFLD following adjustment for confounders (OR 3.06 [95% CI 2.11–4.42];  $p < 0.0001$ ). However, offspring whose fathers had obesity were also at higher odds of NAFLD (crude OR 1.85 [1.26–2.72;  $p = 0.002$ ]).

The negative control design, provided evidence of a specific maternal effect which could not be explained by the shared confounding structure, having compared effect size estimates between maternal and paternal BMI categories after mutual adjustment.

**Conclusion:** We found evidence of higher maternal pre-pregnancy BMI influencing NAFLD development, having accounted for shared parental confounding. This suggests early life exposures could be compounding existing environmental factors that perpetuate NAFLD development. Ultimately this supports the role of the maternal-infant dyad in NAFLD pathogenesis, reflective of the obesogenic environment our patients live in.

### OS-199

#### Get Tested LeEDs: Clinical impact and cost-effectiveness of opt-out emergency department testing for bloodborne viruses (BBVs)

Elizabeth Smout<sup>1</sup>, Jack Williams<sup>2</sup>, Alec Miners<sup>2</sup>, Khine Phyu<sup>3</sup>, Lee Parker<sup>3</sup>, Amy Evans<sup>3</sup>, Joscelyne McLaren<sup>3</sup>, Mark Aldersley<sup>3</sup>, Gareth Hughes<sup>1</sup>, Murad Ruf<sup>4</sup>, Emma Page<sup>3</sup>. <sup>1</sup>Public Health England, Field Service, National Infection Service; <sup>2</sup>London School of Hygiene and Tropical Medicine, Department of Health Services Research and Policy; <sup>3</sup>Leeds Teaching Hospitals Trust; <sup>4</sup>Gilead Sciences Ltd, Medical Department  
Email: elizabeth.smout@nhs.net

**Background and aims:** Innovative testing approaches and care pathways are required to meet global HIV, hepatitis B virus (HBV) and hepatitis C virus (HCV) elimination goals. Routine testing for BBVs within emergency departments (EDs) is recommended by European Centre for Disease Prevention and Control (ECDC) but paucity of supporting evidence is highlighted. We evaluated the introduction of

## ORAL PRESENTATIONS

integrated, opt-out testing for HIV, HBV and HCV infections in EDs at Leeds Teaching Hospitals NHS Trust, UK.

**Method:** From October 2018–July 2019, HBV (HBV surface antigen [HBsAg]), HCV (HCV antibody [anti-HCV] and reflex HCV-RNA) and HIV antibody testing were opportunistically offered, on an opt-out basis through electronic record modification, to all ED attendees aged 16–65 years who had a routine blood test for urea and electrolytes. Linkage to care (LTC) was attempted for patients who were newly diagnosed or who had disengaged from care.

We analysed testing uptake, BBV seropositivity and LTC at six months following diagnosis and developed an economic model to evaluate hepatitis screening cost-effectiveness from a UK NHS perspective.

**Results:** Over 9 months, 16, 053/28, 178 (57.0%) ED attendees were tested for  $\geq 2$  BBVs. 299 active BBV infections were identified: 73 HBsAg-positive (0.5% seroprevalence), 156 HCV-RNA (1.0%) and 70 HIV-positive (0.4%) ED attendees.

Nearly all (94.9%, 148/156) HCV-RNA positive individuals required LTC. A smaller but substantial proportion of HBsAg-positive (53.4%, 39/73) and HIV-positive (24.3%, 17/70) individuals required LTC. 69.3% (27/39) of HBsAg-positive and just 39.2% (58/148) HCV RNA-positive individuals were successfully linked to care, with 25.0% (37/148) commencing treatment. Nearly all (94.1%, 16/17) of eligible HIV-positive individuals were successfully linked.

Testing for HCV and HBV was highly cost-effective, with incremental cost-effectiveness ratios of £6, 024 and £16, 812, respectively.

**Conclusion:** Integration of routine BBV testing within the ED was feasible, effective and sustainable, identifying a large number of active BBV infections requiring LTC. Our integrated approach achieved good LTC rates although further work is necessary, particularly for HCV.

Our findings support utility of opt-out BBV testing in EDs in line with the ECDC guidance and demonstrate cost-effectiveness of routine hepatitis testing in the UK at much lower seroprevalence than that stated in the guidelines.

### OS-551

#### The effect of COVID-19 on the progress of the hepatitis C elimination program in Georgia

Amiran Gamkrelidze<sup>1</sup>, Alexander Turdziladze<sup>1</sup>, Maia Tsreteli<sup>1</sup>, Vladimer Getia<sup>1</sup>, Ana Aslanikashvili<sup>1</sup>, Sophia Surguladze<sup>1</sup>, Lia Gvinjilia<sup>2</sup>, Tinatin Kuchuloria<sup>2</sup>, Irina Tskhomelidze<sup>2</sup>, Shaun Shadaker<sup>3</sup>, Paige A. Armstrong<sup>3</sup>. <sup>1</sup>National Center for Disease Control and Public Health Georgia, Tbilisi, Georgia; <sup>2</sup>The Task Force for Global Health, Tbilisi, Georgia; <sup>3</sup>National Center for HIV/AIDS, Viral Hepatitis, STD and TB Prevention, CDC, Division of Viral Hepatitis, Atlanta, United States  
Email: a.gamkrelidze@ncdc.gov

**Background and aims:** Georgia, with a population of 3.7 million, has an estimated 150,000 adults living with chronic hepatitis C virus (HCV) infection. The country initiated the world's first national HCV elimination program in 2015, with free screening and treatment available to all citizens. Despite great progress, the COVID-19 pandemic has created new challenges for the program. This analysis describes the progress made in HCV screening since program initiation and the impact of the COVID-19 pandemic on testing.

**Method:** A national database was created to collect screening data for the HCV program, for the purpose of surveillance and program monitoring and evaluating. This analysis uses data from the national HCV screening registry and treatment databases linked by individuals' national IDs, and the 2014 general population census.

**Results:** As of January 23, 2021, 2, 100, 693 adults have been tested for antibody to HCV (anti-HCV) (73.4% of the adult population), of whom 157, 515 (7.5%) were anti-HCV positive. Overall, 113, 315 (71.9%) of anti-HCV positive individuals received follow-up viremia testing, and 90, 498 (79.9%) were found to have chronic HCV infection. The COVID-19 pandemic has led to a decline in testing in the national HCV elimination program. Screening rates dropped after restrictions

were imposed in March, 2020, from as high as 87, 997 in February, to just 37, 010 in April. Testing briefly increased in the summer, with 113, 658 tests performed in July, due in part to relaxed restrictions and intensified integrated screening programs (HCV, tuberculosis, and HIV). Overall, the number of individuals tested in 2020 decreased by 51% (288, 343) compared to 2019 (584, 987).

Figure:

**Conclusion:** Although the program has made significant progress toward HCV elimination, the ongoing pandemic has led to a decline in testing rates. In response, Georgia intends to increase integrated screening, and seek active approaches to link patients to care. The lessons learned and impact on the program demonstrate how a pandemic can prove challenging for public health programs, and highlights the need to employ innovative strategies to avoid loss of progress.

### OS-1381

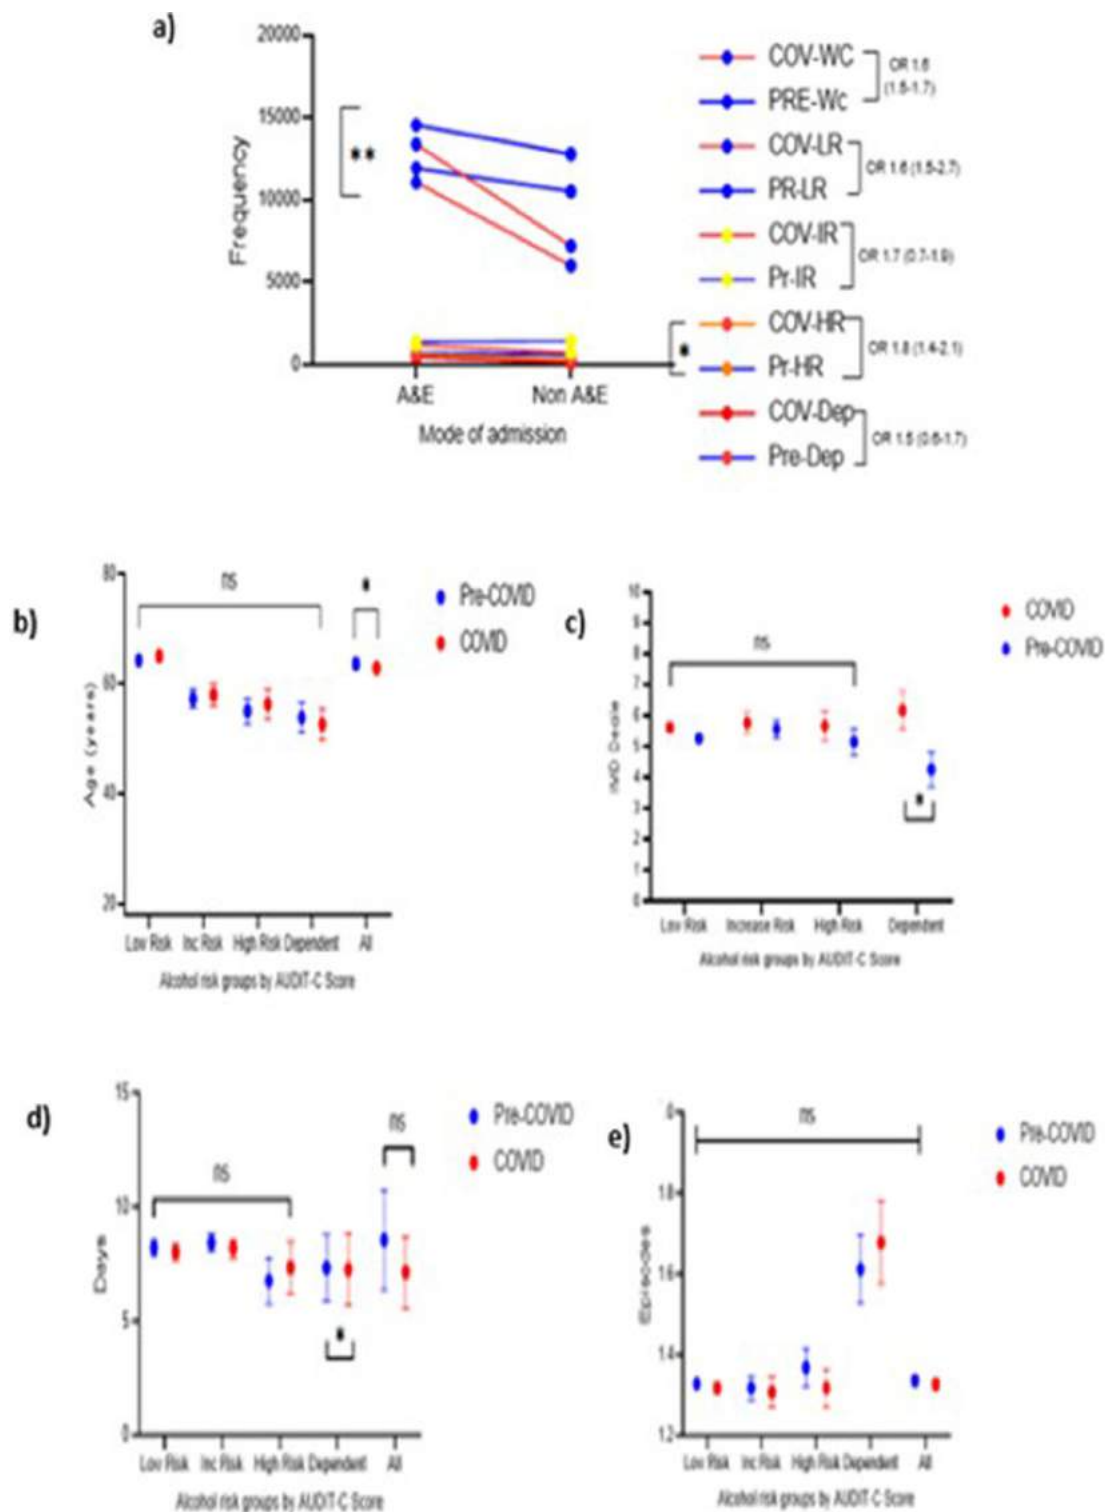

#### Effect of COVID-19 on alcohol use disorder among hospitalised patients: a retrospective cohort control study

Mohsan Subhani<sup>1,2</sup>, Abhishek Sheth<sup>3</sup>, Stuart Unitt<sup>2</sup>, Joanne Morling<sup>3,4</sup>, Guruprasad Aithal<sup>1,3</sup>, Stephen Ryder<sup>2,3</sup>.

<sup>1</sup>Nottingham University Hospitals NHS Trust and the University of Nottingham, Nottingham; <sup>2</sup>Nottingham University Hospitals NHS Trust, NIHR Nottingham Biomedical Research Centre, Nottingham, United Kingdom; <sup>3</sup>Nottingham University Hospitals NHS Trust and the University of Nottingham, NIHR Nottingham Biomedical Research Centre, Nottingham, United Kingdom; <sup>4</sup>Nottingham University Hospitals NHS Trust and the University of Nottingham, Division of Epidemiology and Public Health, Nottingham  
Email: subhani@doctors.org.uk

**Background and aims:** The Covid-19 pandemic has presented significant challenges to health care services. Hospitals have reported a two-fold increase in admissions due to alcohol-related liver disease. Patients are sicker, and higher numbers are requiring high dependency care. More representative data on the impact of Covid-19 on alcohol use disorder (AUD) among hospitalised patients is lacking. We aim to describe the epidemiology of AUD during the pandemic among hospitalised patients, compare it with the Pre-pandemic cohort and identify key demographic characteristics which can be used to risk-stratify individuals presenting to healthcare for targeted alcohol support services.

**Method:** Retrospective cohorts were defined as Pre-pandemic (Pre-Covid-19) (1<sup>st</sup> April to 31<sup>st</sup> October 2019) and Pandemic (Covid-19) (1<sup>st</sup> April to 31<sup>st</sup> October 2020) admitted to Nottingham University Hospital UK. All patients were offered alcohol assessment by AUDIT-C. Increased and high-risk alcohol use was defined as AUDIT-C 5–7, 8–10, and alcohol dependence 11–12. Variation in AUDIT-C was determined by age, sex, ethnicity and admission type/speciality. Patients admitted directly to intensive care were excluded. The data

**Figure 1:** Comparison between Pandemic vs Pre-pandemic cohorts a) mode of admission (COV: Covid-19, Pre: Pre-Covid-19, WC-whole cohort, LR-low-risk, IR-increased-risk, HR-high-risk, Dep-alcohol-dependent) b) mean age c) index of multiple deprivations d) length of stay e) number of admissions  
 \*Pandemic- colour red; Pre-pandemic- colour blue

Figure: (abstract: OS-1381)

## ORAL PRESENTATIONS

for all hospital admissions for defined study periods was extracted from electronic medical records. Multinomial logistic regression analysis was carried out to ascertain if primary and secondary outcomes influenced AUD. Subgroup analysis for Covid-19 positive patients was conducted.

**Results:** Total  $n = 20598$  and  $n = 27356$  were included in Pandemic and Pre-pandemic cohorts. Overall, 18% (95% CI 16.7–18.4) were screened positive for AUD; higher proportions were alcohol-dependent in Pandemic cohort. Patients in all 3 alcohol-risk groups were significantly younger ( $p < 0.05$ ) than low-risk group. Male sex and white ethnicity were associated with a remarkably higher prevalence of AUD. In Pandemic cohort, the alcohol-dependent group had a sixteen-fold increased risk (OR 15.8,  $p < 0.001$ ) of mental and behavioural disorders. The Covid-19 positive patients with concomitant AUD had a longer hospital stay and died at a significantly younger age (mean difference 8 years,  $p < 0.05$ ). Emergency was the predominant mode of admission. Substantial proportion of increased/high-risk AUD were cared for by surgical specialities.

**Conclusion:** Our study highlights the impact of COVID-19 pandemic on drinking behaviours. A higher proportion of those admitted during this pandemic were alcohol dependent and admitted as a medical emergency. Overall patients were from higher socio-economic status and, if had COVID-19 infection, died at a significantly younger age. The pandemic is proposed to have serious implications for mental health. In alcohol dependence, the risk of mental and behavioural disorders is a significant concern.

### OS-2202

#### Mortality and cause of death in people with chronic hepatitis B-a nationwide register-based cohort study

Signe Bollerup<sup>1</sup>, Sofie Hallager<sup>1</sup>, Frederik Engsig<sup>1</sup>, Amanda Mocroft<sup>2</sup>, Peer Brehm Christensen<sup>3</sup>, Jan Gerstoft<sup>4</sup>, Nina Weis<sup>1</sup>. <sup>1</sup>Copenhagen University Hospital, Hvidovre, Department of Infectious Diseases, Hvidovre, Denmark; <sup>2</sup>Copenhagen University Hospital, Rigshospitalet, Centre of Excellence for Health, Immunity and Infections (CHIP) and PERSIMUNE, Copenhagen, Denmark; <sup>3</sup>Odense University Hospital, Department of Infectious Diseases; <sup>4</sup>Copenhagen University Hospital, Rigshospitalet, Department of Infectious Diseases, Copenhagen, Denmark

Email: signe.bollerup@regionh.dk

**Background and aims:** In this nationwide cohort study, we aimed to determine adjusted all-cause mortality and cause of death in persons with chronic hepatitis B compared with the general population in a setting with low prevalence of chronic hepatitis B.

**Method:** We used several nationwide registries to identify persons aged  $\geq 18$  diagnosed with chronic hepatitis B in 2002–2016 in Denmark and included 10 age- and sex matched controls from the general population for each person with chronic hepatitis B. The study population was followed from six months after first chronic hepatitis B registration until death, emigration or December 31, 2017. Mortality rate ratios adjusted for age, sex, employment, region of origin and comorbidity were calculated using Poisson regression. Unadjusted cause specific mortality rate ratios with 95% confidence intervals were calculated assuming a Poisson distribution.

**Results:** A total of 6,988 persons with chronic hepatitis B and 69,847 controls were included in this study. During a median follow-up of 7.7 years (range 0.0–15.5), 315 (5%) persons with chronic hepatitis B and 1,525 (2%) without chronic hepatitis B died. The figure shows a Kaplan Meier plot of survival starting at 6 months after chronic hepatitis B diagnosis. The adjusted all-cause mortality rate ratio was 1.5 (95% CI 1.2–2.0). Persons with chronic hepatitis B had increased mortality due to liver disease (mortality rate ratio 12.3 [8.6–17.7]), neoplasm except hepatocellular carcinoma (HCC) (mortality rate ratio 1.6 [1.2–2.0]), endocrine disease (mortality rate ratio 3.2 [1.8–5.4]), genitourinary disease (mortality rate ratio 3.2 [1.2–7.6]) and external causes (mortality rate ratio 3.3 [2.5–4.7]).

Figure: Kaplan Meier plot of survival after inclusion in study in persons with chronic hepatitis B and controls.

**Conclusion:** This study showed an increased all-cause mortality in persons with chronic hepatitis B in comparison with the general population which remained after adjustment for several confounding factors. Excess death was mainly related to liver disease. However, rates of death from neoplasms (excluding HCC), endocrine disease, genitourinary disease and external factors were also increased in persons with CHB.

### OS-2750

#### Estimating the contribution of viral hepatitis and other etiologies to the burden of cirrhosis: a worldwide systematic review

Catharina Alberts<sup>1</sup>, Gary Clifford<sup>1</sup>, Francesco Negro<sup>2</sup>, Yvan Hutin<sup>3</sup>, Catherine de Martel<sup>1</sup>. <sup>1</sup>International Agency for Research on Cancer, World Health Organization, Lyon, France; <sup>2</sup>University Hospitals, Divisions of Gastroenterology and Hepatology and of Clinical Pathology, Geneva, Switzerland; <sup>3</sup>World Health Organization Regional Office for the Eastern Mediterranean, Department for Universal Health Coverage/Communicable Diseases, Cairo, Egypt

Email: demartelc@who.int

**Background and aims:** The International Agency for Research on Cancer estimated that, worldwide, the fraction of hepatocellular carcinoma (HCC) attributable to hepatitis B virus (HBV) and hepatitis C virus (HCV) were 56% and 20%, respectively (2015). Currently, estimates for cirrhosis are lacking. We conducted a systematic review to estimate the prevalence of HBV and HCV among cirrhotic patients worldwide.

**Method:** We included studies published between 1993 and 2019 with case series of cirrhotic patients that reported on the prevalence of both HBV and HCV infection in at least 20 adults. We excluded studies using first-generation assays for HCV. We extracted available information on the prevalence of HBV and HCV infection, heavy alcohol consumption, non-alcoholic fatty liver disease (NAFLD), or on the etiology of HCC cases, and calculated prevalence stratified by UN region.

**Results:** In total, 507 studies from 73 countries included over 1 million cases of cirrhosis. In most European and American regions, HCV was more prevalent among cirrhosis cases (ranging between 17–25% and 33–35%, respectively) compared to HBV (4–17% and 3–13%). In Asian and African regions, both HBV and HCV were prevalent with combined HBV and HCV prevalence  $> 50\%$ , albeit with large variations between sub-regions e.g. with highest prevalence of HBV in Eastern Asia and sub-Saharan Africa (see Figure). Heavy alcohol consumption (395 studies) varied from  $< 10\%$  in Northern Africa and Western Asia to 40–50% in South America, Oceania and Western Europe. Only 112 studies reported the prevalence of NAFLD ranging from 15% in North America to 1% in sub-Saharan Africa. In the 69 studies reporting etiology for both cirrhosis and HCC, the prevalence

of viral infections was greater among HCC than in cirrhotic patients, and this effect was stronger for HBV than for HCV.

Figure:

**Conclusion:** Similar to HCC, HBV and HCV prevalence varies worldwide and is an important cause of cirrhosis, yet, the combined fraction of HBV and HCV is lower than for HCC. Limited data on heavy alcohol consumption and NAFLD prevalence also suggests major geographical variations. This review provides much needed country-level, regional, and global data on the etiological fractions of cirrhosis to help set priorities for liver disease prevention, especially for viral hepatitis in Asian and African regions. Systematic, ongoing collection of representative data on the etiology of cirrhosis and HCC is required to evaluate progress towards hepatitis elimination.

## Rare liver diseases (including paediatric and genetic)

Email: martamagazm@gmail.com

**Background and aims:** PSVD is a rare disease usually with preserved liver function. Yet, some patients develop complications of portal hypertension or liver failure and require liver transplantation (LT). Data regarding LT are limited. The objective was to describe indications and outcome of LT in patients with PSVD.

**Method:** Retrospective VALDIG network multicentre study, 80 PSVD patients who underwent LT between 1996 and 2019: 51 came from a prospective international cohort of 587 patients and 29 additional were transplanted with the misdiagnosis of cirrhosis. Those patients without an underlying-disease or that have a similar life-expectancy to healthy patients, ie autoimmune hypothyroidism, were classified as mild underlying-disease. The remaining with potentially associated disorders with reduced life-expectancy, such as severe lupus were classified as severe.

**Results:** Indications for LT were 24 (30%) refractory ascites, 16 (20%) hepatic encephalopathy, 13 (16%) hepatopulmonary syndrome, 8 (10%) liver failure, 4 (5%) spontaneous bacterial peritonitis, 2 (2%) hepatorenal syndrome, 2 (2%) hepatocellular carcinoma, 1 (1%) recurrent portal hypertension related bleeding and other indications 10 (12%). Patients were categorized according to severity of the underlying-disease, 48 had a mild underlying-disease, the remaining 32 severe. Mean post-LT follow-up was 60 ± 60 [1–265] months. Twenty-four patients died after a median of 44 ± 70 [1–235] months, eight due to hepatic related conditions and 16 due to the underlying-disease. Post-LT cumulative survival was 82%, 81% and 69%, at 1, 2, 5 years. Post-LT survival was significantly better in patients without a severe underlying-disease (p = 0.05) (Figure).

Figure:

Six patients (7.5%) required a new LT (hepatic artery thrombosis n = 2, acute liver failure n = 2, graft loss n = 1, and unresolvable biliary complication n = 1). Consequently, overall graft survival was 81%, 78% and 66%, at 1, 2, 5 years respectively. Seventeen patients (21%) experienced acute rejection, and two developed chronic rejection. There were no reports of de novo post-transplant neoplasia.

**Conclusion:** The present large series, shows that when required, LT is associated with a good long-term outcome provided PSVD is not associated with a severe underlying-associated disease. Therefore, the severity of the underlying-disease must be taken into account when considering LT for these patients.

OS-1396

### cJun N-terminal kinase signaling prevents biliary cyst formation through a Caspase-8-dependent function of receptor-interacting serine/threonine kinase 1 during aging

Katrin Mueller<sup>1</sup>, Hanna Honcharova-Biletska<sup>2</sup>, Christiane Koppe<sup>1</sup>, Anne Schneider<sup>1</sup>, Lap Kwan Chan<sup>2</sup>, Fabian Geisler<sup>3</sup>, Thomas Longerich<sup>4</sup>, Mathias Heikenwälder<sup>5</sup>, Achim Weber<sup>2</sup>, Mihael Vucur<sup>6</sup>, Tom Luedde<sup>6</sup>. <sup>1</sup>RWTH Aachen University Hospital, Clinic for Gastroenterology, Metabolic Disorders and Internal Intensive Medicine, Aachen, Germany; <sup>2</sup>University Hospital Zürich, Institute for Pathology and Molecular Pathology, Zürich, Switzerland; <sup>3</sup>University Hospital rechts der Isar, Technical University Munich, Internal Medicine II, Munich, Germany; <sup>4</sup>University Hospital Heidelberg, Institute for Pathology, Heidelberg, Germany; <sup>5</sup>German Cancer Research Center, Chronic Inflammation and Cancer, Heidelberg; <sup>6</sup>University Hospital Düsseldorf, Department of Gastroenterology, Hepatology and Infectious Diseases, Düsseldorf, Germany  
Email: tom.luedde@med.uni-duesseldorf.de

**Background and aims:** The c-Jun N-terminal kinase (JNK) signaling pathway mediates adaptation to stress signals and has been associated with cell death, cell proliferation and malignant transformation in the liver. However, up to now its function was

experimentally studied mainly in young mice. The long-term effects of JNK deficiency in the liver have remained unclear.

**Method:** For this study we have been using multiple genetic mouse models, including different cre-recombinase approaches (LPC-KO and Sox9-creERT2) and genetic subcrossings. Furthermore, we performed cell death analyses, a three-dimensional reconstruction method of the intrahepatic bile duct system in mice, an in vitro kinase activity array for the investigation of the protein interaction processes, and immunohistochemical stainings in human liver samples.

**Results:** We show here that aging JNK1/2<sup>LPC-KO</sup> mice (LPC: liver parenchymal cells) spontaneously developed large biliary cysts. 3D reconstruction of serial biliary stainings as well as genetic subcrossing to biliary-specific cre-lines versus hepatocyte-specific cre-lines demonstrated that these cysts originated from biliary cells, arguing against a trans-differentiation defect of hepatocytes in JNK-deficient livers. Mechanistically, we could show that cyst formation in livers of JNK1/2<sup>LPC-KO</sup> mice was depending on a Caspase-8-dependent function of receptor interacting protein kinase 1 (RIPK1), a known regulator of programmed cell death, namely apoptosis and necroptosis. An unbiased kinase-substrate-array in cholangiocytes suggested that JNK-deletion might trigger overactivation of the kinases MK-2/3, resulting in the putative over-phosphorylation of RIPK1 and

Figure:

subsequent inhibition of cell death of biliary cells during aging. In line, we showed that RIPK1 was overexpressed in human cyst epithelium of a subset of patients with polycystic liver disease.

**Conclusion:** Collectively, these data reveal a previously unrecognized functional interaction between JNK signaling and RIPK1 in age-related progressive biliary cyst development. Thus, they provide a novel functional linkage between stress-adaption and programmed cell death (PCD) in the maintenance of liver homeostasis during aging and a potential hub for a new molecular targeting of human polycystic liver disease.

**Rapid and durable effect of odevixibat on clinical and biochemical parameters of cholestasis in children with progressive familial intrahepatic cholestasis**

Richard Thompson<sup>1</sup>, Lorenzo D'Antiga<sup>2</sup>, Binita M. Kamath<sup>3</sup>, Lise Kjems<sup>4</sup>, Quanhong Ni<sup>4</sup>, Mohammad Ali Shagrani<sup>5</sup>, Eyal Shteyer<sup>6,7</sup>, Nisreen Soufi<sup>8</sup>, Patrick Horn<sup>4</sup>. <sup>1</sup>Institute of Liver Studies, King's College London, London, United Kingdom; <sup>2</sup>Azienda Ospedaliera Papa Giovanni XXIII, Bergamo, Italy; <sup>3</sup>Hospital for Sick Children and the University of Toronto, Toronto, Canada; <sup>4</sup>Albireo Pharma, Inc., Boston, United States; <sup>5</sup>King Faisal Specialist Hospital and Research Centre, Riyadh, Saudi Arabia; <sup>6</sup>Hebrew University of Jerusalem, Faculty of Medicine, Jerusalem, Israel; <sup>7</sup>Shaare Zedek Medical Center, Juliet Keidan Department of Pediatric Gastroenterology, Jerusalem, Israel; <sup>8</sup>Children's Hospital Los Angeles, Los Angeles, United States  
Email: patrick.horn@albireopharma.com

**Background and aims:** Odevixibat, an ileal bile acid transporter inhibitor, is in development to treat cholestatic liver diseases. Here, we describe a pooled analysis on the timing and magnitude of effects of odevixibat on serum bile acids (sBAs), pruritus, and biochemical

markers from the phase 3 PEDFIC 1 (P1) and PEDFIC 2 (P2) studies in children with progressive familial intrahepatic cholestasis (PFIC).

**Method:** In P1, children with PFIC1 or PFIC2 were randomized to oral placebo (Pbo) or odevixibat 40 or 120 µg/kg/day for 24 weeks. P2 is an ongoing, 72-week, open-label extension study enrolling patients from P1 or new patients with any type of PFIC; all P2 participants receive odevixibat 120 µg/kg/day. Currently, 69 patients have received treatment in P2. This pooled analysis covers 48 weeks of combined data from these studies. Primary outcomes assessed were proportion of patients with sBA response (ie, ≥70% reduction from baseline or sBAs ≤70 µmol/L) and change in pruritus based on a patient's proportion of positive pruritus assessments (PPAs) over time (ie, scratching score ≤1 or a ≥1-point drop from baseline on the PRUCISION® instrument). Mean changes in autotaxin (linked to cholestatic pruritus intensity) and plasma 7α-hydroxy-4-cholesten-3-one (p-C4; marker of bile acid synthesis) levels were also summarized.

**Results:** Overall, 77 patients received odevixibat. This included 19 who received Pbo in P1 and rolled into P2, 42 who received odevixibat in P1 (of these, 34 rolled into P2), and 16 newly enrolled patients in P2. Treatment with odevixibat was associated with rapid improvement in sBAs, pruritus, autotaxin, and p-C4 levels (ie, by week 1–4), with clinical benefits sustained through 48 weeks of treatment (Figure, panels A-D, respectively). Overall, 61 of 77 patients (79%) experienced any treatment-emergent adverse event (TEAE), incidence comparable to that in patients treated with placebo in P1 (17/20 [85%]). Eight patients reported severe TEAEs, and none had serious adverse events deemed related to treatment.

**Conclusion:** In this pooled analysis of children with PFIC, treatment with odevixibat was generally well tolerated and was associated with

Figure:

## ORAL PRESENTATIONS

rapid control of biochemical and clinical markers of cholestasis, with durable effects over time.

### OS-1921

#### Factors related to liver impairment during SARS-CoV-2 infection

Lidia Canillas<sup>1,2</sup>, Giulia Pagano<sup>1</sup>, Teresa Broquetas<sup>1,2</sup>, Judit Romero<sup>1,2</sup>, Esther Garrido<sup>1,2</sup>, Ana Viu<sup>1,2</sup>, Jose A. Carrión<sup>1,3</sup>, Nuria Cañete Hidalgo<sup>1,2</sup>, Susanna Coll<sup>1,2</sup>, Xavier Bessa<sup>1,2</sup>, Montserrat Garcia-Retortillo<sup>1,2</sup>, Marc Puigvehí<sup>1,2</sup>. <sup>1</sup>Hospital del Mar, Barcelona, Spain; <sup>2</sup>IMIM, Barcelona, Spain; <sup>3</sup>Universitat Autònoma de Barcelona, Bellaterra, Spain  
Email: mpuigvehi@psmar.cat

**Background and aims:** Abnormal liver function tests (LFTs) have been reported in 22–53% of patients with SARS-CoV-2 infection. LFTs impairment has been suggested to be related with greater severity of respiratory disease, use of hepatotoxic treatments, and higher mortality. We aimed at evaluating factors related to LFTs abnormality during SARS-CoV-2 infection.

**Method:** Retrospective observational study including the first consecutive 600 patients admitted with coronavirus disease (COVID-19) in our tertiary center (Hospital del Mar, Barcelona, Spain). Sociodemographic data, comorbidities (including chronic liver disease -CLD-), SARS-COV-2 infection severity (defined by PaFi < 200 or organ dysfunction leading to intensive care unit -ICU-admission), laboratory tests, treatments received, and mortality data were collected. LFTs abnormality grade (absent to grade 4) was defined using aspartate aminotransferase (AST), alanine aminotransferase (ALT) and total bilirubin levels (TBIL), using the common terminology criteria for adverse events. Patients were further divided into mild (absent or grade 1 LFTs abnormality), and severe (grade 2/3/4 LFTs abnormality).

**Results:** A total of 595 patients were evaluated: median age 62 years, 361 (60.7%) males and 45 (7.6%) had CLD, of which 5 (11.1%) with cirrhosis. COVID-19 was severe in 250 (42%) patients. LFTs abnormality was found in 366 (61.5%) patients: 228 (38.3%) grade 1, 70 (11.8%) grade 2, 61 (10.3%) grade 3 and 7 (1.2%) grade 4. Patients with severe LFTs abnormality had a variable liver profile on admission: 89 (64.5%) and 49 (35.5%) showed mild and severe LFTs abnormality at the time of admission, respectively. Median time from the onset of symptoms to maximum LFTs impairment was 12 [IQR 9–16] days (4 [IQR 1–7] days from hospital admission). In a multivariate analysis [OR (CI 95%)], severe LFTs abnormality was independently related with PaFi < 200 [2.47 (1.18–5.14),  $p = 0.016$ ], and higher interleukin-6 [1.63 (1.01–2.62),  $p = 0.046$ ] and ferritin [2.68 (1.64–4.37),  $p < 0.001$ ] levels on admission. Global mortality was 10.3%: 9% and 14.5% in patients with mild and severe LFTs abnormality, respectively ( $p = 0.061$ ). Worsening of LFTs during admission ( $n = 89$ ) was independently related with ICU admission [5.34 (3.08–9.28),  $p < 0.001$ ] and use of immunomodulatory drugs [2.57 (1.50–4.39),  $p = 0.001$ ], but not antibiotic drugs. Patients with CLD didn't show greater LFTs abnormality, more severe COVID-19 infection, admission to ICU, neither mortality (all  $p = ns$ ).

**Conclusion:** Liver impairment appeared during the first days of admission, and was related with COVID-19 severity. The worsening of LFTs during COVID-19 was related with immunomodulatory but not antibiotic treatment. Patients with CLD did not present a more severe LFTs abnormality, greater severity nor mortality from COVID-19.

#### Preclinical antiviral profile of AB-836, a potent, highly selective hepatitis B virus capsid inhibitor

Nagraj Mani<sup>1</sup>, Andrew G. Cole<sup>1</sup>, Steven G. Kultgen<sup>1</sup>, Andrzej Ardzinski<sup>1</sup>, Tim Chiu<sup>1</sup>, Andrea Cuconati<sup>1</sup>, Bruce D. Dorsey<sup>1</sup>, Kristi Fan<sup>1</sup>, Ingrid Graves<sup>1</sup>, Ju-Tao Guo<sup>2</sup>, Troy O. Harasym<sup>1</sup>, Zhanying Hu<sup>2</sup>, Rose Kowalski<sup>1</sup>, Jeevan Kunta<sup>1</sup>, Angela M. Lam<sup>1</sup>, Amy C.H. Lee<sup>1</sup>, Boya Liu<sup>1</sup>, Eugen Mesaros<sup>1</sup>, Cornelis Rijnbrand<sup>1</sup>, Holly M. Steuer<sup>1</sup>, Kim Stever<sup>1</sup>, Sunny Tang<sup>1</sup>, Xiaowei Teng<sup>1</sup>, Emily P. Thi<sup>1</sup>, Michael J. Sofia<sup>1</sup>. <sup>1</sup>Arbutus Biopharma Inc, Warminster, United States; <sup>2</sup>Baruch S. Blumberg Institute, Doylestown, United States  
Email: nmani@arbutusbio.com

**Background and aims:** The global prevalence of chronic hepatitis B infection imposes tremendous healthcare burden with treatments limited to nucleos(tide) analogs (NAs) and pegylated interferon-alpha. HBV antivirals with better curative potential are needed. Capsid inhibitors have demonstrated encouraging results in clinical trials. The aim of the study was to evaluate the *in vitro* and *in vivo* anti-HBV activities of AB-836, a novel HBV capsid inhibitor.

**Method:** HepDE19 cells were used for efficacy and mechanism of action studies. HBV genotypes (Gt) and core- and NA-resistant variants were evaluated in a HepG2/plasmid DNA transfection system. The effect on cccDNA establishment was determined in HBV-infected HepG2-hNTCP cells and primary human hepatocytes (PHH). X-ray crystallography data of the AB-836 chemotype bound to core protein (Cp-Y132A) was used for *in silico* docking of AB-836. Pharmacokinetic (PK) properties were assessed in rodent and non-rodent species. A hydrodynamic injection (HDI) mouse model of HBV was used for *in vivo* efficacy studies.

**Results:** AB-836 inhibited HBV replication with an EC<sub>50</sub> of 0.01 μM, with no significant cytotoxicity (CC<sub>50</sub> >25 μM). The presence of 40% human serum caused a slight reduction in potency (2.3-fold). AB-836 induced formation of empty capsid particles devoid of pgRNA and rcDNA. In a *de novo* HBV infection system, AB-836 inhibited cccDNA establishment and HBsAg production with an EC<sub>50</sub> of 0.18 μM and 0.20 μM, respectively. AB-836 showed pan-genotypic activity against isolates from Gt A to H. AB-836, docked into the Cp-Y132A X-ray structure, showed a unique binding mode characteristic of its chemotype. Core variants Y38F, I105V, and T109M showed no significant decrease in potency (<2 fold); L30F and I105T showed modest decrease in potency (<10-fold); while L37Q and T33N/Q resulted in greater reductions (20 to 65-fold). NA-resistant variants remained fully susceptible to AB-836. PK results showed low systemic clearance with oral bioavailability of 30–100% in rats, dogs, monkeys, and mice. In a HDI mouse model of HBV, oral administration of AB-836 at 3 and 10 mg/kg once daily resulted in a dose-dependent antiviral effect with up to 2.5 log<sub>10</sub> reductions in serum HBV DNA after 7 days of treatment.

**Conclusion:** AB-836 is a novel class II capsid inhibitor that showed potent, selective inhibition of HBV *in vitro* and *in vivo*, with a unique binding mode to core protein, and a favorable preclinical profile for clinical advancement.

### OS-1021

#### Immunogenicity and cytokine patterns of newly identified CD4 T cell epitopes within the three open reading frames of the hepatitis E virus

Benedikt Csernalabics<sup>1</sup>, Stefan Marinescu<sup>1</sup>, Katharina Wild<sup>1</sup>, Lars Maurer<sup>2</sup>, Katharina Zoldan<sup>1</sup>, Marcus Panning<sup>3</sup>, Maïke Hofmann<sup>1</sup>, Christoph Neumann-Haefelin<sup>1</sup>, Bertram Bengsch<sup>1</sup>, Robert Thimme<sup>1</sup>, Viet Loan Dao Thi<sup>2</sup>, Tobias Böttler<sup>1</sup>. <sup>1</sup>University Hospital Freiburg,

Department of Internal Medicine II, Freiburg, Germany; <sup>2</sup>University Hospital Heidelberg, Department of Infectious Diseases and Virology, Heidelberg, Germany; <sup>3</sup>University Hospital Freiburg, Institute of Virology, Freiburg, Germany  
Email: tobias.boettler@uniklinik-freiburg.de

**Background and aims:** The roles of virus specific CD4 T cells in shaping the neutralizing antibody repertoire and facilitating viral clearance in response to viral infections are well accepted. However, little is known about their specificity and dynamics in the context of acute and resolved Hepatitis E Virus (HEV) infection. Therefore, we aimed to identify HEV-specific CD4 T cells targeting different regions of the viral polyprotein, unravel their differentiation fate and correlate their presence and function with neutralizing antibodies targeting naked and quasi-enveloped virions in patients with acute and resolved HEV-infection.

**Method:** HEV-specific T cell epitopes for the open reading frames (ORF) 1 and 2 were predicted *in silico* using the IEDB analysis resource consensus tool and epitope candidates were confirmed *in vitro* by flow cytometric intracellular cytokine staining after antigen-specific expansion of PBMCs from 33 HLA-typed individuals with HEV-infection (rHEV) and 7 acutely infected (aHEV) patients. ORF3-specific CD4 T cells were analyzed by stimulation with an overlapping peptide (OLP) library spanning the entire ORF 3 and subsequent intracellular cytokine staining. Antibodies targeting naked and quasi-enveloped virions were determined in a neutralization assay.

**Results:** Strong and multi-specific CD4 T cell responses were identified in all aHEV patients and in 23 out of the 33 rHEV donors. In these individuals, a total of 21 different HEV epitopes, originating from ORF1 and 2 were identified. 6 out of 21 HEV epitopes were restricted by the HLA alleles DRB1\*01:01, DRB1\*04:01, DRB1\*07:01 or DRB1\*15:01. Preliminary results indicate a strong positive correlation between the total magnitude of IFN $\gamma$ -producing HEV-specific CD4 T cells targeting the capsid-protein and titers of neutralizing antibodies against naked HEV virions. While ORF 1 and ORF 2 epitopes induce strong CD4 T cell responses in HEV patients, we detected fewer ORF 3-specific CD4 T cell responses. Overall, stronger and broader T cell responses were observed in aHEV, comparing to rHEV patients.

**Conclusion:** Our results provide important insights into the role of HEV-specific CD4 T cells during and after HEV infection and suggest a solid maintenance of CD4 T cells specific for ORF 1 and 2-derived epitopes and implicates them in the generation of neutralizing antibodies. In contrast, ORF 3-derived epitopes seemed less immunogenic, inducing only weak HEV-specific CD4 T cell responses.

### OS-1024

#### Recapitulating hepatitis e virus-host interactions and facilitating antiviral drug discovery in human liver organoids

Pengfei Li<sup>1</sup>, Yunlong Li<sup>2</sup>, Jiaye Liu<sup>1</sup>, Yang Li<sup>2</sup>, Ruyi Zhang<sup>1</sup>, Monique Versteegen<sup>3</sup>, Yining Wang<sup>1</sup>, Zhongren Ma<sup>4</sup>, Denis Kainov<sup>5</sup>, Yijin Wang<sup>6</sup>, Marco Bruno<sup>2</sup>, Robert De Man<sup>2</sup>, Luc Van De Laan<sup>3</sup>, Maikel Peppelenbosch<sup>2</sup>, Qiuwei Pan<sup>2</sup>. <sup>1</sup>Erasmus MC-University Medical Center, Department of Gastroenterology and Hepatology, Netherlands; <sup>2</sup>Erasmus MC-University Medical Center, Department of Gastroenterology and Hepatology, Rotterdam, Netherlands; <sup>3</sup>Erasmus MC-University Medical Center, Department of Surgery, Netherlands; <sup>4</sup>Northwest Minzu University, Biomedical Research Center, China; <sup>5</sup>Norwegian University of Science and Technology, Department of Clinical and Molecular Medicine, Norway; <sup>6</sup>Southern University of Science and Technology, School of Medicine, China  
Email: p.li@erasmusmc.nl

**Background and aims:** Hepatitis viruses naturally have narrow host and tissue tropisms, which is a fundamental impediment for the development of robust experimental models. The advent of organoid technology provides a unique opportunity for moving the field forward. Compared to 2D cultured cancer cell lines, organoids are

## ORAL PRESENTATIONS

much better in recapitulating the architecture, composition, diversity, organization and functionality of cell types of the origin tissue/organ. We aim to establish human liver organoid-based hepatitis E virus (HEV) models for mapping virus-host interactions and discovering new therapeutics.

**Method:** Human fetal and adult intrahepatic organoids were isolated and cultured from different donor tissues. Full-length genotype 3 (GT3) HEV genome, variant harboring an RdRp mutation G1634R, subgenomic GT3 and GT1 HEV replicon coupled with a *Gaussia luciferase* reporter gene and HEV replication defective replicon were used. The genome-wide transcriptomic analysis was performed. A library of 94 safe-in-man board-spectrum antiviral agents were screened.

**Results:** We demonstrate that 3D cultured organoids from fetal and adult human liver with cholangiocyte-like phenotype, are highly permissive to the replication of GT1 and GT3 HEV. Liver organoids, further differentiated towards hepatocyte-like phenotype, are also permissive to HEV replication. By inoculation with infectious HEV particles, staining of viral proteins and replicating double-strand viral RNA, and testing the infectivity of produced viral particles, we demonstrate that liver organoids support the full life cycle of HEV infection. Genome-wide transcriptomic analysis reveals a robust host response triggered by HEV replication, in particular type I interferon signaling. This may explain the self-limiting nature of *de novo* HEV infection in liver organoids, which highly resembles acute HEV infection in healthy individuals. Moreover, we successfully screened a library of safe-in-human broad-spectrum antiviral agents and identified bequinar and homoharringtonine as potent HEV inhibitors, which are also effective against the ribavirin resistance variant harboring G1634R mutation in liver organoids.

**Conclusion:** We successfully established innovative HEV models using organoids cultured from fetal and adult human liver. With this, the understanding of HEV-host interactions is catalyzed and antiviral drug discovery is boosted.

### OS-1062

#### Identification and characterization of neutralizing human monoclonal antibodies against Hepatitis E virus

Katja Dinkelborg<sup>1</sup>, George Ssebyatika<sup>2</sup>, Lucas Hüffner<sup>1</sup>, Prossie Lindah Nankya<sup>2</sup>, Luisa J. Ströh<sup>3</sup>, Heiner Wedemeyer<sup>4,5</sup>, Thomas Pietschmann<sup>1,5,6</sup>, Thomas Krey<sup>2,3,5,6,7</sup>, Patrick Behrendt<sup>1,4,5</sup>.  
<sup>1</sup>Twincore, Zentrum für Experimentelle und Klinische Infektionsforschung GmbH, Hannover, Germany; <sup>2</sup>University of Lübeck, Institute of Biochemistry, Center of Structural and Cell Biology in Medicine, Lübeck, Germany; <sup>3</sup>Institute of Virology, Hannover Medical School, Hannover, Germany; <sup>4</sup>Medizinische Hochschule Hannover, Department of Gastroenterology, Hepatology and Endocrinology, Hannover, Germany; <sup>5</sup>German Center for Infectious Disease Research (DZIF), Partner Sites Hannover-Braunschweig and Hamburg-Lübeck-Borstel-Riems, Germany; <sup>6</sup>Excellence Cluster 2155 RESIST, Hannover Medical School, Hannover, Germany; <sup>7</sup>CSSB, Center for Structural Systems Biology, Hamburg, Germany

**Background and aims:** Hepatitis E virus (HEV) is the leading cause of viral acute hepatitis worldwide. Although healthy patients can recover spontaneously from HEV infection, it poses a serious threat to patients with pre-existing liver disease, immunosuppressed patients and pregnant woman. Despite the high prevalence, no specific therapy is available to date. Even though HEV circulates as pseudo-enveloped virus, HEV vaccine studies demonstrated that antibodies protect from viral infection. Of note, Hepatitis A virus (HAV), which also exists in such a pseudo-enveloped state, can be efficiently neutralized by specific antibodies.

The aim of this study is to investigate the antibody response against HEV and identify human neutralizing antibodies that can be used as new therapeutic option for the treatment of HEV infection.

**Method:** Fluorescently labeled parts of HEV's ORF2 capsid protein were used in multi-color FACS to isolate antigen-specific memory B

cells from PBMCs of convalescent individuals. Single cell sequencing of the isolated B cells facilitated the identification of paired heavy and light chain B cell receptor sequences and the expression of antibody fragments in insect cells. The expressed antibody fragments are currently analyzed for antigen binding and their ability to neutralize viral infection in a GT3 based cell-culture infection model.

**Results:** We identified ~5000 sequences of ORF2 capsid-specific antibodies from two convalescent patients. We expressed 92 selected antibodies in form of single chain variable fragments (scFvs) and observed pronounced differences in their binding capacity to ORF2. Preliminary analysis of the neutralizing activity of these scFv in an *in vitro* infection model revealed a dose-dependent inhibition of HEV infection (an example is shown in the figure). In total, six out of the 42 scFvs tested to date reduced viral titers at least by 50% at a concentration of 10 µg/ml, three of them by over 90%.

Figure:

**Conclusion:** We have identified and expressed antibody fragments derived from B cells of convalescent patients that potentially neutralize HEV infection. We will evaluate our best candidates as intact IgG molecules. Based on recent experiences gained with other pathogens, e.g., SARS-CoV-2 or Ebola virus, such human monoclonal antibodies constitute a promising novel therapeutic option that could facilitate treatment of HEV infection *in vivo*.

### OS-1742

#### IFN response blocks cell division-mediated HDV spread and suppresses HDV persistence when combined with antivirals abrogating *de novo* infection

Zhenfeng Zhang<sup>1</sup>, Tobias Walther<sup>1</sup>, Florian Lempp<sup>1</sup>, Yi Ni<sup>1,2</sup>, Stephan Urban<sup>1,2</sup>. <sup>1</sup>University Hospital Heidelberg, Department of Infectious Diseases, Heidelberg, Germany; <sup>2</sup>German Center for Infection Research (DZIF)-Heidelberg Partner Site, Heidelberg, Germany  
Email: stephan.urban@med.uni-heidelberg.de

**Background and aims:** HBV/HDV co-infection causes the most severe form of viral hepatitis. HDV exploits HBV envelope proteins for dissemination and *de novo* entry into hepatocytes. However, HDV can also spread through cell division which challenges the HDV-eliminating efficiency of antivirals targeting either *de novo* infection, e.g. Hepcludex/bulevirtide (formerly Myrcludex B) or assembly (e.g. Lonafarnib). Here we investigated the effect of the HDV-induced IFN response and the administration of IFNs on cell division-mediated HDV spread. Furthermore, we determined the synergistic effects of co-treatments *in vitro*.

**Method:** HDV infected cells were split to allow cell division following reseeding. The effect of IFN response was evaluated by blocking the PRR-mediated endogenous IFN response or by application of IFNs. H7NB2.7 cell line stably expressing the HBV envelope proteins and the viral receptor NTCP was generated to support both HDV spreading pathways. The anti-HDV effects of mono- or co-treatment with Hepcludex, Lonafarnib, IFN-alpha, and IFN-lambda1 was measured in H7NB2.7 cells.

**Results:** Cell division-mediated HDV spread was profound in HuH7-NTCP cells (deficient for IFN production), but limited in HepaRG-NTCP cells (IFN competent). Exogenous IFN treatment significantly suppressed this spread during HuH7-NTCP cell division but had little effect on the HDV replication in resting cells. Blocking IFN signaling or infecting with low HDV titers (weak IFN activation) also favored cell division-mediated HDV spread in HepaRG-NTCP cells. Consistently, the effect of IFN treatment was more pronounced when virus-induced IFN response was low. In H7NB2.7 cells, all inhibitors showed the expected antiviral effects when applied individually. However, co-treatments targeting both spreading pathways (e.g. Hepcludex plus IFN-alpha) showed synergism.

**Conclusion:** Both virus-induced IFN response and IFN treatment efficiently restricts cell division-mediated HDV spread. IFN treatment under conditions with low virus-induced IFN responses is accordingly more profound. Combination of inhibitors targeting different spreading pathways suppresses HDV persistence synergistically. The findings unveil a novel mode-of-action of IFN (independent from activation of cellular immune responses), confirm the clinical observation of the Myr-203 study demonstrating a strong synergism of Myrcludex B and peg-IFN-alpha, and help to design future combination therapies.

**OS-2482**

**Decrease of intrahepatic cccDNA and HBV integration in chronic hepatitis B patients with functional cure**

Weiqiang Gan<sup>1</sup>, Na Gao<sup>1</sup>, Lin Gu<sup>1</sup>, Zhishuo Mo<sup>1</sup>, Xiuqing Pang<sup>1</sup>, Ziyang Lei<sup>1</sup>, Zhiliang Gao<sup>1</sup>. <sup>1</sup>The Third Affiliated Hospital of Sun Yat-Sen University, Department of Infectious Diseases, Guangzhou, China  
Email: ganweiq@mail.sysu.edu.cn

**Background and aims:** The present study aimed to explore the level of intrahepatic cccDNA and HBV integration, its relationship with virological markers and its value in predicting virological relapse in CHB patients with functional cure.

**Method:** A total of 90 patients were included in the study, including 40 CHB patients with functional cure, 40 treatment naïve CHB patients for positive control and another 10 CHB patients for HBV integration analysis. The patients with functional cure were followed up for 24 weeks to see whether relapse happened after drug cessation. The level of intrahepatic cccDNA and synchronous serum virological markers were detected. 10 CHB patients for HBV integration analysis were composed of seven treatment naïve CHB patients and 3 CHB patients with functional cure. We used deep whole genome sequence to search for HBV integration.

**Results:** Ten out of 40 functional cure patients had undetectable cccDNA. The intrahepatic cccDNA and serum HBcrAg level were significantly lower in the functional cure group than that in CHB group. Only one patient had virological relapse during the followup. For HBV integration analysis, the numbers of integration sites were 398, 1558 and 4 in HBeAg positive CHB group, HBeAg negative CHB group and functional cure group respectively. 42.85% of integration sites were located in protein coding gene and integration sites preferentially located in CpGs ( $p = 0.001$ ,  $X^2 = 10.57$ ), exon ( $p < 0.001$ ,  $X^2 = 12.766$ ), promoter ( $p = 0.016$ ,  $X^2 = 5.817$ ) compared to the expected.

**Conclusion:** The intrahepatic cccDNA level was significantly decreased in CHB patients with functional cure. Patients with functional cure had a very low risk of virological relapse. HBV integration in functional cure patients was apparently lower than CHB patients.

**OS-2826**

**Profiling anti-HBs; immune complex peaks, epitope occupancy, ADCC phenotype and neutralization profiles associated with functional cure in a genotype A chronic hepatitis B cohort.**

Hui Xu<sup>1</sup>, Stephen Locarnini<sup>1</sup>, Darren Wong<sup>2</sup>, Danni Colledge<sup>1</sup>, Rachel Hammond<sup>1</sup>, Thao Huynh<sup>1</sup>, Tim Shaw<sup>1</sup>, Sally Soppe<sup>1</sup>, Peter Revill<sup>1</sup>, Alexander Thompson<sup>3</sup>, Anuj Gaggar<sup>4</sup>, Renae Walsh<sup>5</sup>, Nadia Warner<sup>1</sup>. <sup>1</sup>The Peter Doherty Institute for Infection and Immunity, Melbourne, Australia; <sup>2</sup>Austin Repatriation, Heidelberg West, Australia; <sup>3</sup>St. Vincent's Hospital Melbourne, Fitzroy, Australia; <sup>4</sup>Gilead Sciences, Inc., Foster City, United States; <sup>5</sup>Clear B Therapeutics, Boston, United States  
Email: nadia.warner@mh.org.au

**Background and aims:** The presence and functionality of antibodies specific to HBV surface antigen (anti-HBs) during CHB has been poorly defined, due to anti-HBs binding to the excessive decoy SVPs rendering anti-HBs undetectable using traditional approaches. The aim of this study was to develop and utilise a set of assays designed to specifically examine anti-HBs, in free and HBs-bound form, to further understand anti-HBs responses associated with functional cure (FC).

**Method:** Longitudinal serum samples from 25 genotype A CHB patients undergoing nucleos(t)ide analogue (NA) treatment were examined; 14 of these patients achieved functional cure (FC) while 11 patients remained infected (non-FC). HBsAg/anti-HBs Immune complexes (HBs-IC) were quantified using a modified diagnostic assay. FCγRIIIa dimer binding (NK cell target) of anti-HBs within convalescent sera was detected using ELISA. Epitope-specific anti-HBs responses were detected using a 19-plex assay, and neutralization efficacy of anti-HBs was measured using an *in vitro* HBV infection model.

**Results:** HBs-IC peaks were detected prior to HBs-loss in 10/14 FC patients. These HBs-IC peaks overlapped with either an ALT flare (8/10 patients), or a rise in ALT (2/10 patients). HBs-IC peaks were detected in 7/11 non-FC patients, but were not associated with an ALT flare.

FCγRIIIa binding was detected in 9/14 FC patients, independent from detection of overlapping HBs-IC/ALT peaks.

FC patients had stable HBsAg epitope occupancy across the study, whereas non-FC patients had a reduction in HBsAg epitope occupancy within the first 12–24 weeks of NA treatment.

Convalescent sera from FC patients recognised more HBsAg epitopes and neutralized HBV infection more potently than anti-HBs derived from vaccines. Neutralisation potency appeared to increase post HBs-loss in 4/5 FC patients examined.

**Conclusion:** Using this toolbox of complementary anti-HBs assays, combined with biochemical data, we were able to identify key anti-HBs profiles associated with either FC, or failure to achieve FC.

Figure 1: Distribution of HBV break points across the HBV genome. This figure included sites from genotype B and C of HBV. Viral junctions determined from chimeric reads. The locations of the genes encoding HBV polymerase (red), core protein (violet), HBsAg (blue) and HBx (yellow) are shown.

## ORAL PRESENTATIONS

These findings shed light on some of the anti-HBs-mediated immunological mechanisms that may be occurring in the liver during and post-FC. Further investigation may inform the development of biomarkers predictive of disease outcome, or the development of antiviral approaches to induce these mechanisms.

### OS-2864

#### Quantification of viral RNA in multiple pieces of liver tissue shows distinct focal differences of hepatitis B infection

Gustaf Rydell<sup>1</sup>, Kasthuri Prakash<sup>1</sup>, Simon B. Larsson<sup>1</sup>, Catarina Skoglund<sup>2</sup>, Johan Ringlander<sup>1</sup>, Maria Andersson<sup>1</sup>, Maria Castedal<sup>2</sup>, Heléne Norder<sup>1</sup>, Magnus Lindh<sup>1</sup>. <sup>1</sup>University of Gothenburg, Department of Infectious Diseases, Gothenburg, Sweden; <sup>2</sup>University of Gothenburg, Department of Surgery, Gothenburg, Sweden  
Email: gustaf.rydell@gu.se

**Background and aims:** Hepatitis B virus (HBV) induces immune responses that may cause liver damage or clear the infection. It is not known to what extent immune clearance is focal, if it changes the balance between so-called covalently closed circular DNA (cccDNA) and HBV DNA integrated into chromosomal DNA, or changes the expression of these templates. We addressed these questions by analyzing multiple pieces of liver tissue.

**Method:** HBV DNA and RNA were quantified by droplet digital PCR assays in 20–30 tissue pieces from each of four liver explants with cirrhosis caused by HBV.

**Results:** The within-patient variability of HBV RNA levels between pieces was up to tenfold in highly active HBV infection, and up to thousand fold in cases with low HBV replication, reflecting uneven distribution of cccDNA and integrations, and of their expression. Core RNA and S RNA levels were similar and correlated strongly when replication was high, supporting transcription from cccDNA. By contrast, enhanced expression of S RNA relative to cccDNA and core RNA was observed when replication was medium-high or low.

**Conclusion:** Immune clearance results in large focal differences in the distribution of HBV infection. Enhanced expression of S RNA relative to cccDNA and core RNA supports that HBV surface antigen can be expressed mainly from integrated HBV DNA.

## Viral hepatitis B-D: Clinical aspects except therapy

### OS-654

#### VALIANT: A targeted long-read approach to study translocation and mRNA isoforms associated with HBV integration

Cameron Soulette<sup>1</sup>, Ricardo Ramirez<sup>1</sup>, Nicholas Van Buuren<sup>1</sup>, Dong Han<sup>1</sup>, Vithika Suri<sup>1</sup>, Patrick Marcellin<sup>2</sup>, Maria Buti<sup>3</sup>, Neeru Bhardwaj<sup>1,4</sup>, Anuj Gaggar<sup>1</sup>, Li Li<sup>1</sup>, Hongmei Mo<sup>1</sup>, Becket Feierbach<sup>1</sup>. <sup>1</sup>Gilead Sciences, Inc., Foster City, United States; <sup>2</sup>Hospital Beaujon AP-HP, Clichy, France; <sup>3</sup>Hospital Universitari Vall d'Hebron, Barcelona, Spain; <sup>4</sup>Foundation Medicine Inc, Cambridge, United States  
Email: becket.feierbach@gilead.com

**Background and aims:** Hepatitis B virus (HBV) infects an estimated 260 million people worldwide and is associated with the development of hepatocellular carcinoma (HCC). Integration of HBV DNA into the host genome may be a key driver of HCC oncogenesis. Standard sequencing approaches are unable to capture the complete architecture of HBV DNA insertions and underestimate the contribution of integrated HBV to viral mRNA production. We present a method for detecting VirAL Integrations AND Translocations (VALIANT): a quantitative workflow that uses targeted long-read sequencing to determine the structure of HBV DNA integrations and full-length HBV RNA transcripts.

**Method:** DNA and RNA were isolated from 42 fresh frozen liver biopsies collected within the GS-US-174-0149 clinical trial. A pan-genotypic panel of biotinylated oligos was developed to enrich for HBV sequences from sheared genomic DNA (~7 kb) and full-length cDNA from poly-adenylated RNA. Samples were sequenced on the PacBio long-read platform and analyzed with VALIANT.

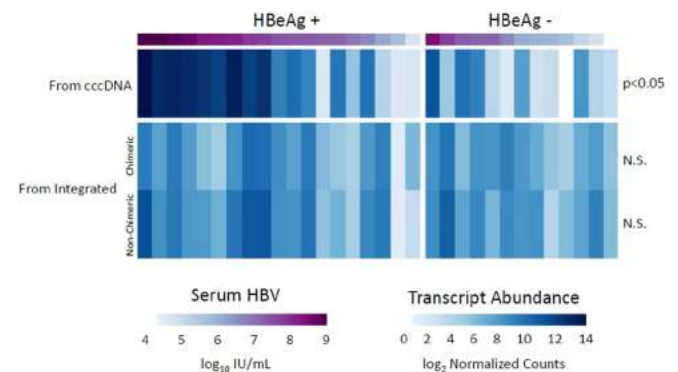

Figure:

**Results:** HBV-targeted long-read DNA sequencing generated high coverage data that spans entire integrations, resulting in the detection of thousands of chimeric HBV-host sequences in each patient. Strikingly, 13 of 42 samples (31%) contained HBV sequences flanked by two different chromosomes, indicating a chromosomal translocation associated with HBV integration. Chromosomal translocations were unique to each biopsy sample, suggesting that each originated randomly, and in some cases had evidence of clonal expansion. From our HBV-targeted cDNA sequencing, we identified transcriptional activity from HBV integrations, including fusion transcripts associated with inter-chromosomal translocations. By inspecting the 3' ends of HBV RNAs, we determined that nearly 95% of HBV transcripts from HBeAg positive patients originate from cccDNA, whereas HBeAg negative patients expressed mostly HBsAg from integrations. In both groups, we detected non-chimeric HBV transcripts from HBV integrations within host genes, which utilize

a non-canonical polyA site in the X ORF. These transcripts would not be properly classified by standard RNA-Seq.

**Conclusion:** Our VALIANT workflow is a powerful tool for studying HBV integration architecture and expression. The existence of multiple unique HBV-associated inter-chromosomal translocations in non-HCC CHB patient liver biopsies suggests a novel mechanism with mutagenic potential that may contribute to progression to HCC.

**OS-887**

**HDV RNA replication is linked with higher serum concentrations of HBV cccDNA transcriptional activity markers-HBcrAg and pre-genomic HBV RNA**

Ivana Carey<sup>1</sup>, Mark Anderson<sup>2</sup>, Christiana Moigboi<sup>1</sup>, Bo Wang<sup>1</sup>, Gavin Cloherty<sup>2</sup>, Geoffrey Dusheiko<sup>1</sup>, Kosh Agarwal<sup>1</sup>. <sup>1</sup>King's College Hospital, Institute of Liver Studies, London, United Kingdom; <sup>2</sup>Abbott Diagnostics, Department of Infectious Diseases, Abbott Park, United States

Email: ivana.kraslova@kcl.ac.uk

**Background and aims:** Persistent HDV infection requires help from HBsAg for the assembly, envelopment, propagation, and entry of HDV into the hepatocytes. HBsAg originates from both cccDNA and integrated HBV DNA encoded transcripts and levels may vary between patients with active HDV replication (HDV RNA positive) and patients with positive anti-HDV antibodies, but persistently negative HDV RNA (non-active HDV). The presence or absence of novel markers of cccDNA transcriptional activity-pre-genomic HBV RNA (pgRNA) and hepatitis B core-related antigen (HBcrAg)-may indirectly differentiate the derivation of virion and subviral HBsAg from cccDNA vs. integrated genomes. We aimed to quantify whether active cccDNA transcription, imputed by testing for pgRNA and HBcrAg, indicate a relative influence of HBsAg derivation, from cccDNA transcription (and hence HBV replication), on persistent HDV infection.

**Method:** We studied serum samples of 120 treatment naïve HBsAg positive, anti-HDV positive patients (70 males, median age 40 years): 53 patients were HDV RNA positive (in-house real-time PCR assay, LLQD = 640 copies/ml) and 67 were persistently HDV RNA negative. We compared HBsAg levels (Abbott Architect [IU/ml]), HBV DNA concentrations (TaqMan Roche [IU/ml]), HBcrAg (CLEIA Fujirebio [ $\log_{10}$ U/ml]) and pgRNA (real-time PCR Abbott Molecular Diagnostic assay (LLQD = 1.65  $\log_{10}$ U/ml) between HDV RNA positive and negative cohorts.

**Results:** There was no difference in the numbers of HBeAg+ patients (2 patients in each group,  $p = 0.81$ ), or median HBV DNA concentrations (27 vs. 22 IU/ml) between HDV RNA positive vs. negative patients. HBsAg levels were significantly higher in HDV RNA positive patients (median: 8068 vs. 1479 IU/ml,  $p < 0.01$ ). HBcrAg concentrations were significantly higher in HDV RNA positive patients (median: 3.6 vs. 2.0  $\log_{10}$ U/ml,  $p < 0.01$ ) as were pgRNA levels (median: 1.99 vs. 1.67  $\log_{10}$ U/ml,  $p < 0.01$ ). Only 5.6% and 3.7% of HDV RNA positive patients did not have detectable pgRNA or HBcrAg respectively.

**Conclusion:** In this study we observed higher concentrations of markers of HBV transcriptional activity in HDV RNA positive versus negative patients. These data suggest that although integrant derived envelope proteins may support assembly of HDV, independently of HBV replication, the spreading cycle of HDV in patients with low serum concentrations of HBV DNA is favoured by ongoing cccDNA transcriptional activity, and hence replication-derived HBsAg. Further studies focusing on the relative fraction of HBV RNAs encoding envelope proteins, that are generated from viral integrants versus progeny virus, (and of HBsAg composition), are needed to understand the maintenance of HDV infection. The apparent facilitation of HDV persistence in patients showing ongoing HBV replication has implications for the design of therapeutic interventions to reduce HBsAg levels and cure HDV infection.

**OS-900**

**Current and past infection of hepatitis B virus do not increase mortality in patients with COVID-19: a territory-wide cohort of 5,639 patients**

Terry Cheuk-Fung Yip<sup>1,2,3</sup>, Vincent Wai-Sun Wong<sup>1,2,3</sup>, Chung Yan Grace Lui<sup>1,2,4</sup>, Yee-Kit Tse<sup>1,2,3</sup>, Henry Chan<sup>1,2,3</sup>, Grace Lai-Hung Wong<sup>1,2,3</sup>. <sup>1</sup>The Chinese University of Hong Kong, Department of Medicine and Therapeutics, Hong Kong, Hong Kong; <sup>2</sup>The Chinese University of Hong Kong, Medical Data Analytics Centre (MDAC), Hong Kong, Hong Kong; <sup>3</sup>The Chinese University of Hong Kong, Institute of Digestive Disease, Hong Kong, Hong Kong; <sup>4</sup>The Chinese University of Hong Kong, Stanley Ho Centre for Emerging Infectious Diseases, Jockey Club School of Public Health and Primary Care, Hong Kong, Hong Kong  
Email: wonglaihung@cuhk.edu.hk

**Background and aims:** We compared the risk of acute liver injury and death in coronavirus disease 2019 (COVID-19) patients with current, past, and no hepatitis B virus (HBV) infection.

**Method:** This was a retrospective cohort study using a territory-wide database in Hong Kong. COVID-19 patients virologically diagnosed from 23 January 2020 to 1 January 2021 were identified. Patients with hepatitis C or no hepatitis B surface antigen (HBsAg) results were excluded. Current HBV infection was defined by positive HBsAg. Past HBV infection was defined by negative HBsAg with positive hepatitis B core antibody and/or antibody to HBsAg if patients were born before the launch of universal neonatal vaccination program, i.e. year 1988. Acute liver injury was defined as alanine aminotransferase (ALT) or aspartate aminotransferase  $\geq 2x$  upper limit of normal (ULN) (i.e. 80 U/L), with total bilirubin  $\geq 2x$ ULN (i.e. 38  $\mu$ mol/L) and/or international normalised ratio  $\geq 1.7$ . The primary outcome was COVID-19-related death.

Figure:

**Results:** Of 5,639 patients (mean age 51 years, 49% male) included, 353 (6.3%) and 359 (6.4%) had current and past HBV infection, respectively. Compared to patients without known HBV exposure, current HBV-infected patients were older, and more likely to have cirrhosis, higher ALT, lactate dehydrogenase (LDH), and lower platelets. Among the three groups, past HBV-infected patients were the oldest, and more had diabetes and cardiovascular disease, higher creatinine, LDH, and neutrophil-to-lymphocyte ratio. At a median

## ORAL PRESENTATIONS

follow-up of 14 (9–20) days, 138 (2.4%) patients died; acute liver injury occurred in 58 (1.2%), 8 (2.3%), and 11 (3.1%) patients with no, current, and past HBV infection, respectively. After adjusting for demographics, comorbidities and laboratory parameters, acute liver injury (adjusted hazard ratio [aHR] 2.45, 95% CI 1.52–3.96,  $p < 0.001$ ), but not current (aHR 1.29, 95% CI 0.61–2.70,  $p = 0.507$ ) or past HBV infection (aHR 0.90, 95% CI 0.56–1.46,  $p = 0.681$ ), was associated with death. Similar results were shown after propensity score weighting (Figure). Corticosteroid, antifungals, ribavirin, and lopinavir/ritonavir use (adjusted odds ratio [aOR] ranged from 2.55–5.63), but not current (aOR 1.93, 95% CI 0.88–4.24,  $p = 0.102$ ) or past HBV infection (aOR 1.25, 95% CI 0.62–2.55,  $p = 0.533$ ), were associated with acute liver injury.

**Conclusion:** Current or past HBV infection were not associated with more acute liver injury and death in COVID-19.

Email: pindra@empal.com

**Background and aims:** Several risk scores have recently been developed to predict hepatocellular carcinoma (HCC) in patients with chronic hepatitis B (CHB). Our aims were to develop and validate an artificial intelligence (AI)-assisted prediction model for HCC risk, and to compare the utility of our model with previous models.

**Method:** Using Gradient Boosting Machine (GBM), a model was developed from 6, 051 chronic hepatitis B patients on entecavir or tenofovir therapy from 4 tertiary hospitals in Korea. Two external validation cohorts were independently established: Asian cohort (3, 420 patients from 3 Korean centers) and Caucasian PAGE-B cohort (1, 640 from 11 Western centers). The primary outcome was HCC development. The performance of PLAN-B model was compared to previous models using Harrell’s c-index.

**Results:** In the derivation cohort and two validation cohorts, mean ages were 48.6–52.8 years and 60.2–70.6% were male. Cirrhosis was present in 26.9–50.2% at baseline. A total of 595 patients (9.8%) developed HCC during a median 5.2 years of follow-up in the derivation cohort. A model using 10 parameters at baseline was derived and showed a good prediction performance (c-index, 0.79). This model was designated as the PLAN-B model and consisted of the

Fig. 1A

Fig. 1B

**Figure 1.** The expected versus the observed HCC development according to PLAN-B model in the (A) Asian and (B) Caucasian validation cohorts. Thick lines represent the observed HCC development and dotted lines represent the expected HCC development.

Figure:

presence of cirrhosis, age, platelet count, antiviral agent (tenofovir or entecavir), baseline serum levels of HBV DNA, alanine aminotransferase, and bilirubin, and HBeAg status, which are listed in order of importance according to Shapley values. PLAN-B showed significantly better predictive power than previous models (PAGE-B, modified PAGE-B, REACH-B, and CU-HCC) in both Asian (c-index, 0.79 vs. 0.64–0.74; all  $p < 0.001$ ) and Caucasian validation cohorts (c-index, 0.81 vs. 0.57–0.79; all  $p < 0.05$  except modified PAGE-B [ $p = 0.22$ ]). When the patients were grouped into 4 groups using a probability result from GBM algorithm, respective groups showed significantly different risk of HCC development from other groups in both Asian (Fig. 1A) and (Fig. 1B) cohorts and there was good correlation between expected and observed risk (Fig. 1A and 1B). Specifically, the group with the minimal risk group (11.2% of Asian cohort and 8.8% of Caucasian cohort) showed <1% of HCC risk during 10 years of follow-up.

**Conclusion:** This AI-based PLAN-B model provides the best prediction power for HCC risk in Asian as well as Caucasian patients with CHB under entecavir or tenofovir treatment.

#### OS-2225

##### Predictive Immune Biomarkers of Persistent HBV DNA Suppression and Low Replicative State After Treatment Discontinuation in CHB Patients

Henry LY Chan<sup>1</sup>, Scott Fung<sup>2</sup>, Ed Gane<sup>3</sup>, Maria Buti<sup>4</sup>, Diana Chen<sup>5</sup>, Ruidong Li<sup>5</sup>, Vithika Suri<sup>6</sup>, Jeffrey Wallin<sup>6</sup>, John F. Flaherty<sup>6</sup>, Anuj Gaggar<sup>6</sup>, Patrick Marcellin<sup>7</sup>, Jorg Peterson<sup>8</sup>, Sang Hoon Ahn<sup>9</sup>, Thomas Berg<sup>10</sup>. <sup>1</sup>Chinese University of Hong Kong, Hong Kong; <sup>2</sup>Toronto General Hospital Research Institute, Canada; <sup>3</sup>University of Auckland, New Zealand; <sup>4</sup>Vall d'Hebron University Hospital, Spain; <sup>5</sup>Gilead Sciences Inc., United States; <sup>6</sup>Gilead Sciences Inc., Foster City, United States; <sup>7</sup>University of Paris, Paris, France; <sup>8</sup>University of Hamburg, Hamburg, Germany; <sup>9</sup>Yonsei University, Seoul, Korea, Rep. of South; <sup>10</sup>University Hospital Leipzig, Leipzig, Germany  
Email: vithika.suri@gilead.com

**Background and aims:** Current international guidelines recommend stopping nucleos(t)ide analogue (NA) therapy in a select group of patients with the aim of promoting sustained off treatment response. However, numerous reports suggest that NA treatment discontinuation results in recurrence of HBV viremia in the majority of patients with low rates of HBsAg loss or maintenance of inactive carrier state. Therefore, the ability to predict outcomes prior to discontinuation would be an asset for safe and effective treatment discontinuation. Here we aimed to identify biomarkers at the end of treatment that can predict off treatment HBV response.

**Method:** Patients ( $n = 359$ ) from GS-US-174-0102/0103/0149 were used to identify predictive biomarkers for HBV DNA suppression (HBV DNA <29 IU/ml) and low-replicative states (LRS) (HBV DNA <2000 IU/ml and ALT  $\leq$ ULN) 24 weeks after TDF  $\pm$  Peg treatment discontinuation in HBeAg positive and negative patients. We profiled 182 relative expression levels in serum or plasma proteins at end of treatment (or last visit prior to treatment withdrawal), using Olink Proteomics. Wilcoxon-Mann-Whitney test was used to compare differences in protein expression, and multiple comparisons were adjusted using Benjamini-Hochberg method, at significant levels of 0.05 for adjusted  $p$  values. Gene ontology and Kyoto Encyclopedia of Genes and Genomes pathway enrichment analyses were conducted.

**Results:** In patients with HBV DNA suppression ( $n = 25$ ) at treatment free follow-up Week 24 (TFFU-24), levels of 29 proteins were found to be significantly higher vs those without suppression ( $n = 334$ ). These proteins included myeloid cell markers (e.g., CD164, CLEC5A, IL-33, CD1c), leukocyte trafficking chemokines (e.g., CCL4, CXCL5, CCL17), NK markers (i.e., KLRD1), and extracellular matrix (ECM) and/or

ECM-associated proteins (e.g., ANGPT1, MMP12, PDGF8, SERPINB8). Pathway analyses show enrichment for ECM remodeling, innate immune response to virus and immune regulation in the DNA suppressed group. For LRS ( $n = 111$ ), CD8a expression levels trended higher in subjects with LRS compared to those without LRS ( $n = 247$ ) at TFFU-24. Feature selection and assessment of predictive performance of the identified biomarkers is ongoing.

**Conclusion:** The results suggest HBV DNA suppression and maintenance of inactive carrier state following treatment discontinuation is associated with higher levels of certain innate and T cell immune responses during treatment.

## Viral hepatitis B-D: therapy

#### OS-44

##### Safety and antiviral activity of VIR-2218, an X-targeting RNAi therapeutic, in participants with chronic hepatitis B infection: week 48 follow-up results

Edward Gane<sup>1</sup>, Young-Suk Lim<sup>2</sup>, Daniel Cloutier<sup>3</sup>, Ling Shen<sup>3</sup>, Andrea Cathcart<sup>3</sup>, Xiao Ding<sup>3</sup>, Phil Pang<sup>3</sup>, Stephen Huang<sup>4</sup>, Man-Fung Yuen<sup>5</sup>. <sup>1</sup>University of Auckland, Auckland Clinical Studies, Auckland, New Zealand; <sup>2</sup>Asan Medical Center, University of Ulsan College of Medicine, Gastroenterology, Seoul, Korea, Rep. of South; <sup>3</sup>Vir Biotechnology, San Francisco, United States; <sup>4</sup>Alnylam Pharmaceuticals, Cambridge, United States; <sup>5</sup>Queen Mary Hospital, The University of Hong Kong, Medicine, Hong Kong  
Email: dcloutier@vir.bio

**Background and aims:** VIR-2218 is an investigational GalNAc-conjugated small interfering ribonucleic acid (siRNA) therapeutic in development for functional cure of chronic hepatitis B virus infection (CHB). VIR-2218 was created using Enhanced Stabilization Chemistry Plus, which retains *in vivo* potency while reducing off-target effects. VIR-2218 targets a conserved region of the X gene and is designed to silence all major HBV transcripts, from both cccDNA and integrated DNA, across all 10 HBV genotypes as a single siRNA. We present final safety and antiviral activity data from a Phase 2 trial of VIR-2218 in participants with CHB.

**Method:** Non-cirrhotic, virologically suppressed participants received 2 subcutaneous doses of VIR-2218 or placebo on Day 1 and Day 29 (Week 4). HBeAg- participants received 20, 50, 100 or 200 mg, and HBeAg+ participants received 50 or 200 mg. Cohorts included 4 or 8 participants randomized 3:1 to VIR-2218 or placebo. Assessments included safety, HBsAg levels and other viral markers, with 12 weeks of follow-up after the 2<sup>nd</sup> dose for all participants and an additional 32-weeks follow-up for participants achieving pre-specified HBsAg declines.

**Results:** Twenty-four CHB participants received VIR-2218 (18 HBeAg-; 6 HBeAg+). Maximum mean HBsAg log<sub>10</sub> IU/ml declines in HBeAg- participants receiving 20, 50, 100, and 200 mg of VIR-2218 were 1.03, 1.23, 1.50, and 1.65, respectively. For the HBeAg+ participants receiving 50 and 200 mg of VIR-2218, the maximum mean HBsAg log<sub>10</sub> IU/ml declines were 1.16 and 1.57, respectively. Most participants achieved maximum HBsAg decline by week 16. Most participants had levels of HBV DNA and HBV RNA <LOQ at baseline, and significant changes were not detected. Declines in qHBeAg and HBcrAg were observed in HBeAg+ subjects receiving 200 mg VIR-2218. No participants discontinued due to an adverse event (AE), and the majority of treatment emergent AEs were mild in severity. No clinically significant ALT elevations were observed.

## ORAL PRESENTATIONS

Figure:

**Conclusion:** Two doses of VIR-2218 at 20–200 mg given 4 weeks apart were well tolerated in CHB participants. Substantial reductions in HBsAg were observed in both HBeAg- and HBeAg+ participants across all dose levels, suggesting that VIR-2218 may silence transcripts from both cccDNA and integrated DNA. The antiviral activity of VIR-2218 demonstrated in this study support continued development as part of combination regimens targeting functional cure.

### OS-211

#### A phase 1 study evaluating the neutralizing, vaccinal monoclonal antibody VIR-3434 in participants with chronic hepatitis B virus infection

Kosh Agarwal<sup>1</sup>, Man-Fung Yuen<sup>2</sup>, Heiner Wedemeyer<sup>3</sup>, Daniel Cloutier<sup>4</sup>, Ling Shen<sup>4</sup>, Andre Arizpe<sup>4</sup>, Phil Pang<sup>4</sup>, Chin Tay<sup>4</sup>, Sneha V. Gupta<sup>4</sup>, Andrea Cathcart<sup>4</sup>, Edward Gane<sup>5</sup>. <sup>1</sup>Institute of Liver Studies, Kings College Hospital, London, United Kingdom; <sup>2</sup>Queen Mary Hospital, The University of Hong Kong, Medicine, Hong Kong; <sup>3</sup>Hannover Medical School (MHH), Dpt. of Gastroenterology, Hepatology and Endocrinology, Hannover, Germany; <sup>4</sup>Vir Biotechnology, San Francisco, United States; <sup>5</sup>University of Auckland, Auckland Clinical Studies, Auckland, New Zealand  
Email: kosh.agarwal@nhs.net

**Background and aims:** VIR-3434 is a fully human, monoclonal antibody in development for the treatment of chronic hepatitis B virus (HBV) infection with three distinct modes of action: 1) entry inhibition via neutralization of all 10 HBV genotypes in vitro, 2) reduction of circulating HBsAg-containing particles in vivo, and 3) potential therapeutic vaccination via Fc engineering. In the Phase 1a part of this study, single doses up to 3,000 mg were well tolerated in healthy participants (see Gupta et al., EASL 2021). We report here the preliminary safety and HBsAg reduction data from a Phase 1b study evaluating VIR-3434 in participants with chronic HBV infection.

**Method:** This is an ongoing randomized, double-blind, placebo-controlled Phase 1 single ascending dose study evaluating VIR-3434 in healthy volunteers (Part A) and participants with chronic HBV infection who are receiving nucleos (t)ide reverse transcriptase inhibitor (NRTI) therapy (Parts B-C). In Part B, non-cirrhotic, virally suppressed, HBeAg-negative participants with HBsAg <1,000 IU/ml are randomized 3:1 to receive a single dose of VIR-3434 or placebo administered subcutaneously. Participants are followed for safety, tolerability, pharmacokinetics, and viral biomarkers. Preliminary blinded safety and HBsAg reduction results through Day 29 for the first cohort evaluating a single dose of 6 mg are presented herein. Dose escalation to 18 mg, 75 mg, and 300 mg single doses is planned and ongoing.

**Results:** In this blinded trial, eight participants were enrolled. Six received a single dose of 6 mg of VIR-3434, and two received placebo on Day 1. Among the six participants who responded, a mean HBsAg reduction of 1.3 log<sub>10</sub> IU/ml was observed (Figure). One Grade 1 adverse event was reported. No clinically significant changes in safety

laboratory parameters were observed. No participant developed clinical or laboratory evidence of immune complex disease.

Figure:

**Conclusion:** A single low dose of 6 mg of VIR-3434 resulted in rapid reductions in HBsAg that were maintained through 2 weeks after dosing. Having observed no safety signals with doses up to 3,000 mg in healthy volunteers, this substantial HBsAg reduction in patients supports the potential for VIR-3434 to have a meaningful role in the functional cure of chronic HBV infection. Additional data from this ongoing study, including the effect of higher doses of VIR-3434, will be presented.

### OS-691

#### Nucleos (t)ide analogue treatment is associated with lower risk of extrahepatic malignancy in chronic hepatitis B patients: A landmark study using nationwide claim data

Donghyeon Lee<sup>1,2</sup>, Sungwon Chung<sup>1</sup>, Goh Eun Chung<sup>1,3</sup>, Boram Yang<sup>4,5</sup>, Joon Yeul Nam<sup>1</sup>, Misook Kim<sup>4</sup>, Yun Bin Lee<sup>1</sup>, Eun Ju Cho<sup>1</sup>, Su Jong Yu<sup>1</sup>, Yoon Jun Kim<sup>1</sup>, Jung-Hwan Yoon<sup>1</sup>, Jeonghoon Lee<sup>1</sup>. <sup>1</sup>Seoul National University College of Medicine, Department of Internal Medicine and Liver Research Institute, Seoul, Korea, Rep. of South; <sup>2</sup>Seoul Metropolitan Government Seoul National University Boramae Medical Center, Department of Internal Medicine, Seoul, Korea, Rep. of South; <sup>3</sup>Seoul National University Hospital, Department of Internal Medicine Healthcare System Gangnam Center, Seoul, Korea, Rep. of South; <sup>4</sup>Seoul National University Hospital, Medical research collaborating center, Seoul, Korea, Rep. of South; <sup>5</sup>Chungnam National University, College of Pharmacy, Daejeon, Korea, Rep. of South  
Email: pindra@empal.com

**Background and aims:** Epidemiologic studies suggested that chronic hepatitis B virus (HBV) infection is a risk factor for various primary extrahepatic malignancy as well as liver cancer. Although nucleos (t)ide analogues (NAs) against HBV could reportedly reduce the risk of hepatocellular carcinoma (HCC), whether NAs could reduce the risk of extrahepatic malignancy is still unclear.

**Method:** We conducted an 18-month landmark study using the nationwide claim data from the National Health Insurance Service of Korea. Patients who were diagnosed with chronic hepatitis B (CHB) in 2012–2014 (n = 90,944) and age, sex, socioeconomic status, and areas of habitat matched-controls from general population (n = 685,436) were included. CHB patients were further classified into NA-treated (n = 6,539) or NA-untreated CHB groups (n = 84,405). Washout period was established two years prior to the cohort entry date. The inverse probability treatment weighting analysis was applied for balancing study groups. The primary outcome was the development of overall extrahepatic malignancy. The development of liver cancers (HCC and intrahepatic cholangiocarcinoma) and death were considered as competing events. We additionally analysed extrahepatic malignancy incidence with different landmark points (12-month and 24-month) as a sensitivity analysis.

**Results:** During the study period (median = 47.4 months), 30,413 patients (3.9%) developed extrahepatic malignancy. The NA-untreated CHB group had significantly higher risk of overall extrahepatic malignancy than both the NA-treated CHB group

(adjusted sub-hazard ratio [aSHR] = 1.27, 95% confidence interval [CI] = 1.11–1.45,  $p = 0.003$ ) and the control group (aSHR = 1.22, 95% CI = 1.18–1.26,  $p < 0.001$ ), while there was no difference between the NA-treated CHB group vs. the control group (NA-treated vs. control, aSHR = 0.96, 95% CI = 0.84–1.09,  $p = 0.55$ ). In both 12-month and 24-month landmark analyses, the NA-untreated CHB group had significantly higher risk of overall extrahepatic malignancy than both the NA-treated CHB group (aSHR = 1.22,  $p = 0.002$ ; aSHR = 1.22,  $p = 0.002$ , respectively) and the control group (aSHR = 1.24,  $p < 0.001$ ; aSHR = 1.20,  $p < 0.001$ , respectively), while there was no difference between the NA-treated CHB group vs. the control group (aSHR = 1.01,  $p = 0.85$ ; aSHR = 0.98,  $p = 0.76$ , respectively).

Figure: Cumulative incidence of extrahepatic malignancy (18-months landmark) (A) Before inverse probability treatment weighting (IPTW) analysis, (B) after IPTW analysis.

**Conclusion:** CHB patients without NA treatment have higher risk of extrahepatic malignancy, which can be attenuated with NA treatment.

**Immunoglobulin-free alternative strategy to prevent HBV mother to child transmission in Cambodia: preliminary results of the ANRS 12345 TA PROHM study**

Olivier Segeral<sup>1</sup>, Bunnet Dim<sup>2</sup>, Christine Durier<sup>3</sup>, Sovann Nhoueng<sup>2</sup>, Kearena Chhim<sup>4</sup>, Say Tiv<sup>5</sup>, Polinn Sar<sup>5</sup>, Sothy Pech<sup>6</sup>, Bunthoeun Nem<sup>7</sup>, Kay Hout<sup>8</sup>, Chanlina Vong<sup>9</sup>, Song Yin<sup>2</sup>, Saren Sovann<sup>2</sup>, Julia Guillebaud<sup>10</sup>, Boraneath Nang<sup>2</sup>, Denis Laurent<sup>11</sup>, Chantana Yay<sup>11</sup>, Samsorphea Chhun<sup>9</sup>, Laurence Borand<sup>2</sup>. <sup>1</sup>University of Health Sciences, ANRS, Phnom Penh, Cambodia; <sup>2</sup>Institut Pasteur du Cambodge, Epidemiology and Public Health Unit, Phnom Penh, Cambodia; <sup>3</sup>Inserm SC10/USO19, Essais thérapeutiques et maladies infectieuses, Villejuif, France; <sup>4</sup>Calmette Hospital, Hepatology, Phnom Penh, Cambodia; <sup>5</sup>Jayavarmen VII Hospital, Maternity, Krong Siem Reap, Cambodia; <sup>6</sup>National Maternal and Child Health Center, Phnom Penh, Cambodia;

<sup>7</sup>Kampong Cham Hospital, Maternity, Krong Kampong Cham, Cambodia; <sup>8</sup>Maternity Department, Takeo Referral Hospital, Takeo, Cambodia; <sup>9</sup>Calmette Hospital, Maternity, Phnom Penh, Cambodia; <sup>10</sup>Institut Pasteur du Cambodge, Virology, Phnom Penh, Cambodia; <sup>11</sup>Kantha Bopha Children's Hospitals Jayavaraman VII, Krong Siem Reap, Cambodia  
Email: oliseg@hotmail.com

**Background and aims:** In Cambodia, HBsAg prevalence among pregnant women, young children and infants of HBsAg-positive mothers is 4.39%, 0.56% and 10.11%, respectively. Intervention to prevent mother-to-child transmission (MTCT) of hepatitis B virus (HBV) is limited to childhood vaccine, for which national coverage is 88.7% (45% for timely birth-dose).

The objective of the TA-PROHM study was to evaluate the effectiveness of an immunoglobulin-free (HBIg) alternative strategy to prevent HBV MTCT in Cambodia: 1/Use of HBsAg/HBeAg rapid diagnosis tests and ALT to decide tenofovir disoproxil fumarate (TDF) prophylaxis 2/TDF initiation, for those eligible, from 24 weeks of amenorrhea and "test and treat" strategy for those seen later 3/early vaccination for all infants at birth.

**Method:** Positive HBsAg pregnant women aged  $\geq 18$  yo were enrolled in a multicenter interventional non-randomized prospective study. Women HBeAg-positive or, following a protocol amendment, HBeAg-negative and ALT $\geq 40$  IU/L received TDF from 24 weeks of amenorrhea to 6 weeks postpartum. Infants received hepatitis B vaccine at birth in delivery room (<2 hours) and at 6, 10 and 14 weeks of age. HBIg were not recommended but could be done if accessible. The primary end point was the proportion of infants with plasmatic HBs Ag positivity confirmed by HBV DNA at 6 months of life.

**Results:** From 2017 to 2019, we screened 21, 251 women for HBsAg and 1, 339 (6.3%) were positive. We enrolled 1, 194 women and 338 (28.3%) were eligible for TDF prophylaxis. At enrollment, median age was 29 years and median gestational age 23 weeks. The median HBV DNA level was 7.9 log<sub>10</sub> IU/ml for TDF-eligible women and 2.5 log<sub>10</sub> IU/ml for non TDF-eligible women. The proportion of eligible women starting TDF was 94.1%. At birth, 86.5% of infants received the first dose of vaccine  $\leq 2$  hours of life, 95.5%  $\leq 24$  hours of life and 15.4% received HBIg. Overall, 4/317 infants (1.26%, 95% CI 0.34–3.20) were infected in the TDF group and 7/711 infants (0.98%, 95% CI 0.4–2.02) in the non TDF group. For infants not receiving HBIg, 4/271 (1.48%, 95% CI 0.40–3.74) were infected in the TDF group and 6/565 (1.06%, 95% CI 0.39–2.30) in the non TDF group. Transmission rate for women treated by TDF for  $\geq 1$  month (N = 259) was 0% (95% CI 0–1.41). In the non TDF group, all mothers of infected infants were HBeAg negative and ALT <40 U/L but 6 of them had an HBV DNA >5.3 Log<sub>10</sub> IU/ml at enrollment.

**Conclusion:** A free-HBIg strategy with maternal use of TDF and early vaccination at birth could be effective to reduce HBV MTCT, specifically if TDF is administered for  $\geq 1$  month prior delivery. For women with low-level viremia, an early vaccination without HBIg could be enough to reduce HBV MTCT.

**OS-1430**

**Short interfering RNA JNJ-3989 combination therapy in chronic hepatitis B shows potent reduction of all viral markers but no correlate was identified for HBsAg reduction and baseline factors**

Edward Gane<sup>1</sup>, Stephen Locarnini<sup>2</sup>, Tien Huey Lim<sup>3</sup>, Simone Strasser<sup>4</sup>, William Sievert<sup>5</sup>, Wendy Cheng<sup>6,7</sup>, Alexander Thompson<sup>8</sup>, Bruce Given<sup>9</sup>, Thomas Schlupe<sup>9</sup>, James Hamilton<sup>9</sup>, Michael Biermer<sup>10</sup>, Ronald Kalmeijer<sup>11</sup>, Maria Beumont-Mauviel<sup>11</sup>, Oliver Lenz<sup>10</sup>, Filip De Ridder<sup>10</sup>, Gavin Cloherty<sup>12</sup>, Danny Ka-Ho Wong<sup>13</sup>, Christian Schwabe<sup>1</sup>, Kathy Jackson<sup>2</sup>, Carlo Ferrari<sup>14</sup>, Ching Lung Lai<sup>13</sup>, Robert G. ## ORAL PRESENTATIONS

Hospital, Perth, Australia; <sup>7</sup>Linear Clinical Research, Perth, Australia; <sup>8</sup>St. Vincent's Hospital, Melbourne, Australia; <sup>9</sup>Arrowhead Pharmaceuticals, Pasadena, United States; <sup>10</sup>Janssen Pharmaceutica NV, Beerse, Belgium; <sup>11</sup>Janssen RandD, Titusville, United States; <sup>12</sup>Abbott Diagnostics, Abbott Park, United States; <sup>13</sup>The University of Hong Kong, Hong Kong, China; <sup>14</sup>University of Parma, Parma, Italy; <sup>15</sup>Hepatitis B Foundation, Doylestown, United States  
Email: edgane@adhb.govt.nz

**Background and aims:** Short RNA interference (siRNA) therapy with JNJ-3989 includes both S and X triggers which silence all HBV RNA transcripts. In AROHBV1001 (phase 2a; NCT03365947), JNJ-3989 (3 monthly doses 25–400 mg) + a nucleos(t)ide analogue (NA) demonstrated antiviral activity in patients (pts) with chronic hepatitis B (CHB). Here we assessed baseline factors associated with HBsAg reduction and compared the effect of JNJ-3989 against the viral markers HBsAg, HBeAg, HBcrAg and HBV RNA.

**Method:** Data from NA experienced or naïve, HBeAg ± ve CHB pts who received 3 s.c. JNJ-3989 doses (days 1, 27, 57) of 100 (n = 8), 200 (n = 8), 300 (n = 16) or 400 mg (n = 8) were used. Pts started/continued with an NA on day 1 and continued throughout the study to Day 392. HBsAg, HBeAg, HBV RNA, HBcrAg was assessed using standard assays.

**Results:** Treatment with JNJ-3989 + an NA resulted in mean (range) HBsAg reductions from baseline at nadir of 1.93 (0.73, 3.84) log<sub>10</sub> IU/ml with 39/40 pts (98%) achieving >1log<sub>10</sub> IU/ml reduction. Baseline HBsAg levels and other viral markers, treatment status (naïve vs NA suppressed) and BMI had no impact on HBsAg reduction. A trend for greater reduction in HBsAg was seen in HBeAg +ve vs HBeAg -ve pts mainly driven by a few (n = 4) HBeAg +ve females who showed the greatest HBsAg response (>2.5 reduction at nadir). Impact of race IL28B status could not be assessed since the majority of pts were Asians with IL28B CC genotype. HBV genotype had no impact on HBsAg reduction but a limited number of pts had data available. Pronounced reductions in HBeAg, HBcrAg and HBV RNA were observed, although HBeAg and HBcrAg reductions were generally smaller than for HBsAg. In pts with baseline levels >1log above LLOQ of the respective marker, the mean (SE, N) reduction at day 113 for HBeAg were -1.47 (0.12, 12) vs -2.12 (0.21, 12) for HBsAg, for HBcrAg -1.20 (0.17, 18) vs -1.97 (0.16, 18) for HBsAg, and -1.93 (0.14, 21) for HBV RNA vs -1.86 (0.15, 21) for HBsAg. Generally, the reductions of the different markers correlated within pts, but individual differences were observed.

**Conclusion:** JNJ-3989 (100–400 mg, Q4W) achieved potent reduction of all viral markers, with trends for more pronounced reductions in HBsAg than other markers, and in HBeAg +ve compared to HBeAg -ve pts. Reductions in HBeAg, HBcrAg and HBV RNA generally correlated with reductions in HBsAg. These findings are being evaluated in larger Phase 2b studies with JNJ-3989 + NA in CHB pts.

### OS-2299

**Second generation Hepatitis B Virus core inhibitors ABI-H2158 and ABI-H3733 have enhanced potency and target coverage for both antiviral inhibition and covalently closed circular DNA establishment activities**

Dawei Cai<sup>1</sup>, Marc Evanhcic<sup>1</sup>, Ran Yan<sup>1</sup>, Renuka Kumar<sup>1</sup>, Yuhua Zong<sup>1</sup>, Qi Huang<sup>1</sup>, Richard Colonna<sup>1</sup>, Luisa Stamm<sup>1</sup>, William Delaney<sup>1</sup>.

<sup>1</sup>Assembly Biosciences, Inc., South San Francisco, United States  
Email: wdelaney@assemblybio.com

**Background and aims:** Core inhibitors are a novel class of HBV antivirals with potential to increase treatment responses and cure rates. We currently have 3 core inhibitors in clinical development: vebicorvir (VBR, Phase 2), ABI-H2158 (2158, Phase 2) and ABI-H3733 (3733, Phase 1). Core inhibitors have multiple mechanisms of action (MOAs) including 1) inhibition of pgRNA encapsidation, which reduces virion formation (antiviral activity) and 2) premature disruption of incoming capsids which inhibits the generation of new covalently closed circular DNA (cccDNA prevention). Core

inhibitors exert their greatest antiviral activity against viral replication, yet both MOAs may be important for optimal responses. Here we determined the human plasma and estimated liver concentrations of VBR, 2158, and 3733 relative to protein-adjusted (pa) EC<sub>50</sub>s for each MOA.

**Method:** Plasma concentrations of VBR, 2158 and 3733 including C<sub>min</sub> 24 hr post QD dosing were measured in Phase 1a/b studies. EC<sub>50</sub>s for antiviral activity (HBV DNA end point) and cccDNA prevention (HBeAg end point) were measured in primary human hepatocytes. pa factors were determined in HepAD38 cells cultured in 2%, 20%, or 40% human serum and extrapolating to 100%. Liver concentrations relative to plasma were estimated from nonclinical PK studies.

**Results:** The C<sub>min</sub> of VBR, 2158, and 3733 at steady-state dosing using 300 mg QD are shown in Table 1 along with their EC<sub>50</sub>s, pa factors and liver enrichment factors. VBR, 2158, and 3733 achieve C<sub>mins</sub> 3-fold, 19-fold, and 28-fold, above their antiviral paEC<sub>50</sub>s respectively. In contrast, C<sub>mins</sub> for VBR, 2158, and 3733 were 0.2-fold, 4-fold, and 6-fold over their respective paEC<sub>50</sub>s to inhibit cccDNA generation. Concentrations of all three core inhibitors are predicted to be enhanced in the liver by 18-fold, 5-fold, and 6-fold, respectively.

Table 1: Key PK and Antiviral Properties of VBR, 2158, and 3733

Parameter	VBR 300 mg QD	2158 300 mg QD	3733 300 mg QD
C <sub>min</sub> (nM)	3102	5852	2454
Antiviral EC <sub>50</sub> (nM)	154	41	12
cccDNA EC <sub>50</sub> (nM)	2210	204	62
pa (fold)	8	8	7
Plasma C <sub>min</sub> /paEC <sub>50</sub> (antiviral)	3	19	28
Plasma C <sub>min</sub> /paEC <sub>50</sub> (cccDNA)	0.2	4	6
Liver:plasma ratio	18	5	6
Liver C <sub>min</sub> /paEC <sub>50</sub> (antiviral)	48	95	170
Liver C <sub>min</sub> /paEC <sub>50</sub> (cccDNA)	3	19	33

**Conclusion:** VBR, 2158, and 3733 achieve plasma concentrations significantly above EC<sub>50</sub> and paEC<sub>50</sub> for antiviral activity. The second generation compounds 2158 and 3733 show enhanced potency and exposures that cover cccDNA prevention activity at significant multiples of paEC<sub>50</sub> at C<sub>min</sub>.

### OS-2478

**VRON-0200, A therapeutic HBV vaccine with an intrinsic checkpoint inhibitor elicits broad CD8+ T cell responses and sustained antiviral declines in preclinical studies**

Mohadeseh Hasanpourghadi<sup>1</sup>, Andrew Lubert<sup>2</sup>, Colin Magowan<sup>2</sup>, Xiang Zhou<sup>1</sup>, Hildegund Ertl<sup>1</sup>. <sup>1</sup>The Wistar Institute, Philadelphia, United States; <sup>2</sup>Virion Therapeutics, Newark, United States  
Email: aluber@viriontx.com

**Background and aims:** HSV-1 glycoprotein D (gD) acts as a checkpoint inhibitor of early T cell activation. Here we describe the immunogenicity and efficacy of a therapeutic HBV vaccine that includes select antigens of both HBV polymerase (N- and C-terminus) and core fused into gD (gD-HBV2; VRON-0200).

**Method:** Groups of C57Bl/6 mice were injected i.v. with an AAV8–1.3HBV vector. At week 4, after high levels of circulating HBV genomes were established, they were vaccinated (n = 5–10/group) with a single i.m. dose of 1 × 10<sup>10</sup> vp of chimpanzee adenoviral vectors expressing sequences of the N-terminus of polymerase within gD (gDPoIN), polymerase and core within gD (gDHBV2), polymerase and core without gD (HBV2) or nothing (controls). Lymphocytes were tested periodically after immunization for frequencies and epitope specificities of IFN-γ producing vaccine-insert-specific CD8<sup>+</sup> T cells. HBV genome copy numbers in sera were assessed before and after vaccination.

**Results:** Vaccination induced CD8<sup>+</sup> T cell responses to the vaccine inserts in blood and spleen and gD enhanced responses. In AAV8-1.3HBV injected mice immunization with the gD containing vaccines caused ~2–3 log<sub>10</sub> sustained declines in HBV genome copies while naïve mice showed ~ 0.5 log<sub>10</sub> increases (Figure). Frequencies of circulating vaccine-insert-specific CD8<sup>+</sup> T cells were inversely correlated with HBV viral loads (r = -0.77; p < 0.0001).

Figure:

**Conclusion:** The inclusion of gD into a therapeutic HBV vaccine enhances CD8<sup>+</sup> T cell responses and is necessary for the observed sustained efficacy of the vaccine to reduce viral loads in the AAV8-1.3HBV mouse model. Mice vaccinated with the gDHBV2 vector showed better viral control than those immunized with gDPOIN stressing the importance of a broad-based immune response. A Phase 1b study of VRON-0200 is in planning.

Email: tarik.asselah@aphp.fr

**Background and aims:** Bulevirtide (BLV) is a first-in-class entry inhibitor used for the treatment of chronic hepatitis delta virus (HDV) infection. Combination therapy of BLV and Peginterferon alfa-2a (pIFN) showed strong synergistic effects on HDV RNA and Hepatitis B surface Antigen (HBsAg) levels in MYR203 trial.

We present here the 24 weeks interim on treatment data of the MYR204 phase 2b trial in HBV/HDV co-infected patients receiving BLV as monotherapy or in combination with pIFN.

**Method:** 175 patients with chronic HDV infection were randomized in a 1:2:2:2 ratio to receive (see Figure): arm A: pIFN; arm B: BLV 2 mg/day and pIFN; arm C: BLV 10 mg/day and pIFN for 48 weeks followed by BLV monotherapy for additional 48 weeks or arm D: BLV 10 mg/day monotherapy. The primary endpoint is undetectable HDV RNA (<LoD) at week 24 after end of treatment; main secondary endpoints include HDV RNA decline by ≥2log<sub>10</sub> IU/ml, ALT normalization, combined response (undetectable HDV RNA or decrease by ≥2log<sub>10</sub> IU/mL from baseline and ALT normalization) and HBsAg decrease.

**Results: Safety:** In the first 24 weeks of treatment, 998 AEs were reported by 151 patients (86.8%), being mostly mild (536) or moderate (296). 181 of 998 AEs were judged as possibly related to BLV and 724 AEs to pIFN. Overall, 7 SAEs (judged as not related to BLV) were reported, one of which (anaplastic astrocytoma, judged as non-related to BLV nor pIFN) reported in a patient in arm B led to death.

**Efficacy:** At week 24, the proportion of patients with HDV RNA decline of ≥2log<sub>10</sub> IU/mL from baseline was 37.5%, 86.0%, 90.0%, and in 72.0% of patients in arms A-D, respectively.

Undetectable HDV RNA was demonstrated in 12.5%, 24%, 34% and 4% of patients at week 24 in arms A-D, respectively.

Both, ALT and combined response had a higher proportion of responders in arm D, followed by arm B, arm C and arm A (Figure 1). HBsAg response (decline by ≥1log<sub>10</sub> IU/ml) was observed in 10 patients receiving combination therapy with BLV and pIFN (12% in arm B and 8% in arm C) and 1 patient in arm A.

Study design. Baseline and 24 weeks interim data	Baseline - levels			Results at week 24 - % of patients with response			
	HDV RNA (log <sub>10</sub> IU/ml) Mean (SD)	ALT (U/ml) Mean (SD)	Compensated cirrhosis (% of patients)	HDV RNA decrease from baseline ≥2 log <sub>10</sub> IU/mL	ALT normalization	Combine response	HBsAg decrease >1 log <sub>10</sub> from baseline
arm A (n=25) pIFN week 0 week 48 week 96	5,197 (1.064)	121.5 (95.9)	33.3%	37.5%	12.5%	12.5%	4.2%
arm B (n=50) 2 mg BLV + pIFN / 2 mg BLV week 0 week 48 week 96 week 144	5,268 (1.355)	107.5 (77.0)	34.0%	86.0%	30.0%	30.0%	12.0%
arm C (n=50) 10 mg BLV + pIFN / 10 mg BLV week 0 week 48 week 96 week 144	5,090 (1.343)	112.6 (98.6)	36.0%	90.0%	24.0%	24.0%	8.0%
arm D (n=50) 10 mg BLV week 0 week 48 week 96 week 144	5,448 (1.098)	118.4 (108.1)	34.0%	72.0%	64.0%	50.0%	0

Figure: Study design. 24 weeks interim data

**Conclusion:** BLV monotherapy and in combination with pIFN is safe and well tolerated through 24 weeks of therapy. Combination therapy and BLV monotherapy resulted in high rates of HDV viral decline, while BLV monotherapy resulted in the highest rate of ALT normalization. Ongoing analysis of safety, ALT normalization and HDV viral suppression on therapy at weeks 48, 96 and SVR 24 will be performed.

Email: pmcarrieri@aol.com

**Background and aims:** Late presentation for care of hepatitis C virus (HCV) infection-defined as having severe liver fibrosis ( $\geq$ F3 Metavir score) when consulting a healthcare specialist for HCV treatment for the first time-increases morbidity and mortality risks in HCV-infected patients. Identifying the socio-behavioural profile of late presenters is essential to improve HCV screening strategies and optimize the global HCV cascade of care. We investigated clinical and socio-behavioural correlates of late presentation for HCV care in HCV mono-infected individuals.

**Method:** This study included chronic HCV mono-infected patients participating in the French national prospective cohort ANRS CO22 HEPATHER which started in 2012. The correlates of late presentation for HCV care were estimated using a Heckman selection probit model, which enabled us to take into account possible selection bias due to missing data in the outcome.

**Results:** Among the 9,174 study patients, 1,236 had available data on liver fibrosis stage at first presentation for HCV care. Of the latter, 591 (47.8%) were late presenters. In a multivariable analysis adjusted for age, sex, and HCV genotype, having diabetes (adjusted coefficient [95% confidence interval]: 0.55 [0.30; 0.80]), current hazardous alcohol use (defined as consuming at least two standard drinks (each containing 11–14 g of alcohol) per day for women or three for men) (0.36 [0.03; 0.69]), and current abstinence but past hazardous alcohol use (0.42 [0.19; 0.64]) (vs. abstinence with no past hazardous use) were all independently associated with late presentation for HCV care.

**Conclusion:** As late presentation severely affects the HCV cascade of care, our findings bring important new evidence about the need to promptly identify and target people with diabetes and/or past or current hazardous alcohol use for HCV screening and treatment, within the wider context of the WHO goal to eliminate HCV by 2030.

#### OS-1390

#### Automated Liver Function Testing in Identifying "Hard to Reach" Hepatitis B and C Patients

Callum Livingstone<sup>1</sup>, Iain Macpherson<sup>1</sup>, Jennifer Nobes<sup>2</sup>, Elizabeth Furrie<sup>2</sup>, Michael Miller<sup>1</sup>, Ellie Dow<sup>2</sup>, John Dillon<sup>1</sup>. <sup>1</sup>University of Dundee, Gut Group, United Kingdom; <sup>2</sup>NHS Tayside, Blood Sciences, United Kingdom  
Email: c.r.livingstone@dundee.ac.uk

**Background and aims:** In Europe, 13.3 million and 15 million people are estimated to be living with chronic HBV and HCV, respectively. Many remain undiagnosed, increasing their likelihood of fibrosis, cirrhosis, hepatocellular carcinoma and ultimately death.

Automated testing of abnormal LFTs for HBV and HCV may aid find undiagnosed patients. Intelligent liver function testing (iLFT) was developed and is now routine in Tayside, Scotland, where all abnormal LFTs are reflex tested for HBV and HCV. Our aim was to assess if iLFT increased case finding in "hard to reach" populations.

**Method:** Retrospective cohort analysis of patients who initiated iLFT, triggered at an ALT value above 30, from August 2018 to August 2020 and received an HBV or HCV outcome.

**Results:** For HCV, 49 patients out of 6791 (0.7%) were confirmed to be HCV antibody positive. 29 antibody positive patients (59%) had detectable HCV RNA levels, predominantly Genotype 3 (34%), suggestive of an active infection. 28/29 patients (97%) commenced treatment on average 65 days from the iLFT request date (95% CI 55.4–74.6 days) and 1 patient failed to attend.

26/28 patients (93%) completed their treatment, 1 experienced side-effects and 1 was lost to follow-up. An intention-to-treat analysis demonstrated 21 patients (75%) to have a sustained viral response (SVR). 19 SVR patients (90%) were discharged or due for discharge and 2 continued under review due to the presence of fibrosis and/or cirrhosis.

Patients who underwent HCV treatment were on average 52-years-old, predominantly declared to having never injected drugs (75%) and primarily resided in more affluent areas (75%).

For HBV, iLFT identified 2 chronic active and 4 inactive carrier HBV infected patients. The 2 chronic active patients were initiated on treatment and all 6 patients remain under review. 1 chronic patient was also found to be Delta antigen positive.

The average age of the 6 HBV patients was 52-years-old and all 6 patients (100%) lived in more affluent areas.

**Conclusion:** iLFT successfully identified patients with HBV and HCV infections, providing an opportunity for cure and/or continued follow-up. Of note, most patients treated for HCV had no overt risk-factors; no history of injecting drugs and residing in more affluent areas. NHS Tayside has already identified approximately 90% of prevalent HCV cases. By utilising iLFT, Tayside now has the potential to identify the remaining 10% "hard to reach" HCV patients, thus offer a cure.

### Viral hepatitis C: Therapy and resistance

#### OS-795

#### Peer support in a national hepatitis C elimination program-pseudo-randomised analysis of impact in 30,729 patients

Davina Jugnarain<sup>1</sup>, Pantelis Samartsidis<sup>2</sup>, Rachel Halford<sup>3</sup>, Stuart Smith<sup>3</sup>, HCV ODNs Clinical Leads<sup>4</sup>, Graham Foster<sup>1</sup>. <sup>1</sup>Queen Mary University of London, United Kingdom; <sup>2</sup>MRC Biostatistics Unit, Cambridge Biomedical Campus, Cambridge, United Kingdom; <sup>3</sup>Hepatitis C Trust, United Kingdom; <sup>4</sup>NHS England, United Kingdom  
Email: g.r.foster@qmul.ac.uk

**Background and aims:** Hepatitis C (HCV) is prevalent in people injecting drugs (PWIDs), around 90% of infections in England. Peer

supporters are individuals with lived experience of a disease who can motivate patients. Previous studies using peer supporters for HCV have been small and did not show unequivocal benefits. As part of NHS England's aim to eliminate HCV ahead of the World Health Organisation's target of 2030, peers have been deployed in treatment networks. We examined the effect of peer supporters on HCV treatment uptake using the English registry.

**Method:** Peer support workers were centrally trained by The Hepatitis C Trust, and introduced to 17 out of 22 regional networks at different times. Time of peer introduction depended on funding and operational readiness. Hence this was a pseudorandomised stepwise implementation of peers to different networks. For patients receiving antiviral therapy, demographic and treatment outcome data were derived from the national registry. Statistical analysis was conducted using a Bayesian Poisson random effects and a Binomial random effects model. We explored the effects of peers immediately and 2 months after deployment.

**Results:** 30,729 patients were treated in the 17 networks during the study period. An increase in numbers starting treatment (OR 1.12; 95% confidence interval [CI], 1.02 to 1.21;  $p = 0.006$ ) and completing treatment (OR, 2.45; 95% CI, 1.49 to 3.84;  $p = 0$ ) was observed. No significant changes were seen in drug service referrals, PWIDs initiating treatment, numbers treated in drug services, completion of adequate treatment, attendance at follow-up nor viral clearance. For the delayed analysis, similar results were observed. However, drug service referrals (RR, 1.15; 95% CI, 0.99 to 1.33;  $p = 0.0355$ ) and numbers treated in drug services exhibited a mild increase (OR 1.19; 95% CI, 1.00 to 1.44;  $p = 0.023$ ).

Figure:

**Conclusion:** Peer support workers appear to be immediately effective in improving initiation and completion of treatment. Although the proportion of people with drug use as a risk factor for infection did not change, peers appear to increase referrals and treatment within drug services. Broadly, this suggests that peer support workers are effective in engaging at-risk groups for HCV and could accelerate attainment of eradication targets.

<sup>1</sup>Faculty of Medicine, Ain Shams University, Paediatrics and Clinical Research Centre (MASRI-CRC), Cairo, Egypt; <sup>2</sup>Egyptian Liver Care Society, Cairo, Egypt; <sup>3</sup>Faculty of Medicine, Cairo University, Endemic Medicine and Hepatogastroenterology, Cairo, Egypt; <sup>4</sup>Faculty of Medicine, Sohag University, Pediatrics, Sohag, Egypt; <sup>5</sup>Faculty of Medicine, Minia University, Minia, Egypt; <sup>6</sup>Faculty of Medicine, Alexandria University, Pediatrics, Alexandria, Egypt; <sup>7</sup>Faculty of Medicine, Assiut University, Pediatrics, Assiut, Egypt; <sup>8</sup>Faculty of Medicine, Mansoura University, Pediatrics, Mansoura, Egypt; <sup>9</sup>National Hepatology and Tropical Medicine Research Institute, Pediatrics, Cairo, Egypt  
 Email: manalhelsayed@yahoo.co.uk

**Background and aims:** DAAs for chronic HCV in children aged 3 years and above had been approved but evidence from real-world experience is needed for brand and generic medicines to inform global policies and fast-track elimination. This project assessed safety and efficacy of generic DAAs in treating Egyptian children with HCV-infection in a multicentre program supported by the Egyptian Liver Care Society (ELCS), an NGO supporting patients with liver disease.

**Method:** The program enrolled 535 children >35 kg with chronic HCV-infection between March 2019 and December 2020 from 7 specialised centres in 6 Egyptian Governorates. The ELCS fully equipped dedicated sites for the HCV-Free Child project, trained physicians, nurses and IT personnel. All children received generic sofosbuvir 400 mg/ledipasvir 90 mg once daily for 12 weeks. Recruited children were sampled for CBC, liver functions, renal functions and HCV-RNA (RT-PCR) at baseline, 4, 8, 12 and 24 (sustained virological response; SVR) weeks of therapy. In addition to baseline ultrasound and Fibroscan. Personal care items and awareness booklets were provided to children during awareness sessions with attending parents at 12 and 24 weeks. The ELCS provided sites with protective equipment and sanitizers to protect personnel and patients during COVID-19 crises and medication was dispensed for 12 weeks while tele-communication was provided for follow-up and awareness.

**Results:** A total 264 children completed their SVR follow-up to-date. Median age of treated patients is 16 years (range:11.5–17.5 years; M/F:1.4/1). On intention-to-treat basis, SVR was reported in 249 (94%) patients; while 13 (5%) lost follow-up and 2 (1%) had discontinued therapy for medical causes. SVR on Per protocol was 100%. Comorbidities were reported in 21 (8%) patients; hemophilia (n = 4), lymphoma (n = 3), thalassemia (n = 3) and cardiac disease (n = 2). Fifty-one (19%) children and adolescents were cancer survivors. Clinical findings were mostly hepatomegaly in 26 (10%), splenomegaly in 3 (1%) patients and splenectomy in 3 (1%) patients. Seventeen patients (6%) were previously treated with Interferon therapy. Maternal history revealed 97 mothers (37%) with known HCV infection and Vaginal delivery in 79 (74%) patients. Risk factors of treated patients were; circumcision or injection by an informal health care provider in 44 (17%), 132 (50%) respectively. Multiple injections (>10 times) were reported in 222 (84%) patients. Most patients (92%) attended at hospital (s), and 123 underwent surgery (47%) and 133 patients underwent dental procedures. Blood transfusion was reported in 85 (32%) patients.

**Conclusion:** Generic DAA therapy is safe and effective therapy in adolescents real-life. NGOs can fulfil unmet needs providing a successful model of service delivery for treatment of children and adolescents to achieve the 2030 elimination goal.

**Modeling HCV elimination recovery following the COVID-19 pandemic in the United States: Pathways to regain progress**  
 Sarah Blach<sup>1</sup>, Chris Estes<sup>1</sup>, Homie Razavi<sup>1</sup>. <sup>1</sup>CDA Foundation, Lafayette, United States  
 Email: sblach@cdafound.org

**Background and aims:** As of 2019, the United States (US) was not on track to achieve the WHO targets for elimination, due to increasing incidence and barriers to treatment. In 2020, the COVID-19 pandemic disrupted HCV services globally, with the US experiencing multiple waves of infections and restrictions. As COVID-19 vaccinations

Figure: (abstract: LBP-2814)

## POSTER PRESENTATIONS

become commonplace and healthcare services normalize, there is an urgent need to reassess the country's progress toward HCV elimination and evaluate scenarios for recovery.

**Method:** We updated a previously validated Markov model to estimate HCV-related morbidity and mortality in the US. HCV epidemiological data were based on published data, with annual treatment data from industry reports through 2020. Three scenarios were developed to bookend possible outcomes for HCV recovery in the wake of the pandemic. These included (1) long-term treatment disruptions; (2) return to pre-COVID-19 treatment forecasts; (3) Achieve WHO targets through increased treatment and harm reduction.

**Results:** From 2014–2019, ~1.2 million patients were treated for HCV, leading to >50% reduction in hepatocellular carcinoma (HCC) cases and >65% reduction in HCV liver-related deaths (LRDs) in 2019 relative to 2014. In 2020, 25% fewer patients were initiated on treatment than in 2019. In the modeled scenarios, between 780, 000 and 2.3 million patients (cumulative) would be initiated on treatment from 2021–2030. WHO Targets (scenario 3) could be achieved in the US by treating at least 240, 000 patients per year and increasing access to harm reduction programs. Compared to scenario 1, scenarios 2 and 3 could avert 19, 400 LRDs and 9, 500 HCC cases and 33, 200 LRDs and 24, 900 HCC cases, respectively.

**Conclusion:** The US has made strides toward HCV elimination, but these gains could easily be lost in the wake of the pandemic if we become complacent. There is time to regain momentum and avert more than 33, 000 deaths while reducing the viral pool to prevent new infections. This requires a swift and coordinated effort from the entire HCV community—including government, industry, patient groups and providers. Political will for HCV elimination is increasing (demonstrated through the endorsement by AASLD, US CDC and USPTF of a one-time universal screening for all adults); however, to prevent further morbidity and mortality, all new or previously diagnosed patients should be immediately linked to treatment, without restriction (EASL, AASLD/IDSA).

### LBP-2886

#### LPCN 1144 improves body composition in biopsy-confirmed NASH patients

Shadi Mehraban<sup>1</sup>, Benjamin Bruno<sup>2</sup>, Kilyoung Kim<sup>3</sup>, Kongnara Papankorn<sup>3</sup>, Nachaippan Chidambaram<sup>3</sup>, Mahesh Patel<sup>4</sup>, Anthony DelConte<sup>5</sup>. <sup>1</sup>Lipocine Inc., Clinical Affairs, Salt Lake City, United States; <sup>2</sup>Lipocine Inc., Clinical Development, Salt Lake City, United States; <sup>3</sup>Lipocine Inc., Product Development, Salt Lake City, United States; <sup>4</sup>Lipocine Inc., Salt Lake City, United States; <sup>5</sup>Saint Joseph's University, Philadelphia, United States  
Email: sm@lipocine.com

**Background and aims:** Non-alcoholic Steatohepatitis (NASH) is a common cause of liver disease and rapidly rising to be the leading indication for liver transplantation. Sarcopenia, loss of muscle mass, occurs in 20–60% of patients with liver disease and reduces survival of cirrhotic patients. There is an unmet need for addressing adverse body composition (BC) in advanced NASH. A decrease in free testosterone (T) and increase in Sex Hormone Binding Globulin (SHBG) are reported with progression of NASH. LPCN 1144, an oral prodrug of endogenous T, is currently being investigated in an ongoing randomized, double-blind, paired biopsy, placebo-controlled, phase 2 study in men with NASH (LiFT, NCT04134091). Here, we present topline BC results post 20 weeks (w) of treatment.

**Method:** Biopsy-confirmed NASH (F1-F3) males were randomized 1:1:1 to three arms; (1) Treatment A: oral T twice daily (BID), (2) Treatment B: oral T with d-alpha tocopherol BID, and (3) oral matching placebo (PL) BID. BC parameters, including appendicular lean muscle mass (APLM), whole body fat mass (WBFM) and whole body lean mass (WBLM), were evaluated using Dual Energy X-ray Absorptiometry (DEXA) scan at baseline and w20. Other key outcomes measured were changes in SHBG, hepatic fat fraction,

alanine aminotransferase (ALT), and aspartate aminotransferase (AST) at w12.

**Results:** APLM was significantly elevated with LPCN 1144 treatment compared to PL ( $p < 0.05$ ). Additionally, treatment with LPCN 1144 resulted in a significant reduction of WBFM compared to PL ( $p < 0.01$ ). Favorable BC changes, defined as a decrease in WBFM and an increase in WBLM, were observed in 64% of the subjects receiving LPCN 1144 compared to 15.4% in the PL arm ( $p < 0.01$ ). Furthermore, LPCN 1144 reduced progression of adverse muscle composition (AMC); 4% in the treatment arm vs 46.2% in the PL arm had an increase in WBFM and a decrease in WBLM ( $p < 0.01$ ). Treatment with LPCN 1144 significantly decreased SHBG from baseline compared to PL ( $p < 0.001$ ). Liver fat, ALT, and AST were also significantly reduced in both treatment arms compared to PL ( $p < 0.001$ ,  $< 0.05$ , and  $< 0.05$ , respectively).

Table:

Group	Relative Change from Baseline (%)			Percentage of Subjects with Favorable Body Composition Post Therapy	Percentage of Subjects with Adverse Muscle Composition Post Therapy
	Appendicular lean muscle mass	Whole body fat mass	Whole body lean mass		
Placebo (N = 13)	-1.65	3.24	-0.47	15.4	46.2
LPCN 1144 Treatment (N = 25)	2.43	-5.07	2.40	64.0	4.0
P Value vs placebo	0.0111	0.0018	0.0473	0.0064	0.0035

**Conclusion:** LPCN 1144 significantly improved BC in biopsy-confirmed NASH male subjects. The forthcoming w36 data in the ongoing LiFT trial is expected to further elucidate the effects of LPCN 1144 on changes in BC. This significant impact of LPCN 1144 on BC can be beneficial in cirrhotic subjects. Larger longitudinal investigations may be required to study this potential effect in advanced liver disease.

### LBP-2891

#### Artificial intelligence and digital single-operator cholangioscopy: automatic identification of papillary projections in patients with indeterminate biliary strictures

Tiago Ribeiro<sup>1,2,3</sup>, Miguel Mascarenhas<sup>1,2,3</sup>, João Afonso<sup>1,2,3</sup>, João Pedro Sousa Ferreira<sup>4,5</sup>, Filipe Vilas-Boas<sup>1,2,3</sup>, Marco Parente<sup>4,5</sup>, Renato Natal Jorge<sup>4,5</sup>, Pedro Pereira<sup>1,2,3</sup>, Guilherme Macedo<sup>1,2,3</sup>. <sup>1</sup>Centro Hospitalar Universitário de São João, Gastroenterology, Porto, Portugal; <sup>2</sup>WGO Gastroenterology and Hepatology Training Center, Porto, Portugal; <sup>3</sup>Faculty of Medicine of the University of Porto, Porto, Portugal; <sup>4</sup>Faculty of Engineering of the University of Porto, Mechanical Engineering, Porto, Portugal; <sup>5</sup>Institute of Science and Innovation in Mechanical and Industrial Engineering, Porto, Portugal  
Email: tiagofcribeiro@outlook.com

**Background and aims:** Digital cholangioscopy revolutionized the diagnostic workup of patients with indeterminate biliary stenosis. The visual impression of these lesions is highly sensitive for the diagnosis of malignancy. Morphologic characteristics such as masses, tumor vessels or papillary projections are common findings in those with malignant biliary strictures. Nevertheless, the specificity and interobserver variability in the detection of these findings are significant limitations. The application of artificial intelligence (AI) tools to a wide range of endoscopic techniques has provided promising results. The application of these systems for automatic characterization of biliary lesions has not been explored. The aim of this study was to develop a deep learning algorithm for automatic detection of papillary projections in D-SOC images.

**Method:** An AI algorithm based on a convolutional neural network (CNN) was constructed for automatic detection of *papillary projections* in D-SOC images. A total of 3920 were extracted from a pool of 85 cholangioscopy exams using the *Spyglass™ DS II system* (Boston Scientific, Marlborough, MA, USA). Each frame was classified by two endoscopists with experience in D-SOC for the presence or absence of *papillary projections*. This pool of images was split in two distinct datasets for training (80%) and validation (20%) of the CNN. The performance of the model was measured by calculating the area under the receiving operating characteristic curve (AUC), sensitivity, specificity, positive and negative predictive values (PPV and NPV, respectively).

**Results:** After the optimization of the architecture of the CNN for automatic detection of papillary projections, our network showed a sensitivity of 99.7%, a specificity of 97.1%, a PPV of 96.2% and a NPV of 99.8%. The overall accuracy of our CNN was 98.2%. The AUC was 0.99 (Figure 1). The image processing speed was of 15 ms/image.

Figure 1: ROC analysis of the network's performance in the detection of papillary projections associated with malignant biliary strictures. ROC-receiver operating characteristic. PP-papillary projections.

**Conclusion:** Our *deep learning* algorithm detected papillary projections, a finding frequently associated with malignant biliary strictures, with high accuracy. The development of AI tools for may positively impact the diagnostic yield of cholangioscopy, potentiating a timely diagnosis and treatment, which may ultimately translate into prognostic gains.

**SZN-043, a hepatocyte targeted R-spondin mimetic, induces hepatocyte proliferation in acute acetaminophen-induced liver injury model**

Mehaben Patel<sup>1</sup>, Maureen Newman<sup>1</sup>, Vincent Meador<sup>2</sup>, Haili Zhang<sup>1</sup>, Wen-Chen Yeh<sup>1</sup>, Trudy Vanhove<sup>1</sup>, Jay Tibbitts<sup>1</sup>, Helene Baribault<sup>1</sup>.

<sup>1</sup>Surrozen, South San Francisco, United States; <sup>2</sup>Pacific Tox Path, LLC, Seattle, United States

Email: meha@surrozen.com.

**Background and aims:** Wnt signaling plays a central role in hepatocyte expansion during development and tissue repair. R-spondins (RSPOs) amplify Wnt signaling via stabilization of Frizzled and LRP co-receptors and their function depends on the presence of Wnt ligands, which are upregulated in injured tissue. The APAP-induced liver injury model in mice reproduces all important clinical features of adverse events and toxicity observed with APAP overdose in humans. To test the efficacy of SZN-043 in an acute liver injury model, we tested the ability of SZN-043 to repair APAP-induced liver damage.

**Method:** SZN-043 efficacy was tested in C57BL/6J (B6) mice which were randomized based on body weight. Mice were fasted overnight to ensure that all animals had an initial, homogeneous, low level of glutathione. Mice then received a single i.p. dose of APAP (300 mg/kg) and were returned to their cage with food. One control group received a single i.p. dose of saline. Two hours later, mice were administered a single dose of negative control anti-GFP (10 mg/kg), SZN-043 (10 mg/kg) or positive control N-acetyl cysteine (1200 mg/kg). Blood and liver tissue samples were collected at 24, 48 and 72 hours. To measure the effect of SZN-043 on hepatocyte proliferation, maturation and zonation, liver tissue markers were analyzed respectively using RT-qPCR. Clinical chemistry included ammonium, ALT, AST and total bilirubin levels. Hepatocyte specific proliferation was analyzed by immunofluorescence staining of Ki67 and Hnf4-alpha. Histopathology was done using hematoxylin and eosin staining.

**Results:** Serum chemistry analysis showed that SZN-043 had no effect on ALT or AST levels but showed a trend towards bilirubin reduction. Compared to anti-GFP, both NAC and SZN-043 significantly reduced the levels of circulating ammonia. As expected, SZN-043, but not NAC, induced Wnt activation as shown by a significant increase of the direct Wnt target genes, *Axin 2* and *Ccnd1* mRNA. Notum, a physiologic negative regulator of Wnt signaling was also significantly induced in response to SZN-043. SZN-043 induced Ki67 positive nuclei specifically in HNF4-alpha-expressing hepatocytes in immunofluorescence, suggesting that SZN-043 induced hepatocyte expansion and maturation to HNF4-alpha positive cells after APAP-induced liver injury. Histopathological analysis at 72 hr after APAP treatment showed large regions of diffuse necrosis in the pericentral regions of the liver samples in mice treated with anti-GFP. In contrast, livers from mice treated with NAC and particularly SZN-043 displayed reduced necrosis.

**Conclusion:** These results provide supporting evidence that SZN-043 can induce hepatocyte specific regeneration in response to APAP overdose. This approach may be beneficial for the treatment of liver diseases.

PO-537

**Protective effect of GOLM1 on acute liver failure in mice**

Linlan Qiao<sup>1</sup>, Junzhou Zhao<sup>1</sup>, Mengyun Ke<sup>1</sup>, Tingyao Chen<sup>1</sup>, Jian Dong<sup>1</sup>.

<sup>1</sup>The First Affiliated Hospital of Xi'an Jiaotong University, Department of Hepatobiliary Surgery, Xi'an, China

Email: dongjiandoctor01@xjtu.edu.cn.

**Background and aims:** Acute liver failure (ALF) is a life-threatening disease with a high mortality rate. However, the pathogenesis of ALF is still unclear. Golgi Membrane Protein 1 (GOLM1), a protein involved in the trafficking of proteins through the Golgi apparatus, plays an important role in anti-apoptosis. Furthermore, some previous studies demonstrated that Growth differentiation factor-15 (GDF15) had protective effect on ALF. Therefore, we tried to explore the role of GOLM1 and GDF15 in ALF.

**Method:** Immunohistochemistry, q-PCR, and western blot analysis were performed to evaluate GOLM1 levels in D-GalN/LPS induced liver failure wild mice tissue samples and normal mice tissue samples at 3 and 6 hours, respectively. Meanwhile, 6 wild type (WT) mice and GOLM1- transgene (TG) mice were selected to establish D-GalN/LPS induced liver failure models. The effect of GOLM1 in the process of liver failure was investigated by HE staining, detection of liver function, the level of inflammatory cytokines, and comparison of survival rate between the GOLM1-TG group and WT group. Serum GDF15 levels and liver GDF15 mRNA levels were detected by ELISA and q-PCR. SPSS (Version 23.0. Armonk, NY: IBM Corp.) was used for statistical analysis, and p value <0.05 was considered statistically significant.

**Results:** The level of GOLM1 mRNA in liver failure wild mice tissues was lower at 3 h and 6 h than the level in control group. Western blot showed that the level of GOLM1 protein in liver failure wild mice tissues was also lower than the level in control group at 3 h and 6 h. The expression of GOLM1 protein in liver failure wild mice tissues was still lower than that in control group at 3 h and 6 h through IHC. HE staining of liver tissue in WT mice and TG mice showed that liver necrosis was more serious in WT mice. Liver function test showed that the liver function of TG mice was less damaged and the level of inflammatory cytokines was lower than control group. The survival rate of TG mice was significantly higher than that of WT mice. IHC detection showed that the expression of GDF15 in GOLM1-TG group liver tissue was significantly higher than that in WT group. ELISA and q-PCR detection showed that the serum GDF15 level and liver GDF15 mRNA level in TG group were significantly higher than those in the control group.

**Conclusion:** GOLM1 may play a protective role in acute liver failure by upregulating the expression of GDF15.

Figure (abstract: PO-537): A. The level of GOML1 mRNA and the expression of GOML1 protein in 3 h and 6 h between D-GalN/LPS induced ALF mice and control mice. B. The gross specimen, HE staining, liver function, and survival rate between GalN/LPS induced liver failure GOML1-TG mice and GalN/LPS induced liver failure WT mice. C. The level of inflammatory cytokines in GOML1 TG mice and WT mice, respectively. D. The expression of GDF15 in liver tissue of GOML1-TG and WT mice in IHC. **PO-559**  
**Chemokine receptor CCR5 and its corresponding chemokines contribute to virus-induced liver injury via conventional NK cells recruitment**

Zhongwei Zhang<sup>1</sup>, Zhongyuan Yang<sup>1</sup>, Weiming Yan<sup>1</sup>, Qiuyu Cheng<sup>1</sup>, Yunhui Liu<sup>1</sup>, Tao Chen<sup>1</sup>, Qin Ning<sup>1</sup>. <sup>1</sup>Tongji Hospital, Tongji Medical College, Huazhong University of Science and Technology, Department and Institute of Infectious Disease, Wuhan, China  
 Email: qning@vip.sina.com.

**Background and aims:** Our previous study demonstrated that conventional natural killer (cNK) cells migrate into liver from peripheral organs and exert cytotoxic effects on hepatocytes post murine hepatitis virus strain 3 (MHV-3) infection in BALB/cj mice, however the mechanisms of migration was not reported yet. This study aimed to investigate the role of chemokine receptors and their corresponding chemokines in the migration of cNK cells in virus-induced liver injury.

**Method:** Mice were injected intraperitoneally with MHV-3 to induced fulminant hepatic failure (FHF), In the Pharmacological inhibition of CCR5 experiment, mice received maraviroc by oral gavage daily.

**Results:** Gene expression analysis indicated that chemokine (C-C motif) receptor 5 (CCR5) in cNK cells own the highest expression comparing with other receptors including CCR1, CXCR3 and CXCR4 after MHV-3 infection in BALB/cj mice. By flow cytometry, the

number of hepatic CCR5+ cNK cells increased and reached peak at 48 hours post MHV-3 infection, while the number of hepatic resident NK cells (rNK) declined steadily. Moreover, its corresponding chemokines macrophage inflammatory protein (MIP)-1 $\alpha$ , MIP-1 $\beta$  and regulated on activation, normal T cell expressed and secreted (RANTES) multiplied throughout the whole course of infection. In vitro, the transwell migration assay displayed a decreased migration of splenic cNK cells towards infectious hepatocyte after blocking CCR5 on cNK cells, and individual neutralization of CCR5 ligands MIP-1 $\beta$  and RANTES but not MIP-1 $\alpha$  decreased cNK cells migration. In vivo, pharmacological inhibition of CCR5 (by the inhibitor, maraviroc) reduced cNK cells infiltration in liver and virus-induced liver injury after MHV-3 infection in mice. Meanwhile, CCR5 knockout (KO) mice displayed reduced infiltration of cNK cells in liver post MHV-3 infection, this was accompanied with attenuated liver injury and improvement of survival time. Adoptive transfer experiments in CCR5 KO mice verified that cNK migrating into liver aggravate liver injury during MHV-3-induced FHF.

**Conclusion:** These results indicated that CCR5 and its ligands MIP-1 $\beta$ , RANTES play a critical role in the hepatic recruitment of cNK cells in MHV-3-induced liver injury, and the CCR5 inhibitor might bear therapeutic potential to ameliorate liver damage during virus-induced FHF.

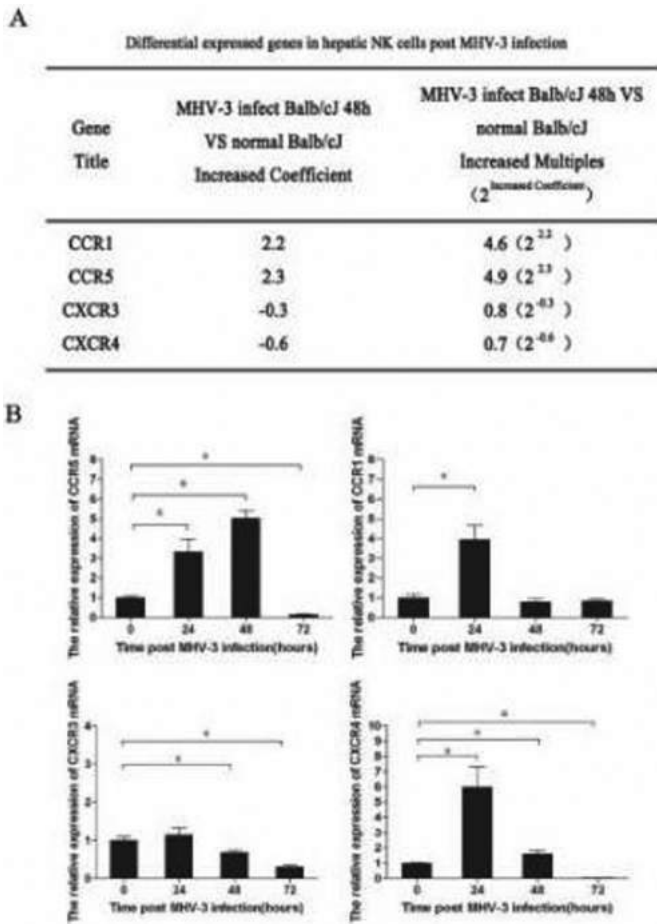

Figure: (abstract: PO-559)

**Development and validation of a non-invasive algorithm to predict significant fibrosis in patients with chronic drug-induced liver injury**

Dong Ji<sup>1</sup>, Zhong-bin Li<sup>1</sup>, Guofeng Chen<sup>1</sup>. <sup>1</sup>5th Medical Center of Chinese PLA General Hospital, Department of Liver Diseases, Beijing, China  
 Email: jjd302@126.com.

**Background and aims:** Currently, there are no satisfactory non-invasive methods for the diagnosis of fibrosis in patients with chronic drug-induced liver injury (DILI). Our goal was to develop an algorithm to improve the diagnostic accuracy of significant fibrosis in this population.

**Method:** Consecutive patients with biopsy-proven chronic DILI from January 2013 to December 2017 were retrospectively enrolled. An algorithm was developed by using multivariate logistic regression, receiver operator characteristic (ROC) curves, and decision curve analysis (DCA) to diagnose significant fibrosis in the training cohort, and the algorithm was subsequently validated in the validation cohort.

**Results:** Totally, 1,130 patients were enrolled and randomly assigned into a training cohort (n=848) and a validation cohort (n=282). Based on the multivariate analysis, LSM, CHE, and APRI were independently associated with significant fibrosis. A novel algorithm, LAC, was identified with the AUROC of 0.81, which was significantly higher than LSM (AUROC 0.78), CHE (AUROC 0.73), and APRI (AUROC 0.68), alone. The best cutoff value of LAC in the training cohort was 5.4. When the LAC algorithm was used to diagnose advanced fibrosis and cirrhosis stages, the optimal cutoff values were 6.2 and 6.7, respectively, and the AUROC values were 0.84 and 0.90 in the training cohort and 0.81 and 0.83 in the validation cohort.

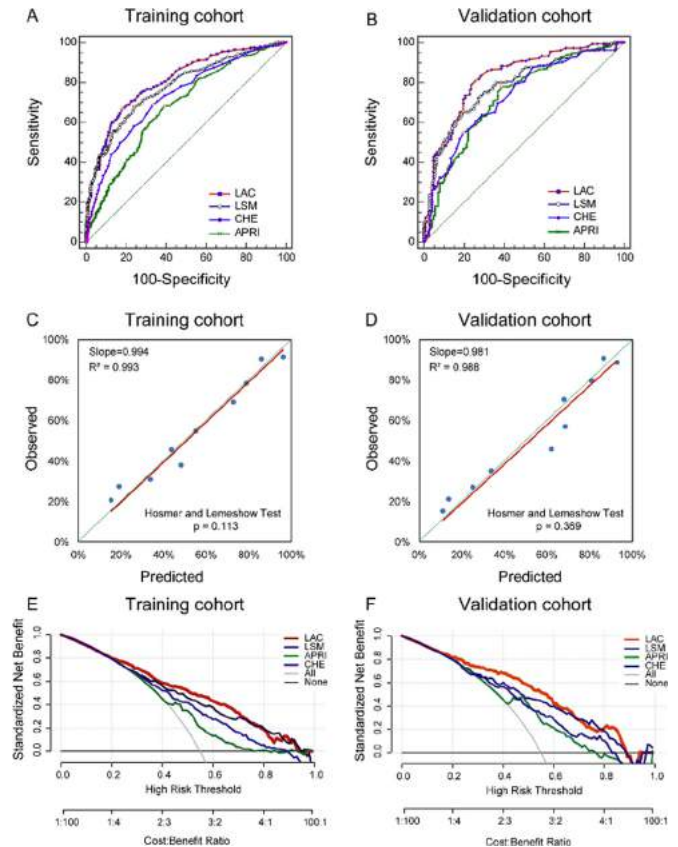

Figure: (abstract: PO-679)

**Conclusion:** The LAC algorithm shows a better performance than LSM, APRI, or CHE alone in predicting significant fibrosis, thus contributing to the accurate assessment of high-risk disease progression and the establishment of optimal treatment strategies for patients with chronic DILI.

**PO-712**  
**Fibrinogen-like protein 2 promotes fulminant hepatitis by inducing neutrophil activation and neutrophil extracellular traps formation**

Xitang Li<sup>1</sup>, Junjian Hu<sup>1</sup>, Suping Hai<sup>1</sup>, Hongwu Wang<sup>1</sup>, Qin Ning<sup>1</sup>, Xiaojing Wang<sup>1</sup>. <sup>1</sup>Department and institute of infectious diseases, Tongji Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, Hubei, China, Department and institute of infectious diseases  
 Email: qning@vip.sina.com.

**Background and aims:** we aim to investigate the role of fibrinogen-like protein 2 (fgl2) in regulating neutrophil and neutrophil extracellular traps (NETs) in fulminant hepatitis (FH).

**Method:** Neutrophil amount and NETs formation were detected in serum and liver of wild type and fgl2<sup>-/-</sup> mice following murine hepatitis virus-3 (MHV-3) infection. Bone marrow-derived neutrophils were stimulated with MHV-3 in vitro to investigate the underlying mechanism of NETs formation.

**Results:** Concomitant with histopathology lesions and increased ALT and AST, abundant neutrophil accumulation and NETs formation were observed in mice following MHV-3 infection. NETs depletion significantly improved the survival rate (from 4% to 28%) of infected mice, implying that NETs contribute to FH progression. Fgl2<sup>-/-</sup> mice showed remarkable reduction of myeloperoxidase levels, along with improved histopathology damage, decreased liver enzymes and expression of inflammatory cytokines. The expression of fgl2 on neutrophils was upregulated post MHV-3 infection. Fgl2 destruction reduced neutrophil accumulation in liver of the infected mice, and

downregulated expression of hepatic ICAM-1, CXCL1, CXCL2 and CXCR2. Both in vivo and in vitro studies revealed that fgl2 promoted NETs generation through the ROS-dependent PAD4 pathway. Moreover, fgl2 directed fibrin deposition in NETs area, aggravating the following coagulation cascade and tissue lesions.

**Conclusion:** Fgl2 promotes FH progression partially via boosting hepatic neutrophil accumulation as well as facilitating NETs formation and subsequent liver injury. Thus, fgl2 might serve as a potential therapeutic target in FH.

**PO-1107**

**Acute liver injury among patients with COVID-19 in a tertiary hospital**

Henry Winston Li<sup>1</sup>, Janus Ong<sup>1</sup>. <sup>1</sup>Philippine General Hospital, Gastroenterology, Manila, Philippines  
Email: winolps2488@gmail.com.

**Background and aims:** The COVID-19 disease primarily affects the respiratory system with principal symptoms including fever, cough, dyspnea and malaise. However, liver involvement has been demonstrated on prior studies with abnormalities seen from 14 to 53% of cases. The prevalence of liver injury was also believed to be associated with increased disease severity and mortality among infected patients. The aim of the study was to determine the clinical characteristics and risk factors for acute liver injury (ALI) among COVID-19 patients admitted in our local setting and to identify potential association of ALI on significant health outcomes.

**Method:** This was a retrospective study of adult patients with COVID-19 admitted at Philippine General Hospital. Acute liver injury was defined as ALT >ULN-mild ALI (up to 2× ULN), moderate ALI (2–5× ULN), severe ALI (>5× ULN). Descriptive analysis was conducted accordingly. Univariate and multivariate analyses of predictors of ALI were performed. Impact of ALI on health outcomes was determined and adjusted for known predictors including age, gender, co-morbidities and FIB-4.

Table 1: Multivariable Predictors of ICU Admission by Category of ALT elevation among patients

Predictors	Univariable		Multivariable.	
	Odds Ratio (95% CI)	p value	Odds Ratio (95% CI)	p value
ALT Category				
Normal	1.00		1.00	
1-<2× UL	1.11 (0.83–1.49)	0.49	1.13 (0.81–1.58)	0.46
2–5× UL	1.22 (0.85–1.75)	0.29	1.19 (0.79–1.79)	0.41
>5× UL	2.26 (0.94–5.45)	0.07	2.62 (0.97–7.08)	0.06
Age	1.05 (1.04–1.06)	<0.01*	1.06 (1.05–1.07)	<0.01*
Sex				
Female	1.00		1.00	
Male	1.74 (1.35–2.23)	0.01*	1.86 (1.40–2.47)	0.01*
Co-morbid Conditions				
	1.73 (1.35–2.21)	0.01*	0.89 (0.66–1.20)	0.43
Hypertension				
Diabetes mellitus	1.57 (1.19–2.07)	0.01*	1.09 (0.80–1.50)	0.58
Malignancy	2.17 (1.28–3.67)	0.01*	1.91 (1.06–3.47)	0.03*
FIB-4 Levels	1.11 (1.06–1.17)	<0.01*	1.02 (0.99–1.05)	0.11

**Results:** A total of 1, 086 patients satisfied inclusion criteria with mean age of 54, M:F ratio 1.2:1. 425/1086 (39%) had ALI-mild ALI 258 (24%), moderate ALI 146 (13%), severe ALI 21 (2%). Chronic liver disease (CLD) (OR: 2.52; p = 0.01), critical COVID-19 (OR: 4.94; p = 0.02), increased AST (OR: 1.04; p = <0.01) and increased ferritin (OR: 1.03; p = 0.01) were all associated with moderate to severe ALI. Although there was a trend towards higher rates of ICU admission with increasing severity of ALI [severe ALI, OR 2.26 (0.94–5.45, p =

0.07), moderate ALI, OR 1.22 (0.85–1.75, p = 0.29), mild ALI, 1.11 (0.83–1.49, p = 0.49), this was not statistically significant. (Table 1) There was a similar but likewise not statistically significant trend in rates of intubation, need for renal replacement and mortality with increasing severity of ALI.

**Conclusion:** ALI occurred commonly among patients admitted for COVID-19 and was associated with CLD, critical COVID-19, AST, and ferritin. Severity of ALI showed a trend towards higher adverse outcomes.

**Background and aims:** Drug-induced liver injury (DILI) is the main cause of acute liver failure (ALF) in the Western World. Acetaminophen (APAP), the most available pain medication in USA, accounts for 50% of ALF in USA and Europe. N-acetylcysteine, routinely used for early stages of idiosyncratic DILI and APAP abuse, has limited effect after 20 hours of overdose. Therefore, additional therapeutic approaches are necessary in this pathology. Cyclin M4 (CNNM4) has a key role in magnesium transport across cell membranes. Here, we investigated if CNNM4 and dysregulated magnesium homeostasis could play a functional role in DILI.

**Method:** Hepatic CNNM4 expression and magnesium levels were assessed in human samples and in mice. Mice were treated with APAP 360 mg/kg by intraperitoneal injection and 24 h thereafter *Cnnm4* siRNA or an unrelated control (siCtrl) were administered via tail vein injection and compared to control group. Mice were sacrificed 48 hours after APAP overdose. Primary hepatocytes treated with GalNAc conjugated *Cnnm4* siRNA or control siRNA were exposed to APAP and mitochondrial ROS and ER stress were evaluated.

**Results:** Patients with APAP overdose and idiosyncratic DILI presented an upregulation of hepatic CNNM4 expression and disturbances in magnesium serum levels. In the liver, we showed that

Figure: (abstract: PO-1185)

CNNM4 overexpression coincides with ER stress and mitochondrial dysfunction, affecting ATP production and ROS generation. Silencing *Cnm4* expression in the liver with nanoparticle- or in hepatocytes with GalNAc-conjugated siRNA protects from APAP-induced liver injury and restores cellular magnesium homeostasis. **Conclusion:** CNNM4 appears as a new therapeutic approach to treat DILI with the added value of ameliorating mitochondrial dysfunction and ER stress that NAC does not provide.

Robles-Díaz<sup>1,2</sup>, Ibon Martínez-Arranz<sup>3</sup>, Inmaculada Medina-Caliz<sup>1</sup>, Aida Ortega-Alonso<sup>1</sup>, Miren Garcia Cortes<sup>1,2</sup>, Jose Pinazo Bandera<sup>1</sup>, J. Sanabria-Cabrera<sup>1</sup>, Enrique del Campo Herrera<sup>1</sup>, Rocio González-Grande<sup>4</sup>, Miguel Jiménez<sup>4</sup>, Maria Isabel Lucena<sup>1,2</sup>, Raul J. Andrade<sup>1,2</sup>. <sup>1</sup>UGC Aparato Digestivo, Servicio de Farmacología Clínica, Instituto de Investigación Biomédica de Málaga-IBIMA, Hospital Universitario Virgen de la Victoria, Universidad de Málaga, Málaga, Spain; <sup>2</sup>Centro de investigación biomédica en red en el área temática de enfermedades hepáticas y digestivas (CIBERehd), Madrid, Spain; <sup>3</sup>OWL Metabolomics, Derio, Bizkaia, Spain, Spain; <sup>4</sup>Servicio de Aparato Digestivo, IBIMA, Hospital Universitario Regional de Málaga, Málaga, Spain, Málaga, Spain  
Email: danielizeo9@hotmail.com.

**Background and aims:** Due to the lack of biomarkers, the diagnosis of drug-induced liver injury (DILI) currently relies in the exclusion of other liver disorders and the interpretation of causality scores, which usually have low sensitivity and poor inter-observer reproducibility. We aimed to develop a new predictive algorithm tool that could help clinicians to effectively distinguish DILI from liver injury of other aetiologies.

**Method:** The study sample comprised 26 Spanish DILI cases -mostly due to anti-infective drugs- and 34 with non-DILI acute liver injury (ALI) -mostly viral hepatitis-. Clinical data (sex, age, BMI, severity and biochemical tests) and serum metabolomic profiles (UHPLC-MS analysis), were used to design different predictive models: Logistic regression, Random Forest, Support Vector Machine and K-NN. These models were developed to find the best methodology to classify the patients. A selection of significant features was applied to each model, first features with low variance were removed and then a univariate selection was performed ( $p < 0.05$ ). In order to avoid bias in the models, the cohort was split into two subcohorts (50%/50%): training and validation

**Results:** Two clinical parameters (AST and ALT) and 17 metabolites were selected for inclusion in the predictive models. Among the metabolites, 47% were fatty acids, 21% were glycerophospholipids, 10.5% amino acids, 5% bile acids and 5% peptides. Specifically, the AST and ALT transaminases and the amino acid tryptophan stood out for their higher statistical significance ( $p < 0.009$ ). Most of the fatty acids used to discriminate between DILI and ALI were polyunsaturated species ( $p < 0.05$ ). PE (20:4/0:0) was the glycerophospholipid that

Figure: (abstract: PO-1335)

reached the highest statistical significance ( $p < 0.02$ ), and Phe-Phe was the only dipeptide included in the model ( $p < 0.03$ ). Based on these variables, Logistic regression, K-NN classifier and Random Forest models were selected as the best choice for classifying the patients in the training cohort, all of them with an area under the receiver operating characteristic curve (AUC) over 0.75 (Figure 1a). The highest AUCs were obtained for the Random Forest Classifier (AUC = 0.89) and the Logistic Regression (AUC = 0.82) in the validation cohort (Figure 1b).

**Conclusion:** A metabolic signature capable of discriminating DILI vs ALI patients with an AUC over ~0.75 has been identified. Further refinement of this model and the development of other mathematical approaches could support a more accurate diagnosis of DILI. Funding: CIBERehd, ISCiii-FEDER PI18/00901, PI19/00883.

**Background and aims:** Autoimmune hepatitis (AIH) and drug-induced liver injury (DILI) present with acute hepatitis and share many clinical features. We hypothesised that the innate immune response to activate the adaptive immune system is key to the pathogenesis of both conditions. However, underlying innate immune subsets involved, their recruitment and cellular crosstalk in liver immunopathology remain unexplored.

**Method:** We performed immunophenotyping of peripheral blood immune cells from patients with AIH (n = 13), on-going DILI (n = 8) and compared with healthy controls (n = 4). Expression of lectin like transcript-1 (LLT-1), CXCL10 on liver tissue was explored with immunohistochemistry. CD70 expression was examined with flow cytometry on liver lymphocytes. CXCL10 secretion on human hepatocytes and biliary epithelial cells (BEC) was analysed by ELISA.

**Results:** Compared to healthy controls, both AIH and DILI were associated with an increased number of NK cells. AIH patients have significant ( $29.9 \pm 5$  vs  $5.7 \pm 1.2$ ;  $p \leq 0.03$ ) and DILI patients have high-level expression ( $15.6 \pm 3.1$  vs  $5.7 \pm 1.2$ ;  $p = 0.056$ ) of liver-homing chemokine receptor CXCR3 compared to control. CXCR3 ligand, CXCL10 expression was observed on hepatocytes and BEC in AIH. TNF $\alpha$  and IFN $\gamma$  stimulated human hepatocytes ( $702$  vs  $75$ ;  $p \leq 0.05$ ) and BEC ( $648$  vs  $5.7$ ;  $p \leq 0.05$ ) to secrete significant amount of CXCL10 chemokine. NK cells have significant expression of CD27 in AIH ( $9.0 \pm 1.8$  vs  $1.2 \pm 0.4$ ;  $p \leq 0.05$ ) and high-level of CD27 ( $5.8 \pm 2.3$  vs  $1.2 \pm 0.37$ ;  $p = 0.01$ ) in DILI compared to controls. CD27 ligand, CD70 was observed on CD1c<sup>+</sup> CD11c<sup>+</sup> ( $54.9 \pm 20.1$ ) and CD123<sup>+</sup> CD303<sup>+</sup> ( $50.5\% \pm 22.9$ ) dendritic cells. In addition, there was a high level of CD161 expression on NK cells in both AIH ( $50 \pm 9.7$  vs  $34 \pm 4$ ) and DILI ( $45 \pm 4.7$  vs  $34 \pm 4$ ) compared to controls. Multi-colour immuno-staining in

AIH demonstrated CD161 ligand, LLT-1 expression on intrahepatic CD68<sup>positive</sup> Kupffer cells.

**Conclusion:** We have reported for the first time the presence of CXCR3<sup>positive</sup>, CD27<sup>positive</sup>, CD161<sup>positive</sup> circulating NK cells in patients with AIH and ongoing DILI. CXCR3<sup>positive</sup> NK cells and CXCL10 expression on hepatocytes and biliary epithelium support NK cells positioning around hepatocytes and BEC. These CD161<sup>positive</sup> CD27<sup>positive</sup> NK cells interact with LLT-1 expressing Kupffer cells and CD70 expressing dendritic cells in AIH and DILI contributing to pathogenesis.

<sup>4</sup>Platform for Clinical Research and Clinical Trials IBIMA, Plataforma ISCiii de Investigación Clínica, Madrid, Spain  
 Email: andrade@uma.es.

**Background and aims:** There is no specific therapy approved for idiosyncratic drug-induced liver injury (DILI) treatment. Previous data show that corticosteroids are often empirically used in DILI patients although its benefit-risk balance remains controversial. We aimed to evaluate the effects of corticosteroids in DILI patients using non-experimental data through propensity score matching (PSM).

**Method:** All cases of idiosyncratic DILI entered in the Spanish DILI registry from 1994 to November 2020 were retrieved (N = 979). The primary outcome was the development of acute liver failure (ALF) that went on to liver-related death/liver transplantation. Patients treated with corticosteroids were compared to those who did not receive any treatment. A nearest neighbor propensity score matching (1:1) was used to reduce confounding factors (age, sex, total bilirubin, alkaline phosphatase, type of liver injury and Model for End-stage Liver Disease score). Matching without replacement was performed using a caliper width of 0.25 on the propensity score scale. Crude and adjusted odds ratio (OR) along with its 95% confidence interval (CI) were estimated.

**Results:** A total of eligible 548 patients, 78 treated with corticosteroids, 2 of them also treated with ursodeoxycholic acid, and 1 with ursodeoxycholic acid and MARS (mean age  $54 \pm 18$  years, 58% women), and 470 who did not receive any treatment ( $54 \pm 18$  years; 48% women), were enrolled. Hepatocellular injury was more frequent in both groups (63% and 66%, respectively). Among patients who received corticosteroids 6.4% developed ALF, compared to 1.9% who did not receive any treatment ( $p = 0.036$ ), and risk of ALF was significantly increased in patients who received corticosteroids (crude OR = 3.50; 95% CI 1.14–10.76,  $p = 0.028$ ). After PSM, 55 well-balanced pairs were matched. Baseline characteristics were no longer significantly different between the treatment and control group. Corticosteroids use was not associated with an increased risk for developing ALF (adjusted OR = 1.71; 95% CI 0.30–9.89;  $p = 0.548$ ). Sensitivity analysis excluding drug-induced autoimmune hepatitis cases (N = 29) showed consistent findings (adjusted OR = 0.99; 95% CI 0.19–5.07,  $p = 0.987$ ).

## POSTER PRESENTATIONS

Figure:

**Conclusion:** This PSM study evidenced that corticosteroids administration in DILI patients was not associated with an increased risk of progression to ALF in DILI patients. Further collaborative studies to validate these findings are clearly needed.

#### ALKBH5-modified HMGB1-STING activation contributes to radiation-induced liver disease via innate immune response

Genwen Chen<sup>1</sup>, Qianqian Zhao<sup>1</sup>, Baoying Yuan<sup>1</sup>, Zhaochong Zeng<sup>1</sup>.  
<sup>1</sup>Zhongshan Hospital Fudan University, Radiation Oncology, Shanghai, China

Email: zeng.zhaochong@zs-hospital.sh.cn.

**Background and aims:** Radiation therapy (RT) is vital for the therapy of primary liver cancer, but inevitable liver injury limits the implement of RT. N6-methyladenosine (m6A) methylation is involved in many molecular functions; however, its role in radiation-induced liver diseases (RILD) remains unknown. Hence, we intend to investigate the role of m6A methylation in RILD.

**Method:** Methylated RNA-immunoprecipitation sequencing (MeRIP-seq) and RNA transcriptome sequencing (RNA-seq) were used to reveal the methylation pattern of human hepatic stellate cells with exposure to irradiation. C3H/HeN mice and STING-deficient mice underwent X-ray irradiation of 24 Gy in three fractions. The m6A methylation of HMGB1 transcript was validated using MeRIP, RIP, luciferase assay and mRNA decay assays.

**Results:** Human hepatic stellate cells shown significant difference of methylation pattern after 8 Gy of X-ray irradiation. Irradiation recruits ALKBH5, an eraser of m6A methylation, and then demethylated HMGB1 transcript at m6A residues in the 3'UTR, following activation of STING-IRF3 signaling. Inserting of the HMGB1 3'UTR into a luciferase reporter resulted in regulation of luciferase activity by ALKBH5 knockdown, which was lost after m6A residue mutation. Strikingly, ALKBH5 deficiency or HMGB1 silencing both attenuated type I interferon production, resulting to less hepatocyte apoptosis. *In vivo* depletion of ALKBH5 abolished the upregulation of HMGB1-mediated STING signaling, leading to slightly liver inflammation, which was consistent to STING<sup>-/-</sup> mice in response to irradiation. Notably, the m6A reader protein YTHDF2 directly binds to m6A-modified site of HMGB1 transcript, which consequently promotes its degradation.

Figure:

**Conclusion:** ALKBH5 demethylates m6A-modified HMGB1 transcript through YTHDF2-mediated degradation, resulting in RILD via innate immune response.

Email: jsh@snuh.org.

**Background and aims:** The etiology of acute hepatitis is dynamically changing according to public health improvement and lifestyle alteration. Therefore, continuous monitoring of profiles of acute hepatitis is required to control the hepatitis disease burden and establish the preventive strategies. The aim of this study is to investigate the etiology and clinical characteristics of current acute hepatitis in South Korea.

**Method:** We prospectively enrolled 214 with acute hepatitis diagnosed by AST >200 IU/L without history of underlying chronic hepatitis. in 12 university hospitals from March 2020 to November 2020. Clinical data as well as a detailed questionnaire survey results on the risk factors for acute hepatitis were collected and entered into the common case report forms. We also collected serum and stool samples from the patients diagnosed non-A, B, C hepatitis, including hepatitis E, toxic and cryptogenic hepatitis.

**Results:** The causes of acute hepatitis were viral hepatitis (n = 79, 36.9%), toxic hepatitis (n = 71, 33.2%), cryptogenic (n = 53, 24.8%), and autoimmune hepatitis (n = 11, 5.0%). There was only one cryptogenic hepatitis patient who received transplantation, and no patient died. Among the patients with viral hepatitis, hepatitis A virus (HAV) was attributable to 75.9% (n = 60), HBV 2.5% (n = 2), HCV 3.8% (n = 3), HEV 10.8% (n = 7), Epstein-Barr virus (EBV) 7.7% (n = 5), and Cytomegalovirus 2.5% (n = 2). Therefore, HEV was the 2<sup>nd</sup> most common cause of acute viral hepatitis. Among the patients with toxic

hepatitis, the most common causative substances were oriental medicine (n=26, 36.1%) followed by diet pills (n=7, 9.7%). Interestingly, there were substantial proportion of patients classified as cryptogenic hepatitis. Compared to viral hepatitis group, the cryptogenic group showed significantly lower maximal ALT level (843 vs 2231 U/L, p < 0.001), and higher albumin (4.3 vs 3.8 mg/dL, p = 0.038) and platelet count (207 vs 85 × 1, 000/mm<sup>3</sup>, p = 0.015), suggesting milder form of hepatitis. However, compared to toxic hepatitis group, the cryptogenic group showed similar characteristics except significantly older age (40.2 vs 53.1 years, p < 0.001).

**Conclusion:** In viral hepatitis, HAV was the most common etiology followed by HEV. The most common causes of toxic hepatitis were oriental medicine and diet pills. Cryptogenic hepatitis were clinically similar to toxic hepatitis, which warrant further study.

**PO-2122**

**Decreased Overall Mortality and Mortality without Liver Transplantation with N-Acetylcysteine in Non-acetaminophen-induced Acute Liver Failure: A Systematic Review and Meta-Analysis**

Adrian Alick Bonghanoy<sup>1</sup>, John Mark Torres<sup>1</sup>, Janus Ong<sup>1</sup>, Eric Yasay<sup>1</sup>, Jonathan Luzano<sup>2</sup>, Amiel Villanueva<sup>2</sup>. <sup>1</sup>Philippine General Hospital, Division of Gastroenterology, Manila, Philippines; <sup>2</sup>Philippine General Hospital, Department of Internal Medicine, Manila, Philippines  
Email: adrianalick1987@gmail.com.

**Background and aims:** To date, there is no established treatment for non-acetaminophen-induced acute liver failure (NAI-ALF) other than liver transplantation. N-acetylcysteine (NAC) is an effective drug for ALF caused by acetaminophen; but its use in NAI-ALF remains uncertain. The study aims to determine the effect and safety of NAC in decreasing mortality among patients with NAI-ALF.

**Method:** A comprehensive literature search of PubMed, EMBASE, Google Scholar, Cochrane, NEJM, Chinese Biomedicine Database and Science Citation Index Expanded was done. Two reviewers independently selected studies, assessed quality, extracted and pooled outcomes including overall mortality and mortality without liver transplantation (MWO<sub>LT</sub>). All selected studies have low risk for bias based on Cochrane risk of bias assessment tool.

**Results:** Four studies in adults and one study in pediatric patients, with a total of 287 patients receiving treatment with NAC and 277 patients in the placebo group, were included in the meta-analysis. No statistical difference was identified between NAC and placebo for overall mortality [OR 0.78 (0.54–1.13), 95% CI; p = 0.19] however, there was a trend showing decreased overall mortality with NAC. In a subgroup analysis excluding the pediatric study, statistical differences were demonstrated between NAC and placebo in overall mortality [OR 0.56 (0.36–0.88), 95% CI; p = 0.01]. In terms of MWO<sub>LT</sub>, there was a significant difference between NAC and placebo, showing NAC decreasing MWO<sub>LT</sub>. [OR 0.35 (0.24–0.50), 95% CI; p = <0.00001]. The identified common side effects of NAC include dyspepsia,

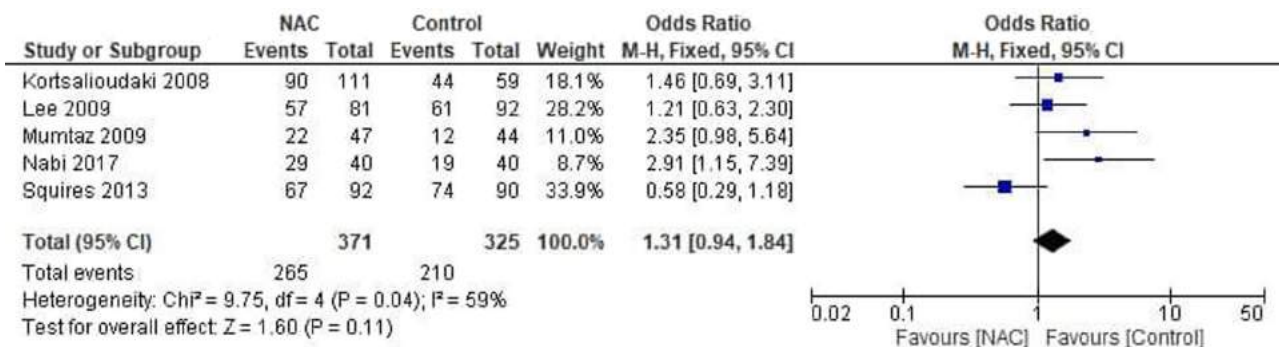

Figure (abstract: PO-2122): Forrest plot on the effect of NAC vs placebo in OVERALL SURVIVAL among adult and pediatric patients

## POSTER PRESENTATIONS

vomiting, and rashes. Otherwise, NAC was well-tolerated among patients.

**Conclusion:** NAC is safe and can decrease overall mortality and MWoLT among adult patients with NAI-ALF.

### PO-2178

#### Low baseline cortisol but not delta cortisol relates to 28-day transplant-free survival in acute liver failure syndromes

Sofia Roth<sup>1</sup>, Emilio Flint<sup>1</sup>, Lea Ghataore<sup>2</sup>, Vishal C. Patel<sup>3</sup>, Arjuna Singanayagam<sup>3,4</sup>, Royce P. Vincent<sup>2</sup>, Evangelos Triantafyllou<sup>3,4</sup>, Yun Ma<sup>3</sup>, William Bernal<sup>3</sup>, Georg Auzinger<sup>3</sup>, Michael Heneghan<sup>3</sup>, Mark McPhail<sup>3</sup>, Charalambos Antoniadis<sup>3,4</sup>, Mirjam Christ-Crain<sup>5</sup>, David R. Taylor<sup>2</sup>, Julia Wendon<sup>3</sup>, Christine Bernsmeier<sup>1,3</sup>. <sup>1</sup>University of Basel and University Centre for Gastrointestinal and Liver Diseases, Department of Biomedicine, Basel, Switzerland; <sup>2</sup>King's College Hospital NHS Foundation Trust, Department of Clinical Biochemistry (Viapath), London, United Kingdom; <sup>3</sup>King's College London, King's College Hospital, Liver Intensive Therapy Unit and Institute of Liver Studies, London, United Kingdom; <sup>4</sup>Imperial College London, St. Mary's Hospital, Hepatology Department, London, United Kingdom; <sup>5</sup>University Hospital Basel, Department of Endocrinology, Diabetes and Metabolism, Basel, Switzerland  
Email: sofia.roth@unibas.ch.

**Background and aims:** Adrenal insufficiency (AI) has been reported in patients with acute liver failure syndromes, yet, its definition, clinical and prognostic significance remains controversial. We sought to determine the diagnostic value of cortisol measurement and the benefit of glucocorticoid (GC) treatment in patients with acute (ALF) and acute-on-chronic liver failure (ACLF).

**Method:** We studied 28-day transplant-free survival (TFS) in relation to previously described different definitions of AI and GC treatment in patients with ALF (n = 29) and ACLF (n = 34) admitted to Liver Intensive Therapy Unit at King's College Hospital. Admission corticosteroid hormone concentrations at baseline (BL) and following short synacthen test (SST, 250 µg) were assessed by chemoluminescence immunoassay (CLIA) and compared to liquid chromatography-mass spectrometry (LC-MS). Clinicians retrieved cortisol results, yet their decision on GC treatment was independent. In addition, we assessed phenotypic and functional characteristics of circulating monocytes in relation to cortisol concentrations.

**Results:** In ALF, patients with AI defined by BL cortisol <275 and <450 nmol/L had higher TFS compared to patients without AI. BL cortisol concentrations <399 nmol/L predicted TFS (sensitivity 82%, specificity 60%). GC treatment improved TFS only in patients with AI defined by BL cortisol <450 nmol/L. In ACLF, detection of AI did not affect TFS, yet BL cortisol <392 nmol/L correlated with TFS (sensitivity 80%, specificity 61%). Benefit from GC treatment was observed only in patients with AI defined by BL <275 nmol/L albeit low numbers. In both, ALF and ACLF, TFS did not differ when AI definition was based on delta cortisol using SST results. Low levels of distinct corticosteroids (cortisone, 11-deoxycortisol, androstenedione) measured by LC-MS affirmed an association with TFS. High BL cortisol in ALF and ACLF correlated with low HLA-DR expression on monocytes.

**Conclusion:** Baseline cortisol levels may serve as a prognostic factor in liver failure patients given values <399 nmol/L indicated TFS. The finding was supported by the correlation of cortisol with low HLA-DR expression on monocytes, previously associated with poor outcome. Furthermore, ALF patients with BL <450 nmol/L and ACLF patients with BL <275 nmol/L benefited from GC treatment suggesting cortisol assessment can be applied for treatment guidance. Conducting an SST was dispensable.

### PO-2203

#### Diagnostic role of liver biopsy in patients with acute liver failure or acute liver injury

Peter Hunyady<sup>1</sup>, Eva Herrmann<sup>2</sup>, Jörg Bojunga<sup>1</sup>, Mireen Friedrich-Rust<sup>1</sup>, Anita Pathil<sup>1</sup>, Stefan Zeuzem<sup>1</sup>, Ulrike Mihm<sup>1</sup>. <sup>1</sup>University Hospital Frankfurt, Department of Internal Medicine 1, Frankfurt am Main, Germany; <sup>2</sup>Goethe-University, Institute of Biostatistics and Mathematical Modelling, Frankfurt am Main, Germany  
Email: mihm@med.uni-frankfurt.de.

**Background and aims:** Severe acute liver injury (ALI) is characterized by jaundice, coagulopathy and elevation of transaminases in patients without underlying liver disease. If complicated by hepatic encephalopathy, the criteria for acute liver failure (ALF) are fulfilled. To determine the etiology of the ALF or ALI in a patient, liver biopsy may be considered. The present study evaluated how often liver biopsy results affected clinical management in patients with ALF or ALI.

**Method:** All patients with ALF or ALI who had undergone liver biopsy from January 2010 to May 2020 at University Hospital Frankfurt, Germany, were enrolled. Patients were identified by electronic search

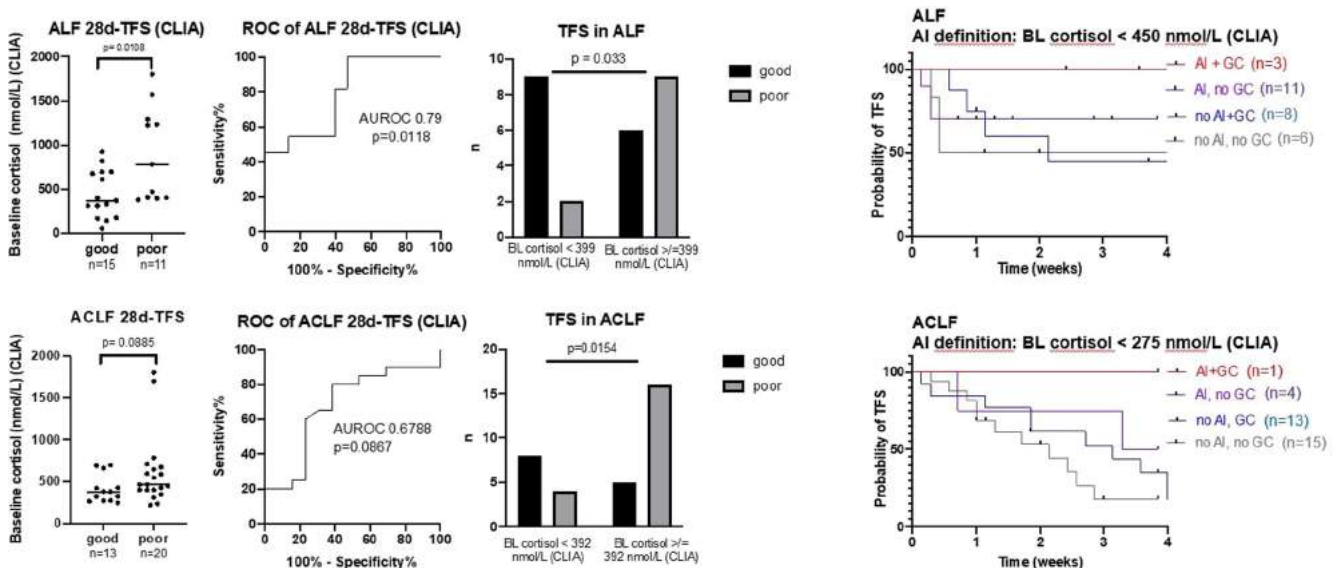

Figure: (abstract: PO-2178)

of the institution's patient database. Data were collected retrospectively of the initial event of ALF/ALI and also of follow-up visits in the institution's outpatient clinic.

**Results:** 66 patients with liver biopsy during ALF/ALI were identified. In 47/66 patients (71%) liver biopsy results did not affect clinical management. In 15/66 patients liver biopsy allowed for investigation of liver involvement by a pre-existing extrahepatic chronic disease (2 patients with AIDS and disseminated tuberculosis; 13 patients with a known hematologic malignancy). In 4/66 patients (6%) the suspected diagnosis was confirmed by the histopathological findings (2 patients with drug-induced liver injury (DILI), 2 patients with autoimmune hepatitis (AIH)).

Postprocedural bleeding occurred in 1/13 patients with a transjugular and in 1/53 patients with a percutaneous liver biopsy. During follow-up in the institution's outpatient clinic, the initial diagnosis was revised in 5 patients, mainly taking into account patient development after corticosteroid withdrawal. So, finally 14 patients were diagnosed with AIH and 33 patients with DILI. In only 2 patients of each group, the initial histopathology had been conclusive for AIH (2/14) or DILI (2/33), respectively.

During ALF/ALI IgG levels were significantly higher in patients with AIH than with DILI ( $2238 \pm 809$  mg/dl vs.  $1096 \pm 264$  mg/dl,  $p < 0,00001$ ). An IgG cut-off-value of 1550 mg/dl was able to distinguish between AIH and DILI with a sensitivity of 92, 9% and specificity of 100% in the study cohort.

Figure:

**Conclusion:** In the present study liver biopsy results did not affect clinical management in the majority of patients with ALF or ALI. Serum IgG levels during ALF/ALI discriminated well between AIH and DILI.

 Email: michel.samson@univ-rennes1.fr.

**Background and aims:** Liver disease is one of the global health problems, in particular, acute liver injury is associated with high mortality rates. The pathogenesis of acute liver injury is known to involve a complex interplay of oxidative stress, apoptosis, autophagy, and necrosis. Carbon tetrachloride (CCl<sub>4</sub>)-induced acute liver injury in mice is a classic experimental model sharing some similarities with human acute liver pathogenesis. Our team and others have shown that RIPK1 is a kinase that is involved in both cell survival and cell death pathways in certain cases of acute hepatitis involving molecular death factors. In the present study, we aim to investigate its role during hepatocyte death induced by a specific hepatotoxic agent, CCl<sub>4</sub>.

**Method:** Two different mouse lines, either deficient (1) for *Ripk1* specifically in liver parenchymal cells (*Ripk1*<sup>LPC-KO</sup>) or (2) for the kinase activity of RIPK1 (*Ripk1*<sup>K45A</sup>) plus their respective wild-type littermates (*Ripk1*<sup>fl/fl</sup>, *Ripk1*<sup>WT</sup>) were exposed to a high dose of CCl<sub>4</sub> that induce severe acute hepatitis. Further, Etanercept (TNF- $\alpha$  receptor decoy) was injected prior and after CCl<sub>4</sub> administration to explore the role of TNF- $\alpha$  and anti-FasL antibody (FasL antagonist) were injected prior CCl<sub>4</sub> administration to explore the respective role of FasL in CCl<sub>4</sub> induced hepatitis. Different clinico-pathological investigations (liver transaminase measurement, liver histology, cleaved-caspase 3 staining, anti-CD45 IHC, qPCR analysis) were conducted to analyse the challenged animals.

**Results:** While inactivation of the RIPK1 kinase activity had no impact on CCl<sub>4</sub> induced hepatotoxicity, its deficiency in liver parenchymal cells potentiated CCl<sub>4</sub> induced hepatotoxicity by massive apoptosis. More oxidative stress and immune infiltration were found in the liver of CCl<sub>4</sub>-injected *Ripk1*<sup>LPC-KO</sup> mice compared to *Ripk1*<sup>fl/fl</sup> mice. Administration of ETA further increased liver damage by apoptosis only in *Ripk1*<sup>LPC-KO</sup> mice. Interestingly; FasL mRNA was only upregulated in CCl<sub>4</sub>-injected *Ripk1*<sup>LPC-KO</sup> mice and over-induced in presence of ETA. Thus, pre-administration of anti-FasL antibody partly reduced liver injury in *Ripk1*<sup>LPC-KO</sup> mice. Notably, the anti-FasL antibody pretreatment had an opposite impact on CCl<sub>4</sub>-injected *Ripk1*<sup>fl/fl</sup> mice, which displayed more liver damage. We hypothesized that, in this last experimental condition, anti-FasL partly prevented the described protective property of soluble FasL against apoptosis.

**Conclusion:** Our study highlighted the protective role of RIPK1 in CCl<sub>4</sub> induced acute liver injury which prevent hepatocytes from death by apoptosis independent of TNF- $\alpha$ . The enhanced hepatic immune cell infiltration, oxidative stress and FasL expression detected in the absence of *Ripk1* promoted apoptosis of hepatocytes. Overall, this study provides a deeper understanding of mechanisms that could occur during acute liver hepatitis.

**Background and aims:** Alcoholic hepatitis (AH) is a distinct clinical entity characterized by a recent onset of jaundice in the context of heavy alcohol use. We aimed to assess the prevalence of AH in patients admitted for acute variceal bleeding (AVB) and to compare clinical outcomes and survival of AH patients with patients with alcohol-related liver disease (ALD) and viral cirrhosis.

**Method:** Ancillary study of the preemptive TIPS cohort, a multicenter, observational study with data from 2138 consecutive patients with cirrhosis and AVB collected from October 2011 to May 2015. 916 patients were selected under the next categories regardless of whether they received or not a p-TIPS: patients with AH clinical criteria (as defined by NIAAA guidelines), ALD cirrhosis actively drinking at the time of AVB (d-ALD) (n = 285), ALD cirrhosis abstinent from alcohol (a-ALD) (n = 227) and viral cirrhosis (n = 305). Main exclusions were related to other or mixed etiologies, and incomplete data. Survival was assessed by the Kaplan-Meier method and log-rank Mantel-Cox test and subanalysis according to CLIF-C AD (acute decompensation score of the CLIF Consortium) was performed.

**Results:** AH patients accounted for 10.8% of the 916 patients included in the study and 16% of the 611 ALD patients. AH patients were younger, had worse prognostic severity scores, and the highest frequency of infections and active bleeding at baseline. The best survival rates were seen in the d-ALD group at all time points (Figure). AH and a-ALD patients presented the lowest survival rates at 42 and 90 days after AVB. A-ALD patients exhibited the worse survival rate at 1 year (65.5%-Figure). Among patients with a CLIF-C AD > 55 the worst survival was observed in the a-ALD group across all time points, while patients from the d-ALD group presented the best survival rates. When focused on patients with CLIF-C AD < or = 55 those with AH exhibited the worst outcomes at any time point.

Figure. Transplant-free survival was 83.8%, 93.3%, 86.3% and 90.4% among AH, ALD cirrhosis active drinkers, ALD cirrhosis abstinent and viral cirrhosis groups at 42 days. At 90 days transplant free-survival was 79.8%, 93%, 79.6% and 84.8% again with statistical significant differences only between AH and ALD active drinkers groups. At 365 days transplant free-survival was 72.7%, 86%, 65.5% and 76.6%. At all time points statistical significant differences were found between d-ALD and the other groups.

Alcohol-related liver disease, ALD; ALD cirrhosis actively drinking, d-ALD; ALD cirrhosis abstinent from alcohol, a-ALD

Figure:

**Conclusion:** The underlying etiology and ALD phenotype have an impact on survival after an AVB. AH patients present the worst short-term outcome, while abstinent ALD patients had the worst long-term survival.

**PO-94**

**Automated quantitation of histological features could predict mortality in patients with severe alcoholic hepatitis**

Tyson<sup>1,2</sup>, Roberta Forlano<sup>1</sup>, Edagul Ulucay<sup>1</sup>, Nikhil Vergis<sup>1,2</sup>, Nikolaos Giannakeas<sup>3</sup>, Alexandros Tzallas<sup>3</sup>, Mark Thursz<sup>1,2</sup>, Robert Goldin<sup>1,2</sup>, Stephen Atkinson<sup>1</sup>, Pinelopi Manousou<sup>1,2</sup>. <sup>1</sup>Imperial College London, Department of Metabolism, Digestion and Reproduction, London, United Kingdom; <sup>2</sup>Imperial College Healthcare NHS Trust, Department of Hepatology, London, United Kingdom; <sup>3</sup>Technological Educational Institute of Epirus, Άρτα, Greece  
Email: luke.tyson@nhs.net.

**Background and aims:** Alcoholic hepatitis (AH) is characterised by acute jaundice and liver dysfunction in patients misusing alcohol. A liver biopsy demonstrating steatohepatitis is often considered necessary for a definitive diagnosis. Presently, biopsies are interpreted according to the Alcoholic Hepatitis Histologic Score (AHHS), which is designed to predict 90-day mortality. As a semi-quantitative score, AHHS carries low reproducibility, even between expert pathologists. The lack of reliability of such scores may affect the power of clinical trials. We have developed a high-throughput machine learning based quantitation of histological features in non-alcoholic fatty liver disease. This methodology estimates the percentage of fat, inflammation, ballooning and fibrosis with higher intra- and interobserver variability than conventional histological assessment. As these histological features are also seen in AH, we applied the same method to liver biopsies from patients with AH aiming to identify features predictive of mortality.

**Method:** Biopsies obtained from 80 patients with severe AH recruited to STOPAH (STeroids Or Pentoxifyline for Alcoholic Hepatitis) were digitalized. Biopsies were obtained between 15 days pre- to 7 days post-treatment. Fat proportionate area (FPA), inflammation percentage (IP), ballooning percentage (BP) and collagen proportionate area (CPA) were expressed as percentage of the whole tissue area. Quantitation results were evaluated against clinical outcomes including mortality by binary logistic regression and Kaplan-Meier survival analysis.

**Results:** IP was inversely associated with mortality at day 90 (OR 0.91, 95% CI 0.84–1.00, p = 0.050). FPA, BP and CPA were not. However, when IP was corrected for CPA (IP/CPA) the association with mortality became stronger (OR 0.01, 95% CI: 0.00–0.48, p = 0.019) than IP alone. Treatment with prednisolone did not affect survival nor IP. Neither the AHHS score, nor the individual components of the score, were predictive of mortality. Youden's index analysis revealed that an IP cut-off of 10% allowed patients to be classified into low-risk (IP > 10%) and high-risk groups (figure, p = 0.017).

**Conclusion:** In severe AH increased inflammation on liver biopsy may be associated with improved survival at day 90, particularly for patients with less fibrosis. This association was not observed for the AHHS score. Quantitation may improve prediction of clinical outcomes in patients with AH.

**Background and aims:** AUD pts have altered gut microbiota that worsens in cirrhosis. In a RCT, fecal microbial transplant (FMT) improved craving and cognitive function compared to placebo in cirrhotic AUD pts. AUD cirrhotic pts have higher toxic BAs and men show feminization. Sulfation is a key step towards detoxification of bile acids (BA) and can inactivate sex steroids, which are modulated by the gut-liver axis. which can worsen outcomes. *Aim:* Define metabolomic correlates of improvement in outcomes with FMT vs placebo in cirrhotic pts with AUD.

**Method:** Cirrhotic men with AUD underwent Phase 1 RCT with FMT vs placebo with f/u for 15 days (Fig A). Safety evaluation, alcohol craving (ACQ) and consumption (Etg), plasma and feces collection were performed at baseline and day 15 for both groups. Metabolomics for aromatic amino acid (AA, putative neurotransmitters and intestinal barrier affecting metabolites), lipidomics,

**Kaplan-Meier survival curves for patients with severe alcoholic hepatitis classified as low or high risk based on their inflammation percentage computed using an automated machine-learning based algorithm**

Figure: (abstract: PO-94)

# POSTER PRESENTATIONS

including BAs were performed and fold-change in ANOVA values pre/post-FMT and post-placebo vs post-FMT states were performed.

**Results:** *Trial:* 20 men with AUD-cirrhosis [65 ± 6.4 years, MELD 8.9 ± 2.7] were included. Groups were comparable with respect to demographics, cirrhosis, and AUD severity at baseline. Liver function and safety labs were stable over time. Craving reduced significantly in 90% of FMT-assigned versus 30% in placebo (p = 0.02). This was

accompanied by ↓ urinary Etg (p = 0.03) and improved intestinal barrier (↓LBP and IL-6). These were not seen in the placebo pts. *Metabolomics:* Unsulfated BAs: no changes were seen in plasma/ feces. *Sulfated BAs:* Plasma ↑ litho and glycolithocholate sulfate moieties post-FMT vs pre-FMT and vs post-placebo. Also, we found ↑ plasma sulfated glycocholate and glycoUDCA increased only post-FMT vs pre-FMT and ↑ deoxy-cholate 12-sulfate and tauroolithocholate

## B. Plasma Sulfated Lithocholate Moieties ↑ Post-FMT

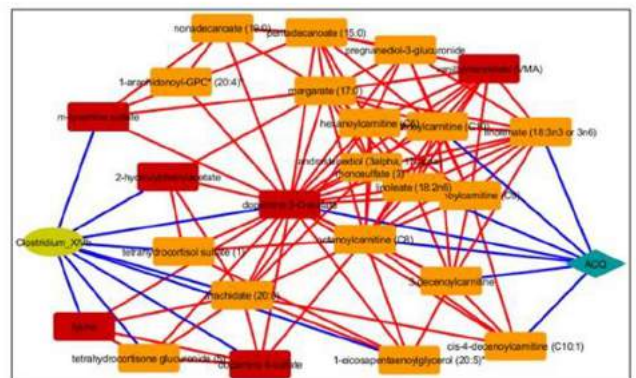

## C. Fecal Sulfated Lithocholate Moieties ↑ Post-FMT

## E. Plasma Dopamine Sulfate ↓ post-FMT

## F. Plasma Dopamine Sulfate negatively linked to ACQ & positive with beneficial bacteria & sex steroids post-FMT

## D. Plasma Sulfated Progesterone hormones Increase post-FMT Vs Baseline

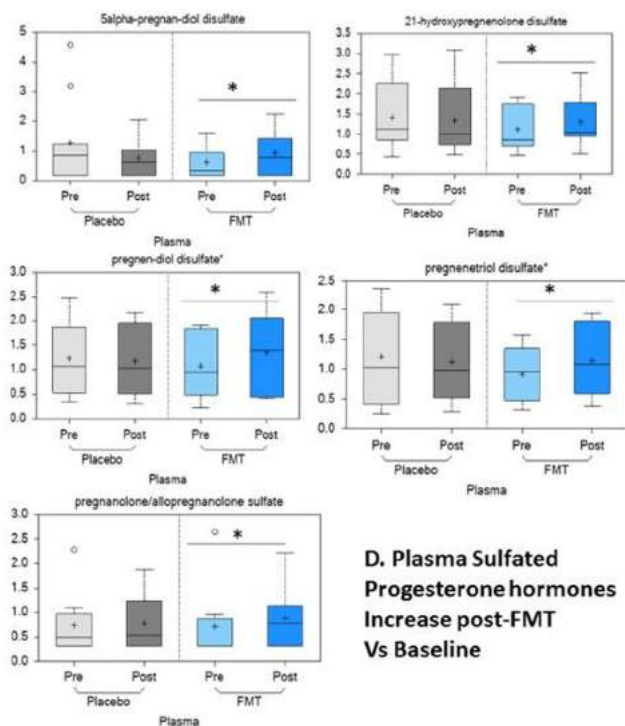

Figure: (abstract: PO-117)

3-sulfate post-FMT vs placebo (Fig. B). Feces ↑sulfated lithocholate moieties post-FMT (Fig. C). **Sex steroids:** In plasma, vs pre-FMT, we found ↑fold change of sulfated progesterone precursors (Figure D), which makes them inactive. No changes in feces were seen. **Lysophospholipids:** Only in plasma we found ↑ lysophospholipids, which are useful for membrane integrity post-FMT vs baseline. **Aromatic AA metabolites:** Plasma dopamine 3-O-sulfate, a neurotransmitter involved in alcohol craving, reduced post-FMT vs placebo (Fig E). Dopamine sulfate also negatively correlated with Post-FMT ACQ indicating the linkage with craving and with beneficial Clostridia post-FMT (Figure F).

**Conclusion:** FMT in AUD men with cirrhosis increases sulfation of toxic secondary BAs, and of progesterone steroids (reducing activity and thus, feminization), increases lysophospholipids that indicating membrane stability, and reduces dopamine, which links with craving and beneficial bacteria. Therefore, there is a multi-faceted effect on the gut-liver-brain axis with FMT in men with cirrhosis and AUD.

**PO-302**  
**Pharmacokinetics, Pharmacodynamics, and toxicology of SZN-043, a hepatocyte-targeted Wnt potentiator, in nonhuman primates**

Jay Tibbitts<sup>1</sup>, Maureen Newman<sup>2</sup>, Jay Ye<sup>2</sup>, Peter Stathis<sup>2</sup>, Trudy Vanhove<sup>2</sup>. <sup>1</sup>Surrozen, South San Francisco, United States; <sup>2</sup>Surrozen, South San Francisco, United States  
 Email: jtibbitts@surrozen.com.

**Background and aims:** Wnt/β-catenin signaling plays an important role in liver homeostasis and is critical to hepatocyte regeneration following liver injury. In severe liver diseases, there is a deficiency of functional hepatocytes and, in chronic patients, often underlying fibrosis caused by activated hepatic stellate cells. Therefore, a hepatocyte-specific molecule that enhances Wnt signaling specifically in hepatocytes, but not in stellate cells, would be desired. SZN-043 is an RSPO-mimetic bispecific fusion protein specifically targeted to hepatocytes through binding to the Asialoglycoprotein Receptor (ASGR1). In preclinical animal models of liver injury and fibrosis, SZN-043 has been shown to amplify Wnt signaling, promote hepatocyte proliferation, demonstrate functional improvement and reduce fibrosis.

**Method:** To inform the potential clinical use of SZN-043, toxicology and pharmacokinetic studies were conducted in non-human primates (NHPs). In a dose-range finding toxicology study in cynomolgus monkeys, SZN-043 was administered intravenously twice weekly at 0, 12.5, 37.5 and 125 mg/kg/dose for two weeks. Main study animals were terminated one day after the last dose and a subgroup of animals were followed for recovery. Assessments included clinical observations, clinical pathology, pharmacodynamics, toxicokinetics, and gross and histopathology. The pharmacokinetics and pharmacodynamics of SZN-043 in NHP were evaluated following a single IV bolus dose of 0.5, 2, or 5 mg/kg or two doses of 12.5 mg/kg separated by 3 days. Serum concentrations of SZN-043 and a biomarker for ASGR1 occupancy (serum alkaline phosphatase, ALP) were measured for up to 25 days using qualified assays following initiation of dosing, and noncompartmental pharmacokinetic parameters calculated.

**Results:** Administration of SZN-043 to NHPs was well-tolerated with no drug-related adverse effects observed, including histopathology. Dose-related increases in ALP due to reduced clearance by ASGR1 were observed, but were expected and not considered adverse. Drug exposure and pharmacodynamic effect were confirmed, with full occupancy of ASGR1 observed. The PK of SZN-043 in NHP was consistent with an IgG-like molecule with evidence of target-mediated drug disposition, whereby exposure increased more than proportional to dose, providing further evidence of occupancy of ASGR1.

**Conclusion:** The data from these studies indicate that SZN-043 can be safely administered to NHPs, with PK suitable for use in humans, and support further investigation of this molecule in settings of

severe hepatocyte loss where SZN-043 may have a rapid impact on hepatocyte regeneration, as well as in cirrhosis.

**PO-345**  
**Alcoholic foamy degeneration: a singular clinical entity that mimics alcoholic hepatitis and may be distinguished by serum triglyceride levels**

Jordi Gratacós-Gines<sup>1</sup>, Emma Avitabile<sup>2</sup>, Martina Perez<sup>1,2</sup>, Alba Díaz<sup>2,3,4</sup>, Marta Cervera<sup>1,2</sup>, Marta Carol<sup>2</sup>, Ana Belén Rubio<sup>2</sup>, Núria Fabrellas<sup>2,4</sup>, Octavi Bassegoda<sup>1</sup>, Laura Napoleone<sup>1,2</sup>, Ann Ma<sup>2</sup>, Adria Juanola<sup>1,2</sup>, Isabel Graupera<sup>1,2,4</sup>, Elisa Pose<sup>1,2,4</sup>, Pere Ginès<sup>1,2,4</sup>. <sup>1</sup>Hospital Clínic de Barcelona, Liver Unit, Barcelona, Spain; <sup>2</sup>Institut d'Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS), Barcelona, Spain; <sup>3</sup>Hospital Clínic de Barcelona, Pathology, Barcelona, Spain; <sup>4</sup>University of Barcelona, Barcelona, Spain  
 Email: EPOSE@clinic.cat.

**Background and aims:** alcoholic foamy degeneration (AFD) is a variant of alcohol related liver disease (ArLD) with a similar clinical presentation than alcoholic hepatitis (AH) but with a specific histological pattern and a dramatically different treatment and prognosis. Since AFD was described in 1983, only case reports or short series have been reported. The aim of the study was to assess the real prevalence of this disease, its natural history and long-term prognosis.

**Method:** retrospective study that reviewed all cases of clinical suspicion of AH in the last 11 years (2010–2020) in Hospital Clínic of Barcelona, and the results of the liver biopsies performed. Liver biopsies were analyzed for the presence of histological criteria of AH, AFD or others (cirrhosis, steatosis, etc.). Patients were characterized at a clinical, histological and prognostic level. Patients with AFD were compared with a control group of 90 patients with diagnosis of AH confirmed by histology. Clinical criteria of AH from the NIAAA were reviewed.

**Results:** of 271 cases of clinical suspicion of AH, 201 (74%) underwent liver biopsy. Of those, 164 (82%) met histological criteria for alcoholic steatohepatitis, 20 (10%) had AFD and 15 (8%) had other findings. Thirteen patients with AFD had portal hypertension and 5 had ascites at diagnosis. Median MELD score at diagnosis was 17 (11–20). The ratio of patients who met clinical NIAAA criteria for AH was similar in the AFD vs HA group (59 vs 63%, p = ns). Patients with AFD presented higher levels of transaminases, cholesterol and triglycerides. Triglyceride levels of 162 mg/dL had an AUROC of 0.88 (0.80–0.96) to differentiate AFD from AH. All patients with AFD had a rapid and spontaneous improvement of liver function from admission, with a median MELD of 9 (8–11) at hospital discharge. In the long-term, 1 (5%) patient died in the AFD group compared to 34 (38%) patients in the AH group (p = 0.02).

Figure:

**Conclusion:** one out of ten patients with clinical suspicion of AH has AFD. AFD is a little-known entity that is frequently misdiagnosed as

## POSTER PRESENTATIONS

AH when liver biopsy is not performed. Moreover, NIAAA criteria, widely used for clinical diagnosis of AH, are not useful to differentiate AFD from AH. Differential diagnosis is relevant because AFD prognosis is markedly better. Although definitive diagnosis is based on histology, high levels of triglycerides should raise suspicion of AFD.

### PO-433

#### Drivers of outcome in compensated alcohol-related cirrhosis: a prospective study

Email: alexandre.louvet@chru-lille.fr.

**Background and aims:** The deleterious impact of heavy alcohol relapse is established in patients with alcohol-related cirrhosis despite a limited body of evidence based on old studies. However, drivers of long-term outcome are still poorly investigated.

**Method:** All patients with biopsy-proven compensated alcohol-related cirrhosis who were included in the CIRRAL cohort (Ganne-Carrié et al. J Hepatol 2018) were evaluated prospectively. Primary end point was 5-year survival. Prognostic variables of survival and event-free survival were assessed using Cox models with stepwise selection on AIC criteria. The prognostic impact of alcohol relapse during follow-up was assessed using a time-dependent covariable. Liver events were defined as transplantation (LT), decompensation (ascites, gastrointestinal bleeding or encephalopathy) or hepatocellular carcinoma (HCC).

**Results:** From 2010 to 2016, 650 patients with compensated alcohol-related cirrhosis were included in 22 centers. At baseline, main characteristics were the following (medians with IQR or percentage): age 58.4 (51.2–64.3) years, male gender 67.4%, BMI 27.5 kg/m<sup>2</sup>, Child-Pugh score A 98.3%, past history of liver decompensation 65.3%, alcohol cessation at inclusion 69.2%. At 5 years, cumulative incidence of any alcohol relapse was 51.4%. We observed 153 deaths during the follow-up, among which 41.8% were related to cirrhosis and 11.8% to hepatocellular carcinoma and 5-year survival was 74.6%. Multivariate analysis identified the following factors at baseline as independently associated with survival: platelet count HR 0.996 (0.993–0.998,  $p = 0.002$ ) and Child-Pugh score >5 HR 2.189 (1.529–3.133,  $p < 0.001$ ) while there was a trend toward significance for age, male gender, coffee consumption and low alcohol consumption at baseline. The following variables at baseline were associated with event-free survival: age HR 1.017 (1.002–1.033,  $p = 0.02$ ), male gender HR 1.413 (1.051–1.901,  $p = 0.02$ ), coffee consumption HR 0.632 (0.464–0.86,  $p = 0.004$ ), platelet count HR 0.995 (0.993–0.998,  $p < 0.001$ ), Child-Pugh score >5 HR 1.941 (1.409–2.673,  $p < 0.001$ ), low alcohol consumption at baseline (1–6 units/week) HR 1.612 (1.132–2.294,  $p = 0.008$ ); alcohol consumption at baseline  $\geq 7$  units/week HR 1.372 (0.962–1.956,  $p = 0.08$ ) was close to significance. Alcohol consumption during the follow-up, regardless of the amount, was associated with a lower survival (HR 1.55, 95%CI 1.12–2.15,  $p = 0.0009$ ) and a lower event-free survival (HR 1.67, 95%CI 1.27–2.24,  $p = 0.0003$ ).

**Conclusion:** This prospective study performed in patients with compensated alcohol-related cirrhosis identifies coffee consumption at baseline as a protective factor of long-term survival while alcohol consumption during the follow-up negatively impacts outcome. Further analysis is required to determine if a “safe” modest alcohol consumption during follow-up exists.

### PO-442

#### SZN-043, a Hepatocyte-targeted-R-spondin mimetic, stimulates hepatocyte proliferation in an acute alcoholic hepatitis model

Trevor Fisher<sup>1</sup>, Tiej Le<sup>1</sup>, Mehaben Patel<sup>1</sup>, Maureen Newman<sup>1</sup>, Wen-Chen Yeh<sup>1</sup>, Trudy Vanhove<sup>1</sup>, Jay Tibbitts<sup>1</sup>, Helene Baribault<sup>1</sup>. <sup>1</sup>Surrozen, South San Francisco, United States

Email: trevor@surrozen.com.

**Background and aims:** Wnt signaling plays a central role in hepatocyte expansion during development and tissue repair. R-spondins (RSPOs) are known enhancers of Wnt signaling, via stabilization of Frizzled and LRP co-receptors. SZN-043 is a bispecific fusion protein and hepatocyte-specific R-spondin mimetic that induces hepatocyte-targeted Wnt signaling and hepatocyte proliferation in normal mice. Severe alcoholic hepatitis (AH) is characterized by reduced hepatocyte proliferation and impaired hepatic regeneration. Since improved hepatocyte proliferative capacity has been linked to increased survival in AH, therapies that can stimulate hepatocyte proliferation may have substantial benefits in these patients. We therefore tested the effect of SZN-043 on hepatocyte expansion and liver function in a commonly used AH-induced liver injury model.

**Method:** 11-month-old female C57BL/6J mice were fed the control Lieber-DeCarli diet ad libitum for 5 days to acclimatize them to liquid diet and tube feeding. Afterward, EtOH-fed groups were allowed free access to a Lieber-DeCarli diet containing 5% (vol/vol) EtOH for 7 weeks, and control groups were pair-fed with an isocaloric control diet. In the second week, and for the remainder of the EtOH feeding, EtOH-fed and pair-fed mice were gavaged twice weekly with EtOH (5 g/kg body weight) or isocaloric maltose dextrin, respectively. Mice were then returned to the control liquid diet, randomized and injected intraperitoneally with either SZN-043 at 30 mg/kg daily for 7 days or an anti-GFP control (10 mg/kg twice weekly). Blood and liver tissue samples were collected at Days 0, 3 or 7 of treatment and analyzed for serum chemistry, gene expression, immunostaining and histopathology.

**Results:** SZN-043 induced Wnt signal activation in the liver as shown by the increase in the Wnt target gene, Axin2, mRNA expression and the induction of proliferation markers, cyclin D1 and Mki-67 (Ki67). This was confirmed by an increase of 2 serum biomarkers of Wnt activation, leukocyte cell-derived chemotaxin-2 (LECT2) and angiogenin. SZN-043 also reduced the mRNA expression of markers of hepatic inflammation, IL1b and IL6. ALT was modestly increased after SZN-043 treatment and AST was greatly reduced when compared to control at Day 3 resulting in a substantial reduction in AST/ALT ratio. Circulating ammonia was significantly decreased at Day 3, when compared to control. No differences were seen between treatment groups in bilirubin, albumin or triglyceride levels.

**Conclusion:** These results show that SZN-043 can stimulate hepatocyte-specific cell regeneration in this commonly used AH-induced liver injury model. SZN-043 may have meaningful clinical benefit in human disease states where hepatocyte proliferation is impaired, such as in severe AH.

**PO-487**

**Binge drinking induces an acute release of markers of hepatic fibrogenesis**

Nikolaj Torp<sup>1,2</sup>, Mads Israelsen<sup>1,2</sup>, Mette Juul Nielsen<sup>3</sup>, Claus Philip Åstrand<sup>1,2</sup>, Pernille Juhl<sup>3,4</sup>, Stine Johansen<sup>1,2</sup>, Camilla Dalby Hansen<sup>1,2</sup>, Bjørn Stæhr Madsen<sup>1,2</sup>, Ida Villesen<sup>3</sup>, Diana Leeming<sup>3</sup>, Torben Hansen<sup>5</sup>, Morten Karsdal<sup>3,6</sup>, Aleksander Krag<sup>1,2</sup>. <sup>1</sup>Odense University Hospital, Department of Gastroenterology and Hepatology, Odense, Denmark; <sup>2</sup>University of Southern Denmark, Institute of Clinical Research, Odense, Denmark; <sup>3</sup>Nordic Bioscience A/S, Herlev, Denmark; <sup>4</sup>Copenhagen University, Department of Biomedical Sciences, København, Denmark; <sup>5</sup>Copenhagen University, Novo Nordisk Foundation Center for Basic Metabolic Research, København, Denmark; <sup>6</sup>University of Southern Denmark, Department of Molecular Medicine, Odense, Denmark  
Email: nikolaj.christian.torp@rsyd.dk.

**Background and aims:** Binge drinking increases the risk of alcohol-related cirrhosis. The fibrogenesis, leading to cirrhosis, is a long-standing process of collagen deposition in the hepatic extracellular matrix (ECM). However, fibrogenic activity is highly dynamic and the acute effects of binge drinking on ECM turnover are largely unknown. We aimed to investigate hepatic fibrogenesis and fibrolysis following a binge drinking episode.

**Method:** We performed a pathophysiological intervention study in 39 participants (16 with ≥F2 fibrosis, 13 with F0-F1, and 10 healthy controls). To mimic binge drinking, participants with alcohol-related liver disease, non-alcohol related liver disease and healthy controls received 2.5 ml of 40% ethanol per kg body weight, infused over 30 minutes via a nasogastric tube. At eight time points within three hours after alcohol infusion, we sampled venous blood simultaneously from the hepatic and right external jugular vein. Additionally, peripheral venous blood was sampled 24 hours after alcohol infusion. Markers of hepatic fibrogenesis (PRO-C3 and PRO-C8) and fibrolysis (C3M) were measured with competitive ELISA assays.

**Results:** The blood alcohol concentration was 0 ± 0 mmol/L at baseline, 34 ± 4 mmol/L at one hour, and declined to 21 ± 3 mmol/L after three hours. Baseline level of peripheral PRO-C3 was 12.6 ng/ml (IQR 9.8; 16.2) and increased by +1.2 ng/ml (p < 0.001) after 24 hours, with no difference between the groups (p = 0.661). Increasing baseline PRO-C3 was associated with a hepatic PRO-C3 increase of +0.03 ng/ml/h (95% CI 0.01; 0.05, p = 0.005) and a systemic PRO-C3 decrease of -0.04 ng/ml/h (95% CI -0.05; -0.02, p < 0.001) during the first three hours. The hepatic level of C3M did not change within three hours (p = 0.829), nor the peripheral PRO-C3 after 24 hours (p = 0.911). Peripheral PRO-C8 at baseline was 3.3 ng/ml (IQR 1.9; 5.5) and did not increase significantly after 24 hours (+0.3 ng/ml, IQR 0.0; 1.1, p = 0.068). However, in the subgroup of participants with elevated PRO-C8 after 24 hours, the increasing trend was seen during the first three hours (+0.22 ng/ml/h, 95% CI 0.08; 0.37, p = 0.003).

**Conclusion:** Binge drinking induces an acute burst release of fibrogenic markers in healthy individuals and in patients with fatty liver disease. Fibrosis degradation C3M is not correlated to fibrosis formation PRO-C3, indicating that even a single episode of binge drinking promotes hepatic fibrogenesis.

**PO-488**

**Has the 5-year mortality of patients with alcoholic cirrhosis changed during the last 20 years?**

Edeline Kaze<sup>1</sup>, Jean Henrion<sup>1</sup>. <sup>1</sup>Jolimont Hospital, Gastroenterology and Hepatology  
Email: kazeedeline@gmail.com.

**Background and aims:** Patients with alcoholic cirrhosis have a poor short-term prognosis. The aim of this study was to determine whether the 5-year mortality of alcoholic cirrhosis has changed over the past two decades.

**Method:** From January 1995 to December 2014, 932 cirrhotic patients who attended the hepatology outpatient clinic of our institution were consecutively listed in a registry. From this registry, 565 patients had alcoholic cirrhosis (61%). 16 patients were excluded because they were lost to follow-up and 114 patients were excluded because the diagnosis of cirrhosis was made more than 2 years before the inclusion in the registry. We separated the 435 remaining patients into two cohorts 10 years apart: the cohort C1 (C1), patients included in the registry between 1995 and 2004 (n = 206) and the cohort C2 (C2), patients included from 2005 to 2014 (n = 229). Epidemiologic data and 5-year mortality were retrospectively compared between both cohorts.

**Results:** The sex ratio was similar between both cohorts (C1: male 68% vs C2: male 71%) as well as the Child Pugh score at inclusion in the registry (C1: 7.28 vs C2: 7). By contrast, the mean age at diagnosis of cirrhosis was significantly higher in the cohort C2 than in the cohort C1 (C1: 52.8 ± 11 years vs C2: 56.5 ± 9.3 years, p < 0.0001). From the 206 patients in the cohort C1, 80 died within 5 years after diagnosis of cirrhosis compared to 83 patients from the 229 patients in the cohort C2 (C1: 39% vs C2: 36%, p = 0.6). When the circumstances of 5-year mortality were compared between the 80 patients from the cohort C1 (Group A) and the 83 patients from the cohort C2 (Group B), the liver-related mortality rate was similar between both groups (Group A: 64 of 80 patients (80%) vs group B: 65 of 80 patients amongst whom the cause of death was known (81%), p = 0.8). Among those patients who died from their cirrhosis, liver-related mortality by end-stage liver disease without precipitating event was not statistically different between both groups (Group A: 36% vs Group B: 29%, p = 0.4). However liver-related mortality precipitated by an acute event was different according to the underlying precipitating event. Patients in Group A died more often from gastrointestinal bleeding than patients in Group B (Group A: 30% vs Group B: 9%, p = 0.003). Patients in Group A died less by sepsis than patients in Group B (Group 1: 1.5% vs Group 2: 14%, p = 0.009). There were no statistically differences concerning liver-related death precipitated by alcoholic hepatitis (Group 1: 17% vs

Figure:

## POSTER PRESENTATIONS

Group 2: 18%,  $p = 0.8$ ) or hepatocellular carcinoma (Group 1: 9% vs Group 2: 15%,  $p = 0.3$ ).

**Conclusion:** Our study demonstrated that the 5-year mortality rate in patients with alcoholic cirrhosis has not changed. However, the type of precipitating events which lead to liver-related death has changed with a rarefaction of mortality provoked by acute gastrointestinal bleeding, but an increase of mortality by sepsis.

### PO-607

#### Acamprosate for the treatment of alcohol use disorder may be safer than baclofen in patients with cirrhosis

Luke D. Tyson<sup>1,2</sup>, Alexandra Cheng<sup>2</sup>, Charles Kelleher<sup>2</sup>, Kirstin Strathie<sup>2</sup>, James Lovendoski<sup>2</sup>, Zebib Habtemariam<sup>2</sup>, Heather Lewis<sup>2</sup>. <sup>1</sup>Imperial College London, The Department of Metabolism, Digestion and Reproduction, London, United Kingdom; <sup>2</sup>Imperial College Healthcare NHS Trust, Department of Hepatology, London, United Kingdom  
Email: luke.tyson@nhs.net.

**Background and aims:** Patients with alcohol use disorder (AUD) and liver cirrhosis benefit from stopping alcohol intake. Baclofen has been trialled for AUD in cirrhotic patients and appears safe. However, in patients without cirrhosis, acamprosate is safer and more efficacious. There are concerns about acamprosate use in cirrhosis, for example that it may precipitate hepatic encephalopathy (HE). The only published report of acamprosate use in cirrhotic patients was for 24 hours in a controlled setting. Our centre uses both medications in selected cirrhotic patients with AUD. We performed an audit to compare the safety of acamprosate to baclofen.

**Method:** We retrospectively reviewed the electronic records of all patients prescribed acamprosate or baclofen in our NHS Trust between 01/04/17 and 31/03/20 to identify cirrhotic patients taking acamprosate or baclofen for AUD. We recorded disease severity, hepatic decompensations, length of treatment, side effects, adverse events, hospital admissions, and abstinence at last follow-up. Data was compared by Student's t-test, Mann-Whitney U test or Chi-squared test as appropriate.

**Results:** 92 patients met inclusion criteria: 48 took acamprosate (median 84 days, range 2–524); 44 baclofen (median 247 days, 8–910). No baseline differences were observed between groups: 41% had Childs-Pugh B or C cirrhosis; 37% had evidence of hepatic decompensation at baseline. There were no significant differences in abstinence, side effects or new decompensation events between groups. However, more patients taking baclofen were admitted to hospital during treatment (figure) and the mean number of admissions per patient was significantly higher (1.6 admissions vs 0.6,  $p = 0.032$ ). Sub-group analysis revealed increased admissions in actively-drinking patients prescribed baclofen to achieve abstinence (mean 2.4 vs 0.6,  $p = 0.020$ ) including when normalised for time on medication (0.9 per 100 days on baclofen vs 0.3 admissions per 100 days on acamprosate,  $p = 0.035$ ). Admissions did not differ when medication was prescribed to maintain abstinence (mean 0.9 vs 1.1,  $p = 0.812$ ). There was an increased number of admissions due to confusion or HE in the baclofen group, although this did not reach significance (14/90 admissions vs 1/34,  $p = 0.055$ ).

**Conclusion:** We describe, for the first time, acamprosate use in cirrhotic patients in clinical practice. Acamprosate may be safer than baclofen, although prospective confirmation is required.

### PO-832

#### Prevalence of steatosis and fibrosis in individuals with high-alcohol consumption assessed by FibroScan: real-world cohort study from the US population

Naim Alkhoury<sup>1</sup>, Fady Tanios<sup>2</sup>, Birol Emir<sup>2</sup>, Deepa Malhotra<sup>2</sup>, Euan McLeod<sup>3</sup>, Katherine Hoover<sup>2</sup>, Mazen Nouredin<sup>4</sup>. <sup>1</sup>Arizona Liver Health, Chandler, United States; <sup>2</sup>Pfizer Inc, New York, United States; <sup>3</sup>Pfizer Ltd, Tadworth, Surrey, United Kingdom; <sup>4</sup>Karsh Division of Gastroenterology and Hepatology, Comprehensive Transplant Center, Cedars-Sinai Medical Center, Los Angeles, United States  
Email: naim.alkhoury@gmail.com.

**Background and aims:** Steatosis is a hallmark of both non-alcoholic and alcoholic fatty liver disease, which can each progress to fibrosis. This analysis aimed to determine prevalence of fibrosis assessed by

Figure 1: Response to treatment, side effects, adverse events and hospital admissions in patients with cirrhosis taking acamprosate or baclofen for alcohol use disorder

Figure: (abstract: PO-607)

transient elastography (FibroScan®) and comorbidities in the US population with hepatic steatosis and heavy alcohol consumption.

**Methods:** Adult subjects in the National Health and Nutrition Examination Survey (NHANES) database (2017–2018) with valid FibroScan® measurements were included (N = 4, 471). Prevalence of liver fibrosis was predicted for the US population with steatosis and heavy alcohol use (>20 or >30 g/day for women or men, respectively). Steatosis was assessed using controlled attenuation parameter (CAP), and fibrosis stage was assessed based on liver stiffness. CAP cutoff of 290 dB/m determined NAFLD; liver stiffness cutoffs were <9.0, <12.1, <18.6 and ≥18.6 kPa for F0-F1, F2, F3 and F4, respectively. Clinical characteristics and comorbidities were evaluated.

**Results:** Overall, 470 subjects (10.5%) had high-alcohol consumption in the eligible FibroScan® cohort (after excluding subjects with viral hepatitis and HIV). Of these, 364 (77.4%) had steatosis. Most subjects (unweighted) had F0-F1 fibrosis (42.6%), followed by F2 (2.5%), F3 (1.4%) and F4 (1.6%). Age-adjusted rates and means of demographics, clinical characteristics and comorbidities were generally similar between high- and low-/no-alcohol consumers with or without steatosis; however, fibrosis stages F2-F3 in high-alcohol consumers were associated with elevated BMI, hypertension, diabetes and elevated liver enzymes (Table 1).

Table 1: Age-adjusted characteristics and comorbidities

	High alcohol	
	Steatosis/ non-steatosis	Fibrosis F2-F3/F0-F1
% of subjects	78/22	4/34*
Characteristics		
Age, years, mean	48/46	46/47
Male, %	53/36	82/62
BMI ≥ 30 kg/m <sup>2</sup> , %	51/12	83/61
Alanine aminotransferase, U/L, mean	25/17	68/31
Aspartate aminotransferase, U/L, mean	23/20	42/28
Comorbidities, %		
Hypertension	34/20	65/35
Diabetes	17/7	25/16
Hypercholesterolaemia	37/30	46/39
Ischaemic heart disease	6/5	17/8

\*Remainder F4 (1%), cryptogenic cirrhosis (0.3%), fibrosis and moderate steatosis (60%).

**Conclusion:** This analysis estimated that the majority of the US population with steatosis and high-alcohol consumption have fibrosis, as indicated by real-world FibroScan® data. These results demonstrate the high incidence of metabolic-related comorbidities in subjects with steatosis, fibrosis and high-alcohol consumption.

**PO-1099**

**The alarming impact of COVID-19 pandemic on alcohol-related liver disease: a population-based Canadian study**

Abdel-Aziz Shaheen<sup>1</sup>, Stephen Congly<sup>1</sup>, Mark G. Swain<sup>1</sup>, Kristine Kong<sup>2</sup>, Carla Coffin<sup>1</sup>, Kelly Burak<sup>1</sup>, Samuel Lee<sup>1</sup>, Matthew Sadler<sup>1</sup>, Meredith Borman<sup>1</sup>, Juan G. Abraldes<sup>3</sup>. <sup>1</sup>Cumming School of Medicine, University of Calgary, Gastroenterology and Hepatology Division, Department of Medicine, Calgary, Canada; <sup>2</sup>Alberta Health Services, Calgary, Canada; <sup>3</sup>University of Alberta, Edmonton, Canada

Email: azshaheen@me.com.

**Background and aims:** During prolonged periods of global lockdown and disruption of clinical services, patients with alcoholic and non-alcoholic cirrhosis had to seek clinical care virtually and reduce their clinic visits. Furthermore, there has been significant increase in alcohol sales. In our study, we aimed to evaluate the impact of COVID-19 restrictions on patients with alcoholic and non-alcoholic cirrhosis as well as alcoholic hepatitis (AH) who were hospitalized.

**Method:** We used validated international clinical classification (ICD-9 and ICD-10) coding algorithms to identify liver-related hospitalizations for non-alcoholic cirrhosis, alcoholic cirrhosis, and AH in the province of Alberta, Canada through 2018–2020. We used administrative databases linked to the provincial laboratory database to identify our cohort. We defined the AH cohort as patients who had a diagnosis code of AH and possessed both of the following criteria: elevated ALT or AST, and elevated international normalized ratio (INR). We compared post COVID-19 restrictions (April–September 2020) to prior study periods. Joinpoint regression was used to evaluate inflection points.

**Results:** We identified 2, 916 hospitalizations for non-alcoholic cirrhosis, 2, 318 hospitalizations for alcoholic cirrhosis, and 1, 408 AH hospitalizations during our study time. Pre- and post-COVID-19 admission characteristics and outcomes for the three cohorts are presented in Table 1. Among alcoholic and non-alcoholic cirrhosis cohorts, there were no significant changes between average monthly admission rate, demographics, ICU admissions, and in-hospital mortality (Table 1). AH patients had a significant increase in average monthly admission (69.5 vs. 39.6,  $P < 0.001$ ) with April 2020 being the inflection point. Although AH patients admitted post COVID-19 restrictions were younger (median age 43 vs. 47,  $P = 0.02$ ), there were no significant differences in admission outcomes pre- and post-COVID-19 among AH cohort.

**Conclusion:** In this large population-based study, pre- and post-COVID-19 monthly admission rates were stable for non-alcoholic and alcoholic cirrhosis, however, there was a significant increase in AH admissions. As alcohol sales surged during the COVID-19 pandemic, future impact on alcoholic liver disease could be detrimental.

Table 1: (abstract: PO-1099): Pre- and post-COVID-19 admission characteristics and outcomes for our three cohorts.

	Non-alcoholic cirrhosis		Alcoholic cirrhosis		Alcoholic hepatitis	
	Pre COVID-19 (n = 2, 295)	Post COVID-19 (n = 621)	Pre COVID-19 (n = 1, 821)	Post COVID-19 (n = 497)	Pre COVID-19 (n = 991)	Post COVID-19 (n = 417)
Average admissions/ month	91.8	103.5	72.8	82.8	39.6	69.5*
ICU admission, n (%)	189 (8%)	50 (8%)	230 (13%)	74 (15%)	111 (11%)	47 (11%)
In-hospital mortality	265 (12%)	66 (11%)	224 (12%)	69 (14%)	76 (8%)	26 (6%)

\*P value <0.05 for pre- and post-COVID-19 among the respective cohort.

### PO-1215

#### Cell specific roles of MLKL in alcohol-associated liver disease

Xiaoqin Wu<sup>1</sup>, Megan McMullen<sup>1</sup>, Xiude Fan<sup>1</sup>, Tatsunori Miyata<sup>1</sup>, Emily Huang<sup>1</sup>, Laura Nagy<sup>1</sup>. <sup>1</sup>Cleveland clinic  
Email: nagy13@ccf.org.

**Background and aims:** Hepatocellular fate in response to death receptor activation depends on the cellular environment. Recent work has investigated the role of mixed lineage kinase like (MLKL)-mediated necroptotic pathway in alcohol- (ALD) and non-alcohol-associated (NAFL/NASH) liver diseases. MLKL is differentially activated in ALD/AH compared to NAFL/NASH in both murine models and patients. *Mkl1*<sup>-/-</sup> mice are protected from liver injury in a Western-diet induced model of obesity, associated with the regulation of hepatocellular autophagy. However, *Mkl1*<sup>-/-</sup> mice are not protected from Gao-binge and chronic ethanol-induced liver injury, despite a normalization of ethanol-induced increases expression of *Tnf-α*, *Il-1β* and *Mcp-1* mRNA in *Mkl1* deficient mice. These findings indicate that MLKL likely functions via cell-specific mechanisms in ALD.

**Method:** Bone marrow transplants between *Mkl1*<sup>-/-</sup> mice and littermate controls were conducted. Mice were then challenged with the Gao-binge (acute on chronic) ethanol model to distinguish potential myeloid vs non-myeloid cell-specific roles of MLKL in ALD. Liver tissue from patients with alcoholic hepatitis (AH) was used for immunohistochemical staining and Western blot.

**Results:** Immunohistochemical staining of liver biopsies from patients with AH revealed that MLKL was localized to both hepatocytes and immune cells. MLKL was expressed in isolated hepatocytes and non-parenchymal cells (NPCs) from the liver of control mice. Interestingly, in chimeric mice expressing MLKL in non-myeloid cells (*Mkl1*<sup>-/-</sup>→WT), hepatic injury and steatosis were exacerbated by Gao-binge ethanol exposure. In contrast, chimeric mice not expressing MIF in non-myeloid cells (WT→*Mkl1*<sup>-/-</sup>) had similar phenotype as WT→WT mice in response to ethanol. In addition, in response to Gao-binge ethanol, *Mkl1*<sup>-/-</sup>→WT mice had elevated numbers of circulating neutrophils, and a more robust infiltration of neutrophils and monocytes into the liver, assessed by NIMP-R14<sup>+</sup> and Ly6C<sup>+</sup> staining, compared to WT→WT mice. *Mkl1* deficiency in myeloid cells also exacerbated ethanol-induced increases in expression of *Il-1β* and *Cxcl5* mRNA in liver.

**Conclusion:** Taken together, these data indicate that myeloid cell-specific MLKL restricts liver injury and inflammation in response to Gao-binge ethanol, associated with an increased accumulation of immune cells in the liver.

**Figure:** None.

### PO-1375

#### Self-reported interest in decreasing alcohol use in patients with alcohol-related liver disease: a national health survey

Anna Kann<sup>1,2,3</sup>, Peter Jepsen<sup>3</sup>, Lone Madsen<sup>1</sup>, Colin Crooks<sup>4,5</sup>, Kate Fleming<sup>6,7</sup>, Anne Illemann Christensen<sup>8</sup>, Cathrine Lau<sup>2</sup>, Joe West<sup>5,9</sup>, Gro Askgaard<sup>1,2,3</sup>. <sup>1</sup>Zealand University Hospital, Medical Department, Section of Gastroenterology and Hepatology, Køge, Denmark; <sup>2</sup>Bispebjerg and Frederiksberg Hospital, Centre for Clinical Research and Prevention, Frederiksberg, Denmark; <sup>3</sup>Aarhus University Hospital, Department of Hepatology and Gastroenterology, Aarhus, Denmark; <sup>4</sup>University of Nottingham, Nottingham Digestive Diseases Centre, School of Medicine, Nottingham, United Kingdom; <sup>5</sup>Nottingham University Hospitals NHS Trust and the University of Nottingham, NIHR Nottingham Biomedical Research Centre (BRC), Nottingham, United Kingdom; <sup>6</sup>University of Liverpool, Department of Public Health Policy and Systems, Institute of Population Health, Liverpool, United Kingdom; <sup>7</sup>University of Liverpool, Liverpool Centre for Alcohol Research, Liverpool, United Kingdom; <sup>8</sup>University of Southern Denmark, National Institute of Public Health, Copenhagen, Denmark; <sup>9</sup>University of Nottingham, Division of Epidemiology and Public Health, School of Medicine, Nottingham, United Kingdom  
Email: annaemiliekann@gmail.com.

**Background and aims:** Heavy drinking is frequent in patients with alcohol-related liver disease (ALD). We examined the association of being interested in decreasing alcohol use with clinical variables in patients with ALD. We then examined whether interest in decreasing alcohol use was associated with initiation of alcohol treatment later.

**Method:** We linked information from the Danish National Health Surveys 2010–2017 with national registries to identify participants diagnosed with ALD and their initiation of alcohol treatment within 2 years after the survey. The health survey included a question regarding interest in decreasing alcohol use (yes/no/don't know). We calculated adjusted relative risks (RR) of being interested in decreasing alcohol use according to alcohol problems (CAGE questionnaire), health-related quality of life (SF-12), and severity of liver disease (cirrhosis or not). We used competing risk regression to calculate the cumulative incidence of alcohol treatment after the health survey.

**Results:** Of 674 patients with ALD of whom 58% had cirrhosis, 41% drank more than 14 drinks per week and 35% were abstainers. Among the 436 alcohol drinkers, 132 (30%) were interested in decreasing use. A larger amount of alcohol, more severe alcohol problems, and low mental quality of life were all associated with being interested in decreasing alcohol use. For example, compared to 1–13 drinks per week, the RR for being interested in decreasing alcohol use was 3.6 (95% CI 2.0–6.4) for 14–27 drinks per week, 5.7 (95% CI 3.2–10) for 28–41 drinks per week and 6.0 (95% CI 3.5–10) for ≥42 drinks per week. Physical quality of life and severity of liver disease were not associated with being interested in decreasing alcohol use. The cumulative incidence of alcohol treatment within 2 years was 30% (95% CI 22–37) for those who reported being interested in decreasing use in the health survey and 6.5% (95% CI 3.2–9.8) for those who reported no interest (figure).

Figure: Cumulative incidence (%) of alcohol treatment in ALD patients according to interest in decreasing alcohol use in the Danish National Health Survey 2010–2017, n = 436.

**Conclusion:** Being interested in decreasing alcohol use among patients with ALD was associated with the presence of alcohol problems, low mental quality of life, but not with severity of liver disease. Self-reported interest in decreasing alcohol use was associated with likelihood of initiation of alcohol treatment later.

**PO-1541**  
**Potential underlying mechanisms in the immune response to COVID in obese heavy drinkers**

Marti Ortega-Ribera<sup>1,2</sup>, Adam Kim<sup>1</sup>, Megan McMullen<sup>1</sup>, Annette Bellar<sup>1</sup>, Vai Pathak<sup>1</sup>, Laura Nagy<sup>1,3,4</sup>. <sup>1</sup>Lerner Research Institute-Cleveland Clinic, Department of Inflammation and Immunity, Cleveland, United States; <sup>2</sup>IDIBAPS, Liver Vascular Biology Research Group, Barcelona Hepatic Hemodynamic Unit, Barcelona, Spain; <sup>3</sup>Cleveland Clinic, Department of Gastroenterology and Hepatology, Cleveland, United States; <sup>4</sup>Case Western Reserve University, Department of Molecular Medicine, Cleveland, United States  
 Email: nagy13@ccf.org.

**Background and aims:** Alcohol abuse has a harmful effect on the innate and adaptive immune response and is associated with increased susceptibility to several respiratory syndromes such as pneumonia or tuberculosis. In the current COVID-19 pandemic, a recent analysis of UK BioBank data by our group revealed that frequent drinking, and especially heavy drinking, is associated with higher risk of death in COVID-19 patients who are also obese. The molecular mechanisms underlying this interaction remains unexplored.

**Method:** Peripheral blood mononuclear cells (PBMC) from lean (BMI < 25) or obese (BMI > 30) heavy drinkers (HD; AUDIT >16, n = 3 each) were treated with a dsRNA homopolymer (pl:C) for 2 h or 24 h to mimic a viral infection *ex vivo*. Additionally, a subgroup of cells was treated with 10 ng/ml LPS (last hour during pl:C treatment). PBMCs from healthy patients were used as controls. Plasma proteomics [Data provided by the MGH Emergency Dept COVID-19 Cohort (Filbin, Goldberg, Hacohen) with Olink Proteomics] from COVID-19 patients were also analyzed. Results were considered as significant when  $p < 0.05$ .

**Results:** Early (2 h) PBMC response to pl:C showed a significant increase in TNF gene expression in lean HD patients (+92%) while the response was significantly higher in the obese HD group (+158%). TNF expression further increased upon LPS stimulation (+1811% lean and +1916% obese). As expected, after 24 h, responses were attenuated, with no induction of TNF in response to pl:C and a mild upregulation after LPS treatment (+47% lean and +22% obese). Analysis of the plasma proteome from COVID-19 patients revealed significant differences in expression of antiviral-related molecules when

comparing lean (n = 41) versus obese (n = 123) patients. Obese patients had increased interferon (IFN) gamma (+35%) and IFN lambda 1 (+19%) production with a significant reduction in the expression of their respective receptors IFNGR1 (-19%) and IL10RB (-7%) when compared to lean patients. Moreover, the dsRNA sensor DDX58 (+10%), its downstream transcription factor ATF2 (+86%) and IFN-induced cytokines, e.g. CXCL10 (+7%) and IL-1beta (+46%) were also increased in obese compared to lean COVID-19 positive patients. **Conclusion:** Our results suggest that heavy drinking patients with obesity have an impaired innate immune response to viral insults (e.g. COVID-19). Current scRNAseq analysis will better delineate the implicated immune populations and molecular pathways involved in this disrupted response.

**PO-1563**  
**Longer-term Outcome from Alcoholic Hepatitis: survival, re-admission rate and out-patient attendance after discharge**

Murray Foster<sup>1</sup>, James Knight<sup>1</sup>, Ewan Forrest<sup>2</sup>. <sup>1</sup>University of Glasgow, Glasgow, United Kingdom; <sup>2</sup>Glasgow Royal Infirmary, Gastroenterology, Glasgow, United Kingdom  
 Email: ewanforrest@hotmail.com.

**Background and aims:** Alcoholic hepatitis (AH) has a high short-term mortality. Few studies have looked at the longer-term outcome of AH patients, although achievement of abstinence from alcohol is associated with better survival. The aim of this study was to review the long-term outcome of patients with AH and their subsequent use of medical services.

**Method:** All patients recruited to the STOPAH trial between March 2011 and February 2014 from hospitals within NHS Greater Glasgow and Clyde were assessed. For those who survived their STOPAH admission, subsequent gastroenterology/hepatology out-patient clinic (OPC) and in-patient episodes were recorded. Kaplan-Meier, Spearman's correlation and Odds Ratio analyses were undertaken: results are presented as medians and 95% confidence intervals. Censorship was until 1/10/2020 for survivors.

**Results:** 140 patients were recruited, with a median follow-up of 667 days (390–1195) until censorship or death. 108 (77%) survived their index STOPAH admission for whom subsequent information was available in 106; the median follow-up until censorship was 1261 days (823–1883). Their survival was 28%. 92% of index admission survivors had a further hospital admission (64% liver-related). Median time to readmission after discharge was 101.5 days (56–161). 59% of readmitted patients did so prior to an OPC consultation. 79 (74%) patients attended at least one OPC appointment, the first being a median of 86 days (68–108) after discharge. Correspondence from the first OPC after index admission indicated no alcohol use in 56%, continued alcohol use in 24% and no record of alcohol intake in 20%. Those attending  $\leq 50\%$  OPC appointments had a lower survival (19%) compared with those attending  $>50\%$  (38%;  $p = 0.02$ ; Figure). There was a correlation between time to first OPC appointment and subsequent attendance rate with those attending sooner after discharge more likely to attend ( $\rho = -0.367$ ;  $p = 0.0009$ ).

Figure:

## POSTER PRESENTATIONS

**Conclusion:** With long-term follow-up, the mortality of AH patients who survive their index admission is high. Most patients were readmitted prior to an OPC consultation, but those who did attend >50% of offered OPCs had a better outcome. Documentation of alcohol use at OPC review was inadequate in a fifth of cases. Prompt and more assertive OPC follow-up might benefit this cohort of patients to improve long-term survival.

### PO-1623

#### Treatment of alcohol withdrawal syndrome in patients with alcohol-related liver disease

Alexander Doyle<sup>1</sup>, Katherine Duncan<sup>2</sup>, William MacKey<sup>2</sup>, Sardar Chaudhary<sup>2</sup>, Ewan Forrest<sup>1,2</sup>. <sup>1</sup>University of Glasgow, Glasgow, United Kingdom; <sup>2</sup>Glasgow Royal Infirmary, Gastroenterology, Glasgow, United Kingdom  
Email: ewanforrest@hotmail.com.

**Background and aims:** Management of alcohol withdrawal syndrome (AWS) in patients with alcohol-related liver disease (ArLD) is poorly studied. Variable metabolism of benzodiazepines (BZDs) and risk of encephalopathy in ArLD patients presents a challenge. We have established a guideline to manage AWS in ArLD using a symptom triggered (ST) approach with the Glasgow Modified Alcohol Withdrawal Score (GMAWS) and prescription of lorazepam. We have reviewed the management of these patients.

**Method:** The medical records of all patients discharged from the Gastroenterology/Liver wards at GRI in the fourth quarter of the years 2015–2019 were reviewed. Patients presenting with or with known ArLD who had been drinking within 1 week of admission were identified. Admission data were collected retrospectively: BZD use calculated as diazepam (mg) equivalent. Alcohol Use Disorder (AUD) was assessed with the FAST score (abbreviated AUDIT:  $\geq 8$  associated with increased BZD use). Severe AWS defined as more than 80 mg BZD/day and/or need for parenteral sedation. MELD-Na scores were determined for all patients.

**Results:** 188 ArLD patients were identified, 128 of whom had a FAST score recorded. BZD use in the first 96 hours of admission correlated with FAST score ( $p < 0.0001$ ;  $\rho$  0.371) and initial GMAWS score ( $p < 0.0001$ ;  $\rho$  0.539), but not with MELD-Na. There was an inverse correlation with FAST score and MELD-Na ( $p = 0.0053$ ;  $\rho$  -0.250). 114 patients had a FAST  $\geq 8$  taking a median of 27 units of alcohol/day (range 4.6–80) and median BZD use of 47.5 mg (range 0–520) in the first 96 hours of admission. 29 (25%) did not require any BZD; 28 (24%) had severe AWS. Logistic regression identified initial GMAWS score ( $p < 0.0001$ ; OR 1.83, 1.36–2.47) and baseline neutrophil-to-lymphocyte ratio ( $p = 0.048$ ; OR 1.08, 1.00–1.18) as associated with severe AWS. There was no association with markers of liver dysfunction. 60 (53%) received diazepam initially, but only 17 (15%) continued this after 24 hours. 93 (82%) received ST treatment initially increasing to 99 (87%) after 24 hours.

**Conclusion:** AWS in ArLD is not associated with markers of liver disease. The need for treatment is unpredictable with about a quarter not needing any BZD treatment, and a further quarter experiencing severe AWS. High FAST score and severity of initial AWS symptoms are most indicative of AWS. AWS in ArLD can be managed effectively using a lorazepam-based ST approach with GMAWS.

### PO-1651

#### Histological lesions can predict response to corticosteroids in patients with severe alcohol-related steatohepatitis

Horia Stefanescu<sup>1</sup>, Marion Jager<sup>2</sup>, Rautou Pe<sup>2</sup>, Adelina Horhat<sup>1</sup>, Davies Susan<sup>3</sup>, Helmut Denk<sup>4</sup>, Hans-Peter Dienes<sup>5</sup>, Viviane Gnemmi<sup>6</sup>, Maria Guido<sup>7</sup>, Rosa Miquel<sup>8</sup>, Valérie Paradis<sup>9</sup>, Ioana Rusu<sup>10</sup>, Peter Schirmacher<sup>11</sup>, Luigi Maria Terracciano<sup>12</sup>, Rudolf E. Stauber<sup>13</sup>, Annette Gouw<sup>14</sup>, Dina Tiniakos<sup>15</sup>, Carolin Lackner<sup>4</sup>. <sup>1</sup>Regional Institute of Gastroenterology and Hepatology, Liver Unit, Cluj-Napoca, Romania; <sup>2</sup>Université de Paris, Hôpital Beaujon, Service d'Hépatologie, Paris, France; <sup>3</sup>Cambridge University Hospitals NHS Foundation Trust, Department of Histopathology, Cambridge, United Kingdom; <sup>4</sup>Medical University of Graz, Institute of Pathology, Graz, Austria; <sup>5</sup>Medical University of Vienna, Department of Pathology, Vienna, Austria; <sup>6</sup>Université Lille, CHU Lille, Service de Pathologie, Lille, France; <sup>7</sup>University of Padova, Department of Medicine, Padova, Italy; <sup>8</sup>Kings College Hospital, Liver Histopathology Laboratory, London, United Kingdom; <sup>9</sup>Hôpital Universitaire Beaujon, Service d'Anatomie et de Cytologie Pathologiques, Paris, France; <sup>10</sup>Regional Institute of Gastroenterology and Hepatology, Department of Pathology, Cluj-Napoca, Romania; <sup>11</sup>University Hospital Heidelberg, Institute of Pathology, Heidelberg, Germany; <sup>12</sup>University Hospital Basel, Institute of Pathology, Basel, Switzerland; <sup>13</sup>Medical University of Graz, Internal Medicine, Graz, Austria; <sup>14</sup>University Medical Center Groningen, Department of Pathology and Medical Biology, Groningen, Netherlands; <sup>15</sup>Newcastle University, Transitional and Clinical Research Institute, Newcastle upon Tyne, United Kingdom  
Email: rudolf.stauber@medunigraz.at.

**Background and aims:** Liver biopsy is useful to confirm alcohol-related steatohepatitis (ASH) in patients with alcohol-related liver disease (ALD) and clinically suspected alcoholic hepatitis (AH). Current EASL guidelines recommend prednisolone for the treatment of severe AH with Maddrey's discriminant function (MDF)  $\geq 32$ . However, steroid treatment may lead to severe side effects like sepsis. Therefore, treatment response is assessed at day 7 using the Lille model and steroids are discontinued in non-responders to limit the risk of unnecessary steroid exposure. The aim of our study was to investigate the potential utility of histologic features of ALD for early prediction of response to corticosteroids as per Lille score in patients with AH in order to avoid the risk of a 7-days steroid exposure for those unlikely to benefit.

**Method:** We analyzed data of a multinational cohort of patients with severe AH and MDF  $\geq 32$ . All patients underwent liver biopsy for the confirmation of clinically suspected AH and were treated with prednisolone. Morphological features of ALD including steatosis, activity (contributed by hepatocellular ballooning, Mallory Denk bodies and lobular neutrophils), canalicular and ductular cholestasis as well as fibrosis stage were assessed using the recently developed ALD-specific SALVE grading and staging system. Association of histological variables with response to steroids (Lille score  $< 0.45$ ) was analyzed by Chi-square test. Logistic regression was performed to ascertain the effects of histological variables on the likelihood of response to steroids.

**Results:** Complete data were available in 119 patients. A Lille score of  $< 0.45$  indicating response to steroids was observed in 72 patients and was associated with steatosis grade ( $p = 0.037$ ) and ductular cholestasis ( $p = 0.029$ ) but not with SALVE fibrosis stage or activity. Logistic regression analysis revealed presence of ductular cholestasis ( $p = 0.016$ , OR 2.8) and steatosis grade  $< 2$  ( $p = 0.047$ , OR 2.2) as histologic predictors of a Lille score of  $\geq 0.45$  indicating non-response to steroids.

**Conclusion:** Liver biopsy may thus be used not only to confirm ASH but also to achieve early prediction of steroid efficacy thus sparing high-risk AH patients from potentially life-threatening side effects of steroid exposure.

**PO-1654**

**Changes in alcohol-related liver disease admissions over the time of minimum unit pricing of alcohol: the GRI Q4 study**

Sardar Chaudhary<sup>1</sup>, William MacKey<sup>1</sup>, Katherine Duncan<sup>1</sup>, Ewan Forrest<sup>1</sup>. <sup>1</sup>Glasgow Royal Infirmary, Gastroenterology, Glasgow, United Kingdom  
Email: sardar.chaudhary2@nhs.scot.

**Background and aims:** Minimum unit price (MUP) of 50 pence per unit of alcohol was introduced in Scotland on the 1<sup>st</sup> of May 2018. This was one of several measures which hoped to reduce alcohol harm and alcohol-related liver disease (ArLD) in particular. Standard discharge coding for ArLD is not sufficiently accurate to determine differences between variable clinical presentations. We assessed ArLD admissions to Glasgow Royal Infirmary (GRI) before and after the introduction of MUP.

**Method:** The medical records of all patients discharged from the Gastroenterology/Liver wards at GRI in the fourth quarter (Q4) of the years 2015–2019 were reviewed (pre-MUP 2015–17; post-MUP 2018–19). All patients with ArLD were identified and admission data were collected retrospectively detailing clinical features of liver disease, blood test results and recent drinking history. Over this time there has been no change to the placement of ArLD patients in GRI. The National Institute of Alcohol Abuse and Alcoholism definition for alcoholic hepatitis (AH) was used. MELD scores were determined for all patients. Active drinking was defined as alcohol use within 8 weeks of admission. The 90-day mortality and readmission rates were assessed.

**Results:** In total 1875 inpatient episodes were reviewed (1164 pre-MUP; 711 post-MUP) of which 319 were with ArLD (212 pre-MUP; 107 post-MUP). Overall, the mean number of ArLD in-patient episodes fell (80.3 pre-MUP; 68 post-MUP) with a similar fall in the individual patients in each quarter (70.7 pre-MUP, 53.5 post-MUP). The proportion of active drinkers was lower post-MUP (64.7%) compared with pre-MUP (70.5%). There were no differences in the proportion of patients presenting with ascites (45.2% *cf.* 47.8%) encephalopathy (21.2% *cf.* 24.3%) or AH (18.3% *cf.* 19.1%) pre- and post-MUP. However there was a reduction in presentations with acute upper GI bleeding (AUGIB): 15.8% *cf.* 7.4%;  $p = 0.02$ ; odds ratio 0.42. The overall severity of liver disease remained unchanged (mean MELD 16 for both time periods). The 90-day mortality (12.4% *cf.* 13.2%) and readmission (48.5% *cf.* 54.4%) rates were not significantly different pre- and post-MUP.

**Conclusion:** Since the introduction of MUP there has been a reduction in the absolute numbers of ArLD in-patient episodes and number of individual patients involved at GRI. However the pattern of clinical presentation was largely unaffected other than a reduction in the proportion of patients presenting with AUGIB. The overall ArLD severity, readmission rates and 90-day mortality were similar pre- and post-MUP.

**PO-1708**

**Hallmarks of neutrophil extracellular trap (NET) components in the course of alcoholic liver disease**

Anna Rycyk<sup>1</sup>, Beata Kasztelan-Szczerbinska<sup>1</sup>, Agata Surdacka<sup>2</sup>, Jacek Rolinski<sup>2</sup>, Agata Michalak<sup>1</sup>, Mariusz Szczerbinski<sup>3</sup>, Halina Cichoz-Lach<sup>1</sup>. <sup>1</sup>Medical University of Lublin, Department and Clinic of Gastroenterology with Endoscopy Unit, Lublin, Poland; <sup>2</sup>Medical University of Lublin, Department and Clinic of Clinical Immunology, Lublin, Poland; <sup>3</sup>Independent Public Clinic Hospital No. 4 in Lublin, Gastroenterology Clinic, Lublin  
Email: anarycyk@op.pl.

**Background and aims:** Neutrophils release neutrophil extracellular traps (NETs) as a defense strategy in response to broad-spectrum infections, but also to sterile triggers. NETs consist of a DNA scaffold decorated with antimicrobial peptides (AMPs) including cathelicidin (LL37) and  $\alpha$ -defensins (HNP1-3), and enzymatically active proteases including peptidyl arginine deiminase type 4 (PAD-4). Damage-

associated molecular patterns (DAMPs), such as high mobility group box 1 (HMGB1), stimulate NET formation. Susceptibility to infections and inflammatory dysregulation are hallmarks of alcoholic liver disease (ALD).

**Method:** We aimed to investigate the systemic concentrations of NET components such as LL37, HNP1-3, and PAD-4, and the NET promoter HMGB1 in patients with ALD. 62 patients with ALD were prospectively recruited and assigned to subgroups based on their 1/gender, 2/severity of liver dysfunction according to Child-Pugh and Model of End-Stage Liver Disease (MELD) scores, and modified Maddrey's Discriminant Function (mDF) 3/presence of ALD complications. 24 age- and sex-matched healthy volunteers served as the control group. Correlation coefficients between their blood concentrations and (i) markers of systemic inflammation [the neutrophil-to-lymphocyte ratio (NLR), C-reactive protein (CRP), white blood cell (WBC) and neutrophil (NEUT) counts], (ii) liver dysfunction severity scores, and (iii) ALD complications were calculated.

**Results:** Systemic concentrations of HNP1-3, PAD-4, and HMGB1 were significantly increased in patients with ALD in comparison with controls. HNP1-3 levels correlated with MELD and mDF scores. ALD subgroups with MELD > 20 and mDF > 32 presented with significantly higher HNP1-3 concentrations. HNP1-3 levels revealed a good predictive AUC for the hepatic encephalopathy and ascites development (0.81 and 0.74, respectively), and for the survival (0.87) in patients of above 40 years of age. PAD-4 levels correlated with standard markers of inflammation (CRP, WBC, NEUT) and revealed a good predictive AUC (0.76) for the survival in the whole ALD group.

**Conclusion:** Our results reveal that systemic blood levels of NET components and the NET promoter are elevated in ALD patients and support the value of HNP1-3 and PAD-4 as biomarkers in the ALD assessment. PAD-4 seems to be an inflammatory mediator, while HNP1-3 the disease severity indicator. HNP1-3 and PAD-4 may be potentially applied as predictors of the patients' survival in ALD.

**PO-1932**

**Results of a screening program of liver fibrosis with transient elastography in subjects with alcohol use disorder**

Elisa Pose<sup>1,2</sup>, Emma Avitabile<sup>1</sup>, Jordi Gratacós-Gines<sup>1,2</sup>, Martina Perez<sup>2</sup>, Marta Cervera<sup>1</sup>, Ana Belén Rubio<sup>1</sup>, Marta Carol<sup>1</sup>, Ana Lopez Lazcano<sup>3</sup>, Anna Lligoña<sup>3</sup>, Hugo Lopez<sup>3</sup>, Lluisa Ortega<sup>3</sup>, Alba Díaz<sup>4</sup>, Núria Fabrellas<sup>5</sup>, Octavi Bassegoda<sup>1,2</sup>, Laura Napoleone<sup>1,2</sup>, Ann Ma<sup>1</sup>, Adria Juanola<sup>2</sup>, Isabel Graupera<sup>2</sup>, Pere Ginès<sup>1,2,5</sup>. <sup>1</sup>Institut d'Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS), Chronic liver disease, Barcelona, Spain; <sup>2</sup>Hospital Clínic of Barcelona, Hepatology, Barcelona, Spain; <sup>3</sup>Hospital Clínic of Barcelona, Psychiatry, Barcelona, Spain; <sup>4</sup>Hospital Clínic of Barcelona, Anatomopathology, Barcelona, Spain; <sup>5</sup>University of Barcelona, Barcelona, Spain  
Email: EPOSE@clinic.cat.

**Background and aims:** Transient elastography (TE) is a non-invasive method used for the assessment of liver fibrosis (LF) through liver stiffness measurement (LS). There is some evidence from population-based studies that patients with alcohol use disorder (AUD) are at high risk for LF. However, to date few studies have evaluated the performance of a screening program for diagnosis of LF in subjects with AUD. The aim of this study was to assess the prevalence of significant LF in subjects with AUD through a screening program based on TE.

**Method:** Consecutive subjects with AUD attending the Addictions Unit of the Hospital Clinic of Barcelona were included prospectively. Those with previously known liver disease were excluded. The presence of significant LF, defined as  $LS \geq 8$  kPa, was evaluated through TE. Liver steatosis was assessed through the controlled attenuation parameter (CAP) and defined as  $CAP \geq 290$  dB/m. Liver biopsy was proposed in all patients with high values of LS to evaluate LF through Metavir scale.

**Results:** 160 patients were screened and 140 included. Main reason for exclusion was lack of informed consent. The majority were men

## POSTER PRESENTATIONS

with a median age of 52 y/o. Median alcohol consumption was 84 SD/week and mean LS value was 4.8 kPa. Thirteen (9%) patients presented  $LS \geq 8$  kPa and all of them underwent liver biopsy. Liver biopsy assessment confirmed the presence of significant LF in 6 (46%). None of the subjects with  $LS < 10$  kPa presented significant LF at liver biopsy. The group with  $LS \geq 8$  kPa was older, presented higher prevalence of metabolic comorbidities and higher values of transaminases. There were no differences in terms of quantity and duration of alcohol consumption. Age was the only factor associated with the risk of presenting high LS values at the multivariate analysis. Median CAP was 245 dB/m (203–289) and 34 (24%) subjects had steatosis. Factors associated with steatosis at the Multivariate analysis age, waist circumference, and FIB-4.

Figure: Distribution curve of liver stiffness values

**Conclusion:** the prevalence of LF in subjects with AUD assessed with a screening program based on TE was of 9%, approximately twice as much as the prevalence reported in previous screening studies in the general population. Only older age was associated with a higher risk

of LF in subjects with AUD. These data reveal a high prevalence of undiagnosed liver fibrosis in this specific population of subjects and call for the implementation of programs of non-invasive assessment of fibrosis in these subjects.

### PO-2043

#### The role of miR-873-5p in Alcohol-related Liver Disease

Rubén Rodríguez Agudo<sup>1</sup>, Naroa Goikoetxea<sup>1</sup>, Marina Serrano-Macia<sup>1</sup>, Irene González-Recio<sup>1</sup>, Pablo Fernández Tussy<sup>1</sup>, Delia Blaya<sup>2</sup>, Jose Maria Herranz<sup>3</sup>, Sofia Lachiondo-Ortega<sup>1</sup>, Maria Mercado-Gómez<sup>1</sup>, Claudia Gil-Pitarch<sup>1</sup>, Carmen Fernández-Rodríguez<sup>1</sup>, Álvaro Eguileor<sup>1</sup>, Petar Petrov<sup>1</sup>, Miren Bravo<sup>1</sup>, Pau Sancho-Bru<sup>2</sup>, Matías A. Avila<sup>3</sup>, Luis Alfonso Martínez-Cruz<sup>1</sup>, Teresa Cardoso Delgado<sup>1</sup>, Jon Mabe<sup>4</sup>, Jorge Simón Espinosa<sup>1</sup>, María Luz Martínez-Chantar<sup>1</sup>. <sup>1</sup>CIC bioGUNE-Centro de Investigación Cooperativa en Biociencias; <sup>2</sup>Hospital Clínic de Barcelona; <sup>3</sup>CIMA (Center for Applied Medical Research) University of Navarre; <sup>4</sup>Fundación Tekniker  
Email: mlmartinez@cicbiogune.es.

**Background and aims:** Alcohol-related liver disease (ALD), the most prevalent type of chronic liver disease has become a major public health problem worldwide, and a leading cause of morbidity and mortality. One of the unmet needs to address ALD is the lack of effective therapies. Just cutting off alcohol intake is presented as effective therapy. Going deeper, alcohol abuse promotes a disbalance in lipid homeostasis that subsequently, induces liver injury and inflammatory response. During this pathological process, sirtuins play a key role, and SIRT1 is the most extensively studied. Increasing evidence suggests the relevance of microRNAs (miRNAs) as therapeutic targets for ALD. Previously, our lab demonstrated the relevance of miR-873-5p as a suitable target for liver diseases, such as NAFLD and fibrosis by modulating among different targets the expression of the gene Glycine-N-Methyl transferase (GNMT), key modulator of One Carbon Metabolism pathway. Considering the unmet need to develop new therapies against ALD, miR-873-5p appears as a suitable candidate to ameliorate the damaged induced by alcohol in the liver. **Method:** MiR-873-5p levels were measured in paired patient liver samples affected by alcoholic hepatitis vs healthy biopsy (n = 16). As a readout to analyze the effect of miR-873-5p, Gnm1 mRNA expression was studied in human tissue from patients with different alcoholic

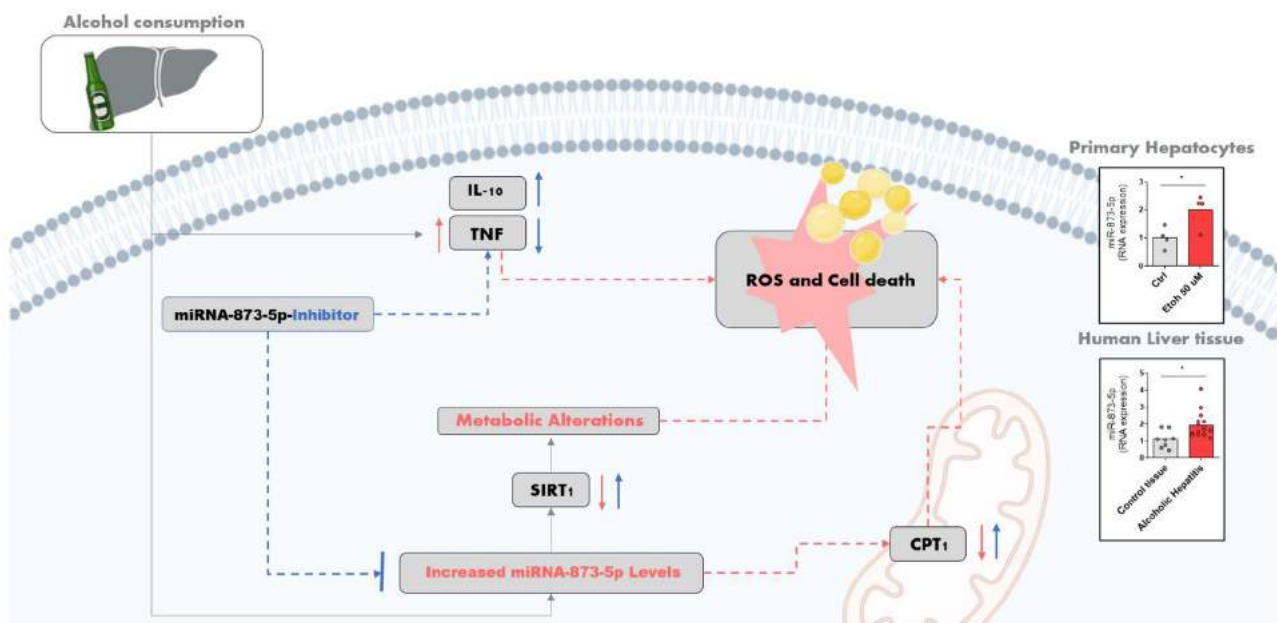

Figure: (abstract: PO-2043)

disturbances (n = 63). The expression levels of miR-873-5p and Gnm1 were further tested in different mice models (BASH and N1IA). In vitro assays in primary hepatocytes were performed in the presence of anti-miR-873-5p, anti-miR-Control or mimic-miR-873-5p under 12 h of ethanol exposure (50 mM). Cell death rate by TUNEL assay, mitochondrial ROS production, seahorse analysis as well as diverse signaling pathways were evaluated in these conditions.

**Results:** Raised levels of miR-873-5p were found in ALD patients. Accordingly, Gnm1 levels were downregulated in unrelated cohorts of patients with different alcoholic disease stages. These results were consistent in primary hepatocytes and mice models. Hepatocytes transfected with anti-miR-873-5p showed minor TUNEL cell death in situ and less ROS production measured by MitoSOX compared with anti-miR-Control under ethanol exposure. The negative modulation of miR-873-5p renders higher levels of SIRT1 and CPT1 in primary hepatocytes with a concomitant reduction of S6 Ribosomal Protein (Ser235/236) phosphorylation. Also, the inhibition of miR-873-5p in primary hepatocytes under ethanol treatment, modulates the inflammatory process, with higher levels of IL10 and a reduction of TNF expression.

**Conclusion:** Targeting miR-873-5p is a valuable therapeutic tool for ALD mediated by SIRT/mTOR regulation.

**PO-2185**

**Human Precision Cut Liver Slices as a model of Alcohol-related Liver Disease: recapitulating disease progression in a dish.**

Elena Palma<sup>1,2</sup>, Nicola Harris<sup>1,2</sup>, Una Rastovic<sup>1,2</sup>, Tsin Shue Koay<sup>1,2</sup>, Ewald Doornebal<sup>1,2</sup>, Sandra Phillips<sup>1,2</sup>, Antonio Riva<sup>1,2</sup>, Daren Ure<sup>3</sup>, Rosa Miquel<sup>4</sup>, Melissa Preziosi<sup>4</sup>, Andreas Prachalias<sup>4</sup>, Krishna Menon<sup>4</sup>, Nigel Heaton<sup>4</sup>, Roger Williams<sup>1,2</sup>, Shilpa Chokshi<sup>1,2</sup>.

<sup>1</sup>Institute of Hepatology, Foundation for Liver Research, London, United Kingdom; <sup>2</sup>King's College London, Faculty of Life Sciences and Medicine, United Kingdom; <sup>3</sup>Hepion Pharmaceuticals, Edison, United States;

<sup>4</sup>Institute of Liver Studies, King's College London, London, United Kingdom

Email: e.palma@researchinliver.org.uk.

**Background and aims:** The canonical experimental models (i.e. cell culture and rodents) for the study of Alcohol-related Liver Diseases (ALD) present limitations which impede the advancement of novel therapies, particularly the difficulty in recapitulating the spectrum of pathological manifestations associated with the development/progression of ALD in humans including steatosis, inflammation, hepatotoxicity, fibrosis and cirrhosis. The need to overcome this barrier to drug development underpins the current study. We describe the development of an immunocompetent ex-vivo human model of ALD based on the culture of Precision Cut Liver Slices (PCLS) and their direct application for the assessment of the therapeutic effects of the cyclophilin inhibitor, CRV431.

**Method:** Tumour-free liver specimens ('healthy' or cirrhotic) were collected from patients (n=22) undergoing resection of liver metastasis. PCLS were made from the resected tissue, cultured for up to 5 days, and exposed to hepatotoxic insults: ethanol 50–250 mM, oleic/linoleic acids 0.1 mM, and LPS 10 µg/ml. The therapeutic effects of 5 µM CRV431 were studied for the duration of the culture. Viability and cell death were evaluated by histology, cytokeratin 18 release, and ATP content. Steatosis was evaluated by Oil-Red-O staining. Fibrosis was measured by gene expression, secretion and histology. Inflammatory cytokines were quantified by luminex. Mitochondrial fitness was evaluated by functional and morphological assays.

**Results:** The exposure of PCLS to ethanol for increasing time periods (up to 5 days) could mimic the clinical features of ALD. Early ethanol exposure was characterised by low overall cell death but increased mitochondrial alterations. The addition of fatty acids and an acute inflammatory hit (LPS) promoted steatohepatitis, inflammatory cytokine production and fibrosis. The cirrhotic PCLS were used to investigate tissue architecture and fibrotic processes in the context of

late stage chronic disease. PCLS treated with CRV431 maintained good viability, mitochondrial function, and low apoptosis over the culture duration. CRV431 also tempered inflammation in the presence of LPS and induced a dramatic decrease in gene expression and deposition of Collagen and Timp-1.

**Conclusion:** In summary, we have developed a versatile immunocompetent platform which can reliably recapitulate the clinical features of ALD and have shown that it can be effectively employed to assess the efficacy of novel immunomodulatory and anti-fibrotic therapeutic agents.

**PO-2331**

**Past hospital contacts due to alcohol do not predict fibrosis stage in alcohol-related liver disease. A study of alcohol diagnoses and morbidity in 18 years leading up to biopsy-proven liver fibrosis in 462 patients**

Ditlev Rasmussen<sup>1</sup>, Maria Kjærgaard<sup>1</sup>, Katrine Prier Lindvig<sup>1</sup>, Mads Israelsen<sup>1</sup>, Kathrine Thorhauge<sup>1</sup>, Nikkolaj Christian Torp<sup>1</sup>, Stine Johansen<sup>1</sup>, Sönke Detlefsen<sup>2</sup>, Aleksander Krag<sup>1</sup>, Maja Thiele<sup>1</sup>.

<sup>1</sup>Odense University Hospital, Department of Gastroenterology and Hepatology; <sup>2</sup>Odense University Hospital, Department of Pathology, Denmark

Email: ditlev.nytoft.rasmussen@regionh.dk.

**Background and aims:** Decompensated alcohol-related liver disease is preceded by several years of excessive drinking. Hospital contacts for alcohol problems are potential opportunities for early detection of cirrhosis. We aimed to investigate whether patients with biopsy-proven severe fibrosis and cirrhosis had more past hospital contacts due to alcohol than alcohol-overusing patients with significant or minimal fibrosis.

**Method:** Liver-healthy patients had a liver stiffness below 6 kPa assessed by transient elastography or a biopsy of F0-F1 fibrosis. Patients with significant fibrosis and advanced fibrosis had liver biopsies with F2 and F3-4 fibrosis, respectively. All patients had a history of alcohol overuse but no decompensations. We linked patient's fibrosis stage to registry data of ICD-10 diagnosis codes for the patients' hospital contacts in the 18 years leading up to liver biopsy. In order to observe changes over time, we split the 18-year period into the first, the second and the last 6-year period before fibrosis assessment. We distinguished between Intoxication (ICD-10 code F10.0), harmful use of alcohol (F10.1) and alcohol dependency (F10.3-F10.5).

**Results:** We studied the past medical record of 462 patients, 261 liver-healthy, 107 with significant fibrosis, and 94 with advanced fibrosis. During the 18 years, 45% of all patients had one or more alcohol-related hospital contacts, with no difference between groups (43%, 50%, and 44% respectively, P=0.57 for difference). The proportion of patients who had at least one alcohol-related contact was similar between the groups throughout the 18-year-period, and this proportion increased for all groups in the last 6-year-period, see figure. The type of alcohol diagnosis through the three six-year periods for the individual patient was not stable over time in any of the groups. A past diagnosis of polyneuropathy was four times as common for patients with advanced fibrosis, and ulcers were more than twice as common.

## POSTER PRESENTATIONS

Figure:

**Conclusion:** More than half of patients who progress to severe alcohol-related fibrosis and cirrhosis do not have any hospital contact with a diagnosis of alcohol use disorder, and the frequency of hospital contacts due to alcohol cannot be used to predict who will experience fibrosis progression within two decades.

### PO-2341

#### High oxidative stress in T cells and monocytes correlates with mortality from alcoholic hepatitis

Huey Tan<sup>1</sup>, Paula Boeira<sup>1</sup>, Euan Yates<sup>1</sup>, Matthew Cramp<sup>1</sup>, Ashwin Dhandu<sup>1</sup>. <sup>1</sup>University of Plymouth, Faculty of Health: Medicine, Dentistry and Human Sciences, Plymouth, United Kingdom  
Email: hueytan@nhs.net.

**Background and aims:** Multiple mechanisms including immune dysfunction drive poor outcomes from alcoholic hepatitis (AH) although the role of oxidative stress in immune cells remains unknown.

**Method:** Patients from University Hospitals Plymouth with AH (discriminant function [DF] > 32); and healthy volunteers (HV) were recruited. Disease severity was scored using Model for end stage liver disease (MELD) and DF. 2'-7'-dichlorofluorescein diacetate (DCFH-DA) staining (fluoresces on oxidation) was assessed by flow cytometry to measure oxidative stress directly in peripheral blood T cells (CD3+) and monocytes (CD14+) and after ex-vivo exposure to tert-butylhydroperoxide (TBH) to simulate maximal oxidative stress with results presented as percentage maximal oxidative stress.

**Results:** 7 HV (4 male, mean age 36) and 34 AH patients (18 male; Mean age 53; Mean MELD 23, DF 81.5) were studied. Samples from AH patients were obtained at baseline before treatment with corticosteroids. 8 AH patients died within 90 days (2 male; mean age 55, mean MELD 29.8, DF 161.8).

Percentage maximal oxidative stress in AH patients was significantly higher than in HV in CD14+ (60.1% vs 41%,  $p = 0.001$ ), but not in CD3+ (54.4% vs 49%;  $p = 0.24$ ). Within AH patients, percentage maximal oxidative stress was significantly higher in non survivors compared to survivors in CD3+ (76.9 vs 47.4%;  $p < 0.05$ ) and CD14+ cells (73.9% vs 55.9%;  $p < 0.05$ ). No correlation was found between MELD or DF scores and percentage maximal oxidative stress in either CD3+ or CD14+ cells.

Figure legend: NS-Not significant, \*\*- $p < 0.01$ .

Figure:

**Conclusion:** In patients dying from AH, both T cells and monocytes showed close to maximal levels of oxidative stress. The role of oxidative stress in the pathogenesis of AH requires further investigation and may represent a novel therapeutic target.

### PO-2389

#### Hospitalization Outcomes of Acute Alcoholic Hepatitis with Protein Energy Malnutrition-A nationwide Analysis

Adnan Malik<sup>1</sup>, Muhammad Malik<sup>2</sup>, Umer Farooq<sup>3</sup>, Khadija Naseem<sup>4</sup>, Mahum Nadeem<sup>5</sup>, Waseem Amjad<sup>6</sup>. <sup>1</sup>Loyola University Medical Center, Maywood, United States; <sup>2</sup>Airedale General Hospital, Steeton, United Kingdom; <sup>3</sup>MacNeal Hospital, Berwyn, United States; <sup>4</sup>Charleston Medical Center, Charleston, United States; <sup>5</sup>OU Health-University of Oklahoma Medical Center, Oklahoma City, United States; <sup>6</sup>Albany Medical Center, Internal medicine  
Email: adnanmalik892@hotmail.com.

**Background and aims:** Acute Alcoholic Hepatitis (AAH) is the severest form of Alcohol Liver Disease (ALD). It is a significant cause of morbidity, mortality, and healthcare resource utilization in the United States. Protein-energy malnutrition (PEM) is one of the adverse sequelae of alcohol consumption. This study examined the demographic characteristics and hospitalization outcomes, including mortality, length of stay (LOS), and total expenditure in hospitalizations for acute alcoholic hepatitis with protein malnutrition.

**Method:** This retrospective study utilizes Nationwide Inpatient Sample (NIS) 2016–2018 employing International Classification of Diseases, Tenth Revision (ICD-10) codes for adult patients with a primary diagnosis of acute alcoholic hepatitis secondary diagnosis of protein malnutrition. In-hospital mortality was the primary outcome, while secondary outcomes included length of stay (LOS) and hospital charges. To adjust for confounding variables, multivariate logistic and linear regression analyses were used.

**Results:** Of 84,693,310 discharges in the NIS 2016-18 database, 1360 hospitalizations were for AAH (Table 1), and 272 (20%) had a concomitant diagnosis of Protein Malnutrition. AAH hospitalizations with protein malnutrition had significant 9.2% mortality (adjusted OR 7.85, 95% CI (1.86–33.08),  $P = 0.005$ ) (Table 2). AAH hospitalizations with PM had 8.65 days increase in adjusted mean LOS (adjusted OR 13.81, 95% CI (0.61–27.02),  $P = 0.04$ ) and a statistically significant average adjusted total hospital cost increase by 27889.5 (OR, with 95% CI (2724.80–53054.31),  $P = 0.030$ ).

**Conclusion:** AAH is a syndrome associated with high mortality and morbidity. Good nutritional status is essential in reducing poor outcomes. Our analysis results emphasize the importance of protein-energy malnutrition being associated with significant mortality and increased length of stay, and total cost of hospitalization. Both enteral feeding and micronutrient supplementation may play an essential role to improve these poor outcomes of PEM with AAH.

Table 1: (abstract: PO-2389)

Outcomes	AAH: (n = 1360)			Adjusted OR/ Adjusted Difference	p value
	Protein Malnutrition: (n = 72) Unadjusted	Without Protein Malnutrition: (n = 1088) Unadjusted

**PO-2417**

**Impact of COVID-19 pandemic on liver transplantation and alcohol-associated liver disease in the United States**

Karthik Goli<sup>1</sup>, Abbas Rana<sup>2</sup>, Fasiha Kanwal<sup>1</sup>, George Cholankeril<sup>1</sup>.

<sup>1</sup>Baylor College of Medicine, Section of Gastroenterology and Hepatology, Houston, United States; <sup>2</sup>Baylor College of Medicine, Division of Abdominal Transplantation, Houston, United States

Email: gcholankeril@gmail.com.

**Background and aims:** The recent surge in unhealthy alcohol use during the COVID-19 pandemic may have detrimental effects on the already rising burden alcohol-associated liver disease (ALD) has placed on liver transplantation (LT) in the United States (U.S.). We aim to evaluate temporal trends in LT during the pandemic and the impact ALD has placed on it.

**Method:** Utilizing data provided by United Network for Organ Sharing registry, we analysed trends and outcomes on waitlist additions, waitlist death, and liver transplant surgeries performed in the U.S. from through November 30, 2020. Patients listed or transplanted after April 1, 2020 was defined as COVID-19 era. Interrupted time-series analyses and Cox hazards models were constructed to compare the rate of LT between eras and aetiologies adjusting for waitlist dropout.

Table 1: Hazard rates for liver transplant within 90 days of listing prior to and during COVID-19 pandemic

	Hazard Ratio [95% C.I.]	p value
<b>Overall<sup>a</sup></b>		
Non-ALD	Reference	
ALD	1.39 [1.33–1.45]	<0.001
<b>Overall within ALD only<sup>b</sup></b>		
ALD: Pre- Pandemic	Reference	
ALD: During Pandemic	1.86 [1.73–2.01]	<0.001
<b>Overall within non-ALD only<sup>b</sup></b>		
Non-ALD: Pre-pandemic	Reference	
Non-ALD: During Pandemic	1.06 [0.99–1.14]	= 0.100
<b>During Pandemic only</b>		
Non-ALD	Reference	
ALD	1.74 [1.62–1.87]	<0.001

<sup>a</sup>Adjusted for waitlist removal due to death and era prior to and during COVID-19 pandemic

<sup>b</sup>Adjusted for waitlist removal due to death

**Results:** Waitlist additions and liver transplant had recovered to pre-pandemic volume from May 2020 onwards. Monthly waitlist dropout (death or clinical deterioration) was observed to be lower during the pandemic. In a time-series analysis, the pandemic was associated with a significant monthly increase in the proportion of liver transplants due to ALD (pre-COVID-19 era rate: -0.138 [0.129–0.147] % per month, COVID-19 era rate: -0.162 [0.159–0.165] % per month, p < 0.001). The monthly rate in liver transplants due to hepatitis C virus infection and non-alcoholic steatohepatitis declined

during the pandemic. Median MELD-Na at listing increased for ALD during the pandemic (pre-COVID-19 era: 22 vs. COVID-19 era: 24; p < 0.001), with a higher percentage listed with a high MELD (MELD-Na ≥ 25). ALD patients listed during the pandemic had a 74% higher rate for 90-LT (HR, 1.74, 1.62–1.87, P < 0.001) than non-ALD patients.

**Conclusion:** ALD patients have presented with a higher acuity of illness necessitating LT during the pandemic. An unintended consequence of the pandemic may be the further prioritization of ALD for LT. Collective efforts are urgently needed to curtail the effect ALD will have on the healthcare system even after the pandemic has subsided.

**PO-2704**

**The Alcohol-Associated Liver Disease Paradox in Chile: An Assessment with data from the National Health Survey 2016–2017**

Juan Pablo Roblero<sup>1</sup>, Juan Pablo Arab<sup>2,3</sup>, Pablo Roblero<sup>4,5</sup>, Francisco Idalsoaga<sup>3</sup>, Luis Antonio Diaz<sup>3</sup>, Gianfranco Oneto<sup>6,7</sup>, Jaime Poniachik<sup>8</sup>. <sup>1</sup>Hospital Clínico Universidad de Chile, Sección de Gastroenterología, Departamento de Medicina., Santiago-RM, Chile; <sup>2</sup>Hospital Clínico de la Universidad Católica de Chile, Departamento de Gastroenterología, Santiago-RM, Chile; <sup>3</sup>Hospital Clínico de la Universidad Católica de Chile, Departamento de Gastroenterología, Santiago, Chile; <sup>4</sup>Pontificia Universidad Católica de Chile, Sociología, Chile; <sup>5</sup>Pontificia Universidad Católica de Chile, Departamento de Sociología, Santiago, Chile; <sup>6</sup>Hospital San Borja Arriarán, Departamento de Gastroenterología, Santiago, Chile; <sup>7</sup>Hospital San Borja Arriarán, Gastroenterología, Santiago, Chile; <sup>8</sup>Hospital Clínico Universidad de Chile, Sección de Gastroenterología, Departamento de Medicina., Santiago, Chile

Email: jproblero@gmail.com.

**Background and aims:** It has been observed that people with a low-income level (<IL) have greater liver injury due to alcohol consumption (AC), even when their consumption levels are lower or equal to those with a high-income level (>IL). The aim of this study was to evaluate alcohol-associated liver disease (ALD) paradox in Chile.

**Method:** The 2016–2017 NHS was a nationally representative cross-sectional study of the population aged 15 years and older, which included blood tests performed on a random subsample (N = 3700). We used the results of these test for persons aged 25–64 years (N = 2190) to evaluate the ALD paradox in Chile. We constructed a logit regression model that estimated the dangerous AC effect (defined as AUDIT ≥ 8 points) on the probability of presenting ALD (defined as GPT ≥ 40 U/L). We controlled for IL, presence of metabolic syndrome (MS), type 2 diabetes mellitus (DM2), obesity and tobacco.

**Results:** The average AC was 39 g of alcohol per week (13 g women <IL; 23 g women >IL; 64 g men, without differences by IL). In women, hazardous AC only increased ALD among those >IL who presented with obesity or MS in combination with T2DM (+36% obesity + MS + T2DM; p < 0.01). In men, hazardous AC only increased ALD among those with <IL (16% without comorbidities, 17% with tobacco, 22% with MS, 26% with obesity, and 28% with all; p < 0.05).

## POSTER PRESENTATIONS

**Conclusion:** ALD paradox can be observed in Chile among men, but not among women. The evaluated associated comorbidities increased the effect of hazardous AC on ALD. It is necessary to investigate how the IL determines the patterns of AC and comorbidities stratifying by sex. Among men, <IL is likely to be associated with more harmful drinking patterns and a greater presence of comorbidities. Among women, >IL is likely associated with higher AC and more harmful consumption patterns.

**PO-2749**

**The combination of ABIC+ELF as a single marker outperforms ABIC alone in predicting 90-day survival in alcoholic hepatitis.**

Freya Rhodes<sup>1,2</sup>, Nikhil Vergis<sup>3</sup>, Mark Thursz<sup>3</sup>, Rachel Westbrook<sup>1,2</sup>, Alison Rodger<sup>4</sup>, Sudeep Tanwar<sup>1,5</sup>, William Rosenberg<sup>1,2</sup>. <sup>1</sup>UCL, Institute for Liver and Digestive Health; <sup>2</sup>Royal Free NHS Foundation Trust, Hepatology; <sup>3</sup>Imperial College, London, Hepatology; <sup>4</sup>UCL, Institute for Global Health; <sup>5</sup>Barts Health NHS Trust, Gastroenterology and Hepatology

Email: Frhodes@doctors.net.uk.

**Background and aims:** Tests predicting mortality could improve management of patients with Alcoholic Hepatitis (AH). Maddrey's Discriminant Function, MELD, ABIC and GAHS were found to predict

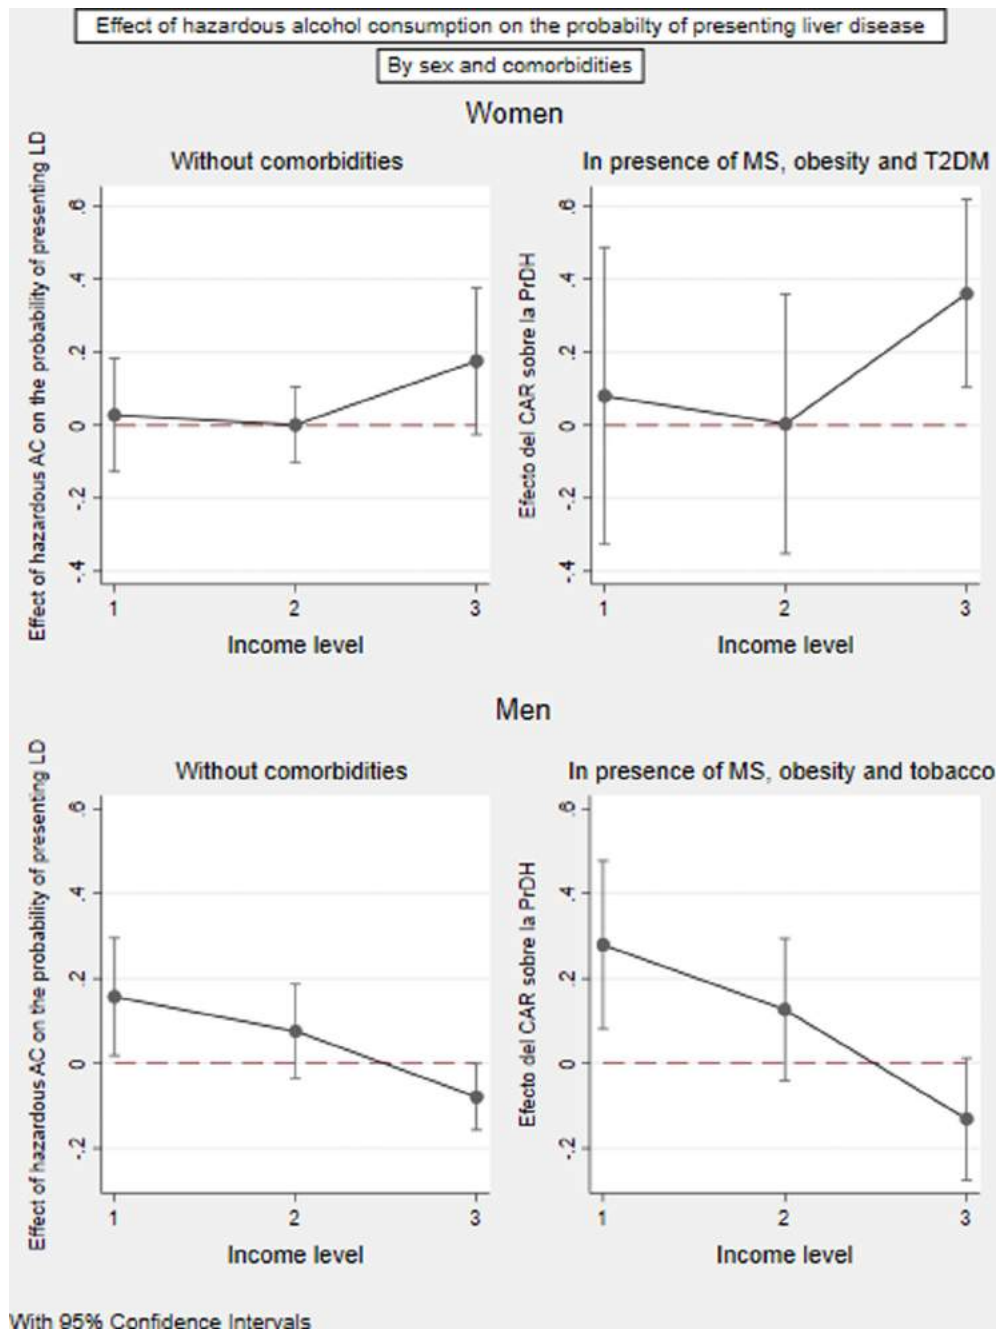

Figure: (abstract: PO-2704)

**Cirrhosis and its complications: ACLF and Critical illness**

mortality in AH in the STOPAH trial, but with sub-optimal scores (90-day AUCs of 0.670, 0.704, 0.726 and 0.713 respectively). The Enhanced Liver Fibrosis (ELF) test is a good prognostic marker for Chronic Liver Disease but has not been studied in AH. We aimed to evaluate the prognostic performance of ELF alone and in combination with other scores in AH.

**Method:** ELF measured in 179 baseline STOPAH serum samples on an Advia Centaur XP, was compared to baseline STOPAH data. Prognostic performance predicting mortality at 28/90/120 days was assessed using logistic regression, AUROC and Kaplan Meier for ELF, ELF components, MELD, GAHS, ABIC, Neutrophil-to-Lymphocyte-Ratio (NLR). FIB4 and Lille were evaluated in sub-analyses.

**Results:** All scores were available for 162/179 participants. ELF ranged from 11.97–21.68, (median = 15.9; IQR 14.9–16.9). ELF predicted mortality at 28/90/120 days; 90-day mortality OR = 1.7 (95% CI 1.3–2.2,  $p < 0.001$ ), AUROC 0.72 (95% CI 0.63–0.81). AUROCs for other markers were not statistically different (ABIC = 0.74; NLR = 0.70; GAHS = 0.75; MELD = 0.74). ELF was positively correlated with CRP ( $\rho = 0.51$ ,  $p < 0.001$ ) and AST ( $\rho = 0.35$ ,  $p < 0.001$ ), but was not associated with infection ( $p = 0.55$ ) or variceal bleeding ( $p = 0.56$ ). Logistic regression revealed that an optimal algorithm combining ABIC+ELF predicted 90-day mortality; AUC = 0.81, (95% CI 0.73–0.89), significantly better than ABIC alone ( $p = 0.01$ ). Both low-ABIC (<6.71) and low ELF (<16.78) predicted 100% 90-day survival-rate ( $n = 17/17$ ), compared to 55% survival for high ABIC/high ELF ( $n = 21/38$ ) ( $p < 0.01$ ). Those with High ABIC/high ELF and Lille <0.45 had a 90-day survival-rate of 90% ( $n = 9/10$ ), compared to 46% (6/13) survival in those with Lille  $\geq 0.45$  ( $p = 0.047$ ). Survival rates were 59% in 17 with sepsis compared to 89% in 83 without sepsis ( $p = 0.001$ ) amongst 100 with high ABIC/low ELF.

Kaplan Meier Survival curve for combined ABIC+ELF at 90-day mortality end-point.

**Combined ABIC + ELF categories**  
 — ABIC < 6.71 and ELF < 16.78  
 — ABIC < 6.71 and ELF  $\geq 16.78$  OR ABIC  $\geq 6.71$  and ELF < 16.78  
 — ABIC  $\geq 6.71$  and ELF < 16.78  
 — ABIC  $\geq 6.71$  and ELF  $\geq 16.78$

ABIC + ELF survival groups	Total N	N of deaths (Survival %)
ABIC < 6.71 and ELF < 16.78	17	0 (100)
ABIC < 6.71 and ELF $\geq 16.78$ OR ABIC $\geq 6.71$ and ELF < 16.78	107	17 (84)
ABIC $\geq 6.71$ and ELF $\geq 16.78$	38	17 (55)
Overall	162	34

Kaplan-Meier survival probability for patients stratified by a combination of ELF with ABIC at 90-day censored study end-point. ABIC threshold of 6.71 taken from published optimum threshold. ELF threshold of 16.78 derived from Youden's (J) index. ABIC = Age, Bilirubin, INR, Creatinine.

Figure:

**Conclusion:** The prognostic performance of ABIC+ELF (AUROC = 0.81) exceeded ABIC alone in STOPAH patients with AH. The addition of Lille allowed further refinement of survival-rates. Validation of ABIC-ELF may establish wide applicability of this test for prognosis in AH.

**PO-552**

**The landscape of mitochondrial dysfunction in circulating leukocytes of patients with acute-on-chronic liver failure is characterized by altered mitochondrial metabolism and structure**

Ingrid Wei Zhang<sup>1,2</sup>, Anna Curto<sup>2</sup>, Cristina López-Vicario<sup>1,2</sup>, Mireia Casulleras<sup>1,2</sup>, Marta Duran-Güell<sup>1,2</sup>, Roger Flores-Costa<sup>1,2</sup>, Ferran Aguilar<sup>2</sup>, María Hernández-Tejero<sup>3</sup>, David Toapanta<sup>3</sup>, Javier Fernandez<sup>2,3</sup>, Vicente Arroyo<sup>2</sup>, Joan Clària<sup>1,2,4</sup>. <sup>1</sup>Institut d'Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS), Barcelona, Spain; <sup>2</sup>European Foundation for the study of chronic liver failure, Barcelona, Spain; <sup>3</sup>Hospital Clínic de Barcelona, Liver ICU, Barcelona, Spain; <sup>4</sup>University of Barcelona, Department of Biomedical Sciences, Barcelona, Spain

Email: IWZHANG@clinic.cat.

**Background and aims:** Patients with acute decompensation (AD) of cirrhosis progressing to acute-on-chronic liver failure (ACLF) present a systemic hyperinflammatory response associated with increased levels of small molecule metabolites in the circulation. To investigate whether these alterations reflect inadequate cell energy output, we assessed mitochondrial morphology and central metabolic pathways with special emphasis on the tricarboxylic acid (TCA) cycle in peripheral leukocytes from AD patients with and without ACLF.

**Method:** Mitochondrial ultrastructure of circulating leukocytes from patients with AD cirrhosis and ACLF was visualized by transmission electron microscopy and compared to healthy subjects. Cytosolic and mitochondrial metabolic fluxes were determined in these cells by plate-based assays measuring NADH and FADH<sub>2</sub> production from various substrates.

**Results:** Mitochondrial ultrastructure in patients with AD cirrhosis was distinguished by cristae rarefaction and swelling. The number of mitochondria per leukocyte was higher in patients, accompanied by a reduction in their size. The severity of these morphological changes peaked in patients with ACLF. Mononuclear leukocytes from both AD and ACLF patients showed increased utilization of carbon and nitrogen sources to meet, preferentially through extra-mitochondrial pathways, the high-energy demand of inflammatory cells. In mononuclear leukocytes from ACLF patients, mitochondrial flux analysis uncovered two break-points in the TCA cycle at the isocitrate dehydrogenase and succinate dehydrogenase level, which were bridged by anaplerotic reactions involving glutaminolysis and nucleoside metabolism.

**Conclusion:** Our findings provide evidence at the organelle and biochemical level that severe mitochondrial dysfunction in leukocytes is a hallmark of patients with AD cirrhosis progressing to ACLF.

Figure: (abstract: PO-552)

**PO-675**  
**Increased incidence of respiratory failure with terlipressin use in patients with hepatorenal syndrome type 1 and severe acute-on-chronic liver failure**

Florence Wong<sup>1</sup>, Chris Pappas<sup>2</sup>, Rajender Reddy<sup>3</sup>, Hugo E. Vargas<sup>4</sup>, Michael Curry<sup>5</sup>, Khurram Jamil<sup>6</sup>, Arun Sanyal<sup>7</sup>. <sup>1</sup>University of Toronto, Medicine, Toronto, Canada; <sup>2</sup>Orphan Therapeutics, Lebanon, United States; <sup>3</sup>University of Pennsylvania, Medicine, Philadelphia, United States; <sup>4</sup>Mayo Clinic, Transplant Hepatology, Phoenix, United States; <sup>5</sup>Beth Israel Deaconess Medical Center, Gastroenterology, Boston, United States; <sup>6</sup>Mallinckrodt Pharmaceuticals, Critical Care Division, Bedminster, United States; <sup>7</sup>Virginia Commonwealth University, Internal medicine, Richmond, United States  
 Email: florence.wong@utoronto.ca.

**Background and aims:** The North American CONFIRM study (NCT02770716) for HRS1 suggests an increased incidence of respiratory failure (RF) in very ill patients with HRS1 treated with terlipressin. This study was to assess the incidence and predictive factors of RF in such patients treated with terlipressin vs. placebo.  
**Method:** 300 patients with HRS1 in the CONFIRM study were randomized in 2:1 ratio to terlipressin vs. placebo, 1–2 mg 6 hourly by bolus injection both with albumin. At enrollment, all patients were assessed for organ failure (OF) per EASL-CLIF criteria (Moreau et al. Gastroenterology 2013) and then classified into grades of acute-on-chronic liver failure (ACLF). All patients had at minimum grade 1 ACLF due to the presence of HRS 1; grades 2 and 3 ACLF represent 2 or 3 OFs respectively. This post-hoc analysis divided patients into grade ≤2

and grade 3 ACLF subgroups; the effects of terlipressin vs. placebo on the incidence of RF between these subgroups were compared.  
**Results:** 200 patients received terlipressin and 99 received placebo (1 patient was not dosed) with a group mean age of 53.8 ± 11.5 yrs, 60% male, median baseline serum creatinine 3.3 mg/dL, and median MELD 33. There were 49.7% vs. 40.6% with grade 1 ACLF, 30.2% vs. 40.6% with grade 2 ACLF, and 20.1% vs. 17.8% with grade 3 ACLF for the terlipressin and placebo arms respectively. The Table shows the incidence of RF between the treatment arms in the ACLF subgroups. The predictors of RF with terlipressin use were baseline INR (odds ratio or OR: 1.81, p = 0.011, baseline mean arterial pressure (OR: 1.037, p = 0.037) and baseline SpO<sub>2</sub> (OR: 0.835, p = 0.014). There was no difference in 90-day survival between the terlipressin and placebo arms for the ACLF grade ≤2 group (55.5% vs. 56.6% respectively).

Table: RF and death incidence by ACLF grade (\*p < 0.05 terlipressin vs. placebo)

	ACLF grade ≤2		ACLF grade 3	
	Terlipressin n = 160	Placebo n = 81	Terlipressin n = 40	Placebo n = 18
Any SAE	98 (61.3%)	48 (59.3%)	32 (80%)	12 (66.7%)
RF as SAE	15 (9.4%)	5 (6.2%)	12 (30%)*	0 (0%)
Death in 30 days	56 (35%)	31 (38.3%)	27 (67.5%)	9 (50%)
Dear from RF in 30 days	8 (5%)	1 (1.2%)	9 (22.5%)*	0 (0%)

For patients with ACLF grade 3, 90-day survival was significantly worse with terlipressin (27.5%) vs. placebo (50%), mainly related to RF. **Conclusion:** Terlipressin should be used with extreme caution in patients with HRS1 and ACLF grade 3, especially in those with compromised oxygen saturation, as they are at risk for RF and increased mortality.

**PO-968**

**Terlipressin improves renal replacement therapy-free survival in hepatorenal syndrome type 1**

Juan Carlos Q. Velez<sup>1</sup>, Alex Befeler<sup>2</sup>, Ira Kurtz<sup>3</sup>, Juan Gallegos-Orozco<sup>4</sup>, Hugo E. Vargas<sup>5</sup>, John M. Vierling<sup>6</sup>, S. Chris Pappas<sup>7</sup>, Khurram Jamil<sup>8</sup>. <sup>1</sup>Ochsner Health System, Department of Nephrology; <sup>2</sup>Saint Louis University, Division of Gastroenterology and Hepatology; <sup>3</sup>UCLA Medical Center, Division of Nephrology; <sup>4</sup>University of Utah, Division of Gastroenterology; <sup>5</sup>Mayo Clinic, Division of Gastroenterology and Hepatology; <sup>6</sup>Baylor College of Medicine, Section of Gastroenterology and Hepatology; <sup>7</sup>Orphan Therapeutics, Scientific Affairs; <sup>8</sup>Mallinckrodt Pharmaceuticals, Department of Scientific Affairs  
Email: juan-carlos.velez@ochsner.org.

**Background and aims:** Hepatorenal syndrome type 1 (HRS-1) is an ominous form of acute kidney injury in patients with decompensated cirrhosis. Recently, the results of the randomized placebo (PBO)-controlled trial (RCT) CONFIRM demonstrated that terlipressin (TERLI) is effective in reversing HRS-1 and in reducing the cumulative need for renal replacement therapy (RRT). However, whether TERLI reduces the need for RRT among survivors has not been determined. **Method:** CONFIRM (NCT02770716) was a North American RCT (N = 300) that compared HRS-1 reversal rates between patients treated with albumin plus TERLI (n = 199) vs. albumin plus PBO (n = 101) (2:1). We conducted a post hoc intention-to-treat analysis to assess the incidence of RRT among CONFIRM survivors to assess longer term benefit. We also conducted a pooled analysis of the 3 TERLI RCTs in HRS-1 (OT-0401 [NCT00089570], REVERSE [NCT01143246], and CONFIRM) to examine 90-day RRT-free survival rates.

**Results:** In CONFIRM, the cumulative incidences of need for RRT for TERLI at day 14, 30, and 90 were 23%, 26%, and 29% compared with 35%, 36%, and 39% for patients assigned to PBO (p = 0.03, 0.07, and 0.1, respectively). Among survivors, significantly fewer TERLI-treated patients remained dependent on RRT at day 14, 30, and 90 (22%, 26%, and 30%, respectively) compared with PBO (39%, 43%, and 46%; p < 0.01, p = 0.03, and p = 0.05, respectively). The 90-day RRT-free survival rate was 35% in the TERLI group vs 30% in the PBO group (p = 0.08), with a numerically longer median number of days in the TERLI group (20 vs 11). Pooled analysis of the 3 RCTs revealed a greater 90-day RRT-free survival rate for TERLI-treated (n = 352) compared with PBO-treated (n = 256) patients (37% vs 29%, p = 0.03; OR [95% CI], 1.47 [1.04, 2.07]).

**Conclusion:** Treatment with TERLI plus albumin decreased the rate of RRT and improved RRT-free survival in survivors with HRS-1. This is the first pharmacological intervention proven to reduce the need for RRT in patients with HRS-1. Because of the significant impact of RRT on quality of life and risk of infections, this observation expands the clinical benefit of TERLI and enhances the reported efficacy of TERLI in inducing HRS-1 reversal.

**PO-984**

**Hepatopulmonary Syndrome is related with the Development of Acute-on Chronic Liver Failure and Poor prognosis in Cirrhotic patients**

Han Seul ki<sup>1</sup>, Moon Young Kim<sup>1</sup>, Seong Hee Kang<sup>1</sup>, Soon Koo Baik<sup>1</sup>. <sup>1</sup>Wonju Severance Christian Hospital, Department of Internal Medicine, Division of Gastroenterology and Hepatology, Weonju, Korea, Rep. of South  
Email: baiksk@yonsei.ac.kr.

**Background and aims:** Hepatopulmonary syndrome (HPS) is characterized as a defect in arterial oxygenation caused by pulmonary vascular dilatation in the setting of chronic liver disease. The long-term prospective data for hepatopulmonary syndrome (HPS) including large number of patients is lacking especially in Asian. We evaluated the long-term prognosis of HPS, especially the development of acute-on chronic liver failure (ACLF) in HPS and related factors.

**Method:** A total of 142 patients with cirrhosis who had been undertaken saline agitated contrast echocardiography to diagnose HPS were enrolled and observed prospectively. The cohort based on our previous study who were followed until December, 2019. All events related with cirrhosis including liver transplantation were recorded and monitored.

**Results:** Median follow-up period was 27 months. 59 patients (41%) were diagnosed as HPS (grade 1 = 24, grade 2 = 23, grade 3 = 12). There were 38 cases of mortality in HPS group and 37 cases were in Non-HPS group (p < 0.01). 5-year survival rate was 47% in HPS group and 62% in non-HPS group. During the study period, 9 patients in non-HPS and 8 patients in HPS were not followed. 5 patients of HPS and 4 patients of non-HPS underwent liver transplant.

In Cox proportional hazards model, HPS and Modified End stage Liver Disease (MELD) score above 18, Child-Turcotte-Pugh (CTP) class B/C were statistically significant risk factors of mortality after adjusting other risk factors (HPS Hazard ratio (HR) = 1.9, p = 0.01; MELD ≥ 18 HR = 2.3, p < 0.01; CTP class B/C HR = 2.9, p < 0.01). In HPS group, CTP class B/C and MELD score above 18 were independent risk factors of mortality (CTP B/C HR = 1.5, 95% CI = 0.5–4.3, p = 0.45; MELD ≥ 18 HR = 2.68, 95% CI = 1.3–5.4, p < 0.01). In additional analysis, the development of ACLF during follow-up was significantly higher in patients with HPS (p < 0.01) and there was more frequent lung involvement of ACLF in HPS group (p = 0.03).

**Conclusion:** In long-term follow-up cohort, patients with HPS showed a poor prognosis compared to non-HPS patients. HPS is a risk factor for the ACLF development independently with hepatic dysfunction and the lung involvement was more common.

**PO-1161**

**Impact of INFECTIONS on the post-operative survival of ACUTE-ON-CHRONIC LIVER FAILURE patients undergoing LIVER TRANSPLANTATION**

Elina Lam<sup>1</sup>, Antonella Putignano<sup>1</sup>, Valerio Lucidi<sup>2</sup>, Desislava Germanova<sup>2</sup>, Antonia Lepida<sup>1</sup>, Trépo Eric<sup>1</sup>, Nathalie Boon<sup>1</sup>, Lukas Otero-Sanchez<sup>1</sup>, Mohamed Zerriouh<sup>1</sup>, Elisa Brauns<sup>3</sup>, Degré Delphine<sup>1</sup>, Christophe Moreno<sup>1</sup>, Thierry Gustot<sup>1</sup>. <sup>1</sup>CUB Hospital Erasme, Gastroenterology, Hepato-Pancreatology and Digestive Oncology, Bruxelles, Belgium; <sup>2</sup>CUB Hospital Erasme, Digestive and Hepatobiliary Surgery, Bruxelles, Belgium; <sup>3</sup>CUB Hospital Erasme, Internal Medicine, Bruxelles, Belgium  
Email: putignano.anto@gmail.com.

**Background and aims:** The prevalence of infections in patients with acute-on-chronic liver failure (ACLF) is high (Fernandez *et al*, Gut 2018), however the role of sepsis on the outcome of ACLF patients undergoing liver transplantation (LT) is currently unknown. In this single center, retrospective study, we investigated the role of infections and septic shock on post-LT outcome of patients with ACLF.

**Method:** Consecutive ACLF patients transplanted in a tertiary Belgian center between 2007 and 2017 were included (EASL-Clif definition).

## POSTER PRESENTATIONS

To evaluate the outcomes, patients were stratified according with the presence of an active but controlled infection 24 hours before LT, defined as an infection treated by antibiotics since at least 48 hours and with stable or improving vasopressors doses in case of shock. Kaplan Meier analysis (Log Rank) was used to estimate cumulative survival and Cox Regression for univariate analysis.

**Results:** Ninety-six patients with ACLF were transplanted (female N = 35, age  $54 \pm 9.9$ ), 26 ACLF-1, 25 ACLF-2 and 45 ACLF-3. Forty-three patients (44.8%) had an infection before LT, 1 ACLF-1 (3.8%), 12 ACLF-2 (48.0%) and 30 ACLF-3 (66.7%). Patients with pre-LT infections had longer post-LT ICU in-stay (7 days, IQR 7) compared to non-infected ones (4 days, IQR 4,  $p = 0.028$ ). The post-LT survival rate of patients with and without infection was 88.4% and 100% at 28-day ( $p = 0.011$ ), 81.4% and 96.2% at 90-day ( $p = 0.016$ ), 72.1% and 88.5% at 1-year ( $p = 0.033$ ) post-LT, respectively. The causes of 90-day post-LT mortality were septic shock (30%), hemorrhagic shock (20%), invasive aspergillosis (10%), cardiac arrest (10%), other cause (20%) and unknown (10%). Risk factors for 90-day mortality in patients with infection at LT were pre-surgical bilirubin level (HR 1.08, CI 1.02–1.14,  $p = 0.009$ ), MELD score (HR 1.10, CI 1.02–1.19,  $p = 0.01$ ), arterial lactates (HR 1.3, CI 1.0–1.6,  $p = 0.017$ ), CLIF-C ACLF score (HR 1.08, CI 1.01–1.17,  $p = 0.033$ ), septic shock (HR 5.32, CI 1.27–22.29,  $p = 0.22$ ), Quick-SOFA score (HR 2.95, CI 1.27–6.86,  $p = 0.012$ ). However, length of antibiotic treatment before LT and MDR bacteria or fungi infections or colonization during the 6 months before LT were not associated with higher mortality.

**Conclusion:** Patients with active but controlled infection at LT show an increased short- and medium-term mortality. However, mortality risk factors are related both to sepsis and to ACLF severity and should be considered to avoid LT futility.

### PO-1387

#### Plasma Soluble CD14 predicted development of hospital acquired infection in decompensated cirrhosis patients from the ATTIRE trial

Louise China<sup>1</sup>, Natalia Becares<sup>1</sup>, Thais H. Tittanegro<sup>1</sup>, Camilla Rhead<sup>1</sup>, Alastair O'Brien<sup>1</sup>. <sup>1</sup>University College London, United Kingdom  
Email: louise.china@ucl.ac.uk

**Background and aims:** Patients with decompensated cirrhosis hospitalised with acute complications have high incidences of hospital-acquired infection (HAI), often with multi-drug resistant organisms (MDRO) leading to high mortality. Empiric/prophylactic antibiotics in the absence of positive microbial culture results can reduce infection and death in certain settings, e.g. variceal bleeding, yet indiscriminate prescribing increases risk of MDROs. A balance is needed, but current antibiotic strategies for decompensated patients are homogenous, leading to overprescribing to mitigate risk of missing infection. However, decompensated cirrhosis is heterogeneous and a precision-approach based on individualised risk could be beneficial. We tested whether serological biomarkers of infection could identify patients at high risk of HAI to aid antimicrobial stewardship. Using samples from the ATTIRE trial we compared the ability of selected serological biomarkers to predict development of HAI in these acutely unwell patients.

**Method:** HAI, defined as new infection >48 hr after trial entry, was diagnosed according to site clinicians' judgement with infection case report forms containing clinical, biochemical, microbiological and radiological data was blindly scrutinized by 3 independent physicians. 135 randomly selected patients (76 without and 59 with new infection) had plasma samples analysed at trial days 1 and 5 using a luminex multiplex assay with WCC and CRP measured at site.

**Results:** Patients were mostly male with alcoholic cirrhosis, mean MELD score 20.2 (SD 7.0) and median age 53.9 years. Overall 177 new infections were diagnosed from 828 randomisations with respiratory infection most commonly diagnosed. Only 44/177 (24.9%) of these new infections were culture positive with only 6/55 (10.9%) of respiratory infections being culture positive. The mean trial treatment day on which patients developed a new infection was 6 (SD 2.5).

Plasma soluble CD14 and WCC was significantly higher at day 5 in patients that were diagnosed with HAI during the trial compared to those not (13, 596 ng/ml vs 5746 ng/ml,  $p = 0.0094$ , CI 1975–13, 727 ng/ml and  $11.4 \times 10^9/L$  vs  $8.9 \times 10^9/L$ ,  $p = 0.0361$ , CI 0.1608–4.743). Conversely, there were no significant differences in Procalcitonin, plasma Calprotectin, Lipopolysaccharide Binding Protein, CRP, CD163 or CCL8 between patients that received HAI diagnosis or not when day 1 or 5 samples were compared.

**Conclusion:** Only increasing plasma soluble CD14 values during hospitalisation, which mediates immune responses to Lipopolysaccharide via monocyte and macrophage activation, and WCC were able to predict decompensated cirrhosis patients at high risk of developing HAI and could be used to aid appropriate antibiotic prescribing.

### PO-1501

#### Ascitic fluid lactic acid is an accurate predictor of mortality in patients with spontaneous bacterial peritonitis

Ilianna Mani<sup>1</sup>, Alexandra Alexopoulou<sup>1</sup>, Theodoros Alexopoulos<sup>1</sup>, Larisa Vasilieva<sup>1</sup>, Emilia Hadziyannis<sup>1</sup>, Danaï Agiasotelli<sup>1</sup>, P. Spyridon Dourakis<sup>1</sup>. <sup>1</sup>Medical School, National and Kapodistrian University of Athens, 2nd Department of Internal Medicine and Research Laboratory, Athens, Greece  
Email: ilianamani@windowslive.com

**Background and aims:** Elevated blood lactic acid was found to predict accurately mortality in severely ill patients with cirrhosis, especially in acute-on-chronic liver failure (ACLF). In the present study, ascitic fluid lactic acid (AFlac) was evaluated as potential predictor of short-term mortality in patients with spontaneous bacterial peritonitis (SBP).

**Method:** Sixty-three consecutive patients with SBP (SBP group), 50 patients without SBP but with acute event (AD/ACLF group) and 12 with decompensated cirrhosis without acute event (DC) (control group) were prospectively studied. AFlac was measured in the first paracentesis of AF on admission using GEM Premier 3500 analyzer (Instrumentation Laboratory, Lexington, USA).

**Results:** Characteristics of SBP group were: 68.3% male, median age 60 (IQR 54–72) years, MELD score 17 (12–29), ACLF 34.9%. AFlac levels were higher in SBP group compared to AD/ACLF or control group ( $p < 0.001$  or  $p < 0.001$ , respectively). In SBP group, ROC curve for 30 days showed that AFlac value of 3.5 mmol/ml was associated with the best prediction of mortality [c-statistic = 0.894, 72% sensitivity, 89.5% specificity, 81.8% positive predictive value (PPV), 82.9% negative predictive value (NPV)]. In Kaplan-Meier curve, patients with high AFlac ( $\geq 3.5$  mmol/ml) had a poor prognosis in 30 days compared to those with low values ( $< 3.5$  mmol/ml) (log-rank  $P = 0.001$ ). In 90 days, prognostic accuracy of AFlac was further enhanced (c-statistic 0.927) with the optimal value at 2.25 mmol/l (93.9% sensitivity, 83.3% specificity, 86.1% PPV, 92.6% NPV).

In multivariate analysis for 30 days, only AFlac [hazard ratio (HR) 1.443, (95% confidence interval -CI 1.146–1.817),  $P = 0.002$ ] and NLR [HR 1.075 (95%CI 1.027–1.125),  $P = 0.002$ ] were independent predictors of mortality after adjusting for age, sex, MELD score and C-reactive protein. The same parameters [HR 1.503 (95%CI 1.193–1.893), ( $p = 0.001$ ) and HR 1.078 (95%CI 1.032–1.127), ( $p = 0.001$ ), respectively] emerged again at 90 days as independent predictors of mortality.

**Conclusion:** Ascitic fluid lactic acid was increased in patients with SBP and was an accurate predictor of short-term mortality. Ascitic fluid lactic acid and NLR were independently associated with mortality in spontaneous bacterial peritonitis.

**PO-1585**

**Potential mechanisms underlying the protective effect of long-term albumin infusion in cirrhosis**

Qianwen Zhao<sup>1,2</sup>, Abeba Habtesion<sup>1</sup>, Fausto Andreola<sup>1</sup>, Nathan Davies<sup>1</sup>, Jane Macnaughtan<sup>1</sup>, Rajiv Jalan<sup>1</sup>. <sup>1</sup>University College London, Institute for Liver and Digestive Health, London, United Kingdom; <sup>2</sup>Department of Gastroenterology and Hepatology, West China Hospital, Sichuan University, Chengdu, China  
Email: r.jalan@ucl.ac.uk.

**Background and aims:** The mechanisms preventing hepatic decompensation and mortality (Lancet 2018;391:2417) following long-term albumin infusion in cirrhosis is unknown. Increased hepatocyte expression of TLR4 in cirrhosis sensitises patients to the 'second hit' resulting in acute on chronic liver failure (ACLF). The aims of this study were to determine (i) whether analbuminaemic (NAR) rats have greater liver injury and sensitivity to LPS (ii) whether albumin infusion is protective in NAR rats (iii) the impact of analbuminaemia and albumin infusion on the gut-liver interface and hepatic TLR4 signaling.

**Methods:** 10 groups of NAR and SD rats were studied (n=4-7 in each group); Naïve, cirrhosis (4-w after bile duct ligation (BDL) and ACLF models (induced by lipopolysaccharide (LPS) to BDL) were studied. BDL groups: ±LPS, ±albumin infusion (1.5 g/kg i.p. for 2 weeks). Markers of liver injury: plasma ALT level and TUNEL staining; markers of gut integrity and permeability: DAB immunohistochemistry ZO-1 expression in ileum and colon tissue; Hepatic TLR4 immunohistochemistry and related pathway genes RT<sup>2</sup> PCR profiler were studied.

**Results:** *Liver injury:* ALT levels and TUNEL positive areas were significantly higher in NAR compared with SD rats (p = 0.01 and p = 0.01), which were corrected with albumin infusion (p = 0.02, p = 0.047). *Effect of LPS administration:* coma-free survival was higher in SD rats than NAR rats (80% vs 40%). *Effect of albumin administration:* Administration of albumin to BDL rats reduced severity of liver injury and mortality after LPS administration [p = 0.001; 40% vs 100%, p = 0.04]. *Markers of gut permeability:* In NAR rats, the histopathological examination of the ileum and colon revealed severe distortion and reduction in ZO-1 expression, which was restored with albumin supplementation (Fig). *Hepatic expression of TLR4 and associated pathways:* Cirrhotic NAR animals had greater hepatic TLR4 expression which was reduced by albumin administration. Hepatic TLR4 gene array confirmed the activation of TLR4 dependent pathways in the cirrhotic NAR animals, which was abrogated by albumin infusion.

**Conclusion:** NAR animals have significantly greater liver injury, increased sensitivity to LPS and mortality which is prevented by albumin administration. Our data show for the first time that the mechanism of the protective effect of albumin is consequent upon restoration of gut junctional proteins and reduction of hepatic TLR4 expression.

Figure 1: TLR4 qPCR data.

TLR4 qPCR was performed and its relative expression was studied using the DDcT method and delineated in a log<sub>2</sub> scale. TLR4 was

upregulated in cirrhotic and ACLF NAR groups compared to SD controls. Albumin administration reduced TLR4 expression in cirrhotic and ACLF groups, in both NAR and SD species.

Figure 2: Gut ZO-1 immunohistochemistry showed ZO-1 was downregulated in NAR naïve group. Albumin infusion restored ZO-1 expression.

**Stem Cell Transplantation in patients with cirrhosis and acute-on-chronic liver failure: A randomized, double-blind placebo control trial**

Enric Reverter<sup>1</sup>, Adria Juanola<sup>1,2</sup>, Verónica Prado<sup>1</sup>, Jordi Gratacós-Gines<sup>1</sup>, Pedro Marin<sup>3</sup>, Enrique J. Andreu<sup>4</sup>, Fatima Aziz<sup>1</sup>, Octavi Bassegoda<sup>1,2</sup>, Isabel Graupera<sup>1,2,5,6</sup>, Elisa Pose<sup>1,2,5</sup>, Javier Fernandez<sup>1</sup>, Pere Ginès<sup>1,2,5,6</sup>. <sup>1</sup>Hospital Clínic de Barcelona, Liver Unit, Barcelona, Spain; <sup>2</sup>Institut d'Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS), Barcelona, Spain; <sup>3</sup>Hospital Clínic de Barcelona, Hematology Department, Barcelona, Spain; <sup>4</sup>Clinica Universidad de Navarra, Cell Therapy Area, Pamplona, Spain; <sup>5</sup>Centro de Investigación Biomédica en Red de Enfermedades Hepáticas y Digestivas (CIBEREHD), Madrid, Spain; <sup>6</sup>Facultat de Medicina, Universitat de Barcelona, Barcelona, Spain  
Email: pginès@clinic.cat.

**Background and aims:** Acute-on-chronic liver failure (ACLF) is associated with high mortality and does not have a specific treatment beyond transplantation. Administration of Mesenchymal Stem Cells (MSCs), with immunomodulatory and pro-regenerative properties, could be a potential treatment for ACLF. The present study evaluates the efficacy and safety of MSCs administration in patients with ACLF. **Method:** Double-blind, placebo-controlled, randomized clinical trial (1:1) evaluating the effects of MSCs infusion in patients with ACLF. 2 × 10<sup>6</sup> MSCs/kg weight were administered on days 1, 4, 11 and 18. Changes in liver function, organ failure according to specific scales (CLIF-OF, CLIF-C ACLF, MELD), inflammatory cytokines and safety of MSCs infusion were assessed. Patients were followed 1-year.

**Results:** Twenty-three patients (78% men, mean age 54 years) with predominant alcohol etiology (69%) were included. Causes of admission were alcoholic hepatitis (57%), infection (22%), hemorrhage and others (21%). Eleven (48%) patients had grade I ACLF, 8 (35%) grade II and 4 (17%) grade III, with predominance of liver failure (96%), coagulation (35%) and renal failure (26%). The baseline CLIF-OF and MELD scores were 10 (10–12) and 32 (29–35). Fourteen (61%) patients received MSCs and 9 (39%) placebo. No differences in liver score changes (CLIF-OF, CLIF-C ACLF or MELD) were observed at days 7, 14, 18 or 28. No significant differences in leukocyte count or CRP were observed between groups at days 7, 14, 18 and 28. There were 5 infections in 3 patients (33%) of the control group and 8 in 6 patients (43%) of the MSCs group. Survival was not different between groups at 28 days (MSCs 50% vs. placebo 56%), 90 day (21% vs 44%) and 365 days (MSCs 21% vs. placebo 33%). Adverse events were similar between groups and mostly attributable to cirrhosis.

## POSTER PRESENTATIONS

Figure:

**Conclusion:** In this pilot study, the administration of MSCs in patients with ACLF compared to placebo did not show an improvement in parameters of hepatic dysfunction or severity of ACLF. The infusion of MSCs was a safe and well tolerated intervention.

### PO-2147

#### Intestinal epithelial cell signalling and cell death in Cirrhosis and Acute-on-Chronic Liver Failure

Stijn Aaron den Daas<sup>1,2</sup>, Ugo Soffientini<sup>1,2</sup>, Abeba Habtesion<sup>3</sup>, Bethlehem Arefaine<sup>1,2</sup>, Roger Williams<sup>1,2</sup>, Sukriti Sukriti<sup>4</sup>, Rajiv Jalan<sup>3</sup>, Shilpa Chokshi<sup>1,2</sup>, Vishal C. Patel<sup>1,2,5</sup>, Gautam Mehta<sup>1,2,3</sup>. <sup>1</sup>Institute of Hepatology, Foundation for Liver Research, London, United Kingdom; <sup>2</sup>King's College London, Faculty of Life Sciences and Medicine, London, United Kingdom; <sup>3</sup>UCL Institute for Liver and Digestive Health, London, United Kingdom; <sup>4</sup>Institute of Liver and Biliary Sciences, New Delhi, India; <sup>5</sup>Institute of Liver Studies, King's College Hospital NHS Foundation Trust, London, United Kingdom  
Email: s.dendaas@researchinliver.org.uk.

**Background and aims:** The precipitating event that drives the progression from cirrhosis to acute-on-chronic liver failure (ACLF) remains unidentified in around a third of cases (Moreau *et al.*, 2013). Endogenous mechanisms, such as translocation of gut-derived products, have been suggested to play a role in these cases but the molecular mechanisms remain unknown. Recent work has highlighted intestinal epithelial cell-derived extracellular vesicles (EVs)

(Bulek *et al.*, 2020), and intestinal epithelial cell death (Zheng *et al.*, 2019), as key steps in propagating intestinal inflammation and permeability. The aim of this study was to investigate EV signalling and cell death in intestinal epithelial cells, in response to bacterial LPS and ACLF patient faecal samples.

**Method:** Intestinal organoids were derived from healthy female C57BL/6J mice and cultured in mouse intestinal organoid medium as described (Sato *et al.*, 2011). Two experiments were undertaken: (i) organoids (n = 4/group) were treated with 100 µg/ml LPS, or control media, for 3 hours; (ii) organoids were treated with 10% human faecal samples from healthy controls (HC, n = 4), ACLF patients (n = 4, median ACLF grade = 3 IQR = 1–3), or control media (n = 4) for 3 hours. Supernatants from experiment (i) were analysed for EV release using Zetaview Nanoparticle Tracking Analyser. Samples from (ii) were analysed for lytic cell death, measuring supernatant LDH (Promega LDH-Glo) and by immunofluorescence [HOECHST, propidium iodide (PI)].

**Results:** (i) Treatment of mouse intestinal organoids with 100 µg/ml LPS for 3 hours causes a significant increase in EV release compared to control ( $5.73 \times 10^9 \pm 1.89 \times 10^9$  vs  $1.23 \times 10^{10} \pm 7.20 \times 10^9$  particles/ml, n = 4, p = 0.025); (ii) treatment of organoids with 10% ACLF faecal samples for 3 hours causes a significant increase in LDH release compared to 10% HC ( $650.9 \pm 190.2$  vs  $259.9 \pm 91.6$ , n = 4, p < 0.05). Immunofluorescence demonstrates increased PI staining in 10% ACLF group compared with control (figure).

**Conclusion:** These data present potential mechanisms for propagation of intestinal inflammation, intestinal cell death and consequently gut-liver signalling of PAMPs and DAMPs in cirrhosis and ACLF. Future studies will delineate the specific inflammasome and cell death pathways involved in these responses. These findings pave the way for targeted molecular therapies to mitigate intestinal inflammation and onset of ACLF in cirrhosis.

### PO-2313

#### IL-1Ra, IL-18 and TREM-1 circulating factors and CD+ve HLADR-low TIM3+ve suppressive monocytes predict development of sepsis within 3 days in patients with acute on chronic failure

Pushpa Yadav<sup>1</sup>, Rakesh Kumar Jagdish<sup>2</sup>, Rashi Sehgal<sup>1</sup>, Rakhi Maiwall<sup>2</sup>, Vijayraghavan Rajan<sup>2</sup>, Ravinder Chaudhary<sup>1</sup>, Mojahidul Islam<sup>1</sup>, Sukriti Sukriti<sup>1</sup>, Deepanshu Maheshwari<sup>1</sup>, Anupam Kumar<sup>1</sup>, Gayatri Ramakrishna<sup>1</sup>, Nirupma Trehanpati<sup>2</sup>, Shiv Kumar Sarin<sup>2</sup>. <sup>1</sup>Institute of Liver and Biliary Sciences, Molecular and Cellular Medicine, New Delhi, India; <sup>2</sup>Institute of Liver and Biliary Sciences, Hepatology, New Delhi, India  
Email: shivsarin@gmail.com.

**Background and aims:** Acute on Chronic Liver Failure (ACLF) patients with systemic inflammatory response (SIRS) have high probability to develop sepsis due to immune dysregulation. There are no early biomarkers of development of sepsis in setting of ACLF. We aimed to investigate dynamics of new circulating biomarkers and monocyte functions overtime in patients with ACLF.

Figure: (abstract: PO-2147): Immunofluorescent staining of mouse intestinal organoids treated with faecal samples. Mouse intestinal organoids were treated with control media, 10% healthy control faecal sample, or 10% ACLF faecal sample for 3 hours. Organoids were washed and incubated for another 24 hours before HOECHST (blue) and propidium iodide (red) staining. Representative images shown.

**Method:** Ninety eight ACLF patients; without clinical SIRS [Group I: (n=25)] with SIRS but no sepsis [Group II: (n=35)] and with sepsis [Group III: (n=38)] and healthy controls (Group IV, n=15) were included. Patients were closely followed from admission and studied at baseline, 6 and 24 hr, day 3 and 7. We measured 40 plasma cytokines using cytokine bead assay and studied HLA-DR expression, phagocytosis, oxidative burst capacity and METosis in monocytes. Monocyte-T cell co-culture assays were done to explore the PD-L1, PD-L2, TIM-3+ve suppressive monocytes regulating T-cells functionality. Clinical correlations of immune dysregulation were determined.

**Results:** ACLF patients (aged 57 ± 6 yr, 70% males, 94% with alcoholic cirrhosis) had MELD of 28 median with range 14–47). At admission, HGF, IL-6, IL-8, MIF, MIP3a and MMP7 was significantly increased (p < 0.01) in Gr.I compared to healthy; Gr.II had increased IL-8, MIP-3a,

MCP-1, VEGFa, compared to Gr.I (p < 0.05). Gr. III had significantly raised (p < 0.001) levels of IL-1Ra, IL-18, and TREM1. Out of 25, 5 patients from Grp. II, developed sepsis within 2–3 days and showed raised levels of IL-1Ra (from 1203 to 35,000 pg/ml), IL-18 (48 to 114 pg/ml), and TREM1 (1273 to 4865 pg/ml) within 1224 hrs of admission. Circulating monocytes showed reduced HLA-DR expression at admission and during hospitalisation till Day 7 but significantly gained the suppressive phenotype with PDL1 and Tim3 expression (p < 0.05) and increased METosis in SIRS and sepsis patients.

**Conclusion:** This prospective study suggests that elevated levels of IL-1Ra, IL-18, TREM1, and TIM3+positive suppressive monocytes can be used as hallmark of sepsis within 12–24 hrs to discriminate ACLF SIRS from sepsis.

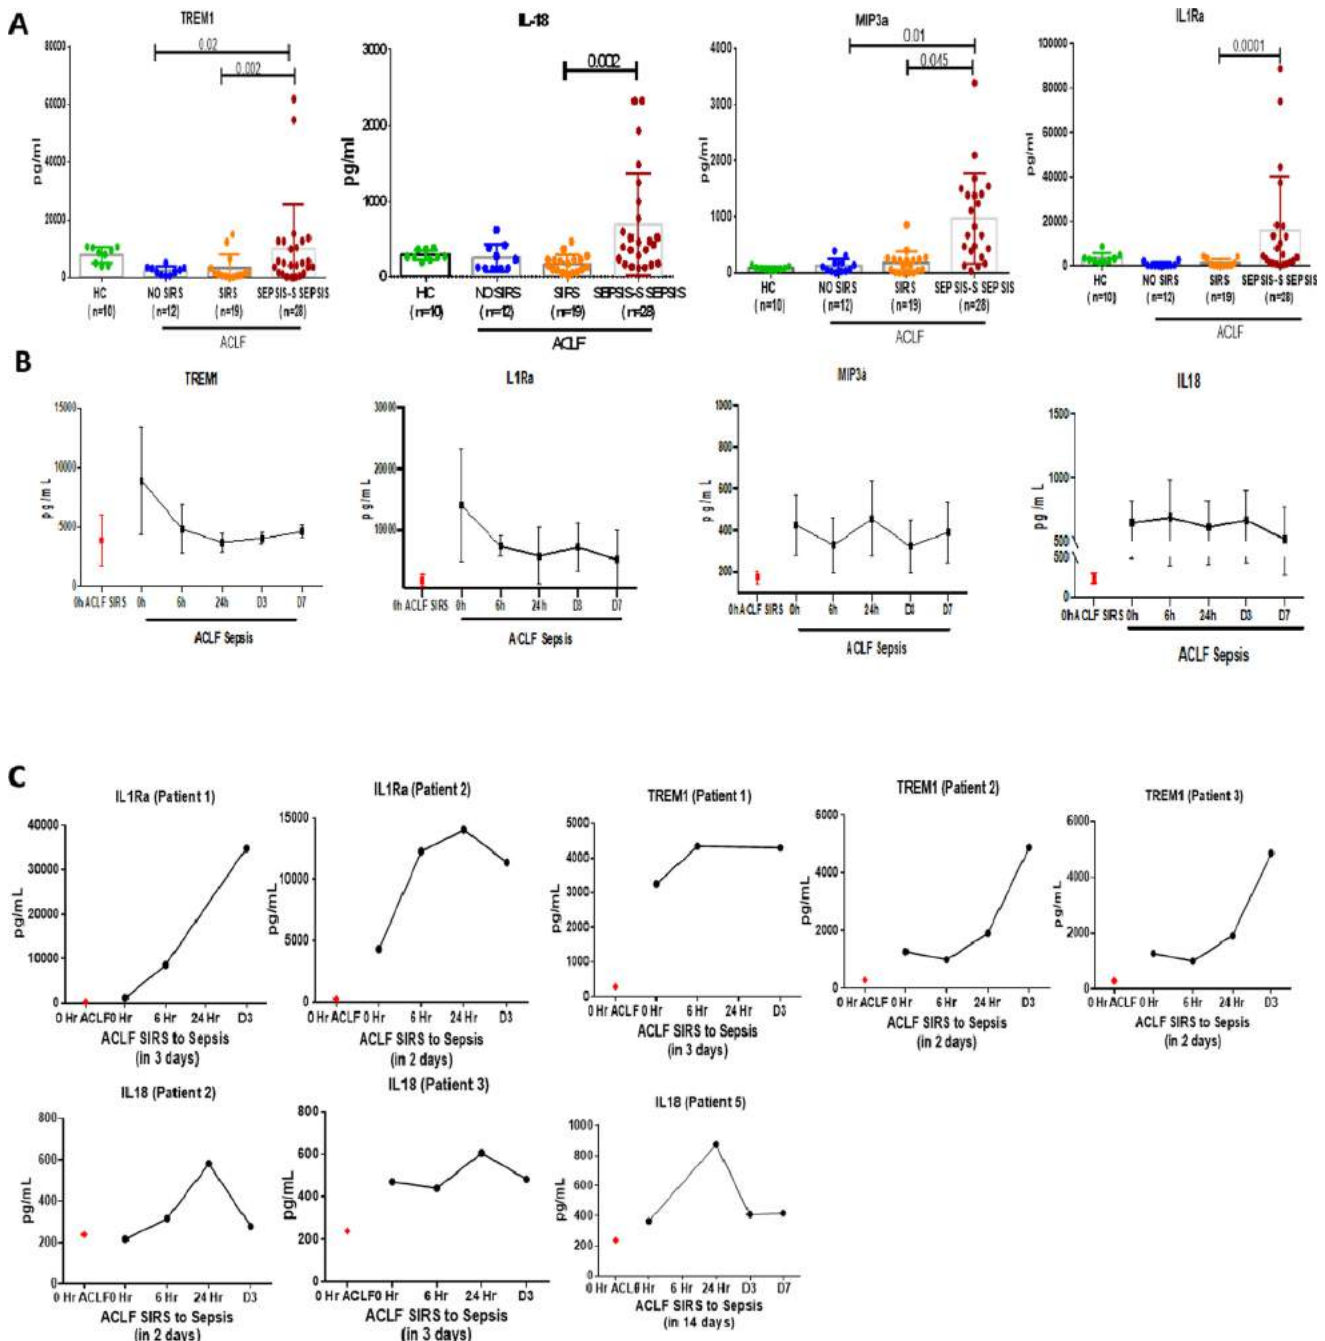

Figure: (abstract: PO-2313)

PO-2358

### Modification of the CLIF-C ACLF score improves the predictive accuracy by adjusting for risk factors mechanical ventilation and pulmonary failure

Martin Schulz<sup>1</sup>, Jan Mengers<sup>1</sup>, Philip Ferstl<sup>1</sup>, Frank Uschner<sup>2</sup>, Nora Ackermann<sup>2</sup>, Georg Guttenberg<sup>2</sup>, Wenyi Gu<sup>2</sup>, Alexander Queck<sup>2</sup>, Maximilian Brol<sup>2</sup>, Christiana Graf<sup>2</sup>, Anna-Lena Laguna de la Vera<sup>2</sup>, Stoffers Philipp<sup>2</sup>, Cremonese Carla<sup>2</sup>, Hans-Peter Erasmus<sup>2</sup>, Martin-Walter Welker<sup>2</sup>, Achim Grünewaldt<sup>2</sup>, Jörg Bojunga<sup>2</sup>, Stefan Zeuzem<sup>2</sup>, Kai Hendrik Peiffer<sup>3</sup>, Christoph Welsch<sup>2</sup>, Gernot Rohde<sup>2</sup>, Jonel Trebicka<sup>2</sup>. <sup>1</sup>Universitätsklinikum Frankfurt am Main, Medizinische Klinik 1, Frankfurt am Main, Germany; <sup>2</sup>Universitätsklinikum Frankfurt am Main, Medizinische Klinik 1, Frankfurt am Main; <sup>3</sup>Medizinische Klinik 1, Frankfurt am Main  
Email: martin.schulz2@kgu.de.

**Background and aims:** Adequate risk stratification is essential in ACLF patients, since ACLF is associated with high short-term mortality. The CLIF-C ACLF score is the superior prognostic model to predict short-term mortality in ACLF patients. This study aims to evaluate, if its predictive accuracy can be improved by adjusting for pulmonary impairment.

**Method:** Retrospectively, data from 498 patients with cirrhosis, admitted to IMC/ICU between March 2015 and June 2019 were collected. ACLF was defined according to EASL-CLIF criteria. To better dissect the role of pulmonary impairment, we performed a 1:1:1 propensity score matching of 147 patients with ACLF either combined with mechanical ventilation (MV), pulmonary failure (PF, PaO<sub>2</sub>/FiO<sub>2</sub> < 200 mmHg) or unimpaired ventilation, adjusting for CLIF-C ACLF score and sex. Cox regression and ROC analysis were performed to evaluate predictive performances of scores.

**Results:** In the whole cohort (n=498) MV and PF (PaO<sub>2</sub>/FiO<sub>2</sub> < 200mmHg) were identified as independent risk factors of mortality. Already 28-day mortality rates were significantly higher in ACLF patients with PF (83.7%) or MV (67.3%) compared to matched ACLF-noMV/noPF (38.8%). ROC analysis confirmed superior predictive accuracy of the CLIF-C ACLF score (28d AUROC=0.8; n=489) but showed poor prediction in patients with ACLF-PF (AUROC=0.49) or ACLF-MV (AUROC=0.66). We adjusted the CLIF-C ACLF score for presence/absence of MV/PF (CLIF-C ACLF-R score), resulting in an improved predictive performance not only in ACLF-patients (AUROC = 0.84 vs. 0.77), but also in cirrhosis overall (AUROC = 0.87 vs. 0.81, see Figure 1).

Figure:

**Conclusion:** While CLIF-C ACLF score underestimates the risk of mechanical ventilation and pulmonary failure in ACLF patients, adjusting for pulmonary impairment can improve the overall predictive accuracy of the CLIF-C ACLF score. Although the modified CLIF-C ACLF score needs to be independently validated, it may be useful to stratify care in decompensated cirrhosis.

PO-2547

### CLIF-SOFA accurately predicts in-hospital mortality in patients with cirrhosis and bacterial infection

Minjong Lee<sup>1</sup>, Ji Hyun Kim<sup>2</sup>, Baek Gyu Jun<sup>3</sup>, Tae Suk Kim<sup>2</sup>, Seong Hee Kang<sup>4</sup>, Ki Tae Suk<sup>5</sup>, Moon Young Kim<sup>4</sup>, Young Don Kim<sup>6</sup>, Gab Jin Cheon<sup>6</sup>, Soon Koo Baik<sup>4</sup>, Dong Joon Kim<sup>5</sup>, Dae Hee Choi<sup>2</sup>. <sup>1</sup>College of Medicine, Ewha Womans University, Korea, Rep. of South; <sup>2</sup>Kangwon National University School of Medicine; <sup>3</sup>Sanggye Paik Hospital; <sup>4</sup>Wonju Severance Christian Hospital; <sup>5</sup>Chuncheon Sacred Heart Hospital; <sup>6</sup>Gangneung Asan Hospital  
Email: minjonglee2@naver.com.

**Background and aims:** Sepsis-3 criteria and the quick Sequential Organ Failure Assessment (qSOFA) have been advocated to define sepsis in the general population. However, these criteria may have certain limitations that fail to reflect liver failure in patients with cirrhosis. We aimed to compare Sepsis-3 criteria and Chronic Liver Failure-SOFA (CLIF-SOFA) scores as predictors of in-hospital mortality in patients with cirrhosis and bacterial infections.

**Method:** Overall, 1,622 consecutive Asian patients with cirrhosis and bacterial infections were assessed for retrospective analysis, examining demographic, laboratory, and microbiologic data at diagnosis of infection. The primary endpoint was in-hospital mortality. Predictive performances of baseline CLIF-SOFA, SOFA, and qSOFA for in-hospital mortality were assessed.

**Results:** CLIF-SOFA proved significantly better for discriminating in-hospital, 1-month and 3-month mortality (area under receiver operating characteristic curve [AUROC]: 0.80, 0.77, 0.67, respectively) (all,  $p < 0.001$ ). CLIF-SOFA scores (adjusted hazard ratio [aHR] = 1.12;  $p = 0.001$ ) and CLIF-C-AD score (aHR = 1.02,  $p = 0.001$ ) were independent predictors of in-hospital mortality with CLIF-SOFA scores showing a significant linear relation with in-hospital mortality. Sepsis-3 criteria and positive qSOFA were not significant risk factors for in-hospital mortality. At CLIF-SOFA scores  $\geq 6$ , in-hospital mortality was  $>10\%$  which is originally suggested cutoff for definition of sepsis.

**Conclusion:** CLIF-SOFA scores showed better predictive performance for mortality than both Sepsis-3 criteria and qSOFA scores in Asian patients with cirrhosis and infections and can be a simple, one-time useful tool of accurately risk stratification in Asian patients with cirrhosis who need timely intervention for infection.

PO-2609

### Geographic variability in rates of intensive care unit admission in patients with chronic liver disease and critical COVID-19: international registry data

Thomas Marjot<sup>1</sup>, Andrew Moon<sup>2</sup>, \_COVID-Hep/SECURE-Liver Contributors<sup>3</sup>, Matthew Armstrong<sup>4</sup>, A. Sidney Barritt<sup>2</sup>, Eleanor Barnes<sup>1</sup>, Gwilym Webb<sup>5</sup>. <sup>1</sup>Oxford University Hospitals NHS Foundation Trust, University of Oxford; <sup>2</sup>University of North Carolina, Chapel Hill; <sup>3</sup>COVID-Hep/SECURE-Liver Contributors; <sup>4</sup>Queen Elizabeth Hospital Birmingham; <sup>5</sup>Cambridge University Hospitals, Addenbrooke's Hospital  
Email: thomas.marjot@ndm.ox.ac.uk.

**Background and aims:** The COVID-19 pandemic has provided a unique opportunity to evaluate global intensive care unit (ICU) admission practices for a common indication. Patients with chronic liver disease (CLD) and cirrhosis may also have limited or variable access to ICU. We aimed to describe international ICU admission rates and outcomes in patients with CLD and critical COVID-19.

**Method:** Data were combined from two international registries (COVID-Hep and SECURE-Liver) for patients with CLD and COVID-19 deemed severe enough to require ICU by the reporting clinician. Rates of ICU admission or decline, and respective outcomes were compared by country.

**Results:** Between 25th March 2020 and 3rd February 2021, 319 patients with CLD and COVID-19 from 27 countries were judged to require ICU. The proportion of patients ultimately accepted to ICU varied according to country (Fig. 1A), although mortality following ICU admission was similar by country (Fig. 1B). To explore this further, we compared cases from the USA and UK, the two greatest contributing countries. Rates of ICU admission differed significantly between the USA and UK [77/79 (95%) vs. 22/77 (29%);  $p < 0.001$ ]. However, there were no differences in mortality after being admitted to ICU (42/75 [56%] vs. 10/22 [45%];  $p = 0.468$ ; Fig. 1B), or after receiving invasive ventilation (29/59 [49%] vs. 9/17 [53%];  $p = 1.000$ ). There were also no differences in age, sex, Charlson Comorbidity Index, or baseline liver disease severity between countries, both in those requiring and admitted to ICU. This included comparable rates of cirrhosis (53/79 [67%] vs. 56/77 [72%];  $p = 0.723$ ). Only four USA patients were declined ICU admission of whom 2 (50%) died, whereas 55 UK patients were declined ICU admission of whom 51 (93%) died. Baseline factors associated with being declined ICU admission in the UK were older age, alcohol-related liver disease, and decompensated cirrhosis. In both USA and UK cohorts, the reason for not admitting patients to ICU was due to this being deemed inappropriate by the responsible clinician, except for one case in both countries where no ICU bed was available. Notably, information relating to patient wishes, long-term outcomes in survivors, and granular detail regarding organ support requirements were not available.

**Conclusion:** Patients with CLD and critical COVID-19 were over 3-times more likely to be admitted to ICU in the USA than the UK despite having similar baseline characteristics. However, the rates of mortality following ICU admission were comparable between the two countries. The differing thresholds for escalation to ICU but similar post admission outcomes warrants further discussion.

**PO-2870**

**Methylation state of circulating cell-free DNA as a prognostic marker for early to late stage chronic liver disease and acute on chronic liver failure**

Aikaterini Tourna<sup>1</sup>, Marilena Stamouli<sup>1</sup>, Bethlehem Arefaine<sup>1</sup>, Guido Alessandro Baselli<sup>2</sup>, Luca Valenti<sup>3</sup>, Shilpa Chokshi<sup>1,4</sup>, Neil Youngson<sup>1,4</sup>, Vishal C. Patel<sup>1,4,5</sup>. <sup>1</sup>Institute of Hepatology London, Foundation for Liver Research, London, United Kingdom; <sup>2</sup>Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Translational Medicine-Department of Transfusion Medicine and Haematology, Milano, Italy; <sup>3</sup>Università degli Studi di Milano, Department of Pathophysiology and Transplantation, Milano, Italy; <sup>4</sup>King's College London, School of Immunology and Microbial Sciences, London, United Kingdom; <sup>5</sup>King's College Hospital NHS Foundation Trust, Institute of Liver Studies, London, United Kingdom  
Email: k.tourna@researchinliver.org.uk.

**Background and aims:** We recently demonstrated circulating cell-free DNA (cfDNA) is present in critically ill patients with chronic liver disease (CLD) as a consistent predictor of mortality. Cirrhotic patients can develop acute-on-chronic liver failure (ACLF) with superimposed organ failure. We now extend this work by identifying cfDNA sources and examine potential to identify organ-specific damage, prior to onset of organ failure. CLIF-C-ACLF score defines ACLF with criteria for liver-kidney-brain-circulatory-respiratory and/or coagulation systems.

**Method:** We generated an extensive biobank from patients with varying severities of liver disease and controls. Spectrum of liver disease covers metabolic-associated fatty liver disease, compensated and decompensated cirrhosis, and ACLF. We developed assays to identify cfDNA origin, utilising organ-specific methylation profiles of genomic regions. Plasma-derived cfDNA underwent enzymatic modification and PCR amplification of organ-specific methylation regions. Amplicons underwent next-generation sequencing (NGS); methylation status was correlated with clinical data. NGS data were validated with targeted methylation-specific quantitative PCR assays.

**Results:** These novel assays can identify six organ system failures relevant to the CLIF-C-ACLF score. cfDNA assays for organ systems not measured by the CLIF score but known to be involved in ACLF (adrenals, gut, pancreas, vascular epithelium) were also developed. Initial data demonstrates liver-specific cfDNA methylation levels

Figure: (abstract: PO-2609)

## POSTER PRESENTATIONS

being distinguishable from healthy controls and early MAFLD, rising consistently with increasing CLD severity.

**Conclusion:** Circulating cfDNA shows promise for CLD stratification and predicting organ failure in ACLF. Vital organs not measured by the CLIF-C-ACLF score can also be interrogated based on their cfDNA signatures, providing novel patho-biological insights into ACLF.

### Cirrhosis and its complications: Experimental and pathophysiology

#### PO-134

##### Genetic variation in the mitochondrial glycerol-3-phosphate acyltransferase is associated with liver injury

Aaron Hakim<sup>1</sup>, Matthew Moll<sup>2</sup>, Joseph Brancale<sup>3</sup>, Jianguyan Liu<sup>2</sup>, Jessica Su<sup>2</sup>, Edwin Silverman<sup>2</sup>, Silvia Vilarinho<sup>3</sup>, Z. Gordon Jiang<sup>1</sup>, Yered Pita-Juarez<sup>1</sup>, Ioannis Vlachos<sup>1</sup>, Xuehong Zhang<sup>2</sup>, Fredrik Åberg<sup>4</sup>, Nezam Afdhal<sup>1</sup>, Brian Hobbs<sup>2</sup>, Michael Cho<sup>2</sup>. <sup>1</sup>Beth Israel Deaconess Medical Center (BIDMC), Boston, United States; <sup>2</sup>Brigham And Women's Hospital, Boston, United States; <sup>3</sup>Yale School of Medicine, New Haven, United States; <sup>4</sup>University of Helsinki, Helsinki, Finland  
Email: remhc@channing.harvard.edu.

**Background and aims:** In contrast to many common metabolic disorders, few genetic associations have been identified for chronic liver disease. This highlights the need for studies with increased sample size and the exploration of novel liver-related endophenotypes. We sought to identify novel genetic loci that modulate the risk of liver injury.

**Method:** We performed genome-wide association studies (GWAS) on circulating levels of alanine aminotransferase (ALT), aspartate aminotransferase (AST), alkaline phosphatase (ALP) and total bilirubin across 312, 671 White British participants in the UK Biobank. We focused on variants associated with elevations in all four liver biochemistries at genome-wide significance ( $p < 5 \times 10^{-8}$ ) and that replicated using Mass General Brigham Biobank in 19, 323 European ancestry individuals. We also analyzed single-cell RNA sequencing data from healthy human livers to determine cell sub-populations expressing identified target genes.

**Results:** We identified 58 distinct genetic loci associated with both ALT and AST, 18 associated with both ALP and total bilirubin, and 5 associated with ALT, AST, ALP and total bilirubin at genome-wide significance in UK Biobank. A genetic locus in the mitochondrial glycerol-3-phosphate acyltransferase (*GPAM*; rs10787429) associated with increased levels of ALT, AST, ALP and total bilirubin and replicated in Mass General Brigham Biobank. This common genetic variant was also associated with an increased risk of alcoholic liver disease (OR 1.34,  $p = 2.6 \times 10^{-5}$ ) and fatty liver disease (OR 1.18,  $p = 5.8 \times 10^{-4}$ ) by ICD-10 codes. We identified significant gene-environment interactions between *GPAM* rs10787429 and elevated body mass index in association with ALT and AST ( $p$ -interaction =  $7.1 \times 10^{-9}$  and  $3.95 \times 10^{-8}$ , respectively), as well as between *GPAM* rs10787429 and weekly alcohol consumption in association with ALT, AST, and alcoholic liver disease ( $p$ -interaction =  $5.2 \times 10^{-3}$ ,  $1.2 \times 10^{-2}$  and  $4.2 \times 10^{-2}$ , respectively). Unlike previously described genetic variants that are associated with an increased risk of liver injury but confer a protective effect on circulating lipids, *GPAM* rs10787429 was associated with an increase in total cholesterol ( $p = 2.0 \times 10^{-17}$ ), LDL cholesterol ( $p = 2.0 \times 10^{-10}$ ), and HDL cholesterol ( $p = 6.6 \times 10^{-37}$ ). Single-cell RNA sequencing data demonstrated hepatocyte-predominant expression of *GPAM* in cells that co-express genes related to VLDL production ( $p = 9.4 \times 10^{-103}$ ).

Figure:

**Conclusion:** Genetic variation in *GPAM* is associated with susceptibility to liver injury. *GPAM* may represent a new therapeutic target in chronic liver disease.

#### PO-624

##### Transcriptomic profiling of liver sinusoidal endothelial cells during cirrhosis progression reveals stage-specific secretory signature

Nicolò Manicardi<sup>1</sup>, Anabel Fernández Iglesias<sup>2,3</sup>, Laia Abad<sup>2,3</sup>, Félix Royo<sup>2,4</sup>, Mikel Azkargorta<sup>4</sup>, Martí Ortega Ribera<sup>3</sup>, Ana Martínez-Alcocer<sup>3</sup>, Felix Elortza<sup>4</sup>, Amelia Hessheimer<sup>2,5</sup>, Constantino Fondevila<sup>2,5</sup>, Juanjo Lozano<sup>2</sup>, Juan Carlos Garcia Pagan<sup>2,5</sup>, Jaime Bosch<sup>6</sup>, Francisco Javier Cubero<sup>7</sup>, Agustín Albillos<sup>2,8</sup>, Javier Vaquero<sup>2,9</sup>, Juan Falcon-Perez<sup>2,4</sup>, Jordi Gracia-Sancho<sup>2,3,6</sup>. <sup>1</sup>Institut d'Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS), Liver Vascular Biology, Barcelona, Spain; <sup>2</sup>CIBEREHD; <sup>3</sup>Institut d'Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS), Liver Vascular Biology, Spain; <sup>4</sup>Center for Cooperative Research in Biosciences (CIC bioGUNE); <sup>5</sup>Hospital Clinic de Barcelona; <sup>6</sup>University of Berne, Hepatology; <sup>7</sup>Universidad Complutense Madrid; <sup>8</sup>Ramon y Cajal Hospital; <sup>9</sup>Gregorio Marañón Research Institute  
Email: jordi.gracia@idibaps.org.

**Background and aims:** The poor prognosis of chronic liver disease (CLD) generates the need to investigate the evolving mechanisms of disease progression, thus disclosing therapeutic targets before development of clinical complications. Considering the central role of the liver sinusoidal endothelium in advanced CLD pathophysiology, the present study aimed at investigating the progression of CLD from a liver sinusoidal endothelial cells (LSECs) holistic perspective. **Method:** RNAseq was applied to define the transcriptome of primary LSECs from healthy and cirrhotic (alcoholic aetiology) human livers, and from rats with acute liver injury, mild liver fibrosis and cirrhosis (due to carbon tetrachloride [CCl<sub>4</sub>] or thioacetamide [TAA] administration). At each stage of the disease the effects of LSECs secretome on neighbouring cells were determined. Proteomic analysis of LSECs-derived extracellular vesicles (EVs) was performed.

**Results:** 1374 genes were differentially expressed in human cirrhotic LSECs compared to healthy, sharing greater homology with CCl<sub>4</sub>-than TAA-cirrhotic rat LSECs. Pathway enrichment analysis of deregulated genes in human cirrhotic LSECs and in rat LSECs isolated during liver cirrhosis progression, revealed predominance of genes related with cellular communication processes and EVs biogenesis. Crosstalk experiments between fibrotic and cirrhotic LSECs secretome subfractions (complete secretome, soluble factors, large EVs and small EVs) and neighbouring hepatic stellate cells and macrophages confirmed activation effects, revealing endothelial EVs as potent angiocrine effectors. Finally, proteomic analysis of LSECs EVs showed stage-specific signatures, including significant over-expression of tropomyosin-1 (TPM-1) in liver cirrhosis progression. Proof-of-concept experiments treating cirrhotic HSCs and *in vitro* activated HSCs with recombinant TPM-1 showed down-regulation of *Col1 (alpha)1*, *(alpha)Sma* and *Rock1* suggesting potential de-activating effects.

**Conclusion:** Through a comprehensive characterization of LSECs transcriptome and secretome across cirrhosis, our study shows

dominance of pathways involved in cellular secretory machinery during disease progression. Our data provide the basis for discovering novel biomarkers and therapeutic targets for new disease-modifying treatments for patients with advanced CLD.

**PO-698**

**Characterizing sensory thresholds and autonomic dysfunction in cirrhotic patients with minimal hepatic encephalopathy**

Email: cmontoliu@incliva.es.

**Background and aims:** Hepatic encephalopathy (HE) associated to cirrhosis is a complex neuropsychiatric syndrome. Near 40% of cirrhotic patients have minimal hepatic encephalopathy (MHE) with mild motor and cognitive impairments that can affect daily life activities.

Cirrhotic patients may have alterations in the peripheral nervous system such as disorders in sensory perception. The awareness of cold and heat pain is mediated by A-delta nerve fibers (myelinated, small diameter) and non-myelinated C fibers, respectively. Whilst vibration is transmitted by larger myelinated fibers (A-alpha). The alteration of these fibres is determined as small fibre neuropathy (SNP). Which includes autonomic and sensory symptoms such as, dysesthesia and allodynia. Consequently, it can produce an alteration of thermal and pain sensibility as well as sudomotor function. Alterations in thermal sensitivity have been described in patients with HE, which have been correlated with the degree of HE and with attention deficits.

The aim of this study is the evaluation and characterization of thermal sensitivity, vibration and heat-pain in addition to sudomotor function in cirrhotic patients and healthy controls, as well as to assess whether there are alterations associated to MHE.

**Method:** Fifty-eight cirrhotic patients were included in the study, 38 without MHE (NMHE) and 20 with MHE, according to the PHES score (Psychometric Hepatic Encephalopathy Score) and 39 healthy controls. Selective and sustained attention were assessed using the Stroop and d2 tests. The evaluation and characterization of sensory thresholds was performed by quantitative sensory testing using a CASE IV device. The following sensory thresholds were measured: vibration, heat pain and cooling both on the hand and foot. Sudomotor function was explored through cutaneous sympathetic response (CSR) conducted by the Synergy UltraPro S100.

**Results:** Results show that the thresholds were higher in NMHE patients compared to controls in all modalities except heat-pain 5.0. Patients with MHE showed higher thresholds than NMHE patients in cooling detection and heat pain when the foot was the test site. The proportion of patients in which over half the tests were outside the normal range was higher in MHE (67%) than in NMHE patients (26%). This hyposensitivity correlates with attention deficits. The amplitude of SSR was significantly reduced in patients with MHE compared to controls and NMHE while latency was significantly higher in both patient groups compared to controls.

**Conclusion:** Patients with MHE have a general decrease in cognitive and sensory abilities as well as alterations in autonomic functions such as thermoregulation. Quantitative sensory tests and SSR could

be used as an indicator of MHE and would allow studying the effects on the sensory system before and after a treatment.

**PO-709**

**Multi-omic analysis unveils biological pathways in peripheral immune system associated to minimal hepatic encephalopathy appearance in cirrhotic patients**

Teresa Rubio<sup>1</sup>, María-Pilar Ballester-Ferré<sup>2,3</sup>, Juan José Gallego Roig<sup>2</sup>, Alessandra Fiorillo<sup>2</sup>, Franc Casanova<sup>2</sup>, Sonia Tarazona<sup>4</sup>, Carla Giménez-Garzó<sup>1</sup>, Amparo Urios<sup>2</sup>, Paloma Lluch<sup>5</sup>, Desamparados Escudero-García<sup>3</sup>, Juan Tosca<sup>3</sup>, Cristina Montón<sup>3</sup>, José Ballester<sup>3</sup>, María Pilar Ríos<sup>6</sup>, Lucía Durbán<sup>6</sup>, Ana Conesa<sup>7</sup>, Vicente Felipo<sup>1</sup>, Carmina Montoliu<sup>2,8</sup>. <sup>1</sup>CIPF Centro de Investigación Príncipe Felipe, Valencia, Spain; <sup>2</sup>INCLIVA Institut d'Investigació Sanitària, Valencia, Spain; <sup>3</sup>Hospital Clínic Universitari, Unidad de Digestivo, Valencia, Spain; <sup>4</sup>Polytechnic University of Valencia, Departamento de estadística e investigación operativa aplicadas y calidad, València, Spain; <sup>5</sup>Hospital Clínic Universitari, Unidad de Digestivo, València, Spain; <sup>6</sup>Hospital Arnau de Vilanova, Servicio de digestivo, València, Spain; <sup>7</sup>University of Florida, Microbiology and Cell science department, Gainesville, United States; <sup>8</sup>University of Valencia, Departamento de Patología, València, Spain  
Email: cmontoliu@incliva.es.

**Background and aims:** Patients with liver cirrhosis may develop minimal hepatic encephalopathy (MHE) which affects their quality of life and life span. It has been proposed that a shift in peripheral inflammation triggers the appearance of MHE. However, the mechanisms involved in this immune system shift remain unknown. In this work we studied the broad molecular changes involved in the induction of MHE with the goal of identifying (1) altered genes and pathways in peripheral blood cells associated to the appearance of MHE, (2) serum metabolites and cytokines with modified levels in MHE patients and (3) MHE-regulated immune response processes related to changes in specific serum molecules.

**Method:** We adopted a multi-omic approach to profile the transcriptome, metabolome and a panel of cytokines of blood samples taken from cirrhotic patients with or without MHE.

**Results:** Transcriptomics analysis support the hypothesis of alternations in the Th1/Th2 and Th17 lymphocytes cell populations as major drivers of MHE. Cluster analysis of serum molecules resulted in 6 groups of chemically similar compounds, suggesting that functional modules operate during the induction of MHE. Finally, the multi-omic integrative analysis suggested a relationship between cytokines CCL20, CX3CL1, CXCL13, IL-15, IL-22 and IL-6 with alteration in chemotaxis, as well as a link between long-chain unsaturated phospholipids and the increased fatty acid transport and prostaglandin production.

**Conclusion:** We found altered immune pathways that may collectively contribute to the mild cognitive impairment phenotype in MHE. Our approach is able to combine extracellular and intracellular information, opening new insights to the understanding of the disease.

**PO-994**

**Hepatic fat loss in cirrhosis: Evaluation of malnutrition using MRI proton density fat fraction (MRI-PDFF)**

Atsushi Nakamura<sup>1</sup>, Takeshi Ichikawa<sup>1</sup>. <sup>1</sup>Kawasaki, Japan  
Email: naka2722@gmail.com.

**Background and aims:** Fatty acids are the largest energy storage in the body, and the liver acts as a central hub for fatty acid metabolism. In LC, protein-energy malnutrition (PEM) increases in relation to the severity of the disease, and fatty liver presents as “burn out” NASH with loss of fat droplets. MRI-PDFF has been used as an alternative to liver biopsy as a non-invasive and accurate method for quantifying liver fat content. In this study, we investigated the relationship between MRI-PDFF and malnutrition.

1) Relationship between muscle mass and PDFF

2) Kaplan-Meier survival curve in liver cirrhosis

Figure: (abstract: PO-994)

**Method:** A total of 389 patients with chronic liver disease (M/F: 365/239, 61 ± 14 y) underwent MRI examination. By etiology, HBV/HCV: 103/111, NAFLD: 121, PBC/AIH: 35, unknown 19. 65 LC (Child A/B/C: 45/14/6) and 33 HCC were included. PDFF (%) and LSM (liver stiffness measurement: kPa) were analyzed by MRI. Nutritional status was assessed by CONUT (controlled nutritional status) score, and sarcopenia was diagnosed by measuring PMI (psoas muscle index) from CT images (244 cases) in the same period.

**Results:** (1) PDFF in CLD: There was no gender difference in PDFF (%), 12.8 ± 8.3 and 5.4 ± 5.1 for NAFLD and non-NAFLD groups ( $p < 0.01$ ). Univariate analysis of PDFF correlated with age, BMI, and was associated with liver inflammation (AST, ALT,  $\gamma$ GTP, ferritin) and nutrient metabolism (alb, TC, TG, HbA1c, TLC) ( $p < 0.05$ ). There were also significant differences between LC and non-LC, and between  $\pm$  HCC ( $p < 0.05$ ).

(2) Malnutrition and PDFF: CONUT score correlated with LSM ( $r = 0.531$ ,  $p < 0.01$ ) and PDFF ( $r = -0.324$ ,  $p < 0.01$ ), and both NAFLD and non-NAFLD groups showed an association between severity of CONUT and decrease in PDFF ( $p < 0.05$ ). On the other hand, PDFF was also correlated with PMI ( $p < 0.01$ ), and the PDFF of sarcopenia patients (38%) was significantly lower (5.0 ± 5.0% vs. 10.0 ± 8.7%,  $p < 0.01$ ).

(3) PDFF in LC: Nine patients died during the observation period (30 ± 18M), and Child Pugh score (HR: 1.374, 95% CI: 1.075–1.744,  $p < 0.05$ ) and PDFF (HR: 0.913, 95% CI: 0.843–0.974,  $p < 0.01$ ) were prognostic factors in Cox proportional hazards model. ROC analysis showed that PDFF  $\leq 2.35\%$  (AUC: 0.89,  $p < 0.01$ ) was predictive of mortality, and BMI (odds ratio: 0.619) and alb (0.086) were independently associated with hepatic fat loss in LC ( $p < 0.01$ ).

**Conclusion:** Decreased PDFF was associated with malnutrition and sarcopenia in CLD, and decreased liver fat mass in LC was a prognostic factor independent of liver function. MRI-PDFF may be a powerful indicator of nutritional status in cirrhosis.

**PO-1051**

**Systemic and hepatic endothelial cell activation biomarkers expression are associated with inflammation and disease progression in patients with cirrhosis**

Jelte Schaapman<sup>1</sup>, Tessa Ostyn<sup>2</sup>, Danny van der Helm<sup>1</sup>, Matthias Van Haele<sup>2</sup>, Johannes van der Reijden<sup>1</sup>, Frederik Nevens<sup>3</sup>, H.W. Verspaget<sup>1</sup>, Tania Roskams<sup>2</sup>, Minneke Coenraad<sup>1</sup>. <sup>1</sup>Leiden University Medical Center (LUMC), Hepatology, Leiden, Netherlands; <sup>2</sup>University Hospitals KU Leuven, Imaging and Pathology, Leuven, Belgium; <sup>3</sup>University Hospitals KU Leuven, Hepatology, Leuven, Belgium. Email: j.j.schaapman@lumc.nl.

**Background and aims:** Vascular endothelium is involved in several pathological processes in cirrhosis, including fibrogenesis and inflammation. Decompensated cirrhosis is characterized by chronic inflammation and molecular activation patterns. Aim of this study was to evaluate circulating and hepatic endothelial cell (EC) activation, inflammation and adhesion markers in cirrhotic patients in relation to systemic inflammation and disease severity.

**Method:** 150 cirrhotic patients and 18 healthy controls were included. Circulating inflammatory and EC biomarkers were measured using a multi-array assay. 80 explanted cirrhotic and 11 control liver tissue specimens were available for immunohistochemical analysis for markers of ECs (CD31, CD34, LYVE-1), EC activation (ICAM-1, VCAM-1, P-selectin, thrombomodulin) and apoptosis (Caspase 3). Marker expression was assessed separately for liver portal and sinusoidal ECs (LSECs) by two pathologists.

**Results:** Median MELD score of cirrhotic patients was 15 (IQR 11–21). Serum concentrations of CRP, ICAM-1, VCAM-1 and thrombomodulin were significantly elevated in patients compared to controls (table). CD31, CD34, LYVE-1, VCAM-1 and thrombomodulin in portal venous ECs and ICAM-1 and LYVE-1 in LSECs were almost universally expressed in both groups. Expression of ICAM-1, P-selectin, Caspase 3 in portal venous ECs and of CD31, CD34, VCAM-1, P-selectin, thrombomodulin and Caspase 3 in LSECs was significantly more frequent in cirrhotic patients compared to controls (table). Circulating ICAM-1, VCAM-1, thrombomodulin levels and ICAM-1 and P-selectin in portal ECs were correlated with MELD score (all  $p < 0.004$ ). In addition, P-selectin expression in portal ECs and LSECs was correlated with CRP (both  $p < 0.05$ ).

**Conclusion:** Circulating EC activation biomarkers are significantly elevated in cirrhotic patients. In addition, the increased expression of several EC activation markers in cirrhotic patients but not controls

indicate EC molecular activation patterns with hepatic inflammation, adhesion and apoptosis, in association with systemic inflammation and clinical disease progression.

Table:

Circulatory inflammation marker	Controls (n = 18)	Cirrhosis (n = 150)	p value
CRP	2.0 (0.4–3.6)	12.4 (4.5–34.6)	<0.001
<b>Circulatory endothelial markers</b>			
ICAM-1	0.4 (0.3–0.4)	1.4 (1.2–2.1)	<0.001
VCAM-1	0.5 (0.4–0.6)	2.5 (1.7–3.5)	<0.001
P-selectin	73.4 (65.0–91.3)	78.4 (58.1–99.8)	0.667
Thrombomodulin	4.2 (3.6–4.7)	8.2 (6.4–10.6)	<0.001
<b>Tissue endothelial markers</b>			
CD31 (s)	0%	100%	<0.001
CD34 (s)	0%	100%	<0.001
ICAM-1 (p)	0%	58.8%	<0.001
VCAM-1 (s)	0%	82.5%	<0.001
P-selectin (p)	27.3%	81.3%	<0.001
P-selectin (s)	0%	49.9%	0.002
Thrombomodulin (s)	0%	97.5%	<0.001
Caspase 3- (p)	0%	78.8%	<0.001
Caspase 3- (s)	0%	100%	<0.001

**PO-1222**

**PNPLA3-associated cirrhosis: HSD17B13 and MBOAT7 variants as modulators of chronic liver injury**

Matthias Reichert<sup>1</sup>, Robin Greinert<sup>2</sup>, Alexander Zipprich<sup>2,3</sup>, Cristina Ripoll<sup>2</sup>, Marcin Krawczyk<sup>1,4</sup>, Frank Lammert<sup>1,5</sup>. <sup>1</sup>Department of Medicine II, Saarland University Medical Center, Saarland University, Homburg, Germany; <sup>2</sup>First Department of Internal Medicine, Martin-Luther University Halle-Wittenberg, Halle, Germany; <sup>3</sup>Department of Internal Medicine IV, Friedrich-Schiller-University Jena, Jena, Germany; <sup>4</sup>Laboratory of Metabolic Liver Diseases, Department of General, Transplant and Liver Surgery, Medical University of Warsaw, Warsaw, Poland; <sup>5</sup>Hannover Medical School, Hannover, Germany  
Email: marcin.krawczyk@uks.eu.

**Background and aims:** Carriers of the adiponutrin (PNPLA3) p. I148M variant, and in particular homozygous patients, have an increased risk for cirrhosis. The hepatoprotective splice variant of HSD17B13 reduces, in turn, liver injury (Abul-Husn *et al.* N Engl J Med 2018), whereas a variant in the MBOAT7 gene aggravates liver damage. Our aim was to investigate the modulation of the risk of advanced cirrhosis in homozygous carriers of the PNPLA3 variant by the HSD17B13 and MBOAT7 variants.

**Method:** In total, 998 patients with cirrhosis were screened for the PNPLA3 variant. Clinical, laboratory and imaging data were collected. Hepatic decompensation was defined as the presence of ascites, history of variceal bleeding, hepatic encephalopathy, or jaundice (i.e., serum bilirubin ≥3.0 mg/dl). Within this cohort, the MBOAT7 (rs641738) and HSD17B13 (rs72613567) polymorphisms were genotyped by PCR-based allelic discrimination assays, and genotype-to-phenotype correlations were analyzed.

**Results:** Overall, 148 patients (15%) were homozygous carriers of the PNPLA3 p.148MM risk genotype (64% men, age range 30–81 years). Aetiology of cirrhosis resembled a typical European cohort (59% alcoholic, viral 14%, NASH 9%, 14% other). Two thirds of the patients were in the decompensated stage of the disease. When comparing patients according to the presence or absence of the protective HSD17B13 variant, 56% of the patients in the compensated stage were carriers versus 36% in the decompensated stage (p = 0.025). Similarly, MELD scores (13.1 versus 10.9; p=0.04), Child-Pugh scores (7.6 versus 7.1; p=0.23) and bilirubin concentrations (3.3 versus 1.7 mg/dl, p=0.035) were significantly higher when the HSD17B13 protective

variant was absent. None of these parameters was influenced by the MBOAT7 alleles.

**Conclusion:** The risk of progressive cirrhosis is increased in homozygous carriers of the PNPLA3 variant p.148MM. Notably, the presence of an HSD17B13 allele mitigates, at least in part, the harmful effects conferred by PNPLA3 homozygosity. As both PNPLA3 and HSD17B13 exert their functions in hepatocellular lipid droplets, the interaction of the metabolic pathways at this intracellular localization should be investigated in the future studies.

**PO-1643**

**Nutritional supplementation with B-Hydroxy-B-methylbutyrate (HMB) in malnourished cirrhotic patients**

Silvia Espina<sup>1</sup>, Vanesa Bernal Monterde<sup>1</sup>, Alejandro Sanz Paris<sup>2</sup>, Javier Fuentes Olmo<sup>1</sup>, Eva Fernandez Bonilla<sup>1</sup>, Yolanda Gonzalez Irazabal<sup>3</sup>, Beatriz Garcia Rodriguez<sup>3</sup>, Maria Pilar Garcia Sobrevela<sup>4</sup>, Jose M. Arbones Mainar<sup>4</sup>. <sup>1</sup>Hospital Universitario Miguel Servet, Gastroenterology and hepatology, Zaragoza, Spain; <sup>2</sup>Hospital Universitario Miguel Servet, Endocrinology, Zaragoza, Spain; <sup>3</sup>Hospital Universitario Miguel Servet, Biochemistry, Zaragoza, Spain; <sup>4</sup>Translational Research Unit, Hospital Universitario Miguel Servet, Instituto Aragonés de Ciencias de la Salud (IACS), Instituto de Investigación Sanitaria Aragón (IIS-Aragón), Adipocyte and Fat Biology Laboratory (AdipoFat), Zaragoza, Spain  
Email: silesipina@gmail.com.

**Background and aims:** HMB is derivative of the BCAA (branched-chain amino acid) leucine. BCAA supplementation in cirrhosis has shown positive effect only on encephalopathy and muscular strength. HMB supplementation increase muscle mass and strength during resistance exercises but there are no data in cirrhosis. The aim was to investigate the effects of oral HMB supplementation on changes in body composition and liver status in patients with cirrhosis and malnutrition.

**Method:** This is a double-blind placebo-controlled trial (NCT03285217). 43 individuals were randomized to receive for 12 wk oral supplementation twice a day with either 220 ml of Ensure® Plus Advance (HMB group, n = 22) or with 220 ml of Ensure® Plus High Protein (HP group, n = 21). Inclusion criteria was liver cirrhosis of any aetiology with at least 1 previous decompensation and clinical malnutrition class B or C screened by Subjective Global Assessment (SGA). Longitudinal and treatment-specific changes were assessed by mixed models.

**Results:** 34 patients completed the clinical trial. Both treatments, with no differences, improved liver function (MELD score, p=0.02) and increased fat mass index (p=0.014) while reduced serum concentrations of LDL cholesterol (p=0.002) and apolipoprotein B (p=0.001). None of the two treatments changed the skeletal muscle mass index (SMI) or appendicular skeletal muscle mass (ASMM). However, we observe in the HMB group an upward trend in hand grip strength and a downward trend in minimal hepatic encephalopathy (MHE).

**Conclusion:** Oral supplementation for 12 weeks, with no differences between treatments, was significantly associated with an increase in fat mass and improved liver function without benefit on muscle mass.

## POSTER PRESENTATIONS

Table 1: (abstract: PO-1643)

	HMB Group			HP Group

**Conflict of interest:** Abbot provided the nutritional supplements at a discounted price but had no part in the study.

### PO-1684

#### Low-grade hyperammonemia induces severe neuronal mitochondrial dysfunction in cellular and animal models of hepatic encephalopathy

Annarein Kerbert<sup>1</sup>, Plamena Stroh<sup>2</sup>, Abeba Habtesion<sup>1</sup>, Andrey Abramov<sup>2</sup>, Rajiv Jalan<sup>1</sup>. <sup>1</sup>University College London, Institute for Liver and Digestive Health, United Kingdom; <sup>2</sup>University College London, Institute of Neurology, United Kingdom  
Email: a.kerbert@ucl.ac.uk.

**Background and aims:** In liver cirrhosis, hyperammonemia plays a key role in the pathophysiology of hepatic encephalopathy (HE). The astrocytes are traditionally believed to be the principal target of ammonia neurotoxicity. The role of neuronal dysfunction in HE is not clear. In this study, we aim to explore the impact of hyperammonemia on mitochondrial function in different brain cell types and in acute brain slices, by using live cell imaging.

**Method:** *In vitro*: to primary co-cultures of astrocytes and neurons, concentrations of 1  $\mu$ M and 5  $\mu$ M ammonium chloride were applied. Cell viability was measured by the use of membrane-impermeable fluorescent dye propidium iodide that stains cells with damaged cell membranes in combination with Hoechst 33342 for assessment of the total cell number. *In vivo*: In a rat model of liver cirrhosis and minimal HE (4 weeks post bile duct ligation (BDL), 3 groups were studied: sham (n = 5), BDL (n = 3) and BDL + the ammonia scavenger Ornithine Phenylacetate (OP; n = 2) 0.3 g/kg i.p. twice daily for 5 days. After sacrificing, the brain was placed in artificial cerebrospinal fluid and immediately sliced at 100  $\mu$ m. Fluorescence measurements of changes in mitochondrial membrane potential (MMP), reactive oxygen species (ROS) production and rate of lipid peroxidation (LP) were performed using a confocal microscope.

**Results:** *In vitro*: Neuronal cultures, treated with ammonia (1  $\mu$ M and 5  $\mu$ M), exhibited reduced cell viability (27.8  $\pm$  2.3% and 41.5  $\pm$  3.7%, respectively) compared to untreated cultures (15.7  $\pm$  1.0%, both p <

0.0001). *In vivo*: Ammonia (umol/L) levels were: sham (56  $\pm$  3), BDL (141  $\pm$  4) and BDL+OP (60  $\pm$  2). BDL led to increased lipid peroxidation (p = 0.0003; Figure) and cytosolic ROS generation (p < 0.0001) in the brain, which was restored by OP (both p < 0.0001). Mitochondrial function was severely compromised in BDL, resulting in hyperpolarization of mitochondrial membranes (p < 0.0001) with consequent overconsumption of ATP and augmentation of mitochondrial ROS production rates (p < 0.0001). Administration of OP in BDL animals, restored mitochondrial membrane potential (p < 0.0001). Neuronal loss was prominent in CA1 areas of the hippocampus in BDL.

**Conclusion:** Our results elucidate for the first time that low-grade hyperammonemia can severely impact on brain mitochondrial function in liver cirrhosis. Besides astrocyte swelling, profound neuronal injury was observed in hyperammonemic rats. These data point towards a novel mechanism of HE development.

### PO-1761

#### Sleep study with actigraphy in patients affected by cirrhosis with and without minimal hepatic encephalopathy

Cristina Ipiens<sup>1</sup>, Juan José Gallego<sup>2</sup>, Alessandra Fiorillo<sup>2</sup>, Franc Casanova<sup>2</sup>, María Pilar Ballester<sup>2</sup>, Rut Victorio<sup>3</sup>, Dalia Rega<sup>2</sup>, Mika Aiko<sup>3</sup>, Nicolás Peñaranda<sup>3</sup>, Carla Gimenez-Garzo<sup>4</sup>, Desamparados Escudero-García<sup>5</sup>, Joan Tosca<sup>5</sup>, Paula Cases<sup>3</sup>, Amparo Urios<sup>2</sup>, Vicente Felipo<sup>4</sup>, Carmina Montoliu<sup>2,6</sup>. <sup>1</sup>Hospital Universitario de La Ribera, Valencia, Spain; <sup>2</sup>Fundación Investigación Hospital Clínico de Valencia. Instituto de Investigación Sanitaria-INCLIVA, Valencia, Spain; <sup>3</sup>Servicio de Neurofisiología, Hospital Clínico Universitario de Valencia, Spain; <sup>4</sup>Laboratorio de Neurobiología. Centro Investigación Príncipe Felipe. Valencia, Spain; <sup>5</sup>Unidad de Digestivo, Hospital Clínico Universitario de Valencia, Spain; <sup>6</sup>Departamento de Patología, Facultad de Medicina, Universidad de Valencia, Spain  
Email: cmontoliu@incliva.es.

**Background and aims:** Sleep disorders are frequently associated with hepatic encephalopathy (HE) and might be some of its first clinical findings, observable even in minimal hepatic encephalopathy (MHE). They are also common in patients with cirrhosis and other

Figure (abstract: PO-1684) Lipid peroxidation in acute hippocampal slices of sham, BDL and BDL+OP treated rats. Red: not oxidized, green: oxidized.

liver conditions without defining signs of HE. Currently, polysomnography is the gold standard for sleep studies, but requires a high consumption of hospital resources and the recording is usually only one-night long. Actigraphy devices offer the chance of making longer ambulatory studies. Sleep-wake patterns are estimated from periods of activity and inactivity reflected by the movements of the patient.

**Method:** An analytical, observational cohort study has been done to analyze the macrostructure of sleep and the wake-sleep cycle using an actigraphy record for 14 days. It was carried out in a sample of 68 individuals from the Hospital Clínico Universitario de Valencia (Spain), grouped into three categories: MHE, cirrhosis without MHE and healthy control subjects. The differences between these three groups were analyzed in terms of time spent in bed, sleep latency, percentage of sleep, interleaved arousals, and sleep fragmentation index, as well as time in bed and sleep of the patient during the day.

**Results:** It is observed that, during the night, patients with pathology, either with cirrhosis or with cirrhosis with MHE, stay longer in bed, have a higher sleep latency, a higher sleep fragmentation index and a lower percentage of sleep, which generally represents a worse quality of night rest. This aspect may be related to the greater immobility and frequent drowsiness that is shown in the daytime record. It is also observed that patients with cirrhosis, with or without MHE, have a significantly higher risk of presenting greater sleep fragmentation, and a risk close to the statistical significance of presenting a longer sleep time during the day.

**Conclusion:** Patients with liver disease might present sleep disturbances and these be the first clinical manifestation in the neurological sphere. This has been observed both in patients with diagnosed MHE and cirrhosis without MHE, which suggests that patients with cirrhosis might present subclinical neurological alterations. The actigraphy record proves to be a useful tool for the diagnosis, while it is a test that stimulates its ambulatory use, consumes few professional resources, and allows a prolonged record while respecting the daily life of patients.

**PO-1787**

**Markers of neutrophil extracellular traps are elevated in patients with Child-Pugh B and C liver cirrhosis or large hepatocellular carcinomas**

Robin Zenlander<sup>1,2,3</sup>, Sebastian Havervall<sup>4</sup>, Maria Magnusson<sup>5,6</sup>, Anna Ågren<sup>7,8,9</sup>, Charlotte Thålin<sup>4</sup>, Per Stal<sup>3,10</sup>. <sup>1</sup>Department of Clinical chemistry, Karolinska University Hospital, Stockholm, Sweden; <sup>2</sup>Department of Laboratory Medicine, Huddinge, Karolinska Institutet, Stockholm, Sweden; <sup>3</sup>Department of Medicine, Huddinge, Karolinska Institutet, Stockholm, Sweden; <sup>4</sup>Division of Internal Medicine, Department of Clinical Sciences, Danderyd Hospital, Karolinska Institutet, Stockholm, Sweden; <sup>5</sup>Division of Paediatrics, CLINTEC, Karolinska Institutet, Stockholm, Sweden; <sup>6</sup>Astrid Lindgren Children's Hospital, Karolinska University Hospital, Stockholm, Sweden; <sup>7</sup>Department of Molecular Medicine and Surgery, Karolinska Institutet, Stockholm, Sweden; <sup>8</sup>Coagulation Unit, Department of Hematology, Karolinska University Hospital, Stockholm, Sweden; <sup>9</sup>Department of Clinical Sciences, Danderyd Hospital, Stockholm, Sweden; <sup>10</sup>Division of Hepatology, Department of Upper GI diseases, Karolinska University Hospital, Stockholm, Sweden  
Email: robin.zenlander@ki.se.

**Background and aims:** Liver cirrhosis is a procoagulant condition despite concomitant thrombocytopenia or reduced production of coagulation factors. Neutrophil extracellular traps (NETs) are web-like structures extruded from neutrophils and composed of DNA and histones, which trap and neutralize invading pathogens. Markers of NETs are elevated in thrombus formation, inflammatory conditions and cancer<sup>1</sup>. However, the role of NETs in the increased thrombosis risk seen in liver cirrhosis and hepatocellular carcinoma (HCC) is unknown. We asked if plasma levels of two NETs markers, MPO-DNA and H3Cit-DNA<sup>2,3</sup> were elevated in liver cirrhosis and HCC, and if they

were associated to clinical parameters or correlated to thrombin-antithrombin complex (TAT).

**Method:** H3Cit-DNA, MPO-DNA and TAT were measured with ELISA in plasma from 95 patients with liver cirrhosis, 82 patients with HCC, and 50 healthy controls. Clinical parameters and laboratory data were collected from medical files. Levels of NETs markers were correlated to clinical and laboratory data.

**Results:** H3Cit-DNA and TAT were both significantly elevated in plasma of liver cirrhosis and HCC patients compared to healthy controls (H3Cit-DNA median 66.4 ng/ml for liver cirrhosis, 63.8 ng/ml for HCC, 31.8 ng/ml for controls; TAT median 3.1 µg/ml for liver cirrhosis, 3.7 µg/ml for HCC, 0.0 µg/ml for controls). MPO-DNA was elevated in liver cirrhosis patients compared with both other groups (0.53 O.D. for liver cirrhosis, 0.33 O.D. for HCC, 0.33 O.D. for controls). H3Cit-DNA was significantly higher in Child-Pugh B and C patients compared to Child-Pugh A and controls and correlated positively with MELD score. H3Cit-DNA was increased in patients with underlying non-alcoholic steatohepatitis (NASH) vs. hepatitis C aetiology, and in HCC patients with tumour burden >8 cm. H3Cit-DNA and MPO-DNA were not higher in patients with previous thrombosis development compared with those without history of thrombosis.

**Conclusion:** Plasma markers of NETs are elevated in liver cirrhosis with reduced liver function. HCC itself is not associated with increased plasma markers of NETs formation, except for larger tumours. Underlying NASH associates to increased levels of NETs in plasma. Our results indicate a potential role of NETs in the development of a procoagulant state in decompensated liver cirrhosis, but further studies are needed.

**GLAST redistributes, clusters and forms homomultimers at the plasma membrane**

Joana Patrícia Ventura Pereira<sup>1</sup>, Boris Goerg<sup>2</sup>, Stefanie Weidtkamp-Peters<sup>3</sup>, Verena Keitel<sup>2</sup>, Dieter Häussinger<sup>2</sup>, Christoph Roderburg<sup>2</sup>, Tom Lüdde<sup>2</sup>, Markus Jördens<sup>2</sup>. <sup>1</sup>Department of Gastroenterology, Hepatology and Infectious Diseases, University Hospital of the, Düsseldorf, Germany; <sup>2</sup>Department of Gastroenterology, Hepatology and Infectious Diseases, University Hospital of the Heinrich Heine University, Düsseldorf, Germany; <sup>3</sup>Center of Advanced Imaging, Heinrich Heine University, Düsseldorf, Germany  
Email: joana.venturapereira@med.uni-duesseldorf.de.

**Background and aims:** In hepatic encephalopathy (HE), high levels of NH<sub>4</sub>Cl in the brain lead to an alteration of glutamate homeostasis but the mechanism involved is not completely known. Since L-glutamate/L-aspartate transporter (GLAST) contributes to glutamate homeostasis, we studied the effect of hyperammonia on GLAST, concretely receptor clustering, membrane translocation and multimerization.

**Method:** We transfected primary rat astrocytes with GLAST tagged with eYFP or/and mCherry. Using living cells before and after exposition to 5 mM NH<sub>4</sub>Cl we (i) performed epifluorescence microscopy to investigate the formation of GLAST clusters in the presence of putative inhibitors/inducers of glutamate exocytosis (ii) studied the alteration of GLAST distribution recurring to Total Internal Reflection Microscopy (TIRFM) (iii) investigated multimerization of GLAST using Fluorescence Resonance Energy Transfer-Fluorescence Life Time microscopy (FRET-FLIM).

**Results:** GLAST redistribution and clustering occurred in cultured rat astrocytes in the presence of NH<sub>4</sub>Cl (n = 18 cells) and Glutamate (n = 5) (Figure). Furthermore we could observe GLAST clustering was

## POSTER PRESENTATIONS

induced by the NO-donor DEANOate (n = 10) and prevented by LNMTA (inhibitor of NO-Synthetase) (n = 4), indicating an involvement of reactive nitrogen oxide species (RNOS) in the clustering process. In addition clustering by NH<sub>4</sub>Cl was absent when the cells were pretreated with a Ca<sup>2+</sup>-chelator (BAPTA) (n = 4) or an inhibitor of the Cyclooxygenase (Indomethacin (n = 6)/Diclofenac (n = 4)). Using TIRF microscopy, a statistically significant increase of eYFP-GLAST (n = 7) and GLAST-eYFP (n = 7) particles was observed in the plasma membrane after 30 sec stimulation of cultured rat astrocytes with NH<sub>4</sub>Cl. We analyzed 39 single-cells by FRET-FLIM microscopy and on 23 cells we detected a significantly decrease in fluorescence lifetime of GLAST-eYFP upon exposure to NH<sub>4</sub>Cl, suggesting a shorter distance between GLAST molecules.

Figure: Redistribution of eYFP-GLAST molecules and their accumulation at the pericytoplasmic regions of the cell (clustering) upon exposure to NH<sub>4</sub>Cl.

**Conclusion:** Our study shows that NH<sub>4</sub>Cl induces rapid GLAST clustering in cultured rat astrocytes. The NH<sub>4</sub>Cl-induced clustering seems to be dependent on calcium, Cyclooxygenase and NO

Synthase. NH<sub>4</sub>Cl causes the redistribution of GLAST in the plasma membrane and seems to induce GLAST multimerization. Next experiments are focus on anisotropy analysis to confirm the formation of GLAST multimers. We also plan to knockout GLAST using CRISPR-Cas9 to investigate the influence of hyperammonia on the functionality of the transporter.

### PO-2213

#### Fingolimod Represents a Novel Therapy in Experimental Model of Hepatopulmonary Syndrome

Sukriti Sukriti<sup>1</sup>, Anupama Kumari<sup>1</sup>, Preeti Negi<sup>1</sup>, Arvind Tomar<sup>1</sup>, Swati Thangariyal<sup>1</sup>, P. Debishree Subudhi<sup>1</sup>, Chitranshu Vashistha<sup>1</sup>, Chhagan Bihari<sup>1</sup>, Rakhi Maiwall<sup>1</sup>, Shiv Kumar Sarin<sup>1</sup>. <sup>1</sup>Institute of Liver and Biliary Sciences, New Delhi, India  
Email: shivsarin@gmail.com.

**Background and aims:** Hepatopulmonary syndrome (HPS) is a serious complication of cirrhosis and is characterized by pathological vasodilation of the pulmonary vasculature resulting in arterial oxygenation defects. There are no effective treatment options. Fingolimod, a functional agonist of sphingosine-1-phosphate (S1P) maintains the vascular tone by reducing nitric oxide production, which represents an attractive therapy for HPS. We aimed to investigate if Fingolimod, is an effective agent to target pathological vasodilation and improvement in an experimental model of HPS.

**Method:** HPS model was developed in mice by common bile duct ligation (CBDL). After 2 weeks of CBDL, the hypoxemia and intrapulmonary shunting on a background of liver fibrosis were seen. Group A (n = 10) received S1P (1 μM/g), Group B (n = 10) fingolimod (100 μM/g) and Group C (n = 10) normal saline, twice a week intraperitoneally for next 3 weeks and were compared with Group D; (n = 10) sham operated. Animals were assessed for PaO<sub>2</sub>

#### Bronchioalveolar Lavage

#### Liver Histology

Figure: (abstract: PO-2213)

(mmHg), vessel formation using 6 µm microspheres, trans-endothelial albumin influx, lung wet-dry ratio, liver histology, hepatocyte proliferation. Bronchioalveolar lavage (BAL) was analysed for alveolar macrophages activation, S1P, nitric oxide levels. mRNA levels for genes of iNOS, eNOS, SPHK1/2, S1P receptors.

**Results:** In CBDL HPS model, after 3 weeks of treatment, animals in Gr.B had significantly improved gas exchange with increased PaO<sub>2</sub> levels (p = 0.032), significantly less intra-pulmonary shunting and trans-endothelial albumin influx (p = 0.023) than Gr. C. Whereas, Gr. A also showed reduction but could not achieve significance. The lung wet to dry ratio showed significant reduction in both the Gr. A and B (p = 0.042; 0.048) than Gr. C. Upon BAL analysis, hemosiderin laden macrophages/20× field showed significant reduction in Gr. B than C (12 ± 5 vs 84 ± 26; P = 0.002). Also, the NO levels in BAL decreased in Gr. B but not in Gr. A. The lung iNOS, eNOS genes were reduced <8-fold in Gr. A and B than C (p < 0.00). Among S1P receptors, S1PR-3 was 2-fold upregulated in Gr. B than Gr. A (p < 0.001). The liver histology showed reduction in ductal proliferation and inflammation, while no morphological changes in Gr. D was observed. The Sirius red staining showed reduction in fibrosis grade from F3 to F1 in Gr. B, F3 to F2 in Gr. A. The PCNA showed significant increase, depicting hepatocytes proliferation in Gr. B than A, C (p < 0.001). Upon follow-up for 8 weeks, Gr. B significantly improved survival than Gr. C (p = 0.042).

**Conclusion:** CBDL in mice induces HPS, which is mediated by excessive NO production. Administration of fingolimod after development of HPS is a novel potential drug for reducing the intrapulmonary shunting, inflammation and fibrosis in HPS. Fingolimod treatment improves experimental HPS by counteracting vasodilation and potentiates an attractive therapeutic strategy for human HPS.

**PO-2279**

**Obese-induced brain sphingolipid dysregulation in bile-duct ligated rats accelerates and exacerbates hepatic encephalopathy**

Rafael Ochoa-Sanchez<sup>1,2</sup>, Mélanie Tremblay<sup>1</sup>, Christopher F. Rose<sup>1,2</sup>.  
<sup>1</sup>Centre de recherche du CHUM (CRCHUM), Montreal, Canada;  
<sup>2</sup>Université de Montréal, Medicine, Montreal, Canada  
 Email: rochoa.sanchez@gmail.com.

**Background:** Hepatic encephalopathy (HE) is a neuropsychiatric syndrome observed in chronic liver disease (CLD/cirrhosis). With an increasing prevalence of obesity-induced cirrhosis and evidence linking blood-derived lipids and brain lipid alterations to neurological impairment, we hypothesize that obese-induced brain lipid dysregulation increases the progression of HE in bile-duct ligated (BDL) rats. Aim: Study the impact of obesity on brain sphingolipids and the development of neurological impairment in a rat model of CLD and obesity.

**Method:** CLD and HE model: 5-week BDL rats and Sham-controls, were used. Groups: Obese-BDL (O-BDL) and Obese-Sham (O-Sham) received high-fat diet (HFD) for 25-days pre-BDL surgery and then proceeded with high-carbohydrate diet (HCD) for 5 weeks post-BDL; Lean-BDL (L-BDL) and Lean-Sham (L-Sham) received regular-diet (RD) pre-BDL surgery and then HCD post-BDL. Body weight (BW), fat-mass, behavior, plasma liver markers and brain hippocampal sphingolipids were measured at 0 (pre-BDL), 3 and 5 weeks post-BDL.

**Results:** Pre-BDL, HFD lead to increased BW and fat mass vs RD which was sustained with HCD in O-BDL vs L-BDL at 3 and 5 weeks. Ammonia, albumin, AST, ALT, ALP and bilirubin were impaired in O-BDL and L-BDL vs Shams at 3 and 5 weeks. High-density (HDL) and low-density (LDL) lipoprotein levels were detected in pre-BDL rats which persisted in O-BDL and L-BDL vs controls at 3 and 5 weeks. LDL and total-cholesterol were higher in O-BDL vs L-BDL at 5 weeks.

Short- and long-term (LTM) memory were impaired in both BDL groups at 5 weeks, whereas at 3 weeks, LTM impairment was found solely in O-BDL. Furthermore at 3 weeks, motor coordination was reduced in O-BDL, but not in L-BDL. At 5 weeks, motor coordination decreased in both BDL groups, with worse performance in O-BDL vs L-BDL. At 3 and 5 weeks, skill learning improved in L-Shams and L-BDL, but not in O-Shams and O-BDL. Muscle-strength was reduced in L-BDL but not in O-BDL vs Shams. Hippocampal sphingomyelin lipids were increased in O-BDL vs L-BDL rats at 0, 3 and 5 weeks, while ceramides were only reduced at 5 weeks.

**Conclusion:** CLD-obesity rat model is characterized by increased fat mass and hyperlipidemia pre- and post-BDL. Neurological decline in O-BDL rats developed earlier and was more severe vs L-BDL rats. In addition, different neurological impairments developed in O-BDL vs L-BDL. Brain sphingolipid alteration in obese-cirrhotic rats may contribute to accelerate/worsen HE.

**PO-2382**

**Role of sex on the development of sarcopenia and ammonia metabolism in bile-duct ligated rats**

Mariana M. Oliveira<sup>1,2</sup>, Alexis Monnet Aimard<sup>3</sup>, Tremblay Mélanie<sup>1</sup>, Christopher F. Rose<sup>1,2</sup>.  
<sup>1</sup>Centre de recherche du CHUM (CRCHUM), Montréal, Canada; <sup>2</sup>Université de Montréal, Medicine, Montréal, Canada; <sup>3</sup>Institute of Neuroscience of la Timone, Marseille, France  
 Email: marianaoliveira39@yahoo.com.br.

**Background and aims:** In chronic liver disease (CLD) loss of muscle mass (sarcopenia) is highly prevalent which leads to an increased risk in hepatic encephalopathy (HE). Muscle plays a compensatory role during liver disease in clearing ammonia since it contains glutamine synthetase (GS). Therefore, diminished muscle mass leads to a further reduced capacity to remove ammonia. Loss of muscle mass has been described in male rats with CLD but has not been explored in female CLD rats. Our aim was to identify whether sex has an effect on muscle mass and blood ammonia levels.

**Methods:** Five weeks after either BDL (n = 8) or Sham (n = 8) surgery in male and female rats, the following were assessed; markers of liver injury and function, HE (open field test for anxiety, rota-rod test for motor coordination and night-time activity), body parameters (weight, composition (MRI) and gastrocnemius muscle weight/circumference and grip strength). In addition, muscle GS activity and muscle ammonia clearance as well as glutamine generation (femoral venous-arterial difference) were evaluated in female vs male BDL rats.

**Results:** Female and male BDL rats had similar levels of impaired liver markers (ALP, AST, bilirubin and albumin (p < 0.001)) and both developed HE (motor-coordination and night activity (p < 0.05)) when compared to respective Shams. Male BDL rats experienced loss of lean mass, muscle weight and strength (p < 0.01) while no differences were found in female BDL vs Sham rats. Male and female BDL rats had similar ammonia clearance and glutamine production by muscle, while GS activity was lower in female vs. male BDL rats (p < 0.01).

**Discussion:** Our results demonstrate that following BDL surgery, female rats develop CLD and HE comparable to male rats. However, contrary to males, female BDL rats did not develop sarcopenia compared to respective controls. Preserved muscle mass in female BDL did not result in lower blood ammonia (higher ammonia clearance) whereas muscle mass loss in male BDL rats was accompanied with an upregulation in GS which may explain the similar blood ammonia levels found in both male and female BDL rats.

#### Impact of a loss-of-function variant in HSD17B13 on hepatic decompensation and mortality in cirrhotic patients

Antonio Gil-Gomez<sup>1</sup>, Javier Ampuero<sup>1,2</sup>, Sheila Gato Zambrano<sup>1</sup>, Rocío Montero-Vallejo<sup>1</sup>, Rocio Munoz Hernandez<sup>1</sup>, Douglas Maya<sup>1</sup>, Rocío Gallego-Durán<sup>1</sup>, Angela Rojas Alvarez-Ossorio<sup>1</sup>, Rubén Francés<sup>3</sup>, German Soriano<sup>4</sup>, Manuel Romero Gomez<sup>1,2</sup>. <sup>1</sup>SeLiver Group at Institute of Biomedicine of Seville (IBiS), Virgen del Rocio University Hospital/CSIC/University of Seville, Spain; <sup>2</sup>UCM Digestive Diseases, Virgen del Rocio University Hospital, Seville, Spain; <sup>3</sup>Instituto de Investigación Sanitaria y Biomédica de Alicante. Dpt. Clinical Medicine, Miguel Hernández University, Alicante, Spain; <sup>4</sup>Department of Gastroenterology Hospital de la Santa Creu i Sant Pau, Barcelona, Spain. Email: mromerogomez@us.es.

**Background and aims:** A common splice variant in HSD17B13 (rs72613567:TA) was recently found to be associated with a reduced risk of developing chronic liver disease (NAFLD/ALD) and its related fibrosis and cirrhosis (Abul-Husn *et al.*, NEJM 2018). By contrast, recent data showed worse outcomes in patients with advanced chronic liver disease carrying the mutation (Scheiner *et al.*, Liver Int, 2020). In this study, we aimed to evaluate the prognosis of cirrhotic patients harbouring this variant.

**Method:** We performed a retrospective analysis in 442 prospectively recruited cirrhotic patients from three different hospitals in Spain followed-up for 5 years. Clinical, demographical and biochemical data was collected, and we performed a genotyping analysis for common variants previously associated to liver disease risk.

**Results:** The majority of patients were male (68.1%), mean age of 59.4 with predominance of alcoholic etiology (48%) over viral hepatitis (43%). Liver function was MELD 12.4 ± 5.3, Child A/B (87.1%). 268 (60.6%) patients harbored the wild-type T- of rs72613567, 130 (29.4%) were heterozygous and 44 (10.0%) homozygous for the variant TA. Surprisingly, patients homozygous for the TA-allele had higher MELD ( $p = 0.041$ ), Child-Pugh score ( $p = 0.014$ ), INR levels ( $p = 0.047$ ), as well as decreased albumin ( $p = 0.007$ ) at baseline. After multivariate analysis, we found that patients with the “low-risk” variant had indeed increased risk of hepatic decompensation (aOR 2.533; 1.071–7.373,  $p < 0.05$ ) and liver related mortality (aOR 2.184; 1.015–4.698,  $p < 0.05$ ). Specifically, these patients had increased risk of developing ascites (Log-R 8.7,  $p < 0.05$ ), hepatic encephalopathy (Log-R 5.5,  $p < 0.05$ ) and higher mortality (Log-R 4.5,  $p < 0.05$ ) at 5 years of follow-up. However, no differences were found in the frequency of HCC (24.5% in T-TA vs 18.2% TA/TA,  $p = 0.232$ ). No association was found for the variant rs738409 in PNPLA3.

**Conclusion:** These findings suggest that the variant rs72613567: TA HSD17B13 has no protective effect, but indeed increases the risk of decompensation and death in patients with advanced chronic liver disease. Further studies focusing on the effects of HSD17B13 genotypes in patients with different stages of liver disease are needed.

### PO-2833

#### Early and late changes in the phenotype of liver sinusoidal endothelial cells (LSECs) along the development of heart failure

Kamila Wojnar-Lason<sup>1,2</sup>, Agnieszka Kij<sup>1</sup>, Patrycja Kaczara<sup>1</sup>, Agnieszka Jasztal<sup>1</sup>, Stefan Chlopicki<sup>1,2</sup>. <sup>1</sup>Jagiellonian Centre for Experimental Therapeutics (JCET), Kraków, Poland; <sup>2</sup>Jagiellonian University Medical College, Faculty of Medicine, Chair of Pharmacology, Kraków, Poland

Email: kamila.wojnar-lason@jcet.eu.

**Background and aims:** Heart failure (HF) is one of the leading causes of death worldwide. During the development of heart failure the hepatic circulation may be impaired, that consequently leads to the tissue hypoxia and alternations in liver function. The aim of the study was to characterize the changes in the phenotype of LSECs during the progression of HF in the unique murine model of this disease

represents by Tgαq\*44 mice, which importantly mimics all the typical characteristics of HF in humans.

**Method:** LSECs and livers were isolated at early (4-month-old mice) and late stage (12-month-old mice) of HF development from Tgαq\*44 female mice ( $n = 6$ ). Organs were fixed and stained by HandE and PSR. LSECs were cultured overnight in medium under hypoxia conditions, and were subsequently used to assess phenotype changes related to HF progression—the expression level of endothelial markers (immunocytochemistry), eicosanoid biosynthesis (UPLC-MS/MS) and changes in cellular metabolism (Seahorse) were investigated.

**Results:** Livers obtained from 12-months old Tgαq\*44 mice did not display fibrosis but were characterized by wider sinusoids as compared with age-matched FVB mice. In the early stage of the development of HF in Tgαq\*44 mice, LSECs were characterized by lower expression of COX-1, eNOS and pro-inflammatory markers, whereas the iNOS expression remained unchanged. The decreased biosynthesis of COX-dependent eicosanoids (PGI<sub>2</sub> measured as 6-keto-PGF<sub>2α</sub>PGE<sub>2</sub>, PGF<sub>2α</sub>) was also observed in LSECs in the early phase of HF. Furthermore, LSECs isolated from young Tgαq\*44 mice displayed increased biosynthesis of anti-inflammatory and vasoprotective EETs, that was reflected by increased level of their metabolites (8-, 9-, 11, 12- and 14, 15-DHET). Interestingly, the biosynthesis of 12- and 15-HETE was decreased in Tgαq\*44 mice LSECs independently of the phase of HF. Additionally, the late phase of HF was associated with changes in the bioenergetics of LSECs towards activation of glycolysis pathway. Mitochondrial stress test (MST) and glycolytic stress test (GST) revealed that LSECs isolated from 12-month-old Tgαq\*44 mice were metabolically more active than age-matched FVB mice.

**Conclusion:** In the early phase of HF LSECs were characterized by endothelium-derived NO deficiency along with decreased expression of COX-1 and a shift in eicosanoid biosynthesis from COX-dependent prostanoids to CYP-450-dependent EETs. Taking into account, that EETs are considered as vasoprotective mediators the activation of EET-dependent may represent a compensatory mechanism in response to decreased bioavailability of NO related to HF development. The late stage of heart failure was dominantly featured by the overactivation of glycolysis pathway and an increased ATP production in LSECs.

Taking together, HF development induces alterations in LSEC phenotype, that may contribute to the liver dysfunction of HF.

### PO-2851

#### In vitro skeletal muscle cell atrophy and mitochondrial dysfunction after exposure to human serum from patients with ESLD and NAFLD

Sophie Allen<sup>1,2</sup>, Alex Seabright<sup>1</sup>, Jonathan Quinlan<sup>1,2</sup>, Amritpal Dhaliwal<sup>2,3,4</sup>, Felicity Williams<sup>2,3,4</sup>, Nick Fine<sup>5</sup>, David Hodson<sup>5,6</sup>, Yu-Chiang Lai<sup>1,5,7</sup>, Matthew Armstrong<sup>2,4</sup>, Ahmed Elsharkawy<sup>2,4</sup>, Carolyn Greig<sup>1,2,7</sup>, Janet Lord<sup>2,3,7</sup>, Gareth Lavery<sup>2,5,6</sup>, Leigh Breen<sup>1,2,7</sup>. <sup>1</sup>University of Birmingham, School of Sport, Exercise and Rehabilitation Sciences, Birmingham, United Kingdom; <sup>2</sup>National Institute for Health Research, Birmingham Biomedical Research Centre at University Hospitals Birmingham, Birmingham, United Kingdom; <sup>3</sup>University of Birmingham, Institute of Inflammation and Ageing, Birmingham, United Kingdom; <sup>4</sup>Queen Elizabeth Hospital Birmingham, Liver Unit, Birmingham, United Kingdom; <sup>5</sup>University of Birmingham, Institute of Metabolism and Systems Research, Birmingham, United Kingdom; <sup>6</sup>Birmingham Health Partner, Centre for Endocrinology, Diabetes and Metabolism, Birmingham, United Kingdom; <sup>7</sup>University of Birmingham, MRC-Versus Arthritis Centre for Musculoskeletal Ageing Research, Birmingham, United Kingdom

Email: l.breen@bham.ac.uk.

**Background and aims:** Sarcopenia, defined as a loss of muscle mass, strength and function is a common complication associated with End Stage Liver Disease (ESLD). Despite its clinical importance, the mechanisms which contribute to the development of sarcopenia in

Figure: (abstract: PO-2851)

ESLD remain unclear. Therefore, we aimed to investigate the mechanistic drivers of sarcopenia in ESLD through the use of an in vitro model utilising ex vivo human serum from ESLD and non-alcoholic fatty liver disease (NAFLD) patients.

**Method:** Fasted blood samples were obtained from 4 age-matched control ( $64.7 \pm 10.0$ ), 4 non-cirrhotic NAFLD ( $61.8 \pm 7.6$ ) and 4 decompensated ESLD ( $60.5 \pm 1.7$ ) patients. C2C12 myotubes were serum and amino acid starved for 1 hour and subsequently conditioned with serum from control, NAFLD and ESLD patients for 4 or 24 hours. After 4 hours C2C12 myotubes were treated with 5 mM leucine for 30-minutes. Myotube diameter was assessed using fluorescent microscopy. Mitochondrial function was measured through: (1) respiration, utilizing a mitochondrial stress test on a XFe24 Seahorse Analyser; (2) mitophagy, assessed using a C2C12 mitoQC cell line. Muscle protein synthesis (MPS) was determined using the surface sensing of translation (SUnSET) technique and signaling markers of anabolic and catabolic pathways was measured via Western blotting.

**Results:** Myotube diameter was reduced in myotubes treated with serum from ESLD patients in comparison to both control (45%) and NAFLD (35%) patients ( $p < 0.001$  for both). A reduction in maximal mitochondrial respiration, coupling efficiency and mitophagy was identified in myotubes conditioned with both NAFLD and ESLD serum in comparison to controls ( $p < 0.05$  for both). No difference in mitochondrial protein content was identified. MuRF-1, a catabolic protein, was elevated in myotubes treated with ESLD serum in comparison to control serum ( $p = 0.03$ ). Leucine treatment did not alter muscle protein breakdown (MPB) signaling in any group. No change in MPS or anabolic signaling markers was identified within or between groups, in the presence or absence of leucine treatment.

**Conclusion:** We show myotube atrophy in cells conditioned with ex vivo human serum from ESLD patients in comparison to control and NAFLD patients, which may be caused through mitochondrial dysfunction and an increase in MPB. This work provides an experimental platform to further probe mechanisms of sarcopenia within ESLD and to develop potential therapeutic targets to mitigate sarcopenia.

## Cirrhosis and its complications: Other clinical complications except ACLF and critical illness

### PO-187

#### Non-malignant portal vein thrombi in patients with cirrhosis consist of intimal fibrosis with or without a fibrin-rich thrombus

Ellen Driever<sup>1</sup>, Fien von Meijefeldt<sup>1</sup>, Jelle Adelmeijer<sup>1</sup>, Robbert J. de Haas<sup>2</sup>, Marius C. van den heuvel<sup>3</sup>, Chandrasekaran Nagasami<sup>4</sup>, John W. Weisel<sup>4</sup>, Robert J. Porte<sup>1</sup>, Anabel Blasi<sup>5</sup>, Nigel Heaton<sup>6</sup>, Stephen Gregory<sup>7</sup>, Pauline Kane<sup>7</sup>, William Bernal<sup>6</sup>, Yoh Zen<sup>6</sup>, Ton Lisman<sup>1</sup>. <sup>1</sup>University Medical Center Groningen, Surgery, Groningen, Netherlands; <sup>2</sup>University Medical Center Groningen, Radiology, Groningen, Netherlands; <sup>3</sup>University Medical Center Groningen, Pathology and Medical Biology, Groningen, Netherlands; <sup>4</sup>Perelman School of Medicine at the University of Pennsylvania, Cell and Developmental Biology, Philadelphia, United States; <sup>5</sup>Hospital Clinic, Anesthesiology, Barcelona, Spain; <sup>6</sup>King's College Hospital, Institute of Liver Studies, London, United Kingdom; <sup>7</sup>King's College Hospital, Radiology, London, United Kingdom  
Email: e.g.driever@umcg.nl

**Background and aims:** Portal vein thrombosis (PVT) is a common complication of cirrhosis. The exact pathophysiology remains largely unknown and treatment with anticoagulants only lead to recanalization of the portal vein in a proportion of patients. A better insight in the structure and composition of portal vein thrombi may assist in developing a more rational treatment approach.

**Method:** Eight prospectively and 63 retrospectively collected non-malignant portal vein thrombi from cirrhotic patients who underwent liver transplantation were included. Histology, immunohistochemistry and scanning electron microscopy were used to assess structure and composition of the thrombi. Most recent CT scans were reanalysed for thrombus characteristics. Clinical characteristics were related to histological and radiological findings.

## POSTER PRESENTATIONS

**Results:** All prospective and retrospective samples showed a thickened, fibrotic tunica intima. Fibrin-rich thrombi were present on top of the fibrotic intima in 4/8 prospective cases and in 21/63 retrospective cases. A minority of the fibrotic areas stained focally positive for fibrin (ogen) (fg, 16% of the cases), Von Willebrand Factor (VWF, 10%) and CD61 (platelets, 21%), while most of the fibrin-rich areas stained positive for those markers (fg, 100%; VWF, 77%; CD61, 100%). No associations were found between clinical characteristics including estimated thrombus age and presence of fibrin thrombi.

**Conclusion:** Here we demonstrated that PVT in cirrhotic patients consists of intimal fibrosis with an additional fibrin-rich thrombus in only a third of the cases. These results suggest that the majority of portal vein thrombi in cirrhotic patients are unlikely to recanalise by anticoagulant therapy.

### PO-342

#### Improved survival and reduced risk of hospital admissions after 12-weeks of resistance training in patients with cirrhosis—a three year follow-up from randomization

Luise Aamann<sup>1,2</sup>, Gitte Dam<sup>1</sup>, Peter Jepsen<sup>1</sup>, Hendrik Vilstrup<sup>1</sup>, Niels Kristian Aagaard<sup>1</sup>. <sup>1</sup>Aarhus University Hospital, Department of Hepatology and Gastroenterology, Aarhus, Denmark; <sup>2</sup>Copenhagen University Hospital Hvidovre, Gastro Unit, Medical division, Denmark  
Email: luise.aamann@gmail.com

**Background and aims:** Cirrhosis is a serious condition that causes frequent acute admissions to the hospital and may shorten life expectancy. Physical activity provides a remarkable variety of health benefits, and exercise may extend lives—even in patients with chronic diseases.

We followed participants from a clinical trial over a period of three years after randomization. The intervention was supervised resistance training for 12 weeks. Our aim was to estimate the effect of resistance training on overall survival estimates and the risk of the first acute hospitalization after three years.

**Method:** 39 participants with cirrhosis Child-Pugh stage A/B were randomly assigned to either a group performing 12 weeks of supervised resistance training or a control group. Regardless of cause, all deaths and acute admissions to the hospital were registered during the three-year follow-up.

Here we present an intention-to-treat analysis including all participants from randomization. We used Cox regression for survival analysis and Fine and Gray regression to analyze time to first admission with death before hospitalization as a competing risk. Both analyses were adjusted for Child-Pugh A or B at randomization.

**Results:** Baseline values were similar between groups. During the follow-up 1 exerciser and 6 controls died. After three years (1095 days), we found a statistically and clinically significant difference in survival in favor of patients randomized to resistance training: adjusted hazard ratio 0.12 (95% CI: 0.01–0.96;  $p = 0.046$ ).

All through the follow-up 9 exercisers and 15 controls were acutely hospitalized at some point. The risk of an acute admission to the hospital three years after randomization was reduced in exercisers compared to controls: adjusted subdistribution hazard ratio 0.40 (95% CI: 0.17–0.92;  $p = 0.032$ ).

**Conclusion:** Twelve weeks of supervised resistance training may increase survival and reduce the risk of acute hospitalization three years after exercise.

However, these data are based on a secondary outcome of a randomized clinical trial and larger studies with survival and hospital admission as primary end points are required to confirm the effect of resistance training.

### PO-485

#### Baveno-VI criteria to predict variceal bleeding and liver decompensation in compensated cirrhosis patients

Yu Jun Wong<sup>1,2</sup>, Martin Putera<sup>1</sup>, Francis Teh<sup>1</sup>. <sup>1</sup>Changi General Hospital, Gastroenterology and hepatology, Singapore; <sup>2</sup>Duke-NUS Medical School, Singapore  
Email: eugene.wong.y.j@singhealth.com.sg

**Background and aims:** Hepatic venous pressure gradient (HVPG) is an invasive approach to identify compensated cirrhosis patients with clinically significant portal hypertension and at risk of liver decompensation. The Baveno-VI criteria can safely omit screening esophagogastroduodenoscopy (EGD) in compensated cirrhosis patients. Beyond the exclusion of high-risk varices, it was uncertain if Baveno-VI criteria could predict the clinically meaningful end points such as variceal bleeding and liver decompensation in compensated cirrhosis patients. We aim to compare the performance of the Baveno-VI and expanded Baveno-VI criteria to predict the risk of liver decompensation among compensated cirrhosis patients.

**Method:** Compensated cirrhosis patients with liver stiffness measurement (LSM) performed from 2013 to 2018 in our institution were prospectively included in a database for analysis. All subjects had paired EGD with LSM. Patients with prior liver decompensation were excluded. All patients were followed-up until the occurrence of liver decompensation (variceal bleeding, ascites and hepatic encephalopathy).

**Results:** We included 304 compensated cirrhosis patients. Median follow-up was 36 (IQR: 22–50) months. Mean age and MELD score were  $55 \pm 11$  and  $8 \pm 3$ , respectively. 14 (4.6%) patients had HRV.

The expanded Baveno-VI criteria spare more EGD than the Baveno-VI criteria (57% vs 28%,  $p < 0.001$ ) without missing more high-risk varices (2.3% vs 1.2%,  $p = 0.25$ ). Patients with favourable Baveno-VI status had a lower rate of missed gastroesophageal varices at baseline (3.5% vs 14.1%,  $p < 0.001$ ) and a lower risk of liver decompensation during follow-up (1.2% vs 5.2%,  $p = 0.008$ ) compared to those with favourable expanded Baveno-VI status.

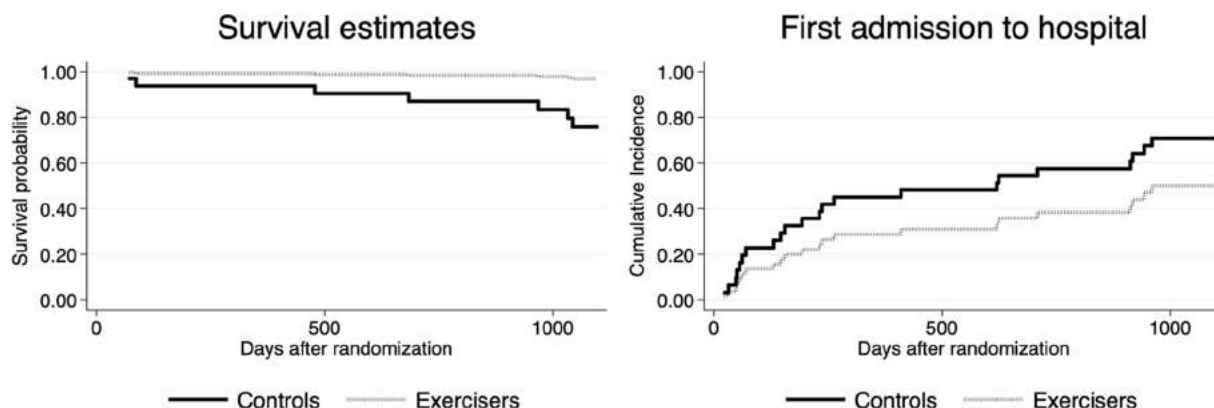

Figure: (abstract: PO-342)

Both criteria had similar risk of developing variceal bleeding (1.2% vs 3.4%,  $p = 0.063$ ), ascites (0% vs 2%,  $p = 0.250$ ) or HE (0% vs 2%,  $p = 0.250$ ) during the follow-up. The Baveno-VI criteria also have a higher sensitivity and negative predictive value to predict liver decompensation than the expanded Baveno-VI criteria (sensitivity: 96% vs 68%, specificity: 31% vs 60%, positive-predictive value: 12% vs 15% and negative predictive value: 99% vs 95%).

**Conclusion:** The Baveno-VI criteria is superior to the expanded Baveno-VI criteria to identify compensated cirrhosis patients at risk of liver decompensation. As HPVG is invasive and not widely available, the Baveno-VI criteria may be a non-invasive alternative to identify compensated cirrhosis patients with clinically significant portal hypertension for early treatment.

**PO-714**

**Prognostic impacts of the change in muscle mass on patients with cirrhosis**

Tae Hyung Kim<sup>1</sup>, Young Kul Jung<sup>1</sup>, Hyung Joon Yim<sup>1</sup>, Young-Sun Lee<sup>1</sup>, Sun Young Yim<sup>1</sup>, Ji Hoon Kim<sup>1</sup>, Yeon Seok Seo<sup>1</sup>, Jong Eun Yeon<sup>1</sup>, Kwan Soo Byun<sup>1</sup>, Soon Ho Um<sup>1</sup>. <sup>1</sup>Korea University College of Medicine, Internal medicine, Seoul, Korea, Rep. of South  
Email: 93cool@hanmail.net

**Background and aims:** Sarcopenia has a negative impact on the prognosis of patients with cirrhosis. Although muscle mass changes are also expected to be an important factor, available data are limited yet.

**Method:** Adults with cirrhosis were included from the prospective cohort who received the abdomen CT annually for HCC surveillance. L3 skeletal muscle index (SMI) was adopted as a proxy of skeletal muscle mass, and we calculated a change of SMI between baseline and one-year ( $\Delta$ SMI/yr).

**Results:** Among a total of 155 patients, 113 and 21 had sarcopenia and Child-Pugh class B/C decompensation, respectively. During a median follow-up of 36 months, five patients died and 19 had undergone complications of cirrhosis. Multivariate Cox regression analyses showed 1% decrease in  $\Delta$ SMI/yr was associated with a 1.15–1.19-fold increased risk of complication occurrence even adjusted for Child-Pugh or MELD score. In addition,  $\Delta$ SMI/yr showed good prediction of aggravation of liver function (Child-Pugh score at 2 years after baseline), especially in female patients ( $n = 46$ ), with a cut-off of  $-2.5\%$  (sensitivity 57.1%, specificity 94.9%).

Figure:

**Conclusion:**  $\Delta$ SMI/yr was significantly associated with prognosis of patients with cirrhosis independent of baseline Child-Pugh and MELD scores.

**PO-835**

**Safety of 11, 043 paracentesis in patients with liver cirrhosis with and without anticoagulant treatment. Large, retrospective, unicentric study**

Jordi Vives Moreno<sup>1</sup>, Eduard Brunet<sup>1</sup>, Cristina Solé<sup>1</sup>, Gemma Solé<sup>2</sup>, Meritxell Casas<sup>1</sup>, Mireia Miquel<sup>1,3</sup>, Jordi Sánchez-Delgado<sup>1,3</sup>, Montserrat Gil<sup>1</sup>, Jose Alberto Ferrusquia<sup>1</sup>, Oliver Valero<sup>4</sup>, Mercedes Vergara<sup>1,3</sup>. <sup>1</sup>Corporació Sanitària Parc Taulí, Parc Taulí Hospital Universitari, Institut d'Investigació i Innovació Parc Taulí I3PT, Universitat Autònoma de Barcelona, Sabadell, Spain; <sup>2</sup>Corporació Sanitària Parc Taulí, Laboratory and analysis service, Parc Taulí Hospital Universitari, Institut d'Investigació i Innovació Parc Taulí I3PT, Universitat Autònoma de Barcelona, Sabadell; <sup>3</sup>Instituto de Salud Carlos III, Centro de Investigación Biomédica en Red de Enfermedades Hepáticas y Digestivas (CIBERehd), Instituto de Salud Carlos III, Madrid; <sup>4</sup>Universitat Autònoma de Barcelona, Applied Statistics Service, Universitat Autònoma de Barcelona, Cerdanyola del Vallès  
Email: jordivivesm@gmail.com

**Background and aims:** Paracentesis is a diagnostic and therapeutic procedure frequently used in patients with liver cirrhosis (LC). Patients with LC have a complex coagulation disorder with alteration in coagulation parameters that poorly correlate with bleeding risk. Moreover, some of these patients receive antiplatelet (APT) or anticoagulation (ACT) treatment. There is no consensus about the use of these therapies during paracentesis. The aim of this study is to evaluate the safety of the paracentesis and the incidence of paracentesis-related haemorrhagic complications (PHC) in patients with LC particularly in those patients receiving APT or ACT.

**Method:** Retrospective, unicentric, and observational study. All paracentesis performed in adult patients with LC in our centre from January 1998 to December 2018 were identified by clinical history registers. PHC were identified by ICD-9-CM codes.

**Results:** A total of 11, 043 paracentesis in 1, 137 patients with LC were identified. The mean age was  $65 \pm 12.2$  years. A 2.4% ( $n = 273$ ) of paracentesis were performed under AP: 1.6% ( $n = 182$ ) treated with acetylsalicylic acid, 0.8% ( $n = 89$ ) with clopidogrel and 0.0002% ( $n = 2$ ) with ticagrelor. And 6.3% ( $n = 698$ ) of paracentesis were performed under AC: 4.5% ( $n = 494$ ) treated with acenocoumarol, 1.8% ( $n = 202$ ) with heparin and 0.006% ( $n = 4$ ) with apixaban. PHC occurred in 36 (0.3%) of all paracentesis performed. In those patients, 78% ( $n = 28$ ) received red blood cells transfusion, 31% ( $n = 11$ ) needed arterial embolization, and 28% ( $n = 10$ ) required plasma transfusion. One (2.8%) patient died because of a severe paracentesis-related bleeding. Variables associated with the development of PHC in the univariate analysis were the use of ACT (8 (1.1%) vs 27 (0.3%);  $p < 0.001$ ) and a higher INR (1.6 vs 1.4;  $p < 0.03$ ), bilirubin (1.9 vs 1.5;  $p < 0.04$ ), urea (73 vs 61;  $p < 0.03$ ) and MELD (17 vs 15;  $p < 0.012$ ) values. APT or heparin treatment, number of platelets and creatinine were not associated with bleeding events. Finally, ACT (OR: 3.23 (1.15–9.09);  $p = 0.027$ ), INR (OR: 6.75 (2.32–19.68);  $p = 0.001$ ) and urea (OR: 1.72 (0.94–3.15);  $p = 0.079$ ) were independently associated in the multi-variate analysis.

**Conclusion:** Paracentesis is an extremely safe procedure with only 0.3% of bleeding complications. Slightly higher risk was observed in patients under AC and those with worse liver function. More studies are needed to confirm these results.

PO-864

**Further analysis of simvastatin safety trial in patients with decompensated cirrhosis provides promising information about improving liver function and reducing cirrhosis severity**

Alberto Muñoz<sup>1</sup>, Florencia Pollarsky<sup>1</sup>, Mónica Marino<sup>1</sup>, Mariano Cartier<sup>1</sup>, Carlos Míguez<sup>1</sup>, Horacio Vázquez<sup>2</sup>, Daniel Alvarez<sup>3</sup>, Pablo Salgado<sup>4</sup>, Gustavo Romero<sup>1</sup>. <sup>1</sup>Hospital Dr. Carlos B. Udaondo, Hepatology Section, Buenos Aires, Argentina; <sup>2</sup>Hospital Dr. Carlos B. Udaondo, Clinical Unit, Buenos Aires, Argentina; <sup>3</sup>Fundación Favaloro, Ultrasound Service, Buenos Aires, Argentina; <sup>4</sup>Facultad de Odontología, Universidad de Buenos Aires, Instituto de Investigaciones en Salud Pública, Buenos Aires, Argentina  
Email: aemunoz@intramed.net

**Background and aims:** There is some evidence concerning the beneficial effects of statins in decompensated cirrhosis (DC) in the clinical research setting. In this regard, the chronic administration of simvastatin to DC patients was associated with reducing Child-Pugh class and Child-Pugh score at the end of a safety trial (EST). We assessed whether chronic simvastatin treatment could avoid liver function deterioration and decrease cirrhosis severity in these DC patients by further analyzing the safety trial.

**Method:** The safety phase IIa trial was conducted on 30 DC patients (Child-Pugh class A [n=6], B [n=22], and C [n=2]), who received simvastatin for up to one year. The primary end points of this further analysis were liver function and cirrhosis severity. The secondary end points were health-related quality of life (HRQOL), hospital readmissions by cirrhosis complications, and survival.

**Results:** Liver function improved at the EST compared to baseline, serum albumin concentration 3.3 ± 0.6 g/dL versus 2.9 ± 0.5 g/dL (p = 0.003); ascites 36.7% versus 63.3% (p = 0.008); and serum sodium concentration 135 ± 4 mEq/L versus 133 ± 4 mEq/L (p = 0.025). Cirrhosis severity reduced at the EST compared to baseline, (Child-Pugh class A: 53.3% versus 20.0%), (Child-Pugh class B: 40.0% versus 73.3%), and (Child-Pugh class C: 6.7% versus 6.7%) (p = 0.012), and Child-Pugh score 6.7 ± 1.7 versus 7.3 ± 1.3 (p = 0.041). Besides, 12 patients (40%) who at baseline were Child-Pugh class B became Child-Pugh class A at the EST. Serum albumin concentration was the only Child-Pugh variable showing a statistically significant difference in all comparisons carried out between Child-Pugh class A (n = 15) and Child-Pugh class B/C (n = 15) at the EST (p = 0.036). The physical component summary and its domains of HRQOL upgraded from baseline to the EST (p < 0.040). The hospitalizations for cirrhosis complications decreased from 76.7% (the year before the safety trial) to 26.7% (the year of the safety trial) (p = 0.002), and the survival rate reached 90%.

**Conclusion:** Chronic simvastatin treatment in DC patients has a promising prospect since improving liver function and reducing cirrhosis severity would improve HRQOL, it would in turn decrease hospital readmissions -by cirrhosis complications- and have a positive impact upon survival rate.

PO-918

**Low myocardial mechano-energetic efficiency is an independent predictor of prognosis in patients with advanced chronic liver disease**

Maurizio Cesari<sup>1</sup>, Anna Chiara Frigo<sup>2</sup>, Salvatore Piano<sup>1</sup>, Paolo Angeli<sup>1</sup>. <sup>1</sup>Unit of Internal Medicine and Hepatology, Department of Medicine, University of Padua, Italy, Department of Medicine, Padova, Italy; <sup>2</sup>Department of Cardiac, Thoracic and Vascular Sciences, University of Padua, Padua, Italy, Department of Cardiac, Thoracic and Vascular Sciences, Padova, Italy  
Email: maurizio.cesari@unipd.it

**Background and aims:** We aimed at investigating if a low myocardial mechano-energetic efficiency (MEE) with energy waste could be a feature of cirrhotic cardiomyopathy and predictive of poor prognosis.

**Method:** We retrospectively interrogated a large data set of 115 cirrhotic patients followed up for 6 years and compared with 50

healthy controls. Echocardiographic and haemodynamic parameters were assessed at baseline according with current guidelines. MEE was estimated by echocardiographic stroke volume (z-derived)/ (heart rate × 0.6).

**Results:** Cirrhotic patients presented low peripheral vascular resistance, a compensatory hyperdynamic syndrome with increased cardiac work, left atrial and left ventricular (LV) dimension and mass. Systolic parameters and MEE were similar between patients and controls. Patients with cirrhosis and refractory ascites showed significantly lower MEE compared with both patients with treatable ascites and patients without ascites (1.68 ± 0.47 vs 1.98 ± 0.64 and 1.80 ± 0.37 ml/s respectively, p < 0.05). Increased age and heart rate and reduced BSA, cardiac dimension and work significantly correlated with lower MEE, mostly in non-alcoholic as compared with alcoholic cirrhosis (1.65 ± 0.42 vs 1.95 ± 0.56 ml/s respectively, p = 0.002). Among the cardiovascular parameters increased early diastolic transmitral and myocardial velocity on tissue Doppler imaging ratio (E/e') was significantly associated to death; left atrium enlargement and reduced MEE were independent predictors of death (see table below).

**Conclusion:** In advanced chronic liver disease LV performance is blunted due to an energetically inefficient cardiac mechanical work which correlates with a poor prognosis. Therefore, the simple basal assessment of myocardial mechano-energetic efficiency can identify patients with a worse prognosis which requires a close follow-up.

Table: Parameters associated with death during follow-up (multivariate Cox's regression analysis)

Predictors	SHR (95% CI)	P
MELD	1.11 (1.07–1.15)	<0.0001
Age (years)	1.06 (1.02–1.09)	0.001
LA volume (ml/m <sup>2</sup> )	1.03 (1.01–1.06)	0.006
MEE (ml/s)	0.57 (0.33–0.98)	0.04
BSA (Kg/m <sup>2</sup> )	0.27 (0.04–1.66)	0.16

E/e' early diastolic transmitral and myocardial velocity on TDI ratio; LA, left atrium; MEE, myocardial mechano-energetic efficiency.

PO-932

**Prevalence and prognostic value of cirrhotic cardiomyopathy as defined according with the new proposed classification**

Maurizio Cesari<sup>1</sup>, Anna Chiara Frigo<sup>2</sup>, Salvatore Piano<sup>1</sup>, Paolo Angeli<sup>1</sup>. <sup>1</sup>Unit of Internal Medicine and Hepatology, Department of Medicine, University of Padua, Italy, Department of Medicine, Padova, Italy; <sup>2</sup>Department of Cardiac, Thoracic and Vascular Sciences, University of Padua, Padua, Italy, Department of Cardiac, Thoracic and Vascular Sciences, Padova, Italy  
Email: maurizio.cesari@unipd.it

**Background and aims:** The prevalence and prognostic relevance of cirrhotic cardiomyopathy (CCM), as defined according with the new core criteria proposed in 2019, is still unknown. We investigated this relevant issue in a large cohort of cirrhotic patients in different stages of liver disease.

**Method:** We retrospectively interrogated a data set of 162 collected cirrhotic patients followed up for at least 6 years, which at baseline underwent standard Doppler echocardiography and were compared with 46 healthy subjects. Left ventricular (LV) geometry, systo/diastolic function, global longitudinal strain and the main hemodynamic parameters were assessed according with current guidelines. Systolic dysfunction was diagnosed if LV ejection fraction ≤50% and/or GLS <18% or >22%.

**Results:** Adequate echocardiographic images permitting speckle tracking analysis were available in 83 patients. No patient presented LV ejection fraction ≤50%; GLS <18% or >22% was evident in 25%; advanced diastolic dysfunction was evident in 10%. Overall the prevalence of CCM was 29%. Patients with and without CCM presented similar clinical, biochemical, hemodynamic and

echocardiographic features at baseline and similar incidence of death after 6 years follow-up (see table below).

Table: Clinical, demographic and biochemical features of cirrhotic patients with and without CCM

Variable	CCM present (n 24)	CCM absent (n 59)	P	Healthy subjects (n 46)
Age (years)	60 ± 12	56 ± 10	NS	55 ± 10
Gender (Male %)	79	70	NS	48
Alcolic etiology (%)	50	43	NS	0
MELD	12 ± 7	12 ± 5	NS	0
Presence of ascites (%)	25	14	NS	0
Dead after 6 yrs FW (%)	38	36	NS	0
BMI (Kg/m <sup>2</sup> )	26 ± 3	26 ± 4	NS	25 ± 5
QTc	452 ± 32	453 ± 27	NS	410 ± 21
MAP (mmHg)	93 ± 11	96 ± 13	NS	97 ± 7
Heart rate (bpm)	71 ± 11	69 ± 10	NS	67 ± 10
Creatinine (µmol/L)	89 ± 37	96 ± 80	NS	NA
Aldosterone (ng/dL)	59 (32–86)	66 (48–84)	NS	NA

The data are reported as mean ± SD or median (and interquartile range) as appropriate. MAP, mean arterial pressure; NA, not available

**Conclusion:** According with the new criteria CCM is detected in 29%, mainly due to altered GLS at rest, but without prognostic relevance and therefore useless for the clinical management of cirrhotic patients.

**PO-974**

**Evaluation of cardiac function in cirrhosis across different prognostic stages; A focus on plasma biomarkers of fibrosis**

Jolanta Zuwała-Jagiello<sup>1</sup>, Monika Pazgan-Simon<sup>2</sup>, Ewa Grzebyk<sup>1</sup>, Joanna Gorka-Dynsiewicz<sup>1</sup>, Jacek Jagas<sup>3</sup>, Simon Krzysztof<sup>4</sup>. <sup>1</sup>Wrocław Medical University, Department of Pharmaceutical Biochemistry, Wrocław, Poland; <sup>2</sup>Wrocław Medical University, Clinic of Infectious Diseases, Liver Diseases and Acquired Immune Deficiency, Wrocław, Poland; <sup>3</sup>Cardiology Department County Hospital, Wrocław, Poland; <sup>4</sup>Wrocław Medical University, Clinic of Infectious Diseases, Liver Diseases and Acquired Immune Deficiency, Wrocław, Poland  
Email: jolanta.zuwala-jagiello@umed.wroc.pl

**Background and aims:** As myocardial fibrosis might be an important contributor to the association of liver cirrhosis with diastolic dysfunction and latent form of cirrhotic cardiomyopathy, we investigated the profile of some cardiac biomarkers, fibrosis, and proinflammatory biomarkers in patients with cirrhosis across different prognostic stages.

**Method:** Overall, 69 patients with liver cirrhosis were included, of whom 22 (32%) patients have compensated cirrhosis with portal hypertension and no varices, and 29 (42%) did not have any decompensating events but conducted regular follow-up and/or prophylactic endoscopic variceal treatment and 18 (26%) had decompensating event, gastrointestinal hemorrhage. We retrospectively screened the cirrhotic patients who had undergone the evaluation of laboratory data regarding plasma cardiac biomarkers [N-terminal pro-B-type natriuretic peptide (NT-pro BNP), high-sensitivity cardiac troponin T (hs-cTnT)], fibrosis biomarkers [carboxy terminal peptide of procollagen type I (PICP), amino terminal propeptide of procollagen type III (PIIINP), matrix metallo-proteinase-degraded type III collagen (C3M), tissue inhibitor of matrix proteinase-1 (TIMP-1) and pentraxin-3], various proinflammatory biomarkers (TNFα, IL-1β, IL-6, IL-8, IL-18) and pentraxin-3 (provides information reflecting the integrated effects of fibrosis, injury, and inflammation). All patients underwent transthoracic echocardiography.

**Results:** Cirrhotic patients with gastrointestinal hemorrhage had higher values of LV volumetric parameters, indexed parameters of LV myocardial mass (LVMM), and higher concentrations of NT-proBNP

(all p < 0.01). The concentrations of pentraxin-3 were greater in patients with varices and gastrointestinal hemorrhage compared to patients with compensated cirrhosis (p < 0.01 and p = 0.02, respectively). PICP and PICP/PIIINP ratio were greater in cirrhotic patients with gastrointestinal hemorrhage compared to patients with varices (p < 0.043 and p < 0.033, respectively). In all patients with cirrhosis, a relationship was found between pentraxin-3 and LVMM/body surface area (r = -0.42, p = 0.01), PIIINP, TIMP-1, and LV end-diastolic volume (r = -0.56 and p = 0.001 and r = 0.35 and p = 0.01, respectively).

**Conclusion:** The dynamics at different prognostic stages of the liver cirrhosis in the plasma fibrosis biomarkers may reflect an increase in fibrotic and decrease in antifibrotic processes already at the latent form of cirrhotic cardiomyopathy. At the same time, the changes found in the circulating procollagen levels may indicate an important role of type I collagen in the development of myocardial structural changes in cirrhosis. Ongoing inflammation has a significant role in the progression of cirrhosis affecting not only the liver but also leading to the development of structural and functional cardiac changes.

Email: j.macnaughtan@ucl.ac.uk

**Background:** Yaq-001 is a non-absorbable, synthetic carbon with high adsorptive capacity for bacterial products including lipopolysaccharide (LPS) and pro-inflammatory cytokines. Studies in cirrhotic rats showed reduced endotoxemia, improvements in end-organ dysfunction and reduced sensitisation to LPS. The aims of this study were to evaluate the safety and tolerability of Yaq-001 in

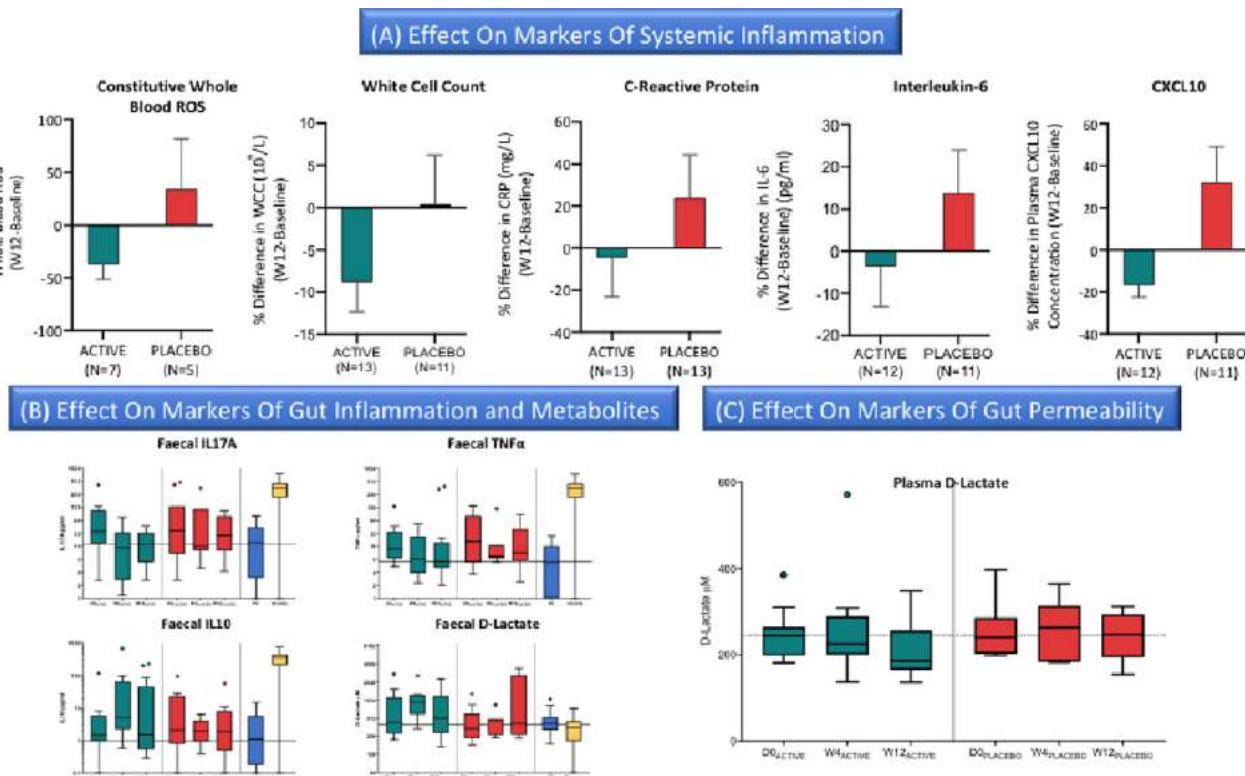

Figure 1: (abstract: PO-1045): Effect of Yaq-001 treatment on indices of systemic (A) and gut (B) inflammation and (C) gut permeability (SD ± SEM). HC and Decomp values from PMID: 32838247

decompensated cirrhotic (DC) patients and characterise immunological and metabolic effects.

**Methods:** This EU-funded H2020 study (CARBALIVE:634579) recruited patients with diuretic-responsive cirrhotic ascites. 28-patients from 8-EU centres were randomised to receive 4g of Yaq-001 (Y) or placebo (P) for 12-weeks. Safety assessments were performed at baseline, weeks 1, 4, 8 and 12. Endotoxin activity assay (EAA, data used for analysis: CV < 20%), organ function, nutrition, markers of systemic and gut inflammation, gut permeability, urinary <sup>1</sup>HMRS, and next generation sequencing of stool were evaluated at baseline, W4 and W12. Data were summarized by group and visit as means (SD) with select efficacy parameters modeled using MMRM.

**Results:** 14-patients were randomised to each group (Y: Age: 57.8 ± 7yrs, M:71%, MELD:12.4 ± 0.9; P: Age: 57.3 ± 10, M:75%, MELD:13.9 ± 1). **Safety:** Yaq-001 was well tolerated with no SAEs, stable MELD score, decompensation events and nutritional status. Compliance:93% (Y) 67% (P). **Endotoxemia:** Trends to reduction in EAA ratio (Y:-2.4% vs P:29.6%) and constitutive whole blood ROS (Y:-37.3% vs P:+34.3%) were observed in the active group. **Systemic inflammation:** Reductions in WCC, CRP, IL6 and CXCL10 in the active group were observed compared with placebo (Y (%): -8.8, -4.3, -3.6, -16.7; P (%) +0.4, +23.9, +13.8, +31.8). **Gut inflammation/permeability:** Improvements in faecal cytokines in Yaq-001 patients trended towards published values for healthy control. Reduction in plasma D-lactate was observed in Yaq-001 compared to placebo suggestive of an improvement in gut barrier integrity. **Metabolism:** Yaq-001 reduced stool ammonia with a trend to increased urinary hippurate. **Microbiome:** No change in bacterial diversity was observed.

**Conclusion:** Yaq-001 was safe and well tolerated. The data suggest proof of mechanism that Yaq-001, modulates systemic endotoxemia and inflammation by impacting gut inflammation and its permeability.

**PO-1102**

**Epidemiology of spontaneous bacterial peritonitis and bacterascites in patients with cirrhosis in Queensland, Australia from 2008 to 2017**

Isanka Ratnasekera<sup>1</sup>, Amy Johnson<sup>2,3</sup>, Elizabeth Powell<sup>2,3</sup>, Andrew Henderson<sup>4,5</sup>, Katharine Irvine<sup>1</sup>, Patricia Valery<sup>6</sup>. <sup>1</sup>The University of Queensland, Mater Research Institute, Brisbane, Australia; <sup>2</sup>Princess Alexandra Hospital, Department of Gastroenterology and Hepatology, Brisbane, Australia; <sup>3</sup>The University of Queensland, Centre for Liver Disease Research, Brisbane, Australia; <sup>4</sup>Princess Alexandra Hospital, Infection Management Services, Woolloongabba, Australia; <sup>5</sup>The University of Queensland, Centre for Clinical Research, Saint Lucia, Australia; <sup>6</sup>QIMR Berghofer Medical Research Institute, Herston, Australia

Email: amy.louise.johnson28@gmail.com

**Background and aims:** Spontaneous bacterial peritonitis (SBP), a common infection in patients with cirrhosis and ascites, is associated with high morbidity and mortality. The aim of this study was to investigate the longitudinal epidemiology of ascites fluid infections in an Australian population.

**Method:** A retrospective, population-based study of patients with cirrhosis admitted to public hospitals in Queensland during 2008–2017 was performed, linking demographic/clinical and microbiology data.

**Results:** Among 103, 165 hospital admissions of patients with cirrhosis, ascites was present in 16, 550 and in 60% (9, 977) a sample of ascitic fluid was tested. SBP was diagnosed in 770 admissions (neutrophil count >250/ml) and bacterascites in 552 (neutrophil count <250/ml with positive culture). The number of admissions with an ascites fluid infection increased by 76% from 2008 to 2017, paralleling an 84% increase in cirrhosis admissions. Patients with SBP had a longer hospital stay (median 15.7 vs 8.6 days from patients without SBP, p < 0.001) and higher in-hospital mortality,

although this decreased from 39.5% in 2008–2010 to 24.8% in 2015–2017 ( $p < 0.001$ ). Common Gram-positive isolates included *Coagulase negative Staphylococci* (37.9%), *Viridans group Streptococci* (12.1%), and *Staphylococcus aureus* (7.2%). Common Gram-negative isolates included *Escherichia coli* (13.0%), *Klebsiella pneumoniae* (3.1%) and *Enterobacter cloacae* (2.6%). The prevalence of antibiotic resistance was  $< 10\%$ .

**Conclusion:** SBP remains associated with high in-patient mortality and long hospital stays. Typical skin and bowel pathogen were common; therefore, empirical antibiotic therapy should target these pathogens. This study provides evidence informing infection management strategies in this vulnerable patient population.

**PO-1165**

**Cirrhocare-a pilot study of digital home-monitoring of advanced cirrhosis to determine feasibility and utility to diagnose new decompensation events**

Konstantin Kazankov<sup>1,2</sup>, Devnandan Amor Chatterjee<sup>1</sup>, Simone Novelli<sup>1</sup>, Alexandra Phillips<sup>1</sup>, Anu Balaji<sup>3</sup>, Maruthi Raja<sup>3</sup>, Rajiv Jalan<sup>1</sup>, Ravan Boddu<sup>3</sup>, Ravi Kumar<sup>3</sup>, Raj Mookerjee<sup>1,2</sup>. <sup>1</sup>Institute for Liver and Digestive Health, UCL Medical School, Royal Free Hospital, London, United Kingdom, Liver Failure Group, University College London (UCL), London, United Kingdom; <sup>2</sup>Aarhus University Hospital, Department of Hepatology and Gastroenterology, Aarhus N, Denmark; <sup>3</sup>CyberLiver Limited, Middlesex, United Kingdom  
Email: r.mookerjee@ucl.ac.uk

**Background and aims:** Patients discharged from hospital following acute decompensation are at high risk of new complications and need close follow-up, limited currently by the growing burden of cirrhosis and impact of COVID-19. Specialist hepatology care in the community is an urgent unmet need, to reduce hospital exposure and manage new decompensation events.

**Method:** We included 20 patients with cirrhosis and recent acute decompensation. Commercially available devices and a smartphone were given to all patients for daily recording of ECG, blood pressure, weight, and % body-water (bioimpedance), Stroop test (hepatic encephalopathy (HE) assessment), as well as self-reported well-being and food/fluid/alcohol intake. Data was Blue-toothed to the Cirrhocare-App, which also had 2-way patient-physician communication. Clinical hepatologists evaluated daily data and facilitated interventions by phone/text messages on the app as required. A propensity matched control cohort ( $n = 20$ ) with advanced cirrhosis, screened after study recruitment closed, was followed as per monitored patients.

**Results:** Patient demographics: Mean age  $59 \pm 10$  years, 14 male, main etiology alcohol (75%); 75% Child-Pugh class B. Fifteen patients (75%) showed good compliance ( $\geq 4$  readings/week), 2 had moderate compliance (2–4/week), and 3 had poor compliance ( $< 2$ /week). In a usability questionnaire scored 1–10, the median score was  $\geq 9$  for any given question.

Median follow-up was 10.1 (IQR 9–12) weeks. One patient died and 1 received a liver transplant (OLT). Besides the planned OLT admission, 8 liver-related admissions occurred in 5 different patients, including one patient who died: 2 admissions due to HE, 1 due to acute kidney injury (AKI), 1 due to both AKI and HE, and 3 in the same patient due to rectal bleeding. The median admission lasted 5 (IQR 4–11) days, and none was  $> 14$  days. Except for the acute bleeds, we identified signs of decompensation in all cases, e.g. failed Stroop test, hypotension or reduction/gain in weight and body fluid, and facilitated 2 short hospitalizations of the 8 total admissions.

Based on early signs of decompensation, we contacted patients on 16 other occasions, revealing new events and guiding intervention such as advice on fluid intake, diuretics and laxatives.

No control died or received OLT, and there were 11 liver-related admissions in 7 patients, lasting a median of 5.5 (IQR 3–12) days with two admissions  $> 14$  days. Controls had 5 unplanned paracenteses compared to 1 in monitored patients.

**Conclusion:** Cirrhocare's novel, multimodal, home-monitoring in patients with advanced cirrhosis is feasible, with good compliance, and prompts early diagnosis of decompensating events and their intervention; and hospital admissions are fewer and shorter in duration than in a control group. We propose Cirrhocare as a tool for managing cirrhosis patients at-risk of acute decompensation, at-home.

**PO-1462**

**Efficacy and safety of albumin infusion for treatment and prevention of hepatic encephalopathy: a systematic review and meta-analysis**

Francis Teh<sup>1</sup>, Jing Hong Loo<sup>2</sup>, Steve Yew-chong Tam<sup>3</sup>, Yu Jun Wong<sup>1,4</sup>. <sup>1</sup>Changi General Hospital, Gastroenterology and hepatology, Singapore; <sup>2</sup>National University of Singapore, Yong Loo Lin School of Medicine, Singapore; <sup>3</sup>Singapore General Hospital, Education resource center, Medical board, Singapore; <sup>4</sup>Duke-NUS Medical School, Singapore  
Email: eugene.wong.yj@singhealth.com.sg

**Background and aims:** The efficacy and safety of albumin infusion for the treatment and prevention of hepatic encephalopathy (HE) among decompensated cirrhosis patients were controversial. We aim to systematically review the existing literature on the efficacy and safety of albumin infusion for prevention and treatment of HE.

**Methods:** We performed a systematic search of 4 electronic databases (PubMed, EMBASE, Scopus and Web of Science) up to 15<sup>th</sup> January 2021. Including free text and MESH term, studies on albumin infusion for treatment and prevention of HE in cirrhosis patients were screened and selected. Primary outcome was the resolution of clinically overt HE. Secondary outcomes were inpatient mortality, length of stay and albumin-associated adverse events. We assessed the pooled relative risk (RR), pooled mean differences (MD), 95% confidence interval (CI) and heterogeneity ( $I^2$ ) using Review Manager Version 5.3.

**Results:** A total of 12 studies (4 treatment studies, 8 prevention studies) from 951 subjects fulfilling our inclusion criteria were identified among 1382 citations. Mean MELD score ranged from 8 to 26. Among cirrhosis patients with HE, treatment with albumin infusion was associated with a lower pooled relative risk of HE (RR = 0.56, 95%CI: 0.41, 0.77;  $I^2 = 20\%$ ). Among cirrhosis patients without HE at baseline, prevention with albumin infusion was associated with a lower pooled risk of developing clinically overt HE (RR = 0.61, 95%CI: 0.41, 0.90;  $I^2 = 63\%$ ). Albumin infusion was associated with a lower pooled relative risk of inpatient mortality (RR = 0.44, 95%CI: 0.28, 0.67;  $I^2 = 0\%$ ) and shorter length of stay (MD = -5.5, 95%CI: -14.1, -3.0;  $I^2 = 100\%$ ). No significant difference in albumin-related adverse events (RR = 1.06, 95%CI: 0.75, 1.51;  $I^2 = 0\%$ ) and overall survival were observed.

**Conclusion:** Albumin infusion is a safe option to treat and prevent HE among cirrhosis patients. Well-powered randomised trial is required to confirm the benefit of albumin infusion for the prevention and treatment of hepatic encephalopathy in decompensated cirrhosis patients.

## POSTER PRESENTATIONS

PO-1471

### Myostatin is associated with sarcopenia and in combination with creatinine phosphokinase or albumin may be used as a screening tool of sarcopenia in liver cirrhosis

Theodoros Alexopoulos<sup>1</sup>, Larisa Vasilieva<sup>1</sup>, Meropi Kontogianni<sup>2</sup>, Roxani Tenta<sup>2</sup>, Alexandra Georgiou<sup>2</sup>, Evangelia Stroumpoulis<sup>3</sup>, Ilianna Mani<sup>1</sup>, Alexandra Alexopoulou<sup>1</sup>. <sup>1</sup>Medical School, National and Kapodistrian University of Athens, 2nd Department of Internal Medicine and Research Laboratory, Athens, Greece; <sup>2</sup>School of Health Sciences and Education, Harokopio University, Department of Nutrition and Dietetics, Athens, Greece; <sup>3</sup>Hippokraton General Hospital, Department of Radiology, Athens, Greece  
Email: thoalex@windowolive.com

**Background and aims:** Sarcopenia is a syndrome affecting muscle mass, strength and function. In patients with liver cirrhosis (LC), sarcopenia is correlated with more frequent complications and increased mortality. Myostatin, a myokine, is produced by muscle cells and adipocytes and is considered a biomarker of skeletal mass and/or sarcopenia. The aim was to evaluate the diagnostic utility of myostatin in LC.

**Method:** Muscle mass and quality measured by computed tomography at L-3 using specialized software (Tomovision, Sliceomatic), muscle strength evaluated by hand dynamometry and physical function assessed by the Short Physical Performance Battery were used to diagnose sarcopenia according to latest EWGSOP-2 criteria. Serum myostatin was measured by ELISA (GDF-8/Myostatin Immunoassay, RandD Systems Europe, Ltd.).

**Results:** 115 consecutive patients with LC [72.2% male, median age 59-years (IQR 52–67), MELD 12 (8–16), 28.7% with compensated LC] were included. Sarcopenia was diagnosed in 34.8% and in 21.7% of total patients it was severe. Serum myostatin was lower in patients with sarcopenia compared to those without ( $p < 0.001$ ) and even lower in severe sarcopenia ( $p < 0.001$ ). In the multivariate model, with sarcopenia as the dependent variable, age [OR 2.406 (95%CI 1.396–4.149),  $p = 0.002$ ] and myostatin concentrations [OR 0.516 (95%CI 0.334–0.795),  $p = 0.003$ ] were independently associated with the presence of sarcopenia after adjustment for sex, MELD score, creatine phosphokinase (CPK) and albumin. In ROC curve analyses, ratios of  $\log_{10}$ myostatin (pg/ml) to CPK (IU/L) and albumin to myostatin showed good diagnostic accuracy to differentiate sarcopenic from non-sarcopenic patients (AUROC 0.731 and 0.728, respectively). The cut-off value of 0.0448 of the  $\log_{10}$ myostatin to CPK ratio showed 85% sensitivity and 52.1% specificity whereas the cut-off value  $2.206 \times 10^7$  of albumin to myostatin ratio showed 85% sensitivity and 49.3% specificity. In patients with more severe liver disease (MELD score

$\geq 15$ ), ratios  $\log_{10}$ myostatin to CPK and albumin to myostatin showed even better diagnostic accuracy to differentiate sarcopenic from non-sarcopenic patients (AUROC 0.829,  $p = 0.001$  and 0.802,  $p = 0.001$ , respectively).

**Conclusion:** Myostatin was proved to be an important emerging biomarker independently associated with sarcopenia, and in combination with CPK or albumin can be used as a screening tool for sarcopenia in clinical practice.

PO-1549

### Circulating microRNAs profiling in acute decompensation of liver cirrhosis

Yasmina Chouik<sup>1,2</sup>, Fanny Lebossé<sup>1,2,3</sup>, Marie-Laure Plissonnier<sup>2</sup>, Teresa Antonini<sup>1</sup>, Kerstin Hartig-Lavie<sup>1</sup>, Miroslava Subic-Levrero<sup>1</sup>, Clothilde Miaglia<sup>1</sup>, Camille Boucheny<sup>4</sup>, Domitille Poinot<sup>1</sup>, Francois Villeret<sup>1,3</sup>, Dr Guichon Céline<sup>5</sup>, Fabien Zoulim<sup>1,2,3</sup>, Massimo Levrero<sup>1,2,3</sup>. <sup>1</sup>Hôpital de la Croix-Rousse, Hospices Civils de Lyon, Hepatology, Lyon, France; <sup>2</sup>Cancer Research Center of Lyon (CRCL), INSERM U1052, CNRS UMR5286, Lyon, France; <sup>3</sup>University of Lyon Claude Bernard 1 (UCLB1), Lyon, France; <sup>4</sup>GHN, Hospices Civils de Lyon, Clinical Research Center, Lyon, France; <sup>5</sup>Hôpital de la Croix-Rousse, Hospices Civils de Lyon, Department of Anesthesiology and Intensive Care, Lyon, France  
Email: yasmina.chouik@inserm.fr

**Background and aims:** Acute decompensation (AD) represents a major cause of hospital admission and mortality in cirrhotic patients but refers to different conditions with distinct clinical characteristics and prognoses. MicroRNAs (miR) are small non-coding RNAs involved in the post-transcriptional regulation of gene expression. Circulating miR are stable molecules and can be used as non-invasive diagnostic or prognostic biomarkers. Recently, serum miR profiles that differentiate between AD in cirrhosis and healthy controls or between AD with or without ACLF have been reported but the direct comparison of carefully selected patients with AD and compensated cirrhosis has not been explored. We aimed at profiling circulating miR in AD and identifying AD subgroups defined by differential circulating miR signatures.

**Method:** We prospectively included 76 patients with alcohol, dysmetabolic or post-hepatitis C virus-related cirrhosis admitted at the Hepatology and Intensive Care units of the Lyon University hospital. Fifty-three patients had an AD of cirrhosis and 23 patients with compensated cirrhosis and no history of AD served as pathological controls (PC). Circulating miR were profiled in plasma on a Nanostring platform, allowing to detect and quantify simultaneously 798 miR in 26 AD and 7 PC consecutive patients. Circulating

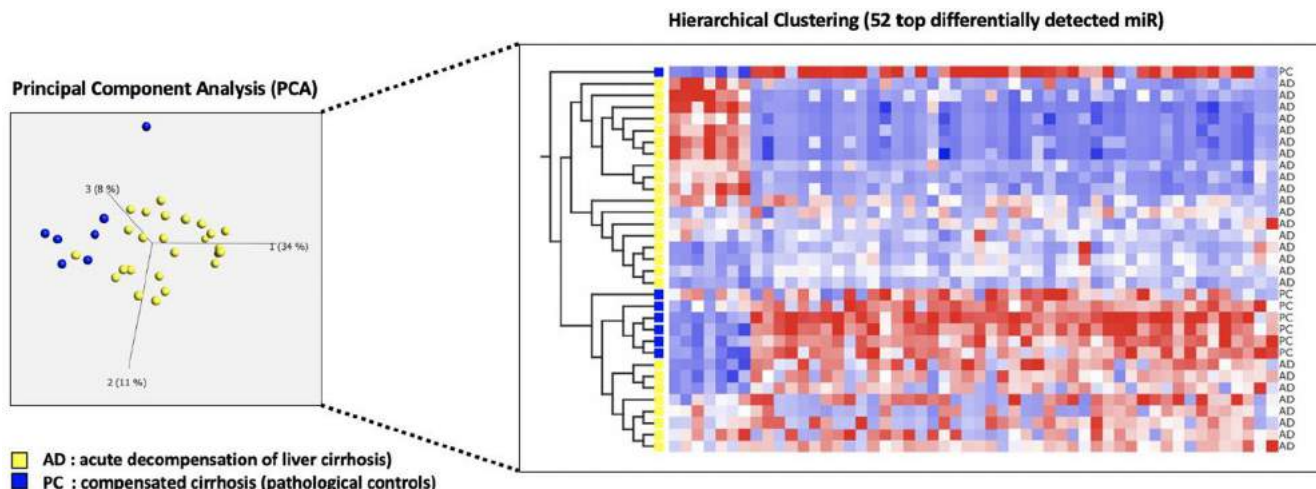

Figure: (abstract: PO-1549)

miR were profiled in plasma on a Nanostring platform, allowing to detect and quantify simultaneously 798 miR.

**Results:** Principal component analysis (PCA) of the circulating miRNAs profiles shows that AD patients are well separated from the PC group (Figure, left panel). We found a major dysregulation of circulating miR in the AD cirrhosis group, with 393 miR, being significantly differentially detected compared to the PC group. We defined a signature of 52 miR capable to separate AD and PC groups and to sub-classify AD patients in 2 groups (Figure, right panel). The majority of the differentially detected miR are down-regulated in AD cirrhotic patients with the exception of 7 miR with increased plasma levels in AD patients. Gene Set Enrichment Analysis (GSEA) shows a strong over-representation of differentially expressed miR in cancerogenesis pathways.

**Conclusion:** Circulating miR are strongly dysregulated in AD of cirrhosis as compared to compensated cirrhosis and might be useful to identify subgroups of patients with different clinical course and prognosis.

**PO-1670**

**Use of rifaximin is not associated with infections by multi-drug resistant bacteria, but with occurrence of rifampicin-resistance in coagulase-negative staphylococci**

Lina Schulte<sup>1</sup>, Jacob Nattermann<sup>1</sup>, Christian Strassburg<sup>1</sup>, Philipp Lutz<sup>1</sup>.  
<sup>1</sup>University Hospital Bonn, Department of Internal Medicine I, Bonn, Germany

Email: s4lischu@uni-bonn.de

**Background and aims:** Patients with cirrhosis are very likely to develop bacterial infections. However, data are still limited if use of rifaximin to prevent recurrent hepatic encephalopathy is associated with infections by multidrug-resistant bacteria or rifampicin resistance. Therefore, we analysed bacteria detected in hospitalized patients with liver cirrhosis with particular respect to intake of rifaximin.

**Method:** Patients with cirrhosis who were admitted to the hepatology ward of the department of Internal Medicine I were retrospectively analyzed for occurrence of bacterial infection and intake of rifaximin over a period of 12 months. Enterococci resistant to vancomycin (VRE), methicillin-resistant staphylococcus aureus (MRSA) and gram-negative bacteria resistant against at least 3 out of four antibiotic classes (carbapenems, fluoroquinolones, piperacillin/tazobactam or third-generation cephalosporins) were considered multi-drug resistant. Statistical analysis was performed with fisher's square test.

**Results:** 341 patients were included, who were admitted for a total of 501 hospital stays. Mean age was 60 years, 59% of patients were male and 55% had alcohol-associated cirrhosis. A total of 202 bacterial infections occurred, the top three being urinary tract infections (n = 73; 36%), spontaneous bacterial peritonitis (n = 35; 17%) and pneumonia (n = 30; 15%). Patients with infection were significantly more likely to die in hospital (24% versus 5%).

N = 23 of the isolated bacteria were multi-drug resistant (MDR): mostly VRE (n = 11) and gram-negative MDR (n = 9), but also MRSA (n = 3). MDR were detected in 9 cases of urinary tract infections, 5 cases of SBP, 3 cases of bacteremia, 3 skin infections, 2 cases of pneumonia and 1 bacterascites episode.

31% of patients were on rifaximin. Although a higher rate of bacterial infection occurred under rifaximin (39% vs 27%; p < 0.05), rate of infections by MDR bacteria were not significantly different (15% vs 9%). Coagulase-negative staphylococci displayed a higher rate of rifampicin resistance in patients taking rifaximin (13/19; 68%) compared to patients without rifaximin (3/28; 11%; p < 0.05), but were in general considered as contamination and not as cause of infection.

**Conclusion:** Our observations indicate that rifaximin intake may induce rifampicin resistance in colonizing coagulase-negative

staphylococci, but seems not to increase the rate of clinical significant infections by MDR.

**PO-1701**

**Low incidence of SARS-CoV-2 infection in a prospective cohort of patients with liver cirrhosis and hepatocellular carcinoma treated at a German tertiary center during the 2020 pandemic**

Thorben Fründt<sup>1</sup>, Lilith Kuballa<sup>1</sup>, Marc Luetgehetmann<sup>2</sup>, Dominik Nörz<sup>2</sup>, Canan Kurnaz<sup>1</sup>, Thomas Theo Brehm<sup>1,3</sup>, Karoline Rutter<sup>1</sup>, Thomas Horvatis<sup>1</sup>, Julian Schulze zur Wiesch<sup>1,3</sup>, Samuel Huber<sup>1</sup>, Ansgar W. Lohse<sup>1</sup>, Henning Wege<sup>1,4</sup>, Johannes Kluwe<sup>1</sup>.

<sup>1</sup>University Medical Center Hamburg-Eppendorf, I. Department of Medicine, Hamburg, Germany; <sup>2</sup>University Medical Center Hamburg-Eppendorf, Institute of Microbiology and Virology, Hamburg, Germany; <sup>3</sup>German Center for Infection Research (DZIF), Partner Site Hamburg-Lübeck-Borstel-Riems, Hamburg; <sup>4</sup>Klinikum Esslingen, Cancer Center Esslingen, Esslingen am Neckar

Email: tfruentd@uke.de

**Background and aims:** Patients with liver cirrhosis (LC) are considered to be at increased risk for mortality when acquiring SARS-CoV-2 infection. During the COVID-19 pandemic, hospitals are regarded as sites with increased risk of infection, resulting in a limitation of in- and outpatient contacts to urgent indications, but data regarding infection rate in cirrhotic patients presenting as outpatients are limited. We conducted a prospective study to assess the incidence of SARS-CoV-2 infections in patients with LC with/without hepatocellular carcinoma (HCC) with physical presentation at our University Medical Center.

**Method:** Patients were enrolled between 1 April and 30 June 2020 at the University Medical Center Hamburg-Eppendorf, Germany, and were questioned for symptoms of upper airway infection at baseline. Presence of SARS-CoV-2 antibodies (IgG/IgM/IgA) was assessed at baseline and every follow-up using an Electro-chemiluminescence immunoassay (Roche Elecsys). Follow-up (FU) visits including liver function test, clinical assessment and questionnaire were conducted after 6–8 weeks (FU-1) and 6 months (FU-2).

**Results:** A total of 143 patients were enrolled at the outpatient department (n = 66) or as inpatients (n = 77): 108 with LC, 35 with LC and HCC (median age: 64 years, range: 19–86). 69% were male. Liver function according to Child Pugh Score (CPS) was: CPS A: 46% (n = 61); CPS B: 37% (n = 50); CPS C: 17% (n = 23). Clinical symptoms indicating upper airway infection were present in 77 patients: shortness of breath (n = 40) and coughing (n = 28) were the most frequent. After a median of 52 days, n = 110 patients completed FU-1, n = 72 were eligible for FU-2 between July 2020 and January 2021. Altogether, 284 visits to the outpatient department were registered and a cumulative number of 760 hospital days. SARS-CoV-2 antibodies were detected in one (0, 93%) asymptomatic patient at baseline and FU-1, an 80-year-old man with stable liver function (CPS A) and advanced HCC, receiving palliative treatment. All of the remaining patients were tested negative at baseline and every follow-up visit.

**Conclusion:** The risk of acquiring SARS-CoV-2 infection at our tertiary medical center during the pandemic was low in LC and HCC patients, when protective measures such as wearing face masks and keeping distance were followed. Of note, we found that SARS-CoV-2 infection in a patient with defined risk factors (older age, LC) was asymptomatic and did not lead to deterioration of liver function.

#### Baseline liver volume is a major prognostic factor in acute decompensation of alcohol-associated cirrhosis: results from the prospective multicentre PROLIV study

José Ursic-Bedoya<sup>1</sup>, Claire Espérance<sup>1</sup>, Ludovic Caillou<sup>2</sup>, Magdalena Meszaros<sup>1</sup>, Marie Pierre Ripault<sup>3</sup>, Safia Aouinti<sup>4</sup>, Laura Jaubert<sup>1</sup>, Ardavan Prost<sup>2</sup>, Lucy Meunier<sup>1</sup>, Barbara Tassy<sup>1</sup>, Stéphanie Faure<sup>1</sup>, Cathy Soulayrac<sup>1</sup>, Hélène Donnadiou-Rigole<sup>1</sup>, Boris Guiu<sup>1</sup>, Nicolas Molinari<sup>4</sup>, Georges-Philippe Pageaux<sup>1</sup>. <sup>1</sup>Chu Montpellier St Eloi, Montpellier, France; <sup>2</sup>University Hospital of Nîmes, Nîmes, France; <sup>3</sup>Centre Hospitalier De Narbonne, Narbonne, France; <sup>4</sup>Hospital Center University De Montpellier, Montpellier, France  
Email: jose.ursic@yahoo.fr

**Background and aims:** Acute decompensation (AD) of alcohol-associated cirrhosis in nonabstinent subjects has a poor short-term prognosis. Abstinence allows an improvement of 2/3 of the patients after 3 months. For those who don't improve, the only treatment that can ameliorate the prognosis is liver transplantation (LT). Prognostic scores at the time of decompensation do not allow to distinguish between the patients who will improve from those who would need LT. So, it appears necessary to find new prognostic factors. We aimed to study prognostic factors in terms of transplant-free survival in the setting of AD of alcohol-associated cirrhosis.

**Method:** PROLIV (Clinical Trials #03508388) is a prospective, multi-centre, observational study. We included patients with alcohol-associated cirrhosis, abstinent or not, hospitalized for AD. The main exclusion criteria were an HCC, an active viral B or C infection, the presence of a TIPS, an occlusive portal vein thrombosis. Patients were followed during 1 year with a visit every 3 months and cross-sectional imaging at inclusion, 6 and 12 months. Measurements included liver and spleen volume. They were semi-automated and made by a single operator blinded to the patient's outcome. The standardized liver volume was calculated per the usual formula based on the body weight. Alcohol consumption was assessed at each visit. The primary study end point was transplant-free survival.

Figure:

**Results:** 156 patients were evaluated and 131 patients were included between April 2018 and September 2019. They were 75% male, median age was 58 years, 60.3% of patients were nonabstinent at the time of admission and 48.1% were admitted for a first episode of AD. Median Child-Pugh, Meld and AD-ACLF scores were 9.4, 18.3 and 53 respectively. The main etiologies of AD were alcohol-associated hepatitis (39.7%) and ascites (26.7%). At 12 months, 31 patients (23.7%) were dead and 16 (12.2%) were transplanted. Two patients were lost to follow-up. Among nonabstinent patients at the inclusion and alive without LT at 3 months, 52% of those who were abstinent during this period had an improvement in Meld score >2 points,

whereas they were only 38.5% of those who continued alcohol consumption in the interval. The mean measured/standardized liver volume ratio was 1.26 in our cohort. 27 variables were included in the survival analyses, 12 of which were significant in univariate analysis. In multivariate analysis, the variables significantly associated with transplant-free survival were hemoglobin (HR = 0.633; 95% CI [0.519; 0.771]), MELD score (HR = 1.111; 95% CI [1.036; 1.191]) and the measured/standardized liver volume ratio (HR = 0.322; IC95% [0.155; 0.666]).

**Conclusion:** Our study is the first to show that liver volume in a patient admitted for AD of alcohol-associated cirrhosis is a predictor of transplant-free survival. This measure could complement the classic cirrhosis scores.

### PO-1730

#### Cirrhotic patients without prior antibiotic exposure may be eligible to lower first-line antibiotic strategies for nosocomial infections: results from a local antibiotic resistance study

Veyre Florian<sup>1</sup>, Caroline Dellestable<sup>1</sup>, Pierre Pradat<sup>1</sup>, Nina Pronina<sup>1</sup>, Fabien Zoulim<sup>1,2,3</sup>, Patrick Miaillhes<sup>4</sup>, Fanny Lebossé<sup>1,2,3</sup>. <sup>1</sup>Hospices Civils of Lyon, Hepatology department, Lyon, France; <sup>2</sup>Lyon 1 university, Lyon, France; <sup>3</sup>Cancerology Research Center of Lyon, Lyon, France; <sup>4</sup>Hospices Civils of Lyon, Department of infectious diseases, Lyon, France  
Email: fanny.lebosse@inserm.fr

**Background and aims:** Although adequacy of first line antibiotic (AB) strategies is crucial for the prognosis of cirrhotic patients with bacterial infections (BI), a rational use of AB is required to limit multidrug resistant bacteria (MRB) emergence. Our aims were to describe AB resistances in our center and to study the relevance of international guidelines for the treatment of BI in cirrhosis.

**Method:** We conducted an exhaustive retrospective study of BI occurring in cirrhotic patients admitted in Hepatology Unit of a tertiary center in 2018. We reported demographical, clinical and AB resistances data for each event. We defined prior antibiotic exposure (PAE) as prior AB treatment within last 6 months and/or norfloxacin prophylaxis regimen.

**Results:** We reported 135 BI in 72 cirrhotic patients, mostly suffering from alcoholic liver disease (n = 46). The median age was 68 years (IQR 59–73) and median MELD score 19 (IQR 14–24). Sixteen percent of patients had norfloxacin prophylaxis regimen and 67% had received previous AB therapy (mostly beta-lactamine) within last 6 months. The majority of BI was nosocomial (65%) whereas 32% were health care associated (HCA) and only 3% community acquired (CA) infections. Most common infections were urinary tract infection (38%) and spontaneous bacteremia (29%). MRB accounted for 44% of BI and were associated with PAE (54% in PAE group vs 18% in non-PAE group, p < 0.0001). MRB infections mostly developed in nosocomial infection (NI) group (83% vs 17% in HCA; p = 0.0004). In NI group, MRB infections were significantly associated to PAE (65% in PAE group vs 21% in non-PAE group; p = 0.0006) while no difference was found in HCA group. According to international guidelines for AB treatment of BI in cirrhosis, AB de-escalation was possible for 53% in NI group, 12% in HCA group whereas respectively none and 14% required increasing antibiotic strategy (p < 0.0001). In NI group, AB de-escalation opportunity was more frequent in non-PAE group (90%) compared to PAE one (44%; p = 0.0003).

**Conclusion:** Our results suggest that local knowledge of AB resistances could lead to local adjustment of international guidelines for the treatment of BI in cirrhosis. We could identify a subgroup of NI with reduced rate of MRB infections, which could be eligible to lower empiric first line antibiotic strategies. Further studies are required to confirm the extent of these findings.

PO-1766

**High risk medication-related problems are associated with lower quality of life in decompensated cirrhosis**

Kelly Hayward<sup>1,2</sup>, Vikas Bansal<sup>1</sup>, Patricia Valery<sup>1,3</sup>, Preya Patel<sup>1</sup>, Penny Wright<sup>2</sup>, Caroline Tallis<sup>2</sup>, Katherine Stuart<sup>2</sup>, Katharine Irvine<sup>4</sup>, Neil Cottrell<sup>5</sup>, Jennifer Martin<sup>6</sup>, Elizabeth Powell<sup>1,2</sup>. <sup>1</sup>The University of Queensland, Centre for Liver Disease Research, Woolloongabba, Australia; <sup>2</sup>Princess Alexandra Hospital, Gastroenterology and Hepatology Department, Woolloongabba, Australia; <sup>3</sup>QIMR Berghofer Medical Research Institute, Herston, Australia; <sup>4</sup>The University of Queensland, Mater Research, Woolloongabba, Australia; <sup>5</sup>The University of Queensland, Faculty of Health and Behavioural Sciences, St Lucia, Australia; <sup>6</sup>University of Newcastle, School of Medicine and Public Health, Newcastle, Australia  
Email: kelly.hayward@uq.edu.au

**Background and aims:** This study aimed to explore patient-related factors associated with 'high risk' medication-related problems (MRPs) to tailor delivery of a medication education intervention for people with decompensated cirrhosis.

**Method:** A post-hoc analysis was conducted in a cohort of out-patients with decompensated cirrhosis who were randomised to receive a patient-oriented medication education intervention during its implementation phase at a tertiary hepatology clinic. Patients received medication interviews with a clinical pharmacist on up to 4 occasions during a 6-month period. The pharmacist identified MRPs (including nonadherence, adverse drug reactions, interactions, indication, dosing, and monitoring issues) in real-time and a clinician panel classified each to be 'low', 'medium', or 'high' risk for patient harm using a severity \* likelihood \* duration risk matrix. Participants completed the Beliefs about Medicines Questionnaire, Brief Illness Perceptions Questionnaire and Chronic Liver Disease Questionnaire (quality of life) at recruitment and follow-up (6-months). Demographic and clinical variables were obtained from medical records. A generalised linear model with Poisson distribution was used to calculate incidence rate ratios (IRR) and 95% confidence intervals (CI). Number of interviews (range 1–4) was an offset in the model. The Wilcoxon signed ranks test was used to analyse paired data.

**Results:** Complete baseline data is available for 50 patients. Mean age was 58.4 ± 9.7 years, 68.0% were male, median Child-Pugh score was 8 (interquartile range 7–9) and patients took 9.9 ± 3.8 medications. Among 334 identified MRPs, 49.4% were classified as 'high risk' (mean 3.3 ± 2.3 per patient). Patients had more 'high risk' MRPs if they reported more *concerns* about their medicines (IRR = 1.08; 95%CI 1.02–1.14) and lower *coherence* of liver disease (IRR = 0.91; 95%CI 0.83–0.99). 'High risk' MRPs were also associated with greater perceived *consequences* of disease on daily life (IRR = 1.08; 95%CI 1.00–1.17) and lower *global quality of life* (IRR = 0.83; 95%CI 0.70–0.99), especially in terms of *systemic symptoms* (IRR = 0.83; 95%CI 0.70–0.98), *emotion* (IRR = 0.86; 95%CI 0.75–0.98) and *worry* (IRR = 0.87; 95%CI 0.78–0.98). 71.5% of 'high risk' MRPs were resolved with pharmacist intervention. This coincided with significant improvement in *global quality of life* (p = 0.049) and *coherence* (p = 0.030) scores at 6-months compared to baseline (follow-up data available for 36 patients; n = 6 deceased, n = 4 failed to attend, n = 1 withdrew, n = 3 'other').

**Conclusion:** Medicines intervention tailored to people with decompensated cirrhosis and with poor disease knowledge and negative beliefs about medicines may improve quality of life by aiding resolution of 'high risk' MRPs.

PO-1767

**The prevalence of sarcopenia and myosteatosi s in cirrhotic patients: preliminary results from an italian multicenter study (EpatoSarco Group)**

Email: simonedicola92@hotmail.it

**Background and aims:** Sarcopenia, myosteatosi s and sarcopenic obesity are important predictors of morbidity and mortality in patients with liver cirrhosis. Most of the studies have been retrospective, including non-European cohort and have mainly involved patients on the waiting list for liver transplantation which could represent a possible selection bias. We conducted a prospective multicenter Italian study aimed at evaluating the prevalence of sarcopenia, myosteatosi s and sarcopenic obesity in a large series of cirrhotic patients.

**Method:** A large series of patients with liver cirrhosis were enrolled from February 2019 in 19 Centers in Italy. Patients were included at the time of a CT-scan performed for any clinical reasons. Patients on the waiting list for liver transplantation, were purposely excluded. CT-scan has been utilized for the assessment of sarcopenia (with Skeletal Muscle Index-SMI) and myosteatosi s. Body weight and height were recorded to derive BMI. Clinical and laboratory data were also collected.

**Results:** 242 cirrhotic patients were enrolled in the study, 72% males (median age 59 ± 11). Median MELD was 13.7 ± 5, 31% were Child-Pugh class A, 49% class B and 20% class C. The median BMI adjusted-for-ascites was 25.9 ± 6 kg/m<sup>2</sup>. Most of the patients were of alcoholic origin (39%), followed by viral etiology (19%) and NASH (13%). Twenty-three percent were obese at diagnosis (BMI>30). Ninety-two patients (38%) showed sarcopenia at enrolment, while 169 patients (70%) presented myosteatosi s. Sarcopenia and myosteatosi s were associated in 70 patients (29%). BMI was significantly lower in sarcopenic vs non sarcopenic patients (22.8 ± 4 vs 27.7 ± 8 p < 0.001). The severity of liver cirrhosis was similar in patients with and without sarcopenia (MELD 14.3 ± 6 vs. 13.3 ± 4.5 p 0.2). Patients with myosteatosi s were older (60 ± 9 vs 55 ± 7 p 0.002), presented lower BMI at enrollment (25.3 ± 6 vs. 27.8 ± 5 p < 0.001), higher value of MELD (12.3 ± 4.2 vs 14.2 ± 5 p 0.02) and higher prevalence of ascites (55% vs 34%, p 0.002).

**Conclusion:** this analysis confirms the high prevalence of sarcopenia in a large series of cirrhotic patients not on the waiting list for liver transplantation. Myosteatosi s was even more common and more frequent in patients with older age and low BMI. The prevalence of sarcopenia was not related to the degree of liver cirrhosis according to MELD score and Child Pugh Class.

<sup>1</sup>Grifols, Bioscience Research Group, Barcelona, Spain; <sup>2</sup>EF CLIF, EASL-CLIF Consortium, Barcelona, Spain; <sup>3</sup>Grifols Chair, Barcelona, Spain; <sup>4</sup>Hospital Clinic, IDIBAPS and CIBERehd, Barcelona, Spain; <sup>5</sup>Grifols, Bioscience Research Group, Raleigh, United States  
 Email: raquel.horrillo@grifols.com

**Background and aims:** Non-oncotic functions of albumin may be related to beneficial effects of albumin administration in cirrhotic patients. These include its antioxidant capacity and the capacity to bind, transport and modulate biologically active molecules such as fatty acids, proinflammatory mediators and reactive oxygen species. In fact, the prevention of mortality by long-term albumin administration in decompensated cirrhotic patients with ascites is currently under investigation (PRECIOSA phase 3 trial, NCT03451292). In the present study, we analyzed the functional status of albumin from patients with decompensated cirrhosis compared to healthy controls (HC), and its correlation with disease markers.

**Method:** Plasma samples from patients with decompensated cirrhosis (n=21) and age-matched HC (n=24) were analyzed. Albumin binding capacity to Sudlow Binding Site II (BSII) was determined using a specific fluorescent marker and fatty acid binding capacity was measured by electronic paramagnetic resonance. Oxidation status of albumin on Cys34 thiol group was assessed by anion exchange chromatography. Albumin early glycation was determined using QuantiLab Glycated Albumin assay.

**Results:** In addition to hypoalbuminemia (Gastroenterology 2019; 157: 149–162), patients with decompensated cirrhosis presented functionally impaired albumin. Albumin from these patients showed a lower binding capacity to BSII and to fatty acids, higher irreversible oxidation, and higher levels of early glycation compared to HC. Interestingly, patients with lower albumin binding capacity to BSII presented worse hepatic (ALT [r = -0.78; p < 0.0001] and AST [r = -0.77; p < 0.0001]) and circulatory functions (PRA; r = -0.50; p < 0.05) and greater disease severity (Child-Pugh; r = 0.48; p < 0.05). Moreover, higher albumin oxidation was linked to greater impairment of hepatic (r = 0.45; p < 0.05) and circulatory functions (r = 0.40; p = 0.08). However, there was no relationship between disease markers and albumin fatty acid binding capacity or glycation.

**Conclusion:** Albumin from patients with decompensated cirrhosis had significant functional impairment. This dysfunctional albumin was correlated with poorer organ function (patients with more impaired albumin binding and more oxidized albumin presented worse hepatic and circulatory functions and greater disease severity). Further investigation is warranted to better understand the role of non-functional albumin in this pathology and the effects of albumin as a therapeutic agent in liver cirrhosis.

### PO-1998

#### A study evaluating outcomes of cirrhotic patients managed virtually in a specialist liver cirrhosis service due to the COVID crisis

Alex Cole<sup>1</sup>, Maria Bashyam<sup>1</sup>, Rooshi Nathwani<sup>2</sup>, David Kockerling<sup>2</sup>, Sujit Mukherjee<sup>2</sup>, Benjamin Mullish<sup>1,2</sup>, Lucia Possamai<sup>1,2</sup>, Heather Lewis<sup>1,2</sup>, Maud Lemoine<sup>1,2</sup>, Nowlan Selvapatt<sup>1,2</sup>, Ameet Dhar<sup>1,2</sup>. <sup>1</sup>Imperial College Healthcare NHS Trust; <sup>2</sup>Imperial College London, United Kingdom  
 Email: mariabashyam@doctors.org.uk

**Background and aims:** Managing patients in a specialist cirrhosis clinic improves survival. The COVID-19 pandemic necessitated the urgent transition to virtual clinics (VC) in these patients. We aimed to evaluate the clinical impact of VC on survival, admission and decompensation rates in cirrhotic patients managed in a specialist

service, and to identify which patients can be managed safely in this setting.

**Method:** We retrospectively analysed cirrhotic patients who had a specialised VC from March to June 2020. Clinical parameters were collected at baseline and 6 months and compared with a cohort of patients reviewed face to face (F2F) in the same specialist cirrhosis clinics from March to June 2019. Patients with COVID-19 were excluded.

**Results:** 127 patients attended for VC, 101 for F2F review. Both groups were matched for age, sex, aetiology, and Child Pugh grade (CP). There was no difference at 6 months in survival, change in MELD/UKELD, decompensation, need for paracentesis (LVP) nor ambulatory review between VC and F2F groups in all cirrhosis grades combined or decompensated patients alone (CP BandC subgroup) (p.0.05) (Table 1). Less patients were admitted in the VC vs the F2F group (p = 0.05) but this was not validated in CP BandC subgroup (p > 0.05).

Table 1: Baseline Patient Demographics and 6 months outcome (\*p > 0.05, \*\*p = 0.05)

	VC (n = 127)	F2F (n = 101)
<b>Age-yrs (range)</b>	60 (30–85)	61 (32–84)
<b>Gender-no (%)</b>		
Male sex	87/127 (69%)	74/101 (73%)
Female sex	40/127 (31%)	27/101 (27%)
<b>Main Aetiology-no (%)</b>		
Alcoholic Liver Disease (ALD)	80/127 (63%)	61/101 (60%)
<b>Baseline Disease Severity:</b>		
CP A-no (%)	59/127 (46%)	49/101 (48%)
CP BandC-no (%)	68/127 (54%)	52/101 (52%)
MELD (median)	10	10
UKELD (median)	50	50
<b>Outcomes at 6 months:</b>		
Survival (all)-no (%)	124/127 (98%)	98/101 (97%)*
CP BandC	3/68 (2%)	3/52 (3%)*
MELD change (median)	0	0*
CP BandC	0	0*
UKELD change (median)	0	0*
CP BandC	0	0*
New decomp (all)-no (%)	37/127 (29%)	28/101 (28%)*
CP BandC	32/68 (47%)	23/52 (44%)*
LVP (all)-no (%)	9/127 (7%)	10/101 (10%)*
CP BandC	9/68 (13%)	10/52 (19%)*
Admissions (all)-no (%)	36/127 (28%)	41/101 (41%)**
CP BandC	29/68 (42%)	27/52 (51%)*
<b>Ambulatory Review (all)-no (%)</b>	18/127 (14%)	12/101 (11%)*
CP BandC	16/68 (24%)	12/56 (21%)*
<b>Median Follow Up (all)- weeks</b>	11	14
CP BandC	9	9

**Conclusion:** Compared to F2F clinics, VC have not resulted in poorer clinical outcomes, even in patients with decompensated cirrhosis. Access to ambulatory care was still required especially for CP BandC patients. Further studies need to confirm the long-term clinical impact, cost-effectiveness and acceptability of VC in management of cirrhotic patients within the setting of a specialist service.

PO-2194

**Multidisciplinary assessment of neurocognitive impairment in a prospective cohort of patients with chronic liver disease: should we only think of hepatic encephalopathy?**

Sultanik Philippe<sup>1</sup>, Marika Rudler<sup>1</sup>, Antoine Santiago<sup>2</sup>, Lyes Kheloufi<sup>1</sup>, Charlotte Bouzbib<sup>1</sup>, Sarah Mouri<sup>1</sup>, Aurélie Plessier<sup>3</sup>, Rodolphe Sobesky<sup>4</sup>, Audrey Coilly<sup>4</sup>, Damien Galanaud<sup>5</sup>, Vincent Navarro<sup>6</sup>, Nicolas Weiss<sup>7</sup>, Dominique Thabut<sup>1</sup>. <sup>1</sup>Sorbonne Universités, Paris, France, Brain Liver Pitié-Salpêtrière (BLIPS) study group, Service d'Hépatogastroentérologie, Groupement Hospitalier Pitié-Salpêtrière-Charles Foix, Assistance Publique-Hôpitaux de Paris, Paris, France, Paris, France; <sup>2</sup>Département de Neuro-Psychologie, Centre Hospitalier Universitaire de Nîmes, Nîmes, Paris, France; <sup>3</sup>Department of Hepatology, DHU Unity, Beaujon Hospital, AP-HP; <sup>4</sup>AP-HP Hôpital Paul Brousse, Centre Hépatobiliaire, Inserm Unité 1193, Univ Paris-Sud, Université Paris-Saclay, FHU Hépatinov, Centre de Référence Maladies Inflammatoires des Voies Biliaires et Hépatites Auto-immunes, Villejuif, France; <sup>5</sup>Sorbonne Universités, Paris, France, Brain Liver Pitié-Salpêtrière (BLIPS) study group, Service de Neuroradiologie, Groupement Hospitalier Pitié-Salpêtrière-Charles Foix, Assistance Publique-Hôpitaux de Paris, Paris, France; <sup>6</sup>Sorbonne Universités, Paris, France, Brain Liver Pitié-Salpêtrière (BLIPS) study group, Service de Neurologie, Unité Epilepsie, Groupement Hospitalier Pitié-Salpêtrière-Charles Foix, Assistance Publique-Hôpitaux de Paris, Paris, France; <sup>7</sup>France Email: psultanik@gmail.com

**Background and aims:** Minimal hepatic encephalopathy (MHE) remains difficult to diagnose. Even asymptomatic, patients (pts) with chronic liver disease (CLD) could display other causes of neurocognitive impairment (NI), like neurodegenerative disorders or sequelae of vascular brain diseases. Precisely exploring the causes of NI is needed in pts for whom liver transplantation is discussed, to fasten the transplant process in case of HE or rule out other neurological diagnosis. The aim of this prospective study was to phenotype pts with CLD referred for a suspicion of MHE, using an extensive work-up, and to assess the proportion of them finally diagnosed with MHE.

**Method:** Work-up was performed in our multidisciplinary outpatient clinics, and included clinical examination by a hepatologist, a neurologist, neuropsychological tests (including PHES and animal naming test) by a neuropsychologist, biochemical markers, electroencephalogram and multimodal brain MRI with spectroscopy. Factors

of brain dysfunction like active alcohol consumption, cardiovascular risk factors were collected. The diagnosis of MHE was made by an adjudication committee involving the aforementioned physicians.

**Results:** 111 pts were referred to our center from March 2018 to January 2021: 75% had cirrhosis (MASH/alcohol/virus/other in 58/57/19/7%), 23% had a liver vascular disease, and 2% other cause of CLD. 70% had a previous history of HE, including 96% with specific treatment. 72% displayed risk factors of NI outside HE, (obesity in 35%, diabetes in 40%, active alcohol consumption in 7%, psychoactive medication in 22%, previous traumatic brain injury (TBI) in 9%, previous ischemic stroke in 10%). 88% of pts reported one or more complains, i.e. altered sleep (75%), memory (67%) and attention impairment (54%). Overall, 63% of pts were diagnosed with MHE. Treatment was started in 17% and upgraded in 33% of those pts. Among pts diagnosed with MHE, 74% displayed another curable cause of NI (anxio-depressive disorders (40%), previous TBI/stroke (27%), altered sleep (21%), neurodegenerative disorders (4%)). 37% of pts were not diagnosed with MHE: 4% did not present any NI, vascular leukopathy was diagnosed in 51% of pts, anxio-depressive disorders in 29%, other psychiatric disorders in 10%, and others causes in 27%. Twenty percent displayed potential mixed causes of NI. In multivariate analysis, only obesity was independently associated with a no-HE diagnosis ( $p=0.009$ ). A treatment was initiated in 73% of pts, including HE medications, medication withdrawal, psychological support or neurocognitive rehabilitation.

**Conclusion:** MHE was not the final neurological diagnosis in 37% of pts with CLD for MHE suspicion. Other diagnosis included curable disorders outside HE, but also non-reversible diagnosis like neurodegenerative disorders.

PO-2273

**The impact of age in clinical outcomes in cirrhotic outpatients**

Marta Tonon<sup>1</sup>, Carmine Gabriele Gambino<sup>1</sup>, Valeria Calvino<sup>1</sup>, Alessandra Brocca<sup>1</sup>, Simone Incicco<sup>1</sup>, Marco Cola<sup>1</sup>, Patrizia Pontisso<sup>1</sup>, Salvatore Piano<sup>1</sup>, Paolo Angeli<sup>1</sup>. <sup>1</sup>University of Padova, Department of Medicine DIMED, Padova, Italy Email: martatonon11@gmail.com

**Background and aims:** The observation of differences in prognostic terms between compensated and decompensated cirrhosis led to the development of prognostic stages of cirrhosis based on the

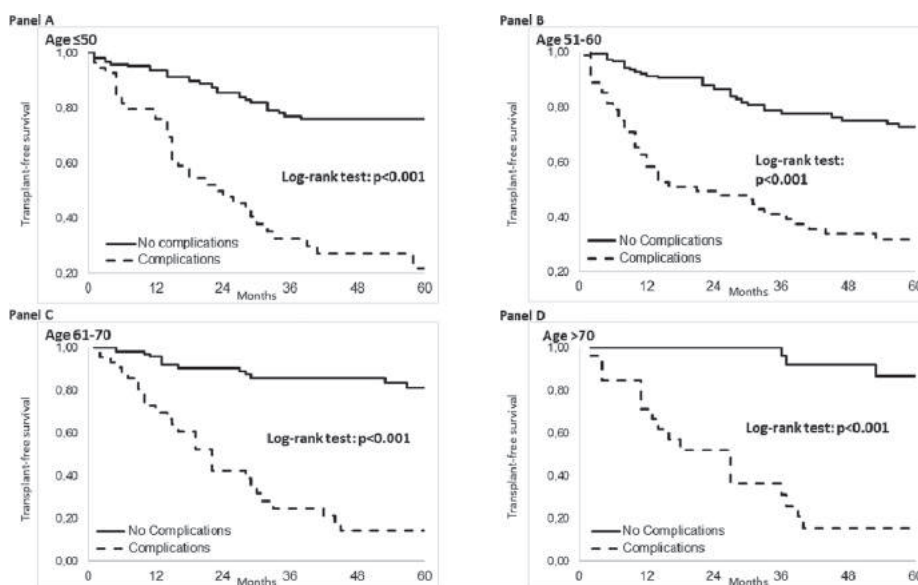

Figure 1: (abstract: PO-2273): 60-month transplant-free survival according to the development of complications in cirrhotic patients according to the class of age

## POSTER PRESENTATIONS

development of complications. However, the role of age in determining survival and the development of complications in patients with cirrhosis has never been considered. The aim of the study was therefore to evaluate the role of age in clinical outcomes of cirrhotic outpatients.

**Method:** From March 2012 to March 2019 650 outpatients with cirrhosis were enrolled in the study and were followed until death, liver transplant or the end of follow-up. Patients were subdivided in 4 classes according to their age: 196 were younger than 50 years old at inclusion, 232 were 51–60 years old, 144 were 61–70 years old and 78 were older than 70 at inclusion.

**Results:** There was no significant difference in 12 and 60-month transplant-free survival in the comparison between the 4 groups. On the contrary, in every group transplant-free survival was significantly lower comparing patients who developed complications during follow-up and patients who didn't. Moreover, there was no difference in complications' development (SBP, HRS, ascites, refractory ascites, ACLF, hepatic encephalopathy, variceal bleeding) comparing the 4 groups. According Cox' regression, MELD score (HR 1.17,  $p < 0.001$ ), mean arterial pressure (HR 0.98,  $p < 0.001$ ) and the development of at least a complication (HR 3.30,  $p < 0.001$ ) were found to be independent predictors of mortality at multivariate analysis.

**Conclusion:** Age doesn't seem to affect transplant-free survival and complications development in patients with cirrhosis. Thus, for patients at any age preventing and treating effectively any possible complication seems to be the key to reduce mortality.

### PO-2524

#### Quality of life improvement is a top-rated but rarely assessed outcome in European and Australian patients with hepatic encephalopathy: Quality of life targeting and monitoring needs to be prioritised

Juha Halonen<sup>1</sup>, Richard Hinde<sup>1</sup>, Bharat Amlani<sup>1</sup>. <sup>1</sup>Norgine Ltd, Harefield, United Kingdom  
Email: jhalonen@norgine.com

**Background and aims:** Quality of life (QoL) is compromised in overt hepatic encephalopathy (HE). Adding rifaximin to lactulose improves QoL within 6 months versus lactulose alone [1]. We analysed how medical specialists value QoL improvement in HE versus other therapy objectives and whether QoL is monitored in patients with HE.

**Method:** This online survey in Sep-Dec 2019 in Belgium, Germany, Netherlands, Sweden, United Kingdom and Australia included hepatologists and gastroenterologists (with special interest in hepatology) who had personally seen and treated at least 5 patients for HE in the last 3 months and completed patient record forms (PRFs) based on their last 3 adult patients. Responses to "how important are each of the following therapy objectives to you for patients receiving HE primary or secondary prophylaxis therapy?" were collected on a Likert scale 1–7 where 1 was 'not at all important' and 7 was 'extremely important'. Mean scores were analysed with a 95% confidence interval (CI). PRF data were used to assess if quality of life was monitored in the last three patients, if they received a prophylaxis, and how many HE episodes patients had experienced. Statistical comparisons used the 2-sided t-test assuming equal variance.

**Results:** The 218 respondents shared 654 PRFs; 347 patients received rifaximin-alpha 550mg (RFX; mostly as a combination 84.1% [292/347]) while 307 were treated without rifaximin. Doctors rated "Improving a patient's quality of life" as the most important treatment objective with a mean score of 6.38 (6.27–6.49), greater than "Reducing the likelihood of further HE episodes" (6.19 (6.08–6.31);  $p = 0.020$ ) or "Improving hepatic encephalopathy symptoms" (6.18 (6.06–6.31);  $p = 0.021$ ) (Figure). Despite this high valuation of QoL improvement, the majority of PRFs lacked QoL data collection from the patient (71.7% [469/654] versus 28.3% [185/654];  $p < 0.001$ ). Whilst 84.5% [553/654] patients received prophylaxis and more patients on RFX versus other treatments were on prophylaxis (94.2%

[327/347] versus 73.6% [226/307];  $p < 0.001$ ), only 88.0% [227/258] received RFX as secondary prophylaxis. To qualify for RFX, patients had on average experienced more HE episodes (3.10 [2.78–3.42] versus 2.09 [1.86–2.32];  $p < 0.001$ ).

Figure:

**Conclusion:** QoL improvement was rated the main therapeutic objective in HE. Considering rifaximin-alpha 550mg as secondary prophylaxis could help align treatment choice with therapeutic targets.

#### Cost-Effectiveness of Rifaximin/alpha versus Lactulose in preventing recurrent episodes of overt hepatic encephalopathy: a systematic review and meta-analysis

Kashif Siddiqui<sup>1</sup>, Sumeet Attri<sup>1</sup>, Massimo Olando<sup>2</sup>, Filippo Lelli<sup>2</sup>, Valeria Maida<sup>3</sup>, Dominique Thabut<sup>4</sup>. <sup>1</sup>Parexel, Mohali, India; <sup>2</sup>Corporate Market Access, Milan, Italy; <sup>3</sup>Corporate Medical Affairs, Milan, Italy; <sup>4</sup>Groupe Hospitalier Pitié-Salpêtrière-Charles Foix, Paris, France  
Email: kashif.siddiqui@parexel.com

**Background and aims:** Several randomized controlled trials have reported rifaximin- $\alpha$  (alone or in addition to lactulose) to be more efficacious than lactulose alone in the treatment of hepatic encephalopathy (HE), with significant improvement in health-related quality of life. Many individual studies have been conducted to assess the cost-effectiveness of rifaximin- $\alpha$ .

**Method:** This systematic review (SR) and meta-analysis (MA) aimed to assess the cost-effectiveness (CE) of rifaximin- $\alpha$  versus lactulose. A systematic search of English-language studies was conducted in MEDLINE®, Embase®, MEDLINE® In-Process, and CENTRAL from database inception through November 2019. Relevant conference proceedings (2018–2020) were searched in Embase® or via the congress website. Studies were eligible if they assessed the cost-effectiveness of rifaximin- $\alpha$  in HE and reported incremental cost-effectiveness ratios. Incremental net benefits (INBs) were estimated for each study using  $INB = \Delta E \times \lambda - \Delta C$  where  $\Delta E$  is the difference in effectiveness,  $\Delta C$  is the difference in costs, and  $\lambda$  is the threshold or gross domestic product per capita for each country. An MA based on the DerSimonian and Laird method was applied to pool INBs across studies [1]. When feasible, subgroup analyses were also performed based on treatment and time horizon of CE. All costs were standardized to the 2019 United States dollar. The heterogeneity of INB among studies was assessed using the Cochran Q test and the I-square statistic.

**Results:** Of the 15 studies identified in the SR, 11 studies contributed to the MA. The pooled INB was estimated at \$20, 156 (95% CI: \$13, 593–\$29, 887) for rifaximin- $\alpha$  with lactulose vs lactulose monotherapy irrespective of time horizons in the second-line (2L) setting

(Table). Significant heterogeneity was observed in the estimates (I-square = 100%). An MA assessing a combination strategy in the first-line (1L) setting and rifaximin- $\alpha$  salvage therapy was not feasible. The pooled INB for rifaximin- $\alpha$  monotherapy vs lactulose monotherapy in the 1L setting was \$3464 (95% CI: \$1601-\$14, 596) with no heterogeneity (I-square = 0%).

**Conclusion:** Rifaximin- $\alpha$  as an add-on treatment to lactulose in the 2L setting or as monotherapy in the 1L setting would be cost-effective.

**Summary of MA results.**

## POSTER PRESENTATIONS

avatrombopag (AVA) in patients with thrombocytopenia associated with CLD undergoing a procedure.

**Method:** Data were collected prospectively or retrospectively in the US. All treatment decisions were at the discretion of the treating physician per routine medical care. Effectiveness end points included change from baseline over time in platelet count (PC) and proportion of patients who received a platelet transfusion (PT) after baseline up to 7 days following a procedure. Subgroup analyses by baseline PC and Child-Turcotte-Pugh (CTP) grade were performed. Safety was evaluated, including serious adverse events (SAEs).

**Results:** Fifty patients were enrolled (48 unique; 2 patients enrolled twice for separate procedures). Mean age was 61.2 years; 82% were Caucasian. Most common aetiologies of liver disease were chronic viral hepatitis (n = 19), alcoholic liver disease (n = 13) and non-alcoholic steatohepatitis (n = 11). Of 40 patients with a reported CTP grade, 26 had grade A, 11 grade B, and 3 grade C. Common procedures were endoscopy (60%), colonoscopy (16%) and liver biopsy (8%). Patients received 40 mg (n = 27), 60 mg (n = 22) or 20 mg (n = 1) AVA per day, with 70% of patients dosed according to the prescribing information. Mean (standard deviation [SD]) PC was  $46.9 \times 10^9/L$  ( $24.52 \times 10^9/L$ ) at baseline (n = 50) and  $85.1 \times 10^9/L$  ( $41.63 \times 10^9/L$ ) (n = 38) on procedure day (day 8–15 after first dose). Mean (SD) change in PC from baseline to procedure was  $41.1 \times 10^9/L$  ( $33.29 \times 10^9/L$ ). No impact of baseline PC and CTP grade was shown on treatment effect. Forty-nine (98%) procedures did not require a PT. No thromboembolic events or clinically significant bleeding occurred. Most adverse events were mild or moderate and none related to AVA. SAEs occurred in 2 patients and included anaemia/pyrexia/abdominal pain and thrombocytopenia.

**Conclusion:** In the real-world setting, AVA at doses of 40 or 60 mg per day for 5 days was well tolerated, increased PC by procedure day and only one patient required PT. The safety and effectiveness of AVA observed in this study in patients with a PC  $<50 \times 10^9/L$  was consistent with reported outcomes in pivotal studies.

 Email: jessica.howell@svha.org.au

**Background and aims:** Diagnosis of liver cirrhosis is a critical step in chronic liver disease management, however access to transient elastography, liver biopsy and laboratory biomarker testing is limited in low resource/remote settings. Dimeric IgA to monomeric IgA ratio (dIgA ratio) is a potential biomarker of gut mucosal leakage, a key feature of cirrhosis. We evaluated the diagnostic performance of a novel point-of-care (POC) dIgA ratio test for cirrhosis.

**Method:** BioPoint® POC dIgA test is an antigen immunoassay-based lateral flow test which uses 15 µL of plasma or whole blood and provides a quantitative result <20 minutes using the Axxin hand-held lateral flow reader. Cirrhosis was defined by Fibroscan >12.5 kPa, clinical evidence of cirrhosis or liver biopsy.

Associations between dIgA ratio, cirrhosis and clinical parameters were determined by linear and logistic regression. ROC analysis was used to determine diagnostic accuracy. APRI score could be calculated in a subset of 680 individuals.

**Results:** 1478 plasma samples from 960 patients with chronic liver disease were included; 280 (29%) had cirrhosis. Median POC dIgA ratio was higher in Child-Pugh class B/C compared with A cirrhosis (1.4 B/C vs 0.6 A,  $p < 0.001$ ) and correlated with bilirubin (Adj  $R^2 = 0.22$ ,  $p < 0.001$ ) and inversely with albumin (Adj  $R^2 = -0.28$ ,  $p < 0.001$ ). POC dIgA ratio test had good diagnostic accuracy for liver cirrhosis in the test cohort (AUROC 0.84) and moderate accuracy in the validation cohort (AUROC 0.74), similar to APRI score (Table 1). Restricting use of POC dIgA cutoff of 0.6 to those aged >30 years improved accuracy for cirrhosis.

**Conclusion:** POC dIgA ratio test had moderate accuracy for cirrhosis which was comparable to APRI. Further studies evaluating the clinical utility and cost-effectiveness of POC dIgA ratio test for liver cirrhosis screening compared with laboratory based APRI score calculation are warranted.

Table 1: (abstract: PO-2683): Performance of POC dimeric IgA ratio for cirrhosis

Ratio dIgA	No Cirrhosis	Cirrhosis	Sensitivity	Specificity	PPV	NPV	AUROC	95% CI	p value

Email: qixiaolong@vip.163.com

**Background and aims:** Concerns have been raised recently about SARS-CoV-2 vaccine responses in the large population of patients with chronic liver diseases (CLD), which may confer an immunocompromised state and is independently associated with high mortality from Coronavirus disease 2019 (COVID-19). The study aimed to explore the safety and immunogenicity of COVID-19 vaccination in patients with CLD in a large Chinese cohort.

**Method:** This multicenter study included CLD patients without a history of SARS-CoV-2 infection, from 11 designated centers in China between 4 October 2020 and 26 February 2021. The primary safety outcome was the incidence of adverse reactions within 7 days after each injection and the overall incidence of adverse reactions within 28 days, and the primary immunogenicity outcome was neutralizing antibody response at least 14 days after the whole-course vaccination.

**Results:** A total of 390 patients with pre-existing CLD were included in the analysis. The median age was 39.0 years (IQR, 33.0–48.3 years) and 185 (47.4%) were male. The median body-mass index was 26.0 kg/m<sup>2</sup> (IQR, 23.7–28.1 kg/m<sup>2</sup>). Of these, 357 (91.5%) patients were Han ethnicity, and 381 (97.7%) patients had non-alcoholic fatty liver disease. Comorbidities other than liver diseases were present in 54 (13.8%) patients, consisting of 44 (11.3%) hypertension, 15 (3.8%) diabetes, 4 (1.0%) arrhythmia and 1 (0.3%) asthma. The number of 7-days adverse reactions after each injection and adverse reactions within 28 days totaled 98 (25.1%) and 115 (29.5%) of patients, respectively. The most common adverse reactions were 71 (18.2%) injection site pain, followed by 23 (5.9%) muscle pain, 21 (5.4%) headache, and 18 (34.6%) fatigue. All adverse reactions were mild and self-limiting, and no grade 3 adverse reactions were recorded. Notably, neutralizing antibodies against SARS-CoV-2 were detected in 372 (95.4%) of patients with CLD. According to the locally weighted

scatterplot smoothing, the neutralizing antibody titers were maintained over the time since whole-course vaccination (Figure 1).

Figure: Correlation between the time since whole-course vaccination and the neutralizing antibody titer. General trend line is shown in red and was calculated using the locally weighted scatterplot smoothing algorithm.

**Conclusion:** The inactivated COVID-19 vaccine appears to be safe with good immunogenicity in patients with CLD.

PO-2753

**Supplementation of branched-chain amino acids improves event-free survival in cirrhotic patients: systematic review and meta-analysis**

Anne van Dijk<sup>1,2</sup>, Alexandra Bruins Slot<sup>1</sup>, Piero Portincasa<sup>3</sup>, Sebastiaan Siegerink<sup>1</sup>, Najiba Charki<sup>4</sup>, Carina Verstraete<sup>1</sup>, Joep de Bruijne<sup>1</sup>, Frank Vleggaar<sup>1</sup>, Karel J. van Erpecum<sup>1</sup>. <sup>1</sup>University Medical Center Utrecht, Gastroenterology and Hepatology, Utrecht, Netherlands; <sup>2</sup>University Medical Center Utrecht, Diabetics; <sup>3</sup>University of Bari Aldo Moro, Biomedical Sciences and Human Oncology, Italy; <sup>4</sup>University Medical Center Utrecht, Utrecht, Netherlands  
Email: adjik20@umcutrecht.nl

**Background and aims:** Dietary supplementation with branched chain amino acids (BCAA) is often used in cirrhotic patients to improve nutritional state and prognosis. We aimed to explore evidence for BCAA supplementation.

**Method:** A systematic search was performed in MEDLINE and EMBASE using search terms “liver cirrhosis,” “hepatocellular carcinoma” (domain) and “BCAA” (determinant) and relevant synonyms. Interventional and observational studies with BCAA supplementation and a disease-control group (i.e. placebo or no intervention) were included. Available data on overall and event-free survival, (*de novo* or recurrent) hepatocellular carcinoma (HCC), liver function, nutritional status and quality of life were extracted. Risk of bias was assessed using ROBINS-I and RoB 2.0 tools. In case of meta-analysis risk ratio (RR) and 95% confidence interval (95%CI) was calculated with a random effects model.

**Results:** Of 4183 studies screened, 50 studies were included (31 randomized controlled trials, 4 prospective case control studies, 13 retrospective case-control studies: in total 2087 BCAA supplementation, 2649 disease-controls). Risk of bias was high/serious for all studies. In cirrhotics in general, long-term BCAA supplementation significantly improved event-free survival (figure; meta-analysis:  $p = 0.01$ ; RR 0.73 95%CI 0.58–0.93), decreased risk of HCC occurrence (meta-analysis:  $p = 0.02$ ; RR 0.71 95%CI 0.52–0.96) and tended to improve overall survival (meta-analysis:  $p = 0.09$ ). No convincing beneficial effects of BCAA supplementation on liver function, nutritional status or quality of life were found. Available studies reported no beneficial effects or contradictory results of BCAA supplementation after specific therapeutic interventions (liver transplantation, large volume paracentesis and variceal ligation, for HCC the following: resection, radiofrequency ablation, transarterial chemoembolization, hepatic arterial infusion chemotherapy,

## POSTER PRESENTATIONS

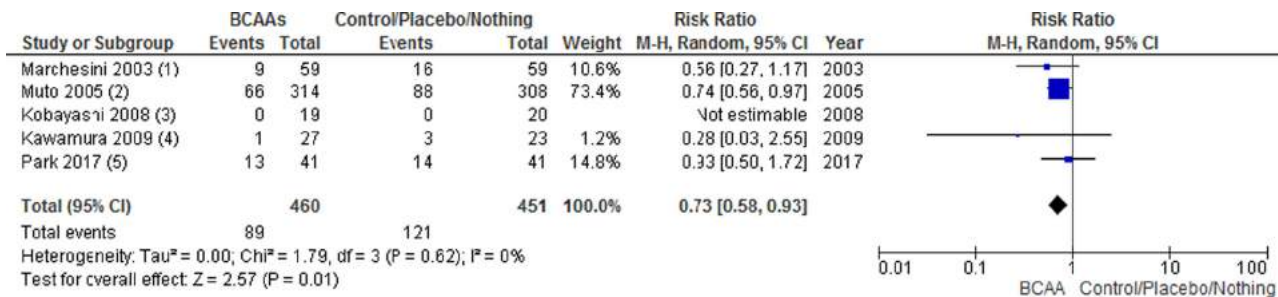

Figure: (abstract: PO-2753): Forest-plot: event-free survival in cirrhotic patients with or without BCAA supplementation

external radiotherapy, systemic therapy with Sorafenib). No study reported detrimental effects of BCAA.

**Conclusion:** Our data indicate that long-term ( $\geq 6$  months) prophylactic BCAA supplementation could improve event-free survival, decrease risk of HCC occurrence and possibly also improve overall survival in cirrhotic patients. Further high-quality placebo-controlled studies are urgently needed.

### PO-2832

#### High prevalence of hormonal changes and hepatic osteodystrophy in Frail patients with cirrhosis An observational study

Surender Singh<sup>1</sup>, Sunil Taneja<sup>1</sup>, Arka De<sup>1</sup>, Nipun Verma<sup>1</sup>, Madhumita Premkumar<sup>1</sup>, Ajay Kumar Duseja<sup>1</sup>, Radha Krishan Dhiman<sup>1</sup>, Virendra Singh<sup>1</sup>. <sup>1</sup>Postgraduate Institute of Medical Education and Research, Hepatology, Chandigarh, India  
Email: drsuniltaneja@hotmail.com

**Background and aims:** Hormonal changes and hepatic osteodystrophy are less often studied complications of cirrhosis. This study describes the differences in hormone levels and hepatic osteodystrophy between Frail and Not frail patients with cirrhosis.

**Method:** 116 outpatients with cirrhosis were prospectively enrolled in this cross-sectional study. Frailty assessment was done using Liver Frailty Index (LFI). Socio-demographic assessment, anthropometry, nutritional assessment, hormone profile, and Dual-energy X-ray absorptiometry (DEXA) scan were done in all patients.

**Results:** 100 (86.2%) males and 16 (13.8%) females with a mean age of 50.16 years (95% CI, 48.43–51.89) were included. Malnutrition was more common in the Frail group as compared to the Not frail group. SGA class-B patients were significantly more in the Frail group (37 (74%) versus 3 (4.5%),  $p = 0.001$ ). The prevalence of low PTH (14 (28%) vs 2 (3%)), testosterone (33 (66%) vs 15 (22.7%)), vitamin D3 (44 (88%) vs 39 (59.1%)) and cortisol (37 (74%) vs 37 (56.1) levels was higher in Frail group ( $p < 0.05$ ). The number of patients diagnosed with hepatic osteodystrophy (34 (68%) vs 21 (31.8%),  $p = 0.001$ ) was significantly higher in the Frail group. The marker of osteoclastic activity, beta cross laps was significantly higher in the Frail group both in males 736 (655–818) vs 380 (329–432),  $p = 0.001$  and females 619 (479–758) vs 313 (83–543),  $p = 0.02$ ). BMD at the lumbar spine and neck of the femur had a significant correlation with frailty, testosterone levels, Beta-cross laps, calcium, and cortisol levels.

Table: The difference in levels of parameters between Frail and Not frail patients

Parameters	Frail (n = 50) Mean (95% CI)	Not frail (n = 66) Mean (95% CI)	P value
Testosterone (nmol/l)			
Females	1.15 (0.79–1.52)	1.74 (0.39–3.9)	0.092
Males	4.28 (2.41–6.15)	19.26 (16.76–21.75)	0.001
Cortisol (nmol/l)	134.85 (109.4–160.29)	218.28 (192.53–244.04)	0.001
PTH (pg/ml)	28.38 (16.86–39.9)	38.59 (34.07–43.1)	0.001
Calcium (mg/dl)	8.26 (8.12–8.4)	8.84 (8.71–8.97)	0.001
Vitamin-D3 (ng/ml)	20.49 (17.76–23.21)	28.22 (24.79–31.64)	0.001
Beta cross laps (pg/ml)			
Females	619 (479–758)	313 (83–543)	0.026
Males	736 (655–818)	380 (329–432)	0.001

Abbreviations: CI, Confidence interval; PTH, Parathyroid hormone.

**Conclusion:** This is the first study that highlights the high prevalence of hormonal changes and hepatic osteodystrophy in Frail patients with cirrhosis and opens a new dimension for research in this field.

### PO-2867

#### Hepatogenous diabetes in patients with cirrhosis and ascites: correlation with inflammatory activity, systemic hemodynamics, renal function, and outcome

Ilias Tsiakas<sup>1</sup>, Georgios Kalambokis<sup>1</sup>, Grigorios Despotis<sup>1</sup>, Maria Christaki<sup>1</sup>, Sempastien Fillipas-Ntekouan<sup>1</sup>, Lampros Lakkas<sup>2</sup>, Spyridon Tsiouris<sup>3</sup>, Xanthi Xourgia<sup>3</sup>, Christina Koustousi<sup>1</sup>, Nikolaos Aggelis<sup>1</sup>, Chalampos Milionis<sup>1</sup>. <sup>1</sup>School of Medicine, University of Ioannina, 1st Department of Internal Medicine, Ioannina, Greece; <sup>2</sup>School of Medicine, University of Ioannina, 2nd Department of Cardiology, Ioannina, Greece; <sup>3</sup>School of Medicine, University of Ioannina, Laboratory of Nuclear Medicine, Ioannina, Greece  
Email: gkalambo@uoi.gr

**Background and aims:** Hepatogenous diabetes (HD) complicates advanced cirrhosis. Its diagnosis often requires an oral glucose tolerant test (OGTT). We investigated the association of HD with inflammation markers, systemic hemodynamics, renal function, and outcome in patients with cirrhosis and ascites.

**Method:** 35 patients with known HD diagnosed by fasting plasma glucose (FPG)/glycosylated hemoglobin (HbA1c) results (Group-1) and 71 with normal FPG and HbA1c levels were evaluated. OGTT diagnosed HD in 34 of 71 patients who started antidiabetics (Group-2) and was normal in 37 (Group-3). Mean arterial pressure (MAP), cardiac output (CO) by cardiac ultrasound, systemic vascular resistance (SVR) calculated as MAP/CO ratio, plasma renin activity (PRA), plasma aldosterone, and serum noradrenalin by radioimmunoassays, glomerular filtration rate (GFR) and renal plasma flow using radionuclide scintigraphy, and renal blood flow (RBF) calculated as renal plasma flow/1-hematocrit were evaluated at baseline, and at 6 and 12 months. Plasma levels of lipopolysaccharide-binding protein (LBP) by ELISA, and tumor-necrosis factor-alpha (TNF-alpha) and

interleukin-6 by cytometric bead array were measured at baseline. Three-year survival was evaluated.

**Results:** Cirrhosis severity was similar in the 3 groups. LBP and TNF-alpha levels were significantly higher in Group-1 than in Group-2 ( $p = 0.03$  and  $p = 0.04$ , respectively) and Group-3 ( $p = 0.01$  and  $p = 0.04$ , respectively). Group-1 patients had significantly lower SVR and higher PRA compared to Group-2 ( $p = 0.04$  and  $p = 0.04$ , respectively) and Group-3 ( $p = 0.01$  and  $p = 0.008$ , respectively). GFR and RBF were also significantly lower in Group-1 compared to Group 2 ( $p = 0.03$  and  $p = 0.04$ , respectively) and Group-3 ( $p = 0.009$  and  $p = 0.01$ , respectively). After 12 months, a significant increase in SVR and a significant decrease in PRA were noted in Group-2 ( $1322 \pm 44$  vs.  $1285 \pm 56$  dyn.sec.cm<sup>-5</sup>;  $p = 0.008$  and  $60.9 \pm 18.7$  vs.  $74.6 \pm 23.4$  pg/ml;  $p = 0.01$ , respectively) together with significant increases in GFR and RBF ( $85 \pm 5$  vs.  $77 \pm 6$  ml/min;  $p = 0.009$  and  $642 \pm 32$  vs.  $614 \pm 38$  ml/min;  $p = 0.03$ , respectively). 3-year survival was significantly higher in Group-2 than in Group-1 (75.3% vs. 55.3%;  $p = 0.01$ ) while it was similar in groups 2 and 3 (81.7%).

**Conclusion:** HD is associated with higher inflammatory activity. Systemic hemodynamics, renal function, and survival are adversely affected by HD but improve significantly with early diagnosis by OGTT and treatment.

**PO-2951**

**An educational intervention that effectively reduces the inappropriate administration of proton pump inhibitors in patients with cirrhosis**

Juvelyn Palomique<sup>1</sup>, Walid Ayoub<sup>2</sup>, Alexander Kuo<sup>2</sup>, Mazen Nouredin<sup>2</sup>, Vinay Sundaram<sup>2</sup>, Mary-Lynn Brecht<sup>3</sup>, Ju Dong Yang<sup>2</sup>. <sup>1</sup>Cedars Sinai Medical Center, Hepatology, Los Angeles, United States; <sup>2</sup>cedars sinai medical center, Hepatology, Los Angeles, United States; <sup>3</sup>University of California Los Angeles, School of Nursing Doctor of Nursing Practice, Los Angeles, United States  
Email: juvelyn.palomique@cshs.org

**Background and aims:** Inappropriate use of proton pump inhibitors (PPI) is common in patients with cirrhosis. PPI's are associated with deleterious effects in cirrhosis including increased risk for hepatic encephalopathy, spontaneous bacterial peritonitis, and liver-related mortality. We aim to decrease the incidence of low-value, non-guideline supported prescription of PPI's in the inpatient setting, by implementing a PPI Clinician Update education.

**Method:** The study was implemented in a single inpatient transplant center. Key medical staff were identified to receive a PPI Clinician Update educational session, including Hospitalist, Gastroenterology

fellows, Hepatology, Liver transplant advanced practice provider (APP). The education session was 20 minutes in duration and utilized a two-page PPI Handout with a PPI deprescribing evidence-based algorithm for provider guidance. Knowledge level was measured using a one group pre-posttest design with a total of 10 questions. The primary outcome measure was the changes in the incidence of inappropriate PPI prescription. Incidence of inappropriate PPI was measured over one week duration four week prior and after the education session among cirrhosis patients admitted to hepatology inpatient service. Secondary outcome was percentage of correct response.

**Results:** A total of 26 providers completed the educational session and pre-posttest. Lack of knowledge regarding outpatient PPI indication were reported as the main barrier to verifying PPI prescription. There was a statistically significant increase in knowledge ( $p = 0.0001$ ) one month after receiving the educational intervention (Figure 1A). There was a decrease in the incidence of inappropriate PPI use from 52% (23/44) to 25% (11/44) ( $p = 0.009$ ) after receiving the educational intervention (Figure 1B). The most common reason for inappropriate PPI prescription was continuation of the patient's home medication without verifying the indication. The posttest survey showed that 46.2% of clinicians strongly agreed that their practice changed after the educational intervention and constructive feedback.

**Conclusion:** The most common reason for inappropriate PPI prescription was due to a continuation of a home medication without verifying the indication. An educational intervention is effective in increasing knowledge and decreasing the inappropriate PPI prescriptions in the inpatient setting.

Email: mattias.mandorfer@meduniwien.ac.at

**Background and aims:** Preclinical studies indicate that bacterial translocation-induced systemic inflammation (SI) promotes liver fibrogenesis, however, evidence from studies in humans is limited. This prospective study investigated whether SI is linked to histological hepatic stellate cell (HSC) activation and blood biomarkers of liver fibrogenesis and matrix turnover in patients with advanced chronic liver disease (ACLD).

**Method:** Biomarkers of SI (CRP, IL-6, PCT), fibrogenesis (formation of type III [PRO-C3] and VI collagen [PRO-C6]), fibrolysis (degradation of type III collagen [C3M]), and matrix turnover (TIMP-1) were assessed

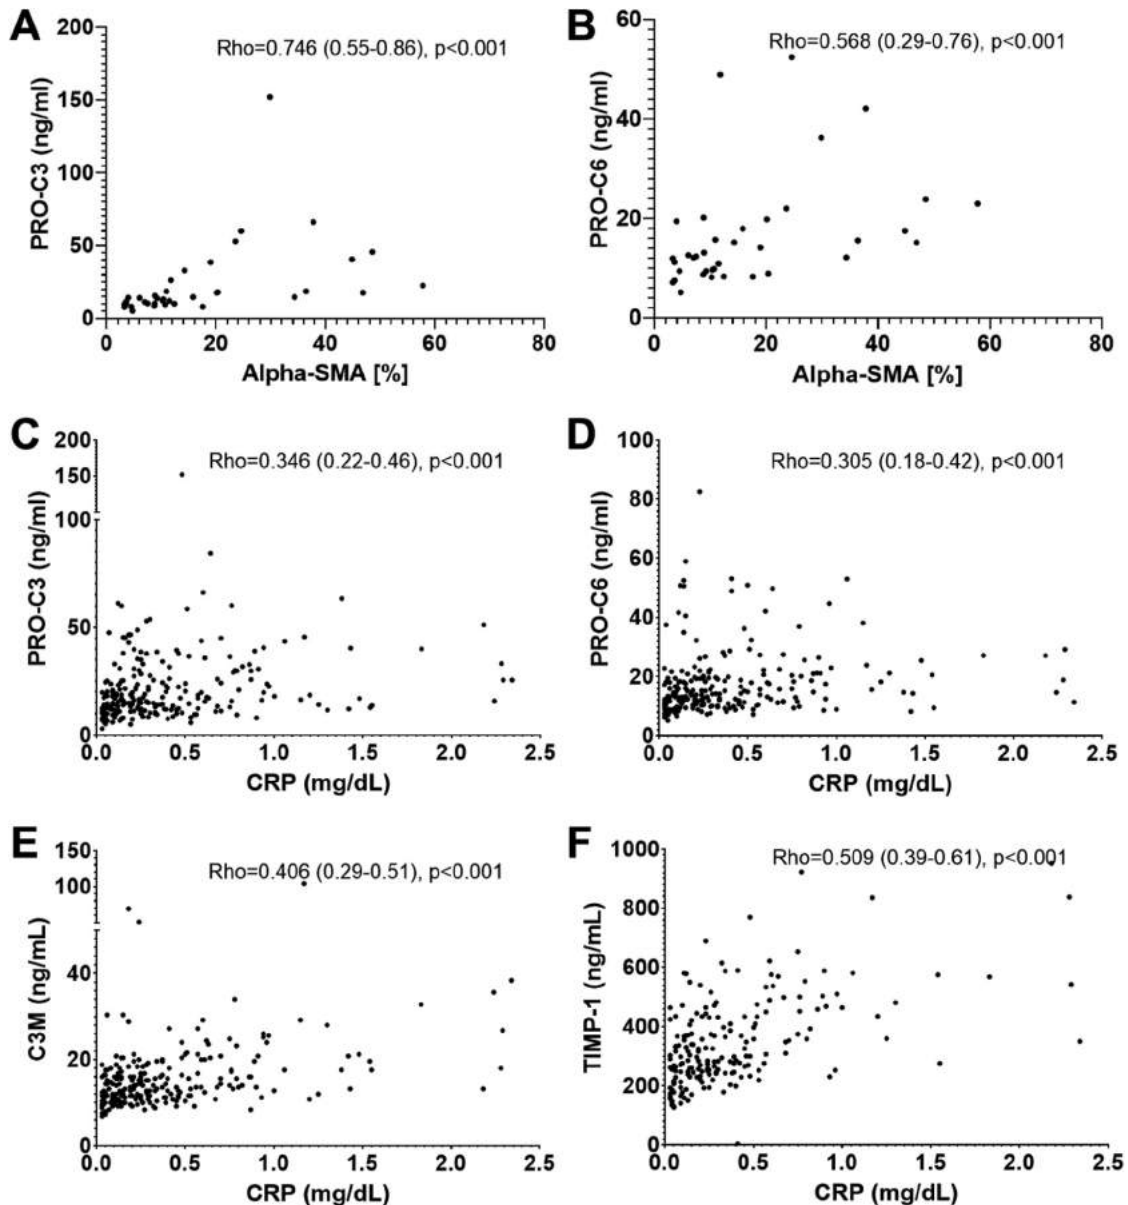

Figure: (abstract: PO-309)

in 234 patients with clinically stable ACLD (hepatic venous pressure gradient [HVPG]  $\geq 6$  mmHg; absence of bacterial infections or acute decompensation) undergoing HVPG-measurement. Alpha-smooth muscle actin proportionate area (alpha-SMA%) was analysed by slide scanner in a subset of patients (n = 38) with concomitant transjugular liver biopsy.

**Results:** Alpha-SMA% strongly correlated with markers of liver fibrogenesis (PRO C3:Spearman's  $\rho = 0.746$ ,  $p < 0.001$ ; PRO-C6: $\rho = 0.568$ ,  $p < 0.001$ ), confirming that these biomarkers reflect HSC activation in ACLD (Figure). Furthermore, alpha-SMA% was directly associated with SI (CRP:  $\rho = 0.517$ ,  $p = 0.001$ ; IL-6:  $\rho = 0.448$ ,  $p = 0.005$ ; PCT:  $\rho = 0.373$ ,  $p = 0.021$ ).

Similarly, PRO-C3 (CRP:  $\rho = 0.346$ ; IL-6:  $\rho = 0.302$ ; PCT:  $\rho = 0.389$ ; all  $p < 0.001$ ) and PRO C6 (CRP:  $\rho = 0.305$ ; IL-6:  $\rho = 0.410$ ; PCT:  $\rho = 0.331$ ; all  $p < 0.001$ ) exhibited direct correlation with SI levels, as well as C3M (CRP:  $\rho = 0.406$ ; IL-6:  $\rho = 0.375$ ; all  $p < 0.001$ ) and TIMP-1 (CRP:  $\rho = 0.509$ ; IL-6:  $\rho = 0.574$ ; PCT:  $\rho = 0.421$ ; all  $p < 0.001$ ; Figure).

Next, multiple linear regression analysis was performed to evaluate the impact of SI on fibrogenesis and matrix turnover while adjusting for HVPG to correct for the underlying severity of liver disease. The following SI biomarkers were independent determinants of fibrogenesis: CRP for PRO-C3 and IL-6 for PRO-C6. Moreover, matrix turnover was upregulated with increasing CRP and IL-6 levels for C3M as well as CRP and IL-6 for TIMP-1.

**Conclusion:** SI is associated with histological and blood biomarkers of liver fibrogenesis. Importantly, the association between SI and blood biomarkers was independent of, and thus, not confounded by the severity of underlying liver disease. These findings support the pathophysiological concept that bacterial translocation-induced SI promotes hepatic fibrogenesis and matrix turnover in patients who

have already progressed to ACLD, which in turn may be ameliorated by targeting the gut-liver axis/SI.

**PO-310**

**Von Willebrand Factor (VWF) propeptide levels are similarly accurate for assessing portal hypertension as compared to VWF antigen**

Ida Villesen<sup>1,2</sup>, Benedikt Simbrunner<sup>3,4</sup>, David J.M. Bauer<sup>3,4</sup>, Rafael Paternostro<sup>3,4</sup>, Philipp Schwabl<sup>3,4</sup>, Bernhard Scheiner<sup>3,4</sup>, Albert Stättermayer<sup>3</sup>, Matthias Pinter<sup>3</sup>, Michael Trauner<sup>3</sup>, Prof. Peter Quehenberger, MD<sup>5</sup>, Morten Karsdal<sup>1</sup>, Thomas Reiberger<sup>3,4</sup>, Diana Leeming<sup>1</sup>, Mattias Mandorfer<sup>3,4</sup>. <sup>1</sup>Nordic Bioscience, Herlev, Denmark; <sup>2</sup>University of Copenhagen, Copenhagen, Denmark; <sup>3</sup>Medical University of Vienna, Dpt. of Internal Medicine III, Div. of Gastroenterology and Hepatology, Vienna, Austria; <sup>4</sup>Medical University of Vienna, Vienna Hepatic Hemodynamic Laboratory, Vienna, Austria; <sup>5</sup>Medical University of Vienna, Department of Laboratory Medicine, Vienna, Austria  
Email: mattias.mandorfer@meduniwien.ac.at

**Background and aims:** Endothelial dysfunction is an important mechanism contributing to portal hypertension (PH) in advanced chronic liver disease (ACLD) and is reflected by increased von Willebrand factor antigen (VWF-Ag) levels. This prospective study aimed to elucidate VWF-release (by measuring its propeptide; VWF-N) and -cleavage (by measuring its ADAMTS13-processed form; VWF-A) as well as their association with PH severity in patients with ACLD.

**Method:** Levels of VWF-N/VWF-A (by ELISA) and VWF-Ag (by immunoturbidimetric assays) were assessed in 229 patients with

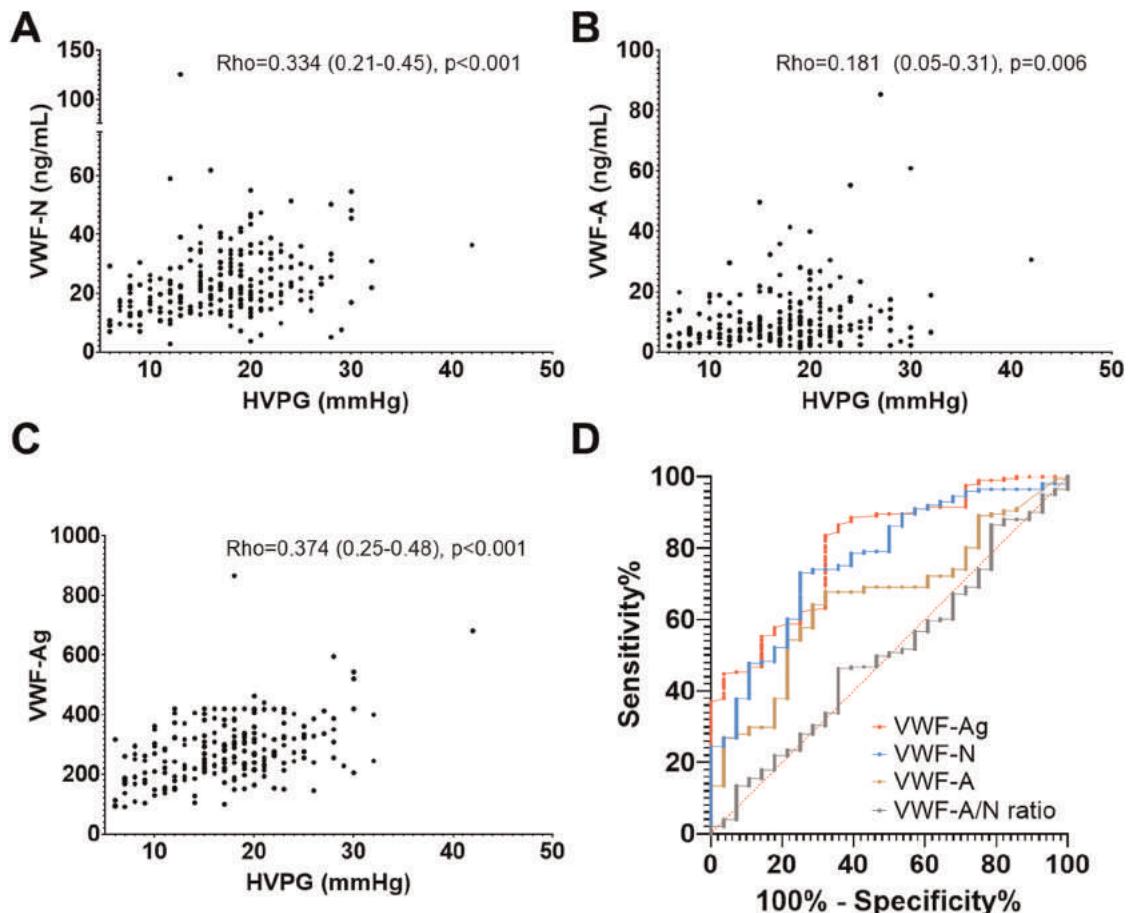

Figure: (abstract: PO-310)

## POSTER PRESENTATIONS

clinically stable ACLD (hepatic venous pressure gradient [HVPG]  $\geq$  6 mmHg; absence of bacterial infections or acute decompensation) undergoing HVPG measurement. Furthermore, ADAMTS13 (i.e., the main VWF-cleaving protease) activity was analysed in a subgroup (n = 166).

**Results:** VWF-N significantly correlated with VWF-Ag (Spearman's  $\rho = 0.627$ ,  $p < 0.001$ ) and HVPG ( $\rho = 0.334$ ,  $p < 0.001$ ; Figure). In contrast, its association with VWF-A levels was markedly weaker ( $\rho = 0.263$ ,  $p < 0.001$ ). Moreover, VWF-A exhibited only very weak correlations with VWF-Ag ( $\rho = 0.207$ ,  $p = 0.002$ ) and HVPG ( $\rho = 0.181$ ,  $p = 0.006$ ). Of note, the association between VWF-Ag and HVPG ( $\rho = 0.374$ ,  $p < 0.001$ ) attained a similar strength, as compared to VWF-N ( $p = 0.225$  for comparison). VWF-Ag, VWF-A, and VWF-N continuously increased across PH severity strata (HVPG 6–9: n = 28 vs. 10–19: n = 121 vs.  $\geq 20$  mmHg: n = 80): Median VWF-Ag was 184/278/291 ( $p < 0.001$ ), VWF-A 5.95/8.15/8.98 ( $p = 0.013$ ), and VWF-N 14.8/21.5/24.1 ( $p < 0.001$ ).

Finally, AUROC analyses identified VWF-Ag (0.80 [0.72–0.89],  $p < 0.001$ ) and VWF-N (0.77 [0.68–0.86],  $p < 0.001$ ) as non-invasive tests for clinically significant PH (HVPG  $\geq 10$  mmHg; CSPH; Figure). In contrast, the other parameters displayed limited accuracy (VWF-A: 0.66 [0.56–0.76],  $p = 0.007$ ) or were not linked (VWF-A/-N ratio) to CSPH.

Interestingly, neither HVPG ( $p = 0.94$ ), VWF-Ag ( $p = 0.88$ ), VWF-N ( $p = 0.49$ ), VWF-A ( $p = 0.82$ ), nor VWF-A/-N ratio ( $p = 0.39$ ) were linked to ADAMTS13 activity.

**Conclusion:** ADAMTS13 activity is unrelated to PH severity and not linked to VWF-related parameters in patients with clinically stable ACLD. In this patient group, levels of VWF-A are determined by increased VWF-release, rather than decreased ADAMTS13-mediated cleavage. VWF-Ag levels and its propeptide, VWF-N, are more suitable as surrogates of PH in patients with ACLD, as compared to VWF-A or ADAMTS13 activity.

### PO-532

#### Clinical outcomes of cirrhotic patients with dysregulated hormones of vascular homeostasis

Email: thomas.reiberger@meduniwien.ac.at

**Background and aims:** Renin, brain-type natriuretic peptide (BNP) and arginine-vasopressin (AVP) regulate circulatory homeostasis and these systems may be distorted in advanced chronic liver disease (ACLD).

**Method:** Plasma profiles of renin, proBNP and copeptin (an AVP biomarker) were assessed in portal hypertensive ACLD patients with compensated (cACLD) or decompensated (dACLD) at study inclusion. Patients with non-selective beta-blockers at the time of characterization were excluded from analysis. Decompensation/further decompensation and mortality were assessed by log-rank tests and Cox proportional hazard models. Multivariate models were adjusted for age, sex, MELD, HVPG, albumin and sodium.

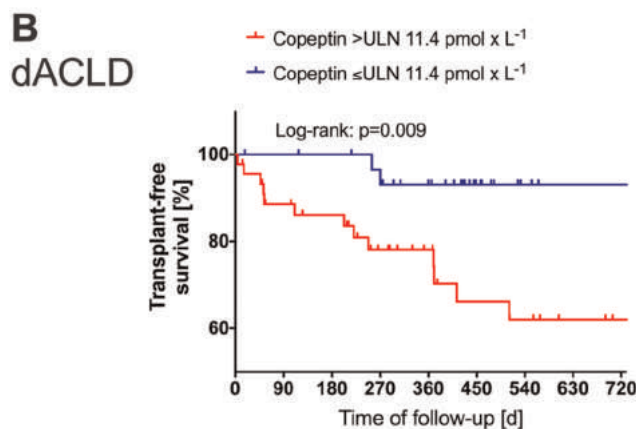

**Results:** Overall, 648 (cACLD: n = 302, dACLD: n = 346) patients were included. Median follow-up was 26.2 [IQR 40.4] months. 34.7% (n = 225) of patients had at least one decompensation event, 7.9% (n = 51) underwent liver transplantation and 24.8% (n = 161) died during follow-up including 82.6% (n = 133) liver-related deaths.

Time to first decompensation was shorter in cACLD patients with elevated renin ( $>39.9 \mu\text{IU/ml}$ ; n = 64/294;  $p = 0.096$ ) and copeptin ( $>11.4 \text{ pmol/L}$ ; n = 17/55;  $p = 0.024$ ). Accordingly, plasma renin (aHR: 1.69; 95% CI: 1.07–2.68;  $p = 0.025$ ) and in tendency copeptin (aHR: 2.69; 95% CI: 0.99–7.33;  $p = 0.053$ ) independently predicted first decompensation. In dACLD, elevated proBNP ( $>125 \text{ pg/ml}$ ; n = 110/172;  $p = 0.012$ ) and copeptin (n = 45/77;  $p = 0.014$ ) were linked to further decompensation-but both did not independently predict further decompensation on multivariate analysis.

Transplant-free survival was shorter in ACLD patients with elevated renin (306/630;  $p < 0.001$ ), proBNP (n = 139/277;  $p = 0.004$ ) and copeptin (n = 62/132;  $p = 0.006$ ), but only elevated copeptin was independently associated with decreased transplant-free survival (aHR: 3.29; 95% CI: 1.36–7.95;  $p = 0.008$ ). In cACLD, increased renin (n = 64/294;  $p < 0.001$ ) was an independent predictor of mortality (aHR: 3.21; 95% CI: 1.73–5.93;  $p < 0.001$ ), whereas in dACLD mortality was independently associated with elevated copeptin (n = 45/80;  $p = 0.009$ ; aHR: 5.77; 95% CI: 1.27–26.33;  $p = 0.024$ ).

Patients at risk

Figure:

**Conclusion:** Elevated levels of renin, proBNP and copeptin are linked to impaired outcomes in ACLD. In cACLD, increased renin might indicate systemic vasodilation preceding clinical decompensation, as it predicts first decompensation and mortality. Increased copeptin (indicative of circulatory stress/failure) is particularly relevant in dACLD, correlating with further decompensation and predicting mortality.

**PO-560**

**Decreasing VWF levels upon NSBB therapy indicate a reduced risk of further decompensation, ACLF and death**

Email: thomas.reiberger@meduniwien.ac.at

**Background and aims:** Bacterial translocation drives systemic inflammation (SI) as well as endothelial dysfunction, and thus, disease progression in cirrhosis. Non-selective beta-blockers (NSBBs) may exert beneficial effects beyond lowering portal pressure. We assessed (i) NSBB-related changes in von Willebrand factor levels (VWF) and (ii) their prognostic value for outcomes in decompensated cirrhosis.

**Method:** We assessed changes in VWF as a surrogate marker for endothelial dysfunction, as well as biomarkers of SI (C-reactive protein [CRP], procalcitonin [PCT]) and of hemodynamic derangement (mean arterial pressure [MAP]) in patients undergoing paired hepatic venous pressure gradient (HVPG) measurements before and under NSBB treatment. Patients were followed until last clinical contact, the occurrence of a significant risk-modifying event (antiviral therapy, alcohol abstinence, or hepatocellular carcinoma), liver transplantation, or death. Follow-up data was analyzed using competing risk regression stratifying patients according to presence ('VWF responders') or absence ('VWF non-responders') of VWF decrease upon NSBB treatment.

**Results:** 159 patients with a median Child-Pugh score of 8 (IQR: 6; 9) were included. Upon NSBB treatment, HVPG response was observed in 77 (48.4%) patients, while 113 (71.1%) patients were VWF responders (median relative decrease: -12.9 [IQR: -19.7; -7.4]%). The rates of HVPG response were comparable between VWF response groups (VWF responders: 47.8% vs. VWF non-responders: 50.0%; p = 0.938). However, VWF responders showed more pronounced relative reductions in SI, i.e. procalcitonin (-16.7 [IQR: -31.3; -2.5]% vs. VWF non-responders: 25.0 [IQR: 19.2; 44.6]%; p < 0.001) and CRP (-22.9 [IQR: -50.1; 10.0]% vs. VWF non-responders: -5.9 [IQR: -31.9; 20.4]%; p = 0.074). Notably, NSBB-induced relative decreases in MAP were less pronounced in VWF responders (-8.3 [IQR: -14.9; -1.2]%) than in VWF non-responders (-12.5 [IQR: -18.5; -5.4]%; p = 0.046). In adjusted competing risk regression models, VWF response was associated with decreased risks of further decompensation (adjusted subdistribution hazard ratio [aSHR]: 0.630 [95%CI: 0.399-0.993]; p = 0.047), acute-on-chronic liver failure (ACLF, aSHR: 0.407 [95%CI: 0.180-0.918]; p = 0.030), and liver-related death (aSHR: 0.434 [95%CI: 0.229-0.819]; p = 0.010).

**Conclusion:** NSBB-related reductions in VWF levels might reflect their anti-inflammatory activity. Decreases in VWF are accompanied by less pronounced adverse effects on systemic hemodynamics and are independently associated with a decreased risk of further decompensation, ACLF and death.

**PO-1032**

**Impact of hyponatremia on morbidity, mortality and resource utilization in portal hypertensive ascites: a nationwide analysis**

Joseph Alukal<sup>1</sup>, Talan Zhang<sup>2</sup>, Paul J. Thuluvath<sup>2</sup>. <sup>1</sup>Institute of Digestive Health and Liver Disease, Mercy Medical Center, Baltimore, United States; <sup>2</sup>Institute of Digestive Health and Liver Disease, Mercy Medical Center and University of Maryland School of Medicine, Baltimore, United States  
Email: jjalukal@gmail.com

**Background and aims:** Ascites and hyponatremia are important milestones of worsening portal hypertension in those with cirrhosis. The objective of our study was to evaluate mortality and resource utilization of hospitalized cirrhotic patients with ascites with or without hyponatremia using a large national cohort.

**Method:** The National In-patient Sample (NIS) database was used to identify all adult hospitalized patients with a diagnosis of cirrhosis and ascites with or without hyponatremia from 2016 to 2017 using ICD-10 codes (cirrhosis K74.60, K70.30; ascites R18.8; hyponatremia E87.1).

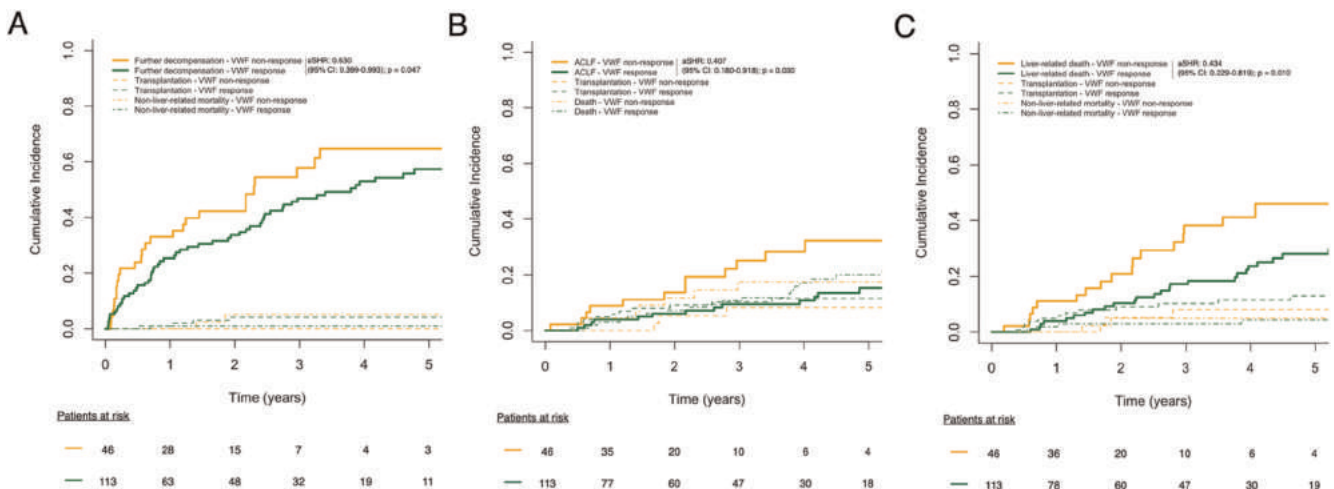

Figure: (abstract: PO-560)

# POSTER PRESENTATIONS

**Results:** During the study period 10, 187 cirrhotic patients were hospitalized with ascites and hyponatremia, and 34, 555 cirrhotic patients were hospitalized with ascites without hyponatremia. Compared to those without hyponatremia, hyponatremic patients had a higher prevalence of acute kidney injury (AKI) (50.3% vs. 32.8%,  $p < 0.001$ ), acute respiratory failure (12.8% vs. 10.4%,  $p < 0.001$ ) and sepsis (16.8% vs. 11.8%,  $p < 0.001$ ); they also had a higher prevalence of liver related complications such as coagulopathy (46.6% vs. 38.1%,  $p < 0.001$ ), hepatic encephalopathy (29.4% vs. 24%,  $p < 0.01$ ), HRS (12.2% vs. 5.7%,  $p < 0.001$ ), SBP (10.3% vs. 6.6%,  $p < 0.001$ ), HCC (10.1% vs. 7.1%,  $p < 0.001$ ) and acute liver failure (ALF) (8.2% vs. 5.7%,  $p < 0.001$ ). Hyponatremia patients underwent a higher number of procedures (mean  $2.9 \pm 3.3$  vs.  $2.3 \pm 2.7$ ,  $p < 0.001$ ) and paracentesis (53% vs. 44%,  $p < 0.001$ ). Comorbidity score ( $20.9 \pm 9.7$  vs.  $12.8 \pm 11.4$ ,  $p < 0.001$ ), length of stay ( $8.5 \pm 9.2$  vs.  $6.5 \pm 7.2$ ,  $p < 0.001$ ), and total charges (\$97, 327 vs. \$72, 278,  $p < 0.01$ ) were also significantly higher in hyponatremic patients (Table 1). In-patient mortality was 38% higher in hyponatremic patients (9.8% vs. 7.1%,  $p < 0.001$ ). Multivariable analysis (OR and 95% Confidence Intervals) showed that age  $>60$  years (1.28; 1.06–1.54,  $p = 0.01$ ), variceal bleeding (2.0; 1.34–2.98,  $p = 0.001$ ), ALF (2.16; 1.67–2.78,  $p < 0.0001$ ), AKI (2.21, 1.82–2.70,  $p = 0.001$ ), HCC (2.29; 1.79–2.94,  $p < 0.0001$ ), sepsis (4.54; 3.77–5.47,  $p < 0.0001$ ) and acute respiratory

failure (6.79; 5.61–8.22,  $p < 0.0001$ ) were independent risk factors for mortality.

**Conclusion:** In hospitalized patients with portal hypertension related ascites, presence of hyponatremia was associated with 38% higher in-patient mortality and 35% higher costs compared to those without hyponatremia.

## PO-1038

### A scoring model to predict mortality in hospitalized patients with decompensated cirrhosis and hyponatremia

Joseph Alukal<sup>1</sup>, Talan Zhang<sup>2</sup>, Paul J. Thuluvath<sup>2</sup>. <sup>1</sup>Institute of Digestive Health and Liver Disease, Mercy Medical Center, Baltimore, United States; <sup>2</sup>Institute of Digestive Health and Liver Disease, Mercy Medical Center and University of Maryland School of Medicine, Baltimore, United States

Email: jjalukal@gmail.com

**Background and aims:** Patients with decompensated cirrhosis who develop hyponatremia have significant morbidity and mortality. The objective of our study was to develop a model to predict in-hospital mortality in such patients using easily available and verifiable clinical parameters.

**Method:** The National In-patient Sample (NIS) database was used to identify all adult hospitalized patients with a diagnosis of cirrhosis, ascites and hyponatremia from 2016 to 2017 using ICD-10 codes

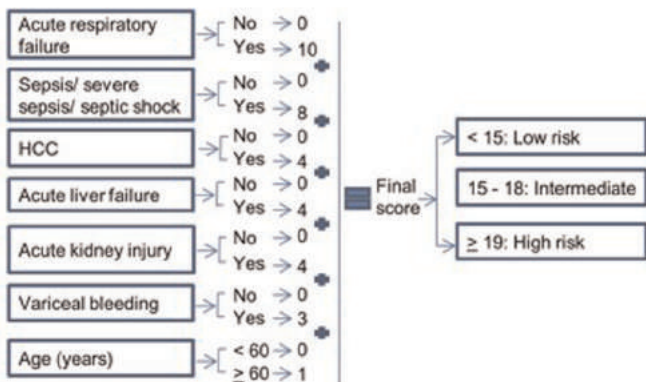

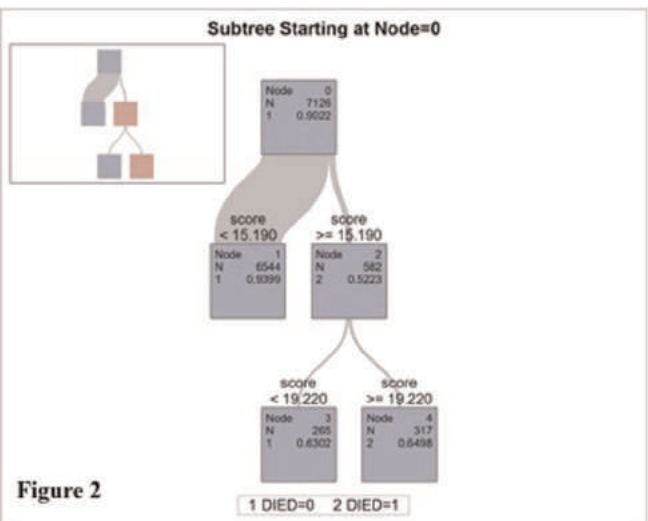

Figure: (abstract: PO-1038)

(cirrhosis K74, K74.60, K70.30; ascites R18.8; hyponatremia E87.1). After identifying independent risk factors for in-hospital mortality, we developed a prediction model using logistic regression analysis. The model was built and validated in a training and a validation dataset respectively. A clinical scoring model was created by first categorizing continuous predictors in the logistic regression models by using cutoff points selected by maximum Youden index and then refitting the logistic models using all predictors as categorical variables. To enhance the clinical utility of the score, we further classified patients into three mortality risk categories (low, intermediate, and high risk) using cutoff points selected by the Decision Tree model.

**Results:** During the study period we identified 10,187 hospitalized cirrhotic patients with ascites and hyponatremia with an overall mortality of 9.8%. Multivariate analysis showed that age, variceal bleeding, acute liver failure, acute kidney injury, hepatocellular cancer (HCC), sepsis and acute respiratory failure were independent risk factors for mortality. The mortality prediction model that incorporated these risk factors had an area under the receiver operating characteristic curve (AUROC) of 0.83 (0.81, 0.85) for the training data and 0.86 (0.83, 0.88) for the validation data (Fig. 1). We created an algorithm to stratify patients into low (score <15), intermediate (score 15–18) and high risk (score >19) categories. The cut-off points were determined based on Decision Tree model (Fig. 2–3). The probability of mortality of the training and validation cohorts as well as the predicted mortality (with 95% CI) based on this algorithm is shown in Figure 4. The predicted mortality in low, intermediate and high-risk groups were 6%, 30% and 60% respectively.

**Conclusion:** The prognostic model created using the NIS database was able to predict mortality in hospitalized patients with cirrhosis and hyponatremia with a very high accuracy.

**PO-1040**

**The natural history of advanced chronic liver disease defined by transient elastography**

Jessica Shearer<sup>1,2</sup>, Rebecca L. Jones<sup>2</sup>, Richard Parker<sup>2</sup>, James Ferguson<sup>3</sup>, Ian Rowe<sup>1,2</sup>. <sup>1</sup>University of Leeds, United Kingdom; <sup>2</sup>St James's University Hospital, United Kingdom; <sup>3</sup>Queen Elizabeth Hospital Birmingham, United Kingdom  
Email: jshearer@doctors.org.uk

**Background and aims:** The clinical course of cirrhosis does not follow a predictable trajectory. Multistate models of disease progression have been adopted to assess its' natural history, mainly in cohorts with biopsy proven cirrhosis. Transient elastography (TE) is commonly used in clinical practice to diagnose liver fibrosis. The aim of this study was to assess survival and competing risk of liver and non-liver related events in a cohort of patients with advanced chronic liver disease (ACLD) defined by TE using electronic health record (EHR) data.

**Method:** TE data was collected from two large secondary care centres in the UK between 2008 and 2019. Patients with ACLD (defined by a liver stiffness measurement (LSM) of >10 kPa) were included. Disease and procedural codes extracted from the EHR were analysed. Validation of the coded information was done in a subset of patients using the full clinical record. Clinical events including decompensation (ascites, bleeding and non-bleeding varices, hepatic encephalopathy), hepatocellular carcinoma (HCC) and death were identified. Estimation of transition probabilities between clinical stages of cirrhosis was done using multistate models and flexible parametric survival models.

**Results:** 3029 patients were included, 1549 with LSM ≥ 15 kPa. Median follow-up was 3.3 years. During follow-up, 9% of patients died, 7.5% of patients developed varices, 2% had bleeding varices and 5.5% had a non-bleeding decompensation event. 2.4% were diagnosed with HCC. Baseline LSM was associated with the development of varices, the transition from compensated cirrhosis to decompensated cirrhosis, and the development of HCC. Disease aetiology was also associated with decompensation and the development of HCC. Example predicted disease trajectories derived from multistate modelling are shown in the **Figure**.

**Conclusion:** Transient elastography is strongly associated with outcomes in two large cohorts of patients with ACLD. EHR data can be used to define clinical progression and outcomes in large patient cohorts and estimates of disease progression in EHR cohorts are comparable to landmark studies of patients diagnosed using liver biopsy. Identification of ACLD using TE is a rational basis for registry-based analyses to facilitate quality improvement and clinical trials in patients with liver disease.

Estimated outcomes for 55 year old male patient with transient elastography value of 20kPa and the indicated liver disease

## POSTER PRESENTATIONS

### PO-1064

#### Emergency room care is essential in improving outcomes of decompensated cirrhosis patients: A Canadian experience

Jesse Stach<sup>1</sup>, Edwin Enns<sup>2</sup>, Kelly Burak<sup>1</sup>, Mark G. Swain<sup>1</sup>, Stephen Congly<sup>1</sup>, Juan G. Abalde<sup>3</sup>, Carla Coffin<sup>1</sup>, Abdel-Aziz Shaheen<sup>1</sup>. <sup>1</sup>Cumming School of Medicine, University of Calgary, Gastroenterology and Hepatology Division, Department of Medicine, Calgary, Canada; <sup>2</sup>Alberta Health Services, Calgary, Canada; <sup>3</sup>University of Alberta, Edmonton, Canada  
Email: azshaheen@me.com

**Background and aims:** Growing evidence highlights the importance of improved outpatient care. However, few studies have evaluated the role of emergency department (ED) care provided to cirrhosis patients and its impact on clinical outcomes. Therefore, we evaluated the implementation of standardized cirrhosis care practices in the ED and its impact on decompensated cirrhosis patient outcomes for those presenting with gastrointestinal bleeding (GIB).

**Method:** We used the electronic medical record system implemented in the four acute care hospitals serving the Calgary Health Zone (CHZ; 1.4 million people), to identify decompensated cirrhosis patients with evidence of GIB who presented to the ED via reviewing ED triages notes between 2017 and 2019. We evaluated implementation of standardized care measures for patients with decompensated cirrhosis such as antibiotic utilization, time to start antibiotics, administration of octreotide, proving endoscopy within 12 hours, consulting gastroenterology service, and performing a follow-up upper endoscopy for patients with banded varices. We then undertook a medical chart review to validate our findings in patients admitted in the last year of the study. Descriptive analysis methods were used.

**Results:** We identified 819 ED presentations for cirrhosis patients presenting with GIB over our study period. Among those identified, 88% were started on appropriate broad-spectrum antibiotics within a median time of 5.1 hours (IQR: 3.2–7.1) from ED presentation. Only 66% were started on octreotide infusion (median time from ED presentation 3.3 hours [IQR: 1.5–4.2]). Only 70% of this cohort were evaluated by the gastroenterology service (median time from ED presentation to consultation of 4.2 hours [IQR: 3.0–5.3]). Urgent upper endoscopy within 12 hours of ED presentation was provided to 58% of our cohort. Of 185 patients who had esophageal variceal banding during hospitalization, only 81 (44%) patients had a follow-up upper endoscopy within 3 months. For our patient cohort, the median length of stay for decompensated cirrhosis patients with variceal bleeding was 7.5 days (IQ: 6.2–8.5), 30-day readmission rate was 20.3% (IQR: 17.7–22.1), and in-hospital mortality was 15.3% (IQR: 12.1–17.5). In our validation study, 74% (139/187) of patients had a history of esophageal, gastric varices, or portal hypertensive gastropathy on endoscopy, while 26% had other etiologies for GIB such as Mallory-Weiss tear, peptic ulcer disease, or unknown etiology.

**Conclusion:** In our cohort, we identified high rates of poor clinical outcomes among decompensated cirrhosis patients presenting to the ED with suspected variceal bleeding. Implementation of various standard of care measures in the ED was suboptimal. Improved integration of high-quality ED management of cirrhosis patient care is essential to lower readmission and in-hospital mortality rates.

### PO-1094

#### Timing of endoscopy for acute variceal bleeding in patients with cirrhosis (CHESS1905): a nationwide cohort study

<sup>38</sup>Department of Medicine and State Key Laboratory of Liver Research, The University of Hong Kong, Hong Kong, China  
Email: qixiaolong@vip.163.com

**Background and aims:** Endoscopy plays an important role in the management of acute variceal bleeding (AVB). This study aimed at determining the optimal timing of endoscopy for AVB in patients with cirrhosis.

**Method:** Cirrhotic patients with AVB who underwent endoscopy within 24 hours after admission were retrospectively enrolled between February 2013 and May 2020 across 34 university hospitals of 30 cities in China. Patients were divided into the urgent endoscopy group (<6 h) and the early endoscopy group (6–24 h). Outcomes included the incidence of 5-day rebleeding and in-hospital mortality after the endoscopy management. A 1:1 propensity score matching (PSM) analysis was performed.

**Results:** A total of 3,319 patients were enrolled in the urgent endoscopy group (n = 2,383) and the early endoscopy group (n = 936), respectively. The overall difference in the incidence of 5-day rebleeding between two groups was not statistically significant (p = 0.24), which remained unchanged after PSM analyses (p = 0.90)

(Figure). Among patients with Child-Pugh class B, the difference of the incidence of 5-day rebleeding was significant (before PSM, p = 0.02; after PSM, p = 0.03) (Figure). Additionally, the overall difference of in-hospital mortality between two groups was not significant after PSM analysis (1.93% vs. 1.18%, p = 0.26).

**Conclusion:** Timing of emergency endoscopy within 24 hours may not be associated with the incidence of rebleeding within 5 days and in-hospital mortality among cirrhotic patients with AVB. However, urgent endoscopy within 6 hours may not be recommended for Child-Pugh class B patients with cirrhosis.

**PO-1103**

**In-hospital mortality after surgery in patients with liver cirrhosis: A nationwide study of 1,662,887 patients**

Jeong-Ju Yoo<sup>1</sup>, Sang Gyune Kim<sup>1</sup>, Young Seok Kim<sup>1</sup>. <sup>1</sup>SoonChunHyang University School of Medicine, Internal Medicine, Bucheon, Korea, Rep. of South

Email: puby17@naver.com

**Background and aims:** Patients with liver cirrhosis have an increased risk of in-hospital mortality after surgery. However, large-scale

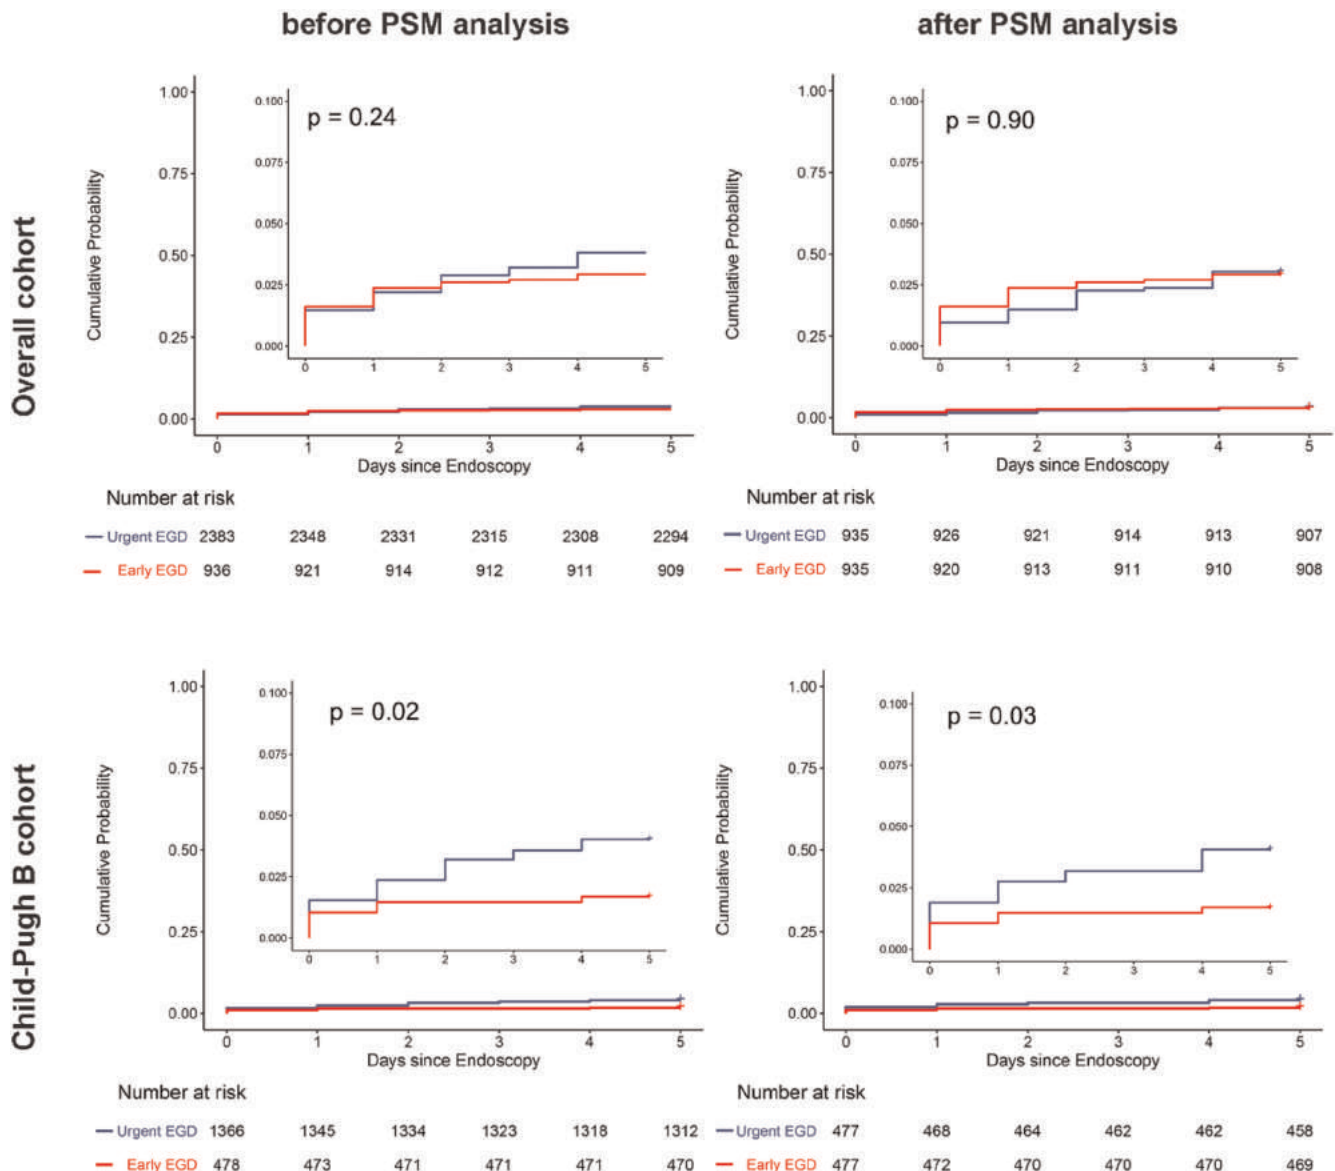

Figure: (abstract: PO-1094)

## POSTER PRESENTATIONS

studies on the prognosis of these patients after surgery are lacking. The aim of the study was to investigate the in-hospital mortality of patients with liver cirrhosis after surgery over five years.

**Method:** We used the Health Insurance Review and Assessment Service-National Inpatient Samples (HIRA-NIS) between 2012 and 2016. In-hospital mortality and hospital stay were analyzed using the data. Mortality rates according to the surgical department were also analyzed.

**Results:** Of the 1,662,887 patients who underwent surgery, 16,174 (1.0%) patients had cirrhosis. The in-hospital mortality was significantly higher in patients with cirrhosis than in those without cirrhosis (8.0% vs. 1.0%). Liver cirrhosis increased in-hospital mortality by about 5.3 times. In addition, the total hospitalization period and use of the intensive care unit were significantly higher in patients with liver cirrhosis. In the liver cirrhosis group, older age [odds ratio (OR) 1.03], male gender (OR 1.43), and low socioeconomic status (OR 1.34) were risk factors of in-hospital mortality. In-hospital mortality after surgery in patients with cirrhosis was the highest in patients who underwent otorhinolaryngology surgery (OR 2.21), followed by neurosurgery (OR 1.88), thoracic and cardiovascular surgery (OR 1.73), and plastic surgery (OR 1.37).

**Conclusion:** The in-hospital mortality of patients with cirrhosis is significantly high, despite advances in cirrhosis treatment. For precise surgical risk assessment of these patients, not only liver function, but also age, sex, and the type of surgery should be considered.

### PO-1146

#### Metamizole intake is associated with acute kidney injury and a higher mortality in patients with decompensated liver cirrhosis

Tammo Lambert Tergast<sup>1</sup>, Benjamin Schulte<sup>1</sup>, Marie Schultalbers<sup>1</sup>, Markus Cornberg<sup>1</sup>, Heiner Wedemeyer<sup>1</sup>, Dirk O. Stichtenoth<sup>2</sup>, Benjamin Maasoumy<sup>2</sup>. <sup>1</sup>Hanover, Department of Gastroenterology, Hepatology and Endocrinology, Hanover, Germany; <sup>2</sup>Hanover, Department of Clinical Pharmacology, Hanover, Germany  
Email: tergast.tammo@mh-hannover.de

**Background and aims:** Analgesia is a considerable challenge in patients with decompensated liver cirrhosis. Current guidelines advise against the use of non-steroidal anti-inflammatory drugs (NSAIDs) due to the nephrotoxic potential. Metamizole is not a typical NSAID and widely considered as a safe alternative treatment option. However, safety has not been systematically investigated for patients with decompensated cirrhosis so far. The aim of this study was to determine the impact of metamizole intake on the clinical course of these patients.

**Method:** Patients were recruited from the well-defined Hannover Ascites Cohort, including 667 patients with decompensated liver cirrhosis. Patients were carefully evaluated for metamizole intake. End points of this study were acute kidney injury (AKI) and death or liver transplantation (LTx) within 28 days. Kaplan-Meier curves were used to illustrate survival, p values were calculated with the log-rank test. To adjust for potential confounders like age, mean arterial pressure (MAP) <65 mmHg, leucocyte count, platelet count, sodium level and MELD score multivariate Cox-regression was performed.

**Results:** In total, 667 patients were included, 36% were female, mean age was 56 years, mean MELD score was 19. Metamizole was used by 22% of patients (n=145/667) at a mean daily dose of 2 g (0.45g–5.00 g). Patients in the metamizole group were younger (p=0.001), had higher CRP (p=0.008), a numerically lower MAP and higher sodium levels (p=0.068 and p=0.098). Leucocyte counts and MELD scores were comparable between both groups (p=0.416 and

Figure 2

Figure: (abstract: PO-1103)

p = 0.210, respectively). Throughout the observation period 52% of patients (n = 346/667) developed AKI, 72% among those with (n = 105/145) and 46% without (n = 241/522) metamizole intake. Moreover, metamizole intake at baseline was associated with an increased risk of AKI (p < 0.001; Figure 1) and with a lower 28-day LTx-free survival (p = 0.001). Multivariate analysis revealed an independent association of metamizole intake with AKI after adjusting for several potential confounders (HR: 1.95, p < 0.001). Of note, metamizole intake was also independently associated with a higher risk of death or LTx (HR: 2.15, p = 0.001).

Figure 1: 28-day incidence of AKI

**Conclusion:** Metamizole intake is independently associated with AKI and mortality in patients with decompensated liver cirrhosis. Thus, metamizole should be used with caution in these patients.

**PO-1151**

**Stratifying the risk of variceal bleeding by non-invasive tools in patients with compensated advanced chronic liver disease: A decision curve analysis**

Sanchit Sharma<sup>1</sup>, Samagra Agarwal<sup>1</sup>, Ankur Jindal<sup>2</sup>, Deepak Gunjan<sup>1</sup>, Kanav Kaushal<sup>1</sup>, Srikant Mohta<sup>1</sup>, Sushrut Singh<sup>2</sup>, Rakesh Kumar Jagdish<sup>2</sup>, Shiv Kumar Sarin<sup>2</sup>, Anoop Saraya<sup>1</sup>. <sup>1</sup>AIIMS Hospital, Gastroenterology and Human Nutrition Unit, New Delhi, India; <sup>2</sup>Institute of Liver and Biliary Sciences, Hepatology, New Delhi, India  
Email: ansaraya@yahoo.com

**Background and aims:** Non-invasive tools (NITs) reliably categorise patients with compensated advanced chronic liver disease (cACLD) into high and low risk group for harbouring varices needing treatment (VNTs). We aimed to assess the performance of this NITs based stratification at baseline to identify similar risk groups for variceal bleeding (VB) events on follow-up.

**Method:** In this retrospective multicentre analysis, patients with cACLD categorised at baseline into different risk groups by NITs (Baveno-VI, expanded Baveno-VI, platelet-albumin, platelet-MELD and ANTICIPATE study platelet criteria) and by endoscopy (high risk vs low risk/no varices) were assessed for VB events in different risk strata on follow-up. Decision Curve Analysis was used to estimate benefit of classifying patients using NITs over endoscopic classification for predicting VB. Decision thresholds for initiating prophylaxis

Figure: (abstract PO-1151): Decision curve plots demonstrating net benefit of basing the decision for prophylaxis for variceal bleeding using different NITs for cACLD across range of threshold probabilities against default strategies of giving prophylaxis based on endoscopic stratification (pink), for all (red) and no (brown)

## POSTER PRESENTATIONS

were defined and number of additional patients needed to treat (NNT) for every additional VB identified by NITs over endoscopy was estimated.

**Results:** 1284 patients (mean age: 44.7 ± 13.5 years, 72.4% males) of hepatitis B (29.2%), non-alcoholic fatty liver disease (24.9%), hepatitis C (20.1%) and alcohol (17.5%) related cACLD were included with 323 (25.2%) patients having high risk varices on endoscopy at baseline. 98 (7.6%) patients developed VB over 20 (9–35) months of follow-up. The 1-year and 3-year rate of VB with all NITs was 5.7–7.4% and 13.2–16.4% among high-risk and 0–2.3% and 0–5% among low-risk subgroups respectively ( $p < 0.001$ , among different risk groups). At thresholds of  $< 3\%$  event rate of VB, Baveno-VI (NNT: 176), Anticipate criteria (NNT-233) and platelet-albumin criteria (NNT-376) were superior to endoscopy while endoscopic classification was superior to NITs above this threshold for deciding the need for prophylaxis.

Table1: Rates of incident variceal bleeding on follow-up in high risk and low risk subgroups of endoscopy and NITs based stratification at baseline

NITs	N (%)	3-year bleeding rate n (%)	p value
Baveno-VI			$< 0.001$
• Low-risk	266 (20.7)	0	
• High-risk	1018 (79.3)	13.2 (10.5–15.8)	
Platelet-albumin criteria			$< 0.001$
• Low-risk	424 (34%)	3.1 (0.9–5.3)	$< 0.001$
• High-risk	860 (67%)	14.6 (11.5–17.6)	
ANTICIPATE (platelet criteria)			$< 0.001$
• Low-risk	378 (29.4%)	1.2 (0–2.5)	
• High-risk	906 (70.6%)	14.4 (11.4–17.2)	
Endoscopic classification			$< 0.001$
• Low-risk/No varices	961 (74.8%)	3.7 (1.9–5.5)	
• High-risk	323 (25.2%)	30 (23.6–35.9)	

**Conclusion:** Use of NITs at baseline can stratify risk of variceal bleeding with good accuracy comparable to endoscopic stratification.

### PO-1152

#### Risk stratification based on liver stiffness and platelets for decompensation events in patients with compensated cirrhosis

Ning Kang<sup>1</sup>, Ruiling He<sup>2</sup>, Lili Zhao<sup>3</sup>, Zhongfang Yan<sup>4</sup>, Jing Gao<sup>3</sup>, Min Gao<sup>3</sup>, Li Zhou<sup>3</sup>, Ying Ma<sup>3</sup>, Chun Yan Wang<sup>3</sup>, Yifei Huang<sup>1</sup>, Xiaoguo Li<sup>1</sup>, Haijun Zhang<sup>1</sup>, Dan Xu<sup>1</sup>, Mingkai Liang<sup>1</sup>, Fengmei Wang<sup>3</sup>, Xiaolong Qi<sup>1</sup>, Jia Li<sup>3</sup>. <sup>1</sup>CHES Center, Institute of Portal Hypertension, The First Hospital of Lanzhou University, Lanzhou, China; <sup>2</sup>Department of Ultrasound, Donggang Branch the First Hospital of Lanzhou University, Lanzhou, China; <sup>3</sup>CHES center, Department of Gastroenterology and Hepatology, Tianjin Second People's Hospital, Tianjin, China; <sup>4</sup>Department of Nutriology, Tianjin Second People's Hospital, Tianjin, China

Email: qixiaolong@vip.163.com

**Background and aims:** Liver stiffness measurement (LSM) by transient elastography (TE) has been proved a good diagnostic performance for clinically significant portal hypertension (CSPH). LSM  $\geq 25$  kPa was chosen as the optimal cut-off for ruling in CSPH, and LSM  $\leq 15$  kPa and platelets (PLT)  $\geq 150, 19L$  can be used to rule out CSPH. Our study aimed to do the risk stratification of decompensation events using LSM and PLT in patients with compensated cirrhosis.

**Method:** Patients with LSM and PLT were enrolled between December 1, 2015, and December 31, 2017, and then followed up for at least two years or until they experienced decompensation events (defined as ascites, upper gastrointestinal bleeding, and hepatic encephalopathy) or death. With LSM and PLT, patients were categorized as three groups: high risk group (LSM  $\geq 25$  kPa), low risk group (LSM  $\leq 15$  kPa and PLT  $\geq 150, 19L$ ), and medium risk group (others).

Figure: (abstract: PO-1152)

**Results:** A total of 360 patients with compensated cirrhosis were included in the analysis. Of them, 246 patients (68.33%) had chronic hepatitis B. The median follow-up time was 35.7 months. During the follow-up, 34 patients (9.44%) had decompensated events (including 27 cases of ascites, 5 cases of upper gastrointestinal bleeding and 2 case of hepatic encephalopathy) and 1 died. The results of univariate COX regression analysis showed that LSM combined with PLT have statistical significance in predicting the occurrence of decompensation events or death in patients with compensated cirrhosis. As the risk of group increased, the rate of decompensation events or death also increased ( $p < 0.001$ , hazard ratio = 3.828 [2.115–6.93]). Kaplan-Meier analysis showed that the higher risk of the group, the higher rate of decompensation events or death ( $p < 0.001$ ). There was a trend of higher rate of decompensation events or death in the high risk group compared to that of low risk and medium risk groups ( $p < 0.001$ ). In addition, compared with the low risk group, the medium risk group had a higher rate of decompensation events or death ( $p = 0.038$ ) (Figure).

**Conclusion:** Risk stratification using LSM and PLT are with a satisfied predictive value for decompensation events or death in patients with compensated cirrhosis.

**PO-1230**

**FIB-4 improves LSM-based prediction of clinical decompensation in overweight or obese patients with compensated advanced chronic liver disease**

Yuly Paulin Mendoza<sup>1</sup>, Mohamed Shengir<sup>2</sup>, Jaime Bosch<sup>1</sup>, Giada Sebastiani<sup>3</sup>, Annalisa Berzigotti<sup>1</sup>. <sup>1</sup>Inselspital, University Hospital of Bern, University Clinic for Visceral Surgery and Medicine, Bern, Switzerland; <sup>2</sup>McGill University, Division of Experimental Medicine, Department of Medicine, Montreal, Canada; <sup>3</sup>McGill University, Division of Gastroenterology and Hepatology, Canada  
Email: annalisa.berzigotti@insel.ch

**Background and aims:** Liver stiffness measurement (LSM) has an independent prognostic value in overweight/obese patients with compensated advanced chronic liver disease (cACLD). Whether the FIB-4 score predicts the first clinical complication and whether its use can improve the prognostic accuracy of LSM has not been well studied in this population.

**Method:** We analyzed the data of 233 overweight/obesity patients (55% with non-alcoholic steatohepatitis) with cACLD identified by LSM (LSM  $\geq 10$  kPa measured by XL probe), recruited from two academic centers and followed-up for a median of 17 months. We assessed the performance of FIB-4 and LSM for clinical complications using the area under the receiver operating characteristics (AUROC) and according to a pre-defined LSM cut-off (21 kPa) and to the optimized FIB-4 cut-off.

**Results:** Fourteen patients (6%) developed clinical complications during follow-up. FIB-4 score and LSM showed a good discriminative performance for clinical complications: AUROC FIB-4: 0.850 (95% confidence interval [CI] 0.766–0.933;  $p < 0.001$ ); LSM: 0.767 (95% CI 0.652–0.883;  $p = 0.001$ ; comparison:  $p = 0.187$ ). A FIB-4  $> 2.67$  had a sensitivity  $> 90\%$  for clinical complications. Accordingly, patients could be classified non-invasively in 4 different risk categories: LSM  $> 21$  kPa + FIB4  $> 2.67$ : high-risk, LSM  $< 21$  kPa + FIB-4  $> 2.67$ : intermediate-risk, LSM  $> 21$  kPa + FIB4  $\leq 2.67$ : intermediate-low Risk and LSM  $< 21$  kPa + FIB-4  $\leq 2.67$ : low risk; actuarial rates of remaining free of any complication were 25%, 73%, 96% and 100%, respectively (Log Rank  $p < 0.001$ ) (Figure).

**Conclusion:** FIB-4 score helps refining the risk of developing clinical complications in overweight/obese patients diagnosed of cACLD based on LSM. Patients with FIB-4  $\leq 2.67$  have an overall low risk of developing complications. Our data support the sequential use of LSM and FIB-4 score in this population.

**PO-1236**

**Beta-blockers to prevent decompensation of cirrhosis: an emulation of the PREDESCI trial**

Elliot Tapper<sup>1</sup>, Zhe Zhao<sup>1</sup>, James Henderson<sup>1</sup>. <sup>1</sup>University of Michigan Hospital, Ann Arbor, United States  
Email: etapper@med.umich.edu

**Background and aims:** The landmark PREDESCI trial showed that non-selective beta-blockers (NSBB) can prevent decompensation or death in patients with cirrhosis and portal hypertension but no conventional indications for NSBB. However, cirrhosis is plagued by a chasm between on-trial therapeutic efficacy and effectiveness, whereby positive trial results are sharply attenuated in real-world patients and adverse events are far more common than expected.

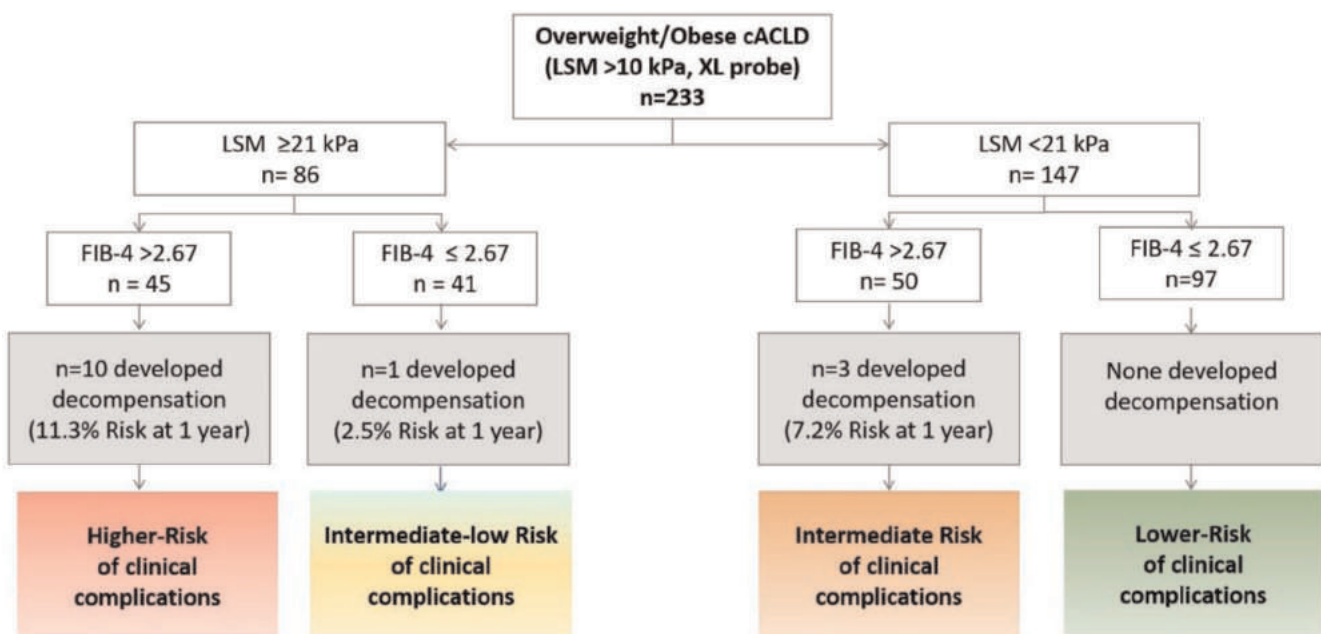

Figure: (abstract: PO-1230)

## POSTER PRESENTATIONS

**Method:** We emulated the PREDESCI trial using observational data, recapitulating trial features by matching the inclusion/exclusion criteria, outcomes, and analytic approach to an analysis of US Medicare data. The primary outcome was time to variceal bleeding, ascites requiring paracentesis, and grade 3–4 hepatic encephalopathy (HE). We evaluated carvedilol, other NSBB (propranolol or nadolol), and, as a negative control, selective beta-blockers (SBB; metoprolol, atenolol, bisoprolol). We used a new-user, landmark design where allocation to treatment arm was defined by the first prescription within 90-days of cirrhosis diagnosis. All patients had  $\geq 1$  year of follow-up prior to cirrhosis diagnosis. Patients were matched 1:1 to balance baseline covariates using inverse-probability weighting.

**Results:** After applying PREDESCI inclusion/exclusion criteria we found 187 patients prescribed carvedilol, 713 prescribed other NSBB, 918 prescribed SBB, and 18, 735 without BB prescriptions within 90-days of the index/diagnosis date. After matching there were no clinical or sociodemographic differences between treatment groups. Comorbidities were common (e.g. diabetes 17%, CHF 39%, COPD 46%) Carvedilol recipients were aged  $74.1 \pm 15.5$  compared to  $75.8 \pm 1.41$  among controls. Alcohol was the etiology for 31.6% vs 29.4%, NAFLD in 49.2% vs 49.2%. For carvedilol compared to control, there were no differences in the rate of incident HE (10.2% vs 8.2%), variceal bleeding (2.1% vs 4.8%), ascites (21% vs 17.6%), and mortality (21.4% vs 18.2%). Time-to-event and competing risk analysis was no different. Comparing other NSBB to control, there was a higher rate of HE, bleeding, ascites and mortality. There was no difference in outcomes for patients receiving SBB compared to control.

Figure:

**Conclusion:** PREDESCI trial data has the potential to revolutionize cirrhosis care. However, our data shows that careful patient selection is required. In our real-world trial emulation among older patients with comorbidities, NSBB do not prevent decompensation.

### PO-1249

#### Safety of direct oral anticoagulants (DOACs) in patients with advanced liver disease

Georg Semmler<sup>1,2</sup>, Katharina Pomej<sup>1,2</sup>, David J.M. Bauer<sup>1,2</sup>, Lorenz Balcar<sup>1,2</sup>, Benedikt Simbrunner<sup>1,2,3</sup>, Teresa Binter<sup>1,2</sup>, Lukas Hartl<sup>1,2</sup>, Jeanette Becker<sup>1</sup>, Matthias Pinter<sup>1,2</sup>, Prof. Peter Quehenberger, MD<sup>4</sup>, Michael Trauner<sup>1</sup>, Mattias Mandorfer<sup>1,2</sup>, Ton Lisman<sup>5</sup>, Thomas Reiberger<sup>1,2,3</sup>, Bernhard Scheiner<sup>1,2</sup>. <sup>1</sup>Medical University of Vienna, Department of Internal Medicine III, Division of Gastroenterology and Hepatology, Vienna, Austria; <sup>2</sup>Medical University of Vienna, Vienna Hepatic Hemodynamic Lab, Vienna, Austria; <sup>3</sup>Medical University of Vienna, Christian Doppler Laboratory for Portal Hypertension and Liver Fibrosis, Vienna, Austria; <sup>4</sup>Medical University of Vienna, Department of Laboratory Medicine, Vienna, Austria; <sup>5</sup>University of Groningen, Surgical Research Laboratory and Section of Hepatobiliary Surgery and Liver Transplantation, Department of Surgery, Groningen, Netherlands  
Email: thomas.reiberger@meduniwien.ac.at

**Background and aims:** While direct oral anticoagulants (DOACs) are increasingly used in patients with liver disease, safety data especially in advanced liver disease are limited. Therefore, the aim of this study was to evaluate (i) the safety of DOAC treatment in patients with advanced liver disease in general, (ii) the safety of DOAC treatment in liver patients undergoing procedures and (iii) to compare calibrated anti-Xa-assay levels and thrombomodulin-modified thrombin generation assays (TM-TGAs) between patients with different degrees of liver dysfunction.

**Method:** Liver disease patients receiving DOAC treatment between 01/2010–09/2020 were retrospectively included. Invasive procedures and bleeding events were recorded. Calibrated anti-Xa peak levels and TM-TGAs were measured in a subgroup.

**Results:** Among 86 patients, 43 patients (50.0%) had a history of hepatic decompensation while 76 patients (88.4%) had evidence for clinically significant portal hypertension. 44 patients (51.2%) had advanced liver dysfunction (Child-B/C) and 23 patients (26.7%) had hepatocellular carcinoma (HCC). 53 (61.6%) patients received edoxaban, 17 (19.8%) apixaban, 10 (11.6%) rivaroxaban, 2 dabigatran (2.3%) and 4 (4.6%) were sequentially treated with two drugs.

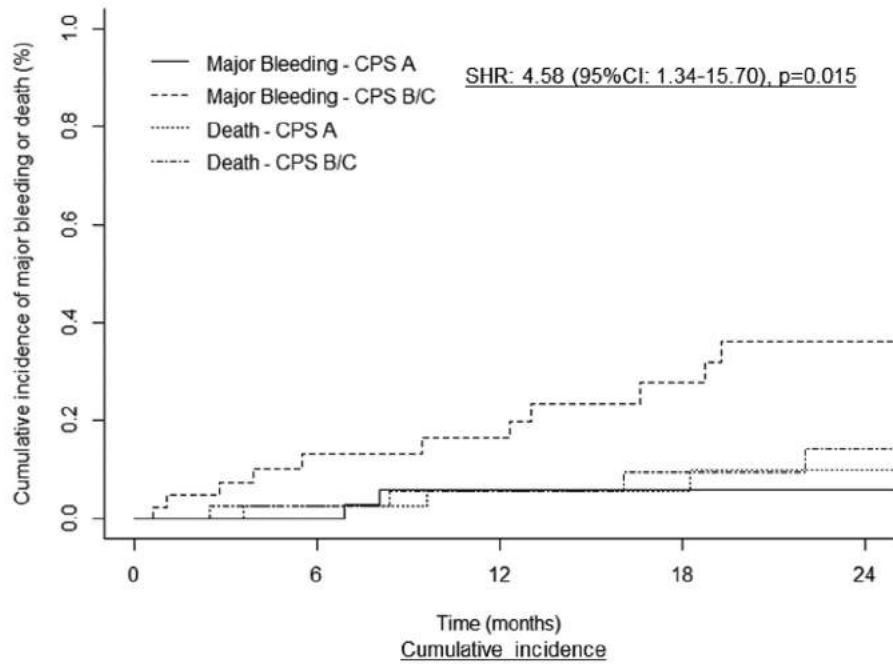

During DOAC treatment, 178 procedures (n=58 variceal band ligations; n=86 abdominal paracenteses) were performed in 42 patients and procedure-related bleedings occurred in 6 patients (3.4%). Additionally, 25 patients (29.1%) experienced spontaneous (11 minor, 14 major) bleedings. Bleedings at 6 months were more common in Child-B/C (24.6% vs. Child-A: 5.0%, subdistribution hazard ratio [SHR]: 3.97 [95%CI: 1.62–9.70], p=0.003) and HCC patients (37.0% vs. 6.8%, SHR: 2.96 [95%CI: 1.33–6.58], p=0.008). Similar results were obtained for major bleedings (Figure).

Spontaneous bleeding during DOAC treatment was associated with a worse survival (after 12 months: 76.2% with bleeding vs. 96.4% without bleeding; p=0.005). Child-Score (adjusted SHR: 1.41 [95%CI: 1.16–1.72], p<0.001) and HCC (aSHR: 3.12 [95%CI: 1.44–6.73], p=0.004) were independently associated with bleeding during DOAC treatment.

Calibrated edoxaban anti-Xa peak levels (n=35) were higher in patients with Child-B/C (345 [95%CI: 169–395] vs. Child-A: 137 [95%CI: 65–224] ng/ml, p=0.042), and were associated with lower endogenous thrombin potential (ETP) in TM-TGA (n=28; anti-Xa  $\geq 100$  ng/ml: ETP: 83 [95%CI: 34–605] vs. <100 ng/ml: ETP: 466 [95%CI: 281–941] nM, p=0.051).

**Conclusion:** DOACs should be used with caution in patients with decompensated liver disease as well as patients with advanced HCC due to a significant rate of spontaneous bleeding events.

**A**

		0	6	12	18	24
Major Bleeding – CPS A:	0%	5.7%	5.7%	5.7%	5.7%	5.7%

## POSTER PRESENTATIONS

PO-1278

### Does continuing anticoagulation increase the risk of bleeding during variceal band ligation in patients with portal hypertension? A meta-analysis and systematic review

Cheng Han Ng<sup>1</sup>, Darren Tan<sup>1</sup>, Jieling Xiao<sup>1</sup>, Mark Muthiah<sup>1,2</sup>. <sup>1</sup>Yong Loo Lin School of Medicine, National University of Singapore, Singapore, Singapore; <sup>2</sup>National University Hospital, Division of Gastroenterology and Hepatology, Department of Medicine, Singapore, Singapore  
Email: mark\_muthiah@nuhs.edu.sg

**Background and aims:** Anticoagulation use is often indicated in patients with portal hypertension, especially in cirrhotic patients, because of the elevated risk of developing portal vein thrombosis. However, the management of anticoagulation therapy in patients requiring variceal band ligation (VBL) for primary or secondary prevention of variceal bleeding remains unclear due to concerns regarding perioperative haemorrhagic complications and a paucity of data. Therefore, this meta-analysis and systematic review aims to evaluate the effects of continuing anticoagulation on the outcomes of VBL.

**Method:** Medline and Embase databases were screened for articles related to anticoagulant usage during VBL. A comparative meta-analysis was undertaken to compare outcomes associated with continuing versus stopping anticoagulation. Dichotomous outcomes were compared using odds ratio (OR) with the Mantel-Haenszel method, while continuous outcomes were evaluated using weighted mean difference (WMD). All analysis was conducted with random effects models.

**Results:** A total 361 patients were included for analysis, with 138 patients continuing anticoagulation during VBL. Continuation of anticoagulation was not associated with significantly increased risk of bleeding (OR: 0.84, 95%CI: 0.27–2.66,  $p=0.77$ ) or postoperative mortality (OR: 1.16, 95%CI: 0.21–6.47,  $p=0.87$ ) compared to patients that halted anticoagulation prior to banding sessions. There was also no significant difference in the rate of variceal recurrence or successful eradication of varices between the two groups. Additionally, the number of VBL sessions required for variceal eradication (WMD:  $-0.02$ , 95%CI:  $-0.59$  to  $-0.54$ ,  $p=0.93$ ) and number of bands used per session (WMD:  $0.16$ , 95%CI:  $-0.27$  to  $0.60$ ,  $p=0.46$ ) did not differ.

**Conclusion:** Results suggest that continuing anticoagulation during VBL is not associated with increased risk of adverse events, and similar rates of variceal eradication in patients with portal hypertension. Further studies are required to support these findings and confirm the safety profile of continuing anticoagulation continuation through VBL.

PO-1316

### Factor VIII/protein C ratio independently predicts liver-related events but does not reflect the hypercoagulable state in patients with advanced chronic liver disease

Lorenz Balcar<sup>1,2</sup>, Bernhard Scheiner<sup>1,2</sup>, Rosa Johanna Nußbaumer<sup>1</sup>, Johanna Weinzierl<sup>1</sup>, Rafael Paternostro<sup>1</sup>, Benedikt Simbrunner<sup>1,2</sup>, Lukas Hartl<sup>1,2</sup>, Mathias Jachs<sup>1,2</sup>, David J.M. Bauer<sup>1,2</sup>, Albert Stättermayer<sup>1,2</sup>, Georg Semmler<sup>1,2</sup>, Matthias Pinter<sup>1</sup>, Prof. Peter Quehenberger, MD<sup>3</sup>, Michael Trauner<sup>1,2</sup>, Thomas Reiberger<sup>1,2</sup>, Ton Lisman<sup>4</sup>, Mattias Mandorfer<sup>1,2</sup>. <sup>1</sup>Medical University of Vienna, Department of Internal Medicine III, Division of Gastroenterology and Hepatology, Vienna, Austria; <sup>2</sup>Medical University of Vienna, Vienna Hepatic Hemodynamic Laboratory, Vienna, Austria; <sup>3</sup>Medical University of Vienna, Department of Laboratory Medicine, Vienna, Austria; <sup>4</sup>University of Groningen, Surgical Research Laboratory and Section of Hepatobiliary Surgery and Liver Transplantation, Department of Surgery, Groningen, Netherlands  
Email: mattias.mandorfer@meduniwien.ac.at

**Background and aims:** Thrombomodulin-modified thrombin generation assay (TM-TGA) results indicate a hypercoagulable state in patients with advanced chronic liver disease (ACLD) which may

contribute to disease progression. The ratio of procoagulant factor VIII and anticoagulant protein C (FVIII/PC) has been suggested as a simple marker that reflects the extent of hypercoagulability. Moreover, it predicted decompensation/death in a small study not accounting for HVPG.

We investigated (i) the prognostic value of FVIII/PC in a large cohort of ACLD patients and (ii) whether FVIII/PC reflects the hypercoagulable state (as assessed by TM-TGA).

**Method:** Patients undergoing HVPG-measurement at the Vienna Hepatic Hemodynamic Lab with evidence of ACLD and information on FVIII/PC were considered. Clinical stages (CS) were defined as follows: Probable compensated ACLD (cACLD): LSM  $\geq 10$  kPa and HVPG  $< 6$  mmHg/0: cACLD and 6–9 mmHg/1: cACLD and HVPG  $\geq 10$  mmHg/2: bleeding/3: non-bleeding decompensation/4:  $\geq 2$  decompensations.

TM-TGA were assessed in a similar cohort of patients ( $n = 152$ ) from the prospective Vienna Cirrhosis Study (VICIS).

**Results:** (i) 518 patients were included in the prognostic sub-study; CS: probable cACLD: 36 (7%)/0:61 (12%)/1:154 (30%)/2:23 (4%)/3:130 (25%)/4:114 (22%), mean HVPG was  $16 \pm 7$  mmHg, and mean MELD  $13 \pm 5$ . FVIII/PC significantly increased across CS (probable cACLD: 2.1 [IQR: 1.5–2.8]/0:2.4 [1.9–3.5]/1:3.2 [2.6–4.7]/2:3.1 [2.7–3.8]/3:4.0 [3.1–5.8]/4:4.1 [3.2–6.3],  $p < 0.001$ ) as well as HVPG ( $p < 0.001$ ) and MELD ( $p < 0.001$ ) strata. Additionally, FVIII/PC was predictive of outcomes (Figure) and independently associated with decompensation/liver-related mortality (e.g., aHR: 1.06 (95%CI: 1.02–1.12),  $p = 0.009$ ), even after adjusting for, e.g., CS, HVPG, hepatic dysfunction, and inflammation.

(ii) Although FVIII/PC showed a weak positive correlation with endogenous thrombin potential in TM-TGA (Spearman's  $\rho = 0.265$ ,  $p = 0.001$ ), this association completely disappeared after adjusting for severity of underlying liver disease.

Figure. Probability of remaining free of decompensation or liver-related death according to FVIII/PC quartiles.

Figure:

**Discussion:** FVIII/PC is correlated with CS, HVPG, and liver dysfunction in ACLD. Even after extensive adjustment for potential confounding factors, it remained a robust prognostic indicator of liver-related events. Importantly, this should not be mistaken as evidence for the concept of procoagulant imbalance as a driver of disease progression, as the correlation between FVIII/PC and thrombin generation is confounded by liver disease severity, and thus, FVIII/PC does not reflect the haemostatic balance.

**PO-1474**

**A new strategy to screen varices needing treatment via risk ranked from 0 to 100% by VARS and VANT tests**

Paul Cales<sup>1</sup>, Federico Ravaioli<sup>2</sup>, Arthur Berger<sup>3</sup>, Oana Nicoara-Farcu<sup>4</sup>, Davide Festi<sup>2</sup>, Horia Stefanescu<sup>4</sup>, Isabelle Cornu<sup>5</sup>, Pierre Nahon<sup>6</sup>, Christophe Bureau<sup>7</sup>, Nathalie Ganne-Carrié<sup>6</sup>, Annalisa Berzigotti<sup>8</sup>, Victor de Lédinghen<sup>3</sup>, Salvatore Petta<sup>9</sup>. <sup>1</sup>Angers University; <sup>2</sup>Bologna University; <sup>3</sup>Bordeaux University Hospital; <sup>4</sup>Regional Institute of Gastroenterology and Hepatology, Cluj-Napoca; <sup>5</sup>Angers University Hospital; <sup>6</sup>Paris Seine-Saint-Denis University Hospitals; <sup>7</sup>Toulouse University Hospital; <sup>8</sup>University of Bern; <sup>9</sup>University of Palermo  
Email: paul.cales@univ-angers.fr

**Background and aims:** The deficit in the screening of varices needing treatment (VNT) significantly impacts mortality in cirrhosis. So, improving this screening should improve the effectiveness of primary prevention of variceal bleeding. Therefore, we evaluated VNT risk factors in a population unrestricted for liver severity to improve the non-invasive screening of VNT.

**Method:** 2290 patients with chronic liver disease were included in a retro-prospective multicenter study. Their characteristics were: age: 59 ± 11 years; male sex: 63.5%; etiologies: virus: 50.0%, NAFLD: 29.5%, alcohol: 20.5%; BMI: 28.4 ± 5.8 kg/m<sup>2</sup>; MELD score: 9.5 ± 3.0; VNT prevalence: 14.9%. The main test descriptors were performance (spared endoscopy rate) and safety (missed VNT rate). VNT tests were evaluated either for patient diagnosis, with safety based on 95% negative predictive value, or population screening with safety based on 95% sensitivity.

**Results:** Independent VNT predictors were etiology, sex, platelets, prothrombin index, liver stiffness, albumin, ALT, and age or BMI through interactions. Most risk factors were then included in two new tests. First, the VANT test, designed for population screening, provided three patient categories: 1. missed VNT <5%, 2. VNT risk = 100% (new category), both resulting in spared endoscopy; 3. intermediate VNT risk: endoscopy is required. VANT outperformed (40.2%, p < 0.001) other safe tests: Baveno VI criteria (24.1%), Anticipate (24.7%), VariScreen (35.3%). VANT was secured with no missed VNT in MELD score >10. Second, the VARS score, used as score to predict VNT risk, was more discriminant for VNT (AUROC: 0.826) than published scores, e.g. Anticipate (0.771, p < 0.001). Sensitivity and specificity for VNT of VARS score reached 100%. For patient diagnosis, VARS was also used as a test to spare endoscopy by using a cut-off for 95% negative predictive value. The performance of VARS test was 62.0% vs 42.9% for the extended Baveno VI criteria (p < 0.001), also constructed for patient diagnosis, and up to 73% in NAFLD. With a 100% safety, the performance of VARS test was 12% (Figure).

Different clinical uses of tests as a function of safety criteria

Figure:

**Conclusion:** VANT and VARS tests rule in or out VNT to spare endoscopies from 40% (population screening) to 62% (individual diagnosis) in main etiologies of chronic liver disease irrespective of liver severity. In addition, VARS score quantifies VNT risk from 0 to 100%. This precise prediction might improve poor compliance to VNT screening.

**PO-1613**

**Clinical significance of substantially elevated von Willebrand factor antigen levels in patients with advanced chronic liver disease**

Email: mattias.mandorfer@meduniwien.ac.at

**Background and aims:** VWF is increasingly used as a non-invasive marker for clinically significant portal hypertension (HVPG ≥ 10 mmHg) and also confers HVPG-independent prognostic information. While quantification of increased VWF levels is not relevant in the context of von Willebrand disease (i.e., the main indication for VWF testing), highly elevated VWF may be of clinical significance in ACLD. Thus, we have modified our analytical approach to quantify very high VWF levels (i.e., >420%) and investigated their prognostic value.

**Method:** Patients undergoing HVPG-measurement at the Vienna Hepatic Hemodynamic Lab with evidence of ACLD and information on VWF were considered. Clinical stages (CS) were defined as follows: Probable compensated ACLD (cACLD): LSM ≥ 10 kPa and HVPG < 6 mmHg; 0: cACLD and 6–9 mmHg; 1: cACLD and HVPG ≥ 10 mmHg; 2: bleeding; 3: non-bleeding decompensation; 4: ≥2 decompensations.

VWF was measured by an immuno-turbidimetric assay (STA LIATEST VWF:Ag) on a STA-R Evolution (both DIAGNOSTICA STAGO S.A.S., Asnières sur Seine, France) analyzer. In order to quantify values >420%, the respective samples were prediluted 1:20 with Owren-Koller buffer.

**Results:** 125 (16%) of 779 included patients had VWF > 420%. The proportion of VWF > 420% increased with disease severity (probable cACLD-0:5 (4%) vs. 1:22 (10%) vs. 2–4:98 (23%), p ≤ 0.001) as well as across HVPG (Figure) and MELD (<10:17 (6%) vs. 10–14:27 (10%) vs. ≥15:80 (35%), p ≤ 0.001) strata. Moreover, patients with VWF > 420% showed higher levels of CRP (0.9 (IQR: 0.4–1.5) vs. 0.2 (0.1–0.6) mg/dL, p ≤ 0.001) as a marker of systemic inflammation.

Figure:

## POSTER PRESENTATIONS

Median VWF was 532% (IQR: 462–611) in the subgroup of patients with >420% and VWF was unrelated to HVPG (Spearman's  $\rho = 0.140$ ,  $p = 0.119$ ), but showed direct correlations of weak/moderate strength with MELD ( $\rho = 0.337$ ,  $p < 0.001$ ) and CRP ( $\rho = 0.291$ ,  $p = 0.001$ ). Among patients with VWF >420%, VWF was predictive of decompensation/liver-related mortality in univariate analysis (per 10%; HR: 1.02 (95%CI: 1.00–1.04),  $p = 0.025$ ), however, this association did not attain statistical significance after adjusting for MELD.

**Conclusion:** The proportion of patients with substantially elevated VWF values (i.e., >420%) steadily increases with disease progression and is particularly high in patients who have profound portal hypertension. While VWF is not reflective of HVPG in these patients, it is correlated with hepatic dysfunction and systemic inflammation. Although the quantification of these high values provides prognostic information (i.e., there was no evidence of a ceiling effect), the lack of an association with clinical outcomes in MELD-adjusted analysis questions their relevance.

### PO-1705

#### Application of a machine learning model to improve performance of endoscopic classification for prediction bleeding in patients with compensated cirrhosis with esophageal varices

Samagra Agarwal<sup>1</sup>, Sanchit Sharma<sup>1</sup>, Manoj Kumar<sup>2</sup>, Shantan Venishetty<sup>2</sup>, Ankit Bhardwaj<sup>2</sup>, Kanav Kaushal<sup>1</sup>, Srikanth Gopi<sup>1</sup>, Srikant Mohta<sup>1</sup>, Deepak Gunjan<sup>1</sup>, Shiv Kumar Sarin<sup>2</sup>, Anoop Saraya<sup>1</sup>. <sup>1</sup>AIIMS Hospital, Gastroenterology and Human Nutrition Unit, New Delhi, India; <sup>2</sup>Institute of Liver and Biliary Sciences, Hepatology, New Delhi, India  
Email: ansaraya@yahoo.com

**Background and aims:** Current endoscopic classification does not stratify and predicts variceal bleeding (VB) in all patients with compensated cirrhosis with esophageal varices (EVs). We aimed to supplement it with a novel machine learning (ML) model for prediction of VB

**Method:** In a retrospective analysis, data from patients of compensated cirrhosis with EVs, laboratory investigations and liver stiffness measurement (LSM) was used to generate an Extreme-gradient boosting (XGBoost) algorithm to predict the risk of VB. The performance characteristics of combination of ML and endoscopic classification were compared with the endoscopic classification alone and was assessed in internal and external validation cohorts

**Results:** Eight hundred and twenty eight patients of compensated cirrhosis with EVs, predominantly related to non-alcoholic fatty liver disease (28.6%), alcohol (23.7%) and hepatitis B (23.1%) were included, with 455 (55%) having the high-risk varices. Over a follow-up of 24 (12–43) months, 163 patients developed VB. Machine learning (ML) model had good performance characteristics to predict VB events with 85–99% accuracy in derivation (n = 497), internal validation (n = 149) and external validation (n = 182) cohorts. In combination with EGD based stratification, the model identified a “true high-risk” group with 1-year and 3-year bleed rates of 31–43% and 64–85%, respectively and a “true low-risk” group with 1-year and 3-year bleed rates of 0–1.6% and 0–3.4%. SHapley Additive exPlanations analysis showed endoscopic classification and LSM to be the major determinants of performance of the model.

Table: Comparison of performance characteristics of machine learning model applied to derivation and validation cohorts, and endoscopic classification applied to whole cohort

	Endoscopic classification alone (n = 828)	Machine Learning Model (XGboost)		
		Derivation Cohort (n = 497)	Internal Validation cohort (n = 149)	External Validation Cohort (n = 182)
Accuracy	0.589	0.987	0.939	0.857
95% CI	(0.555–0.623)	(0.974–0.995)	(0.888–0.972)	(0.821–0.905)
No	0.803	0.789	0.839	0.813
Information Rate (NIR)				
P value	1.0	<0.001	<0.001	0.043
[Accuracy >NIR]				
Kappa	0.225	0.963	0.736	0.441
Sensitivity	85.2%	94.3%	62.5%	41.2%
Specificity	52.4%	100.0%	100%	95.9%
Positive Predictive Value	30.5%	100.0%	100%	70.0%
Negative Predictive Value	93.6%	98.5%	93.2%	87.6%
Incidence of variceal bleed	19.7%	21.1%	16.1%	18.6%

**Conclusion:** Application of ML model in combination with EGD predicts VB more accurately than EGD alone in patients with compensated cirrhosis with esophageal varices

Email: cvillanueva@santpau.cat

**Background and aims:** Non-selective  $\beta$ -blockers can prevent decompensation of cirrhosis. However, a survival benefit has not been demonstrated. Carvedilol might be particularly adequate in early compensated cirrhosis. It has intrinsic vasodilator activity and may ameliorate hepatic vascular resistance, a relevant mechanism of

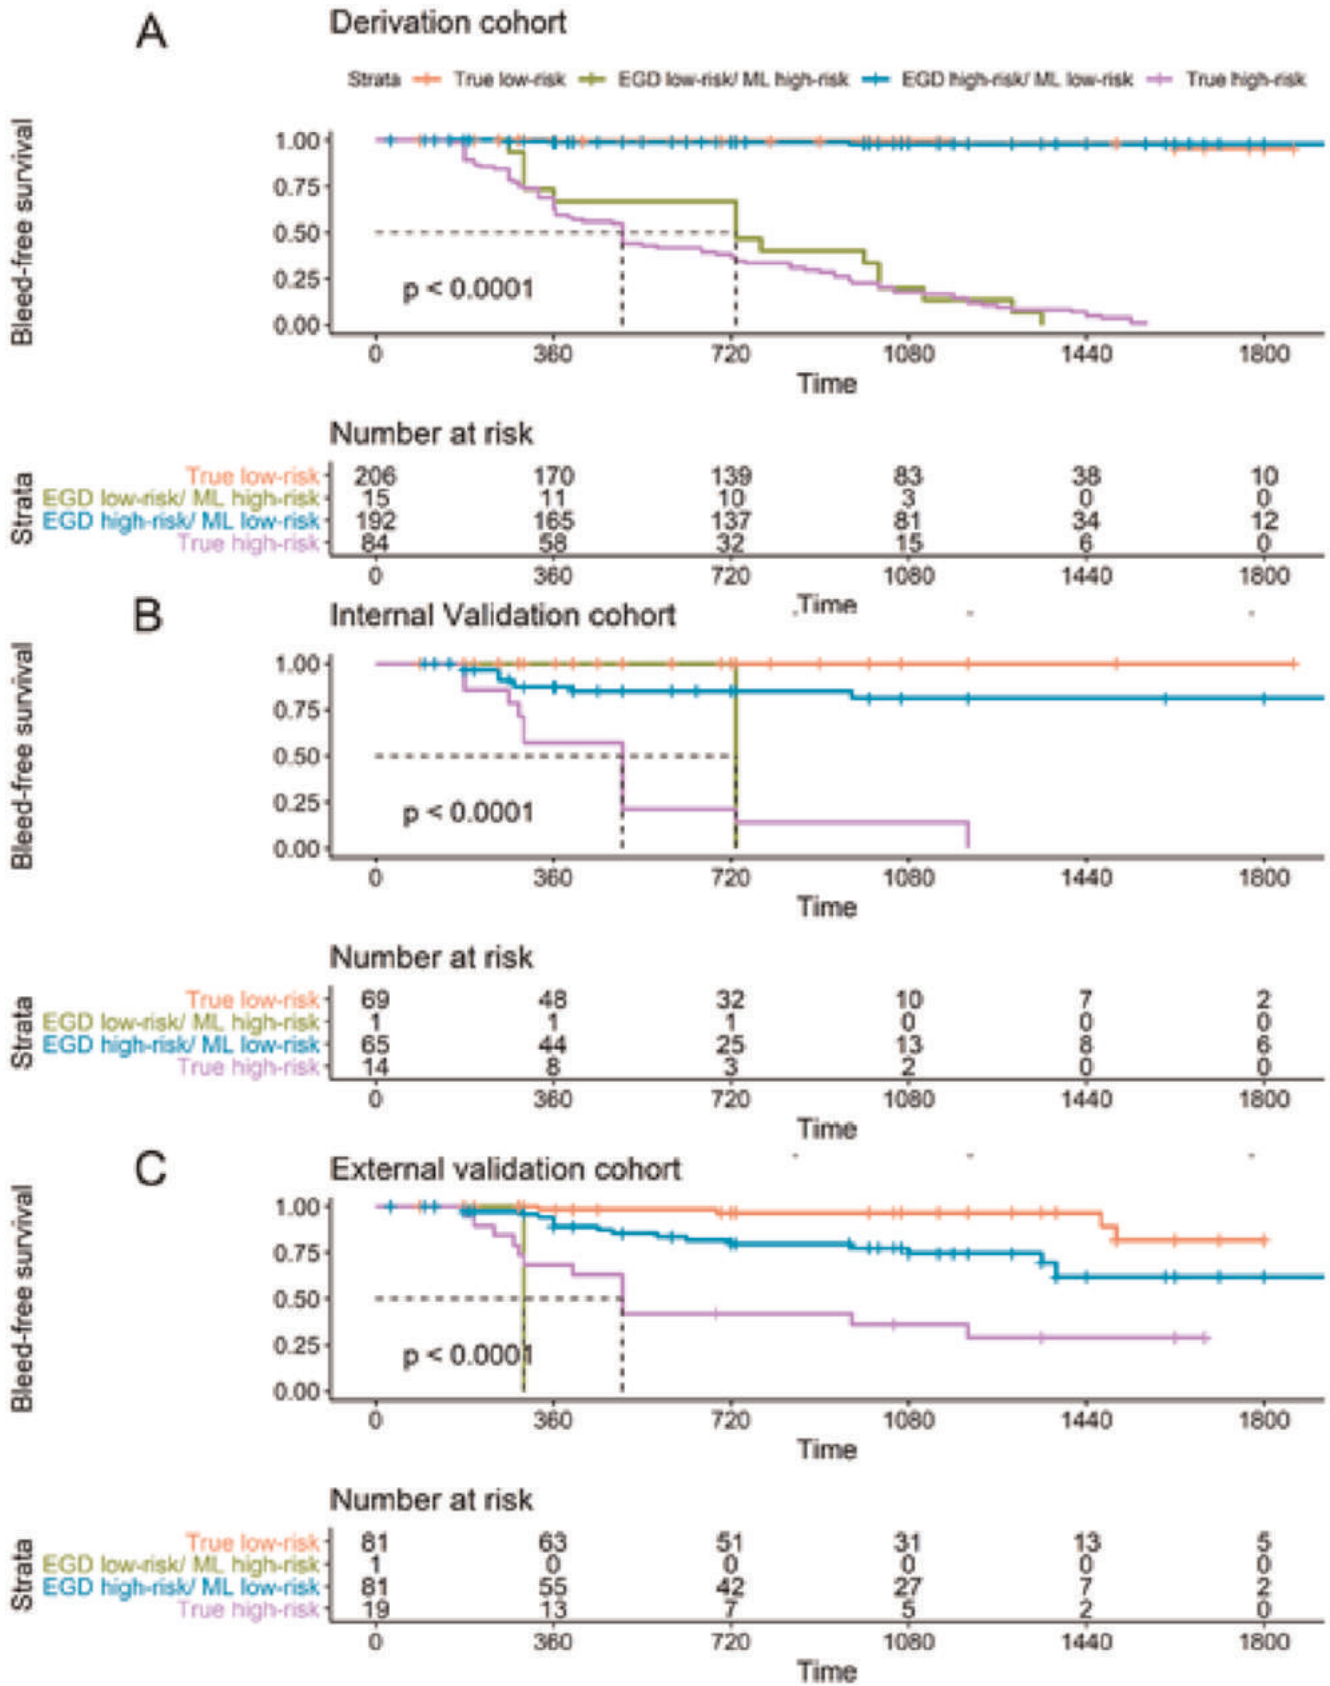

Figure: (abstract: PO-1705): Kaplan-Meier plots demonstrating bleed-free survival in patients stratified according to combination of endoscopic and machine learning (ML) classification in derivation (Figure-A) and internal/external validation cohorts (Figure-B and C).

## POSTER PRESENTATIONS

portal hypertension (PH) in early cirrhosis. Carvedilol has greater HVPG-decreasing effect than traditional- $\beta$ -blockers. Our aim was to assess whether carvedilol may prevent decompensation of cirrhosis and may improve survival in compensated cirrhosis with clinically significant PH (CSPH).

**Method:** By systematic review we identified RCTs comparing carvedilol vs control therapy (no-therapy, placebo or EVL) for primary or pre-primary prevention of bleeding in cirrhosis and CSPH. We performed a competing-risk time-to-event meta-analysis using individual patient data (IPD) obtained from principal investigators of RCTs. Only compensated patients were included. Primary outcomes were prevention of decompensation (competing-events: OLT and death) and death (OLT was competing-event). Adjusted models for risk evaluation were built using propensity score for baseline covariates using the Inverse Probability of the Treatment Weights (IPTW) approach.

**Results:** Among 125 full-text studies evaluated, 5 RCT were eligible for meta-analysis and 4 were finally included (no data was provided from 1). Overall, 352 patients with compensated cirrhosis were included, 181 treated with carvedilol and 171 controls (79 received EVL and 92 placebo). There were no major differences in baseline characteristics between groups and standardized differences were  $<10\%$  by IPTW. The risk of developing decompensation was lower in patients treated with carvedilol than in controls (SHR = 0.506, 95% CI = 0.289–0.887,  $P = 0.017$ ;  $I^2 = 0.0\%$ ), with a significant reduction on the risk of ascites (SHR = 0.491, 95% CI = 0.247–0.974,  $P = 0.042$ ;  $I^2 = 0.0\%$ ). The risk of death was also lower with carvedilol than in controls (SHR = 0.417, 95% CI = 0.194–0.896,  $P = 0.025$ ;  $I^2 = 0.0\%$ ). The benefit of therapy with carvedilol was consistent across prespecified subgroups, reflecting etiology, liver dysfunction, presence of varices, age and control therapy.

**Conclusion:** In patients with compensated cirrhosis and CSPH, long-term therapy with carvedilol not only prevents decompensation of cirrhosis but improves survival. The study suggests a beneficial clinical effect from screening patients with compensated cirrhosis for CSPH to start carvedilol therapy.

### PO-2136

#### Clinical decompensation and outcomes in patients with biopsy proven cirrhosis and a hepatic venous pressure gradient $\leq 10$ mm Hg

Ankur Jindal<sup>1</sup>, Manoj Kumar<sup>1</sup>, Guresh Kumar<sup>1</sup>, Shiv Kumar Sarin<sup>1</sup>.

<sup>1</sup>Institute of Liver and Biliary Sciences, New Delhi, India, India

Email: shivsarin@gmail.com

**Background and aims:** Clinically significant portal hypertension (CSPH), defined by hepatic venous pressure gradient (HVPG)  $>10$  mmHg predicts clinical decompensation (CD) in compensated cirrhosis. A proportion of cirrhotics at presentation have HVPG  $\leq 10$  mmHg despite presence of varices and CD. Their natural history and clinical spectrum is largely unknown.

**Method:** Consecutive patients with HVPG  $\leq 10$  mmHg and biopsy proven cirrhosis ( $n = 196$ ) or LSM  $> 15$  kPa ( $n = 65$ ) were included. Patients with non-cirrhotic portal hypertension were excluded. We analyzed the patterns and predictors of CD at presentation and follow-up, HVPG response to carvedilol and survival outcomes.

**Results:** Of 261 patients, 129 (49.4%) patients had CD at first presentation. The most common CDs were ascites ( $n = 77$ ) and jaundice ( $n = 65$ ). 78 patients had single CD and 51 patients had  $\geq 2$  CD. Each mmHg change in HVPG increased chances of CD by 72%. Baseline HVPG  $> 7.5$  [OR: 1.7;  $p = 0.002$ ], presence of esophageal varices [OR: 3.9;  $p = 0.024$ ] and serum albumin  $< 3.2$  [OR: 0.04;  $p < 0.001$ ] were independently associated with CD. 14.4% patients developed new CD after a median duration of 23.1 months. Despite comparable baseline HVPG, higher follow-up HVPG was recorded in patients with new CD ( $15.3 \pm 3.7$  vs.  $8 \pm 2$  mm Hg;  $p < 0.001$ ). LSM  $> 26.6$  kPa [OR: 1.1], presence of portosystemic shunt (s) [OR: 4.4] and serum albumin [OR: 0.27] at baseline predicted new CD. Overall

HVPG response ( $>10\%$  reduction) ( $n = 60$ ) was 23%, higher with HVPG  $> 8$ – $10$  mmHg (33.3% vs 15.2%;  $p = 0.05$ ) but it did not influence survival. 5-year mortality was higher in patients with  $\geq 2$  CD [23.5%] compared to single and no CD [10.2% and 3% respectively;  $p < 0.001$ ]. Neither HVPG nor LSM predicted higher mortality. Presence of ascites [HR: 2.75,  $p = 0.05$ ], HE [HR: 8.76;  $p < 0.001$ ] and new CD on follow-up [HR: 6.84;  $p < 0.001$ ] were independent predictors of 5-y mortality.

Table: Comparison of patients based on HVPG groups

	HVPG 6–8 mmHg (n = 146)	HVPG $> 8$ to 10 mmHg (n = 115)	P value
Alcoholic cirrhosis	16 (11)	22 (19.1)	0.03
Viral cirrhosis	51 (34.9)	21 (18.3)	0.02
Esophageal varices	50 (34.2)	60 (52.2)	0.006
Platelet count ( $\times 10^3/\text{cu.mm}$ )	150 (93–195)	115 (82–160)	0.002
Serum albumin (g/dl)	3.4 + 0.67	3.09 + 0.54	$< 0.001$
LSM (kPa)	25.26 + 14.68	30.2 + 16.78	0.012
Portosystemic shunt	17 (11.6)	13 (11.3)	NS
Ascites	26 (17.8)	46 (40)	$< 0.001$
Jaundice	22 (15.1)	46 (40)	$< 0.001$
HE	4 (2.7)	18 (15.7)	$< 0.001$
Variceal bleed	7 (4.8)	11 (9.6)	NS
New CD on follow-up	27 (18.5)	24 (20.9)	NS

**Figure:** 5-year mortality in cirrhotics with HVPG  $\leq 10$  based on baseline clinical decompensation

**Conclusion:** Nearly one-half of cirrhotics with HVPG  $\leq 10$  mmHg had clinical decompensation and indicates need to reassess and reduce the level of defining CSPH. Early interventions to reduce portal pressure in patients with HVPG  $> 8$  mmHg may improve long-term outcomes.

### PO-2162

#### Value of Hitachi Shear Wave Elastography (SWE) to rule-in and rule-out the presence of esophageal varices in patients with compensated advanced liver disease

Simona Bota<sup>1</sup>, Marcel Razpotnik<sup>1</sup>, Christian Urak<sup>1</sup>, Florian Hucke<sup>2</sup>, Markus Peck-Radosavljevic<sup>1</sup>. <sup>1</sup>Klinikum Klagenfurt am Wörthersee, Department of Internal Medicine and Gastroenterology (IMuG), Hepatology, Endocrinology, Rheumatology and Nephrology and Emergency Medicine (ZAE) with Centralized Endoscopy Service, Klagenfurt, Austria; <sup>2</sup>Department of Internal Medicine and Gastroenterology (IMuG), Hepatology, Endocrinology, Rheumatology and Nephrology and Emergency Medicine (ZAE) with Centralized

Endoscopy Service, Klagenfurt, Austria  
Email: bota\_simona1982@yahoo.com

**Background and aims:** Liver stiffness (LS) assessed by Transient Elastography (TE) in combination with platelet count was introduced in the Baveno VI consensus to guide the need of screening gastroscopy for esophageal varices in patients with compensated advanced liver disease (cALD). According to the Baveno VI consensus, patients with an LS <20 kPa and platelet count >150,000 cells/mm<sup>3</sup> have a very low risk for esophageal varices, and screening gastroscopy can be avoided safely. We aimed to assess the value of the Hitachi SWE to rule-in and rule-out the presence of esophageal varices in patients with cALD.

**Method:** LS was measured with Hitachi SWE (Arietta V70) and Transient Elastography (TE) (FibroScan®, Echosens, France). Reliable LS measurements with both methods were defined as the median value of ten valid measurements with an IQR/Med < 30% and expressed in kilopascals (kPa).

Recent gastroscopy (not older than six months) had been conducted in all patients.

**Results:** Our cohort included 195 patients with chronic liver diseases and different degrees of liver fibrosis, of which 107 were diagnosed as cALD (mean age 57.3 ± 12.4 years, 69.1% men). The most common etiology was alcohol use (50.4%). Esophageal varices were diagnosed in 43.9% of these patients.

The best predictive LS cut-off value by Hitachi SWE for the presence of F4 fibrosis was >8.7 kPa (Se 94.4%, Sp 92.5%, AUC = 0.965).

The rate of reliable measurements was 100% for Hitachi SWE and 94.3% for TE.

None of the patients with esophageal varices had LS assessed by TE <20 kPa and platelet count >150,000 cells/mm<sup>3</sup>, showing very good performance of the Baveno VI criteria.

LS assessed by Hitachi SWE was significantly higher in cALD cohort with esophageal varices than in those without varices: 14.1 ± 4.2 kPa vs. 11.2 ± 3.7 kPa, p = 0.0003. The best LS cut-off value assessed by Hitachi SWE for predicting the presence of esophageal varices was >11.7 kPa (Se 66%, Sp 70%, AUC = 0.742); while for a cut-off value >16.5 kPa more than 90% Sp was observed.

None of the patients with esophageal varices assessed by Hitachi SWE had LS < 11.7 kPa and platelet count >150,000 cells/mm<sup>3</sup>, demonstrating a very good performance to rule out the presence of esophageal varices.

Rule-in esophageal varices performance of LS assessed by Hitachi SWE and platelets count was significant lower. When both criteria (LS > 16.5 kPa, platelet count <150,000 cells/mm<sup>3</sup>) were fulfilled, a significantly higher positive predictive value (PPV = 76.9%, 10/13 patients) was calculated to rule-in esophageal varices compared to the presence of one criterion only (PPV = 57.3%, 47/82 patients)

**Conclusion:** LS assessed by Hitachi SWE combined with platelet count seems to be a reliable method to rule-out the presence of the esophageal varices in cALD patients, comparable to what can be achieved with LS through TE. To rule-in varices, the performance is significantly lower.

#### PO-2238

##### **Influence of Shunt occlusion on Organ Functions in Hyperammonemic patients with Cirrhosis having Porto-systemic Shunt: a randomized controlled trial**

Amar Mukund<sup>1</sup>, Shakti Choudhury<sup>2</sup>, Tara Prasad Tripathy<sup>1</sup>, Venkatesh Hosur Ananthashayana<sup>1</sup>, Vinod Arora<sup>2</sup>, Vijayraghavan Rajan<sup>2</sup>, Shiv Kumar Sarin<sup>2</sup>. <sup>1</sup>*Institute of Liver and Biliary Sciences, Intervention Radiology, New Delhi, India;* <sup>2</sup>*Institute of Liver and Biliary Sciences, Hepatology, New Delhi, India*  
Email: dramarmukund@gmail.com

**Background and aims:** Cirrhosis patients with large spontaneous portosystemic shunts (SPSS) present with recurrent hepatic encephalopathy (HE) or gastric variceal bleeding. These shunts also deprive the liver of portal blood rich in nutrients and regenerative factors.

Plug-Assisted Retrograde Transvenous Obliteration (PARTO) of these shunts redirects the portal blood towards the liver. We evaluated the long-term effects of PARTO on change in the liver volume and functional status.

**Method:** Patients having SPSS with recurrent HE were randomized to receive standard medical treatment (SMT, control group) or shunt occlusion. SMT included, management of complications of decompensated cirrhosis, including HE, hyperammonemia and nutrition. Patients of both groups were evaluated for any change in the total liver volume (on CT volumetry). Clinical outcomes, MELD-Na, plasma ammonia levels and T scores in DEXA for bone density were analysed.

**Results:** Out of 40 patients in the study population, NASH (18, 45%) and alcohol associated (11, 27.5%) cirrhosis were commonest. The most common SPSS types were gastrosplenic shunts (n = 17, 42.5%) followed by splenoportal shunts (n = 11, 27.5%), paraumbilical vein (n = 6, 15%), gastrosplenoportal shunts (n = 3, 7.5%). The indications of PARTO were recurrent HE in 13 (65%) patients and large gastric varices with hyperammonemia in the rest. PARTO was successful in all the patients and all patients showed resolution of symptoms and clinical improvement within 7 days. The plasma ammonia levels improved post-PARTO shunt closure from 198 ± 99 to 107 ± 47 µ/dl (p = 0.001) whereas this remained unchanged in the SMT group [145 ± 70.5 to 157.8 ± 50.03 µ/dl, p = 0.139]. The mean serum albumin pre and post PARTO shunt closure [2.5 ± 0.6 and 2.8 ± 0.4 respectively] was significantly higher than control group [2.9 ± 0.4 and 2.6 ± 0.4 respectively] (p value <0.05). Post-PARTO shunt closure, there was a significant increase in liver volume (18 of 20 patients, p = 0.03), reduction in MELD-Na score (p = 0.03), plasma ammonia level (16 of 18 patients, p = 0.001) and improvement in DEXA-T scores (7 of 11 patients, p = 0.01). There was a 10.8% increase in the total liver volume from pre-procedure (mean volume = 1064 ± 368cc, median ± IQR = 968 ± 534) to post-procedure (mean volume = 1179 ± 375cc, median ± IQR = 1028 ± 510), providing an average 10.8% (difference of mean volume = 61cc) increase in mean liver volumes. On the other hand, there was a significant decrease in liver volume in SMT/control group on follow-up CT (14%, p = 0.003).

**Conclusion:** Large SPSS in cirrhotic patients diverts the mesenteric flow away from liver and can lead to a progressive reduction in the liver volume. The closure of such shunts by PARTO, besides reducing the incidence of HE and plasma ammonia levels, achieves about 10% increase in hepatic volume and synthetic functions.

#### PO-2294

##### **Prognostic impact of Hepatic venous pressure gradient cut-off of 10 mm Hg to predict clinical decompensations in patients with compensated cirrhosis with liver stiffness above 25 kilopascals**

Ankur Jindal<sup>1</sup>, Sanchit Sharma<sup>2</sup>, Samagra Agarwal<sup>2</sup>, Manoj Kumar<sup>1</sup>, Anoop Saraya<sup>2</sup>, Shiv Kumar Sarin<sup>1</sup>. <sup>1</sup>*Institute of Liver and Biliary Sciences, Hepatology, New Delhi, India;* <sup>2</sup>*AIIMS Hospital, Gastroenterology and Human Nutrition Unit, New Delhi, India*  
Email: shivsarin@gmail.com

**Background and aims:** Hepatic venous pressure gradient (HVPG) > 10 mmHg is an important predictor of clinical decompensations in patients with compensated cirrhosis. Liver stiffness measurement (LSM) is a non-invasive tool which correlates with HVPG upto 12 mmHg. We aimed to assess the predictive relevance of HVPG for clinical decompensations when stratified using LSM.

**Method:** Patients with compensated cirrhosis with valid measurement of baseline HVPG and LSM were retrospectively assessed for future clinical decompensations (ascites, variceal bleeding and hepatic encephalopathy). Optimal cut-offs for best diagnostic accuracy were identified and patients were stratified at cutpoints of 25 kilopascals (kPa) for LSM and 10 mm Hg for HVPG and incident clinical decompensation rates were compared

**Results:** 626 patients (mean age: 44.7 ± 13.5 years, 72.4% males) with compensated cirrhosis related to alcohol (30.3%), non-alcoholic steatohepatitis (26.4%), hepatitis C (16.6%), hepatitis B (10.2%) were

Figure: (abstract: PO-2294): Kaplan-Meier plots demonstrating clinical decompensation -free survival in patients stratified according to combination of liver stiffness measurement (LSM) of 25 kPa and hepatic venous pressure gradient (HVPG) of 10 mm Hg into different risk strata.

included. Patients were followed-up for a median duration of 26 (inter-quartile range 7–55) months over which 132 (21.0%) patients developed clinical decompensations. 1-, 3-, 5- and 7-year decompensation rates were significantly higher in patients with LSM > 25 and HVPG < 10 (22.3%, 43.4%, 43.4%, 43.4%) in comparison to those with LSM < 25 and HVPG > 10 (13.7%, 18.2%, 19.7%, 19.7%) (Log-rank test  $p = 0.018$ ). Patients with LSM > 25 had similar decompensation rates irrespective of HVPG (Log-rank test  $p = 0.99$ ). On univariate analysis, HVPG > 10 (Hazard Ratio 2.34 (1.79–3.05);  $p = 0.001$ ), LSM > 25 (HR 3.16 (2.68–3.84);  $p < 0.001$ ) and non-viral etiology (HR 1.65 (1.33–2.05);  $p = 0.02$ ) were all significant for predicting future decompensations, however on multivariate Cox-proportional hazards model only LSM > 25 was significant (Multivariate HR 2.81 (2.30–3.43);  $p < 0.001$ ).

**Conclusion:** Almost 40% patients with compensated cirrhosis and LSM > 25 kPa have follow-up clinical decompensations irrespective of HVPG, obviating the need for its measurement. However, for patients with LSM < 25 kPa, HVPG cut off of 10 mmHg is accurate to predict decompensations.

**PO-2298**

**Prediction of cardiac outcomes post-transjugular intrahepatic portosystemic shunt placement using cirrhotic cardiomyopathy criteria**

Claire Harrington<sup>1</sup>, John Laurenzano<sup>2</sup>, Nikhilesh Mazumder<sup>1</sup>, Jing Gao<sup>1</sup>, Anthony Borgmann<sup>2</sup>, Deepakl Gupta<sup>2</sup>, Lisa VanWagner<sup>3</sup>, Manhal Izzy<sup>2</sup>, Justin Boike<sup>3</sup>. <sup>1</sup>McGaw Medical Center of Northwestern University, Chicago, United States; <sup>2</sup>Vanderbilt University Medical Center, Nashville, United States; <sup>3</sup>Northwestern Memorial Hospital, Chicago, United States  
Email: justinboike@gmail.com

**Background and aims:** Transjugular intrahepatic portosystemic shunts (TIPS) have become a common treatment for the complications of portal hypertension, namely variceal bleeding, refractory ascites, and hepatic hydrothorax. Unfortunately, cardiac decompensation has been described as a serious complication after TIPS, occurring in up to 20% of patients. Despite the frequency of this complication, there is limited data available to help predict who will be at highest risk. Recently, the criteria for cirrhotic cardiomyopathy (CCM) were revised to include systolic dysfunction represented by ejection fraction (EF) < 50% (CCM-SD) and/or at least 2 diastolic dysfunction criteria (CCM-DD). The aim of this study is to evaluate the impact of CCM, per the new criteria, on cardiovascular (CV) outcomes post-TIPS.

**Method:** This is a retrospective cohort of 397 adult patients that underwent TIPS from two urban, tertiary hospitals between 01/2010 and 12/2015. Medical record review identified demographic, clinical, laboratory, and echocardiographic variables, when available, pre- and post-TIPS. Cardiovascular outcomes were defined as the incidence of myocardial infarction, coronary revascularization, atrial fibrillation/flutter or congestive heart failure (CHF).

**Results:** Among 397 patients undergoing TIPS (mean age 58.6, 62% male, 76% non-Hispanic), a total of 50 (12.6%) patients met criteria for CCM diagnosis prior to TIPS with 10 patients meeting criteria for CCM-SD and 40 for CCM-DD. Within 1 year after TIPS, 148 (37.3%) had a CV outcome. 43 patients (10.8%) developed post-TIPS CHF. The presence of CCM (OR 2.0,  $p = 0.032$ ), increasing left atrial volume index (LAVI) (OR 1.25,  $p = 0.034$  for every 10 ml/m<sup>2</sup> increase) and increasing severity of aortic stenosis (OR 2.27 for AV gradient > 20 mmHg,  $p = 0.037$ ) were associated with CV outcomes. CCM was also associated post TIPS CHF admission (OR 2.29,  $p = 0.025$ ).

**Conclusion:** The presence of Cirrhotic Cardiomyopathy, per the new criteria, in patients undergoing TIPS placement can increase the risk of both CV events and specifically CHF post-TIPS. Additional parameters, including elevated LAVI and the presence of aortic stenosis, may significantly increase the risk for post-TIPS CV events. Close follow-up post-TIPS in patients with these risk factors may be warranted.

**PO-2305**

**Rifaximin for Prophylaxis of Post-TIPPS Hepatic Encephalopathy- A Meta Analysis**

Aminah Abdul Razzack<sup>1</sup>, Nabeel Hussain<sup>2</sup>, Syed Adeel Hassan<sup>3,4</sup>, Reem Gulzar<sup>5</sup>, Alvina Karam<sup>6</sup>, Priyanka Panday<sup>7</sup>, Prathima Guntipalli<sup>8</sup>, Ramya Pakala<sup>8</sup>, Sirisha Kumari Gara<sup>8</sup>. <sup>1</sup>Dr NTR University of Health Sciences, India; <sup>2</sup>Saba University School of Medicine, Netherlands Antilles; <sup>3</sup>University of Louisville, United States; <sup>4</sup>University of Louisville, Department of Medicine, Louisville, United States; <sup>5</sup>Fatima Jinnah Medical University for women, Pakistan; <sup>6</sup>Khyber Medical College, Pakistan; <sup>7</sup>Kathmandu Medical College, Nepal; <sup>8</sup>Larkin Community Hospital, United States  
Email: aminahrazack1@gmail.com

**Background and aims:** The main drawback of transjugular intrahepatic portosystemic shunt (TIPSS) is development of hepatic encephalopathy. The effectiveness of rifaximin in preventing an episode of hepatic encephalopathy in patients who have underwent TIPSS is not well known.

To determine whether rifaximin is effective for prevention of Post-TIPSS hepatic encephalopathy when compared to placebo.

**Method:** Electronic databases (pubmed, Embase, Scopus, Cochrane) were searched from inception until 2<sup>nd</sup> February 2021. Unadjusted Risk ratios (rrs) were calculated from dichotomous data using Mantel Haenszel (M-H) random-effects with statistical significance to be considered if the confidence interval excludes 1 and p < 0.05. The primary outcome of interest was incidence of first episode of hepatic encephalopathy.

**Results:** A total of three studies with 535 participants (Rifaximin = 258; Placebo = 277) were included. Average follow-up period was 6 months. Mean age was 57.1 and 56.5 years in the rifaximin and placebo groups respectively. Patients receiving Rifaximin had lower odds of incidence of hepatic encephalopathy as compared to placebo (RR 0.69; 95%CI 0.52–0.92; p = 0.01, I<sup>2</sup> = 0). We had no publication bias in our results (Egger’s regression p > 0.05).

**Conclusion:** Rifaximin is superior to placebo for pharmacological prophylaxis of Post-TIPPS hepatic encephalopathy.

**PO-2381**

**The modifications of adipose tissue and muscle mass are associated to the reduction of hepatic encephalopathy after TIPS**

Stefania Gioia<sup>1</sup>, Silvia Nardelli<sup>1</sup>, Lorenzo Ridola<sup>1</sup>, Ludovica Cristofaro<sup>1</sup>, Oliviero Riggio<sup>1</sup>. <sup>1</sup>Sapienza, Università di Roma, Department of translational and precision medicine  
Email: stensgioia@hotmail.com

**Background and aims:** Sarcopenia and myosteatosis have been associated to a poor prognosis of cirrhosis and to a higher incidence of

hepatic encephalopathy (HE). Recently, aberrations in adipose tissue (high visceral adiposity and low subcutaneous adiposity) have attracted progressive substantial attention but their clinical implications and their co-incidence in cirrhotic patients are poorly investigated.

The aim of the study was to evaluate the modifications of visceral and subcutaneous adipose tissue after TIPS and to investigate their relationships with the modifications of muscle alterations and with the incidence of post-TIPS HE.

**Method:** 35 cirrhotic patients submitted to TIPS were studied. The modification of skeletal muscle index (SMI), muscle attenuation, subcutaneous adipose tissue index (SATI), visceral adipose tissue index (VATI), assessed by CT-scan, and overt HE and plasma ammonia were evaluated before and after a mean follow-up of 19 ± 15 months after TIPS.

**Results:** During the follow-up, the mean SMI and muscle attenuation increased significantly; SATI significantly increased (p = 0.004) while VATI significantly decreased (p = 0.007), although not uniformly in all patients. MELD remained stable or worsened after TIPS and was not significantly different between the groups with or without improvement of the body composition. The number of episodes of overt HE during the follow-up was significantly reduced in the patients with improved SMI and in patients with improved SATI. Finally, inverse correlations were observed between delta ammonia and delta SMI (r = -0.61; p < 0.005), delta ammonia and delta SATI (r = -0.40; p < 0.05), delta ammonia and delta muscle attenuation (r = -0.40; p < 0.05).

**Conclusion:** Other than muscle, also adipose tissue modifies after TIPS. As confirmed for sarcopenia and myosteatosis, the improvement of subcutaneous adipose tissue was associated to the amelioration of cognitive impairment independently of liver function probably suggesting an active role of the adipose tissue in the inter-organ ammonia trafficking.

**PO-2403**

**A single assessment of acute hemodynamic response to intravenous propranolol predicts hepatic decompensation in cirrhotic patients with portal hypertension**

Benedikt S. Hofer<sup>1,2,3</sup>, Benedikt Simbrunner<sup>1,2,3</sup>, David J.M. Bauer<sup>1,2</sup>, Rafael Paternostro<sup>1,2</sup>, Philipp Schwabl<sup>1,2,3</sup>, Bernhard Scheiner<sup>1,2</sup>, Lukas Hartl<sup>1,2</sup>, Mathias Jachs<sup>1,2</sup>, Albert Stättermayer<sup>1</sup>, Michael Trauner<sup>1</sup>, Mattias Mandorfer<sup>1,2</sup>, Thomas Reiberger<sup>1,2,3</sup>.

<sup>1</sup>Medical University of Vienna, Department of Internal Medicine III, Division of Gastroenterology and Hepatology, Vienna, Austria; <sup>2</sup>Medical University of Vienna, Vienna Hepatic Hemodynamic Lab, Vienna, Austria; <sup>3</sup>Medical University of Vienna, Christian Doppler Lab for Portal Hypertension and Liver Fibrosis, Vienna, Austria

Email: thomas.reiberger@meduniwien.ac.at

**Background and aims:** Non-selective beta-blockers (NSBB) are indicated for the prophylaxis of variceal bleeding. The acute hemodynamic response to intravenous propranolol (ivPROP-R), defined by a ≥10% decrease of hepatic venous pressure gradient (HVPG), has been shown to be associated with decreased rates of variceal bleeding and an increased probability of survival. We further

Figure: (abstract: PO-2305)

## POSTER PRESENTATIONS

explored the prognostic value of ivPROP-R in patients with compensated (cACLD) and decompensated (dACLD) advanced chronic liver disease.

**Method:** We analyzed ACLD patients undergoing HVPG measurements with an intraprocedural assessment of ivPROP-R included in the prospective Vienna Cirrhosis Study (NCT03267615).

**Results:** 98 ACLD patients (mean age:  $56.4 \pm 11.5$  years; 69.4% male; 88.8% varices; 72.4% dACLD) with a mean HVPG of  $19.9 \pm 4.4$  mmHg were included in this study. Overall, ivPROP-R was achieved in 57 (58.2%) patients (51.9% in cACLD vs. 60.6% in dACLD;  $p = 0.435$ ). With the exception of a lower proportion of male patients in the ivPROP-R group, there were no significant differences in baseline characteristics between ivPROP-R and non-responders (ivPROP-NR). 39/57 (68.4%) and 18/57 (31.6%) patients with ivPROP-R, as well as 25/41 (61.0%) and 16/41 (39.0%) patients with ivPROP-NR, were subsequently treated with carvedilol or propranolol, respectively. During a median follow-up of 9.6 (IQR: 6.5–18.2) months, patients with ivPROP-R demonstrated a significantly lower risk of variceal bleeding (at 12 months: 3.6% vs. 14.9%; log-rank  $p = 0.038$ ). First/further hepatic decompensation occurred in 24.6% of patients with ivPROP-R versus 39.0% among ivPROP-NR (log-rank  $p = 0.096$ ). Achieving ivPROP-R was independently linked to a reduced risk of first/further decompensation (adjusted HR: 0.30; 95%CI: 0.13–0.69;  $p = 0.005$ ). Mean transplant-free survival tended to be longer in patients with ivPROP-R ( $34.2$  (95%CI: 29.2–39.2) vs.  $25.2$  (95%CI: 19.8–30.6) months;  $p = 0.191$ ). The trend towards a survival-benefit in patients with ivPROP-R seemed to be more pronounced in dACLD patients (at 12 months: 83.9% ivPROP-R vs. 66.9% ivPROP-NR; log-rank  $p = 0.061$ ).

Figure:

**Conclusion:** A single assessment of ivPROP-R is a valuable prognostic marker in patients with ACLD, since achieving ivPROP-R was associated with a decreased risk of variceal bleeding and hepatic decompensation.

### PO-2529

#### Effects and safety of atrial natriuretic peptide administered to cirrhosis patients with ascites: a systematic review and meta-analysis

Rasmus Hvidbjerg Gantzel<sup>1</sup>, Mikkel Breinholt Kjær<sup>1</sup>, Peter Jepsen<sup>1</sup>, Niels Kristian Aagaard<sup>1</sup>, Hugh Watson<sup>1</sup>, Lise Lotte Gluud<sup>2,3</sup>, Henning Grønbaek<sup>1</sup>. <sup>1</sup>Aarhus University Hospital, Department of Hepatology and Gastroenterology, Århus N, Denmark; <sup>2</sup>University of Copenhagen, Department of Clinical Medicine, Hvidovre, Denmark; <sup>3</sup>Copenhagen University Hospital, Gastro Unit, Hvidovre, Denmark  
Email: ragant@rm.dk

**Background and aims:** Atrial natriuretic peptide (ANP) is elevated in patients with cirrhosis and portal hypertension. Here, ANP undertake a physiological attempt to counterbalance anti-natriuretic factors and vasoconstriction. Since only small studies have investigated ANP in cirrhosis patients with ascites, we systematically reviewed the literature and meta-analysed results, with an aim to conclude on the effects and safety of ANP as treatment for cirrhotic ascites.

**Method:** We searched MEDLINE, Scopus, Web of Science, Embase, and Cochrane Library for all studies investigating an intravenous administration of ANP to cirrhosis patients with ascites. Inclusion was not limited by treatment duration or dose, nor by follow-up duration. Both RCTs and non-controlled studies were included. The primary outcome was change in renal sodium excretion. Secondary outcomes comprised change in renal water excretion, changes in plasma aldosterone concentration (PAC) and renin activity (PRA), and safety.

**Results:** 19 studies (215 patients) were included. Continuous ANP infusion increased sodium excretion from  $5.6 \mu\text{mol}/\text{min}$  (95% CI: 3.7–7.4) at baseline to  $27.0 \mu\text{mol}/\text{min}$  (95% CI: 41.5–103.5) at peak response. An infusion rate of  $>30 \text{ ng}/\text{kg}/\text{min}$  induced a higher natriuretic response compared with  $\leq 30 \text{ ng}/\text{kg}/\text{min}$  ( $p < 0.01$ ). Natriuresis was more pronounced in study cohorts with mild/moderate ascites compared with moderate/severe and refractory ascites ( $p < 0.01$ ). ANP induced an increase in water excretion, although with a less significant dose-response gradient ( $p = 0.08$ ). Remarkably, PAC and PRA were lower in study cohorts that achieved a higher sodium balance compared with treatment non-responder study cohorts ( $p < 0.01$ ). Finally, the most frequent complication was blood pressure falls. Infusion rates of  $\leq 30 \text{ ng}/\text{kg}/\text{min}$  were in general well-tolerated, while higher infusion rates were prone to cause blood pressure falls with limited chance for recovery.

**Conclusion:** As the first to compile results on effects and safety of ANP in patients with cirrhotic ascites, we conclude that ANP infusions induce meaningful natriuresis, most pronounced with infusion rates of  $>30 \text{ ng}/\text{kg}/\text{min}$  and in patients with mild/moderate ascites, though with higher tolerance at infusion rates of  $\leq 30 \text{ ng}/\text{kg}/\text{min}$ . Future pharmaceutical trials in this field are justified, and may benefit from including PAC and PRA to investigate their potential as predictors of responsiveness.

### PO-2572

#### Achieving an effective pressure reduction after TIPS for cirrhotic patients with variceal bleeding

Xiaozhe Wang<sup>1</sup>, Xuefeng Luo<sup>1</sup>, Li Yang<sup>1</sup>. <sup>1</sup>West China Hospital of Sichuan University, Department of Gastroenterology and Hepatology  
Email: xiaozhe.wang@foxmail.com

**Background and aims:** The target portosystemic pressure gradient (PPG), is recommended to be less than 12 mm Hg after transjugular intrahepatic portosystemic shunt (TIPS) creation. However, there are few reports on the relevance between post-TIPS altered hemodynamics and clinical events during the follow-up since covered stents have been used. We would like to compare the outcomes of patients with portal pressure gradient (PPG)  $>12 \text{ mmHg}$  and those with  $\text{PPG} \leq 12 \text{ mmHg}$  after TIPS creation.

**Method:** Two hundred and sixteen cirrhotic patients who underwent de novo TIPS placement due to variceal bleeding between June 2015 and April 2019 in our department were retrospectively reviewed. TIPS

procedure was performed under local anaesthesia. The intrahepatic tract was dilated with an 8 × 60 mm angioplasty balloon, followed by the placement of an 8-mm Fluency ePTFE-covered stent (Bard, Murray Hill, USA). Persistent visualised collaterals on post-TIPS portography were embolised. Patients were evaluated at 1, 3, and 6 months after discharge and every 6 months until liver transplantation, death, or loss to follow-up. The primary end point was variceal rebleeding, which was defined as a single episode of clinically significant rebleeding from portal hypertensive sources.

**Results:** The haemodynamic success of TIPS (final PPG ≤ 12 mmHg) was not achieved in 37 patients (17.1%). In group 1 (PPG >12 mmHg), the median PPG was reduced from 27 mmHg (IQR, 25–30 mmHg) to 15 mmHg (IQR, 14–19 mmHg). In group 2 (PPG ≤ 12 mmHg), the median PPG was reduced from 20 mmHg (IQR, 17–23 mmHg) to 8 mmHg (IQR, 6–10 mmHg). The median percentage reduction of PPG was 44% (IQR, 31%–51.5%) in group 1 and 60% (IQR, 51.2%–68.5%) in group 2. There was no significant difference between group 1 and 2 in terms of 1-year probability of remaining free of variceal rebleeding (91.8% vs 90.1%), 1-year probability of hepatic encephalopathy (29.1% vs 29.5%), 1-year probability of shunt dysfunction (14.5% vs 17%) and 1-year probability of survival (91.9% vs 97.8%). In group 1, variceal rebleeding occurred in six patients. TIPS dysfunction was confirmed in each patient. Five patients received shunt revision, and one underwent endoscopic treatment. Still, three out of six patients died of variceal rebleeding after discharge. During follow-up, another three patients died due to liver failure 56, 112 and 480 days after TIPS placement, respectively.

**Conclusion:** In our cohort, the cumulative rates of variceal rebleeding, hepatic encephalopathy and mortality were similar between the two groups and were consistent with patients who had a final PPG ≤ 12 mmHg in previous reports. Further studies are required to assess the efficacy of a small diameter TIPS which may lead to a PPG > 12 mmHg, complemented by drugs, endoscopic or interventional procedures.

**PO-2621**

**Fixed 8-mm diameter VCX stents do not provide clinical advantages compared to former underdilated VTS stents in cirrhotic patients treated with TIPS for refractory ascites**

Sohaib Mansour<sup>1</sup>, Arnaud Lemmers<sup>1</sup>, Eric Trepo<sup>1,2</sup>, Degré Delphine<sup>1</sup>, Thierry Gustot<sup>1,2</sup>, Christophe Moreno<sup>1,2</sup>, Pierre Deltenre<sup>1,3</sup>. <sup>1</sup>CUB Hopital Erasme, Université Libre de Bruxelles, Department of Gastroenterology, Hepatopancreatology and Digestive Oncology, Anderlecht, Belgium; <sup>2</sup>Université Libre de Bruxelles, Laboratory of Experimental Gastroenterology, Anderlecht, Belgium; <sup>3</sup>Clinique Saint-Luc, Department of Gastroenterology and Hepatology, Bouge, Belgium  
Email: sohaib.mansour@ulb.be

**Background and aims:** In patients with cirrhosis and refractory ascites (RA) treated with TIPS, new Viatorr controlled expansion (VCX) stents calibrated at 8 mm are designed to avoid passive expansion as opposed to conventional Viatorr TIPS Stent (VTS) for which the diameter may passively increase to 10 mm after TIPS insertion even if liver tract was underdilated at 8 mm, which may further increase portocaval shunting. We aimed to compare 1-year transplant-free survival, occurrence of hepatic encephalopathy (HE) and ascites persistence 1 year after TIPS insertion in patients with cirrhosis and RA treated either with fixed 8-mm diameter VCX stents or with VTS stents initially underdilated to 8 mm.

**Method:** Files of patients with cirrhosis who received TIPS for RA from 2010 to 2020 were retrospectively reviewed.

**Results:** 78 patients were included (32 treated with fixed 8-mm diameter VCX stents and 46 treated with underdilated VTS stents). Characteristics of patients were similar at baseline in both groups. 48 patients (62%) were male, median age was 62 years (95% CI: 57–64) and 59 patients (76%) had alcoholic-related cirrhosis. During follow-up, (median: 417 days [95% CI: 255–556]), 17 patients (5 treated with VCX stents and 12 with VTS stents) underwent stents dilatation, 42

died and 6 were transplanted. Compared to patients treated with underdilated VTS stents, patients treated with fixed 8-mm diameter VCX stents disclosed similar 1-year transplant-free survival (66%, [95% CI: 48–83%] vs. 69% [95% CI: 56–83%], p = 0.7), similar incidence of HE (50% [95% CI: 34–72] vs. 44% [95% CI: 31–63], p = 0.6), similar incidence of HE requiring hospitalization (37% [95% CI: 22–62] vs. 37% [95% CI: 24–57], p = 0.9) and similar incidence of ascites persistence (53% [95% CI: 30–75] vs. 64% [95% CI: 48–80], p = 0.7) 1 year after TIPS insertion. In multivariable analyses adjusted for age and MELD score, at 1 year, fixed 8-mm diameter stents were not associated with death or liver transplantation (HR: 1.35 [95% CI: 0.58–3.11], p = 0.5), HE (HR: 1.19 [95% CI: 0.59–2.40], p = 0.6), HE requiring hospitalization (HR: 1.04 [95% CI: 0.45–2.39], p = 0.9) or resolution of ascites (HR: 1.19 [95% CI: 0.52–2.72], p = 0.7). Exclusion of patients in whom stent was dilated during follow-up did not change the results.

**Figure:** Kaplan-Meier survival curves of patients with cirrhosis and refractory ascites treated with fixed 8-mm diameter VCX stents or former underdilated VTS stents

**Conclusion:** Fixed 8-mm diameter VCX stents were not associated with better survival or with lower rates of liver-related events than underdilated VTS stents in patients with cirrhosis and RA.

**PO-2655**

**Splenic vein flow for non-invasive screening for esophageal varices in advanced liver disease patients**

Sergii Kozlov<sup>1,2</sup>, Elina Manzhali<sup>3,4</sup>, Oleksandr Danylenko<sup>5</sup>, Oleksandr Kozlov<sup>5,6</sup>, Andrii Dolot<sup>6,7</sup>. <sup>1</sup>Bogomolets National Medical University, Surgery, Kyiv, Ukraine; <sup>2</sup>Verum Expert Clinic, Radiology, Kyiv, Ukraine; <sup>3</sup>Bogomolets National Medical University, Gastroenterology, Kyiv, Ukraine; <sup>4</sup>Verum Expert Clinic, Gastroenterology, Kyiv, Ukraine; <sup>5</sup>Bogomolets National Medical University, Kyiv, Ukraine; <sup>6</sup>Verum Expert Clinic, Kyiv, Ukraine; <sup>7</sup>Oberig Universal Clinic, Kyiv, Ukraine  
Email: sergiinikol@gmail.com

**Background and aims:** Current work aimed to evaluate the prognostic value of splenic venous flow (SVF) as a possible non-invasive screening test of esophageal varices (EV) in patients with advanced liver disease (ALD). Despite esophagogastroduodenoscopy (EGD) is still the “gold standard” for revealing esophageal varices (EV) in patients with advanced liver disease (ALD), searching for an optimal diagnostic algorithm is actual. Many biochemical/elastography modalities were presented in modern literature to substitute this invasive and uncomfortable (for patients) examination. We tend to use the hemodynamic parameters of the portal system to solve the problem.

**Method:** Using Doppler sonography, we evaluated splenic vein flow in 377 patients; 87 of them (control group) had no varices, and 290 ALD patients had proved with endoscopy presence of EV. The mean, median and interquartile range (IQR) were calculated (we obtained abnormally distributed data), and Mann-Whitney U test was used for two groups comparisons. The receiver operating characteristic (ROC) curve and area under the ROC curve (AUROC) were computed using EZR statistics software.

**Results:** Significant difference (p = 0.000, U test) of SVF was obtained in patients with ALD + EV versus control group: 1.06 l/min versus 0.32 l/min (mean), with median 0.88 l/min (IQR 0.58–1.27) versus 0.29 l/min (IQR 0.22–0.40). Area under the curve and cut-off values in the prediction model area were 0.93 and 0.55 l/min, respectively, with a sensitivity of 0.804 and specificity of 0.943 (Fig). According to literature data, the AUROCs for predicting varices using the shear method of wave elastography yielded around 0.80, which is less accurate than in the proposed model.

## POSTER PRESENTATIONS

Figure: ROC of splenic vein flow in the prediction of varices revealing.

**Conclusion:** Splenic vein flow increases markedly in variceal patients with hepatic CSPH, and its measurement could be a helpful screening tool in selection patients who should be referred (if SVF exceeded 0.5 L/min) to endoscopy examination. Our model demonstrated more accuracy in varices prediction (AUROC = 0.93) than systems based on elastography. One more conclusion is that increased splenic vein flow plays a significant role in the pathogenesis of portal hypertension and esophageal varices formation, but further investigations are needed.

### PO-2685

#### Using dimeric to monomeric IgA ratio to diagnose portal hypertension in liver disease: a pilot cohort study

Jessica Howell<sup>1,2,3</sup>, Huy Van<sup>4</sup>, Tim Spelman<sup>2</sup>, Minh Pham<sup>2</sup>, Mary Garcia<sup>4</sup>, Fan Li<sup>4</sup>, Rohit Sawhney<sup>5</sup>, John Lubel<sup>6</sup>, William Kemp<sup>6</sup>, Stephen Bloom<sup>5</sup>, Avik Majumdar<sup>7</sup>, Joseph Doyle<sup>2,8</sup>, Geoff McCaughan<sup>7</sup>, Purnima Bhat<sup>9</sup>, Margaret Hellard<sup>2,8</sup>, Kumar Visvanathan<sup>3</sup>, Alexander Thompson<sup>1,3</sup>, David Anderson<sup>4</sup>. <sup>1</sup>St Vincent's Hospital Melbourne, Gastroenterology, Fitzroy, Australia; <sup>2</sup>Burnet Institute, Disease Elimination, Melbourne, Australia; <sup>3</sup>University of Melbourne, Medicine, Fitzroy, Australia; <sup>4</sup>Burnet Institute, Life Sciences, Melbourne, Australia; <sup>5</sup>Eastern Health, Gastroenterology, Box Hill, Australia; <sup>6</sup>Alfred Hospital, Gastroenterology, Melbourne, Australia; <sup>7</sup>Royal Prince Alfred Hospital, AW Morrow Gastroenterology and Liver Centre, Sydney, Australia; <sup>8</sup>Alfred Hospital, Infectious Diseases, Melbourne, Australia; <sup>9</sup>Australian National University, Gastroenterology, Canberra, Australia  
Email: jessica.howell@svha.org.au

**Background and aims:** Portal hypertension (PHT) diagnosis in liver cirrhosis is vital to prevent life-threatening variceal bleeding. Platelet count and transient elastography are used to triage PHT risk and endoscopy to confirm diagnosis of varices, however these tests are expensive and difficult to access in remote/low resource settings. Dimeric IgA to monomeric IgA ratio (dlgA ratio) is a potential biomarker of gut mucosal leakage present in portal hypertension. We evaluated the diagnostic performance of a novel point-of-care (POC) dIgA ratio test for PHT.

**Method:** BioPoint<sup>®</sup> POC dIgA test is an antigen immunoassay-based lateral flow test which uses 15 µL of plasma or whole blood and provides a quantitative result <20 minutes using the Axxin hand-held reader. PHT was defined as platelet count <150 and splenomegaly (liver ultrasound), or clinical evidence of portal hypertension on gastroscopy. Associations between dIgA ratio, PHT and clinical parameters were determined by linear and logistic regression. ROC analysis was used to determine diagnostic accuracy.

**Results:** 1407 plasma samples from 960 patients with chronic liver disease were included; 280 (29%) had cirrhosis, 121 (9%) had PHT and 21 (2%) had current varices. Median dIgA ratio was higher in patients with PHT (1.14 vs 0.4,  $p < 0.001$ ), ascites (1.4 vs 0.7,  $p < 0.001$ ) and hepatic encephalopathy (1.4 vs 0.82,  $p < 0.001$ ). A POC dIgA ratio cutoff of 0.6 had good diagnostic accuracy and high NPV for PHT and varices in both the test (AUROC 0.84 and 0.83) and validation cohorts (AUROC 0.86, Table 1).

**Conclusion:** POC dIgA ratio test had good accuracy for the presence of PHT and varices. Given limited access to transient elastography and endoscopy in low resource settings, the high NPV of POC dIgA test for PHT in this study warrants further clinical utility and cost-effectiveness studies in low-resource settings.

### PO-2788

#### Umbilical hernia repair in Cirrhosis: TIPS insertion improves one-year survival but not long-term outcomes

Abdullah Malik<sup>1</sup>, Stuart Robinson<sup>1</sup>, Gourab Sen<sup>1</sup>, Mark Hudson<sup>1</sup>, Derek Manas<sup>1</sup>, Steven Masson<sup>1</sup>, John Hammond<sup>1</sup>. <sup>1</sup>Freeman Hospital, Liver Unit, High Heaton, United Kingdom  
Email: abdullah.malik@nhs.net

**Background and aims:** Umbilical hernia occur in up to 20% patients with cirrhosis. Management is controversial with a paucity of studies. We aimed to determine outcomes and factors predicting mortality following repair of symptomatic umbilical hernia in patients with cirrhosis.

**Method:** Retrospective study of patients with cirrhosis undergoing repair of hernia in a single centre from 1998 to 2020. Survival following surgery was estimated using the Kaplan-Meier method, comparing use of TIPS perioperatively (TIPS vs. nTIPS). Cox proportional hazards model and logistic regression analysis were used to determine predictors of overall survival (OS) and 1-year mortality, respectively. Statistical significance was set at  $p < 0.05$ .

Table 1: (abstract: PO-2685) Performance of POC dimeric IgA ratio for portal hypertension (PHT)

Ratio dIgA	No PHT	PHT	Sensitivity	Specificity	PPV	NPV	AUROC	95% CI	p value
Test cohort (n = 306; 40% cirrhosis, 5% healthy controls)									
≤0.6	161	11	86%	71%	51%	94%	0.84	0.78–0.89	<0.001
>0.6	66	68							
Validation cohort (n = 652, 1097 samples; 24% cirrhosis, 3% healthy controls)									
≤0.6	875	8	80%	83%	15%	99%	0.86	0.80–0.92	<0.001
>0.6	182	32							
Presence of varices (validation cohort, 1097 samples)									
	No Varices	Varices							
≤0.6	877	6	71%	82%	7%	99%	0.83	0.73–0.93	<0.001
>0.6	199	15							

PPV, positive predictive value; NPV, negative predictive value.

**Results:** One-hundred and eleven patients with cirrhosis underwent hernia repair (emergency n = 81, 73%). Mortality at 30d and 1y was 4.5% and 16%, respectively. TIPS was performed in 29 patients (26%) preoperatively. Age, pre-operative bilirubin, sodium, creatinine, prothrombin time, albumin and UKELD were no different between groups ( $p > 0.05$ ). Median overall survival was no different between TIPS and nTIPS (55 vs 64 months, respectively,  $p > 0.05$ ). ITU admission (HR 2.7,  $p = 0.002$ ) and pre-operative sodium  $< 130$  (HR 3.0,  $p = 0.011$ ) predicted long-term mortality. Predictors of mortality at one-year were age  $> 60$  (HR 7.4  $p = 0.008$ ) and ITU admission (HR 8.7  $p = 0.002$ ). TIPS insertion (n = 29) was associated with survival at one year (OR 7.2,  $p = 0.027$ ) but not with long-term survival ( $p > 0.05$ ). Sixteen (14%) patients underwent transplantation.

Figure:

**Conclusion:** Symptomatic umbilical hernias in patients with cirrhosis can be treated safely with acceptable long-term outcomes, however this remains a high risk intervention. Pre-operative sodium may identify high-risk patients, and allow appropriate counselling of such patients. TIPS may improve short-term outcomes but further prospective trials are warranted.

Email: bettina.hansen@utoronto.ca

**Background and aims:** The utility of common surrogate end points and associated thresholds used in primary biliary cholangitis (PBC) have not been assessed in cirrhotic patients, particularly those who are compensated.

**Method:** We included cirrhotic patients from the Global PBC Study Group Database that were diagnosed with PBC from 1990 to 2011 and treated with ursodeoxycholic acid (UDCA) for at least 1 year. Cirrhosis was established through biopsy or by clinical diagnosis. Liver biochemistry was considered baseline if within 6 months of start of follow-up. A compensated population was selected by excluding those with history of decompensation, biochemical criteria for Child Pugh-B/C (defined by 3 points in at least one or by 2 points in at least two of the following parameters: bilirubin, international normalized ratio [INR], albumin), and CP-score greater than 6, if known. Transplant-free survival was estimated with a Kaplan-Meier curve and compared between compensated and decompensated cirrhotic groups and within the compensated cirrhosis population with the log-rank test.

**Results:** We selected 573 patients with cirrhosis. A compensated population was selected (n = 419) after 154 patients were excluded (12 due to unknown decompensation status, 47 due to lab criteria for CP-B/C, and 95 due to prior decompensation). Their age at the start of follow-up after a cirrhosis diagnosis was 57.2 years (SD 11.4), as compared to 60.5 years (SD 11.1) in those excluded (decompensated). The 5-year transplant-free survival of those with compensated cirrhosis was 82% compared to 37% in those who were decompensated (Figure,  $p < 0.001$ ). In patients who are compensated, those with abnormal bilirubin and ALP  $> 1.67 \times$  ULN demonstrated worse transplant-free survival ( $p < 0.001$  and  $p = 0.01$ ), signaling they can also be extended to a compensated cirrhotic population.

**Conclusion:** The transplant-free survival of a compensated cirrhotic population is improved compared to those who are decompensated. The common surrogate end points and associated thresholds for ALP and bilirubin demonstrate utility for risk stratification in a compensated cirrhotic population.

**Survivin inhibition ameliorates liver fibrosis via inducing senescence in hepatic stellate cells**

Sachin Sharma<sup>1</sup>, Shaikh Maryam Ghufra<sup>1</sup>, Sampa Ghose<sup>2</sup>, Chhagan Bihari<sup>3</sup>, Subhrajit Biswas<sup>1</sup>. <sup>1</sup>Amity University, <sup>1</sup>Amity Institute of Molecular Medicine and Stem Cell Research, Noida, Uttar Pradesh, India; <sup>2</sup>All India Institute of Medical Sciences, Department of Medical Oncology, New Delhi, India; <sup>3</sup>Institute of Liver and Biliary Sciences, Department of Pathology, New Delhi, India  
Email: sachin.research@hotmail.com

**Background and aims:** Hepatic fibrosis is a wound healing response of liver during hepatic injury, characterized by activation of hepatic stellate cells (HSCs) and accumulation of extracellular matrix (ECM) proteins. The anti-apoptotic survivin is one of the regulatory factors that promotes cell division in proliferative activated HSCs. There was some clinical benefit shown in cancer by inhibiting survivin but unexplored in liver fibrosis. During fibrosis resolution, the activated HSCs converted to a less proliferative and deactivated senescence stage. In this study, we have targeted survivin protein to limit the fibrogenic activation of HSCs to ameliorate liver fibrosis.

**Method:** Here we targeted survivin expression through survivin inhibitor YM155 and siRNA-mediated knockdown in HSCs *in vitro*. Male Balb/c mice were treated with CCl<sub>4</sub> twice/week by *i.p.* injections for 6 weeks, followed by treatment with 10 mg/kg of survivin inhibitor YM155. We have analysed the ALT and AST level of mice serum to check liver injury. And sirius red, HandE and senescence-associated beta-galactosidase (SA-beta-gal) staining of liver section along with flow cytometry-based cell cycle assays were performed to

understand HSCs activation. Expression of survivin, αSMA, collagen, Ki67, p53 and p21 were examined through qPCR, western blots, immunohistochemistry and immunofluorescence.

**Results:** CCl<sub>4</sub> induced fibrotic liver shown increased survivin, collagen I and αSMA expression in peri-portal region. SA-beta-gal assay shown increased number of senescent cells in the peri-portal region. In contrast survivin inhibition in fibrotic liver not only reduced ALT, AST level in mice serum but also decreased αSMA, collagen and other extracellular matrix proteins. siRNA mediated knockdown of survivin in HSCs induced G2/M cell cycle arrest and became multinucleated. Immunohistochemistry and immunofluorescence results showed overexpression of p53 and p21 in HSCs after survivin inhibition. Lower expression of proliferative marker Ki67 and overexpression of SA-beta-gal in both activated HSCs and fibrotic peri-portal region with YM155 treatment confirmed senescence mediated deactivation of HSCs and regression of fibrosis *in vivo*.

**Conclusion:** Targeting the overexpressed survivin in activated HSCs decreased its fibrogenic activation and induced senescence that ameliorates liver fibrosis.

**Precision-cut liver slices as a dynamic tool to model liver fibrosis in vitro**

Liza Dewyse<sup>1</sup>, Vincent De Smet<sup>1</sup>, Hendrik Reynaert<sup>2</sup>, Leo A. van Grunsven<sup>1</sup>. <sup>1</sup>Vrije Universiteit Brussel, Liver Cell Biology Research Group, Belgium; <sup>2</sup>University Hospital Brussels (UZBrussel), Gastroenterology and Hepatology  
Email: liza.dewyse@vub.be

**Background and aims:** Chronic liver disease, including liver fibrosis, accounts for two million deaths worldwide each year. Besides causal treatments, which can slow down fibrosis progression, no anti-fibrotic liver therapies are currently available, mainly due to the lack of robust and representative *in vitro* models. The most representative

Figure: (abstract: PO-89)

*in vitro* model of human liver disease could be the use of precision-cut liver slices (PCLS), as these maintain the architecture and microenvironment as found *in vivo*. However, the major drawback of this model is that slice preparation results in cut surfaces, which eventually triggers the induction of spontaneous fibrosis progression in culture, as hepatic stellate cells (HSC) will activate within 96 hours upon slicing. The aim of this study was to establish stable PCLS cultures that allow direct and as well as hepatocyte-damage induced HSC activation in a reciprocal way (induction and inhibition).

**Method:** Human and mouse liver tissues were sliced with a Leica vibrating blade microtome VT1200S. Slices were eventually punched into 3 mm diameter discs (PCLS). PCLS were cultured during a period of 5 days in the presence or absence of valproic acid (VPA). RNAseq analysis was performed on PCLS cultured in the presence or absence of VPA over a time period of 5 days. In the presence of VPA, PCLS were exposed on day 3 for 48 hours to a direct trigger of 10 ng/ml TGFβ or an indirect trigger of 20 mM acetaminophen (APAP), a known hepatotoxic compound.

**Results:** In this study, we established stable mouse and human PCLS culture conditions demonstrating sustained viability, sustained albumin protein expression and low levels of culture-induced fibrosis for at least 5 days by the addition of VPA to the culture medium. More insight into the mechanisms by which VPA inhibits this PCLS culture-induced fibrosis will be obtained by the RNAseq analysis. Direct HSC activation could be induced by treatment with TGFβ, which could be blocked by simultaneous exposure to an Alk5 inhibitor. Hepatocyte-damage dependent HSC activation was established in mouse PCLS by the exposure of APAP. This HSC activation could be blocked by N-acetylcysteine, a compound used in the clinic to treat acetaminophen overdose or verteporfin, a YAP inhibitor. HSC activation and fibrosis induction by both compounds could be confirmed on both transcriptional and translational level.

**Conclusion:** The obtained results demonstrate the potential of both human and mouse PCLS as a reliable model to mimic inducible liver fibrosis. In the future, this model allows to perform mechanistic studies and offers the opportunity to model other chronic human liver diseases, such as non-alcoholic fatty liver disease or cholestasis.

**PO-410**

**The inhibition of the YAP-1/CTGF pathway improves chronic biliary fibrosis in the Abcb4<sup>-/-</sup> model by modulation of hepatic stellate cell physiology**

Liangtao Ye<sup>1,2,3</sup>, Andreas Ziesch<sup>2,3</sup>, Andrea Ofner<sup>2,3</sup>, Tobias Simon Schiergens<sup>4</sup>, Gerald Denk<sup>2,3</sup>, Najib Ben Khaled<sup>2,3</sup>, Simon Hohenester<sup>2,3</sup>, Mayr Doris<sup>5</sup>, Ujjwal M. Email: liangtao.ye@med.uni-muenchen.de

**Background and aims:** No effective medical treatment for primary sclerosing cholangitis (PSC) has yet been established. The yes-associated protein 1 (YAP-1) was shown to be a mediator of fibrosis in different models of liver fibrosis. However, the effect of YAP-1 inhibition as potential treatment of chronic biliary fibrosis has yet to be investigated. We addressed this issue by assessing: i. the expression of YAP-1 in human liver samples with non-biliary fibrosis vs. liver fibrosis in advanced PSC, ii. the function of YAP/connective tissue growth factor (CTGF) in promoting fibrogenesis in human hepatic stellate cell (HSC), and iii. the effects of YAP-1 inhibition in Abcb4<sup>-/-</sup> mice.

**Methods:** Human liver sections were investigated by whole slide analysis after sirius red staining or immunohistochemistry for collagen 1alpha1 (col1alpha1) and alpha-smooth muscle actin (alpha-SMA). Abcb4<sup>-/-</sup> mice were treated with different concentrations of Verteporfin (VP) and Metformin (MF), which were used as YAP-1 inhibitors. Primary human HSC (phHSC) and LX-2 cells were used for *in vitro* study. The biological effects of YAP-1/CTGF silencing by siRNA or of its inhibition by VP and MF were assessed by western blot and collagen contraction assay.

**Results:** Expression of YAP-1 and its downstream target CTGF were significantly higher in fibrotic liver tissues vs. non-fibrotic controls in liver samples from patients with biliary (all advanced PSC) and non-biliary fibrosis (p < 0.05; **A, B**). Treatment with VP and MF caused a significant reduction of liver fibrosis in Abcb4<sup>-/-</sup> mice, as judged by quantitative analysis of sirius red, alpha-SMA and col1alpha1 staining (p < 0.05, **C-F**). This was accompanied by a reduced mRNA expression of YAP-1 (**G**) and CTGF (p < 0.05). The significantly lower alpha-SMA expression indicated a reduced activation of HSC. In phHSC, YAP-1 and CTGF increased upon spontaneous activation when seeded on uncovered plastic indicating its functional role for HSC activation. Silencing of YAP-1 and CTGF inhibited transforming growth factor beta (TGF-beta) induced alpha-SMA, platelet-derived growth factor beta (PDGF-beta) expression (**H**) and the contractility (**I, J**) of LX-2 cells.

**Conclusion:** We conclude that YAP-1 is a checkpoint of fibrogenesis in chronic cholestasis capable of modulating the activation of HSC, and provide evidence of VP and MF as inhibitors of biliary fibrosis. YAP-1 is therefore a potential target for treatment of chronic cholestatic liver diseases such as PSC.

Email: uxiafernandez.paz@usc.es

**Background and aims:** G protein-coupled receptor 55 (GPR55) is a putative cannabinoid receptor, and l-α-lysophosphatidylinositol (LPI) is its only known endogenous ligand. Although GPR55 has been linked to energy homeostasis in different organs, its specific role in lipid metabolism in the liver and its contribution to the pathophysiology of non-alcoholic fatty liver disease (NAFLD) remains unknown.

**Method:** We measured (1) GPR55 expression in the liver of patients with NAFLD compared with individuals without obesity and without liver disease, as well as animal models with steatosis and non-alcoholic steatohepatitis (NASH), and (2) the effects of LPI and genetic disruption of GPR55 in mice, human hepatocytes, and human hepatic stellate cells.

**Results:** Notably, we found that circulating LPI and liver expression of GPR55 were up-regulated in patients with NASH. LPI induced adenosine monophosphate-activated protein kinase activation of acetyl-coenzyme A carboxylase (ACC) and increased lipid content in human hepatocytes and in the liver of treated mice by inducing *de novo* lipogenesis and decreasing β-oxidation. The inhibition of GPR55 and ACCα blocked the effects of LPI, and the *in vivo* knockdown of GPR55 was enough to improve liver damage in mice fed a high-fat diet and in mice fed a methionine-choline-deficient diet. Finally, LPI

POSTER PRESENTATIONS

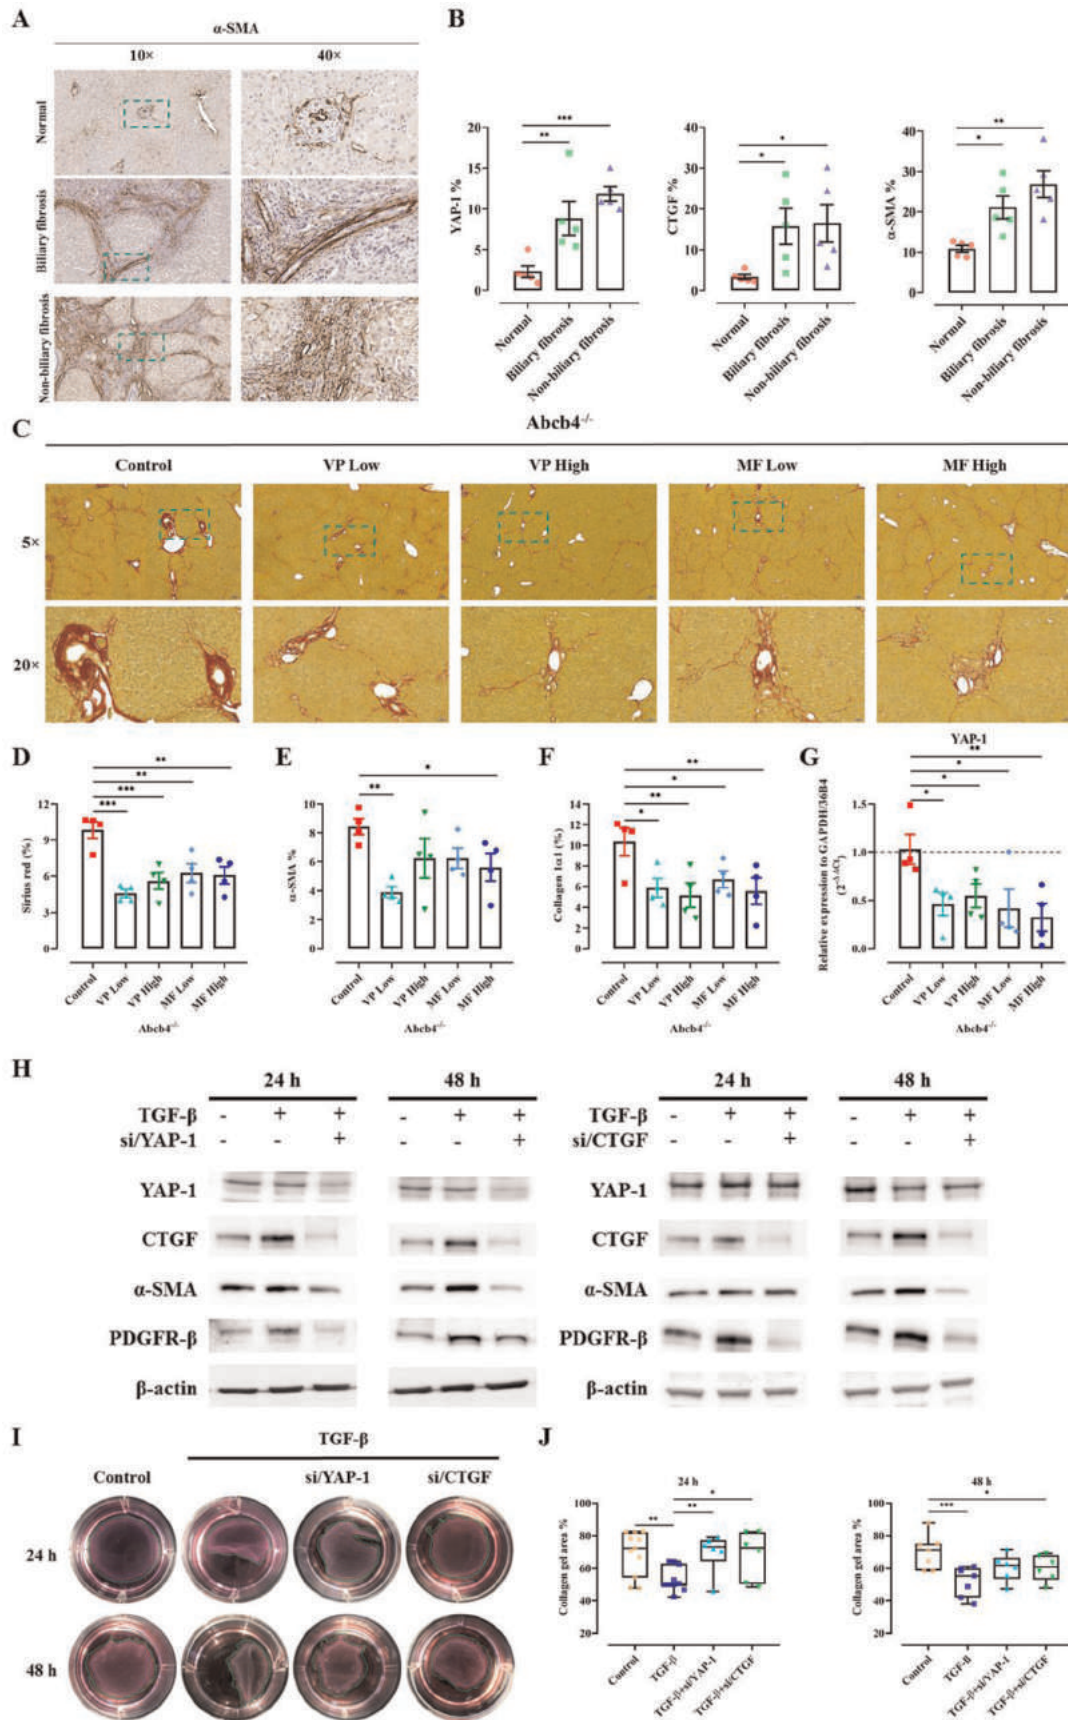

Figure: (abstract: PO-410)

promoted the initiation of hepatic stellate cell activation by stimulating GPR55 and activation of ACC.

Figure:

**Conclusion:** The LPI/GPR55 system plays a role in the development of NAFLD and NASH by activating ACC.

Gonzalez-Rellán<sup>1</sup>, Natalia Lima<sup>1</sup>, Violeta Heras<sup>1</sup>, Begoña Porteiro<sup>1</sup>, Daniel Beiroa<sup>1</sup>, Ana Senra<sup>1</sup>, Susana Bravo<sup>2</sup>, Juan Cuñarro<sup>1</sup>, Sulay Tovar<sup>1</sup>, Maria Luz Martinez-Chantar<sup>3</sup>, Miguel Fidalgo<sup>1</sup>, Guadalupe Sabio<sup>4</sup>, Miguel Marcos<sup>4</sup>, Miguel Lopez<sup>1</sup>, Carlos Dieguez<sup>1</sup>, Rubén Nogueiras<sup>1</sup>. <sup>1</sup>CiMUS, Department of Physiology, University of Santiago de Compostela, Spain; <sup>2</sup>Proteomic Unit, Health Research Institute of Santiago de Compostela (IDIS), Spain; <sup>3</sup>CIC BioGUNE, Spain; <sup>4</sup>Spain  
Email: ruben.nogueiras@usc.es

**Background and aims:** p53 family members control several metabolic and cellular functions. The p53 ortholog p63 controls lipid metabolism in hepatocytes and contributes to the development of liver steatosis. Here, we aimed to explore the potential role of p63 in NASH.

**Method:** We measured the levels of hepatic p63 in (1) patients NASH; (2) a variety of mice models of NASH with fibrosis; (3) human primary hepatic stellate cells (HSCs); (4) human HSCs LX-2. We manipulate the expression of p63 *in vivo* and *in vitro* with either genetic or virogenetic tools.

**Results:** P63 is upregulated in patients with NASH, correlating positively with fibrosis score and collagen 1a1 expression. P63 expression is also increased in different animal models of diet-induced NASH and chemically induced liver fibrosis. Mice with hepatic downregulation of p63 fed a high fat diet or choline deficient and high fat diet (CDHFD) for 52 weeks display reduced collagen deposition, hydroxyproline levels and expression of collagen markers. Similar results were found when these mice were challenged to methionine and choline deficient diet. Consistent with this, the hepatic overexpression of TAp63 $\alpha$  isoform accelerates the fibrosis induced by CDHFD.

**Conclusion:** Our findings indicate an unexpected role of p63 in the metabolic and profibrotic actions in liver disease.

**PO-567**

**B-cell-mediated fibrogenesis in non-alcoholic steatohepatitis**

Anja Moncsek<sup>1</sup>, Cheuk Ting Wu<sup>1</sup>, Joachim C. Mertens<sup>1</sup>. <sup>1</sup>University Hospital Zürich, Gastroenterology and Hepatology, Zürich, Switzerland  
Email: anja.moncsek@usz.ch

**Background and aims:** Non-alcoholic steatohepatitis (NASH) is characterized by steatosis, inflammation and hepatocellular injury with different degrees of fibrosis. The hepatic inflammatory response is the major driving force for disease progression, as it promotes liver fibrogenesis, which can ultimately lead to cirrhosis and hepatocellular carcinoma.

In NASH mice, the B cell response involves upregulation of B cell-activating factor (BAFF) in the liver, which drives B cell survival and maturation. In addition, BAFF inhibition and B cell depletion has been shown to ameliorate fibrosis in mice.

A pro-fibrogenic role of B cells has been suggested to involve the production of pro-inflammatory factors that stimulate hepatic stellate cells (liver resident fibroblasts) and liver macrophages but the molecular mechanism remains elusive. Therefore, we wanted to investigate the profibrotic role of B cells in NASH in detail.

**Method:** 10-week-old C57BL/6J mice were fed a fat-, fructose- and cholesterol-enriched (FFC) diet for up to 40 weeks. To explore intrahepatic immune cells, multiplex flow cytometry and immunofluorescence staining were performed. In addition, hepatic B cells were isolated via immunomagnetic separation and characterized in terms of expression and secretion of pro-fibrotic factors and chemoattractant using quantitative PCR and immune assays, respectively. Furthermore, co-culture studies were employed to analyze and modulate the potential of NASH-related B cells to activate fibroblasts *in vitro*.

**Results:** FACS analysis of intrahepatic immune cells and immunofluorescence staining of liver sections revealed that B cell abundance in NASH mice liver is not significantly increased. However, B cells locate in direct proximity to stromal cells allowing for direct cell-cell interaction.

As expected, mRNA analysis of liver tissue demonstrated and upregulation of BAFF in 40-week-old NASH mice compared to mice receiving standard chow.

Analysis of isolated hepatic B cells showed an increase in *Tgfb* and specifically *Pdgfb* mRNA in B cells from mice that received FFC diet for 40 weeks. In addition, analysis of chemoattractants revealed an increase of *Ccl4* mRNA in B cells from NASH mice. To confirm these results, ELISA verification is ongoing using cell culture supernatants of isolated B cells.

Preliminary *in vitro* co-culture experiments using 3T3 fibroblasts demonstrated the ability of isolated hepatic B cells to activate fibroblast as shown by increased *Acta2* mRNA expression.

**Conclusion:** B cells seem to be more activated in NASH mice, since FFC-fed mice exhibit enhanced BAFF expression in the liver. In addition, B cells contribute to fibrosis in NASH either directly by stimulating fibroblast activation through secretion of PDGF-B and indirectly by producing chemotactic factors such as CCL4 that recruit additional immune cells with profibrotic activity.

**PO-663**

**Pharmacokinetics, safety, and tolerability of multiple-dose CC-90001, a c-Jun N-terminal kinase (JNK) inhibitor, in healthy Japanese and non-Japanese adults**

Allison Gaudy<sup>1</sup>, Barbara Burkhardt<sup>1</sup>, Jian Chen<sup>1</sup>, Leon Carayannopoulos<sup>1</sup>, Maria Palmisano<sup>1</sup>, Ying Ye<sup>1</sup>. <sup>1</sup>Bristol Myers Squibb, United States  
Email: allison.gaudy@bms.com

**Background and aims:** CC-90001 is a selective inhibitor of c-Jun N-terminal kinase (JNK), a stress-activated protein kinase implicated in the pathogenesis of non-alcoholic steatohepatitis (NASH) and other fibrotic diseases. This Phase 1 study compared the pharmacokinetics

## POSTER PRESENTATIONS

Table: (abstract: PO-663)

CC-90001 Dose	Ratio (%) of Geometric Mean, JPN vs non-JPN (90% CI)			
	AUC <sub>tau</sub>		C <sub>max</sub>	
	Day 1	Day 7	Day 1	Day 7
100 mg	107.0 (87.6, 130.0)	88.9 (71.9, 110.0)	117.0 (96.5, 142.0)	102.0 (79.8, 130.0)
200 mg	108.0 (78.7, 147.0)	84.8 (68.6, 105.0)	107.0 (71.6, 159.0)	103.0 (87.8, 122.0)
400 mg <sup>a</sup>	119.0 (92.8, 152.0)	91.4 (72.7, 115.0)	129.0 (97.6, 170.0)	115.0 (95.2, 138.0)

<sup>a</sup>n = 9 non-JPN on Day 7; CI, confidence interval.

(PK), safety, and tolerability of CC-90001 in healthy Japanese (JPN) participants (ppts) and non-JPN ppts.

**Method:** This was a Phase 1, open-label, randomized, parallel-design study of CC-90001 (100, 200, or 400 mg) administered orally once daily (QD) for 7 days to age- and weight-matched cohorts of JPN and non-JPN adults (NCT03958864). JPN ppts were born in Japan, had not lived outside of Japan for >10 years, and had parents and grandparents of JPN origin. Non-JPN ppts were of European or Latin American descent.

**Results:** Sixty ppts were enrolled and received CC-90001 (10 JPN and 10 non-JPN ppts per dose). The majority of ppts were men (37/60; 62%) and the mean age of the study population was 38 years. On Day 1 and Day 7, similar CC-90001 plasma exposure (AUC<sub>tau</sub>) and peak plasma concentration (C<sub>max</sub>) were observed in JPN and non-JPN ppts at all doses (Table). Overall, 25/60 ppts (42%) reported ≥1 treatment-emergent adverse event (TEAE), and there were no apparent differences in TEAEs experienced by JPN vs non-JPN ppts. All TEAEs were mild (n = 23 ppts) or moderate (n = 2 ppts) in intensity; there were no serious TEAEs or deaths. One ppt (400 mg; non-JPN) discontinued the study on Day 6 due to TEAEs of chest discomfort, arthralgia, headache, dyspnea, and oral hypoesthesia which were all possibly related to CC-90001; all events resolved by the end of the study.

**Conclusion:** Oral administration of 100–400 mg CC-90001 QD for 7 days was generally well-tolerated; similar PK profiles were observed in JPN and non-JPN ppts after single and multiple doses. Phase 2 studies in patients with NASH and advanced fibrosis and idiopathic pulmonary fibrosis are ongoing.

### PO-692

#### HBV-infection induces collagen VI expression by hepatocytes promoting stellate cell-activation and liver fibrosis

Email: joachim.lupberger@unistra.fr

**Background and aims:** Chronic fibrotic liver disease is a major public health burden and represents the main risk factor for hepatocellular carcinoma (HCC) worldwide. Upon chronic liver injury, inflammation, and oxidative stress, stellate cells are activated causing an excessive deposition of collagens ultimately leading to a destruction of the normal liver architecture. The development of novel antifibrotic drug targets and therapies is thus urgently needed but hampered by a lack of understanding of the underlying molecular mechanism.

**Method:** Using hepatitis B virus (HBV) as a model, we analyzed the proteomic and phospho-proteomic changes caused in infected HepG2-NTCP cells using liquid chromatography-mass spectrometry (LC-MS) with tandem mass tag (TMT) labels<sup>1</sup>. Disease-relevant proteomic dysregulation was studied using Gene Set Enrichment

Analysis (GSEA)<sup>2</sup> and validated in primary human hepatocytes (PHH) and by perturbation studies.

**Results:** We demonstrated that HBV infection of hepatocytes significantly modulates signaling pathways involved in the remodeling of extra-cellular matrix (ECM), which we validated on the transcriptomic level in HBV-infected PHHs. A leading-edge gene driving the enrichment was collagen VI being significantly upregulated upon HBV infection in hepatocytes, suggesting a relevance for HBV-associated liver fibrosis. HBV proteins notably induce Akt phosphorylation. By screening the impact of disease-relevant signaling pathways on collagen VI expression, we observed a correlation between a PI3K-Akt transcriptional signature and collagen VI expression in non-tumor liver tissue of HCC patients with HBV. Incubation of stellate cell line LX-2 with collagen VI strongly induced the expression of LX-2 activation markers compared to cells incubated with collagen I, suggesting a regulatory role of collagen VI for liver fibrosis.

**Conclusion:** Our proteomic and phospho-proteomic analysis of HBV infection highlights new mechanisms for HBV virology and virus-induced liver disease progression. HBV proteins induce Akt signaling and therefore highlight a role for Akt signaling and collagen VI in the dynamics of liver disease progression also potentially relevant for other disease etiologies stimulating PI3 K/Akt signaling. Collagen VI-relevant signaling pathways in hepatocytes may thus serve as potential antifibrotic drug targets in the liver.

#### Pharmacokinetics, safety, and tolerability of CC-90001, a c-Jun N-terminal kinase (JNK) inhibitor, in participants with hepatic impairment

Kofi A Mensah<sup>1</sup>, Allison Gaudy<sup>1</sup>, Melissa Araujo<sup>1</sup>, Liangang Liu<sup>1</sup>, Francisco Ramirez-Valle<sup>1</sup>, Maria Palmisano<sup>1</sup>, Ying Ye<sup>1</sup>. <sup>1</sup>Bristol Myers Squibb, United States

Email: Kofi.Mensah@bms.com

**Background and aims:** CC-90001 is a selective inhibitor of c-Jun N-terminal kinase (JNK), a stress-activated protein kinase implicated in the pathogenesis of non-alcoholic steatohepatitis (NASH) and other fibrotic diseases. This Phase 1 study compared the pharmacokinetics (PK), safety, and tolerability of CC-90001 in participants (ppts) with hepatic impairment (HI) with normal-matched adults.

**Method:** This was an open-label, multicenter, parallel-design study (NCT03742882). Ppts with HI were grouped into cohorts of 8 by Child-Pugh score (mild [5–6], moderate [7–9], or severe [10–13]). Two cohorts each of 8 ppts with normal hepatic function were sex-, age-, and weight-matched to ppts with moderate and severe HI. All ppts received 1 oral dose of 200 mg CC-90001 on Day 1. Blood samples were collected on Days 1–7 to assess PK end points, which were compared across arms by ANOVA. Safety was monitored throughout the study and was reviewed for ppts with mild and moderate HI prior to dosing ppts with severe HI.

**Results:** Forty ppts were enrolled and received CC-90001; 1 ppt with mild HI discontinued at Day 6 for personal reasons but was included in all analyses. Most ppts were men (26/40, 65%), mean age was 58 years, and mean BMI was 29.8 kg/m<sup>2</sup>. Compared with normal-matched ppts, after a single dose of CC-90001, ratios of geometric mean exposure (AUC<sub>0-t</sub>) were similar in ppts with mild or moderate HI, but higher in ppts with severe HI (Table). Ratios of geometric mean peak concentration (C<sub>max</sub>) were similar to normal-matched ppts regardless of HI. Median T<sub>max</sub> was delayed in ppts with moderate or severe HI relative to normal-matched ppts. Treatment-emergent adverse events (TEAEs) were reported by 6/40 ppts (15%) and were of mild (5/6 ppts) or moderate (1/6 ppts) intensity. There was no apparent relationship between TEAE incidence and HI. No ppts with severe HI had CC-90001-related TEAEs.

Degree of HI	Ratio (%) of Geometric Mean, HI vs Normal-Matched (90% CI)	
	AUC <sub>0-t</sub>	C <sub>max</sub>
Mild	71.90 (57.86, 89.35)	100.68 (77.06, 131.54)
Moderate	92.77 (74.81, 115.05)	88.42 (67.43, 115.93)
Severe	160.51 (115.16, 223.72)	117.77 (75.56, 183.56)

CI, confidence interval.

**Conclusion:** Mild to moderate HI had a minimal effect on CC-90001 AUC<sub>0-t</sub> compared with normal-matched ppts. Severe HI modestly increased CC-90001 AUC<sub>0-t</sub> but C<sub>max</sub> was unchanged. CC-90001 was generally well tolerated. Phase 2 studies in patients with NASH and advanced fibrosis and in patients with idiopathic pulmonary fibrosis are ongoing.

 Email: manuel.winkler@medma.uni-heidelberg.de

**Background and aims:** Organ-specific microvascular endothelial cells (EC) actively regulate their tissue microenvironment through various paracrine acting signaling molecules, so called angiocrine factors. In the liver, the microvasculature is formed by discontinuous liver sinusoidal ECs (LSEC). LSEC are known to contribute to a variety of processes in liver development, health and disease. The transcription factor GATA4 acts as master regulator of LSEC specification during liver development. Herein, we studied the role of GATA4 in LSEC during adult liver homeostasis.

**Method:** We conditionally deleted GATA4 in LSEC using the EC subtype-specific Clec4g-iCre driver mouse with late-embryonic endothelial Cre-activity in LSEC. Murine livers were examined by histology, electron microscopy, immunohistochemistry/-fluorescence and in-situ hybridization. LSECs were isolated and supplied to gene expression profiling, CHIP- and ATAC-sequencing. Liver regeneration was investigated by partial hepatectomy and perisinusoidal liver fibrosis by choline-deficient l-amino acid-defined (CDAA) diet. Furthermore, we compared transcriptomic data from Gata4-deficient LSEC with single cell RNA-sequencing data of EC from healthy and cirrhotic human livers.

**Results:** LSEC-restricted deletion of Gata4 in mice caused transformation from discontinuous liver sinusoids into continuous capillaries including the formation of a continuous basement membrane. These mice developed a perisinusoidal liver fibrosis with collagen depositions in the space of Disse. In LSEC, increased chromatin accessibility and upregulation of several fibrosis-associated genes were detected including de novo expression of profibrotic angiocrine signaling molecules such as the hepatic stellate cell activating cytokine PDGFB. Transcription factor MYC was found to act in a counter-regulatory manner to GATA4. Moreover, impaired angiocrine Wnt signaling disturbed metabolic liver zonation. In CDAA diet-induced perisinusoidal liver fibrosis, LSEC showed repression of GATA4, activation of MYC and a similar profibrotic angiocrine switch. In human cirrhotic livers, GATA4-positive LSEC and endothelial GATA4 target genes were reduced, while non-LSEC endothelial cells and MYC target genes including PDGFB were enriched.

**Conclusion:** GATA4-deficiency in LSEC causes angiocrine-mediated liver fibrosis. Thus, primary LSEC dysfunction is a key driver and the GATA4/MYC/PDGFB axis is a potential target for prevention and treatment of liver fibrosis.

**Therapeutic targeting of integrin alpha v beta 1 in liver fibrosis**

Emma Shepherd<sup>1</sup>, Deepika Balakrishna<sup>2</sup>, Ellie Northall<sup>3</sup>, Mark Sabat<sup>4</sup>, Daniel Carney<sup>4</sup>, Ron de Jong<sup>5</sup>, Hiroaki Yashiro<sup>6</sup>, Derek Erion<sup>6</sup>, Rohan Manohar<sup>6</sup>, Patricia Lalor<sup>3</sup>. <sup>1</sup>Centre for Liver and Gastroenterology Research, Institute of Immunology and Immunotherapy, Birmingham, United Kingdom; <sup>2</sup>Takeda Pharmaceuticals, Biological Sciences, Gastroenterology Drug Discovery Unit, San Diego, United States; <sup>3</sup>Centre for Liver and Gastroenterology Research, Institute of Immunology and Immunotherapy, Birmingham; <sup>4</sup>Takeda Pharmaceuticals, Medicinal Chemistry, Gastroenterology Drug Discovery Unit, San Diego, United States; <sup>5</sup>Ron de Jong Consulting, LLC, San Diego, United States; <sup>6</sup>Takeda Pharmaceuticals, Gastroenterology Drug Discovery Unit, Cambridge, United States  
 Email: e.l.shepherd@bham.ac.uk

**Background and aims:** Inhibition of TGF-β is a promising therapeutic approach to reduce organ fibrosis but is associated with safety liabilities. Arg-Glu-Asp (RGD) integrins are known to be the principal mediators of TGF-β activation in chronic fibrosis, and integrin inhibition allows for localized and therapeutically safe inhibition of TGF-β. Of the many integrin heterodimers, more than half contain either alphaV or beta1. Recent data suggest that the RGD integrin alphaVbeta1 plays a role in liver fibrosis but there remains limited data for alphaVbeta1 (αVβ1) inhibition in human NASH tissue and preclinical NASH models. The aim of this study was to investigate the

<sup>n</sup>n = 9 non-JPN on Day 7; CI, confidence interval.

## POSTER PRESENTATIONS

effect of 2 aVb1 inhibitory small molecules in human NASH tissue and a diet induced preclinical NASH model.

**Method:** Expression of aVb1 heterodimers and phosphorylation of SMAD3 (pSMAD3) by Meso Scale Discovery (MSD) analysis. Adhesion to LAP was measured by xCELLigence impedance assay and adhesion assays. The effect of aVb1 inhibition *in vivo* was assessed in rats fed a Choline Deficient High Fat Diet (CDHFD) by MSD, qRT-PCR and histology. Effects of aVb1 inhibitors in perfused donor and cirrhotic human liver wedges was assessed by histology and qRT-PCR.

**Results:** We report that aVb1 integrin expression is up regulated in cirrhotic NASH tissue and was expressed on human hepatic stellate cells (HSCs) at higher levels than other primary liver cells. *In vitro* pharmacological inhibition of aVb1 resulted in decreased pSMAD3 in an overexpressing cell line, and abrogated human HSC binding to LAP but did not affect binding to other extracellular matrix ligands including fibronectin. Inhibition of aVb1 *in vivo* in CDHFD fed rats reduced pSMAD3, fibrogenic gene expression and histological liver fibrosis. Finally, perfusion of human liver wedges with an aVb1 inhibitor resulted in decreased integrin expression and gene expression associated with fibrosis (for e.g., LOX, Col1A1, TGF- $\beta$ 1, PGDFRb, TIMP1 and CTGF).

**Conclusion:** In this study we have shown that 2 aVb1 inhibitors caused ligand-specific blockade of HSC function *in vitro* and reduced liver fibrosis *in vivo*. Importantly, our data demonstrate that these inhibitors can be delivered to cirrhotic human liver tissue *ex vivo* and still mediate phenotype regulation. Taken together, these data suggest that integrin inhibition in the context of chronic human fibrosis may be beneficial as a therapeutic strategy.

### PO-1069

**The AST/ALT ratio: a second line component of the hepatic fibrosis screening by FIB-4 calculated automatically in 131, 861 subjects**

Denis Ouzan<sup>1</sup>, Corneille Jeremie<sup>2</sup>, Guillaume Penaranda<sup>3</sup>, Fino Antony<sup>4</sup>, Dubertrand Jean Marie<sup>4</sup>. <sup>1</sup>Institut Arnauld Tzanck, Hepatology, Saint-Laurent-du Var, France; <sup>2</sup>Laboratoire Bioesterel Biogroup, Mougins; <sup>3</sup>Laboratoire Alphabio Européen, Marseille, France; <sup>4</sup>Laboratoire Bioesterel Biogroup, Mandelieu  
Email: denis.ouzan@wanadoo.fr

**Background and aims:** Screening for hepatic fibrosis in the general population is a major public health issue. We have shown in a previous study (EASL 2020 FRI225) that Fib-4, a simple score combining age, measurement of ALAT/ASAT activity and platelet count made it possible to detect hepatic fibrosis in the general population and to find a possible cause of liver disease. In a study presented at the EASL 2020 (Yeoman A et al, EASL 2020, Abs. GS08) on 17, 700 patients with elevated ALAT, an AST/ALT ratio >1 was found in 12% of cases and showed severe fibrosis or cirrhosis on Fibrosan in 28 and 29% of cases, respectively.

**Method:** FIB-4 was calculated in an automated way since the 1 October 2020 in a group of 80 medical analysis laboratories of the French Alpes Maritimes area in all the subjects who benefited from a platelet and AST/ALT assay, i.e., in 131, 861 subjects during the last 3 months of 2020. The results of Fib 4, which express the risk of fibrosis are reported according to age: low risk if <1.30 (<65 years) and <2 (>65 years), intermediate risk if between 1.3 and 2.67 (<65 years), and if between 2 and 2.67 (>65 years), and high risk if >2.67 regardless of age. The AST/ALT ratio was calculated in all patients with high ALT.

**Results:** Among the 131 861 subjects, half were over 65 years of age, 56% were women and 44% men. ALT elevation was found in 12 472 of them (9.5%). The distribution of Fib-4 test according to age was as follows: low risk 107, 148 (81.3%), intermediate risk 16, 297 (12.4%), high risk 8, 416 (6.4%). The rate of high risk of fibrosis was higher in subjects >65 compared to subjects <65 years of age: 10.9% and 1.8%,

and higher in subjects whose prescribing physician was a gastroenterologist compared to general practitioners: 10.9% and 4.8%,  $p < 0.0001$ , respectively. An AST/ALT > 1 ratio was observed among 8.5% of the 12 472 subjects with elevated ALAT. Among subjects with elevated ALAT, the percentage of subjects with an AST/ALT ratio >1 was 67.3% for Fib-4 high risk, 25.1% for Fib-4 intermediate risk, and 7.6% for low-risk liver fibrosis by FIB-4 ( $p < 0.001$ ). 20% of subjects at high risk of fibrosis (FIB4 > 2.67) had an elevated ALT with an AST/ALT > 1 ratio in 8.5% of them. FIB 4 score was >1.3 (<65)/2 (>65 years) in 32% of patients with elevated ALT.

**Conclusion:** The AST/ALT ratio that is part of the FIB4 calculation appears to be a second-line component that may, in subjects with elevated ALAT, reinforce the risk of fibrosis as defined by FIB4 automatically assessed during biological analysis under the condition that transaminases and platelets count analysis are prescribed. The high-risk of fibrosis in subjects with FIB4 > 2.67 is reinforced.

### PO-1125

**Using the Enhanced Liver Fibrosis test in Primary Care: A practical pathway to prioritise patients with fibrosis in Fatty Liver Disease**

Alexander Hinkson<sup>1</sup>, Jo Ann Wong<sup>1</sup>, Timothy Canter<sup>1</sup>, Elaine Ong<sup>1</sup>, Ian Rowe<sup>1</sup>, Paul Glynn<sup>2</sup>, Rebecca L. Jones<sup>1</sup>, Richard Parker<sup>1</sup>. <sup>1</sup>St James's University Hospital, Leeds Liver Unit, Leeds, United Kingdom; <sup>2</sup>Lingwell Croft Surgery, Leeds, United Kingdom  
Email: alex.hinkson@doctors.org.uk

**Background and aims:** Non-alcoholic fatty liver disease (NAFLD) and Alcohol-related liver disease (ALD) are the most common causes of chronic liver disease in the UK. A minority of patients who have significant hepatic fibrosis will experience adverse health outcomes due to liver disease. There is a need to effectively triage patients with or without hepatic fibrosis to appropriate services. We assessed the use of the Enhanced Liver Fibrosis (ELF) score in primary care to stratify patients' risk of fibrosis to guide referrals to secondary care.

**Method:** Patients with suspected NAFLD or ALD in three primary care practices in Leeds underwent ELF testing to guide referral to a Community Hepatology Clinic (CHEP). Patients with ELF < 9.5 (based on analysis of local data) were deemed at low risk of significant fibrosis and not referred to secondary care. Patients with ELF > 9.5 were referred for transient elastography (TE) and a CHEP clinic review. Comparison was made with referrals from local primary care practices in Leeds, who did not have access to ELF testing. Cost analysis was performed by summing the costs of blood tests including ELF, TE, and clinic reviews for all patients with available data-478 patients on CHEP pathway and 292 patients referred directly.

**Results:** In total 882 patients were referred on the CHEP pathway, of which 838 had an ELF test. ELF was <9.5 in 464 (55.4%) of patients. Of the 269 patients with ELF > 9.5, 225 (51%) had a TE < 15 kPa and 44 (10%) patients had a TE > 15 kPa. Of the 169 patients with ELF < 9.5 and a subsequent TE, only three (0.7%) had stiffness > 15 kPa and one had fibrosis > F2. Per patient costs were lower in the CHEP pathway (Table).

Referral type	CHEP pathway	Standard referral
Diagnosis		
NAFLD	65.1%	57.1%
ALD	32.0%	28.6%
Other		
Liver stiffness by transient elastography (kPa)		
<9.5	73.8%	60.4%
8–15	26.0%	18.5%
≥15	11.8%	17.1%
Biopsy	7.3%	6.8%
Discharged after clinic	53.3%	9.6%
Cost per patient	£251.73	£354.76

**Conclusion:** Most patients assessed had ELF score <9.5 and were effectively screened out with low risk of fibrosis, preventing unnecessary referral to secondary care. In patients with raised ELF and low TE, further investigations consistently revealed low levels of fibrosis. The CHEP pathway enabled many more patients to be screened for significant liver disease in primary care, reducing referrals of low-risk patients and with a substantial cost saving per patient.

**PO-1441**  
**Characterization and study of hepatic stellate cells in a 3D bioengineered model of fibrosis**

Sara Campinoti<sup>1</sup>, Omolola Ajayi<sup>1</sup>, Sveva Fagiolino<sup>1,2</sup>, Lorenzo Cacioli<sup>1</sup>, Lai Wei<sup>1,2</sup>, Dipa Natarajan<sup>1</sup>, Shilpa Chokshi<sup>1,2</sup>, Luca Urbani<sup>1,2</sup>. <sup>1</sup>Institute of Hepatology London; <sup>2</sup>King's College London, Faculty of Life Sciences and Medicine  
 Email: sveva.fagiolino@kcl.ac.uk

**Background and aims:** Chronic liver disease (CLD) poses a significant health burden world-wide. Its progression is characterized by chronic injury, inflammation, and fibrosis brought by an excess accumulation of extracellular matrix (ECM) by activated hepatic stellate cells (HSCs). Several aspects of the molecular mechanisms underlying this chronic inflammation remain poorly understood, mainly due to the inability of conventional cell culture models to mimic the in vivo microenvironment.

Our project aims at using 3D bioreactor-based bioengineered systems as a tool to examine the crosstalk between hepatic cells and ECM in CLD.

**Method:** Human HSCs were isolated from total and partial hepatectomy. 3D-culture systems were generated by combining decellularized human liver ECM-scaffolds with seeded HSCs. 3D cultures were maintained using a custom-made confined-perfusion bioreactor (Figure).

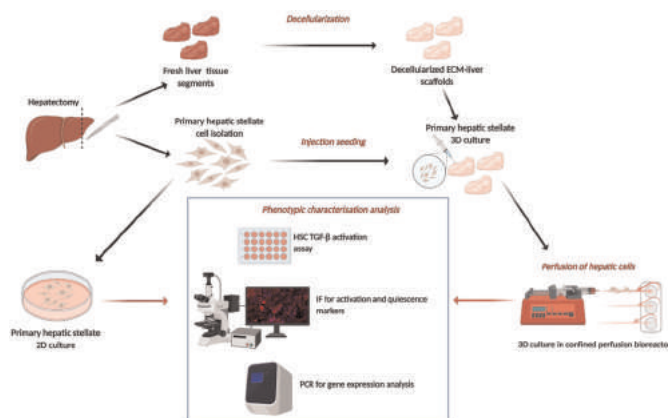

Figure:

Using immunostaining and gene expression analysis we provided a phenotypic analysis of the different cell subsets, quantified HSC activation and analysed ECM deposition.

**Results:** We successfully isolated human HSCs and provided an in-depth cell characterization in comparison with commercially available HSC lines. Primary HSC activation and ECM production was achieved in 2D and within the 3D constructs in confined perfusion bioreactors. However, we described consistent differences between HSC cell lines, highlighting that isolation and culture methods can have an impact in cell's phenotype and activation. Furthermore, culture of HSCs in 3D ECM-scaffolds with low stiffness reduced cell activation in comparison to standard 2D culture activation assays.

**Conclusion:** The confined perfusion bioreactor supported the culture of liver constructs populated with primary human stellate cells, generating a 3D model which reflects better liver pathogenesis than standard 2D cultures. Our 3D bioengineered model could host the co-culture of different liver cell types, representing a useful tool to investigate the liver microenvironment in CLD.

**PO-1505**  
**Fibrosis Biomarkers CA15-3 and Thrombospondin-2 are Associated with Higher Hepatic Collagen Content in Non-alcoholic Steatohepatitis (NASH)-related Fibrosis**

Sean Felix<sup>1,2</sup>, James M. Estep<sup>1</sup>, Aybike Biredinc<sup>1</sup>, Fanny Monge<sup>2</sup>, Lakshmi Alaparthi<sup>2</sup>, Maria Stepanova<sup>1,2</sup>, Brian Lam<sup>1,2</sup>, Bijal Rajput<sup>1</sup>, Pegah Golabi<sup>1,2</sup>, Thomas Jeffers<sup>1,2</sup>, Samuel Hellings<sup>3</sup>, Elizabeth Brown<sup>3</sup>, Thomas Spires<sup>3</sup>, Melissa Yarde<sup>3</sup>, Yi Luo<sup>3</sup>, Anthony Sanfiz<sup>3</sup>, John Thompson<sup>3</sup>, Mary Ellen Cvjic<sup>3</sup>, Edgar Charles<sup>3</sup>, Lei Zhao<sup>3</sup>, David Gordon<sup>3</sup>, Azza Karrar<sup>1</sup>, Albert Tan<sup>2</sup>, Hala Abdelaal<sup>2</sup>, Fatema Nader<sup>4</sup>, Zachary Goodman<sup>1,2</sup>, Zobair Younossi<sup>1,2,5</sup>. <sup>1</sup>Beatty Liver and Obesity Research Program, Inova Health System, Department of Medicine, Falls Church, United States; <sup>2</sup>Centers for Liver Disease, Inova Fairfax Medical Campus, Department of Medicine, Falls Church, United States; <sup>3</sup>Bristol Myers Squibb, Princeton, United States; <sup>4</sup>Centers for Outcomes Research in Liver Diseases, Washington, DC, United States; <sup>5</sup>Falls Church, United States  
 Email: abirerdi@gmail.com

**Background and aims:** Hepatic fibrosis in NASH is partially determined by dynamic equilibrium between fibrogenesis and fibrolysis; which can be measured, in part, by circulating biomarkers. Our aim is to investigate the changes in serum extracellular matrix (ECM) and fibrosis biomarkers in relation to hepatic collagen content in patients with NAFLD.

**Method:** Baseline serum and clinical data were available for patients with NAFLD. ECM proteins (C3M, C5M, C6M, PRO-C3, PRO-C5 and PRO-C6) were measured in serum using ELISA with another 50 fibrosis biomarkers measured by Luminex-based assays. Liver biopsies were read by a study pathologist and hepatic collagen was quantified using Computer Assisted Morphometry (CAM) following the acquisition of digitalized images of Sirius-Red stained slides using an Aperio Scanscope XT scanner. Aperio's positive pixel count algorithm was used to quantify % collagen. Values for % collagen were grouped into upper quartile (Q4 >4.0% n = 35) and below median quartile (Q1 ≤ 2.0%, n = 72). Multivariate analysis was used to identify changes in biomarkers concentrations that were independently associated with % collagen as quantified by CAM.

**Results:** We included 150 patients with NAFLD [100 NASH, 33% male, 71% white, 44% type 2 diabetes, 34% advanced fibrosis (≥F3)]. Univariate analysis revealed that subjects with the highest quartile (Q4) of collagen had significant differential concentrations in a number of important remodeling proteins (Figure) (p < 0.05). PRO-C3 positively correlated with collagen deposition (rho (p) = 0.2, p = 0.01). In multivariate model, higher levels of CA15-3 and Thrombospondin-2 were independently associated with higher % hepatic collagen (OR: 1.074 (CI: 1.001–1.15), p = 0.04], and OR: 1.14 (CI: 1.056–1.23), p < 0.0001, respectively).

## POSTER PRESENTATIONS

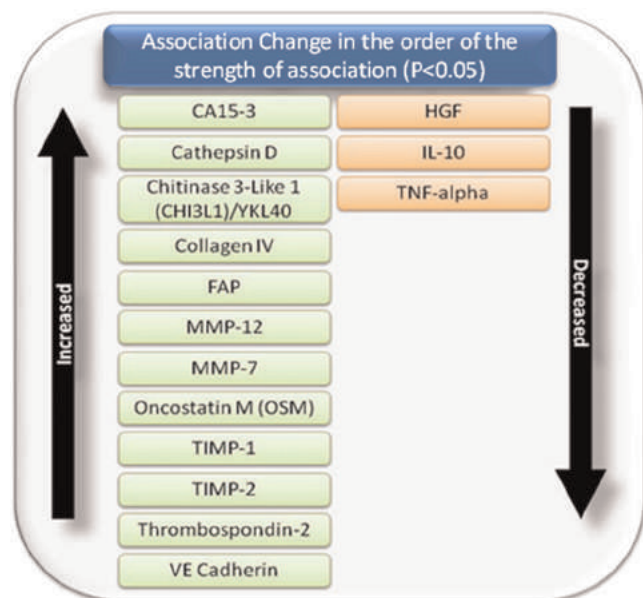

Figure:

**Conclusion:** CA15-3 (also known as MUC1 or epithelial membrane antigen), and Thrombospondin-2 are associated with higher hepatic collagen in patients with NAFLD. CA15-3 reflects extracellular matrix deposition and collagen remodeling while Thrombospondin-2 mediates cell-to-cell and cell-to-matrix interactions. Our findings highlight the potential role of CA15-3 and Thrombospondin-2 in quantifying ECM remodelling in NASH-related liver fibrosis.

### PO-1579

#### Chinese traditional medicine Yiqi Huoxue recipe attenuates hepatic fibrosis via the YAP/TAZ signaling

Wen Zhao<sup>1,1</sup>, Dandan Zhao<sup>1</sup>, Lu Li<sup>1</sup>, Yuemin Nan<sup>1</sup>. <sup>1</sup>Third Hospital of Hebei Medical University, Traditional and Western Medical Hepatology, Shijiazhuang, China

Email: nanyuemin@163.com

**Background and aims:** Chinese traditional medicine Yiqi Huoxue (YQHX) has been shown to attenuate liver fibrosis in animal and human studies. Yet, the exact molecular mechanisms underlying its anti-fibrotic activity remain to be elucidated. Recently, the YES-associated protein (YAP)/transcriptional co-activator with PDZ-binding motif (TAZ) signaling has been implicated in the pathogenesis of liver fibrogenesis. The aim of the present study was to investigate whether the YAP/TAZ signaling is involved in the therapeutic effect of YQHX on hepatic fibrosis in rats and patients with chronic hepatitis B (CHB)-associated liver fibrosis.

**Method:** Wistar rats were used to generate a model of carbon tetrachloride (CCl<sub>4</sub>)-induced liver fibrosis. The experimental rats were randomly divided into three groups: normal control group, hepatic fibrosis model group, and YQHX treatment group. CHB patients with significant liver fibrosis were enrolled and assigned to receive nucleoside/nucleotide analogues (NAs) or NAs plus YQHX in combination. Histological analysis was performed in liver tissue sections of each group. Immunohistochemistry (IHC), real-time qRT-PCR, and Western blot (WB) were conducted to examine effects of YQHX treatment on liver fibrosis markers and key molecules in the TGF- $\beta$ /Smad pathway, and YAP/TAZ signaling. The plasma YAP levels in CHB patients and healthy controls were measured by the enzyme-linked immunosorbent assay (ELISA).

**Results:** YQHX treatment markedly alleviated the morphological alterations in CCl<sub>4</sub>-induced liver fibrosis in rats, and resulted in significant decreases in mRNA and protein levels of hepatic fibrosis markers, including Col I and  $\alpha$ -SMA in the YQHX treatment group versus the model group. Furthermore, YQHX treatment significantly suppressed the CCl<sub>4</sub>-mediated activation of the TGF- $\beta$ /Smad pathway in rats. Notably, CCl<sub>4</sub> induced up-regulation of YAP, TAZ, and CTGF in the model group, which were significantly abrogated by YQHX in the YQHX treatment group in rats. In consistency with the major findings in rats, CHB patients treated with NAs and YQHX in combination achieved significantly higher percentage of improvement in liver fibrosis than those given NAs alone (71.1% vs. 28.6%;  $p=0.057$ ). In addition, hepatic and plasma YAP levels were significantly decreased in response to YQHX treatment in CHB patients with liver fibrosis.

**Conclusion:** This study has demonstrated that YQHX treatment attenuates liver fibrosis in rats and CHB patients and that YQHX may exert its anti-fibrotic activity through inhibiting the YAP/TAZ signaling. As such, the findings may help better understanding the mechanisms for YQHX in the treatment of liver fibrosis.

### PO-1580

#### Prospective screening of significant liver fibrosis in a large cohort of 131, 861 French subjects using, since October 2020, automatic calculation of FIB-4 in routine blood tests.

Denis Ouzan<sup>1</sup>, Corneille Jeremie<sup>2</sup>, Guillaume Penaranda<sup>3</sup>, Fino Antony<sup>4</sup>, Dubertrand Jean Marie<sup>5</sup>. <sup>1</sup>Institut Arnault Tzanck, Hepatology, Saint-Laurent-du-Var, France; <sup>2</sup>Laboratoire Bioesterel; <sup>3</sup>Laboratoire Alfabio Européen, Marseille, France; <sup>4</sup>Laboratoire Bioesterel Mandelieu, Mandelieu, France; <sup>5</sup>Laboratoire Bioesterel Mandelieu, Mandelieu

Email: denis.ouzan@wanadoo.fr

**Background and aims:** Screening for hepatic fibrosis in the general population is a major public health issue. We have shown in a previous study (EASL 2020, Abs FRI225) that FIB-4, a simple score combining age, measurement of ALT/AST activity and platelets count made it possible to detect hepatic fibrosis in the general population and to find a possible cause of liver disease.

**Method:** FIB-4 was calculated in an automated way since October 2020 in a group of 80 clinical laboratories of the French Alpes Maritimes area, in all the subjects who benefited from a platelets and AST/ALT assays. The results of FIB-4, which express the risk of fibrosis, are reported according to age: no risk if <1.30 (<65 years old) and <2 (>65 years old), low risk if between 1.3 and 2.67 (<65 years old) and if between 2 and 2.67 (>65 years old), and high risk if >2.67 regardless of age. ELF score was secondary calculated in a subgroup of 183 patients.

**Results:** During the 3 last months of year 2020, 131, 861 subjects were screened, half were over 65 years old, 56% were women and 44% men. ALT elevation was found in 12, 472 of them (9.5%). The distribution of FIB-4 according to age was as follows: low risk of fibrosis for 107, 148 (81.3%) subjects, intermediate risk of fibrosis for 16, 297 (12.4%) subjects, and high risk of fibrosis for 8, 416 (6.4%) subjects. The rate of high risk of fibrosis was higher in subjects >65 years old compared to subjects <65 years old: 10.9% and 1.8%, and higher in subjects whose prescribing physician was a gastroenterologist compared to general practitioners: 10.9% and 4.8%,  $p < 0.0001$ , respectively. Initial testing using FIB-4 was followed by assessment with the Enhanced Liver Fibrosis (ELF) test in 183 subjects with intermediate risk (132) or high risk (51) with FIB-4 for liver fibrosis. ELF score >9.8 that indicates advanced fibrosis has been observed in 71/132 (54%) subjects with indeterminate risk score and in 45/51 (88%) of those with FIB-4 high risk score of fibrosis. This comparison is ongoing in a larger series.

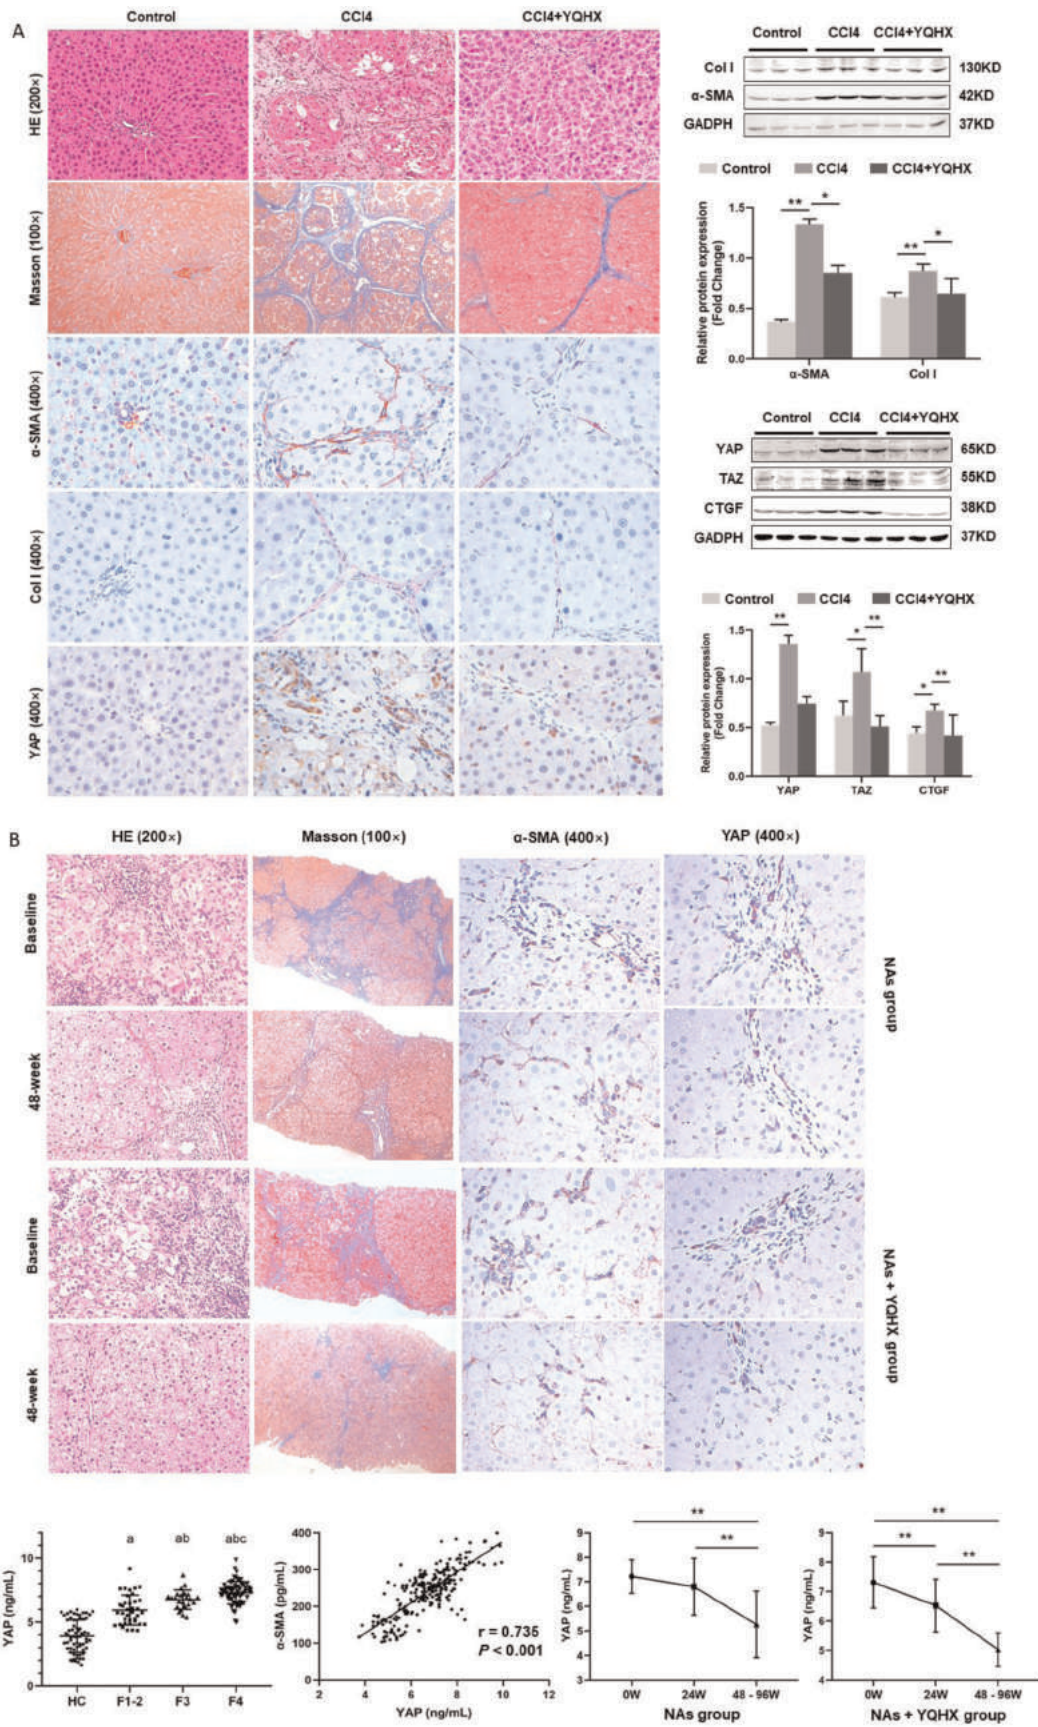

Figure: (abstract: PO-1579)

## POSTER PRESENTATIONS

**Conclusion:** Our study strongly supports this easy-to-implement strategy using a simple FIB-4 measure resulting from the use of available routine test results. Liver fibrosis was suspected by FIB-4 score in of a large cohort of patients 18.8% (12.4% with intermediate and 6.4% with high risk of fibrosis). With the FIB-4 thresholds used as function of age, the still in progress work in a larger series at the time of writing this abstract, shows that 54% of subjects in the indeterminate zone with FIB-4 were confirmed to be at risk of advanced fibrosis with the ELF test.

### PO-1582

#### Inter-system reproducibility of liver stiffness measurement with two different two-dimensional shear wave elastography techniques using transient elastography as the reference method

Victor Baldea<sup>1</sup>, Felix Bende<sup>1</sup>, Alexandru Popa<sup>1</sup>, Radu Cotrau<sup>1</sup>, Lupusoru Raluca<sup>1</sup>, Alina Popescu<sup>1</sup>, Roxana Sirli<sup>1</sup>, Ioan Sporea<sup>1</sup>. <sup>1</sup>Victor Babes University of Medicine and Pharmacy, Gastroenterology, Romania  
Email: isporea@umft.ro

**Background and aims:** Several companies have developed different shear wave elastography (SWE) machines able to quantify liver stiffness (LS) as a marker of fibrosis. This study aimed to compare the technical success rate and reliability of measurements made using two-dimensional shear wave elastography (2D-SWE) with SuperSonic Imagine Aixplorer MACH 30 (2D-SWE.SSI) and General Electric LOGIQ P (2D-SWE.GE) ultrasound systems and to assess the inter-system reproducibility of the resultant liver stiffness measurements.

**Method:** We prospectively enrolled 228 patients with different chronic liver diseases (CLD) and 21 subjects without liver disease that were referred to our ultrasound department for liver fibrosis assessment. LS assessment was done using the same intercostal approach with all 3 systems. The technical success rates and measurement reliability of the two techniques were compared. LS values measured using the two SWE techniques and TE were compared using Spearman correlation coefficients and 95% Bland-Altman limits of agreement. Intra-class correlation coefficients (ICC) were used to analyze the inter-platform reproducibility of LS measurements.

**Results:** The two SWE techniques (2D-SWE.SSI, 2D-SWE.GE) and TE showed a similar technical success rate (96.4% vs 95.6% vs. 98.4%,  $p = 0.186$ ) and similar reliability of LS measurements (98.8% vs. 99.6% vs. 99.2%,  $p = 0.604$ ), with significant differences between mean LS measurements (7.5 kPa vs. 7.1 kPa vs. 7.2 kPa,  $p = 0.0001$ ). A strong correlation (2D-SWE.SSI vs. 2D-SWE.GE,  $r = 0.85$ ; 2D-SWE.SSI vs TE,  $r = 0.82$  and 2D-SWE.GE vs. TE,  $r = 0.76$ ) was observed across systems with various degrees of inter-system reproducibility (ICC, 0.43–0.90). The best agreement was observed between TE and 2D-SWE.SSI (ICC, 0.90) and the worst agreement between 2D-SWE.SSI and 2D-SWE.GE (ICC, 0.43). The Bland-Altman analysis revealed that the mean difference between 2D-SWE.SSI and 2D-SWE.GE values was 0.4 kPa (limits of agreement:  $-12.4$  to  $13.1$ ).

**Conclusion:** No significant differences have been found between the feasibility of both systems when compared to TE. However, significant inter-system variability was observed in LS measurements made using both SWE techniques. Therefore, we advise caution when interpreting LS results from different SWE systems and cut-off values should not be used interchangeably.

### PO-1589

#### Non-alcoholic steatohepatitis-related costs changes in the context of fibrosis progression status in European patients

Jörn Schattnerberg<sup>1</sup>, Manuel Romero Gomez<sup>2</sup>, Anum Shaikh<sup>3</sup>, Leonardo Ruiz Casas<sup>3</sup>, Gabriel Pedra<sup>3</sup>, Margarida Augusto<sup>4</sup>, João Diogo da Rocha Fernandes<sup>5</sup>. <sup>1</sup>Metabolic Liver Research Programm, I. Department of Medicine, University Medical Center Mainz, Mainz, Germany; <sup>2</sup>UCM Digestive Diseases, Virgen del Rocio University Hospital, Institute of Biomedicine of Seville, University of Seville, Seville, Spain; <sup>3</sup>HCD Economics, Daresbury, United Kingdom; <sup>4</sup>Novo Nordisk A/S, London, United Kingdom; <sup>5</sup>Novo Nordisk A/S, Søborg, Denmark  
Email: leo.ruiz@hcdeconomics.com

**Background and aims:** Little is known on the impact of liver fibrosis progression on the costs of non-alcoholic steatohepatitis (NASH). In this analysis the effect of fibrosis progression on NASH related costs in France, Germany, Italy, Spain and United Kingdom (EU5) populations of the GAIN study were assessed.

**Method:** GAIN is a retrospective study conducted in 2018–2019, in which a sample of secondary care physicians (including hepatologists, gastroenterologists, endocrinologists and diabetologists), recruited from public and private hospitals and practices, provided clinical and resource use information on patients suffering from NASH via an online survey. Participating patients completed a survey including information on direct non-medical and indirect (productivity-related) costs. Average annual direct medical and total costs (direct medical, direct non-medical and indirect costs) were estimated for all patients. An analysis of variance (ANOVA) was conducted comparing difference in mean costs by fibrosis progression status, together with an analysis testing the impact of progression on both medical and total costs after adjustment for confounders.

**Results:** Out of 2533 patients recruited in the EU5, 60% were male, average age was 56 (standard deviation [SD]: 12) and average body mass index was 30 (SD: 6). Average years since diagnosis was 2.5 (SD: 2.9). Direct medical costs and fibrosis progression status were collected for 2349 patients (93%), while total costs were collected for 644 (27%) patients. The ANOVA showed differences between progressed and non-progressed fibrosis status of €1236 and €10004 for direct medical and total costs, respectively ( $p < 0.001$ ). The multivariable regression analysis found fibrosis progression was correlated with costs after adjusting for clinical and sociodemographic factors, such as age, gender, comorbidities, diagnosis information and treatment decisions (pharmacological, surgical and lifestyle changes). Medical and total costs of patients that progressed increased by 22% and 76%, respectively, vs patients that did not progress ( $p < 0.05$ ), all others remaining constant.

\* $p < 0.001$ . **Definition of fibrosis status progression:** The physicians were asked in the survey what was the fibrosis stage (0–4) of their patients at two time points: at diagnosis and at the date of consultation. If a patient's fibrosis stage changed to a higher stage, it would be defined that their fibrosis condition progressed. However, if the fibrosis stage changed to a lower stage or remained the same, the patient's fibrosis status would have not progressed. **Abbreviations:** NASH, non-alcoholic steatohepatitis; SD, standard deviation. **Direct medical costs** include pharmacological treatments, consultations, tests and examinations, hospitalizations and surgical procedures. **Total costs** include direct medical costs, direct non-medical costs (such as parking, requirement for aids, transportation and transfer payments) and indirect costs (productivity-related costs, including short/long term absences and early retirement).

Figure: Annual costs due to NASH and fibrosis status progression (€)

**Conclusion:** The relationship of fibrosis progression and increase in NASH-related costs were retained after adjustment for relevant and potential confounders, which highlights the importance of tackling

fibrosis progression in NASH to reduce future costs not only from the health care systems perspective, but also from the societal perspective.

**PO-1609**

**The impact of liver fibrosis progression on the Health-related quality of life of patients with non-alcoholic steatohepatitis in clinical practice in Europe**

Manuel Romero Gomez<sup>1</sup>, Jörn Schattenberg<sup>2</sup>, Anum Shaikh<sup>3</sup>, Leonardo Ruiz Casas<sup>3</sup>, Gabriel Pedra<sup>3</sup>, Margarida Augusto<sup>4</sup>, João Diogo da Rocha Fernandes<sup>5</sup>. <sup>1</sup>UCM Digestive Diseases, Virgen del Rocio University Hospital, Institute of Biomedicine of Seville, University of Seville, Sevilla, Spain; <sup>2</sup>Metabolic Liver Research Programm, I. Departament of Medicine, University Medical Center Mainz, Mainz, Germany; <sup>3</sup>HCD Economics, Daresbury, United Kingdom; <sup>4</sup>Novo Nordisk A/S, London, United Kingdom; <sup>5</sup>Novo Nordisk A/S, Søborg, Denmark  
Email: leo.ruiz@hcdeconomics.com

**Background and aims:** The disease burden of non-alcoholic steatohepatitis (NASH) has been previously studied, however little is known on the impact of liver fibrosis progression on health-related quality of life (HRQoL). In this analysis, the effect of fibrosis progression on HRQoL in the EU population of the GAIN study was assessed.

**Method:** GAIN is a retrospective study from 2018 to 2019 in which a sample of secondary care physicians (including hepatologists, gastroenterologists, endocrinologists and diabetologists), recruited from public and private hospitals and practices, provided clinical and resource use information on patients with a NASH diagnosis via an online survey. A subgroup of participating patients completed a survey including information on the HRQoL in the EU population. HRQoL was measured by the EQ-5D-5L and the Chronic Liver Disease Questionnaire for non-alcoholic steatohepatitis (CLDQ-NASH). An analysis of variance (ANOVA) comparing HRQoL scores by fibrosis progression status was performed. Further analyses to test the impact of progression on HRQoL after adjustment for confounders were conducted by a multivariable regression analysis.

**Results:** Out of 2533 patients recruited in France, Germany, Italy, Spain and United Kingdom, 60% were male, average age was 56 (standard deviation [SD]: 12), average body mass index was 30 (SD: 6) and average years since diagnosis was 2.5 (SD: 2.9). 629 (25%) patients responded to the EQ-5D-5L questionnaire and 607 (24%) responded to the CLDQ-NASH. The ANOVA showed differences between progressed and non-progressed fibrosis status of 0.16 and

0.62 points for the EQ-5D-5L and CLDQ-NASH outcomes, respectively (p < 0.001). These differences are higher than the established minimal clinically important differences for both EQ-5D-5L (0.07) and CLDQ-NASH (0.5). The multivariable regression analysis confirmed the impact of fibrosis progression on HRQoL after adjusting for potential confounders where clinical, sociodemographic and treatment decision factors were included. Patients that progressed had lower EQ-5D-5L and CLDQ-NASH scores of 0.12 and 0.34 points, respectively, vs patients that did not progress (p < 0.05).

**Conclusion:** This relationship of fibrosis progression and low HRQoL retained significance after adjustment for potential confounders. These results imply that halting or reversing fibrosis progression could impact HRQoL.

**PO-1831**

**Combinations of an acetyl CoA carboxylase inhibitor, FXR agonist and GLP-1R agonist inhibits fibrosis progression in the rat choline-deficient, L-amino acid defined, high-fat diet model of advanced fibrosis**

Archana Vijayakumar<sup>1</sup>, Jenny Egecioglu Norlin<sup>2</sup>, Pia Steen Petersen<sup>3</sup>, Sanne Veidal<sup>3</sup>, Michael Feigh<sup>3</sup>, James Trevasik<sup>1</sup>, Markus Robert Latta<sup>2</sup>. <sup>1</sup>Gilead Sciences; <sup>2</sup>Novo Nordisk; <sup>3</sup>Gubra ApS  
Email: archana.vijayakumar@gilead.com

**Background and aims:** Semaglutide (SEMA; glucagon-like peptide-1 receptor agonist), firsocostat (FIR; acetyl CoA carboxylase inhibitor) and cilofexor (CILO; farnesoid X receptor agonist) are being investigated in patients with advanced fibrosis due to NASH. In the AMLN diet-induced murine NASH model, combinations of these agents lowered liver fat, expression of fibrogenesis markers, and NAFLD activity score (driven by improved steatosis and inflammation) more than monotherapies. Here we evaluated the effect of pairwise and triple combinations of SEMA, ACCi (FIR analog) and CILO on fibrosis progression in the rat choline-deficient, L-amino acid defined, high-fat diet (CDHFD) model of advanced fibrosis.

**Method:** Male Sprague-Dawley rats were fed CDHFD for 12 weeks and treated with SEMA (0.06 mg/kg, sc, qd), ACCi (10 mg/kg, po, qd) and CILO (30 mg/kg, po, qd) alone or in all pairwise and triple combinations from weeks 6–12 (n = 15/group). Separate groups of rats were sacrificed before start of dosing (Baseline), dosed with Vehicle (Veh), or maintained on standard chow. Histopathological and biochemical analyses were performed on terminal liver and plasma biomarkers were measured by ELISA.

**Results:** SEMA-containing groups demonstrated 9–14% weight loss vs. Veh. Liver fibrosis assessed histologically (picosirius red (PSR) staining) or biochemically (hydroxyproline (HYP) content) was increased by CDHFD in Baseline (PSR: 4.6%, HYP: 0.1 µg/g) and Veh (PSR: 9.8%, HYP: 0.2 µg/g) vs. chow (PSR: 1.2%, HYP: 0.03 µg/g) (p < 0.05). All monotherapies partially inhibited fibrosis progression (PSR: 42–52%, HYP: 46–70%) (Figure). Fibrosis progression assessed by PSR was inhibited by 79%, 87%, 69%, and 87%, and HYP increase was inhibited by 93%, 82%, 76% and 99%, in the SEMA + CILO, SEMA + ACCi, ACCi + CILO and triple combination groups, respectively (all p < 0.05 vs. Veh) (Figure). Similar trends were observed in immunostaining for markers of fibrogenesis (Col1a1 and α-SMA), activated macrophages and Kupffer cells (Galectin-3) and macrophages (CD68), and plasma biomarkers (HA, PIIINP, TIMP-1, CK18-M30); numerically greater reductions were observed in triple vs. pairwise combinations.

\*p < 0.001. Definition of fibrosis status progression: The physicians were asked in the survey what was the fibrosis stage (0–4) of their patients at two time points: at diagnosis and at the date of consultation. If a patient's fibrosis stage changed to a higher stage, it would be defined that their fibrosis condition progressed. However, if the fibrosis stage changed to a lower stage or remained the same, the patient's fibrosis status would have not progressed. Abbreviations: CLDQ-NASH, Chronic Liver Disease Questionnaire for non-alcoholic steatohepatitis; SD, standard deviation.

Figure: Health-related quality of life and fibrosis status progression

Figure: (abstract: PO-1831)

**Conclusion:** Pairwise and triple combinations of SEMA, ACCi and CILO almost completely inhibited fibrosis progression in the rat CDHFD model of advanced fibrosis. These data support evaluation of combinations of SEMA, FIR, and CILO to treat patients with advanced fibrosis due to NASH.

**PO-1857**

**AI digital pathology using qFibrosis reveals heterogeneity of fibrosis regression in hepatitis B and C patients with SVR**

Feng Liu<sup>1</sup>, Yameng Sun<sup>2</sup>, Dean Tai<sup>3</sup>, Yayun Ren<sup>3</sup>, Elaine Chng<sup>3</sup>, Aileen Wee<sup>4</sup>, Pierre Bedossa<sup>5</sup>, Rui Huang<sup>1</sup>, Jian Wang<sup>1</sup>, Lai Wei<sup>6</sup>, Hong You<sup>2</sup>, Huiying Rao<sup>1</sup>. <sup>1</sup>Peking University Hepatology Institute, Peking University People's Hospital Beijing Key Laboratory of Hepatitis C and Immunotherapy for Liver Diseases, Beijing, China; <sup>2</sup>Liver Research Center, Beijing Friendship Hospital, Capital Medical University, Beijing, China; <sup>3</sup>Histoindex Pte. Ltd., Singapore; <sup>4</sup>Department of Pathology, Yong Loo Lin School of Medicine, National University of Singapore, National University Hospital, Singapore; <sup>5</sup>LiverPat SAS, France; <sup>6</sup>Hepatopancreatobiliary Center, Beijing Tsinghua Changgung Hospital, Beijing, China  
Email: rao.huiying@163.com

**Background and aims:** Liver fibrosis is a dynamic process and complex fibrosis patterns comprising progressive and regressive features have been observed, particularly in post-intervention samples. Conventional staging systems are static assessments of fibrosis and lack granularity to examine the heterogeneity of fibrosis features in pre- and post-treatment biopsies, resulting in a less than adequate evaluation of fibrosis regression. The aim of this study is to understand the fibrosis dynamics and its relation to evaluating post-treated viral hepatitis cases by employing second harmonic generation/two-photon excitation fluorescence (SHG/TPEF)

microscopy which provides a reproducible and quantitative analysis for fibrosis features.

**Method:** 158 paired pre- and post-treatment liver biopsies from hepatitis B (n = 100) and C patients (n = 58) were examined. All hepatitis B patients achieved sustained virologic response (SVR) after 78 weeks of treatment. Hepatitis C cases achieved SVR after 24 weeks. Liver fibrosis was quantitatively assessed by qFibrosis employing SHG/TPEF microscopy and by collagen proportionate area (CPA), according to hepatic regions comprising portal tract (PT), periportal (PP), zone 2 (Z2), pericentral (PC), and central vein (CV).

**Results:** For biopsies staged F5/6 (Ishak system), all post-treatment cases contained significantly less CPA (11–70%) across all regions when compared to pre-treatment samples, suggesting significant fibrosis reduction, especially septal thinning. For the F3/4 cohort, a similar CPA trend was observed, except in the PC and CV regions where more CPA (9–14%) was observed in the post-treatment cases at 24 weeks. This suggested that the time frame was likely insufficient for resolution of some portal-central bridging. In the F0/1/2 cohort, less CPA (9–42%) was observed across all regions at 78 weeks of treatment while more CPA (30–42%) was observed at the PP and Z2 regions at 24 weeks treatment, suggesting fibrous expansion of residual portal areas.

**Conclusion:** Following successful antiviral treatment, the pre-and post-treatment liver biopsies provide quantitative evidence for the heterogeneity of fibrosis features even within the same fibrosis stage. Quantitative qFibrosis approach has the potential to provide new insights into the dynamics of fibrosis regression in viral hepatitis cases, as early as 24 weeks after SVR.

Figure: (abstract: PO-1857) Difference in CPA between pre- and post-treatment liver biopsies from hepatitis B and C patients with SVR

**The hepatoprotective role of the antiretroviral drug Rilpivirine is associated with altered autophagy in in vitro and in vivo models of liver fibrosis**

Federico Lucantoni<sup>1,2</sup>, Aleksandra Gruevska<sup>1,2</sup>, Ángela B. Moragrega<sup>1,2</sup>, Alberto Martí-Rodrigo<sup>1</sup>, Juan V. Esplugues<sup>1,2,3</sup>, Ana Blas-García<sup>1,2,3,4</sup>, Nadezda Apostolova<sup>1,2,3</sup>.  
<sup>1</sup>Universidad de Valencia, Departamento de Farmacología, Valencia, Spain; <sup>2</sup>FISABIO, Valencia, Spain; <sup>3</sup>CIBERehd, Spain; <sup>4</sup>Universidad de Valencia, Departamento de Fisiología, Valencia, Spain  
 Email: lucantoni.federico@hotmail.it

**Background and aims:** Hepatic stellate cells (HSC) play a fundamental role in the liver response to injury, being at the core of liver fibrosis, a major component of virtually all chronic liver disease and a clinical phenomenon for which there are no specific treatments. Autophagy is considered crucial for the trans-differentiation of HSC from quiescent cells to myofibroblasts. Our group has recently described that the anti-HIV drug Rilpivirine (RPV) displays hepatoprotective effects in both animal models and in vitro, including STAT1-dependent induction of apoptosis in HSC. Given this, we studied if RPV affected autophagy in activated HSC.

**Method:** An *in vitro* approach consisted of HSC (the human cell line LX-2 and human HSC primary cells-hHSC), activated with TGF- $\beta$  (10 ng/ml) and co-exposed to RPV (1–8  $\mu$ M) for 24 or 48 h. We also employed a mouse model of chronic liver disease induced with a high fat diet (HFD) for 12 weeks, in which animals were co-treated with RPV or vehicle.

**Results:** In LX2 cells co-treated with TGF- $\beta$  and RPV, the analysis of several autophagic protein markers by WB (LC3, Atg5, Atg7, Beclin-1) revealed minor changes compared to cells exposed to TGF- $\beta$  only. However, we observed increased formation of autophagolysosomes and lysosomes in both activated LX-2 and hHSC treated with RPV, through single-cell imaging of Lysotracker Red and Cyto-id fluorescent probes. By employing dual fluorescent eGFP-mCherry-p62 or -LC-3 indicators coupled to live cell imaging, we found that activated LX-2 treated with RPV accumulated increased levels of LC3 and p62 in autophagolysosomes. In the same line, livers of HFD mice exposed to RPV displayed decreased p62 and increased LC3-II protein levels, both markers of enhanced autophagy, compared to vehicle-treated HFD mice. The role of autophagy in the response of HSC to treatment with RPV was confirmed by silencing several primary mediators of autophagy-SQSTM1/p62, ATG5 or Beclin1- in activated LX-2 cells. We observed that cells lacking any of the aforementioned proteins and, subsequently, with altered/diminished autophagy, registered increased viability (assayed through an acid phosphatase assay) following RPV treatment.

**Conclusion:** RPV enhances the process of autophagy in TGF- $\beta$ -induced HSC and in livers of HFD mouse model of chronic liver injury. These findings may be of relevance in the search of novel anti-fibrotic targets for the treatment of liver diseases.

**PO-2113**

**Proteomic profiling of hepatic stellate cell differentiation from induced pluripotent stem cells: new tools to understand liver development and fibrosis**

Raquel A. Martínez García de la Torre<sup>1</sup>, Julia Vallverdú<sup>1</sup>, Mikel Azkargorta<sup>2</sup>, Félix Elortza<sup>2</sup>, Juan José Lozano<sup>1,3</sup>, Pau Sancho-Bru<sup>1,3</sup>.  
<sup>1</sup>Insititut d'Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS) University of Barcelona, Barcelona, Spain; <sup>2</sup>Proteomics Platform, CIC bioGUNE, Basque Research and Technology Alliance (BRTA), CIBERehd, ProteoRed-ISCI, Derio, Spain; <sup>3</sup>Centro de Investigación Biomédica en Red de Enfermedades Hepáticas y Digestivas (CIBERehd), Barcelona, Spain  
 Email: rmartinezg@clinic.cat

**Background and aims:** Hepatic Stellate Cells (HSCs) are the main fibrogenic cell type in chronic liver disease. Understanding the embryonic development of HSCs and their activation is key to

develop new therapeutic strategies. By sequential addition of factors, we have generated functional human HSCs from Induced Pluripotent Stem Cells (iPSC-HSC). Here we performed a proteomic analysis to understand how the iPSC-HSC's differentiation mimics the embryonic development of HSCs and to uncover pathways involved in activation and liver fibrosis.

**Method:** Human iPSC-HSC were obtained following the protocol described in Coll et al. 2018; Vallverdú et al. 2021. Samples were collected and processed every two days for proteome analysis. Four independent differentiations were analysed and human primary HSCs were used as control. qPCR and FACS analysis were used for validation.

**Results:** The sequential proteomic profiling of the differentiation showed a reduction of pluripotent markers (RIF1, POU5F1, DPPA4) and an increase in HSC markers (LUM, DCN, PTN, COL1A1 and MMP2) along differentiation. A Pearson's correlation analysis indicated that differentiation occurred in three stages: undifferentiated phase (from day 0 to 4), intermediate foetal stage (from day 6 to 8) and final maturation stage (from day 10 to 12). Developmental markers of foetal HSC, such as VIM, ALCAM, FBLN1 and DCN were sequentially expressed at the foetal stage and were maintained during maturation phase, indicating recapitulation of the embryonic development *in vitro*. Comparison of iPSC-HSC with primary HSCs revealed that signalling pathways involved in HSC activation such as TGF $\beta$ , PDGFR, VEGF signalling or autophagy were expressed early at the foetal stage, while most pathways involved in liver fibrosis were not expressed. Moreover, we identified a group of proteins that did not change across differentiation but were highly expressed in primary HSCs. DAVID bioinformatics predicted that RORA could be upstream them, thus regulating HSC differentiation. *In vitro* experiments with an agonist (SR1078) confirmed that RORA signalling regulates both HSCs differentiation and the quiescent phenotype.

**Conclusion:** The proteomic characterization of iPSC-HSC differentiation uncovered the recapitulation of embryonic development of HSCs and pathways involved in cell activation. This study indicates that iPSC-HSC differentiation is a good model to study HSCs biology and explore mechanisms of liver fibrosis.

**PO-2415**

**An integrated approach on immune cell subtype characterization reveals common inflammatory pathways in non-alcoholic steatohepatitis (NASH) and primary sclerosing cholangitis (PSC)**

Milessa Silva Afonso<sup>1</sup>, Abhishek Aggarwal<sup>2</sup>, David Lopez<sup>3</sup>, Adrien Guillot<sup>4</sup>, Swetha Pendem<sup>1</sup>, Sangeetha Mahadevan<sup>2</sup>, Frank Tacke<sup>4</sup>, Lauri Diehl<sup>2</sup>, Ruchi Gupta<sup>1</sup>.  
<sup>1</sup>Gilead Sciences, Fibrosis, San Mateo, United States; <sup>2</sup>Gilead Sciences, NonClinical Safety and Pathobiology; <sup>3</sup>Gilead Sciences, Biology Core Support; <sup>4</sup>Charité University Medicine, Department of Hepatology and Gastroenterology  
 Email: milessa.silvaafonso@gilead.com

**Background and aims:** Inflammation is a key driver for the progression of chronic liver diseases, however the similarities and differences in the immune contributors to liver diseases with different etiologies such as NASH and PSC is not fully understood. Therefore, we used novel technologies to map the immune landscape in the progression of NASH and PSC to provide the basis for therapeutically modulating immune responses.

**Method:** Transcriptomes of liver biopsies from 158 NASH and 77 PSC patients were analyzed using 200 inflammation signature genes established by the Broad Institute (MIT). To understand the alteration in immune profiling in non-lobular vs lobular areas in liver biopsies from healthy controls (n = 11), and patients with PSC (n = 11), F0-F1 (n = 21), and F4 NASH (n = 12), a 12-plex Ultimapper™ immunofluorescence assay (Ultivue Inc.) was performed. The spatial distribution of immune cell subsets was characterized by a novel sequential multiplex immunostaining method (Figure 1).

**Results:** RNAseq revealed that 64% and 47% of the inflammation signature genes were upregulated in livers from cirrhotic NASH and

Figure: (abstract: PO-2415) Sequential multiplex immunostaining of biopsies from healthy, NASH and PSC livers

PSC Ishak 6 patients as compared to healthy livers. The highest upregulated genes in both diseases were *CCL20*, *CXCL6/8*, *LIF* and *SLAMF1*. The upregulation in inflammation signature genes was observed as disease progressed and it correlated with fibrosis markers ( $\alpha$ SMA:  $r = 0.88$ , ELF:  $r = 0.82$ ). This increase was accompanied by a 4.5- ( $p < 0.05$ ) and 6.2-fold ( $p < 0.01$ ) increase in CD8<sup>+</sup> and CD4<sup>+</sup> T cells, respectively, in non-lobular areas of NASH vs healthy livers. PSC liver samples also showed 11.9-fold {3.2% [0.2–6.2 CI] vs 0.2% [0.1–0.4 CI] healthy} elevation in CD8<sup>+</sup> T cell infiltration, as well as an 18.5-fold ( $p < 0.05$ ) increase in CD4<sup>+</sup> T cells vs healthy. A 5.9-fold higher infiltration of FoxP3<sup>+</sup> regulatory T cells in F4 NASH (0.13% [–0.004–0.26 CI] vs 0.02% [0.01–0.06 CI] F0/F1) and PSC (0.63% [–0.007–1.3 CI] vs 0.01% [0.003–0.02 CI] in Normal) was observed. In the innate immune component, CD163<sup>+</sup> macrophages were 9-fold ( $p < 0.05$ ) higher in the fibrotic NASH compared to F0/F1. PSC livers showed 11-fold increase in CD163<sup>+</sup> macrophages {0.5% [0.16–0.82 CI] in Normal to 5.5% [1.4–9.6 CI] PSC}. Soluble CD163 was 1.4- ( $p < 0.02$ ) and 2.5-fold ( $p < 0.0001$ ) higher in NASH and PSC vs healthy, respectively. These data were further confirmed using sequential multiplex immunostaining and unbiased analysis on whole slide imaging from liver sections.

**Conclusion:** These results contribute to the understanding of the liver immune microenvironment and establish similarities in the inflammatory signature and its involvement in the progression of

NASH and PSC. Together, these approaches provide disease understanding and enable therapeutic discoveries to treat liver diseases.

**PO-2695**

**FIB-4 based algorithm for screening significant fibrosis in diabetes with or without fatty liver in primary care setting**

Eileen Yoon<sup>1</sup>, Dae Won Jun<sup>1</sup>, Su Hyun Park<sup>2</sup>, Seong Ji Choi<sup>2</sup>, Jai Hoon Yoon<sup>2</sup>, Kang Nyeong Lee<sup>2</sup>, Hang Lak Lee<sup>2</sup>, Oh Young Lee<sup>2</sup>, Byung Chul Yoon<sup>2</sup>, Ho Soon Choi<sup>2</sup>. <sup>1</sup>Department of Internal Medicine, Hanyang University Hospital, Hanyang University College of Medicine; <sup>2</sup>Hanyang University Hospital, Hanyang University College of Medicine  
Email: noshin@hanyang.ac.kr

**Background and aims:** Apart from the NAFLD patients, the effectiveness of FIB-4 or NFS based screening in all diabetic patients regardless of fatty liver status is unknown. We investigated cost-effectiveness of screening algorithm in diabetes in primary care clinic. **Method:** A total of 1,288 who visited the health examination center and underwent the magnetic resonance elastography (MRE) were enrolled. The performance of FIB-4 and NFS was compared in diabetes patients. And diagnostic performance and cost-effectiveness according to screening algorithm were evaluated in three kinds of target population (diabetes, sonographic fatty liver, and elevated liver enzyme group). If FIB-4 value ( $\geq 1.3$ ) falls into intermediate or

high-risk group, FIB-4 was followed by transient elastography. Lifestyle modification and monitoring prescribed to suspected significant hepatic fibrosis if hepatic fibrosis suspected in transient elastography.

**Results:** The prevalence of significant fibrosis ( $\geq F2$ ) was 3.9% in total cohort, 5.9% in patients with sonographic NAFLD patients, and 14.2% in diabetes. Prevalence of significant fibrosis was considerable in patient with diabetes without fatty liver (6.7%). Area under the curve of the receiver operating characteristic (AUROC) of FIB-4 and NFS for significant fibrosis was similar in sonographic NAFLD subjects. But AUROC was of FIB-4 was slightly higher than NFS in diabetes without statistical significance (0.688 vs. 0.582,  $P = 0.05$ ). Application of FIB-4 based algorithm for detecting significant fibrosis in diabetes showed comparable positive predictive value (31.4% vs. 7.6%) and sensitivity (22.0% vs. 18.0%) compared to sonographic NAFLD without decreasing NPV (96.9% vs. 96.5%). FIB-4 based algorithm in diabetic patients reduced unnecessary referral rate by 23.8% compared to NAFLD subjects. One-time FIB-4 based screening and lifestyle modification showed cost-effectiveness ratios (ICER) of 21, 849 \$USD per quality-adjusted life year.

**Conclusion:** FIB-4 based transient elastography screening algorithm for significant hepatic fibrosis in patients with diabetes was cost effective.

**PO-2790**

**Liver fibrosis accumulation depends on underlying disease aetiology**

Email: adam.watson@hertford.ox.ac.uk

**Background and aims:** Traditional histological fibrosis assessment is categorical and describes progression from portal tract expansion, to bridging fibrosis to nodule formation. Morphometry by collagen proportionate area (CPA) estimation provides a quantitative evaluation of fibrosis. The aim of this study was to evaluate fibrosis progression using categorical scores and morphometry according to liver disease aetiology.

**Method:** Consecutive patients who had undergone liver biopsy for the assessment of diffuse liver disease were included. Liver histology slides stained with Sirius red were scanned to produce digital images which were then manually processed using ImageJ to calculate the CPA. Fibrosis was independently assessed using the Ishak staging system and categorised as mild (F0-2), moderate (F3-4) or severe (F5-6) fibrosis. All analyses were blinded. Aetiology was classified as either alcohol related liver disease (ARLD), non-alcoholic fatty liver disease (NAFLD), viral (chronic hepatitis B or C), or autoimmune (PBC, PSC or autoimmune hepatitis; AIH) liver disease. ANOVA was used to test for significance between groups.

**Results:** We included 137 patients (mean age 52 years, 39% female) for whom CPA strongly correlated with Ishak stage ( $r_s = 0.76$ ,  $p < 0.0001$ ). Mean CPA was 7.5% for mild fibrosis ( $n = 28$ ), 9.3% for moderate fibrosis ( $n = 56$ ) and 25.9% for severe fibrosis ( $n = 53$ ). As fibrosis progressed through categorical classifications the mean CPA also increased in the ARLD ( $n = 26$ ), NAFLD ( $n = 57$ ) and viral ( $n = 35$ ) groups ( $p < 0.0001$ ); however, there was no significant increase in CPA for the autoimmune group ( $n = 19$ ;  $p = 0.11$ ). There was no variation in CPA across aetiological groups for mild ( $p = 0.19$ ) and severe fibrosis ( $p = 0.15$ ); however, there was a significant difference

between ARLD and autoimmune groups for moderate fibrosis ( $p = 0.036$ ).

Figure: Mean CPA (%) for aetiological groups at each stage of fibrosis, with 95% confidence intervals shown.

**Conclusion:** Our data suggest that disease progression in patients with PBC, PSC and AIH is characterised primarily by architectural changes without significant changes in the amount of fibrosis, while in other aetiologies, fibrosis increases are commensurate with architectural changes. These findings may be confounded by the aetiological heterogeneity within the autoimmune group, therefore, confirmation of these findings in larger studies is warranted.

**Gut microbiota and liver disease**

**PO-418**

**Rifaximin and Fecal Microbiota Transplant beneficially modulate gut metagenomic virulence factors in cirrhosis: Analysis of two trials**

Jasmohan S. Bajaj<sup>1</sup>, Amirhossein Shamsaddini<sup>2</sup>, Andrew Fagan<sup>1</sup>, Richard Sterling<sup>1</sup>, Chathur Acharya<sup>1</sup>, Hannah Lee<sup>1</sup>, Edith Gavis<sup>1</sup>, Masoumeh Sikaroodi<sup>2</sup>, Patrick Gillevet<sup>2</sup>. <sup>1</sup>Virginia Commonwealth University and Richmond VAMC, Richmond, United States; <sup>2</sup>George Mason University  
Email: jasmohan.bajaj@vcuhealth.org

**Background and aims:** Cirrhosis is linked with altered gut microbiota and higher pathobionts, which can carry several virulence factors (VFs). However, the role of therapies such as rifaximin or fecal microbiota transplant (FMT), in reducing this burden in cirrhosis is unclear.

**Aim:** Define change in metagenomic VF abundance with a trial of rifaximin in compensated cirrhosis and randomized trial of capsule FMT in decompensated cirrhosis.

**Methods:** Rifaximin trial: 20 cirrhotic outpts with compensated cirrhosis were given open-label 550 mg BID rifaximin for 8 weeks. Stool was collected pre/post rifaximin. Capsule FMT trial: 20 cirrhotic outpts with hepatic encephalopathy (HE) already on lactulose and rifaximin were randomized 1:1 into receiving 15 capsules of FMT enriched in beneficial Lachnospiraceae and Ruminococcaceae or placebo. Stool was collected at baseline and 4 weeks post-intervention. Changes were compared to metagenomics of the healthy donor. Microbial analysis: Metagenomics was performed

## POSTER PRESENTATIONS

Figure: (abstract: PO-418) Changes in Virulence Factor Abundances after Rifaximin and Fecal Microbiota Transplant

for VFs using the virulence factor database. Comparisons pre vs post-rifaximin and pre vs post-FMT and post-FMT vs post-placebo were performed.

**Results:** Rifaximin trial: 20 pts (14 men, MELD 10, 60 yrs) were included and safely completed the trial. There was an increase in beneficial taxa belonging to *Butyricimonas* and *Ruminococcus*. Fig A shows reduction in VFs that code for pili, fimbrial proteins and fibronectin that are related to Enterobacteriaceae spp after rifaximin compared to baseline. FMT trial: 10 randomized to FMT vs 10 placebo; groups were matched for demographics and cirrhosis severity (8 men/group, MELD 11 both, age 64 vs 63 yrs). MELD and disease remained stable at 4 weeks. Post-FMT showed a reduction in capsule encoding and secretion system vs pre-FMT (Fig B). Post-FMT there was a reduction in several VFs belonging to Enterobacteriaceae spp (pili, enterobactin, chaperonins) vs post-placebo (Fig C). There was an increase in 2 factors belonging to Mycobacteria (Zn metallophrotease and Phop/R) post-FMT, which were not transmitted by the donor.

**Conclusion:** Virulence factors that increase the pathogenicity of Enterobacteriaceae spp are reduced by rifaximin therapy in compensated cirrhosis and by capsule FMT in decompensated patients with cirrhosis. Precision therapies aimed at reducing the VFs in pathogens could potentially improve outcomes and may be mechanisms of action of rifaximin and FMT.

### PO-799

#### Response failure to ursodeoxycholic acid treatment in primary biliary cholangitis is associated with a distinct stool and urine secondary bile acid profile

Laura Martinez-Gili<sup>1</sup>, Alexandros Pechlivanis<sup>1</sup>, Sofina Begum<sup>2</sup>, George Mells<sup>3</sup>, Elaine Holmes<sup>2</sup>, David Jones<sup>4</sup>. <sup>1</sup>Imperial College London, Division of Systems Medicine, Department of Metabolism, Digestion and Reproduction, London, United Kingdom; <sup>2</sup>Imperial College London, Division of Digestive Diseases, Department of Metabolism, Digestion and Reproduction, London, United Kingdom; <sup>3</sup>Cambridge University Hospitals NHS Foundation Trust, Department of Hepatology; <sup>4</sup>Newcastle University, Institute of Translational and Clinical Research, Newcastle-upon-Tyne, United Kingdom  
Email: laura.martinez@imperial.ac.uk

**Background and aims:** Primary biliary cholangitis (PBC) is an autoimmune cholestatic liver disease that can lead to progressive liver damage. The first-line treatment for PBC is ursodeoxycholic acid (UDCA); a hydrophilic bile acid which delays disease progression and improves biochemical markers of liver damage such as serum alkaline phosphatase (ALP). Patients who do not respond to UDCA have persistently altered serum biochemistry which is associated with higher risk of liver transplant and lower survival. Mechanisms underlying treatment failure remain unknown. We profiled patient bile acids (BA) to investigate whether differing treatment responses relate to changes in BA metabolism.

**Method:** Serum, urine and faeces of 454 patients in the UK-PBC cohort treated with UDCA for 1 year were collected and BA profiled with Ultra-Performance Liquid Chromatography coupled to Mass Spectrometry (UPLC-MS). Linear mixed effects models were fitted to each BA feature to assess differences across treatment responses, while adjusting for age, gender, body mass index, alcohol consumption, smoking, antibiotics and proton pump inhibitors as fixed effects, and sample collection site as random effect. Likelihood ratio test was used to assess significance, p values adjusted using the

Benjamini-Hochberg method and null hypothesis rejected with adjusted p value <0.1.

**Results:** We defined 3 response groups: responders with good prognosis (R\_GP; n = 224), with a >40% reduction or normalised ALP levels after 1 year of treatment, responders with bad prognosis (R\_BP; n = 16), with reduced ALP still higher than 1.67 times the upper limit of normal, and non-responders (NR; n = 214), who failed to reduce ALP. 12 stool and 8 urine BA were differently abundant, while there were no differences in serum. Stool BA displayed opposite trends in R\_BP and R\_GP with respect to non-responders (Figure); faecal UDCA increased in R\_GP (95% CI [0.05, 0.23]) but not in R\_BP (95% CI [-0.2, 0.25]). Urine BA decreased in R\_GP, except for 12-Dehydrocholic acid (95% CI [0.06, 0.36]). In addition, the total pool of glycosylated BA in R\_GP was higher in stool (95% CI [0.04, 0.17]), and lower in urine (95% CI [-0.19, -0.55]) compared to NR.

Figure:

**Conclusion:** Response to UDCA treatment is associated with a different bile acid signature in PBC, mainly involving microbial-derived secondary BA. These findings suggest a contribution of the intestinal microbiota to the response phenotype.

**PO-1558**

**Hepatobiliary Phenotype of Individuals with Chronic Intestinal Disorders-The Gut-Liver Axis in UKBiobank**

Jessica Voss<sup>1</sup>, Carolin Victoria Schneider<sup>1</sup>, Moritz Kleinjans<sup>1</sup>, Tony Bruns<sup>1</sup>, Christian Trautwein<sup>1</sup>, Pavel Strnad<sup>1</sup>. <sup>1</sup>Medical Clinic III, Gastroenterology, Metabolic diseases and Intensive Care, University Hospital RWTH Aachen, Medical Clinic III, Aachen, Germany  
Email: pstrnad@ukaachen.de

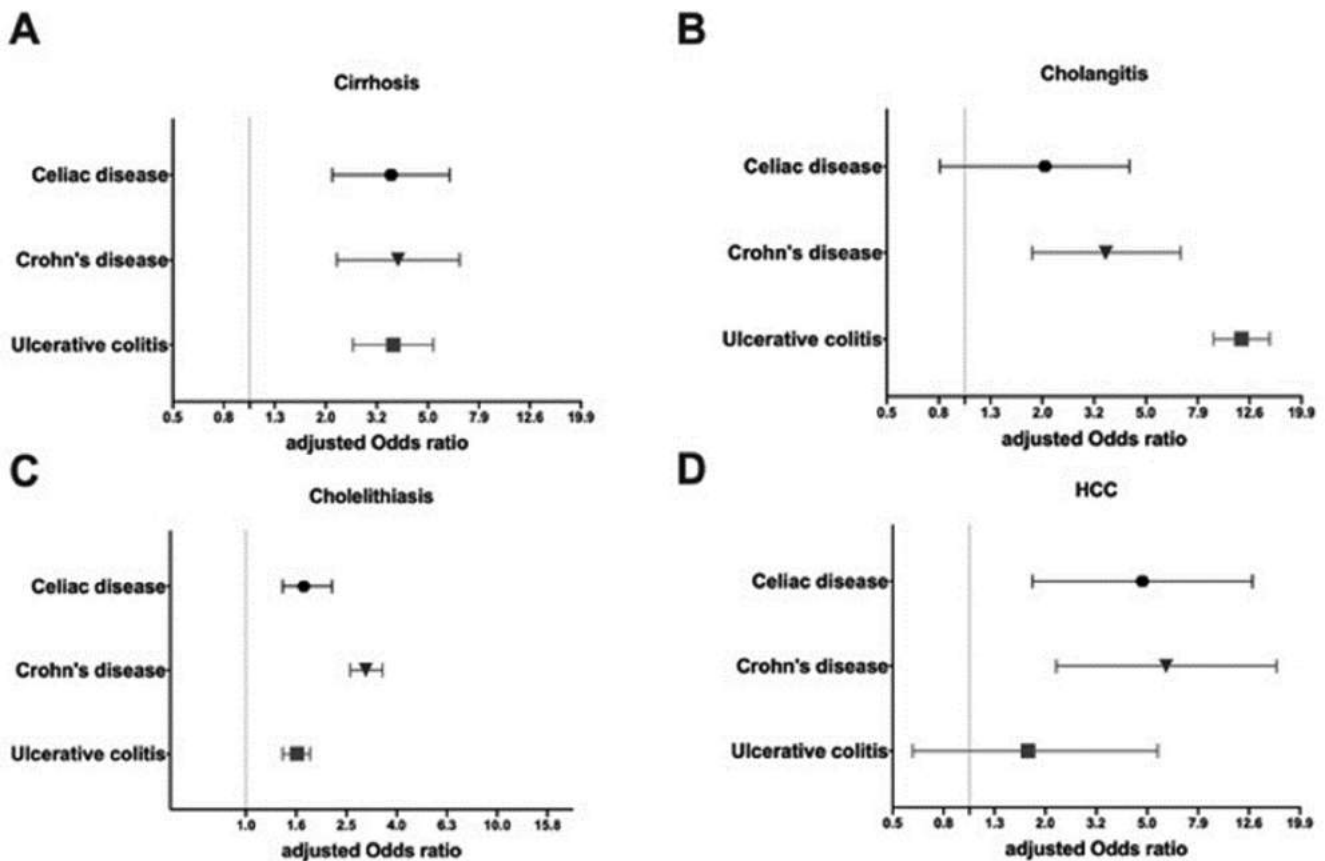

Figure: (abstract: PO-1558): Odds ratios to display selected ICD10 diagnoses in individuals with celiac disease, Crohn's disease, and ulcerative colitis compared to controls. Adjusted odds ratios (OR) with their corresponding 95% confidence intervals (CI) are shown. Odds ratios were adjusted for age, sex, BMI, alcohol consumption and diabetes mellitus. HCC, hepatocellular carcinoma.

## POSTER PRESENTATIONS

**Background and aims:** While experimental data demonstrate a close relationship between the gut and the liver, the clinical consequences of this functional circuit remain poorly defined. Thus, we assessed the hepatobiliary phenotype of individuals with celiac disease (CeD), Crohn's disease (CD) and ulcerative colitis (UC) using the UK Biobank community sample.

**Method:** Baseline liver function tests and the frequency of hepatobiliary diseases were analyzed in 2377 CeD, 1738 CD, 3684 UC subjects, and 488941 controls prospectively recruited in 22 participating centers in the United Kingdom. Associations were adjusted for age, sex, BMI, diabetes, and alcohol consumption.

**Results:** Compared to controls, individuals with CeD, but not CD/UC displayed higher AST/ALT values. Subjects with CD/UC but not CeD had increased GGT levels. Elevated ALP and cholelithiasis were significantly more common in all intestinal disorders, but were most prominent in subjects with CD (aOR = 3.0 [2.6–3.5]). Non-alcoholic steatohepatitis and hepatocellular carcinoma (HCC) were enriched in CeD and CD (HCC: aOR = 4.8 [1.8–13.0] in CeD, aOR = 5.9 [2.2–16.1] in CD), while cholangitis was more common in CD/UC individuals. Chronic hepatitis, autoimmune hepatitis, and cirrhosis were more prevalent in all intestinal disorders. Non-alcoholic steatohepatitis was the most prevalent cause of cirrhosis in CD and CeD, while cholangitis was the most frequent one in UC. In UC/CD, a history of intestinal surgery was associated with elevated liver enzymes and increased occurrence of gallstones.

**Conclusion:** Our data demonstrate that different intestinal disorders predispose to distinct hepatobiliary phenotypes. An increased occurrence of liver cirrhosis and HCC in all analyzed disorders warrants a more thorough hepatologic surveillance, particularly in individuals with additional risk factors such as obesity or diabetes.

### PO-1763

#### Rifaximin suppresses gut-derived systemic inflammation and promotes a gut microenvironment with reduced mucin degradation conducive to gut barrier repair in patients with cirrhosis and hepatic encephalopathy

Vishal C. Patel<sup>1,2,3</sup>, Sunjae Lee<sup>4</sup>, Mark J. W. McPhail<sup>5</sup>, Ane Zamalloa<sup>1</sup>, Elizabeth Witherden<sup>4</sup>, Sidsel Støy<sup>6</sup>, Godhev Manakkat Vijay<sup>5</sup>, Xiaohong Huang<sup>5</sup>, Selin Gencer<sup>7</sup>, Muireann Coen<sup>7</sup>, Thomas Tranah<sup>5</sup>, Julia Wendon<sup>5</sup>, Kenneth Bruce<sup>8</sup>, Dusko Ehrlich<sup>9</sup>, Lindsey A. Edwards<sup>5</sup>, Saeed Shoaie<sup>4</sup>, Debbie L. Shawcross<sup>5</sup>. <sup>1</sup>King's College Hospital NHS Foundation Trust, Institute of Liver Studies, United Kingdom; <sup>2</sup>Institute of Hepatology, London, United Kingdom; <sup>3</sup>King's College London, Institute of Liver Studies, Department of Inflammation Biology, School of Immunology and Microbial Sciences, FoLSM., London, United Kingdom; <sup>4</sup>King's College London, Centre for Host-Microbiome Interactions, Dental Institute, London, United Kingdom; <sup>5</sup>King's College London, Institute of Liver Studies, London, United Kingdom; <sup>6</sup>Aarhus University Hospital, Department of Hepatology and Gastroenterology, Aarhus, Denmark; <sup>7</sup>Imperial College London, Biomolecular Medicine, Division of Computational and Systems Medicine, Department of Surgery and Cancer, London, United Kingdom; <sup>8</sup>King's College London, Institute of Pharmaceutical Science, London, United Kingdom; <sup>9</sup>Institut National de la Recherche Agronomique, Metagenopolis, Paris, France  
Email: debbie.shawcross@kcl.ac.uk

**Background and aims:** Rifaximin is efficacious in the prevention of recurrent hepatic encephalopathy (HE) but its mechanism of action remains unclear. We postulated that rifaximin reduces gut microbiota-derived endotoxemia and systemic inflammation, a known driver of HE.

**Method:** A randomised placebo-controlled double-blind study of rifaximin versus placebo [NCT02019784] was performed in 38 patients with cirrhosis and HE. Rifaximin- $\alpha$  550 mg (TARGAXAN) twice daily (n = 19) or placebo (n = 19) was administered for 90-days. Primary outcome: 50% reduction in neutrophil oxidative burst (OB) at 30-days. Secondary outcomes: Psychometric Hepatic Encephalopathy Scale (PHES) testing, shotgun metagenomic

sequencing of saliva and faeces, plasma/faecal metabolome, blood bacterial DNA, neutrophil Toll-like Receptor-4 expression (TLR4) and plasma/faecal cytokine analysis.

**Results:** Patients were well-matched: baseline median MELD [11 rifaximin versus 10 placebo], ammonia and HE grade. Participants on rifaximin- $\alpha$  normalised their HE grade by day-30 [grade 1 to 0; p = 0.014]. Trail's A improved on rifaximin- $\alpha$  over 90-days; p = 0.012 and line tracing was significantly improved compared to placebo; p = 0.023. Neutrophil OB did not change but reduced neutrophil TLR-4 expression was observed in rifaximin-treated patients with a significant reduction in plasma tumour necrosis factor- $\alpha$  (TNF- $\alpha$ ); p < 0.001. Rifaximin- $\alpha$  suppressed oralisation of the gut microbiome by reducing *Streptococcus spp*, *Veillonella parvula* and *Veillonella atypica*, mucin-degrading species rich in sialidase. Rifaximin- $\alpha$  promoted a gut microenvironment rich in TNF- $\alpha$  and IL-17E augmenting local host antimicrobial immunity and gut barrier repair. Those on rifaximin- $\alpha$  were less likely to develop an infection; odds ratio for developing an infection on rifaximin- $\alpha$  compared to placebo was 0.208 (0.045–0.959).

**Conclusion:** Rifaximin- $\alpha$  improved HE reducing oralisation of the gut with mucin-degrading species such as *Streptococcus spp*, *Veillonella parvula* and *Veillonella atypica* ameliorating bacterial translocation and systemic inflammation in association with improved clinical outcomes including reducing the likelihood of developing infection. These novel data for the first time link rifaximin- $\alpha$  as having a role in gut barrier repair as a mechanism by which it ameliorates bacterial translocation and systemic endotoxemia in cirrhosis.

### PO-2010

#### Ethanol induced alterations in intestinal microbiota correlate with decreased intestinal nuclear receptor (PXR) pathway related proteins

Sudrishti Chaudhary<sup>1</sup>, Adil Bhat<sup>1</sup>, Anupama Kumari<sup>1</sup>, Archana Rastogi<sup>1</sup>, Guresh Kumar<sup>1</sup>, Jaswinder Singh<sup>1</sup>, Shiv Sarin<sup>1</sup>, Shvetank Sharma<sup>1</sup>. <sup>1</sup>Institute of Liver and Biliary Sciences, New Delhi, India  
Email: shvetanks@gmail.com

**Background and aims:** Alcohol associated liver disease (ALD) leads to gut bacterial dysbiosis and intestinal dysfunction along with increased gut permeability. Pregnane X receptor (PXR), a ligand activated nuclear receptor has been implicated in transcriptional regulation of intestinal barrier integrity and inflammation. We investigated whether intestinal PXR expression plays a role in gut microbiota homeostasis affecting hepatic function in a mouse model of ALD.

**Method:** Male C57BL/6N type mice were fed with Lieber-DeCarli diets 0% to 25% (w/v) alcohol (gradual increase up to 12 weeks) whereas pair fed mice received an isocaloric liquid diet as control. Serum levels of ALT/AST and endotoxins were determined. Fecal microbiota was assessed using 16 s rRNA. Proteome linked to liver steatosis, injury and intestinal barrier integrity were evaluated by LC-MS.

**Results:** Chronic EtOH feeding increased serum ALT, lipopolysaccharide and liver injury in mice. These injurious effects in liver (both necrosis and fibrosis) were pronounced at 12 wks compared to 4 or 8 weeks. Alcohol exposure resulted in loss of normal villus structure of the ileum and downregulation of intestinal epithelial tight junction proteins *in vivo* and *in vitro*. Proteomic analysis of intestinal tissue revealed downregulation (>1.5-fold than control, p < 0.05) of several proteins involved in antimicrobial defence (Defa20, Reg3b and Reg3d) and anti-oxidative proteins (Sod1, GPX, GR, and Gsto1) whereas inflammation and injury related proteins linked with the RelA mediated NfKB pathway (Tgfb1, Il1rap, and Ccr6) showed upregulation (FC > 1.5, p < 0.05) in EtOH fed mice. Moreover, EtOH-exposure in mice showed downregulation of proteins such as Cyp3a11 (FC < 1.5, p < 0.05) important for xenobiotic/bile acid detoxification linked to PXR. Further, gut microbiome alterations

revealed significant changes in EtOH versus control mice that may contribute to a higher inflammatory response. Short chain fatty acid producing bacteria such as *Chlorobaculum* and *Lachnospira* were altered prominently in EtOH and positively correlated ( $r > 0.7$ ,  $p < 0.05$ ) with the PXR proteins involved in tight junctions and PPAR signaling. *Coriobacterium* and *Galenea*, the secondary bile acid-producing bacteria correlated negatively with the downregulated protein Apo1 and Cyp1a2 involved in drug metabolism and AMPK signaling pathway ( $r < 0.7$ ,  $p < 0.05$ ).

Figure: Functional annotation of change in intestinal PXR associated pathways and correlation with microbiota identified by KEGG analysis

**Conclusion:** Long term EtOH consumption promotes disruption in intestinal PXR expression. The identified bacterial families correlate with PXR linked proteins and pathways suggesting an important role of nuclear receptors in tissue injury which could be explored as therapeutic targets in advance stage of alcoholic liver disease to prevent dysbiosis.

**PO-2363**

**Role of farnesoid-X receptor agonist in ameliorating NASH-disrupted intestinal permeability: Potential impact of autophagy on tight junctions**

Rasha Tawfiq<sup>1</sup>, Noha Nassar<sup>2</sup>, Olfat Hammam<sup>3</sup>, Mohamed Elmazar<sup>1</sup>, Dalaal Abdallah<sup>2</sup>, Yasmeen Attia<sup>1</sup>. <sup>1</sup>The British University in Egypt- Faculty of Pharmacy, Pharmacology and Biochemistry, Cairo, Egypt; <sup>2</sup>Cairo University-Faculty of Pharmacy, Egypt; <sup>3</sup>Theodor Bilharz Research Institute, Pathology Department, Egypt  
Email: dalaal.abdallah@pharma.cu.edu.eg

**Background and aims:** Multiple lines of evidence point to the role of impaired intestinal permeability and bacterial translocation (BT) in promoting pro-inflammatory events in the liver mediated by Toll-like receptors (TLRs) leading to the progression of steatosis to non-alcoholic steatohepatitis (NASH). A relation between autophagy and intestinal integrity exists, however, the pivotal role of farnesoid-X-receptor (FXR) in maintaining intestinal homeostasis and autophagy is noticeable. The present study aimed at investigating the effect of the FXR agonist, obeticholic acid (OCA), on BT and autophagy to ameliorate NASH-related incidents and its mechanism of action.

**Method:** Eight-week male mice (n = 3–7) were fed an atherogenic high fat diet (AHFD) for 13 weeks. Mild intestinal inflammation was induced by 0.5% dextran sulfate sodium (DSS) in drinking water applied in cycles of 7 days followed by a 10-day interval of drinking water. OCA treatment started at week 10 (5 mg/kg/day, p.o. for 4 weeks). Intestinal permeability was evaluated using FITC-dextran, serum LPS, LBP levels by ELISA and tight junction (TJ) proteins, zonulin (ZO)-1, claudin-1 and occludin, by immunohistochemistry (IHC). Histopathological examination of liver, ileum and colon samples was performed along with IHC of ileal and hepatic TLR-4 and transforming growth factor (TGF)-beta1. Autophagy genes

expression, ULK1, BCLN-1, ATG5, were determined using qRT-PCR and LCII/I ratio was assessed by western blotting. Hepatic and ileal pAkt protein levels were assessed by ELISA. Statistical significance ( $p < 0.05$ ) was determined using one-way ANOVA followed by Tukey-Kramer post hoc test.

**Results:** OCA preserved intestinal integrity through potentiating ZO-1, claudin-1 and occludin protein expression accompanied with histopathological amelioration of intestinal inflammation and NASH and normalization of serum FITC level with no change in LPS and LBP. This was accompanied by ileal autophagy activation where ATG5 gene was upregulated and ileal LC3II/I increased. Moreover, OCA immunomodulatory effect was obvious in reduction of hepatic and ileal TLR-4 and TGF- beta1, however, no noticeable change was shown in pAkt.

**Conclusion:** The FXR agonist, OCA, ameliorated bacterial translocation through affecting intestinal permeability, autophagy and immunity subsequently NASH-related events in a combined animal model of NASH and intestinal impairment through TLR4/TGF-beta1 suppression independently of PI3k/Akt.

**PO-2914**

**Fecal microbiota transplantation (FMT) for corticosteroids (CS) non-responders and non-eligible (NoReNE) patients with severe alcoholic hepatitis (SAH)**

Natalia Bystrianska<sup>1</sup>. <sup>1</sup>FD Roosevelt University Hospital, HEGITO (Division of Hepatology, Gastroenterology and Liver Transplantation, Banská Bystrica, Slovakia  
Email: naty2121@centrum.sk

**Background and aims:** Severe alcoholic hepatitis is one of the most serious forms of alcohol associated liver disease (ALD) with high mortality. The only recommended treatment option-corticosteroids (CS) show modest short-, and none long-term survival benefit. Unfortunately, the number of these patients (pts) is increasing and there is no alternative treatment. Recently, fecal microbiota transplantation (FMT) has gained attention as a potential therapeutic approach for ALD. We aimed to evaluate the impact of FMT on survival in NoReNE patients (pts) with SAH as determined by Lille-model.

**Method:** From 1/2018 to 12/2020, we performed FMT in 23 SAH patients. We recorded demographic, clinical and laboratory parameters before and after FMT. We used frozen faecal material from unrelated donors, delivered via upper GI tract in dose 100 ml over 5 days. Donors were selected according to general recommendations.

**Results:** We analyzed 23 patients (9 women and 14 men) with mean age, MELD-Na score, and Maddrey function of 46, 29, and 72, 5 respectively. In our cohort 18 pts were NoRe, and 5 pts were NE for full course CS. Sixteen pts had acute-on-chronic liver failure (ACLF) : ACLF 1:6 pts, ACLF 2: 6 pts, ACLF 3: 4 pts. Our data showed no statistically significant difference in MELD score, ACLF score, CRP and INR before and 7 days after FMT, except total bilirubin (p-value = 0.077). Observed 30-, and 90-day mortality was 26%, and 61%, respectively; in literature, these figures are 20–35% and 75% respectively.

## POSTER PRESENTATIONS

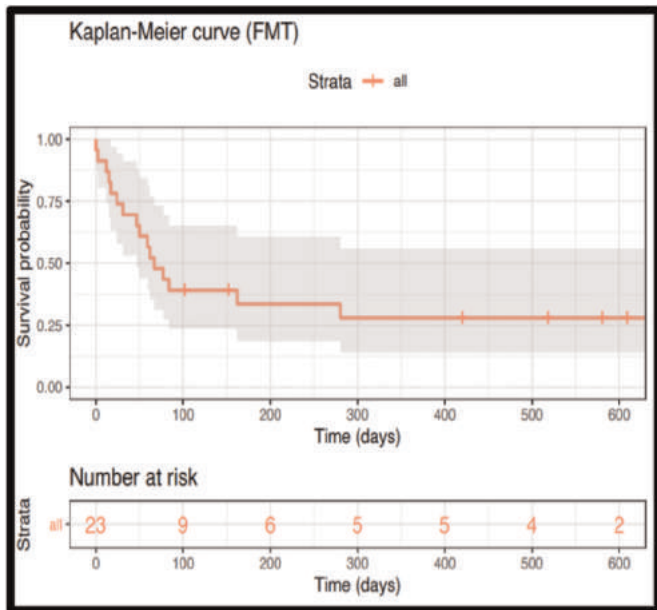

Figure:

**Conclusion:** SAH in CS non-responders/-eligibles is associated with high mortality, especially with ACLF. FMT offers alternative treatment option but we haven't documented clear survival benefit. We need larger, deeper and more granular analysis to determine, which patient's characteristics predict survival benefit.

## Imaging and drug targeting

#### Artificial Intelligence in medical imaging of the liver- a convolutional neural network solution for Computed Tomography exam phases recognition

João Martins Cortez Filho<sup>1,2</sup>, Luis Gustavo Rocha Vianna<sup>3</sup>, Ana Ciconelle<sup>3</sup>, Bruno Aragão Rocha<sup>3,4</sup>, Jean Michel Rocha Sampaio Leite<sup>5</sup>, Lucas Salume Lima Nogueira<sup>1,2</sup>, Lenon Liberdade Alvares Guimarães<sup>3</sup>, Maurício Ricardo Moreira da Silva Filho<sup>4</sup>, Lorena Carneiro Ferreira<sup>4</sup>, Brunna Oliveira<sup>6</sup>, Wesley Borges de Paiva<sup>4</sup>, Ricardo di Lazzaro Filho<sup>3,7</sup>, Suzane Kioko Ono<sup>1,2</sup>. <sup>1</sup>Faculdade de Medicina da Universidade de São Paulo (FMUSP), São Paulo, Brazil; <sup>2</sup>Hospital das Clínicas da Universidade de São Paulo (HCFMUSP), São Paulo, Brazil; <sup>3</sup>MaChiron, São Paulo, Brazil; <sup>4</sup>InRad-Instituto de Radiologia, São Paulo, Brazil; <sup>5</sup>Faculty of Public Health, University of São Paulo, São Paulo, Brazil; <sup>6</sup>USCS-Municipal University of São Caetano do Sul, São Caetano do Sul, Brazil; <sup>7</sup>Instituto de Biociências-USP, São Paulo, Brazil  
Email: joao.mcfilho@fm.usp.br

**Background and aims:** Contrast-enhanced Computed Tomography (CT) liver exams most commonly have four phases: unenhanced, arterial, portal and delayed, that are important to characterize different focal liver lesions, such as hepatocellular carcinoma. Those exams are usually in DICOM format, which contain exam-related information in tags that could identify each phase, but there is no standard in the annotation of those tags. i.e. there is large variation

between different CT machines and technologists. Hence, lack of standardized DICOM tags impairs the creation of automatic solutions using those labels. The aim of this project is to generate a fully automated solution to recognize each phase of the exam from the original DICOM data using only imaging data, which will facilitate the creation of CT exams databases and development of artificial intelligence (AI) systems for liver segmentation and lesions identification.

**Method:** A database with 121 CT scans of healthy liver donors and chronic hepatitis patients was built from the radiology archive of our institution. We developed an AI algorithm using convolutional neural networks (CNN) to assign a score to each input slice for all possible phases. The corresponding phase with the highest score is then chosen as the predicted label and compared to the true label of each volume to evaluate its accuracy, using a confusion matrix, as shown below. From the database, for training, validation and testing, about 70%, 15% and 15% of the patients were randomly selected, respectively, totalling 484 volumes and 67177 slices. All implementation was performed using Python with Keras and Tensorflow packages.

**Results:** The best CNN model predicted the correct phase in 85.4% of the images and in 94.4% of the volumes of the testing set, when combining each slice prediction into a single volume prediction. When analysing the volume prediction for each phase, the model predicted correctly 100% of the unenhanced, 94.4% of the arterial, 94.4% of the portal and 88.9% of the delayed volumes.

Figure:

**Conclusion:** We developed an algorithm to recognize the CT phases of exams in DICOM format, with good performance. This algorithm is important for the creation of CT liver exams databases and our study successfully demonstrated its deployment in practice. This fully automated AI solution can potentially be incorporated in other radiology-pipelines, improving the accuracy of algorithms for liver segmentation and identification of focal lesions.

### PO-629

#### Multiparametric MRI as non-invasive tool to assess disease activity in autoimmune hepatitis

Johannes Hartl<sup>1</sup>, Roman Zenouzi<sup>2</sup>, Elizabeth Shumbayawonda<sup>3</sup>, Kelly Matt<sup>3</sup>, Andrea Dennis<sup>4</sup>, Ansgar Lohse<sup>2</sup>, Rajarshi Banerjee<sup>5</sup>, Christoph Schramm<sup>6,7,8</sup>. <sup>1</sup>University Hospital Hamburg-Eppendorf

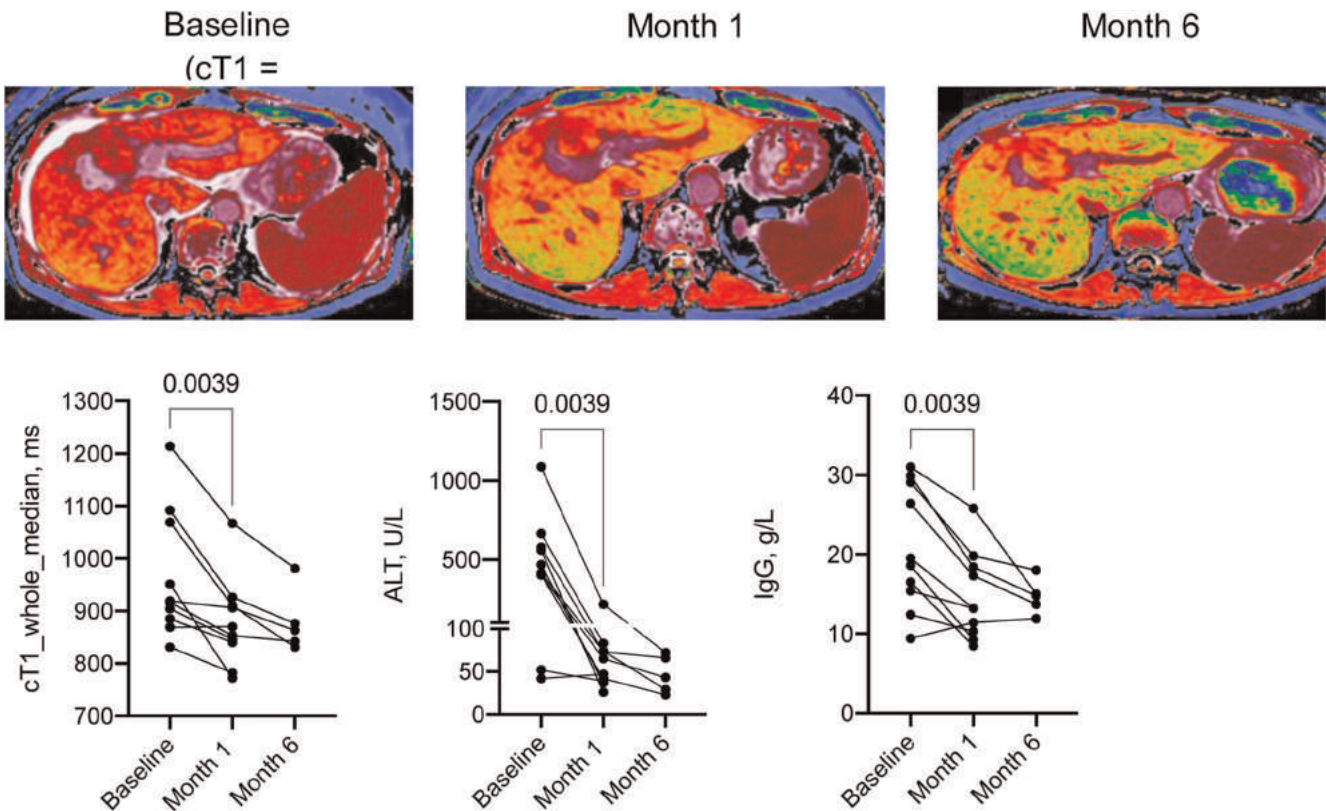

Figure (abstract: PO-629): Exemplary mpMRI imaging in a patients with AIH, whereby mpMRI was performed at diagnosis and after 1 and 6 months of immunosuppressive treatment (upper row). Changes of cT1 as well as of ALT and IgG upon immunosuppression of the total cohort (lower row). Data points represent individual patients. Data points corresponding to individual patients are connected via lines.

(UKE), 1st Medical Centre, Hamburg, Germany; <sup>2</sup>University Hospital Hamburg-Eppendorf (UKE), 1st Department of Medicine, Hamburg, Germany; <sup>3</sup>Perspectum Ltd, Oxford, Northern Ireland; <sup>4</sup>Perspectum Ltd, Oxford, Northern Ireland; <sup>5</sup>Perspectum Ltd; <sup>6</sup>University Hospital Hamburg-Eppendorf (UKE), 1st Department of Medicine, Hamburg, Germany; <sup>7</sup>University Hospital Hamburg-Eppendorf (UKE), Martin Zeitz Centre for Rare Diseases, Hamburg, Germany; <sup>8</sup>University Hospital Hamburg-Eppendorf (UKE), Hamburg Center for Translational Immunology, Hamburg, Germany  
Email: j.hartl@uke.de

**Background and aims:** Up to 50% of patients with autoimmune hepatitis (AIH) show evidence of ongoing hepatic inflammation on histological assessment despite of biochemical markers within the range of normal. Hence, there is an unmet need for novel, non-invasive surrogate markers of disease activity in AIH. Therefore, we herein explored in a prospective proof-of-principle study the diagnostic performance of non-invasive imaging with multiparametric MRI (mpMRI) in assessing the degree of hepatic inflammation. **Method:** A total of 17 treatment-naïve patients who underwent liver biopsy to establish the diagnosis of AIH were prospectively enrolled into the study. MRI was carried out within 48 hours after liver biopsy, and after 1 and 6 months of treatment. mpMRI was performed using LiverMultiScan<sup>®</sup> software (Perspectum Ltd, UK). Median cT1 across

the whole liver, and mean cT1 of regions of interest of the right and the left liver lobe were measured.

**Results:** cT1 whole liver values strongly correlated with hepatic inflammation as assessed by modified hepatitis activity index score (mHAI) ( $r = 0.58$ ,  $p = 0.016$ ,  $n = 17$ ), but not with liver fibrosis ( $r = 0.23$ ,  $p = 0.66$ ,  $n = 17$ ). At baseline, cT1 readouts showed a strong positive correlation with serum ALT levels ( $r = 0.62$ ,  $p = 0.0096$ ,  $n = 17$ ), while IgG did not correlate with neither cT1 ( $r = 0.19$ ,  $p = \text{ns}$ ,  $n = 17$ ), mHAI, nor ALT. However, after one and six months of follow-up, the correlation of cT1 with IgG was excellent ( $r = 0.75$ ,  $n = 10$ ,  $p = 0.026$ , and  $r = 1.0$ ,  $p = 0.016$ ,  $n = 5$ ). A decrease of ALT and IgG was paralleled by a significant decrease of cT1 within the first month of treatment ( $p = 0.039$ , respectively; Fig.) A large variability of cT1 values was noted in the six patients who had achieved complete biochemical remission (range: 927 ms to 772 ms), whereby mpMRI depicted high degrees of hepatic inflammation in some patients with biochemical markers within the upper range of normal. Hepatic inflammation showed a heterogenous distribution across liver slices (Fig. 1), with significant differences of cT1 in regions from the right and left liver lobe within patients ( $p = 0.032$ ).

**Conclusion:** cT1 assessed by mpMRI might represent a valuable non-invasive surrogate marker for AIH activity that allows to monitor resolution of hepatic inflammation upon immunosuppression and identify patients with ongoing disease activity despite biochemical remission. Using mpMRI, which provides the opportunity to assess whole liver slices, confirmed the focal nature of AIH.

**Background and aims:** Genes, and lack of effective therapy has become a promising alternative for cancer treatment. RNA interference (RNAi), especially small interfering RNA (siRNA), with its good stability and gene silencing effect, brings a new opportunity for gene therapy. However, siRNA therapeutics still has the disadvantages of low targeting and effectiveness. Methods for quantitative analysis in vivo. To overcome the above disadvantages of siRNA therapy, we designed and synthesized a kind of siRNA transport vector with aggregation-induced emission and Nuclear magnetic resonance imaging characteristics targeted by hepatoma cells.

**Method:** Survivin siRNA was carried by PEI and interacted with T7-AIE/Gd NPs which were self-assembled of DSPE-PEG-PEI, DSPE-PEG-DTPA (Gd), DSPE-PEG-Mal and TPE. The in vitro physicochemical properties, MRI and AIE fluorescent imaging abilities, cytotoxicity and intracellular localization was evaluated. Then the subcutaneous xenograft model was established by subcutaneously injecting nude mice with LM3 cells. The in vivo antitumor, MRI and fluorescent

imaging, promotion of apoptosis and autophagy in tumor cells activities of the functionalized nanocarriers were estimated in this study.

**Results:** Survivin siRNA@T7-AIE/Gd NPs was synthesized and the characteristic of the nanodots was showed in figure 1. The siRNA@T7-AIE/Gd NPs have excellent MRI and AIE fluorescent imaging abilities in mice (figure 2). Survivin siRNA@T7-AIE/Gd NPs can effectively promote the autophagy and apoptosis of tumor cells (figure 3, 4). ATG7 and ATG12-ATG5-ATG16L1 was activated and the autophagy-dependent DNA damage was significantly increased in Survivin siRNA@T7-AIE/Gd NPs group (figure 4, 5).

**Conclusion:** a novel theranostic siRNA delivery system with dual-mode imaging characteristics of AIE/MRI was synthesized for targeted and image-guided gene therapy of HCC (Scheme).

### PO-985

#### The liver fibroinflammatory marker $\alpha$ 1 is reduced with aldafermin therapy in a randomized, double-blind, placebo-controlled, multicenter study in patients with non-alcoholic steatohepatitis

Angelo Paredes<sup>1</sup>, Lei Ling<sup>2</sup>, Rajarshi Banerjee<sup>3</sup>, Cynthia Guy<sup>4</sup>, Juan Frias<sup>5</sup>, Ziad H. Younes<sup>6</sup>, James F. Trotter<sup>7</sup>, Nadege T. Email: lling94080@yahoo.com

**Background and aims:** The iron-corrected T1 relaxation time (cT1) is a novel imaging marker of intrahepatic fibro-inflammatory activity and is used in the UK Biobank population health study as the reference for liver fibroinflammatory disease. A threshold of cT1 >825 ms has been shown to predict clinical outcomes (ascites,

variceal bleeding, hepatic encephalopathy, hepatocellular carcinoma, liver transplantation, mortality; hazard ratio of 9.9,  $p=0.007$ ; Jayaswal et al., Liver Int 2020). In contrast, liver fat content, as measured by MRI-PDFF, is not predictive of clinical outcomes. Aldafermin, an engineered FGF19 analog, produced fibrosis regression and NASH resolution in a 24-week, randomized, double-blind, placebo-controlled trial in patients with NASH. Here we report the effect of aldafermin on the novel imaging marker cT1 in this trial. **Method:** 78 subjects were randomized 1:2 to receive placebo ( $n=25$ ) or aldafermin 1 mg ( $n=53$ ) SC QD for 24 weeks at 9 US study sites. Key inclusion criteria included biopsy-proven NASH with NAS  $\geq 4$ , F2 or F3 fibrosis and absolute liver fat content  $\geq 8\%$ . Patients underwent the LiverMultiScan™ acquisition protocol (Perspectum Diagnostics) at baseline and week 24. cT1 maps were obtained on multiparametric magnetic resonance imaging scanners standardized across field

# POSTER PRESENTATIONS

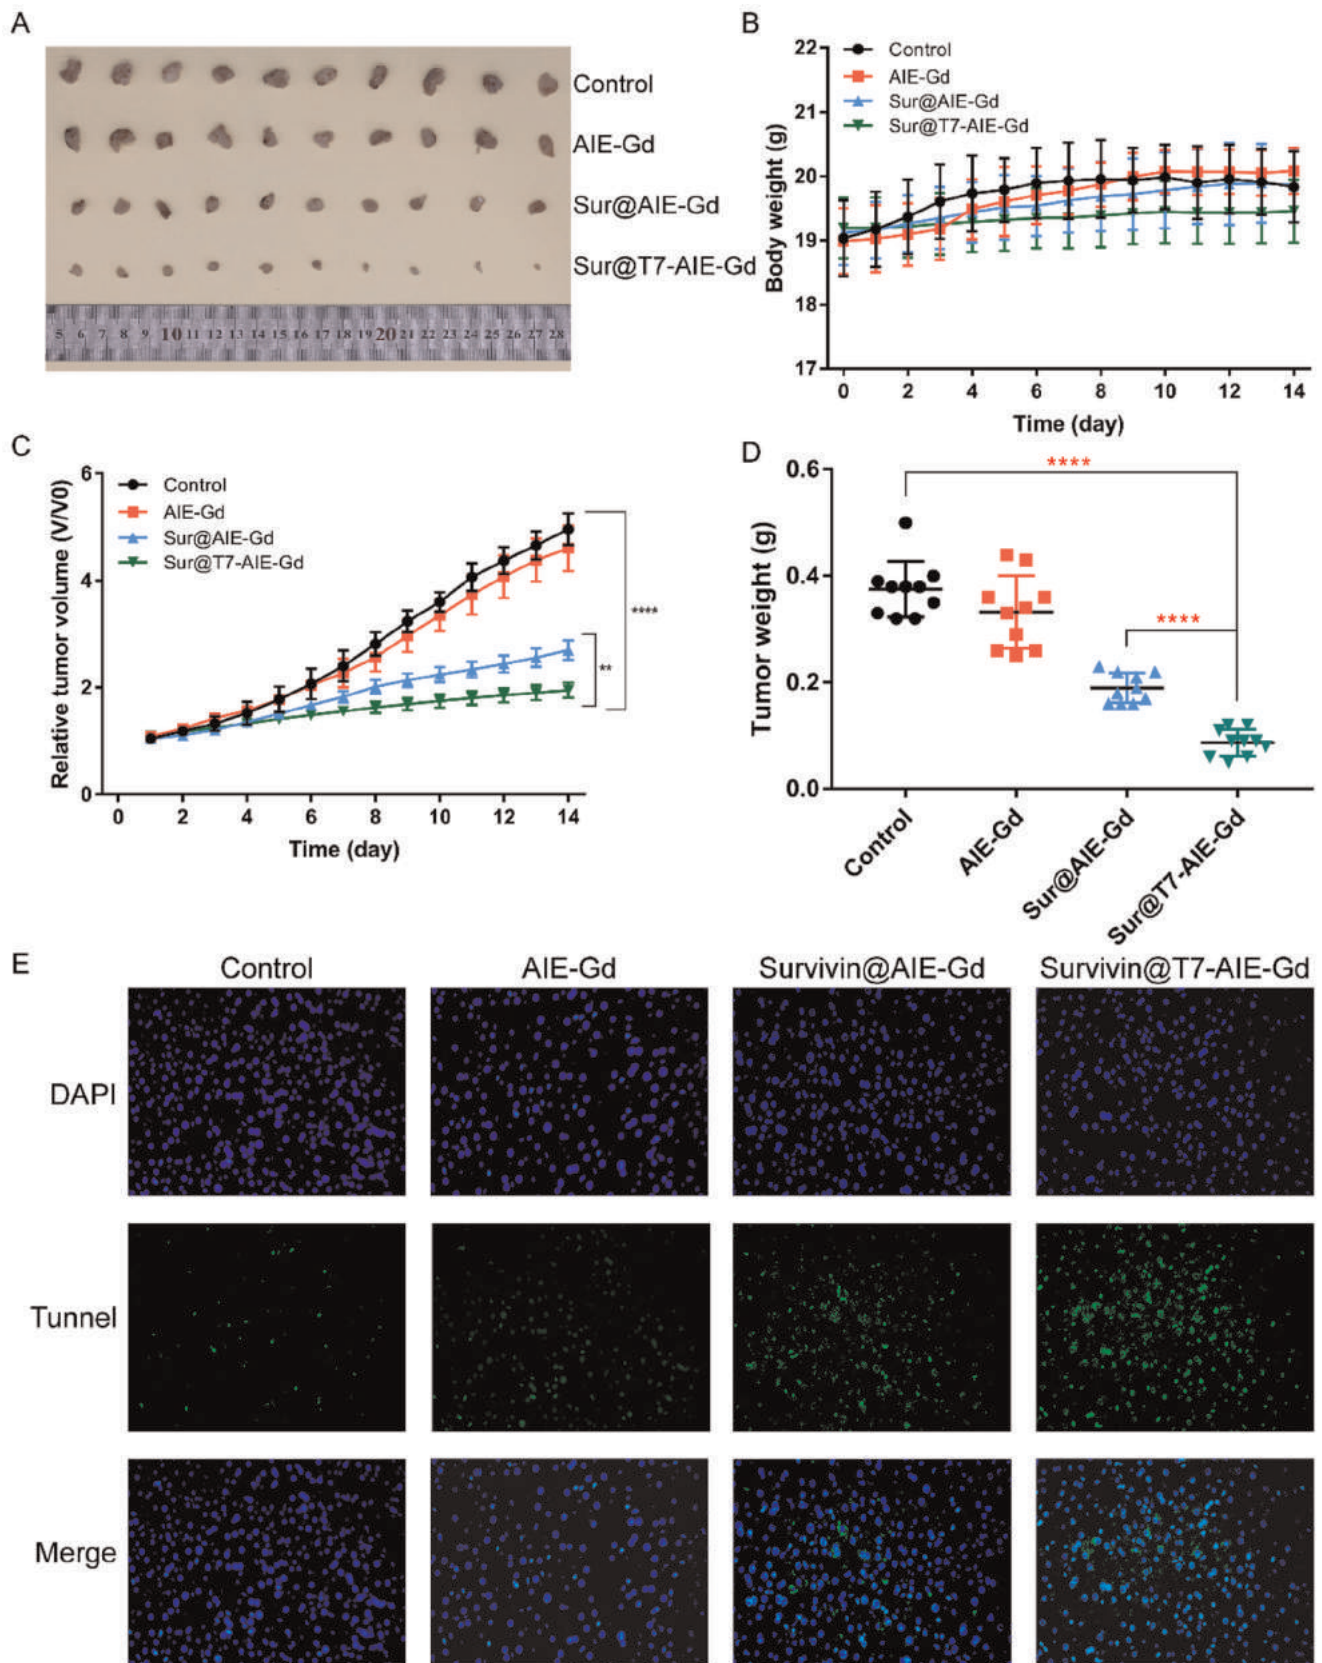

Figure 3: (abstract: PO-738)

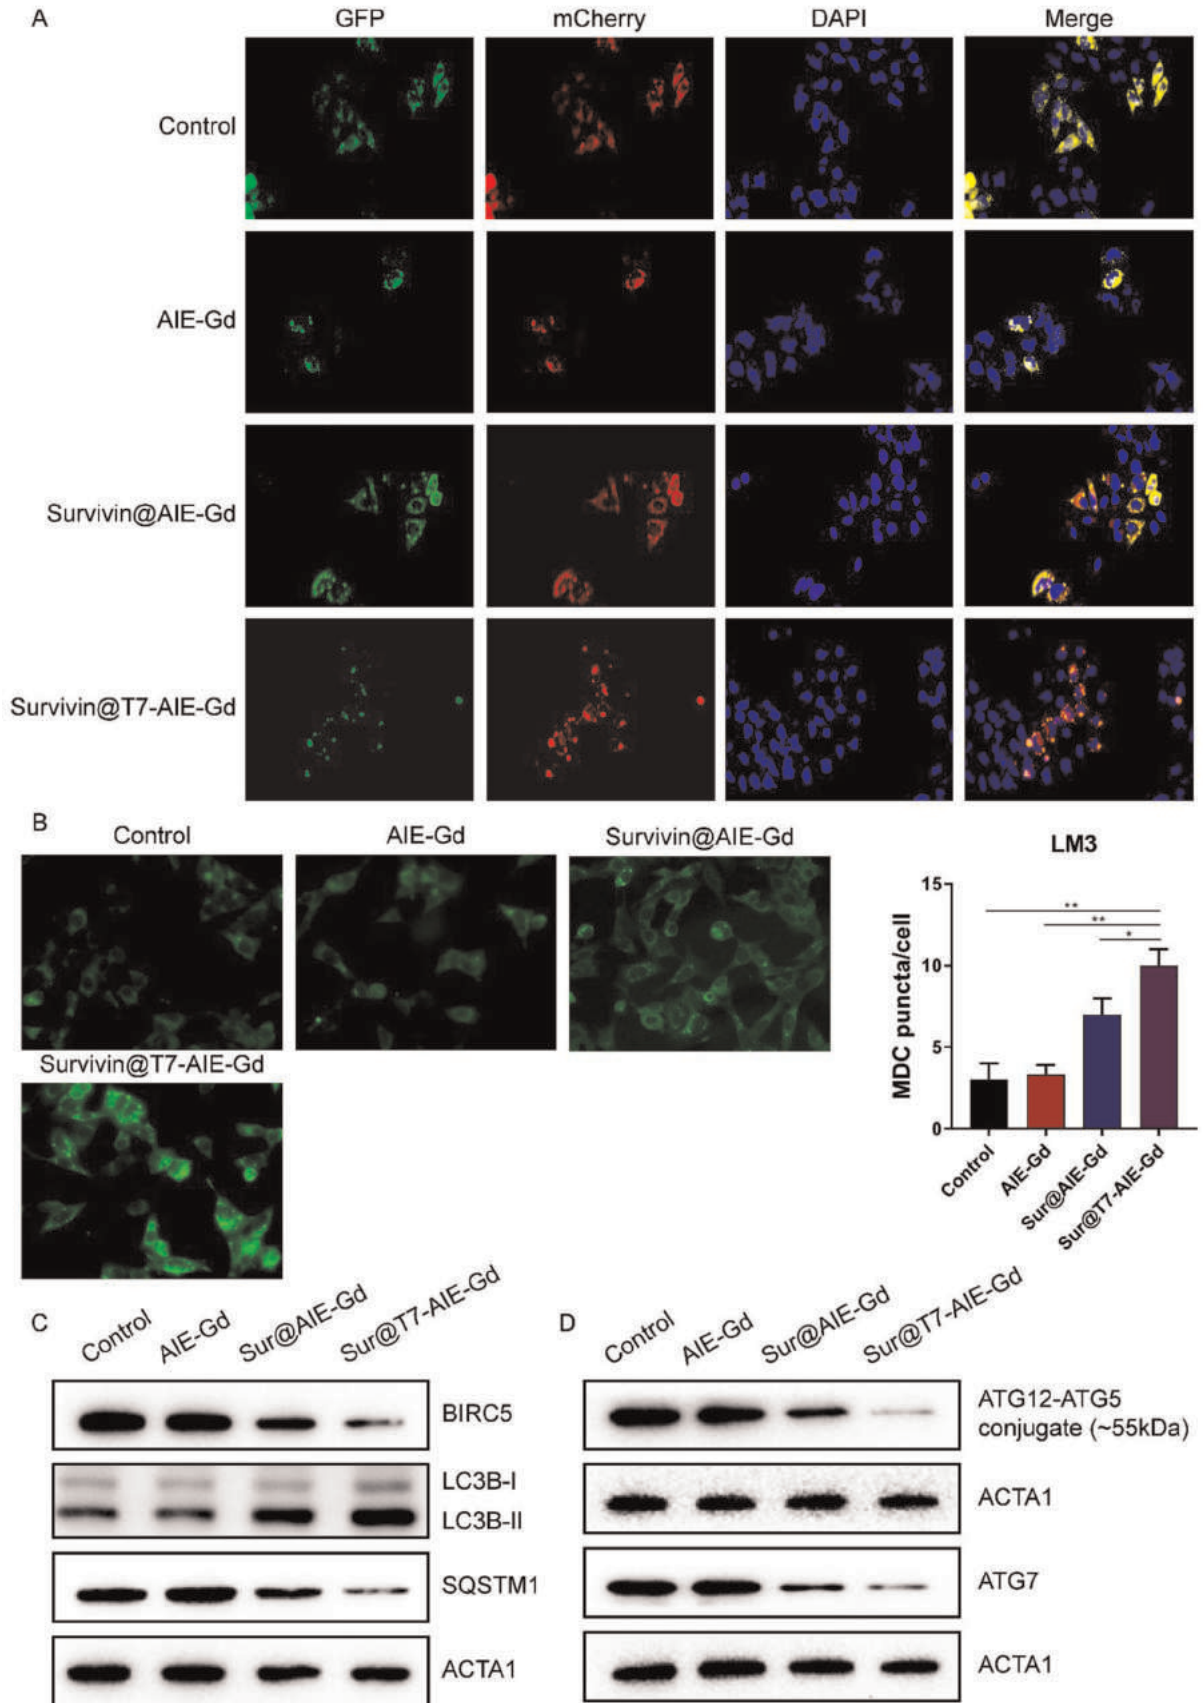

Figure 4: (abstract: PO-738)

# POSTER PRESENTATIONS

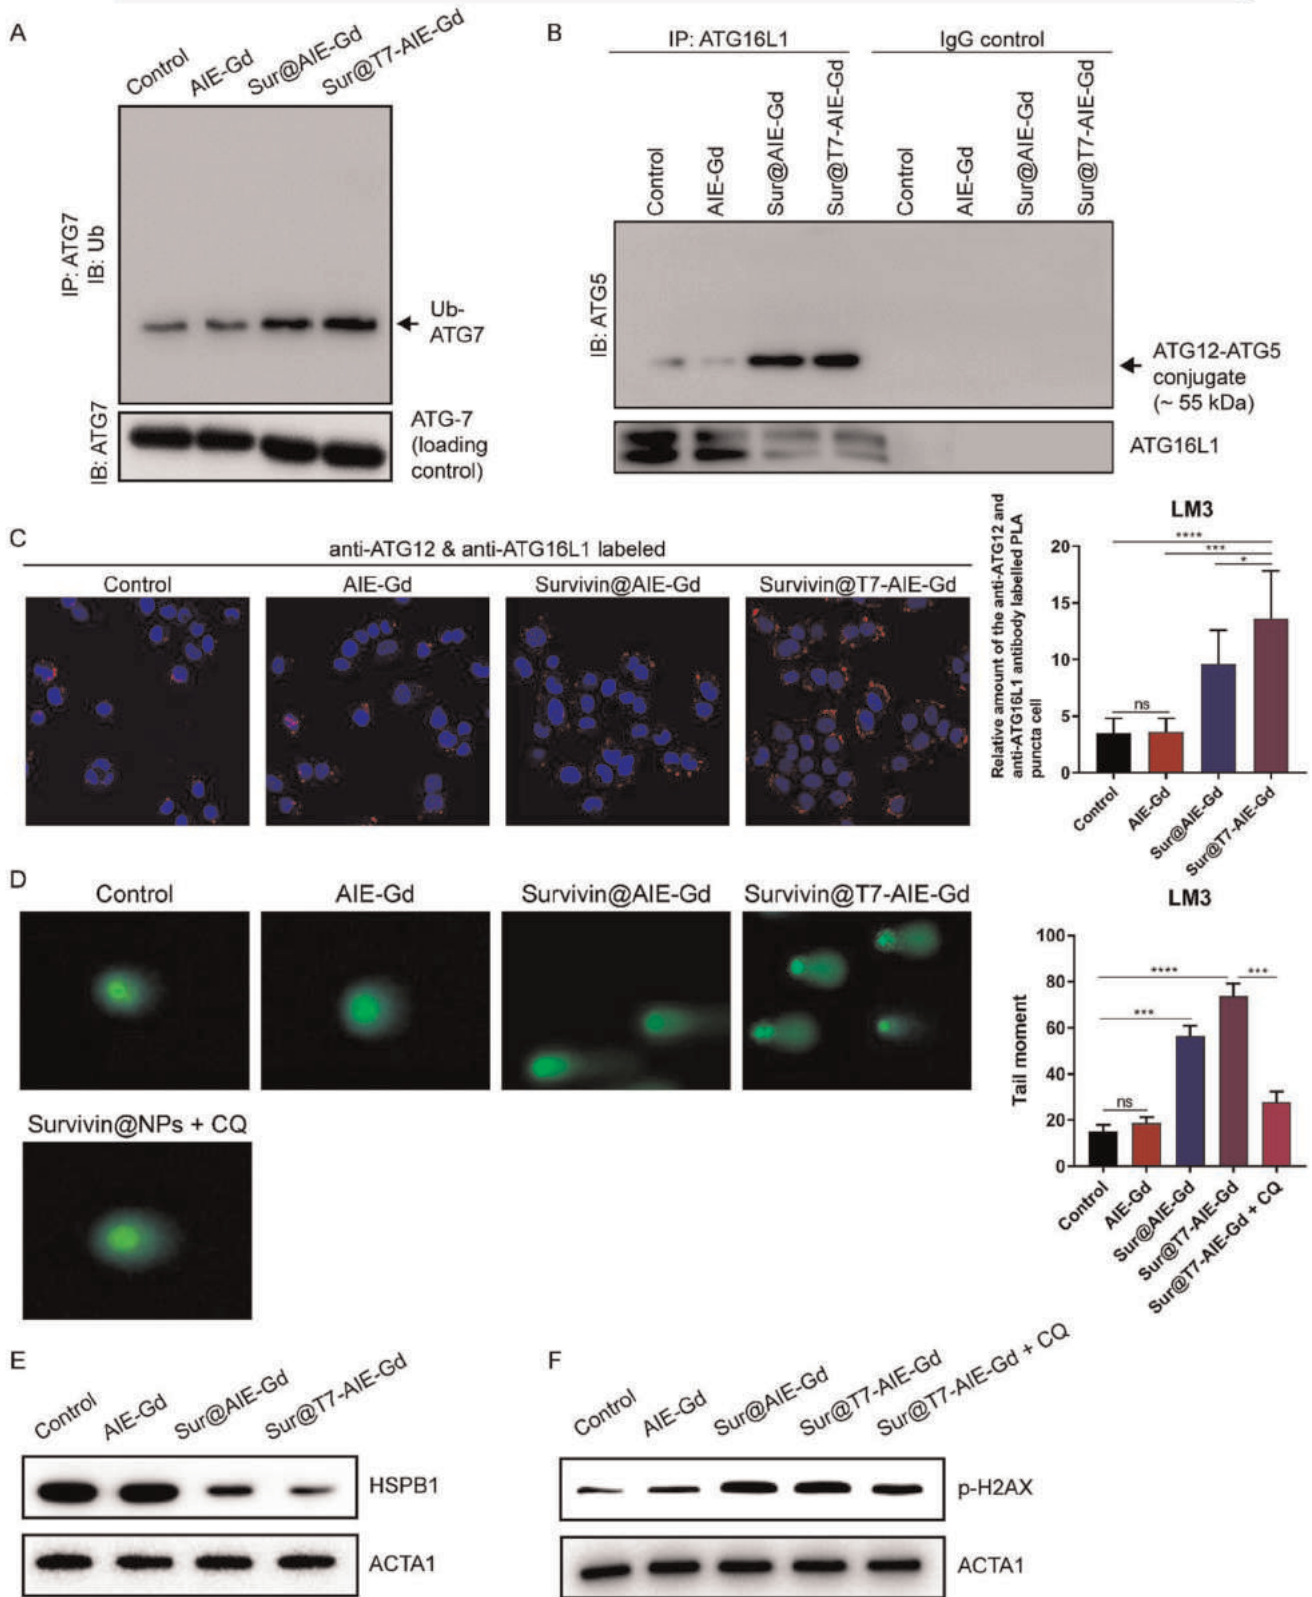

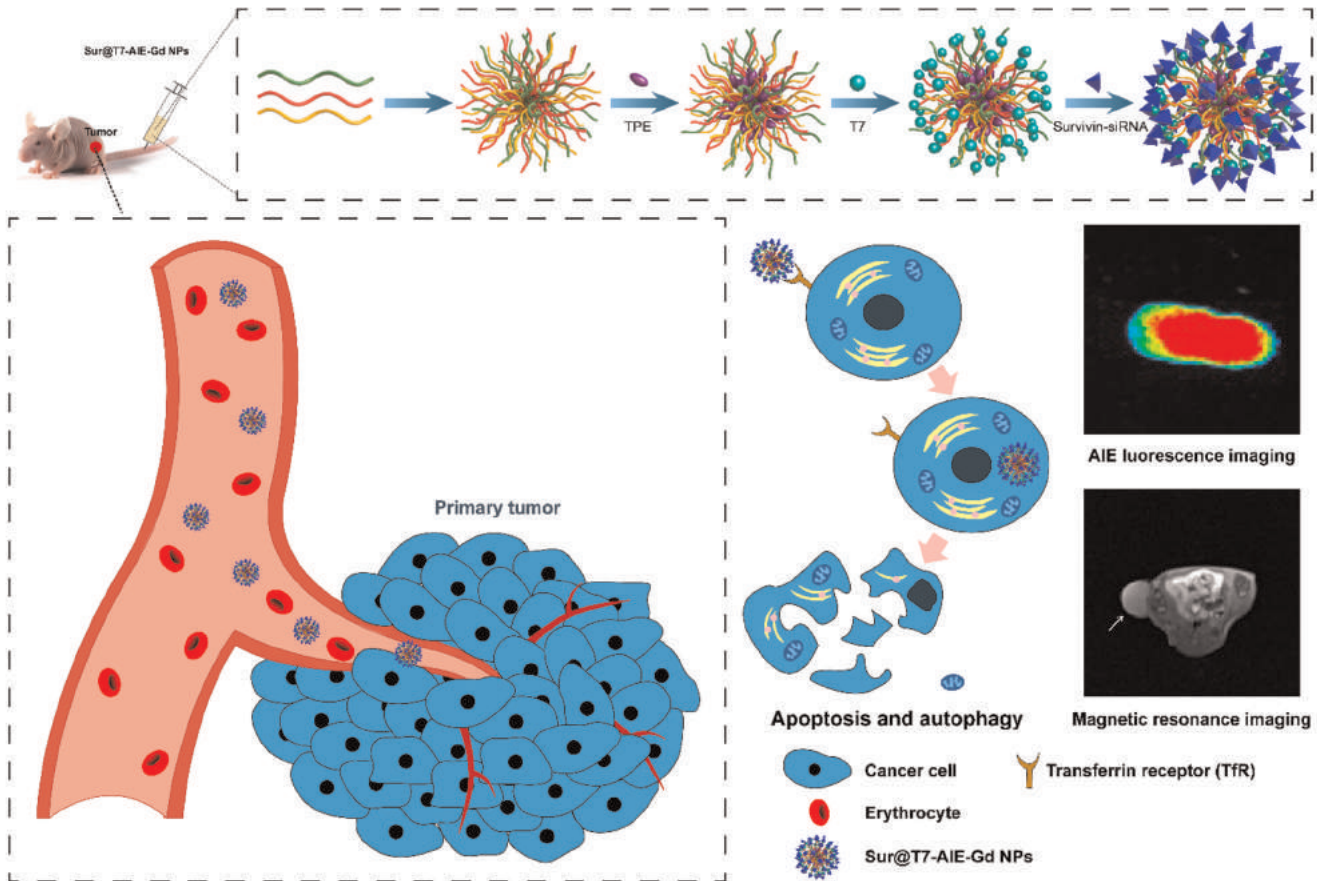

Figure 5: (abstract: PO-738)

Scheme: (abstract: PO-738)

strengths and vendors. Images were analyzed by trained central readers blinded to treatment assignment, clinical and histological information.

**Results:** At baseline, mean cT1 values were 906 ms and 902 ms in the aldafermin and placebo groups, respectively. At week 24, cT1 values declined significantly in aldafermin-treated subjects (−78 ms,  $p < 0.001$  vs baseline). In contrast, a numeric increase in cT1 was observed in placebo-treated subjects (+9 ms,  $p = 0.79$  vs baseline). Aldafermin reduced the proportion of subjects at risk (cT1 >825 ms) (67% at baseline vs 38% at week 24 in the aldafermin group; 89% at baseline vs 78% at week 24 in the placebo group). cT1 correlated with histological grade of ballooning ( $\rho = 0.56$ ,  $p < 0.001$ ), inflammation ( $\rho = 0.42$ ,  $p = 0.014$ ) and steatosis ( $\rho = 0.70$ ,  $p < 0.001$ ), as well as ALT ( $\rho = 0.51$ ,  $p = 0.002$ ), AST ( $\rho = 0.53$ ,  $p = 0.001$ ), ELF ( $\rho = 0.48$ ,  $p = 0.004$ ) and Pro-C3 ( $\rho = 0.37$ ,  $p = 0.027$ ) at week 24.

**Conclusion:** Compared to placebo, aldafermin demonstrated significant reductions in cT1 values, consistent with its anti-inflammatory and anti-fibrotic effect on the NASH liver. Given the prognostic value of cT1 on clinical outcomes, aldafermin treatment may provide benefits to the at-risk patient population defined as having cT1 >825 ms.

**PO-1023**

**Intravital dynamic and correlative imaging reveals the mechanism of canalicular bile flux**

Nachiket Vartak<sup>1</sup>. <sup>1</sup>Leibniz Research Centre for Working Environment and Human Factors, Systems Toxicology, Dortmund, Germany  
Email: vartak@bioimaging.tech

**Background and aims:** Small-molecule flux in tissue-microdomains is essential for organ function, but knowledge of this process is scant due to the lack of suitable methods.

**Method:** We developed two independent intravital imaging techniques, namely Fluorescence Loss After Photoactivation (FLAP) and Intravital Arbitrary Region Image Correlation Spectroscopy (IVARICS), that allow the quantification of advection (flow) and diffusion in individual bile canaliculi and in interlobular bile ducts of intact livers in living mice.

**Results:** Photoactivation of CMNB-caged fluorescein in entire lobules demonstrated the establishment of diffusive gradients in the bile canalicular network and the sink function of interlobular ducts. In contrast to the bile canalicular network, vectorial transport was detected and quantified in the mesh of interlobular bile ducts. These results were confirmed through the orthogonal IVARICS method. The results challenge the prevailing ‘mechano-osmotic’ theory of canalicular bile flow. After active transport across hepatocyte membranes bile acids are transported in the canaliculi primarily by diffusion. Only in the interlobular ducts, diffusion is augmented by regulatable advection.

**Conclusion:** In conclusion, the liver consists of a diffusion dominated canalicular domain, where hepatocytes secrete small molecules and generate a concentration gradient and a flow-augmented ductular domain, where regulated water influx creates unidirectional advection that augments the diffusive flux.

Email: yuoshima1118@gmail.com

**Background and aims:** Liver regeneration after hepatectomy is triggered by mechanical stimulus to vascular endothelial cells secondary to relative increase of portal vein flow in the remnant liver. This study aimed to analyse time-course changes in portal vein flow after hepatectomy and to evaluate its association with liver regeneration.

**Method:** A 70% hepatectomy, which preserves only the right and caudate lobes, was performed in five Lewis rats and the portal vein flow was measured just before hepatectomy, and 1, 24, 72, 168 hour after hepatectomy, using three-dimensional phase-contrast magnetic resonance imaging (3D PC-MRI). Flow parameters, such as flow volume rate, flow velocity, and wall shear stress (WSS), were assessed in the main portal vein (PV) and branches to the right and caudate lobes, and their associations with corresponding liver volume were evaluated.

**Results:** The whole liver volume at postoperative day 7 was 4.3 times as large as the preoperative volume of the right and caudate lobes and equivalent to 88.2% of the preoperative whole liver. The liver volume of the right and caudate lobes at d7 were 4.6 and 3.7 times as large as their preoperative volume, respectively. The flow volume rate of the main PV was 53.4% at 1 h, 56.3% at 1d, 75.6% at d3, and 102.9% at d7, compared with that before hepatectomy, whilst that in the branches of right lobe and caudate lobe at d7 was 4.3 and 13.2 times as much as that before hepatectomy, respectively. The flow volume rate per liver volume in the whole liver, right lobe, and caudate lobe was 2.2/2.8/1.5 before hepatectomy, 4.1/3.6/5.8 at 1 h, 3.0/2.4/3.6 at d1, and 2.6/2.4/3.6 ml/min/cm<sup>3</sup> at d7, respectively. The WSS tended to remain constant over time. The range of WSS at each branch was 1.5–2.3 Pa in the main PV, 1.3–1.8 Pa in the right lobe branch, and 0.6–1.5 Pa in the caudate lobe branch.

**Conclusion:** Abovementioned flow parameters were successfully analyzed over time in the intrahepatic PV branches, as well as their corresponding liver volume. The flow volume rate per liver volume at d7 was similar with that before hepatectomy in each of the right and caudate lobe. The WSS was constant during the process of liver regeneration after 70% hepatectomy, suggesting WSS itself may not be requisite for liver regeneration after hepatectomy.

### PO-855

#### Potential effect of a novel long-acting Glucagon/GIP/GLP-1 triple agonist, HM15211, in preclinical model of cholestatic liver disease

Jung Kuk Kim<sup>1</sup>, Jong Suk Lee<sup>1</sup>, Yohan Kim<sup>1</sup>, Jae Hyuk Choi<sup>1</sup>, Hyunjoon Kwon<sup>1</sup>, Eun Jin Park<sup>1</sup>, Jong Soo Lee<sup>1</sup>, Sung Min Bae<sup>1</sup>, Sang Hyun Lee<sup>1</sup>, In Young Choi<sup>1</sup>. <sup>1</sup>Hanmi Pharm. Co., Ltd., Korea, Rep. of South  
Email: iychoi@hanmi.co.kr

**Background and aims:** Cholestatic liver diseases such as PSC and PBC are characterized by destruction of intra- and/or extra-hepatic bile duct, leading to hepatic/biliary inflammation and fibrosis, and end-stage liver disease. To date, only limited therapy with suboptimal effect is available for this devastating disorder. Recently, we developed a novel long-acting Glucagon/GIP/GLP-1 triple agonist, HM15211, and its therapeutic potential was observed across animal

models of NASH and fibrosis. The present study further explore whether HM15211 could also provide desired therapeutic effect on cholestatic liver diseases.

**Method:** To induce cholestasis-induced liver inflammation and fibrosis, the mice were subjected to common bile duct ligation (BDL mice). 2 days post surgery, BDL mice were administered either with HM15211 or obeticholic acid (OCA). After 2 weeks treatment, hepatic bile acid and hydroxyproline contents were measured. The liver tissue were subjected to HandE, Sirius red staining, and immunohistochemistry for CK-19 and myeloperoxidase (MPO), followed by histological grading. Hepatic expression level of relevant marker genes was evaluated by qPCR.

**Results:** In BDL mice, HM15211 treatment reduced hepatic hydroxyproline (–21.9, –43.7% vs. vehicle for OCA, HM15211), MPO positive cell (63.4, 73.5, 33.3 cells/field for vehicle, OCA, HM15211) and CK-19 positive area (3.9, 3.6, 2.8% for vehicle, OCA, HM15211) greater than OCA. Consistently, HM15211, but not OCA, treatment significantly reduced histological score for portal inflammation, bile duct hyperplasia (1.5, 1.3, 0.7 for vehicle, OCA, HM15211), parenchymal necrosis (2.1, 2.3, 1.0 for vehicle, OCA, HM15211), and fibrosis (1.7, 1.8, 1.0 for vehicle, OCA, HM15211). Similar results were also observed when determining hepatic expression of related marker genes such as TGF-beta and collagen, confirming anti-inflammatory and anti-fibrotic effects of HM15211 in BDL mice. To explore potential benefits of HM15211 on bile acid homeostasis, hepatic bile acid level was measured, and more reduction was observed for HM15211 treatment compared to OCA (–27.4, –76.7% vs. vehicle for OCA, HM15211). Together with reduced hepatic CYP7A1 expression, these results suggest additional favorable effect of HM15211 on hepatic bile acid homeostasis.

**Conclusion:** In BDL mice, the desired treatment effects of HM15211 are well-corroborated. These results warrant further evaluation for therapeutic potential of HM15211 in PSC and PBC.

Email: j.kotlinowski@uj.edu.pl

**Background and aims:** Primary biliary cholangitis (PBC) is an autoimmune disease characterized by progressive destruction of the intrahepatic bile ducts. The immunopathology of PBC involves excessive inflammation; therefore, negative regulators of inflammatory response, such as Monocyte Chemoattractant Protein-1-Induced Protein-1 (MCP1) may play important roles in the development of PBC. The aim of this work was to verify whether Mecip1 expression protects against development of PBC.

## POSTER PRESENTATIONS

**Method:** Genetic deletion of *Zc3h12a* was used to characterize the role of *Mcip1* in the pathogenesis of PBC in 6-52-week-old mice.

**Results:** We found that *Mcip1* deficiency in the liver (*Mcip1*<sup>fl/flAlbCre</sup>) recapitulates most of the features of human PBC, in contrast to mice with *Mcip1* deficiency in myeloid cells (*Mcip1*<sup>fl/flLysMCre</sup> mice), which present with robust myeloid cell-driven systemic inflammation. In *Mcip1*<sup>fl/flAlbCre</sup> livers, intrahepatic bile ducts displayed proliferative changes with inflammatory infiltration, bile duct destruction, and fibrosis leading to cholestasis. In plasma, increased concentrations of IgG, IgM, and AMA autoantibodies (anti-PDC-E2) were detected. Interestingly, the phenotype of *Mcip1*<sup>fl/flAlbCre</sup> mice was robust in 6-week-old, but milder in 12-24-week-old mice, suggesting early postnatal origin of the phenotype. Hepatic transcriptome analysis of 6-week-old and 24-week-old *Mcip1*<sup>fl/flAlbCre</sup> mice showed 812 and 8 differentially expressed genes, respectively, compared with age-matched control mice, and revealed a distinct set of genes compared to those previously associated with development of PBC.

**Conclusion:** *Mcip1*<sup>fl/flAlbCre</sup> mice display early postnatal phenotype that recapitulates most of the features of human PBC.

**Acknowledgment:** This work was supported by research grants from National Science Centre, Poland no. 2015/19/D/NZ5/00254 and 2017/27/B/NZ5/01440 to JeKo, and 2018/29/B/NZ6/01622 to JeKo.

### PO-903

#### Cholangiopathy-related necroptotic cell death recapitulated in human cholangiocyte organoids for screening novel drug targets

Shaojun Shi<sup>1</sup>, Monique M.A. Versteegen<sup>1</sup>, Jan Ijzermans<sup>1</sup>, Luc J.W. van der Laan<sup>1</sup>. <sup>1</sup>Erasmus MC-University Medical Center, Surgery, Rotterdam, Netherlands  
Email: s.shi@erasmusmc.nl

**Background and aims:** Necroptosis is an emerging type of programmed cell death in liver diseases. However, detailed knowledge of necroptosis mechanisms in cholangiopathy is scarce due to the lack of appropriate in vitro models. We aimed to recapitulate necroptotic signalling in human intrahepatic cholangiocyte organoids (ICOs) for the study of cholangiopathy and application in preclinical drug screening.

**Method:** Immunostaining of receptor-interacting protein kinase (RIP)3 and cytokeratin 19 (KRT19) was performed on biopsies from patients with various chronic liver diseases and graft livers in liver transplantation (n = 16). ICOs were generated from the human graft livers (n = 6). Cell death was induced in ICOs by combinations of TNF- $\alpha$  (T)/Smac mimic (S) or T/S/Z-VAD-FMK (Z) and evaluated by ATP assay and transmission electron microscopy (TEM). Mediators of apoptosis, necroptosis, and nuclear factor kappa B (NF- $\kappa$ B) signalling were assessed by immunostaining. Inflammatory genes were determined via RT-PCR. Ethanol metabolite- and bile-induced biliary damage were evoked in ICOs by palmitoleic acid in ethanol (POA/EtOH) and patient-derived bile.

**Results:** RIP3 was exclusively expressed in cholangiocytes in liver grafts and patients with chronic liver diseases. Apoptosis and necroptosis were evoked in ICOs by T/S or T/S/Z exposure without little inter-donor variation. Apoptosis- (T/S) and necroptosis (T/S/Z)-related morphologic features were seen and further confirmed by immunostaining of active caspase 3, cleaved caspase 8, and phospho-mixed lineage kinase domain-like protein (pMLKL). Exposure to POA/EtOH or bile induced cell death in ICOs. Apoptotic and necroptotic ICOs displayed divergent inflammatory gene transcription. Distinct NF- $\kappa$ B signalling was activated in apoptotic (p100) and necroptotic (p65) ICOs. Of note, necroptosis but not apoptosis could be effectively prevented by established necroptosis inhibitors, including necrostatin-1, 7-Cl-O-Nec-1, GSK872, and necrosulfonamide. Emricasan, an FDA-approved caspase inhibitor, failed to attenuate apoptosis but switch it into necroptosis. Drug screening identified Dabrafenib as an inhibitor for both apoptosis and necroptosis, effectively preventing POA/EtOH- and bile-induced cell death.

Figure:

**Conclusion:** RIP3 plays an exclusive role in biliary damage in liver diseases. ICOs recapitulate apoptosis and necroptosis, as well as concomitant inflammatory pathways, and are useful for drug screening. Dabrafenib is identified as a potent apoptosis and necroptosis inhibitor and represents a protective agent against biliary damage.

### PO-1026

#### Serum nuclear magnetic resonance metabolomic signature can discriminate between immunoglobulin G4-related sclerosing cholangitis and primary sclerosing cholangitis

Emmanuel Selvaraj<sup>1,2,3</sup>, Daniel E. Radford-Smith<sup>4</sup>, Rory Peters<sup>1</sup>, Michael Orrell<sup>1</sup>, Kate Lynch<sup>1</sup>, Daniel C. Anthony<sup>4</sup>, Michael Pavlides<sup>1,2,3</sup>, Alessandra Geremia<sup>1</sup>, Adam Bailey<sup>1,3</sup>, Emma Culver<sup>1</sup>, Fay Probert<sup>5</sup>. <sup>1</sup>University of Oxford, Translational Gastroenterology Unit, Nuffield Department of Medicine, Oxford, United Kingdom; <sup>2</sup>University of Oxford, Oxford Centre for Clinical Magnetic Resonance Research, Radcliffe Department of Medicine, Oxford, United Kingdom; <sup>3</sup>NIHR Oxford Biomedical Research Centre, The Joint Research Office, Oxford, United Kingdom; <sup>4</sup>University of Oxford, Department of Pharmacology, Oxford, United Kingdom; <sup>5</sup>University of Oxford, Department of Chemistry, Oxford  
Email: emmanuel.selvaraj@cardiov.ox.ac.uk

**Background and aims:** Global serum metabolomics can be used to identify biomarkers of disease. We performed serum metabolomic profiling in patients with immunoglobulin G4-related sclerosing cholangitis (IgG4-SC) and primary sclerosing cholangitis (PSC) to assess for evidence of a distinctive signature that could discriminate between these conditions, predict response to therapy and provide a biomarker for disease relapse.

**Method:** Stored serum samples collected prospectively from patients with IgG4-related disease (IgG4-RD; n = 39 at diagnosis prior to therapy), PSC (n = 100; 81 large duct; 19 small duct) and healthy controls (HC; n = 16) were prepared for nuclear magnetic resonance (NMR) spectroscopy using a standardised protocol. Principal component analysis (PCA) and orthogonal partial-least squares discriminatory analysis (OPLS-DA) were used to identify discriminatory serum metabolites. Clinical data was obtained from review of electronic databases for correlation with metabolomics data and to adjust for confounders.

**Results:** Lactate, glucose, and glutamine were increased in IgG4-RD compared to PSC (p < 0.0001), whereas -CH<sub>3</sub> lipoprotein resonances were decreased (p < 0.001). OPLS-DA modelling with an optimised threshold diagnosed IgG4-RD-as opposed to PSC-with an accuracy of 86%, sensitivity 85% and specificity 90%, adjusted for age, gender, comorbidities, serum IgG4 level and medications. Both IgG4-RD and PSC were independently distinguishable from HC with an accuracy of 96% and 91%, respectively. When only IgG4-SC patients (n = 23) were included with large-duct PSC patients (n = 81), the accuracy was 88%.

When IBD was excluded as a comorbid condition (IgG4-SC n = 2, PSC n = 78), the diagnostic accuracy improved to 98%.

Figure:

**Conclusion:** The metabolomic signature determined by serum NMR in patients with IgG4-RD and more specifically IgG4-SC, is distinct from PSC and HC in our cohort. Metabolomic profiling has the potential to be incorporated as an additional criterion to improve the diagnosis of IgG4-RD and help distinguish IgG4-SC from PSC.

**PO-1311**

**The peri-ductular CCL24 rich niche promotes bile duct fibrosis related liver damage in primary sclerosing cholangitis**

Michal Segal<sup>1</sup>, Neta Barashi<sup>1</sup>, Adi Mor<sup>1</sup>, Arnon Aharon<sup>2</sup>, Douglas Thorburn<sup>3</sup>. <sup>1</sup>Chemomab Ltd, RandD, Tel-Aviv, Israel; <sup>2</sup>Chemomab Ltd, Clinical, Tel-Aviv, Israel; <sup>3</sup>UCL Institute for Liver and Digestive Health, Royal Free Hospital, London, United Kingdom  
Email: michal@chemomab.com

**Background and aims:** PSC is a chronic cholestatic liver disease characterized by peri-biliary inflammation and fibrosis. IL4 and IL13, representing a Th2 type inflammatory response were describe as part of PSC related inflammation. CCL24 is a chemokine that signals through the CCR3 chemokine receptor and was previously shown to be elevated in Th2 response and play a key role in pro-fibrotic processes. The aim of this study is to establish CCL24s pivotal role in PSC related pathophysiology and describe the CCL24 rich niche as main driver of fibrosis.

**Method:** Expression of CCL24 in primary human biliary epithelial cell (BEC) and M2 Macrophages was quantified using real time PCR and ELISA. Human primary hepatic stellate cells (pHSC) proliferation was assessed by CFSE staining and FACS. Serum samples from PSC patients, were analysed for CCL24 levels and ELF score. Multivariate linear regression analysis was used to test the dependence of CCL24 and ELF with respect to disease severity.

**Results:** Human BECs and monocytes derived macrophages were cultured with and without IL4, IL13 or both. Using Real time PCR and ELISA we demonstrated that in BEC CCL24 transcription and secretion was significantly increased. M2 macrophages polarized by IL4 resulted in robust increase of CCL24 expression and secretion. One of the hallmarks of biliary fibrosis is peri-ductular increase in number of fibroblasts. Incubation of pHSC with CCL24 promoted fibroblast proliferation while Inhibition of CCL24, by CM-101, a monoclonal antibody neutralizing CCL24, resulted in reduction of proliferation back to normal levels. Multi-variate analysis demonstrated that, in PSC patients sera, CCL24, ELF and Bilirubin are strong predictors of each other, the positive association increased with disease severity (r = 68%, p = 0.017 for patients with ALP >1.5 ULN).

**Conclusion:** We show that the immune response driving biliary fibrosis is characterized by creation of a CCL24 rich niche. Cholangiocytes (BEC) and M2 macrophages secrete CCL24 and drive the vicious circle in which fibroblast proliferation and activation, as well as inflammatory cells recruitment enhance CCL24 secretion and perpetuate bile duct fibrosis related damage. The key role of CCL24 in PSC pathophysiology is further supported by the bidirectional dependency of CCL24 and ELF, in PSC patient's sera, that is increased with disease progression. CM-101, a monoclonal antibody neutralizing CCL24, is currently studied in a phase 2 study as potential novel treatment for PSC.

**Is it the scale (rather than the nature) of the inflammatory response in autoimmune hepatitis that determines treatment response?**

Jessica Dyson<sup>1,2</sup>, Ben Millar<sup>1</sup>, Lin Lee Wong<sup>1,3</sup>, Kile Green<sup>4</sup>, Anastasia Resteu<sup>4</sup>, Stuart Kendrick<sup>5</sup>, uk-aih consortium<sup>1</sup>, David Jones<sup>1,2</sup>. <sup>1</sup>Newcastle University, Translational and Clinical Research Institute, Newcastle-upon-Tyne, United Kingdom; <sup>2</sup>Liver Unit, Freeman Hospital, Newcastle-upon-Tyne, United Kingdom; <sup>3</sup>Royal Devon and Exeter Hospital, Gastroenterology, United Kingdom; <sup>4</sup>Newcastle University, Faculty of Medical Sciences, Newcastle-upon-Tyne, United Kingdom; <sup>5</sup>GlaxoSmithKline, Research and Development, United Kingdom  
Email: jessica.dyson1@nhs.net

Email: jessica.dyson1@nhs.net

**Background and aims:** Autoimmune hepatitis (AIH) is traditionally considered to be highly treatable with immunosuppression. However, UK-AIH data show an incomplete response to therapy in 41% and significant treatment-related morbidity. Typically, standard induction with treatment tapering is used for all patients with no baseline risk stratification. This study used transcriptomics, on pre-treatment liver biopsies, to explore whether the inflammatory response in AIH prior to therapy is similar or divergent in high and low risk patients.

**Method:** RNA was isolated from formalin-fixed paraffin embedded (FFPE) biopsy curls using the AllPrep FFPE RNA extraction (Qiagen, UK). Transcriptomics were performed using Nanostring nCounter, analyzing 770 gene targets with statistics performed using R software. Pre-treatment, diagnostic biopsies were assessed for 29 patients with defined clinical outcomes and 16 liver transplant donor biopsies (control group). 'Low risk' was defined as ALL of normal ALT/IgG, no flares or progression to cirrhosis and on azathioprine (AZA) or mycophenolate mofetil (MMF) only. 'High' risk was defined as ANY of >5 mg prednisolone or >3 mg budesonide, raised ALT and/or IgG, immunosuppression other than AZA/MMF, history of flares or progression to cirrhosis. A threshold of log-fold increase or decrease in gene expression compared to controls with a corrected p value <0.05 was used for significance.

**Results:** 200 genes were significantly differentially expressed between AIH as a whole and controls (138 upregulated in AIH and 62 downregulated with highly significant gene clustering [p < 10<sup>-15</sup>]). There were 14 low risk and 15 high risk patients with minimal difference in the nature of the transcriptome (89% and 87% of the upregulated and downregulated genes, respectively, showed significance in both groups). However, there was a significant difference (p < 10<sup>-15</sup>) in the degree of gene upregulation (but not downregulation) in high risk compared to low risk patients (Figure).

## POSTER PRESENTATIONS

Figure:

**Conclusion:** The nature of the inflammatory transcriptome is very similar between high and low risk AIH patients suggesting a similar disease process in the two groups. There is, however, a marked amplitude difference with significantly high transcription of disease-linked genes in high risk patients. The augmented active response in high risk patients could be modified by treatment. Baseline biomarkers of the inflammatory response may allow us to titrate therapy more effectively.

### PO-1578

#### Should normal liver blood tests be the treatment target in primary biliary cholangitis?

David Jones<sup>1,2</sup>, Aaron Wetten<sup>1,2</sup>, Ben Millar<sup>1</sup>, Laura Ogle<sup>1</sup>, George Mells<sup>3</sup>, Steven Flack<sup>3</sup>, Jonathan Badrock<sup>3</sup>, Richard N. **Background and aims:** Second-line therapy for primary biliary cholangitis (PBC) has entered routine clinical practice for patients showing an incomplete response to first-line therapy with ursodeoxycholic acid (UDCA). Incomplete response is based on persistent elevation of liver biochemistry after 1 year of therapy. A number of biochemistry-based criteria have been described but it is unclear which is optimal and how they relate to the disease process. This study aimed to explore the relationship between UDCA response criteria and the underpinning disease mechanisms in PBC.

**Method:** O-link serum proteomics analysis of inflammatory markers was performed in 400 fully characterized PBC patients from the UK-PBC cohort treated for a minimum of 12 months with UDCA 13–15 mg/kg/day and for whom full biochemical response data were available. UDCA response was assessed using Paris 1 and 2, the POISE criteria and complete normalization of liver blood tests.

**Results:** Ongoing elevation of 19 protein markers (compared to healthy controls) was seen in UDCA-treated PBC patients and these formed the study panel. The study group included 182 (46%) PBC patients with normalised liver blood tests (160 of whom with bilirubin <0.6× upper limit of normal). Of the 218 patients with abnormal liver blood tests, 165 (76%) were Paris 1 responders, 107 (49%) were POISE responders and 92 (42%) were Paris 2 responders. For 17 (89%) of the protein markers there was significant variation across the study groups, with a significant increase according to the stringency of UDCA-response cut-offs (e.g. IL-4RA in Figure). Critically, significant elevation of protein markers was seen in UDCA-responders by all response criteria who had abnormal liver blood tests (88% of markers for Paris 1, 50% for POISE and 44% for Paris 2). However, none of the protein markers were significantly elevated in those with normal liver blood tests as compared to healthy controls.

Figure:

**Conclusion:** This study demonstrates that proteomics are better markers of the biological processes in PBC than serum biochemistry. Ongoing disease activity is seen in patients with persistent abnormal liver blood tests even if they are classed as responders to UDCA therapy (irrespective of the response criteria used). This data shows that disease control in PBC requires normalization of liver blood tests and this should become the goal for both drug trials and clinical practice.

### PO-1822

#### Cellular immune responses to human betaretrovirus in patients with primary biliary cholangitis

Hiatem Abofayed<sup>1</sup>, Bruna Dutra<sup>1</sup>, Hussain Syed<sup>1</sup>, Mandana Rahbari<sup>1</sup>, Andrew L. Mason<sup>1</sup>. <sup>1</sup>University of Alberta, medicine, Edmonton, Canada Email: abofayed@ualberta.ca

**Background and aims:** We have characterized cellular immune responses to a human betaretrovirus (HBRV) infection in patients with primary biliary cholangitis (PBC) and reported that the intrahepatic proinflammatory cellular immune responses to HBRV greatly exceed the autoimmune response, suggesting that HBRV infection plays an important role in mediating PBC Hepatology, 2018;68 (Suppl)1101A. As part of the process, we identified 22 HBRV Gag and Env peptides (15-mer) that individually stimulated cellular immune responses in PBC patients by ELISpot. As serological diagnostics can only identify a small proportion of those with HBRV infection, our goal was to develop an interferon (IFN-gamma) release

assay in peripheral blood mononuclear cells (PBMC) and construct an "HBRV QuantiFERON" assay.

**Method:** Intrahepatic lymphocytes were isolated from transplant recipients' liver by flushing the portal vein (PBC n = 9, other hepatic disease n = 9) and PBMC were isolated from PBC patients (n = 32) and other liver diseases (n = 30). Following lymphocytes stimulation with 22 HBRV peptide pool, ELISpot was used to measure IFN-gamma spot forming colonies and Mesoscale V-Plex ELISA to quantify IFN-gamma production. To assess for inhibitory factors, 8µg anti-PD1 (nivolumab) was included with the stimulation assay.

**Results:** Following stimulation with 22 HBRV peptide pool, ELISpot analyses of intrahepatic lymphocytes from PBC patients showed a median of 111 spot forming colonies vs 9 in control subjects (Fig. 1A,  $p < 0.001$ ). A higher proportion of PBC patients PBMC showed a greater than 10 pg of IFN-gamma production following HBRV pool peptide stimulation versus control subjects 50% vs. 8.7% ( $p < 0.03$ ). Following addition of anti-PD-1, the response rate increased to 72% vs. 17% ( $p = 0.0003$ ) in PBC vs. liver disease control (Fig. 1B).

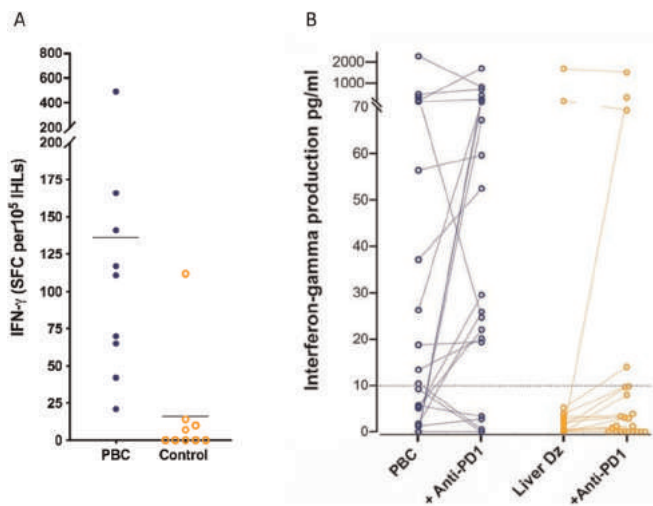

Figure 1:

**Conclusion:** Herein, we show that all PBC patients' intrahepatic lymphocytes and up to 75% of PBMC produce IFN-gamma following stimulation with the characterized peptide pool. The improved sensitivity of the QuantiFERON™ assay with the use of anti-PD1,

suggests that PBC patients' PBMC may express PD1 and have an exhausted phenotype in response to HBRV. This study provides further evidence of HBRV infection playing a role in the pathogenesis of PBC. The IFN-gamma release assay will be further refined as a diagnostic tool to determine the prevalence of HBRV in patients with liver disease and other disorders.

**PO-2285**

**Vitamin B6 deficiency associates with liver transplantation-free survival in primary sclerosing cholangitis**

Peder Rustøen Braadland<sup>1</sup>, Annika M. Bergquist<sup>2</sup>, Christian Rupp<sup>3</sup>, Robert Voitl<sup>3</sup>, Amandeep K. Dhillon<sup>1</sup>, Trine Folseraas<sup>1</sup>, Marius Trøseid<sup>4</sup>, Arve Ulvik<sup>5</sup>, Øyvind Middtun<sup>5</sup>, Per Ueland<sup>5</sup>, Tom Hemming Karlsen<sup>1</sup>, Mette Vesterhus<sup>6</sup>, Martin Kummer<sup>1</sup>, Johannes R. Hov<sup>1</sup>. <sup>1</sup>Norwegian PSC Research Center, Oslo, Norway; <sup>2</sup>Unit of Gastroenterology and Rheumatology, Karolinska University Hospital, Stockholm, Sweden; <sup>3</sup>Dept. of Internal Medicine IV, Heidelberg University Hospital, Heidelberg, Germany; <sup>4</sup>Section of Clinical Immunology and Infectious Diseases, Oslo, Norway; <sup>5</sup>BEVITAL AS, Bergen, Norway; <sup>6</sup>Haraldsplass Deaconess Hospital, Bergen, Norway  
Email: pbraadland@gmail.com

**Background and aims:** We recently reported that patients with primary sclerosing cholangitis (PSC) have a reduced gut microbial potential to synthesize pyridoxal 5'-phosphate (PLP; the active form of vitamin B6, Kummer et al. 2020). PLP concentrations in plasma were also lowered, which associated with shortened survival. Here, we measured additional B6-related markers in this and several other cohorts aiming to define and validate the degree of B6 deficiency and the relationship with inflammation and prognosis.

**Method:** In total 530 PSC patients (71% male; median age 42 years; 72% IBD) and 100 healthy controls (HCs) were included; two cohorts from Norway (Oslo and Bergen, HC and PSC; plasma) and German and Swedish cohorts (both PSC only; serum). Targeted metabolomics was performed using LC-MS/MS (BEVITAL, Bergen, Norway). End point was defined as the earlier event of either liver transplantation (LTX) or death from all causes.

**Results:** In accordance with our derivation cohort, PLP concentrations were lower in PSC compared to HCs in an independent cohort. In a pooled Norwegian cohort, biochemical B6 deficiency (plasma PLP <20 nM) was prevalent in PSC (96/239 [40%] vs. 0/100 HCs). Plasma PLP may in part be degraded by alkaline phosphatase (ALP), which correlated inversely with PLP ( $r = -0.36$ ). We also observed an elevated ratio of the PLP catabolite, 4-pyridoxic acid (PA), to the sum

Figure: (abstract: PO-2285)

## POSTER PRESENTATIONS

of PLP and pyridoxal (PL), which putatively implies inflammation-driven PLP catabolism. However, both PL and PA were also reduced, and the HK-ratio elevated, suggesting reduced activity in the PLP-dependent kynurenine pathway of tryptophan metabolism and hence functional B6 deficiency. PLP strongly predicted LTX-free survival in both the Norwegian, German (n = 150) and Swedish (n = 141) cohorts (figure). The association of PLP with outcome was independent of Mayo risk score (MRS) in the Norwegian cohort (adj. HR for log<sub>10</sub>(PLP) = 0.12, p < 0.0001), but was at least partly explained by MRS in the validation cohorts (Germany: HR = 0.47, p = 0.25; Sweden: HR = 0.12, p = 0.013).

**Conclusion:** Low PLP was associated with PSC and predicted reduced survival. Both an altered gut microbiome, ALP, inflammation-driven B6 catabolism and intracellular, altered distribution of vitamin B6 may contribute to the lowered circulating PLP. However, functional deficits in PLP-dependent pathways suggest a commonality of real, intracellular B6 deficiency in PSC, which may have a clinical impact.

### PO-2388

#### FXR Controls Effector Cytokine Production and Phenotype in Biliary Atresia

Alexander Miethke<sup>1</sup>, Annika Yang vom Hofe<sup>1</sup>, Astha Malik<sup>1</sup>, Tiffany Shi<sup>2</sup>, Brandee Wagner<sup>3</sup>. <sup>1</sup>Cincinnati Children's Hospital Medical Center, Division of Gastroenterology, Hepatology and Nutrition, Cincinnati, United States; <sup>2</sup>Cincinnati Children's Hospital Medical Center, Division of Immunobiology, Cincinnati; <sup>3</sup>Metacrine, Inc., San Diego, United States

Email: alexander.miethke@cchmc.org

**Background and aims:** Biliary atresia (BA) is a progressive, inflammatory cholangiopathy of infancy that leads to fibrosis and obliteration of the extra and intrahepatic bile ducts. Farnesoid X receptor (FXR) is a bile acid activated nuclear receptor responsible for regulating de novo bile acid synthesis. We aimed to investigate the immunomodulatory functions of FXR in BA using both murine and human specimens.

**Method:** Newborn Balb/c mice were injected with type A rhesus rotavirus (RRV) within 24 hours of birth to induce experimental BA. Mice were dosed daily with FXR agonist, M044, at 10 mg/kg. Liver mononuclear cells (LMNCs) were isolated from RRV infected neonatal mice at 7 days after RRV infection. They were also separated from the explanted liver of an 8-month-old infant with BA. Cells were treated with M044 for 3 hours *in vitro*, cultured in presence of LPS for 16 hours, restimulated with PMA/Ionomycin, and subsequent subjected to intracellular flow cytometry.

**Results:** LMNCs isolated from RRV infected neonatal mice (Figure 1) or human explant specimen, when treated with M044 *in vitro* prior to LPS stimulation, showed a significant reduction of Ifng expression in macrophages (MP), CD4, CD8, and NKT cells were not responsive to the FXR agonist treatment. *In vivo* treatment of RRV infected mice with FXR agonist for 7 days resulted in a significant reduction of Ifng expression in hepatic immune cells (%Ifng+/MP: 0.8 ± 0.1% vs 1.6 ± 0.03%, %Ifng+/CD4: 11.2 ± 0.3% vs 17.9 ± 0.6%, %Ifng+/CD8: 2.1 ± 0.1% vs 9.8 ± 0.1% in M044 vs vehicle treated RRV infected mice; P < 0.002 for all subsets). 7-day-serum total bilirubin levels as biomarker for ductal obstruction were significantly reduced following administration of M044 (1.5 ± 0.7 vs 8.7 ± 1.2 mg/dL in M044 vs vehicle, P < 0.0001). M044 treatment improved survival by 2 days over RRV infected vehicle controls (n = 8 mice per group; P = 0.04).

	Macrophages	CD4	CD8	NKT
	14.3	19.7	19.4	45.6
UT	11.7	20.3	18.5	43
	11.8	15.9	21	49.4
	9	11.7	14.2	40.7
Treated	10.6	10	15.4	43
	8.55	10	14.9	39.4

Figure 1: Table showing %reduction in Ifng expression in subsets of hepatic immune cells isolated from RRV infected neonatal mice. Cells were either treated with LPS alone (UT) or with 1.0 μM FXR agonist.

**Conclusion:** Based on these preliminary findings— decrease in production of inflammatory cytokines, the improved biomarkers of liver injury, and increased survival—FXR agonists may provide a therapeutic strategy to block progression of liver disease in biliary atresia beyond their effects on bile acid homeostasis.

### PO-2681

#### Altered DNA methylation characterizes autoimmune hepatitis

Pinelopi Arvaniti<sup>1</sup>, Angeliki Lyberopoulou<sup>1</sup>, Eirini Sevdali<sup>2</sup>, Matthaios Speletas<sup>2</sup>, Nikolaos Gatselis<sup>1,3</sup>, Maria Ioannou<sup>4</sup>, Yves Renaudineau<sup>5,6</sup>, George Dalekos<sup>1,3</sup>, Kalliopi Zachou<sup>1,3</sup>.

Email: zachoukalliopi@gmail.com

**Background and aims:** AIH is a chronic liver disease of unknown aetiology and favourable response to immunosuppression. Little is known about the impact of epigenetics on disease's pathogenesis. Our aim was to investigate the presence of DNA methylation modifications in AIH.

**Method:** CD19 (+) and CD4 (+) cells were isolated from 10 AIH patients at diagnosis (time-point 1; tp1), 9 primary biliary cholangitis (PBC) patients and 10 healthy controls (HC). 8/10 of AIH patients were also investigated on biochemical remission (time-point 2; tp2). Their global DNA methylation (5<sup>mC</sup>)/hydroxymethylation (5<sup>hmC</sup>) state was assessed by ELISA. The mRNA of DNA methyl-transferases (DNMT1, DNMT3A, DNMT3B) and Ten-Eleven Translocation deoxynucleases (TET1, TET2, TET3) was determined by quantitative RT-PCR. Epigenome wide association study (EWAS) in CD4 (+) cells was performed by Illumina HumanMethylation 850 K array in AIH and HC. Differences in total 5<sup>mC</sup>/5<sup>hmC</sup> state between AIH-tp1 and HC were also assessed by immunohistochemistry (IHC) on paraffin embedded liver sections.

**Results:** Global DNA 5<sup>mC</sup>/5<sup>hmC</sup> did not differ between groups. Reduced TET1 and increased DNMT3A mRNA levels were found in CD19 (+) and CD4 (+) lymphocytes from AIH-tp1 patients compared to HC and PBC, respectively. CD4 (+) DNMT3A mRNA levels of AIH-tp1 patients were negatively correlated with serum IgG levels (p = 0.03). Immunosuppression (AIH-tp2) decreased DNMT3A in both CD19 (+) and CD4 (+) cells (p = 0.02 and p = 0.03, respectively). EWAS in CD4 (+) cells from AIH-tp1 and AIH-tp2 patients revealed, altered methylation of genes implicated in immune responses, such as HLADP, TNF,

InRNAs and CD86. IHC showed no changes of total 5<sup>mC</sup>/5<sup>hmC</sup> level in hepatocytes, however, increased 5<sup>hmC</sup> staining of periportal infiltrating lymphocytes in AIH-tp1 was detected.

**Conclusion:** Altered expression of TET1 and DNMT3A, characterizes peripheral immune cells in AIH. DNMT3A is associated with disease activity and decreased after complete biochemical response. Furthermore, DNA methylation modifications of specific genes implicated in immunologic pathways of peripheral CD4 (+) lymphocytes and dense 5<sup>hmC</sup> staining of periportal lymphocytes support the notion that epigenetics may play an important role in AIH pathogenesis.

Email: Engel.Bastian@mh-hannover.de

**Background and aims:** Detection of autoantibodies is a mainstay of diagnosing autoimmune hepatitis (AIH). However, conventional autoantibodies for workup of AIH lack either sensitivity or specificity leading to substantial diagnostic uncertainty. We aimed to identify more accurate serological markers of AIH with a protein macro-array and a solid phase ELISA.

**Method:** IgG antibodies with binding capacities to many human and foreign proteins were identified with a protein macro-array and confirmed with solid phase ELISAs in AIH patients. Subsequently, polyreactive IgG (pIgG) were exemplarily quantified by reactivity against human huntingtin-interacting protein 1-related protein in bovine serum albumin blocked ELISA (HIP1R/BSA). Diagnostic fidelity of HIP1R/BSA binding pIgG to diagnose AIH was assessed in a retrospective training, a retrospective multicenter validation and a prospective validation cohort, in cryo-conserved samples from 1568 adults from ten centers from eight countries.

**Results:** Sera from AIH patients exhibited IgG binding to various autoantigens on the protein macro-array. In subsequent ELISAs, AIH patients exhibited higher concentrations of IgG with broad reactivity against protein (human autoantigens and foreign antigens) and non-protein antigens than patients with non-AIH liver diseases and healthy controls. Polyreactivity of IgG was quantified by reactivity

against HIP1R/BSA. Reactivity against HIP1R/BSA had a 26–37% and 6–45% higher specificity to diagnose AIH than conventional anti-nuclear antibodies and anti-smooth muscle antibodies, respectively, and a significantly higher sensitivity to diagnose AIH than liver kidney microsomal antibodies and anti-soluble liver antigen/liver pancreas antigen. Importantly, HIP1R/BSA reactivity was present in up to 88% of patients with seronegative AIH and in up to 71% of AIH patients with normal IgG levels. Under therapy pIgG returns to background levels of non-AIH liver diseases.

Figure:

**Conclusion:** pIgG could be used as a new promising marker to improve the diagnostic workup of liver diseases with a higher specificity for AIH compared to conventional antibodies and a utility in autoantibody negative AIH. Likewise, pIgG could be a major source of assay interference in untreated AIH.

### PO-127

#### Quality of life is impaired in both physical and mental health domains, in patients with Autoimmune Hepatitis: A systematic review and meta-analysis

Selena Dixon<sup>1</sup>, Jill Carlton<sup>2</sup>, Marrisona Martyn-St James<sup>2</sup>, Dermot Gleeson<sup>1</sup>. <sup>1</sup>Sheffield Teaching Hospitals NHS Foundation Trust, Liver Unit, Sheffield, United Kingdom; <sup>2</sup>University of Sheffield, School of Health and Related Research (SchARR), Sheffield, United Kingdom  
Email: selenadixon@doctors.org.uk

**Background and aims:** Quality of life (QoL) has been measured using Patient-Reported Outcome Measures (PROMs) in patients with Autoimmune Hepatitis (AIH). We performed a meta-analysis of QoL in patients with AIH, compared to that in controls.

**Methods:** Medline, EMBASE and PsycINFO were searched from inception to September 2020. Study protocol was registered on PROSPERO (CRD 42020182668). Between-group QoL outcomes were pooled in a random-effects meta-analysis, as standardised mean differences (SMD) with 95% confidence intervals (CI). Study authors were contacted for missing data. Heterogeneity was assessed using I<sup>2</sup> statistic. Study quality was assessed by two review authors independently.

**Results:** Sixteen cross-sectional studies using fourteen different QoL PROMs (n = 2337 adults with AIH from nine countries) were included. Pooled effects of Short-Form (SF)-36 and SF-12 PROM summary scores from nine studies (n = 993) showed that Physical Component Summary (PCS) and Mental Component Summary (MCS) scores were impaired in patients with AIH compared to controls. For PCS, SMD -0.59 (95% CI -0.87, -0.31), p < 0.00001 and for MCS, -0.43 (-0.57, -0.29), p < 0.00001. I<sup>2</sup> was 87% and 47%, respectively. Sensitivity analysis, excluding lower quality studies, reduced heterogeneity for MCS (I<sup>2</sup> = 0%) but not PCS (I<sup>2</sup> = 93%) outcomes. QoL was also reduced in all eight SF-36 subscales (SMD -0.25 to -1.11), with General Health (-1.11), Vitality (-0.82) and Role Physical (-0.70) domain scores most impaired.

Seven studies used mental health-specific PROMs. Control data was available in four (n = 1184). Pooled effects of PROM scores for depression (SMD 0.58 (95% CI 0.28, 0.89), I<sup>2</sup> = 85%, p = 0.00002) and

## POSTER PRESENTATIONS

anxiety (0.44 (0.33, 0.56),  $I^2 = 18\%$ ,  $p < 0.00001$ ) were higher (worse) in patients with AIH versus controls.

Studies evaluating the relationship of QoL to remission status, presence of cirrhosis, co-morbidities or corticosteroid therapy were limited, or reported conflicting results. Study quality was variable.

**Conclusions:** Pooled evidence from cross-sectional studies indicates that patients with AIH have impaired QoL compared to controls, in both physical and mental health domains. However, statistical heterogeneity is evident for some outcomes and results should be interpreted with caution.

### PO-210

#### A Dose-Finding, Positive Proof of Concept Study of HTD1801 in Patients with Primary Sclerosing Cholangitis

Kris Kowdley<sup>1</sup>, Lisa Forman<sup>2</sup>, Bertus Eksteen<sup>3</sup>, Nadege T. Gunn<sup>4</sup>, Vinay Sundaram<sup>5</sup>, Charles Landis<sup>6</sup>, Stephen Harrison<sup>7</sup>, Anita Kohli<sup>8</sup>, Cynthia Levy<sup>9</sup>, Adrian Di Bisceglie<sup>10</sup>, Gideon Hirschfield<sup>11</sup>. <sup>1</sup>Liver Institute Northwest, Seattle, United States; <sup>2</sup>University of Colorado School of Medicine, Aurora, United States; <sup>3</sup>Aspen Woods Clinic, Calgary, Canada; <sup>4</sup>Pinnacle Research; <sup>5</sup>Cedars-Sinai Medical Records Office, Los Angeles, United States; <sup>6</sup>University of Washington School of Medicine, United States; <sup>7</sup>Pinnacle Clinical Research, San Antonio, United States; <sup>8</sup>Arizona Liver Health, Chandler, United States; <sup>9</sup>University of Miami, Coral Gables, United States; <sup>10</sup>HighTide Therapeutics, Rockville, United States; <sup>11</sup>University of Toronto-St. George Campus, Toronto, Canada  
Email: adibisceglie@hightidetx.com

**Background and aims:** Primary sclerosing cholangitis (PSC) is a progressive, inflammatory and cholestatic liver disease, without present effective medical therapy. HTD1801 is an ionic salt of berberine and ursodeoxycholic acid, with predicted enhanced anti-inflammatory, anti-cholestatic and anti-fibrotic effects. We report a proof of concept randomized, placebo controlled, two-part study of HTD1801 over 18 weeks in patients with PSC and elevated serum alkaline phosphatase (ALP).

**Method:** Subjects were initially randomized into one of three treatment groups: (1) placebo (2) HTD1801 500 mg BID or (3) HTD1801 1000 mg BID. Those who had been on UDCA were required to discontinue it at randomization. The primary end point for part 1 of the study was change in ALP at 6 weeks and differences in serum ALP and GGT among the three groups were compared using Mixed-Effect Model Repeated Measures. In part 2 of the study, HTD1801 was continued for an additional 6 or 12 weeks and safety and biochemical efficacy were evaluated.

**Results:** A total of 59 subjects were enrolled into the study and 55 received at least one dose of study drug. Their mean age was 43 years (range 21–75), 32 were male (58%) and 46 were white (84%); the cohort included 35 subjects with IBD (64%) and their mean serum ALP level was 375 (range 122–1048). A total of 16 subjects received placebo, 15 the lower dose of HTD1801 and 24 the higher dose of HTD1801 during part 1 of the study. At week 6, there was a statistically significant difference in ALP and GGT in both HTD1801 treatment groups compared to placebo (Fig. 1a). Among the 32 subjects not on UDCA at randomization, ALP reduction was dose

dependent (36% with high-dose HTD1801, 27% in low-dose vs 10% in PBO) (Fig. 1b). In part 2 of the study, ALP reduction was maintained through 18 weeks of treatment in both HTD1801-treated groups, while ALP and GGT recrudesced substantially among those who crossed over from HTD1801 to placebo. HTD1801 was generally well tolerated. Only 4 subjects experienced serious adverse events (motor accident, *C. difficile* colitis, colostomy hemorrhage, partial SBO respectively), none of which were attributed to study drug.

**Conclusion:** HTD1801 improved biochemical markers of cholestasis in a dose-dependent manner in patients with PSC and was safe and well-tolerated. Further study of HTD1801 is warranted for treatment of PSC.

### PO-254

#### Effectiveness of obeticholic acid in patients with primary biliary cholangitis stratified by biochemical marker status in the real-world setting in the United States

Robert G. Gish<sup>1</sup>, Darren Wheeler<sup>2</sup>, Jay Lin<sup>3</sup>, Femi Adegunle<sup>2</sup>, Melissa Lingohr-Smith<sup>3</sup>, Chiara Bassanelli<sup>2</sup>, Amy Law<sup>2</sup>. <sup>1</sup>Loma Linda University, Loma Linda, United States; <sup>2</sup>Intercept Pharmaceuticals, Inc., New York, United States; <sup>3</sup>Novosys Health, Green Brook, United States  
Email: melissa.smith@novosyshealth.com

**Background and aims:** In the clinical trial setting, obeticholic acid (OCA) has been shown to improve biochemical markers of hepatic injury and cholestasis in patients with primary biliary cholangitis (PBC) intolerant or inadequately responsive to ursodeoxycholic acid. Limited data are available on OCA real-world effectiveness. Therefore, we examined the real-world treatment effectiveness of OCA in subgroups of PBC patients according to their baseline biochemical marker status.

**Method:** Adult patients diagnosed with PBC (ICD-10: K74.3) and newly treated with OCA (May 2016–September 2019) were selected from a US administrative claims and laboratory database. The date of the first OCA prescription claim was designated as the index date. Patients were required to have continuous medical/pharmacy insurance enrollment 6 months prior to index dates (baseline period). Patients were stratified by their alkaline phosphatase (ALP) level ( $>$  or  $\leq 180$  IU/L) and separately by their total bilirubin (TBili) level ( $>$  or  $\leq 0.7$  mg/dL) at baseline. Patient demographics, clinical characteristics, and lab test values were examined. Biochemical responses to treatment were determined according to Toronto criteria (ALP  $\leq 1.67 \times$  ULN) using the latest lab test values in the baseline and follow-up periods.

**Results:** Among 319 PBC patients initiated on OCA, 181 with ALP level at baseline (median age: 62 years; 92.3% female), 69.1% ( $n = 125$ ) had ALP  $> 180$  IU/L (median: 284.0 IU/L) and 30.9% ( $n = 56$ ) had ALP  $\leq 180$  IU/L (median: 147.5 IU/L); from baseline to follow-up, median ALP decreased to 232.0 IU/L ( $-18.3\%$ ) and 132.0 IU/L ( $-10.5\%$ ), respectively. Among 182 PBC patients with baseline TBili lab results (median age: 63 years; 91.8% female), 35.7% ( $n = 65$ ) had TBili  $> 0.7$  mg/dL (median: 1.40 mg/dL) and 64.3% ( $n = 117$ ) had TBili  $\leq 0.7$  mg/dL (median: 0.50 mg/dL); from baseline to follow-up, median TBili decreased to 1.00 mg/dL ( $-28.6\%$ ) and 0.40 mg/dL ( $-20.0\%$ ),

Figure: (abstract: PO-210)

respectively. Biochemical responses to OCA treatment according to Toronto criteria are shown in the figure.

Figure:

**Conclusion:** In this real-world study of PBC patients in the US, OCA was effective in achieving biochemical responses after 1 and 2 years of treatment across patient subgroups with differing biochemical marker status. These real-world findings are generally consistent with that reported in the clinical trial setting.

**PO-344**

**Immunohistochemical staining of cholangioscopy-directed biopsies of cholangiocarcinoma in Primary Sclerosing Cholangitis**

Stephanie Yan<sup>1</sup>, Sooraj Tejaswi<sup>2</sup>, Kristin Olson<sup>3</sup>. <sup>1</sup>University of California, Davis, Gastroenterology and Hepatology, Sacramento, United States; <sup>2</sup>University of California, Davis, Davis, United States; <sup>3</sup>University of California, Davis, Pathology, Sacramento, United States  
Email: soorajt@gmail.com

**Background and aims:** Primary sclerosing cholangitis (PSC) is associated with a high risk of cholangiocarcinoma (CCA).<sup>1</sup> Two pathways of carcinogenesis are known: the classic type with a yet-to-be identified precursor, and the more common intestinal metaplasia-dysplasia-carcinoma sequence.<sup>2</sup> Thus, intestinal metaplasia (IM) is a CCA precursor. Intestinal-type CCA demonstrates a distinct immunohistochemical (IHC) phenotype. We aimed to determine the feasibility of IHC staining of biliary biopsies obtained via cholangioscopy, identify IM in patients with CCA in PSC and compare the IHC profiles of CCA in PSC, CCA without PSC, and intraductal papillary neoplasm of the bile duct (IPNB).

**Method:** We performed IHC staining of cholangioscopic biopsies of 12 patients divided into 4 subgroups: 3 conventional CCA, 3 CCAs in PSC, 3 PSC with benign active inflammation, and 3 IPNB. An expert GI pathologist reviewed these.

**Results:** Adequate tissue for IHC staining was obtained by cholangioscopy-directed biopsies in 11/12 patients (91.6%). Intestinal phenotypes (MUC2, CK20, CDX2) were not detected in PSC with benign active inflammation or non-PSC CCA. In PSC cases with CCA, 2/3 markers were detected in 1/3 patients only. In the IPNB group, 2/3 cases stained positive for two intestinal markers. No similarities were noted between PSC-CCA and IPNB cases.

	MUC1	MUC2	MUC5AC	MUC6	CK7	CK20	CDX2
PSC active inflammation	1 +	-	+	+	+	-	-
	2 +	-	+	+	+	-	-
	3 +	-	+	+	+	-	-
PSC CCA	1 +	-	*	*	+	-	-
	2 +	+	*	*	-	*	+
	3 +	-	+	+	+	-	-
CCA without PSC	1 +	-	-	+	+	*	-
	2 +	-	*	-	+	-	-
	3 n/a	n/a	n/a	n/a	n/a	n/a	n/a
IPNB	1 +	+	+	+	+	-	+
	2 +	-	-	-	+	-	-
	3 +	*	-	-	-	+	+

\*indicates cases with clear staining but involving ≤10% cells, thus classified as negative

**Conclusion:** Cholangioscopy-directed biopsies provided adequate tissue for IHC staining. Intestinal markers were only noted in 1 PSC-CCA case and 2 IPNB cases. Intestinal markers were absent in benign PSC and non-PSC CCA.

Larger longitudinal studies sampling different areas of the hilum and extrahepatic bile duct plus serial sampling over time may help identify patterns to risk stratify patients and evaluate the prognosis of premalignant changes such as intestinal metaplasia, to eventually help devise surveillance strategies for carcinogenesis in PSC.

Email: lessioigerussi@gmail.com

**Background and aims:** Machine learning (ML) is revolutionizing medicine, with clustering as one of the most promising ML approaches for prognostication. We explored whether clustering could support disease subphenotyping to enhance risk stratification in primary biliary cholangitis (PBC).

**Method:** ML was applied to the largest international dataset of PBC patients. The dataset was split into a derivation cohort (training set) and a validation cohort (validation set), and six key clinical features were analyzed: total serum bilirubin, alkaline phosphatase (ALP), albumin, sex, age at diagnosis and treatment with UDCA. The outcome was a composite of liver-related death or liver transplantation. Classification, clustering and standard survival analysis were performed.

**Results:** Training set was composed of 11, 819 subjects, while validation set was composed of 1, 069 subjects. Four clusters with different prognosis were generated in training set and later evaluated in validation set (Figure). Cluster 1 (n = 3, 566) included patients with excellent prognosis, whereas Cluster 2 (n = 3, 966) consisted of individuals at slightly worse prognosis differing from Cluster 1 only for lower median levels of albumin. Young patients with florid cholestasis represented the Cluster 3 (n = 2, 379), whereas patients in Cluster 4 (n = 1, 908) showed signs of advanced liver failure and had the worst prognosis. After restricting the analysis to patients with albumin values at baseline within the normal range, we found that patients with baseline albumin levels between 1.0 and 1.2 × LLN had worse 15-year survival compared to those with levels ≥1.2 × LLN (70.7% vs 84.6%, respectively, p < 0.001).

Figure:

**Conclusion:** Clustering identified four groups of PBC patients with different long-term prognosis. Reference ranges for serum albumin should be reappraised in this condition.

Email: p.j.trivedi@bham.ac.uk

**Background and aims:** The aim of this study was to compare the effectiveness of second-line therapies in primary biliary cholangitis (PBC), with regards Obeticholic acid (OCA) and non-licensed therapy (fibric acid derivatives; FA) across a nationwide multicentre cohort of patients (pts).

**Method:** Efficacy and safety data was accrued from 12 centres across the UK. Biochemical parameters are presented relative to the upper limit of normal (ULN). Efficacy was determined according to the magnitude of reduction in liver biochemistry from baseline to 12 months (mo), and by pre-specified response criteria (Paris).

**Results:** Between August 2017-March 2020 we captured data from 457 PBC pts who initiated second-line therapy (n=349 OCA, 48 bezafibrate, 60 fenofibrate). At baseline, the OCA group appeared to be higher risk, as evidenced by greater ALP values than those initiating FA therapy (2.9 v 2.3 × ULN; p=0.001), and with a greater proportion being ursodeoxycholic acid non-responders (63.5% vs 45.4%; p=0.001), having cirrhosis (16.5% v 8.3%; p=0.03), or abnormal bilirubin values (22.1% v 12%; p=0.02). At 12mo, the magnitude of ALP reduction was 29.3% and 56.7% in the OCA and FA groups (p < 0.001 between groups), with 2% and 49% of pts attaining normal ALP values (Figure). By contrast, 50.8% and 28.1% attained a normal ALT at 12mo (p < 0.001 between groups; Figure). Moreover, 37.3% of the OCA group who had an abnormal bilirubin at baseline normalised values at 12mo (p < 0.05). 12mo composite biochemical response rates were 71.1% and 83.1% under OCA and FA therapy, respectively (p=0.141 between groups). In patients with cirrhosis under OCA treatment (n = 57), significant reductions in ALP, ALT and bilirubin were observed at 12 mo (p < 0.05 for all comparisons), with 61.5% attaining full biochemical response. The number of pts with an elevated bilirubin or cirrhosis in the FA group was too small to permit subgroup analysis therein. Escalation in anti-pruritus therapy was observed in 26.1% and 23.2% of pts (p=n.s.). Mild-moderate elevations in liver biochemistry (DILIN classification) were reported in 4.6% and 12.0% of pts under OCA and FA therapy, respectively (p < 0.05).

**Conclusion:** In this non-randomised study, the magnitude of ALP reduction was greater with FA derivatives, whereas rates of ALT and

bilirubin normalisation were more pronounced under OCA. The need for anti-pruritus treatment is similar between groups, although putative rates of drug-induced liver injury appear greater under FA therapy.

**PO-860**

**Hepatolithiasis is a frequent and prognostic finding in patients with primary sclerosing cholangitis**

Bellal Jubran<sup>1</sup>, Marwa Ismail<sup>2,3</sup>, Maya Stein<sup>4</sup>, Derek Little<sup>5</sup>, Bettina Hansen<sup>2</sup>, Aliya Gulamhusein<sup>6</sup>, Gideon Hirschfield<sup>6</sup>.

<sup>1</sup>University of Toronto, Gastroenterology and Hepatology, Toronto, Canada; <sup>2</sup>University of Toronto; <sup>3</sup>Institute of Health Policy Management and Evaluation; <sup>4</sup>University of Toronto, Internal Medicine; <sup>5</sup>University of Toronto, Gastroenterology and Hepatology; <sup>6</sup>University of Toronto, Toronto Centre for the Study of the Liver  
Email: bellal.jubran@mail.mcgill.ca

**Background and aims:** Intrahepatic biliary stones (hepatolithiasis) is not well characterised clinically in patients with primary sclerosing cholangitis (PSC).

**Methods:** Chart reviews were conducted in patients with a histologic or radiographic diagnosis of PSC, followed at the Toronto Centre for Liver Disease. Radiographic data were collected between the years 2008–2018. Depending on frequency of testing, magnetic resonance imaging (MRI) and ultrasound (US) data was reviewed every 3–5 years. We assessed factors associated with hepatolithiasis based on sex, race, age and phenotype of PSC and inflammatory bowel disease (IBD). Qualitative radiographic findings on image report review, episodes of cholangitis, endoscopic retrograde cholangiopancreatography (ERCP) and occurrence of cholangiocarcinoma (CCA), death and transplant were documented. Data are reported with median and IQR and analyzed using chi-squared and Mann-Whitney U tests.

**Results:** 302 patients were reviewed. The median time to follow-up, defined as from date of diagnosis to last clinic visit or to transplantation date, was 98 months (IQR = 54.5–141.5). The mean age at diagnosis was 38 (SD = 15.1) years; 54% of patients were male. A total of 224 patients had IBD (74%). Of the 302 patients, 80 patients (26%) had evidence of hepatolithiasis on US or MRI. Patients with hepatolithiasis were more likely to be younger (37.4 vs 39.1, p = 0.025), male (65% vs. 50%, p = 0.021), and have large duct disease (99% vs. 88%, p = 0.004). Imaging report review revealed patients with hepatolithiasis were more likely to have intrahepatic biliary thickening (76% vs. 45%, p < 0.001), extrahepatic biliary thickening (69% vs. 50%, p = 0.003), focal biliary dilation (96% vs. 78%, p < 0.001) and disease characterised by more reported strictures on qualitative imaging report review (89% vs 69%, p < 0.001). Concomitant presence of cholelithiasis was greater in the hepatolithiasis vs. the non-hepatolithiasis group (45% vs. 19%, p < 0.001). Patients with hepatolithiasis were more likely to have experienced acute ascending cholangitis (50% vs. 20%, p < 0.001) and need for ERCP (50% vs. 35%, p = 0.020). CCA was numerically higher in the hepatolithiasis group (8.75% vs. 4%, p = 0.1). Patients with hepatolithiasis received transplant more frequently (26.3% vs 12.2%, p < 0.001) with no significant difference in mortality.

Figure 1: Comparison of clinical outcomes during follow-up

Figure:

**Conclusion:** Hepatolithiasis is common in PSC and associated with increased clinical and radiologic disease burden.

**PO-872**

**Circulating B-cell activating factor of the tumour necrosis family (BAFF) and interleukin 21 levels predict treatment response in patients with autoimmune hepatitis**

Maaïke Biewenga<sup>1</sup>, Sebastiaan Heidt<sup>2</sup>, Manon Vergunst<sup>2</sup>, Camiel Marijnissen<sup>1</sup>, Adriaan Van der Meer<sup>3</sup>, Robert De Man<sup>3</sup>, Annemiek Van der Eijk<sup>4</sup>, Leendert Trouw<sup>2</sup>, Bart Van Hoek<sup>1</sup>. <sup>1</sup>Leiden University Medical Center, Gastroenterology and Hepatology, Netherlands; <sup>2</sup>Leiden University Medical Center, Immunology, Netherlands; <sup>3</sup>Erasmus Medical Center, Gastroenterology and Hepatology, Netherlands; <sup>4</sup>Erasmus Medical Center, Virology, Netherlands

Email: m.biewenga@lumc.nl

**Background and aims:** Increased serum IgG and autoantibodies suggest involvement of B-cell immunity in autoimmune hepatitis (AIH). The aim of this study was to assess levels of the important B-cell cytokines B-cell activating factor of the tumour necrosis family (BAFF), interleukin 21 (IL-21) and circulating B-cell populations in AIH and correlate these to presentation and treatment response.

**Method:** BAFF and IL-21 levels were determined in 10 healthy controls and 66 AIH patients before treatment. Treatment response was evaluated after 12 months. Flowcytometry was performed on isolated peripheral blood mononuclear cells of 10 AIH patients and 12 healthy controls.

**Results:** Based on the BAFF and IL-21 level, patients could be divided in 3 groups: 27 (41%) patients with normal BAFF and IL-21 (normal BAFF), 27 (41%) patients with elevated BAFF but normal IL-21 (high BAFF) and 12 (18%) patients with elevated IL-21 (high IL-21). Patients with high BAFF presented with higher bilirubin compared to patients with normal BAFF and high IL-21 (159 vs 26 vs 89 µmol/L; p = 0.001). After 12 months remission was reached in 54% of patients with high BAFF, 34% of patients with normal BAFF and none (0%) of patients with high IL-21 (p = 0.006). During follow-up 3 patients (25%) with high IL-21 developed primary sclerosing cholangitis (PSC) variant syndrome. Autoimmune associated B-cells were more prevalent in AIH patients compared to healthy controls (4.4% vs 1.4%; p = 0.003). Increase in BAFF was related to an increase in naïve B-cells (p = 0.01; r = 0.78) and to a decrease in class switched B-cells (p = 0.003; r = -0.85) and non-class switched B-cells (p = 0.005; r = -0.83).

Figure:

**Conclusion:** Using BAFF and IL-21 levels, different immunological phenotypes with a different presentation, treatment response and outcome were identified. Patients with high BAFF were often icteric at diagnosis but responded well to treatment. BAFF level was also related to shifts in circulating B-cell populations. Patients with high IL-21 had the poorest treatment response and are at risk to develop PSC variant syndrome.

**PO-1017**

**Non-invasive scores of hepatic fibrosis in autoimmune hepatitis**

Marco Ferronato<sup>1</sup>, Luigi Muratori<sup>2</sup>, Marco Lenzi<sup>2</sup>. <sup>1</sup>University of Bologna, Internal Medicine, Bologna; <sup>2</sup>University of Bologna, Internal Medicine, Bologna, Italy

Email: marco.ferronato@studio.unibo.it

**Background and aims:** Assessment of liver fibrosis stage is essential to determine prognosis and guide treatment strategies in autoimmune hepatitis (AIH). Several non-invasive markers have been proposed, but unlike studies in chronic viral hepatitis or NAFLD, they showed poor diagnostic accuracy in AIH patients. We aim to validate additional, low-cost and non-invasive tools to assess the hepatic fibrosis level among AIH patients. Moreover, we want to assess the reliability of these tests among different types of presentation of AIH.

**Method:** 122 consecutive AIH patients (88 female sex, mean age 46 ± 18 years) have been retrospectively studied. Among these, 52% had acute hepatitis at presentation (jaundice and/or transaminases >10× upper limit of normal), while the remaining 48% had non-acute onset (insidious or asymptomatic). We calculated the following non-invasive scores: fibrosis 4 score (FIB-4), AST to platelet count ratio (APRI), AST to ALT ratio (AAR), red blood cell width distribution to platelet count ratio (RDW/PC) and spleen diameter to platelet count ratio (SD/PC). All non-invasive scores were compared to the histological grading of liver fibrosis, evaluated according to Ishak. **Results:** The histological grading was 1 in 27, 2 in 41, 3 in 27, 4 in 17, 5 in 10. Advanced fibrosis (AF) (Ishak grading ≥4) was observed in 27 patients (22.1%). The distribution of the histological fibrosis was identical in acute versus non-acute onset and irrespective of age at onset. The non-invasive scores which best reflect the distribution of the histological grading were SD/PC (ANOVA p < 0.001), FIB-4 (ANOVA p = 0.002), and RDW/PC (ANOVA, p = 0.005). In addition, SD/PC, RDW/PC, AAR and FIB-4 are the best indicator of AF (p < 0.001 for all). The area under receiver operator curve (AUROC) for SD/PC, FIB-4, RDW/PC, APRI, AAR were respectively 0.814, 0.770, 0.768, 0.708, 0.694. The AUROC of SD/PC and FIB-4 in the non-acute subgroup were 0.902 and 0.834, while in patients with acute presentation they were 0.754 and 0.724; the comparison using DeLong's test didn't reach statistical

significance. There were no relevant differences for RDW/PC, APRI and AAR among the two types of presentation [Figure].

Figure: ROC curves of SD/PC, FIB-4, RDW/PC and AAR for the diagnosis of advanced fibrosis; blue line = all AIH patients, green line = non-acute AIH patients, red line = acute AIH patients.

**Conclusion:** Performance of FIB-4, SD/PC, and RDW/PC is good for the diagnosis of AF in AIH and it seems in line with what has been published in literature for other chronic liver diseases. We observed higher diagnostic accuracy of SD/PC and FIB-4 among patients with a non-acute presentation, that wasn't statistically significant probably due to limited sample size. Longitudinal application of these scores might be helpful to non-invasively monitor the progression of liver fibrosis alongside the complete biochemical response.

**PO-1074**  
**The FGF19 analogue aldafermin enriches the lactate-consuming, bile acid-sensitive commensal microbe *Veillonella* in patients with primary sclerosing cholangitis**

Ulrich Beuers<sup>1</sup>, Lei Ling<sup>2</sup>, Duy Dinh<sup>3</sup>, Hsiao Lieu<sup>2</sup>, Alex DePaoli<sup>2</sup>, Rohit Loomba<sup>4</sup>, Gideon Hirschfield<sup>5</sup>. <sup>1</sup>Amsterdam UMC, Amsterdam, Netherlands; <sup>2</sup>NGM Biopharmaceuticals, South San Francisco, United States; <sup>3</sup>Diversigen, Houston, United States; <sup>4</sup>University of California, San Diego, San Diego, United States; <sup>5</sup>Toronto Centre for Liver Disease, UHN, Toronto, Canada  
 Email: lling94080@yahoo.com

**Background and aims:** Primary sclerosing cholangitis (PSC) is a rare, chronic cholestatic liver disease characterized by inflammation and fibrosis of intra- and extra-hepatic bile ducts. Emerging evidence suggests that alterations in bile acids and the microbiome are not simply a consequence but could be a potential cause of PSC. Aldafermin, a non-tumorigenic FGF19 analogue, suppressed bile acid synthesis and decreased hepatic inflammation and fibrosis markers in a randomized, double-blind, placebo-controlled phase 2 study in patients with PSC. Here we report results of aldafermin on the gut microbiota from this study.

**Method:** 62 subjects, with PSC by EASL criteria and an elevated ALP > 1.5 × ULN at baseline, were randomized to daily aldafermin 1 mg, 3 mg or placebo for 12 weeks. Stool samples were collected at baseline and week 12, extracted, and sequenced in the 16S rDNA V4 region on the MiSeq platform. Serum bile acids were measured by mass spectrometry method. We compared pre- and post-treatment

in alpha diversity, beta diversity and taxonomy. A principal coordinate analysis was used to show differences between groups. P values were calculated using Kruskal-Wallis or Mann Whitney tests with Benjamini-Hochberg false discovery rate correction.

**Results:** 81% of reads produced were mapped to the SILVA (v4) database. There were no differences in alpha diversity for each treatment group at baseline or week 12 (Figure 1). UniFrac-based principal coordinates analysis did not reveal any clustering in treatment groups by time. No changes were observed among phyla (*Bacteroidetes*, *Firmicutes*, *Proteobacteria*, *Fusobacteria*, *Actinobacteria*, *Tenericutes*, *Verrucomicrobia*, *Cyanobacteria*, *Euryarchaeota*, *Lentisphaerae*, *Deferribacteres* and *Synergistetes*) or the top 30 most abundant genera over time or between aldafermin and placebo. Subjects who received aldafermin, but not placebo, had a statistically significant increase from baseline in the relative abundance of a rare genus *Veillonella* at week 12 (1.7- and 5.8-fold increase in the 1 mg and 3 mg groups, respectively, vs no increase in the placebo group). *Veillonella* abundance was inversely correlated with deoxycholic acid ( $\rho = -0.46$ ,  $p = 0.001$ ).

Figure 1. PSC patients treated with aldafermin had stable gut microbial composition and diversity over time.

**Conclusion:** PSC patients treated with aldafermin had stable gut microbial composition and diversity. No taxonomic differences were observed except for an increase in the rare genus *Veillonella*. These results echo our previous findings in non-alcoholic steatohepatitis, suggesting that *Veillonella* may serve as a microbiome-based marker for response to aldafermin irrespective of disease etiology.

## POSTER PRESENTATIONS

**Background and aims:** Primary biliary cholangitis (PBC) is characterized by inflammation and destruction of bile ducts, ultimately leading to biliary cirrhosis. Due to low prevalence and slow disease progression it is difficult to investigate the prognosis of subgroups or to evaluate the effectiveness of therapeutic interventions on clinical outcomes. National registry data for Germany do not exist so far. Thus, the German PBC Cohort was implemented as a non-interventional study (NIS).

**Method:** A confirmed PBC diagnosis according to EASL guidelines (at least two of three criteria positive: elevated alkaline phosphatase (AP), AMA-M2 positivity, PBC compatible liver biopsy) was requested and treatment with at least one licensed PBC medication. Subgroups were classified (Paris II criteria) according to their response to therapy with ursodeoxycholic acid (UDCA) as responders (R) or primary (P-IR) or secondary incomplete responders (S-IR). Newly diagnosed patients (ND) were diagnosed within the last six months prior to inclusion.

**Results:** As of January 10<sup>th</sup> 2021, there are 34 recruiting sites (n = 21 academic, n = 4 non-academic hospitals, n = 9 outpatient practices) participating in the PBC cohort of whom 29 sites recruited 320 patients (91% female, mean (SD) age 61.0 (11) years, mean BMI 27.5 (6) kg/m<sup>2</sup>, 15% (n = 45/320) with cirrhosis).

PBC diagnosis was confirmed by elevated AP and AMA-M2 positivity in 235/320 (73%) cases, 95/320 (30%) underwent biopsy, 51/320 (16%) fulfilled all three diagnostic criteria.

Our PBC cohort consisted of responders (N = 188, 59%), or primary (N = 61, 19%) or secondary (N = 43, 13%) incomplete responders, respectively. Median disease duration was 278.5 [127.5; 483] vs. 397.5 [192; 604] vs. 485 [237; 729] weeks. 28 (9%) patients were newly diagnosed. Cirrhosis was present in 13% (R), 21% (P-IR), 12% (S-IR), and 21% (ND), respectively.

In patients with baseline data available n = 297 received UDCA. Mean UDCA daily dosage at initiation of therapy was 13.3 (R), 13.8 (P-IR), 12.5 (S-IR), and 11.0 (ND) mg/kg. 35 patients received obeticholic acid (OCA), 34 of them were incomplete responders. In 30, 12, and 10 individuals bezafibrate, prednisolone, or budesonide were prescribed, respectively.

All but one incomplete responder patients (of 98 with respective data) continued UDCA treatment. In 6/298 (2%) patients a discontinuation of PBC therapy was reported.

39/302 (13%) PBC patients complained on chronic fatigue, 70/295 (24%) reported on chronic pruritus with mild (56%), moderate (30%) or severe (14%) intensity.

**Conclusion:** The German PBC Cohort has been successfully established as prospective nationwide registry and reports important real-world data on therapy and clinical symptoms.

### PO-1418

#### Risk of primary biliary cholangitis in first degree relatives: a prospective cohort study

Johannes Hartl<sup>1,2</sup>, Claudia Kroll<sup>3,4</sup>, Felix Stahl<sup>5</sup>, Ansgar Lohse<sup>1,2</sup>, Christoph Schramm<sup>1,2,6</sup>, Marcial Sebode<sup>2,7</sup>. <sup>1</sup>University Medical Centre Hamburg-Eppendorf (UKE), 1st Department of Medicine, Hamburg, Germany; <sup>2</sup>European Reference Network on Hepatological Diseases (ERN RARE-LIVER); <sup>3</sup>University Medical Centre Hamburg-Eppendorf (UKE), 1st Department of Medicine, Hamburg, Germany; <sup>4</sup>University Medical Centre Hamburg-Eppendorf (UKE), Martin Zeitz Centre for Rare Diseases; <sup>5</sup>Institute of Clinical Chemistry and Laboratory Medicine, Hamburg, Germany; <sup>6</sup>University Medical Centre Hamburg-Eppendorf (UKE), Martin Zeitz Centre for Rare Diseases, Hamburg, Germany; <sup>7</sup>University Medical Centre Hamburg-Eppendorf (UKE), 1st Department of Medicine, Hamburg, Germany  
Email: j.hartl@uke.de

**Background and aims:** In first degree relatives (FDR) of patients with primary biliary cholangitis (PBC), an increased risk of anti-mitochondrial antibodies (AMA) and PBC has been reported. However, studies on testing for PBC-specific anti-nuclear antibodies (ANA),

such as sp100 and gp210, in FDR and regular follow-ups of both FDR being tested positive or negative for PBC-specific antibodies are lacking. We herein prospectively analysed the prevalence and incidence of clinical, biochemical and serological features of PBC in FDR at a single tertiary centre.

**Method:** 231 FDR of 134 PBC patients and 93 age- and sex-matched healthy controls were prospectively screened for biochemical markers of cholestasis and for PBC-specific antibodies including AMA, MIT3, gp210 and sp100. All participants completed a comprehensive survey in order to assess environmental risk-factors for PBC such as urinary tract infection. FDR with biochemical or serological features of PBC were invited for further examination. All participants were invited for a follow-up after 2 and 4 years.

**Results:** In 23% (54/231) of FDR, screening results prompted further examination, which resulted in the diagnosis of PBC in 5/231 (2.2%) FDR. In 4 of the 5 identified cases, the affected family members were sisters, all were diagnosed at an early stage. In 16 (7%) additional cases, PBC-specific antibodies were detected, but these individuals showed no signs of cholestasis. In detail, the prevalence of disease specific antibodies at baseline was as follows: AMA-IFT: 5% (10/231), MIT3: 3% (8/231), SP100: 2% (4/231), and gp210: 0%. 188 and 75 FDR participated in the 2- and 4-year follow-up, respectively. Thereby, 48/188 (26%) and 22/75 (33%) individuals showed biochemical or serological features requiring further assessment. No further diagnoses of PBC were established, 7 additional cases with PBC-specific antibodies were identified. In total, 28/231 (12%) FDR showed at least at one time-point PBC-specific antibodies, 67% of those were female, and the highest prevalence was observed among sisters (23%). In contrast, only 1/93 healthy control (1%, p = 0.002) showed typical antibodies. None of the previously reported environmental risk factors could be confirmed in this cohort.

**Conclusion:** The prevalence of PBC and PBC-specific antibodies is considerably increased in FDR, and especially in sisters of PBC patients. Therefore, screening in this group enables early diagnosis and timely treatment in order to prevent disease progression. Short term development of clinical PBC in carriers of autoantibodies seems to be rare.

### PO-1428

#### The measurement properties of the Dutch PBC-40: a validation study

Rozanne de Veer<sup>1</sup>, Geraldine Da Silva<sup>1</sup>, Maria van Hooff<sup>1</sup>, Maren Harms<sup>1</sup>, Herold Metselaar<sup>1</sup>, José Willems<sup>2</sup>, Elaine Utomo<sup>3</sup>, Adriaan Van der Meer<sup>1</sup>. <sup>1</sup>Erasmus University Medical Center Rotterdam, Gastroenterology and Hepatology, Netherlands; <sup>2</sup>Dutch Liver Patients Association, Hoogland, Netherlands; <sup>3</sup>Independent Researcher, Berkel en Rodenrijs, Netherlands  
Email: r.deveer@erasmusmc.nl

**Background and aims:** Patients with primary biliary cholangitis (PBC) have an impaired health-related quality of life (HRQoL). Practice guidelines recommend evaluating the HRQoL in all PBC patients. The aim of this study was to assess the reliability and validity of a Dutch translation of the PBC-40, a PBC-specific measure of the HRQoL.

**Method:** The PBC-40 was translated into Dutch following standardized forward-backward procedures. Participants received the Dutch PBC-40 and the RAND-36 (a validated Dutch version of the 36-Item Short Form Health Survey) through postal mail. Internal consistency between the items within the PBC-40 domains were assessed by Cronbach's alpha. Values between 0.70 and 0.95 were considered as adequate internal consistency. Content validity was subjectively assessed (face validity). In addition, score distributions were analyzed on floor and ceiling effects. Construct validity was assessed by hypotheses testing using Pearson's correlation between the PBC-40 domains and RAND-36 scales.

**Results:** In total, 177 patients with PBC were included. The mean (SD) age was 61.1 (9.9) years and the majority of patients was female (n = 164; 92.7%). From the total of 7080 PBC-40 items, 61 items (0.9%)

were missing and 342 items (4.8%) were answered with the 'does not apply' option. Each PBC-40 domain had a Cronbach's alpha >0.70, with the highest in the domain fatigue (0.95) (Table). Face validity was considered adequate. Floor effects were present in 2 domains (cognition 19.3% and itch 27.0%). No ceiling effects were observed. All domains were significantly correlated with the corresponding RAND-36 scale (s) ( $p < 0.001$  for all). The strongest correlation was between the PBC-40 domain fatigue and the RAND-36 vitality scale ( $r = -0.834$ ).

PBC-40 Domain	Median domain score (IQR)	Cronbach's alpha	Floor (%)	Ceiling (%)	Corresponding RAND-36 scales	Pearson's r*
Symptoms	2.4 (1.8-3.0)	0.81	1.7	0	Physical functioning Physical pain	-0.535 -0.620
Itch	1.7 (1.0-2.6)	0.83	27.0	0	Physical functioning	-0.322
Fatigue	3.1 (2.2-3.7)	0.95	1.7	0	Vitality	-0.834
Cognition	2.3 (1.4-3.0)	0.94	19.3	0.6	Mental health component summary	-0.579
Social	2.2 (1.6-3.2)	0.91	5.1	0.0	Social functioning	-0.779
Emotional	2.3 (1.3-3.0)	0.78	10.8	1.7	Mental health Role emotional	-0.708 -0.478

\* $p < 0.001$  for all

**Conclusion:** These findings demonstrate the reliability and validity of the Dutch PBC-40 for the assessment of the HRQoL in patients with PBC. This PBC-specific measure can be used in Dutch-speaking patients with PBC for both research and clinical purposes.

**PO-1484**

**Prevalence of immunological tolerance among type 1 autoimmune hepatitis patients on long-term remission**

Laura Patricia Llovet<sup>1</sup>, Lydia Sastre<sup>1</sup>, Montserrat García-Retortillo<sup>2</sup>, Mar Riveiro Barciela<sup>3</sup>, Mercé Roget<sup>4</sup>, Thais Leone<sup>1</sup>, Estibaliz Ruiz-Ortiz<sup>5</sup>, Odette Viñas<sup>5</sup>, Albert Parés<sup>1,6,7</sup>, Alberto Sanchez-Fueyo<sup>8</sup>, Maria Carlota Londoño<sup>1,6,7</sup>, <sup>1</sup>Hospital Clínic Barcelona, Liver Unit, Barcelona, Spain; <sup>2</sup>Hospital del Mar, Department of Gastroenterology, Barcelona, Spain; <sup>3</sup>Hospital Vall d'Hebron, Liver Unit, Barcelona, Spain; <sup>4</sup>Hospital Mútua Terrassa, Liver Unit, Terrassa, Spain; <sup>5</sup>Hospital Clínic Barcelona, Immunology Department, Barcelona, Spain; <sup>6</sup>CIBEREHD; <sup>7</sup>IDIBAPS; <sup>8</sup>King's College Hospital, Liver Unit, United Kingdom  
Email: mlondono@clinic.cat

**Background and aims:** The incidence of relapse following an attempt at immunosuppression (IS) discontinuation in autoimmune hepatitis (AIH) is unknown given the retrospective nature of published studies and the lack of standardization in inclusion and exclusion criteria, and follow-up. To rigorously determine the proportion of AIH patients tolerating IS withdrawal, we conducted a prospective, multicentre, single arm trial (NCT03711669) in type 1 AIH patients meeting strict clinical, biological and histological criteria.

**Method:** Inclusion criteria: age >18 years, biochemical remission for at least 3 years, liver biopsy with a modified hepatitis activity index (mHAI) <3. Exclusion criteria: need of >7.5 mg/d of prednisone to maintain remission, cirrhosis, concomitant liver disease. Immunosuppression was gradually reduced (50% of previous dose) at 1 month-interval until complete withdrawal. In patients receiving combined therapy, azathioprine (AZA) was firstly reduced. The primary end point was disease remission 1 year after complete IS discontinuation.

**Results:** 53 (11%) of 501 patients with AIH met the clinical inclusion criteria, 12 declined to participate, 2 had cirrhosis in the screening biopsy, and 2 had high ALT levels in the screening visit. Finally, 37 patients initiated IS withdrawal: 21 (57%) patients reached the primary end point and 16 (43%) had a flare. In 6 (37%) patients the flare occurred during weaning and in 10 (63%) it happened a median

time of 9 months (3-24) after complete IS withdrawal. All flares were mild (median peak of ALT 96 U/L [51-704]) and resolved after the introduction of previous IS (only 4 patients needed steroids to control de flare). There was a trend towards higher ALT levels in patients who developed a flare (Table).

Table: Characteristics of patients at starting IS withdrawal

Variable	All (n = 37)	Flare (n = 16)	Remission (n = 21)	p
Age (years)	60 (22-80)	53 (42-75)	65 (22-80)	0.165
Female sex (n, %)	19 (51%)	8 (50%)	11 (52%)	0.886
ALT (U/L)	16 (5-40)	20 (10-34)	14 (6-23)	0.053
IgG (g/L)	10 (6-14)	10 (8-14)	10 (6-14)	0.403
Time on remission (years)	4 (3-11)	4 (3-10)	3.5 (3-11)	0.728
mHAI	1 (0-3)	1 (0-3)	1 (0-2)	0.423
Transient elastography (kPa)	4.8 (3.6-9.1)	4.9 (3.6-8.5)	4.6 (3.9-9.1)	0.773
Immunosuppression (n, %)				0.430
AZA	27 (74%)	12 (75%)	15 (72%)	
Steroids	5 (13%)	1 (6%)	4 (19%)	
AZA + Steroids	5 (13%)	3 (19%)	2 (9%)	

Median (range)

**Conclusion:** Patient selection using strict clinical and histological criteria allows for safe ISW in 57% of patients but shows a low applicability. No clinical, serological or histological features predict the development of flares. Liver biopsy might not be required before an attempt of IS discontinuation. New strategies are needed to increase the success of IS withdrawal.

**PO-1486**

**Patient perspective on treatment and prognosis in Primary Biliary Cholangitis: a descriptive study**

Maria van Hooff<sup>1</sup>, Rozanne de Veer<sup>1</sup>, Maren Harms<sup>1</sup>, Geraldine Da Silva<sup>1</sup>, José Willemse<sup>2</sup>, Herold Metselaar<sup>1</sup>, Elaine Utomo<sup>3</sup>, Adriaan Van der Meer<sup>1</sup>, <sup>1</sup>Erasmus University Medical Center Rotterdam, Gastroenterology and Hepatology, Rotterdam, Netherlands; <sup>2</sup>Dutch Liver Patients Association, Hoogland, Netherlands; <sup>3</sup>Independent Researcher, Berkel en Rodenrijs, Netherlands  
Email: m.vanhooff@erasmusmc.nl

**Background and aims:** Better understanding of patient expectations regarding their disease prognosis and management could improve patient care and counseling. In this study we evaluated the patient perspective on their treatment and prognosis in relation to objective disease parameters in primary biliary cholangitis (PBC).

**Method:** Patients with PBC registered at the Dutch Liver Patient Association or the Erasmus MC were sent a questionnaire in August 2020 to obtain self-reported data regarding treatment status, need for additional therapy, and expected survival ('impaired', equal' or 'superior') compared to their peers. In the Netherlands obeticholic acid (OCA) is not generally available. Bezafibrate (BZF) can be used off-label. Patients consented to medical chart review to collect objective disease parameters in order to assess their survival free of liver transplantation (based on the GLOBE score) and need for further treatment (defined by alkaline phosphatase (ALP) >1.67x upper limit of normal (ULN) and/or bilirubin >1.0x ULN).

**Results:** In total, 176 patients responded. The mean (SD) age was 61 (10) years, 163 (92.6%) were female and 168 (95.5%) reported the use of ursodeoxycholic acid (UDCA). The median UDCA dose was 13.9 (IQR 11.7-15.4) mg/kg/day, whereas 62 (36.9%) patients reporting a daily dose <13 mg/kg. Use of BZF and/or OCA was reported by 38 (21.6%) patients. A lifelong need for UDCA was expected by 161 (95.8%) patients. Only 4 (2.4%) patients reported to forget UDCA regularly (i.e. on a weekly basis). Among the 167 patients with available laboratory results, 52 (31.1%) had an ALP >.67x ULN and/or

## POSTER PRESENTATIONS

a bilirubin  $>1.0 \times \text{ULN}$ , while 36 (69.2%) of the latter group did not consider themselves in need of additional therapy. The GLOBE score was available in 153 patients, predicted survival was lower compared to the matched general population in 29 (19.0%) patients, among whom 12 (41.4%) expected their survival to be similar to their peers. Of the 124 (81.0%) patients with a normal survival based on the GLOBE score, 42 (33.9%) expected to have impaired survival.

**Conclusion:** While UDCA compliance is high, and patients are generally aware of the need for lifelong therapy, the self-reported UDCA dosage is often lower than advised. With respect to prognosis and the need for additional therapy, discrepancies frequently exist between patients' perspectives and their objective disease parameters. This implies a need for better patient guidance in PBC care.

### PO-1512

#### Multimarker analysis combining markers of fibrosis and inflammation in primary sclerosing cholangitis

Guri Fossdal<sup>1,2,3</sup>, Lasse Melvær Giil<sup>2</sup>, Trine Folseraas<sup>1,4</sup>, Peder Rustøen Braadland<sup>1,4</sup>, Morten Asser Karsdal<sup>5</sup>, Henning Grønbaek<sup>6</sup>, Eystein Husebye<sup>3</sup>, Tom Hemming Karlsen<sup>1,4</sup>, Johannes Roksund Hov<sup>1,4</sup>, Mette Vesterhus<sup>1,2,3</sup>. <sup>1</sup>Norwegian PSC Research Center, Oslo University Hospital, Oslo, Norway; <sup>2</sup>Haralds plass Deaconess Hospital, Bergen, Norway; <sup>3</sup>Department of Clinical Science, University of Bergen, Bergen, Norway; <sup>4</sup>Institute of Clinical Medicine, University of Oslo, Oslo, Norway; <sup>5</sup>Fibrosis Biology and Biomarkers, Nordic Bioscience, Herlev, Denmark; <sup>6</sup>Department of Hepatology and Gastroenterology, Aarhus University Hospital, Aarhus, Denmark  
Email: guri.fossdal@outlook.com

**Background and aims:** There is a need to establish prognostic tools in primary sclerosing cholangitis (PSC). We have reported associations with clinical outcome for several biomarkers. In this head-to-head metaanalysis of a broad biomarker panel, we compare and combine markers of fibrosis, inflammation or metabolites from microbiota, aiming to detect improved prognostic value.

**Method:** We included 138 non-transplant Norwegian PSC patients (78% males; mean age  $41 \pm 22$  years; 74% IBD) recruited 2008–2012, with biomarker data available from multiple previous studies. Revised Mayo risk score was calculated using the published algorithm. End point was defined as LTX or all-cause death. Combinations of biomarkers were explored by factor analysis.

**Results:** An end point was reached by 53% of patients. Univariate Cox-regression analysis using standardized variables demonstrated strong predictive ability with C-index in the similar range as Mayo score for several variables (Table). Factor analysis adjusted for sex, age and Mayo risk score identified two groups of biomarkers predicting clinical outcome, combining biomarkers reflecting fibrosis and inflammation. Group 1 (ELF test, Pro-C3, CD163, CD206, IL8, kynurenine/tryptophan ratio [KTR]) had HR 1.63, 95% CI (1.06, 2.49),  $p=0.026$ ; group 2 (BGM, KTR, neopterin) had HR 1.51, 1.63, 95% CI (0.18, 1.93),  $p=0.001$ .

**Conclusion:** Our results indicate that a combination of biomarkers of fibrosis and inflammation may have stronger predictive ability than single markers in PSC. Validation in independent panels is warranted to identify the optimal biomarker combination.

#### MARC1 p.A165T polymorphism is associated with decreased liver injury and enhanced antioxidant activity in serum in patients with AIH

Maciej K. Janik<sup>1,2</sup>, Wiktor Smyk<sup>1,2</sup>, Beata Kruk<sup>3</sup>, Benedykt Szczepankiewicz<sup>4</sup>, Barbara Górnicka<sup>4</sup>, Magdalena Lebieźńska-Arciszewska<sup>5</sup>, Yaiza Potes<sup>5</sup>, Inês C.M. Simões<sup>5</sup>, Susanne N. Weber<sup>6</sup>, Frank Lammert<sup>2,6,7</sup>, Mariusz Więckowski<sup>5</sup>, Piotr Milkiewicz<sup>1,2,8</sup>, Marcin Krawczyk<sup>2,3,6</sup>. <sup>1</sup>Medical University of Warsaw, Liver and Internal Medicine Unit, Department of General, Transplant and Liver Surgery, Warsaw, Poland; <sup>2</sup>European Reference Network on Hepatological Diseases (ERN RARE-LIVER); <sup>3</sup>Medical University of Warsaw, Laboratory of Metabolic Liver Diseases, Department of General, Transplant and Liver Surgery, Laboratory of Metabolic Liver Diseases, Centre for Preclinical Research, Warsaw, Poland; <sup>4</sup>Medical University of Warsaw, Department of Pathology, Warsaw, Poland; <sup>5</sup>Nencki Institute of Experimental Biology, Laboratory of Mitochondrial Biology and Metabolism, Warsaw, Poland; <sup>6</sup>Saarland University, Department of Medicine II Saarland University Medical Center, Homburg, Germany; <sup>7</sup>Hannover Medical School, Hannover, Germany; <sup>8</sup>Pomeranian Medical University, Translational Medicine Group, Szczecin, Poland  
Email: mjanik24@gmail.com

**Background and aims:** The progression of autoimmune hepatitis (AIH) varies markedly between patients, which suggests the role of genetic modifiers. Recent analysis of individuals with fatty liver demonstrated that *MARC1* p.A165T polymorphism might have protective effects. Here, we analyse *MARC1*, as well as the *HSD17B13*, *PNPLA3*, *TM6SF2* and *MBOAT7* variants in patients with AIH.

**Method:** The study cohort was composed of 313 non-transplanted adults with AIH, in addition a group of 30 patients who underwent liver transplantation for AIH was included in the analyses. The *MARC1* (rs2642468), *HSD17B13* (rs72613567), *PNPLA3* (rs738409), *TM6SF2* (rs58542926) and *MBOAT7* (rs641738) polymorphisms were genotyped using TaqMan assays. Analysis of mitochondrial damage markers was conducted in relation to the *MARC1* variant.

**Results:** Presence of the *MARC1* minor allele was associated lower ALT ( $p=0.04$ ) and AST ( $p=0.02$ ). Among patients who were treated for AIH for at least 6 months, ones who carried the *MARC1* variant

had lower AST ( $p = 0.01$ ), ALP and GGT (both  $P < 0.01$ ), and lower APRI ( $p = 0.02$ ). *MARC1* protective genotype correlated with higher catalase ( $p = 0.02$ ) and higher total antioxidant activity ( $p = 0.003$ ) in serum. On the other hand, the *PNPLA3* polymorphism correlated MELD ( $p = 0.02$ ) whereas *MBOAT7* (rs641738) increased the odds of developing hepatocellular carcinoma (HCC) (OR = 3.71, 95% CI 1.22–11.28,  $P = 0.02$ ) during follow-up. None of the tested variants increased the risk of liver transplantation or death.

**Conclusion:** Patients with AIH who carry the *MARC1* polymorphism have lower liver injury which is coupled with improved resistance to oxidative stress. Genotyping of the *MARC1*, *PNPLA3* and *MBOAT7* variants in patients with AIH might help to assess their risk of progressive liver disease.

Email: chuhan.chung@gilead.com

**Background and aims:** Magnetic resonance cholangiopancreatography (MRCP) is the primary method of PSC diagnosis but its prognostic utility is unclear. We developed a machine learning (ML) algorithm using MRCP images and evaluated its ability to predict disease progression in patients with PSC.

**Method:** Baseline MRCP and liver biopsy images were available from 122 patients with compensated PSC enrolled in a 96-week, phase 2b clinical trial of simtuzumab (NCT01672853). Activation maps, obtained from feeding the MRCP slices to a convolutional neural network, were trained on a binary outcome of PSC-related clinical events (e.g., hepatic decompensation, ascending cholangitis, cholangiocarcinoma). Discrimination of the resultant ML MRCP score at baseline (range, 0 to 1) for clinical events and histologic progression to cirrhosis were determined and compared with other clinical parameters including a semi-quantitative MRCP risk score (Muir, AASLD 2017), Ishak fibrosis stage, collagen proportionate area (CPA), serum alkaline phosphatase (ALP) and ELF, Mayo risk score, the PReSTO algorithm, and ML-based histologic features (PathAI; Boston, MA [Travis, EASL 2020]).

**Results:** The median age was 45 years, 63% were male, 54% had bridging fibrosis or cirrhosis, 52% had ulcerative colitis, 52% were on

Parameter	PSC-Related Clinical Events		Progression to Cirrhosis	
	AUROC (95% CI)	p-value vs. ML MRCP score	AUROC (95% CI)	p-value vs. ML MRCP score
<b>Cholangiography</b>				
ML MRCP score	0.93 (0.86, 1.00)	--	0.77 (0.63, 0.90)	--
MRCP risk score*	0.69 (0.59, 0.80)	0.0004	0.71 (0.58, 0.83)	0.5374
<b>Fibrosis</b>				
Ishak fibrosis stage	0.67 (0.56, 0.79)	0.0003	0.71 (0.59, 0.84)	0.6122
CPA	0.53 (0.41, 0.65)	<0.0001	0.68 (0.55, 0.82)	0.4702
ML Ishak score (trichrome)	0.68 (0.55, 0.81)	0.0008	0.85 (0.74, 0.96)	0.2840
ML Ishak score (PSR)	0.66 (0.55, 0.77)	<0.0001	0.75 (0.63, 0.86)	0.8451
<b>Clinical Parameters</b>				
ALP	0.68 (0.57, 0.79)	<0.0001	0.75 (0.66, 0.85)	0.8958

Mayo risk score	0.69 (0.58, 0.80)	0.0004	0.69 (0.53, 0.84)	0.4759
PReSTo†	0.70 (0.58, 0.81)	0.0007	0.69 (0.53, 0.84)	0.5013

PSR, picrosirius red.

\* MRCP risk score = 1 x hepatic dysmorphism + 1 x portal hypertension + 1 x peri-hepatic lymph nodes (Muir, AASLD 2017).

† PReSTo: ML model based on age, ALP, AST, bilirubin, albumin, sodium, hemoglobin, platelets, and PSC duration (Eaton, Hepatology 2020;71:214-24).

Figure: (abstract: PO-1644): Discrimination of the ML MRCP score and other parameters for disease progression in PSC

## POSTER PRESENTATIONS

ursodeoxycholic acid, and the median ALP at baseline was 265 U/L (IQR, 126–455). Over a median follow-up of 23 months (range, 0.5–24.7), 25 patients (20%) had a PSC-related clinical event (ascending cholangitis [n = 14], cholangiocarcinoma [n = 1], ascites [n = 2], encephalopathy [n = 2], variceal hemorrhage [n = 2], jaundice [n = 4]) and 18/105 (17%) progressed to cirrhosis. The AUROC of the ML MRCP score for predicting PSC-related clinical events was 0.93 (95% CI 0.86, 1.00), significantly higher than that of the semi-quantitative MRCP risk score, fibrosis assessments, and other clinical parameters (Table). The AUROC of the ML MRCP score for histologic progression to cirrhosis was 0.77 (95% CI 0.63, 0.90), which was not significantly different from the other parameters (Table), but improved by addition of the ML fibrosis score based on trichrome-stained slides (AUROC 0.89; 95% CI 0.80, 0.97). The ML MRCP score was weakly correlated with the MRCP risk score ( $\rho = -0.20$ ;  $p = 0.025$ ), ELF ( $\rho = -0.18$ ;  $p = 0.042$ ), and PReSTo ( $\rho = -0.19$ ;  $p = 0.036$ ), but not the other parameters.

**Conclusion:** A deep learning approach to MRCP image analysis is able to predict disease progression in PSC and its prognostic utility exceeds that of other clinical and histologic assessments. Validation of these findings may provide a quantitative, ML-based assessment of PSC-related prognosis based on routinely collected MRCP images.

### PO-1664

#### Incidence of hepatic outcomes in patients with cirrhosis due to primary biliary cholangitis: A population-based epidemiology study

Lina Titievsky<sup>1</sup>, Erik Ness<sup>1</sup>, Amy Law<sup>1</sup>, Ellie Goldman<sup>1</sup>, Darren Wheeler<sup>1</sup>, Monica Bertoia<sup>2</sup>, John D. Seeger<sup>2</sup>, Mindie Nguyen<sup>3</sup>, Yuval Patel<sup>4</sup>, Femi Adekunle<sup>5</sup>, Chiara Bassanelli<sup>5</sup>. <sup>1</sup>Intercept Pharmaceuticals, Inc., New York, United States; <sup>2</sup>Optum Life Sciences, United States; <sup>3</sup>Stanford University, Redwood City, United States; <sup>4</sup>Duke University, Durham, United States; <sup>5</sup>Intercept Pharmaceuticals, Inc., London, United Kingdom  
Email: lina.titievsky@interceptpharma.com

**Background and aims:** Primary biliary cholangitis (PBC) is a progressive cholestatic autoimmune disease characterized by inflammatory destruction of the intrahepatic bile ducts leading to cirrhosis and associated complications. Published data showing that PBC patients with advanced disease have worse prognosis compared to patients with early disease, though these were conducted in tertiary care setting, without explicitly focusing on cirrhosis. This study aimed to evaluate the incidence rates (IR) of hepatic related events in PBC patients with vs. without cirrhosis in a population-based setting.

**Method:** Patients with a diagnosis of PBC between October 2016 and September 2019 were identified from a US Electronic Health Records (EHR) Database using either an International Classification of Diseases, 10th revision (ICD-10) diagnosis code (K74.3, 'primary biliary cirrhosis') or an affirmation of Natural Language Processing term of 'biliary cirrhosis' on 2 or more dates within 6 months. The presence of cirrhosis was defined by ICD-10 codes for cirrhosis during baseline (one-year period prior to cohort entry). IRs for a priori specified hepatic outcomes and all-cause mortality were calculated as the number of incident outcomes within the follow-up period divided by the total person-time at risk per 100 Person-Years (PY) with corresponding 95% confidence intervals (CI).

**Results:** A total of 3,940 PBC patients with or without cirrhosis were included. Baseline characteristics showed PBC patients with cirrhosis as compared to those without cirrhosis were older (median age of 66 vs 63 years), less likely to be female (78% vs. 88%), demonstrate impairment in markers of liver function and have a lower platelet count (median of 167 vs.  $237 \times 10^3/\text{ul}$ ). As compared to PBC patients without cirrhosis, IR (per 100 PY) of all-cause mortality was higher in PBC patients with cirrhosis: 8.3 vs. 2.8. For hepatic outcomes, IRs (per 100 PY) were several magnitudes greater among PBC with cirrhosis patients as compared to PBC without cirrhosis patients (liver

transplant: 3.1 vs 0.3; liver failure: 34.6 vs 4.7; and decompensating events: 12.0 vs 3.7).

Figure:

**Conclusion:** To our knowledge, this is the first population-based longitudinal epidemiologic study in PBC patients, to evaluate the incidences of decompensating events, liver failure, liver transplant and death by cirrhosis status. We found IRs of key clinical outcomes to be significantly larger in those with cirrhosis.

### PO-1748

#### Improvement in itch correlates with improved sleep in GLIMMER, a Phase 2b trial of linerixibat for the treatment of cholestatic pruritus in primary biliary cholangitis

David Jones<sup>1</sup>, Robyn von Maltzahn<sup>2</sup>, Helen Smith<sup>2</sup>, April Thompson<sup>3</sup>, M. Celeste Ferreira-Cornwell<sup>3</sup>, Megan McLaughlin<sup>3</sup>, Matthew Allinder<sup>3</sup>, Nazneen Haque<sup>2</sup>, Marlyn J. Mayo<sup>4</sup>, Cynthia Levy<sup>5</sup>. <sup>1</sup>Newcastle University, United Kingdom; <sup>2</sup>GSK, United Kingdom; <sup>3</sup>GSK, United States; <sup>4</sup>University of Texas Southwestern, United States; <sup>5</sup>Miller School of Medicine, University of Miami, United States  
Email: robyn.x.von-maltzahn@gsk.com

**Background and aims:** Pruritus is a common symptom in primary biliary cholangitis (PBC) and can affect sleep; this may impair quality of life, but objective data are limited. In the GLIMMER trial, the impact of linerixibat on itch in patients with PBC was evaluated. The present analysis explores the relationship between itch severity and sleep interference.

**Method:** Patients in the GLIMMER trial recorded itch (twice daily) and degree of sleep interference from itch (each morning) on a 0–10 numeric rating scale. Worst daily itch and sleep interference scores were averaged over 1 week to generate mean scores (weekly itch score [WIS] and weekly sleep score [WSS]). Monthly itch/sleep scores

were based on the most severe WIS and WSS scores in a given month (MIS and MSS, respectively), i.e. worst weekly score for that month. Analyses consisted of prespecified exploratory psychometric evaluations between WIS, WSS and other patient-reported outcome (PRO) measures used in the study; in particular, the 5-D itch measure, which was assessed at initial study period (Day 1), baseline (Day 28), Week 12 of treatment (Day 112) and final study period (Day 140). MIS and MSS calculations and analyses were post hoc as was the correlation of MIS versus MSS (Months 1–3) using Bland-Altman repeated measures analysis.

**Results:** The intent-to-treat (ITT) population comprised 147 patients. All analyses were conducted on the ITT population; however, psychometric analyses were conducted on a subset for whom all PRO data were available. Improvements in change in MIS and MSS from baseline were highly correlated ( $r = 0.84$ ;  $p < 0.0001$ ; Figure). Convergent validity analyses of WSS at baseline showed moderate correlations with the 5-D itch total ( $r = 0.59$ ;  $p < 0.0001$ ) and 5-D itch sleep item scores ( $r = 0.58$ ;  $p < 0.0001$ ).

Bland-Altman repeated measures correlation of change from baseline using Months 1, 2 and 3 MSS and MIS, across all treatment groups (ITT population).  $r$ , correlation coefficient

Figure: Bland-Altman repeated measures correlation of change from baseline using Months 1, 2 and 3 MSS and MIS, across all treatment groups (ITT population).  $r$ , correlation coefficient

**Conclusion:** Itch symptoms closely correlated with sleep interference, suggesting a possible close clinical relationship between itch and sleep; a significant correlation between 5-D itch total and WSS support this. In addition to improving the direct impact of the symptom of itch, an improvement in itch may have an impact on sleep. This is of importance, as sleep disturbance is a common complaint of patients with PBC that adds to disease burden.

**Funding:** GSK Study 201000.

#### PO-1755

##### Younger age is associated with lower self-reported quality of life among patients with autoimmune disease during Canada's response to the COVID-19 pandemic

Christina Plagiannakos<sup>1,2</sup>, Surain Roberts<sup>1,2</sup>, Monika Saini<sup>1</sup>, Catherine Vincent<sup>3</sup>, Lawrence Worobetz<sup>4</sup>, Andrew L. Mason<sup>5</sup>, Jennifer Flemming<sup>6</sup>, Cynthia Tsien<sup>7</sup>, Karim Qumosani<sup>8</sup>, Gideon Hirschfield<sup>1,2</sup>, Harry Janssen<sup>1,9</sup>, Aliya Gulamhusein<sup>1,2</sup>, Bettina Hansen<sup>1,2</sup>. <sup>1</sup>University Health Network, Toronto Centre for Liver

Disease, Toronto Western and General Hospital, Toronto, Canada; <sup>2</sup>University of Toronto, Institute of Health Policy, Management and Evaluation, Toronto, Canada; <sup>3</sup>University of Montreal, Department of Medicine, Montréal, Canada; <sup>4</sup>University of Saskatchewan, Department of Medicine, Saskatoon, Canada; <sup>5</sup>University of Alberta, Division of Gastroenterology and Liver, Edmonton, Canada; <sup>6</sup>Queen's University, Department of Medicine, Kingston, Canada; <sup>7</sup>University of Ottawa, Department of Medicine, Ottawa, Canada; <sup>8</sup>Western University, Schulich School of Medicine and Dentistry, London, Canada; <sup>9</sup>University of Toronto-St. George Campus, Department of Medicine, Toronto, Canada  
Email: christina.plagiannakos@uhn.ca

**Background and aims:** On March 11<sup>th</sup> 2020, COVID-19 was classified as a pandemic and a state of emergency (SoE) was declared across Canada. On September 23<sup>rd</sup> 2020, the government of Canada announced a second wave of COVID-19. We leverage our national multisite registry of patients with autoimmune liver disease to investigate changes in self-reported quality of life (QoL) in a combined cohort of patients with Autoimmune Hepatitis (AIH) and Primary Biliary Cholangitis (PBC) during the COVID-19 pandemic.

**Method:** We included patients with AIH or PBC who had completed at least 1 QoL survey between July 2019 and January 2021. Surveys completed prior to March 11<sup>th</sup> 2020 were classified as Pre-SoE, after March 11<sup>th</sup> as Wave 1, and surveys completed after September 23<sup>rd</sup> as Wave 2. QoL surveys included the Short-Form 36 (SF-36) and the Itch Numeric Rating Scale (iNRS), for PBC patients only. Mixed effects linear and negative binomial regressions estimated mean QoL scores across time stratified by age and adjusted for diagnosis and disease duration.

**Results:** There were 570 participants from 7 tertiary liver clinics across Canada included in the analysis, of whom 62.1% ( $n = 354$ ) had PBC and 37.9% ( $n = 216$ ) had AIH. Females represented 87.4% ( $n = 498$ ), and 78.6% ( $n = 448$ ) were Caucasian. A total of 40.9% ( $n = 233$ ) were 55 years of age or younger. Median duration of disease was 7.7 years [2.96–13.8]. A total of 385 assessments were completed before the SoE, 267 during Wave 1, and 241 during Wave 2.

We observed a significant decreasing trend in estimated mean SF-36 Mental Component scores in younger patients ( $p = 0.017$ ), while older patient QoL remained stable ( $p = 0.123$ , Figure 1a). Longer disease duration was associated with better scores, regardless of time ( $p = 0.011$ ). For the SF-36 Physical Component, estimated mean scores were overall worse in younger PBC patients than older patients ( $p = 0.034$ ). There was a non-significant weak decrease over time for all patients ( $p = 0.191$ , Figure 1b)

For PBC patients, estimated mean iNRS scores worsened over time ( $p = 0.015$ ), and older age was associated with lower reported itch ( $p = 0.007$ , Figure 1c).

**Conclusion:** Younger patients reported worse mental and itch related QoL scores across time, suggesting that these patients are impacted differently than older patients during Canada's response to the pandemic. More attention into this problem is required.

#### PO-1790

##### National audit of diagnosis, management and surveillance in primary sclerosing cholangitis (PSC) in the United Kingdom.

Evangelia Fatourou<sup>1</sup>, Sarah Hyde<sup>2</sup>, Dominic King<sup>3</sup>, Martine Walmsley<sup>4</sup>, Graeme Alexander<sup>1</sup>, Palak Trivedi<sup>3,5,6,7</sup>, Simon Rushbrook<sup>2</sup>, Douglas Thorburn<sup>1</sup>. <sup>1</sup>Royal Free Hospital, Sheila Sherlock Liver Centre and UCL Institute for Liver and Digestive Health, London, United Kingdom; <sup>2</sup>Department of Hepatology, Norwich Medical School, University of East Anglia; <sup>3</sup>Liver Unit, University Hospitals Birmingham (UK), Birmingham, United Kingdom; <sup>4</sup>PSC Support, Oxford, UK; <sup>5</sup>NIHR Birmingham BRC Centre for Liver and Gastrointestinal Research, University of Birmingham, UK; <sup>6</sup>Institute of Immunology and Immunotherapy, University of Birmingham (UK), Birmingham, United Kingdom; <sup>7</sup>Institute of Applied Health, University of Birmingham (UK)  
Email: evangelia.fatourou@nhs.net

## POSTER PRESENTATIONS

Figure: (abstract: PO-1755)

**Background and aims:** PSC is a rare disorder and as such clinical care can be heterogeneous. We audited PSC management across the UK against audit standards set by the British Society of Gastroenterology (BSG).

**Method:** All UK PSC investigators were invited to complete an electronic questionnaire encompassing demographics, diagnosis, bowel and biliary tract cancer surveillance, and risk stratification data (March 2019-Jan 2021).

**Results:** 1,795 patients across 30 centres (liver units  $n = 1548$ , general gastroenterology units  $n = 247$ ) were included. Median age at diagnosis was 51 years and 62.2% were men. Magnetic resonance cholangiography (MRCP) was performed as a diagnostic investigation in 1616 patients (90.0%) and 777 (43.3%) had a liver biopsy. Most were monitored by a hepatologist ( $n = 1610$ , 89.7%). 931 patients (51.9%) received non-licensed therapy with Ursodeoxycholic acid.

Concurrent IBD was present in 1264 patients (70.4%) with 256 (20.3%) having had a colectomy. Where classified, pancolitis (Montreal classification E3) was the commonest disease distribution (673/939, 71.7%) with 1.6% ( $n = 15$ ) having isolated ileal disease. In those without IBD, 140 (27.6%) patients had not had a colonoscopy and biopsies to exclude diagnosis.

785 patients (43.7%) had not undergone disease staging or risk stratification within the last 2 years; where performed, it was most commonly by transient elastography ( $n = 645$ , 78.7%). Surveillance for biliary tract cancer was not undertaken in 515 patients (28.7%); when performed, it was most commonly by ultrasound (US) ( $n = 568$ , 47.1%) or alternating MRCP/US ( $n = 429$ ,  $n = 35.6\%$ ). Ca 19-9 was utilised in 730 patients.

Among those with colitis, only 572 (77.8%) underwent annual colonoscopy surveillance. Of those patients who had any surveillance, 623 patients (49.2%) had protocol colonic biopsies and 417 patients (32.9%) had dye spray.

**Conclusion:** There is unwarranted variation in the care of patients with PSC in the UK. In particular relating to risk stratification, exclusion of colitis and surveillance for biliary tract and colonic cancer. The lack of uniformity in clinical practice highlights the need for better education of clinicians about PSC management and the potential role of clinical networks for rare liver diseases within the UK.

### PO-1799

#### Among cancer patients, autoimmune hepatitis with cirrhosis increases mortality

Morten Daniel Jensen<sup>1</sup>, Peter Jepsen<sup>1,2</sup>, Hendrik Vilstrup<sup>1</sup>, Lisbet Groenbaek<sup>1,3</sup>. <sup>1</sup>Aarhus University Hospital, Department of Hepatology and Gastroenterology, Aarhus, Denmark; <sup>2</sup>Aarhus University Hospital, Department of Clinical Epidemiology, Aarhus, Denmark; <sup>3</sup>Regional Hospital Horsens, Department of Medicine, Horsens, Denmark  
Email: moje@clin.au.dk

**Background and aims:** Autoimmune hepatitis (AIH) is a chronic inflammatory liver disease associated with a high mortality. Patients with AIH have an increased risk of cancer, but the effect of AIH on cancer prognosis remains unclear. We examined mortality risks from the time of cancer diagnosis in a nationwide cohort of patients with AIH and compared with persons with cancer from the general population.

**Method:** This study was based on nationwide Danish healthcare registries. We identified all persons diagnosed with AIH between 1994 and 2018. We included 215 patients with AIH who developed cancer after AIH diagnosis and 2121 population controls matched by age, cancer type, and date of cancer diagnosis. For AIH patients and controls, we used the pseudo-value approach to estimate cumulative mortality risk and mortality risk ratio, adjusted for age, smoking, and alcohol consumption.

**Results:** The 10-year cumulative mortality after a cancer diagnosis was 61.1% (95% confidence interval [CI] 52.7–69.5) for AIH patients and 49.6% (95% CI 46.9–52.4) for population controls. The 10-year mortality risk was 1.3 (95% CI 1.1–1.5) times higher in AIH patients with cancer compared with controls with cancer. In AIH patients, those with cirrhosis had a higher 10-year mortality risk at 74.4% (95% CI 60.6–86.3) as compared with 53.0% (95% CI 42.8–63.9) in patients without cirrhosis. Comparing only AIH patients without cirrhosis with their matched controls yielded a 10-year mortality risk ratio of 1.1 (95% CI 0.9–1.4).

Figure:

**Conclusion:** Among patients with cancer, those with AIH had a 1.3-fold higher 10-year mortality than those without AIH. Importantly, this excess mortality was restricted to AIH patients with cirrhosis.

**PO-2015**

**Immunological Background Pinpoints Patients at High Risk of Immune-related Hepatitis Recurrence during Check-points Inhibitors Rechallenge**

Mar Riveiro Barciela<sup>1,2,3</sup>, Ana Barreira<sup>1,3</sup>, Ana Callejo-Pérez<sup>4</sup>, Eva Muñoz-Couselo<sup>4</sup>, Nely Díaz-Mejía<sup>4</sup>, Maria Teresa Salcedo<sup>5</sup>, Luisa Roade<sup>1,2,3</sup>, Adriana Palom<sup>1,3</sup>, Maria Buti<sup>1,2,3</sup>. <sup>1</sup>Liver Unit, Internal Medicine Department, Hospital Universitari Vall d'Hebron, Vall d'Hebron Barcelona Hospital Campus, Barcelona, Spain; <sup>2</sup>Centro de Investigación Biomédica en Red de Enfermedades Hepáticas y Digestivas (CIBERehd), Instituto de Salud Carlos III, Madrid, Spain; <sup>3</sup>Universitat Autònoma de Barcelona (UAB), Department of Medicine; <sup>4</sup>Oncology Department, Instituto de Oncología Vall d'Hebron (VHIO), Hospital Universitari Vall d'Hebron, Vall d'Hebron Barcelona Hospital Campus, Barcelona, Spain; <sup>5</sup>Pathology Department, Hospital Universitari Vall d'Hebron, Vall d'Hebron Barcelona Hospital Campus, Barcelona, Spain  
Email: mar.riveiro@gmail.com

**Background and aims:** Immunotherapy has improved the survival of patients with many types of advanced tumours. However, its increasing widespread use has been associated with immune-related adverse events (irAEs) such as severe immune-related hepatitis, leading to permanent discontinuation of immunotherapy

according to the international guidelines. We report the outcome of a cohort of patients who presented severe immune-related hepatitis and were retreated with check-point inhibitors (CPI) after the resolution of the irAE.

**Method:** This is a prospective non-interventional study that included all consecutive patients with oncological disease who developed grade 3 or 4 immune-related hepatitis and were rechallenged with check-point inhibitors (CPI) in a university hospital in Barcelona (Spain).

**Results:** 21 patients who with severe immune-related hepatitis were included (52.4% female, median age of 62, 76.2% treated with anti-PD1 or anti-PD1/PD-L1). All of them discontinued CPI therapy temporary and were mainly retreated with the same CPI after a median time of 10 weeks (range, 1.5–53.5) from the severe immune-related hepatitis. Recurrence of the immune-related hepatitis was observed in six patients (28.6%), 4 of them grade-3 and 2 grade-4. There was a trend to a high rate of recurrence among those treated with concomitant chemotherapy (p=0.115). Five (83.3%) of 6 subjects with recurrence of the immune-related hepatitis had either an underlying autoimmune disease or significant antinuclear antibodies titers (p = 0.029).

Figure: Flowchart of the study

**Conclusion:** Retreatment with check-point inhibitors is a feasible option after a severe immune-related hepatitis, even with the same check-point inhibitors, with a risk of recurrence of 29%. Given the higher risk of recurrence of the immune-related hepatitis in patients with underlying autoimmune diseases or positive antinuclear antibodies, the decision to rechallenge should be taken with caution in these patients.

**PO-2230**

**Safety and efficacy of the JAK-inhibitor tofacitinib in patients with primary sclerosis cholangitis: a multicentre, retrospective study**

Ida Schregel<sup>1</sup>, Cynthia Levy<sup>2</sup>, Stephanie Ioannou<sup>3</sup>, Emma Culver<sup>4</sup>, Martti Färkkilä<sup>5</sup>, Olivier Chazouillères<sup>6</sup>, Tobias Müller<sup>7</sup>, Jeremy Nayagam<sup>8</sup>, Deepak Joshi<sup>8</sup>, Ehud Zigmund<sup>9</sup>, Oren Shibolet<sup>9</sup>, Joost Ph Drenth<sup>10</sup>, Frank Hoentjen<sup>10</sup>, Anja Geerts<sup>11</sup>, Tobias Weismüller<sup>12</sup>, Taotao Zhou<sup>12</sup>, Christoph Schramm<sup>1</sup>. <sup>1</sup>University Medical Center Hamburg-Eppendorf, Hamburg, Germany; <sup>2</sup>University Miami Miller School of Medicine, Miami, United States; <sup>3</sup>Jackson Memorial Hospital, Miami, United States; <sup>4</sup>John Radcliffe Hospital, United Kingdom; <sup>5</sup>Helsinki University Central Hospital, Helsinki, Finland; <sup>6</sup>Hôpital Saint Antoine, Assistance Publique-Hôpitaux de Paris, Faculté de Médecine Pierre et Marie Curie, Paris, France; <sup>7</sup>Charité Campus Virchow Clinic, Berlin, Germany; <sup>8</sup>King's College Hospital, United Kingdom; <sup>9</sup>Tel-Aviv Sourasky Medical Center, and Sackler Faculty of Medicine, Tel Aviv, Israel; <sup>10</sup>Radboud University Medical Center, Nijmegen, Netherlands; <sup>11</sup>Ghent University Hospital, Gent, Belgium; <sup>12</sup>UKB University of Bonn, Bonn, Germany  
Email: i.schregel@uke.de

**Background and aims:** Tofacitinib, mainly inhibiting JAK1/3, has been licensed for the treatment of ulcerative colitis. It is unknown whether tofacitinib can be safely and effectively used in patients with primary sclerosing cholangitis (PSC), an immune-mediated bile duct disease frequently associated with inflammatory bowel disease (IBD). We therefore retrospectively collected data on PSC patients treated with tofacitinib in order to assess safety and efficacy of tofacitinib on liver and bowel disease.

## POSTER PRESENTATIONS

**Method:** Data was collected from 11 centres from Europe, North America and Western Asia participating in the international PSC study group (IPSCSG) and the European Reference Network on Hepatological Diseases (ERN RARE LIVER). Patients with PSC and associated colitis were included if they received past or ongoing treatment with tofacitinib. Data was collected prior to baseline, after 3-months follow-up, at last dose of tofacitinib given and at last follow-up.

**Results:** 28 patients with large duct PSC (71% male) were included in the analysis of whom 6/28 had evidence of cirrhosis. Median age at diagnosis was 37 (range 19–65) years. In 43% (12/28) treatment with tofacitinib was stopped, in 8/12 due to lack of efficacy, of which 5 patients received or were awaiting colectomy. The median treatment period before discontinuation of tofacitinib was 6 months (1–21).

In those patients where baseline and follow-up colonoscopy were reported (n = 17), colitis activity improved in the majority of patients (65%). Faecal calprotectin dropped from a median of 788 µg/g (124–2000) at baseline to 342 µg/g (15–2327, p = 0.09). At follow-up, one patient had developed high-grade dysplasia and one patient colorectal carcinoma.

ALP and total bilirubin levels did not show statistically significant differences between baseline and 3 month- and last follow-up under tofacitinib: 150 U/l (56–818) at baseline vs. 217 U/l (41–979) at 3 month-follow-up. For those still on treatment with tofacitinib, median ALP was 218 U/l (56–818) at baseline and 127 U/l (49–1132) at last follow-up (p = 0.87). Overall, there was no deterioration in liver biochemistry after commencing tofacitinib.

One patient developed bacterial cholangitis during treatment with tofacitinib. Two patients died, one of them due to metastatic colorectal carcinoma and the other due to unclear causes. No new cases of hepatobiliary malignancy occurred.

**Conclusion:** In a retrospective analysis of 28 patients with PSC and associated colitis, treatment appeared to be well tolerated and without significant worsening of liver enzymes over a median treatment period of 10 months (1–29). The majority of patients, most of them with several prior treatment regimens, demonstrated an improvement in their colitis activity. Further studies are needed to assess the impact of tofacitinib on the long-term course of PSC.

### PO-2259

#### Intravenous ketamine and progressive cholangiopathy in covid-19 patients

Kilian Bock<sup>1</sup>, Heiner Wedemeyer<sup>1</sup>, Vincent Mallet<sup>2</sup>. <sup>1</sup>Hannover Medical School, Gastroenterology, Hepatology and Endocrinology, Hannover, Germany; <sup>2</sup>Université de Paris, AP-HP, Hôpital Cochin, DMU Cancérologie et spécialités médico-chirurgicales, Service d'Hépatologie, Paris, France

Email: bock.kilian@mh-hannover.de

**Background and aims:** Many institutions worldwide experienced or are experiencing shortages of vital anaesthetic drugs that are also commonly used in intensive care units (ICU) because of the coronavirus infectious disease 2019 (Covid-19) pandemic. Ketamine has been proposed as an off-label second-line agent for maintenance sedation of patients with acute respiratory distress syndrome (ARDS) requiring mechanical ventilation, including those with Covid-19. We report a series of five Covid-19 patients from five different centers with, dose-dependent, ketamine cholangiopathy.

**Method:** Five cases of cholangiopathy after covid-19 between march 20, 2020 and April 6, 2020 were retrospectively analysed.

**Results:** The median (range) age of patients was 59 (35–65) years, and three (60%) were males. All had undergone mechanical ventilation for a median (range) period of 40 (39–59) days, and had received intravenous ketamine at a dose of 0.6 (0.1–2.2) mg/kg/h for 16 (6–26) days. Jaundice under ketamine correlated with total ketamine exposure (R<sup>2</sup> = 0.95) and not with initial serum C-reactive protein level (R<sup>2</sup> = 0.14). All patients had recurrent episodes of cholangitis after a median (range) period of 6 (4–8) months after

ketamine withdrawal. The nadir of arterial oxygen saturation (SaO<sub>2</sub>) was 81 (71–93) percent. All patients received norepinephrine for 10 (2–15) days with a maximum dose of 0.4 (0.1–0.6) µg/kg/min. Maximum arterial lactate level was 2.4 (1.5–4.9) mmol/L. All patients developed acute kidney injury, and three (60%) required renal replacement therapy. At the end of follow-up, one patient had died with sepsis and decompensated cirrhosis; one patient was on the waiting list for a liver transplant with jaundice, pruritus, portal hypertension, and a median (interquartile range) liver stiffness of 64.1 (4.5) kilopascal; one patient had overt sclerosing cholangitis; and two patients had recurrent episodes of biliary sepsis. The two most severe patients had received higher doses of ketamine: 2.2 mg/kg/d for 16 and 14 days, respectively. The patient with sclerosing cholangitis had received lower doses of ketamine (0.16 mg/kg/h) for 26 days, which corresponded to the longest exposition period in the series.

**Conclusion:** In conclusion, intravenous ketamine at the recommended doses for maintenance sedation of patients undergoing mechanical ventilation for ARDS, including Covid-19 patients, can be associated with biliary obstructions, cholestatic liver injury, biliary cirrhosis, and end stage liver disease. Covid-19 patients who underwent maintenance sedation with ketamine, especially those who developed jaundice in the intensive care unit, should be screened for long-term liver injury, including cholangiopathy.

Figure: ERCP showed contrast medium filling defects in the ductus hepatocholedochus and rarefaction of the intrahepatic biliary tract. Biliary Cast has been removed.

Email: shivsarin@gmail.com

**Background:** Early identification of non-response to corticosteroids is critical in patients with flare of autoimmune hepatitis (AIH) causing acute-on-chronic liver failure (ACLF). We aimed to identify this subgroup among patients with AIH-ACLF within the first week who merit early liver transplantation.

**Methods:** Patients with AIH-ACLF treated with steroids over 2012–2020 with no infection/overt hepatic encephalopathy at baseline were identified from APASL-ACLF database and were assessed for outcomes. Diagnosis of AIH-ACLF was based on simplified or probable IAIHG score and APASL ACLF definition. Clinical assessment and baseline laboratory parameters, MELD score and change in laboratory parameters at day 3 were assessed to predict non-response. Performance of a recently derived SURFASA score (for acute severe AIH) ( $SURFASA = -6.80 + 1.92 * (DO-INR) + 1.94 * (\Delta\%3-INR) + 1.64 * (\Delta\%3-bilirubin)$ ) was also evaluated for AIH-ACLF patients.

**Results:** 57 of 165 patients (age- $38.2 \pm 15.0$  years, 68.4% females) of AIH-ACLF with median MELD 24 (IQR: 22–27) and median AARC score 7 (IQR: 6–9) were given prednisolone 40 mg per day. Liver biopsy was available in 45 out of 57 patients and showed interface hepatitis (80%), and underlying cirrhosis in (64%). Overall, 90-day survival was 51.7%. Twentyfive (43.8%) patients developed incident infections and had worse survival (28.0%;  $p = 0.03$ ). Both SURFASA score and MELD predicted poor outcome (need for liver-transplant or death) with good accuracy within first 3 days of steroid administration (AUROC 0.795 (95% confidence interval:0.678–0.911) for SURFASA and 0.837 (0.733–0.94) for baseline MELD) which were significantly better than  $\Delta$ MELD at 3 days (AUROC-0.541 (0.395, 0.687)). At optimal cut point of  $-1.2$  for SURFASA and 24 for MELD, need for transplant/death could be predicted with a sensitivity and specificity of 74.2% and 73.1% for SURFASA and 77.4% and 73.1% for MELD respectively.

Figure: Receiver Operator Characteristics (ROC) curves for predictors of 90-day survival. Numbers on plot represent value of respective prognostic variable. Area under curve for MELD score and SURFASA score are 0.837 (95%CI: 0.733-0.94) and 0.795 (95% CI: 0.678-0.911) respectively

**Conclusion:** Both baseline MELD and SURFASA score can predict non-response to steroids within first 3 days of treatment initiation in AIH-ACLF.

**PO-2327**

This abstract has been withdrawn.

### PO-2657

#### **Patient perspectives on pruritus in intrahepatic cholestasis of pregnancy: a multinational survey**

Andrew McKibben<sup>1</sup>, Jenny Chambers<sup>2</sup>, Catherine Williamson<sup>3</sup>, George Saade<sup>4</sup>, Will Garner<sup>1</sup>, Vyechi Low<sup>5</sup>, Elaine Chien<sup>1</sup>. <sup>1</sup>Mirum Pharmaceuticals, Foster City, United States; <sup>2</sup>ICP Support, Sutton Coldfield, United Kingdom; <sup>3</sup>King's College London, Women's Health, London, United Kingdom; <sup>4</sup>University of Texas Medical Branch at Galveston, Maternal-Fetal Medicine, Galveston, United States; <sup>5</sup>Harvard University

Email: amckibben@mirumpharma.com

**Background and aims:** To provide information about the presentation and severity of intrahepatic cholestasis of pregnancy (ICP), its management, and its broader burden from the patient perspective.

**Method:** A multinational survey of women with current or previous ICP (funded by Mirum Pharmaceuticals). The 30-question web-based survey was distributed to participants via an ICP patient support group. Responses were collected between August 25 and September 10, 2020.

**Results:** Of 688 women who responded, 352 lived in the UK, 162 in the US, 54 in Australia, 19 in Canada, 10 in New Zealand, 8 in Ireland; 32 were from 19 other countries. Most (94%) had ICP in a previous pregnancy. The median worst itch reported was 9 on a numerical rating scale (NRS) (0 for 'no itch,' 10 for 'worst itch you can possibly imagine'), with 90% of women reporting a worst itch of  $\geq 7$  and 42% reporting a 10. Itch severity was associated with a higher degree of reported sleep disturbance and worsening fatigue. 59% reported that itch led to disruption of day-to-day responsibilities and routines, 44% of whom reported that the disruption lasted  $>30$  days. 33% reported missing school or work. Itch severity was also associated with greater frequency of reported mood changes including but not limited to anxiety, irritability, and feelings of hopelessness.

58% of women reported taking  $\geq 2$  medications for itch and 29% took  $\geq 3$ , of which the most commonly used were ursodeoxycholic acid (UDCA; 76%), antihistamines (46%), topical creams or ointments (38%). These medications achieved only partial resolution (UDCA 45%; antihistamines 24%; creams/ointments 52%) or had no impact (UDCA 35%; antihistamines 61%; creams/ointments 40%).

**Conclusion:** This international survey underscores the burden of pruritus in ICP. A large proportion of participants had disruptions to sleep, worsening fatigue, adverse impacts on mood and other substantial impacts to quality of life. Most women reported either partial or no resolution of ICP-associated pruritus with existing therapies. These data highlight the high unmet need for development of safe and effective therapies for patients with ICP.

### PO-2701

#### **Artificial Intelligence and Digital Single-Operator Cholangioscopy: automatic identification of tumor vessels in patients with indeterminate biliary strictures.**

Miguel Mascarenhas<sup>1</sup>, Tiago Ribeiro<sup>2</sup>, João Afonso<sup>2</sup>, João Pedro Sousa Ferreira<sup>3</sup>, Filipe Vilas-Boas<sup>2</sup>, Renato Natal Jorge<sup>3</sup>, Pedro Pereira<sup>2</sup>, Guilherme Macedo<sup>2</sup>. <sup>1</sup>Centro Hospitalar Universitário de São João, Gastroenterology, Porto; <sup>2</sup>Centro Hospitalar Universitário de São João, Gastroenterology; <sup>3</sup>Faculdade de Engenharia da Universidade do Porto, Engenharia Mecânica

Email: miguelmascarenhassaraiva@gmail.com

**Background and aims:** The diagnosis and characterization of biliary strictures is a significant clinical challenge. The introduction of digital single-operator cholangioscopy (D-SOC) allowing direct visual inspection of the bile ducts and guided tissue sampling significantly increased the diagnostic yield in patients with indeterminate biliary strictures. The identification of dilated, irregular and tortuous vessels, often described as tumor vessels, is a frequent element in biliary strictures with a high probability of malignancy. In recent years, the development of artificial intelligence (AI) algorithms for application to endoscopic practice has been intensely studied. This study aimed to develop and validate a convolutional neural network (CNN) for automatic detection of tumor vessels in D-SOC images.

**Method:** A deep learning algorithm was developed and trained for automatic recognition of tumor vessels in D-SOC images. A total of 6475 images from 85 patients who underwent D-SOC (Spyglass™, Boston Scientific, Marlborough, MA, USA). Each frame was classified by two endoscopists with experience in D-SOC regarding the presence or absence of tumor vessels. This pool of images was subsequently divided for constitution of two distinct datasets for training (80%) and validation (20%) of the CNN. The performance of the CNN was measured by calculating the area under the receiving

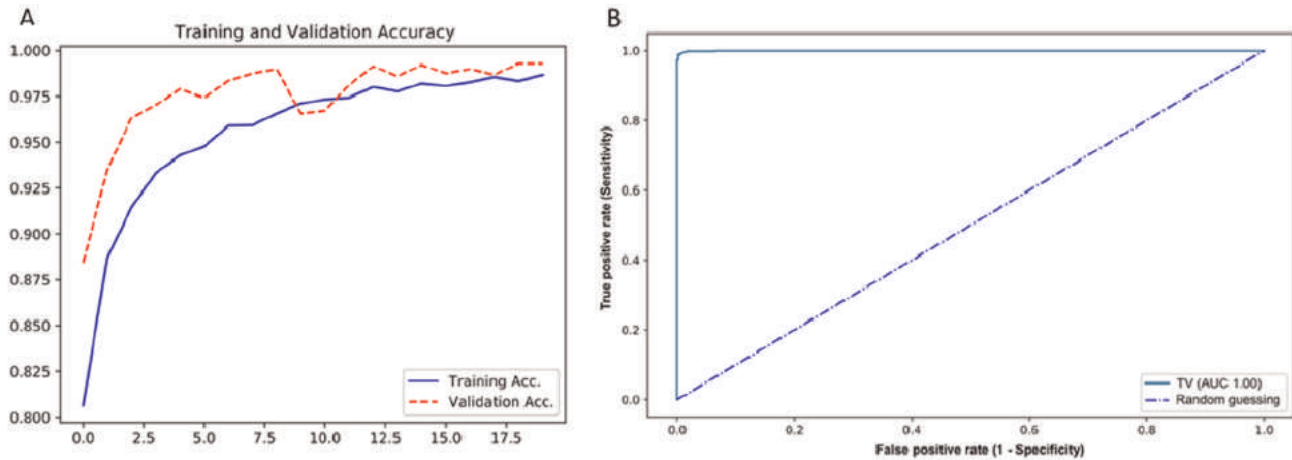

Figure: (abstract: PO-2701)

operating characteristic curve (AUC), sensitivity, specificity, positive and negative predictive values (PPV and NPV, respectively).

**Results:** Our CNN had an overall accuracy of 99.3% for detection of tumor vessels (Figure 1A). The sensitivity, specificity, PPV and NPV were 99.3%, 99.4%, 99.6% and 98.7%, respectively. The AUC was 1.00 (Figure 1B). The CNN had an image processing rate of 20 ms/frame.

**Conclusion:** Our CNN was able to detect tumor vessels with high sensitivity, specificity, and accuracy. The incorporation of AI tools to D-SOC systems may significantly enhance the detection of macroscopic characteristics associated with high probability of biliary malignancy, thus optimizing the diagnostic workup of patients with indeterminate biliary strictures.

**PO-2719**

**Cholangiopathy associated with checkpoint inhibitors: a case series**

Philip Berry<sup>1</sup>, Sreelakshmi Kotha<sup>1</sup>, Sophie Papa<sup>2</sup>, Yoh Zen<sup>3</sup>, Deepak Joshi<sup>3</sup>, Michael Heneghan<sup>3</sup>. <sup>1</sup>Guy's and St Thomas' NHS Foundation Trust, Gastroenterology, Hepatology and Nutrition, London, United Kingdom; <sup>2</sup>Guy's and St Thomas' NHS Foundation Trust, Medical Oncology, London, United Kingdom; <sup>3</sup>Kings College Hospital NHS Foundation Trust, Institute of Liver Studies, London, United Kingdom  
Email: philip.berry@gstt.nhs.uk

**Background and aims:** Cholestatic liver function profiles are common in immune-related hepatitis (irH) during treatment with checkpoint inhibitors (CPI) for malignancy. We investigated the

spectrum of bile duct injury and associated natural history in this cohort.

**Method:** Clinical data in patients with radiologic or histological evidence of bile duct injury from 2018 to 2020 was collected. Biopsies were reviewed by a single histopathologist (YZ).

**Results:** CPI were prescribed to 60 patients during the study period. 7 patients with bile duct disease were identified (Table 1). Pembrolizumab was the most commonly implicated CPI (5/7). Median CPI cycles prior to irH was 4. Median alanine aminotransferase and alkaline phosphatase were 500 U/L and 889 U/L respectively. There was no association with autoimmune or viral markers. Clinical jaundice and radiological evidence of bile duct pathology was seen in 5/7. Liver biopsy was performed in 5 patients and repeated in one. 3 patients had primary sclerosing cholangitis (PSC) like changes characterized by periductal concentric fibrosis and epithelial injury. In the case with sequential biopsies, the 1<sup>st</sup> showed severe small-duct cholangitis with significant inflammatory changes and minimal fibrosis, while the 2<sup>nd</sup> biopsy a year later exhibited less inflammatory, more fibrotic portal tract changes. One had features of obstructive large-duct cholangiopathy, one had cancer cells within a small blood vessel of the portal tract and 2 had mild hepatic changes. All patients were treated first-line with prednisolone, 3 with MMF and one with tacrolimus with clinical response in 3. 6 received ursodeoxycholic acid. 4 patients died after a mean follow-up of 7 weeks.

Table: (abstract: PO-2719)

Case	Demographics	Malignancy	CPI	Cycle	Bili, micmol/L	ALT, U/L	ALP, U/L	Radiology
1	79, M	Melanoma	Pembrolizumab	2	64	155	3380	Cholangiopathy
2	45, M	Melanoma	Ipilimumab, Nivolumab	4	64	800	790	Cholangiopathy
3	42, M	NSCLC	Atezolizumab	4	400	603	889	Biliary dilatation and liver metastases
4	71, F	Urothelial bladder	Pembrolizumab	4	11	500	1703	Normal
5	70, M	NSCLC/mucinous adenocarcinoma	Pembrolizumab	10	9	250	489	Normal
6	61, M	NSCLC	Pembrolizumab	6	391	600	400	Cholangiopathy
7	73, M	Epithelioid mesothelioma	Pembrolizumab	2	156	201	1910	Cholangiopathy

## POSTER PRESENTATIONS

**Conclusion:** Within this heterogenous cohort we identified a PSC-like, potentially progressive phenotype that responded poorly to immunosuppression. Cholangiopathy should be suspected and actively diagnosed if the response to first-line treatment is poor.

### PO-2724

#### **Budesonide versus prednisolone in the treatment of autoimmune hepatitis: a cross-sectional patients' survey**

Ceyhun Oztumer<sup>1</sup>, Laith Al-Rubaiy<sup>2</sup>. <sup>1</sup>Brighton and Sussex Medical School, Brighton, United Kingdom; <sup>2</sup>St Mark's Hospital, London, United Kingdom

Email: c.oztumer1@uni.bsms.ac.uk

**Background and aims:** Autoimmune hepatitis (AIH) is a chronic liver disease that can lead to cirrhosis and liver failure. Prednisolone is the first-line treatment, though budesonide has recently been shown to be effective in inducing and maintaining remission in AIH patients while having a significantly lower incidence of side effects. We aimed to assess the real-life experiences of AIH patients in terms of their treatment and side effects.

**Method:** A cross-sectional study was conducted in partnership with a patient charity, AIH Support. Patients with a diagnosis of AIH completed an anonymous, self-reported questionnaire in 2016 assessing their treatment choices, prescribed medications, and side effects. An identical questionnaire was disseminated in 2020 to patients diagnosed with AIH after the previous survey closed in July 2016 to enable comparison between the two surveys. Survey responses were analysed using descriptive statistical analyses and chi-squared tests.

**Results:** There were 190 respondents (87% female) in 2016 and 170 respondents (88% female) in 2020. On diagnosis, significantly more patients were prescribed prednisolone than budesonide in both the 2016 survey (90% vs 10%) and 2020 survey (76% vs 22%). Of those patients prescribed either prednisolone or budesonide on diagnosis, only 3% (2016) and 5% (2020) recall being given a choice between the two medications, and only 67% (2016) and 62% (2020) recall potential side effects of steroids being discussed prior to commencing treatment. Patients receiving budesonide were significantly less likely to experience side effects including moon face, weight change, sleep disturbance, and mood swings ( $p < 0.05$  for all). Overall, the proportion of patients experiencing more than one side effect was 92% for prednisolone and 54% for budesonide.

**Conclusion:** Despite the significantly higher incidence of side effects, prednisolone continues to be prescribed more frequently than budesonide on diagnosis of AIH. More emphasis on informing patients of potential side effects is needed to enable increased patient choice in their treatment. Additional randomised trials are required to assess the efficacy of budesonide before it can be implemented in national guidelines as a possible first-line treatment for AIH.

### PO-2761

#### **Ischemic cholangiopathy in biliary atresia: immunohistochemical and molecular evidence**

Patricia Quelhas<sup>1</sup>, Michele Breton<sup>1</sup>, Rui Oliveira<sup>2</sup>, Maria Augusta Cipriano<sup>2</sup>, Pranavkumar Shivakumar<sup>3,4</sup>, Jorge Bezerra<sup>3</sup>, Sandra Vieira<sup>5</sup>, Carlos Kieling<sup>5</sup>, Ignacio Verde<sup>6</sup>, Jorge Luiz dos Santos<sup>1</sup>.

<sup>1</sup>Avenida Infante Dom Henrique, Faculty of Health Sciences, Health Science Investigation Center (CIC-UBI), Hormones and Metabolism Group, Covilhã, Portugal; <sup>2</sup>Praceta Carlos da Mota Pinto, Anatomopathology Service, Hospital Center of Coimbra University (SAP-CHUC, Coimbra, Portugal; <sup>3</sup>3333 Burnet Ave, University of Cincinnati College of Medicine, Department of Pediatrics, Cincinnati, United States; <sup>4</sup>Cincinnati Children's Hospital and the University of Cincinnati College of Medicine, Division of Gastroenterology, Hepatology and Nutrition and UC Department of Pediatrics, Cincinnati, United States; <sup>5</sup>R. Ramiro Barcelos, 2350, Pediatric Gastroenterology and Hepatology Unit, Clinical Hospital of Porto Alegre (HCPA), Federal University of Rio Grande do Sul (UFRGS, Brazil); <sup>6</sup>Avenida Infante Dom Henrique, Faculty of Health Sciences, Health Science Investigation Center (CIC-UBI), Covilhã, Portugal

Email: jlsantos@fcsaude.ubi.pt

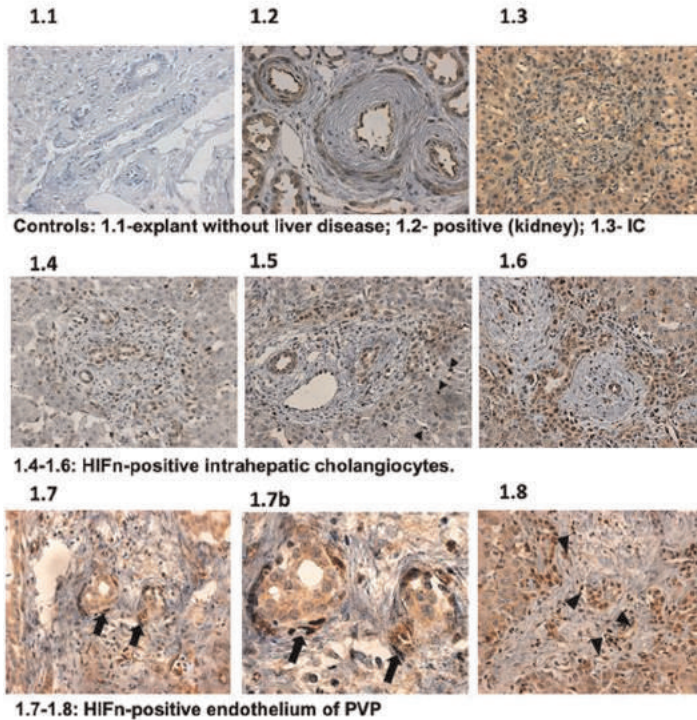

**Background and aims:** Biliary atresia (BA) is a severe cholangiopathy of infancy whose etiology remains undeciphered. The most frequent clinical form of BA is the isolated variant (iBA). We investigated the role of an ischemic cholangiopathy (IsChol) involving the peribiliary vascular plexus (PVP) as a pathogenic mechanism in BA.

**Method:** The cohorts comprised patients with iBA (N = 20) and intrahepatic cholestasis (IC; N = 5) serving as controls, at the time of exploratory laparotomies. Clinical and laboratory data on these patients were prospectively collected. Wedge liver biopsy (BA = 16; IC = 5) and porta hepatis (PH; BA only, N = 11) specimens were collected and paraffin-embedded. A segment of the liver specimen (BA = 11; IC = 4) was also collected in RNAholder and stored at  $-80^{\circ}\text{C}$ . Immunohistochemical (IHC) analyses were performed on liver and PH specimens to confirm the presence of IsChol. IHC staining with anti-HIF1 $\alpha$  antibody to evaluate HIF nuclear positivity (HIFnP) was performed in paraffin-embedded sections. Frozen liver samples were used to determine gene expression of hypoxia-related molecules (HIF-1 $\alpha$ , VEGFA, VEGFR2, CK19, Caspase 3, VCAM1, Fibrocystin, GSS, GSR) by RT-PCR. IHC signals were correlated with gene expression and prognostic features using statistical approach.

**Results:** IHC staining in liver and PH samples from iBA patients revealed the presence of HIFnP in cholangiocytes and endothelial cells of arteriolar vessels, including PVP, in 6/16 patients. Controls failed to show HIFnP. In cholangiocytes, HIFnP was localized to the interlobular bile ducts and areas of marginal ductular reaction (hepatic progenitor cell compartment, HPC). Importantly, a larger proportion of PH specimens (9/11) showed HIFnP in biliary remnants and the endothelium of hepatic artery branches. RT-PCR analysis showed overexpression of genes (GSS, GSR, CK19, VEGFA, VEGFR2) linked to REDOX status, ductular reaction, and angiogenesis in BA patients compared with IC controls. Comparing iBA cases with and without HIFnP showed a trend towards decreased GSR expression in the biliary HIFnP subset ( $p < 0.07$ ).

**Conclusion:** Our work identified evidence of IsChol involving PVP in iBA patients affecting HPCs. Patients with HIFnP in intrahepatic cholangiocytes showed deregulated hepatic REDOX status. These results have potential prognostic and future therapeutic implications targeting the vascular pathologies in patients with BA.

**Artificial Intelligence for automatic diagnosis of biliary strictures malignancy status in Single-Operator Cholangioscopy.**

Miguel Mascarenhas<sup>1</sup>, Tiago Ribeiro<sup>1</sup>, João Afonso<sup>1</sup>, João Pedro Sousa Ferreira<sup>2</sup>, Filipe Vilas Boas<sup>1</sup>, Ana Santos<sup>1</sup>, Hélder Cardoso<sup>1</sup>, Renato Natal Jorge<sup>2</sup>, Pedro Pereira<sup>1</sup>, Guilherme Macedo<sup>1</sup>. <sup>1</sup>Centro Hospitalar Universitário de São João, Gastroenterology; <sup>2</sup>Faculdade de Engenharia da Universidade do Porto, Engenharia Mecânica  
Email: miguelmascarenhassaraiva@gmail.com

**Background and aims:** Diagnosis and characterization of biliary strictures is challenging. The introduction of digital single-operator cholangioscopy (D-SOC) allowing direct visual inspection of the lesion and targeted biopsies significantly improved the diagnostic

yield in patients with indeterminate biliary strictures. However, the diagnostic efficiency of D-SOC remains suboptimal. Convolutional neural networks (CNNs) have shown great potential for the interpretation of medical images. We aimed to develop a CNN-based system for automatic detection of malignant biliary strictures in D-SOC images.

**Method:** We developed, trained and validated a CNN based on D-SOC images. Each frame was labeled as normal/benign findings or as a malignant lesion if histopathological evidence of biliary malignancy was available. The entire dataset was split for 5-fold cross validation. Also, the image dataset was split for constitution of training and validation datasets. The classification provided by the CNN was compared with the labelling of the lesion (Figure 1). The performance of the CNN was measured by calculating the area under the receiving

## POSTER PRESENTATIONS

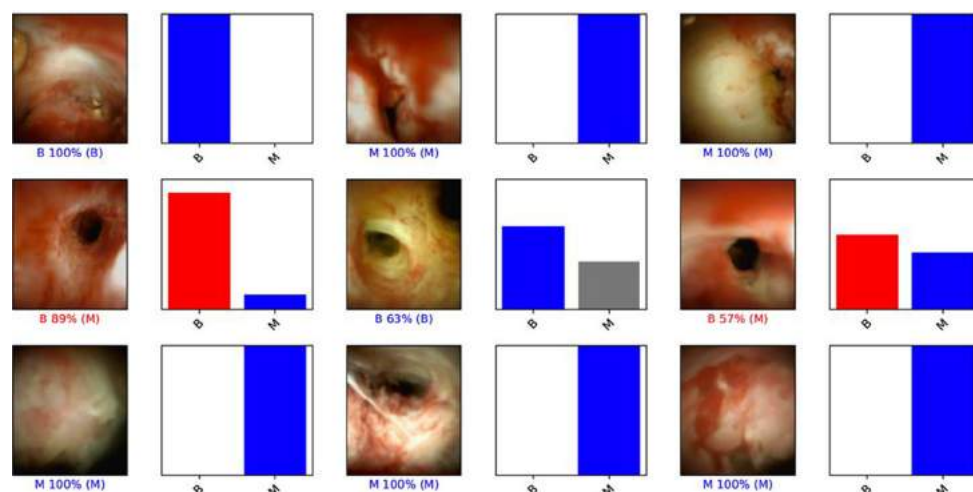

Figure 1: Output obtained during the training and development of the convolutional neural network. The bars represent the probability estimated by the network. The finding with the highest probability was outputted as the predicted classification. A blue bar represents a correct prediction. Red bars represent an incorrect prediction. B-benign biliary findings; M-malignant stricture.

Figure 1: (abstract: PO-2801)

operating characteristic curve (AUC), sensitivity, specificity, positive and negative predictive values (PPV and NPV, respectively).

**Results:** A total of 11855 images from 85 patients were included (9695 of malignant strictures and 2160 of benign findings). The model had an overall accuracy of 94.9%, a sensitivity of 94.7%, a specificity of 92.1% and an AUC of 0.988 in cross-validation analysis. The image processing speed of the CNN was 7 ms/frame.

**Conclusion:** The developed deep learning algorithm accurately detected and differentiated malignant strictures from benign biliary conditions. The introduction of artificial intelligence algorithms to D-SOC systems may significantly increase its diagnostic yield for malignant strictures.

### PO-2830

#### A novel histological scoring system for primary sclerosing cholangitis: Impact on disease outcome

Nelli Sjöblom<sup>1</sup>, Sonja Boyd<sup>1</sup>, Hannu Kautiainen<sup>2</sup>, Johanna Arola<sup>1</sup>, Martti Färkkilä<sup>3</sup>. <sup>1</sup>Helsingin yliopisto, Pathology, Helsinki, Finland; <sup>2</sup>Helsingin yliopisto, Department of General Practise and Primary Health Care, Helsinki, Finland; <sup>3</sup>Helsingin yliopisto, Gastroenterology, Helsinki, Finland

Email: nelli.sjoblom@helsinki.fi

**Background and aims:** Primary sclerosing cholangitis (PSC) is a progressive cholestatic liver disease, which may lead to liver cirrhosis or cholangiocarcinoma. Liver histology and stage of fibrosis are predictive markers of disease progression. Histological cirrhosis is defined as a significant end point. PSC specific histological scoring method is lacking at present. We aimed to develop a tailored classification system for PSC, the PSC-histocore, that is based on histological features associated with disease progression.

**Method:** The cohort consisted of 300 PSC patients diagnosed between 1988–2018. Their data was collected from the PSC registry (Helsinki University Hospital) and liver specimens from the Biobank of Helsinki. Nine histological features included in the Nakanuma scoring system and four additional parameters typical for PSC histology were evaluated and compared with the clinical and laboratory data. A compound end point consisting of liver transplantation, development of cholangiocarcinoma or death served as outcome measurement.

**Results:** Parameters of stage (fibrosis, bile duct loss, ductulus proliferation, and chronic cholestasis) and grade (portal

inflammation, portal oedema, hepatitis activity, and cholangitis activity) were found to be independent predictive risk factors for the compound end point. ( $p < 0.001$ ). High disease grade (2–3) and stage (2–4) correlated with clinical end points better when evaluated with the PSC-histocore system compared to Nakanuma classification. The risk for disease progression in sequential ERC examinations was elevated with high total PSC-histocore.

**Conclusion:** PSC-histocore is a novel potential histological classification system for PSC. Our findings support the applicability of liver histology as a marker for disease progression.

**Artificial intelligence and digital single-operator cholangioscopy: automatic identification of neoplastic biliary nodules in patients with indeterminate biliary stenosis.**

João Afonso<sup>1</sup>, Miguel Mascarenhas<sup>1</sup>, Tiago Ribeiro<sup>1</sup>, João Pedro Sousa Ferreira<sup>2</sup>, Filipe Vilas-Boas<sup>1</sup>, Marco Parente<sup>2</sup>, Renato Natal Jorge<sup>2</sup>, Pedro Pereira<sup>1</sup>, Guilherme Macedo<sup>1</sup>. <sup>1</sup>Centro Hospitalar Universitário de S. João, Gastroenterology, Porto, Portugal; <sup>2</sup>Faculdade de Engenharia da Universidade do Porto, Engenharia  
Email: joaoafonso28@gmail.com

**Background and aims:** Digital single-operator cholangioscopy (D-SOC) provides direct visual exploration of the biliary tract. This tool has become essential for distinguishing benign from malignant biliary strictures. The visual aspect of these lesions is highly sensitive for the diagnosis of malignancy. Macroscopic characteristic such as tumor vessels, papillary projections, masses and nodules are common findings in patients with malignant biliary strictures. Recent endoscopic literature has demonstrated large interest in artificial intelligence (AI) systems for detection of endoscopic lesions. However, the application of these systems for automatic characterization of biliary lesions has not been explored. This study aimed to develop a convolutional neural network for automatic detection of biliary nodules in D-SOC images.

**Method:** A convolutional neural network (CNN) was designed for automatic identification of biliary nodules using D-SOC images. A total of 3010 frames were extracted from a pool of 85 cholangioscopies (Spyglass™ DS II system, Boston Scientific, Marlborough, MA, USA). Each frame was classified by two endoscopists with experience in D-SOC regarding the presence or absence of nodules. Two image datasets were built for training and validation of the CNN (80% and 20% of the full image dataset, respectively). The performance of the model was measured by calculating the area under the receiving operating characteristic curve (AUC), sensitivity, specificity, positive and negative predictive values (PPV and NPV, respectively).

**Results:** After the optimization of the architecture of the CNN for automatic detection of biliary nodules, our network showed a sensitivity of 100%, a specificity of 99.1%, a PPV of 97.2% and a NPV of 100%. The overall accuracy of the *deep learning* system was 99.3%. The AUC was 1.00. The image processing speed was of 16 ms/image.

Figure 1: ROC analysis of the network's performance in the detection of biliary malignant nodules. ROC - receiver operating characteristic. N - nodules.

**Conclusion:** The integration of AI tools in D-SOC platforms may contribute to the optimization of the diagnosis of biliary malignancy, which may lead to a timelier treatment and better outcomes. Our deep learning algorithm has demonstrated high performance levels for the detection of malignant nodules of the biliary tract, with high sensitivity, specificity and overall accuracy.

PO-2898

**Artificial intelligence and digital single-operator cholangioscopy: automatic identification of neoplastic masses in patients with indeterminate biliary strictures**

Tiago Ribeiro<sup>1,2</sup>, Miguel Mascarenhas<sup>1,2,3</sup>, João Afonso<sup>1,2</sup>, João Pedro Sousa Ferreira<sup>4,5</sup>, Filipe Vilas-Boas<sup>1,2</sup>, Marco Parente<sup>4,5</sup>, Renato Natal Jorge<sup>4,5</sup>, Pedro Pereira<sup>1,2,3</sup>, Guilherme Macedo<sup>1,2,3</sup>. <sup>1</sup>Centro Hospitalar Universitário de São João, Gastroenterology, Porto, Portugal; <sup>2</sup>WGO Gastroenterology and Hepatology, Porto, Portugal; <sup>3</sup>Faculty of medicine of the university of Porto, Porto, Portugal; <sup>4</sup>Faculty of Engineering of the University of Porto, Department of mechanical engineering, Porto, Portugal; <sup>5</sup>Institute of science and innovation in mechanical and industrial engineering, Porto, Portugal  
Email: tiagofcribeiro@outlook.com

**Background and aims:** The characterization of indeterminate biliary strictures is a significant diagnostic challenge. Digital cholangioscopy allows direct visual inspection of the morphology of biliary strictures. The visual impression of these lesions is highly sensitive for the diagnosis of malignancy. Morphologic characteristics such as masses, tumor vessels or papillary projections are common findings in those with malignant biliary strictures. However, specificity and inter-observer variability remain significant limitations. Artificial intelligence (AI) tools have recently been applied with success to a wide spectrum of endoscopic modalities. The application of these systems for automatic cholangioscopic characterization of biliary lesions has not been explored. The aim of this study was to develop a neural network for automatic detection of biliary masses in D-SOC images.

**Method:** A convolutional neural network (CNN) was constructed for automatic identification of biliary masses in D-SOC images. A total of 3580 frames were extracted from a pool of 85 cholangioscopies (Spyglass™ DS II system, Boston Scientific, Marlborough, MA, USA). Each frame was classified by two endoscopists with experience in D-SOC regarding the presence or absence of masses. Two different image datasets were built for training and validation of the CNN (80% and 20% of the full image dataset, respectively). The performance of the model was measured by calculating the area under the receiving operating characteristic curve (AUC), sensitivity, specificity, positive and negative predictive values (PPV and NPV, respectively).

**Results:** The overall accuracy of the *deep learning* system was 99.9%. After the optimization of the architecture of the CNN for automatic detection of biliary masses, our network showed a sensitivity of 100%, a specificity of 99.8%, a PPV of 99.6% and a NPV of 100%. The AUC was 1.00. The image processing speed was of 17 ms/image.

Figure 1: Output obtained during the training and development of the convolutional neural network. The bars represent the probability estimated by the network. The finding with the highest probability was outputted as the predicted classification. A blue bar represents a correct prediction. B - benign biliary findings; M - Masses.

**Conclusion:** Our neural network demonstrated high performance levels for the detection of biliary masses. The accurate automatic detection of this and other macroscopic characteristics associated with biliary malignancy may positively influence the diagnostic capacity of cholangioscopy, which may ultimately translate into prognostic gains.

**Hepatitis B vaccine NON-RESPONDERS show higher frequencies of REGULATORY B CELLS, but lower levels of IL-10 expression compared to responders**

Laureen Pohl<sup>1</sup>, Nina Körber<sup>1</sup>, Birgit Weinberger<sup>2</sup>, Beatrix Grubeck-Loebenstein<sup>2</sup>, Andrea Wawer<sup>3</sup>, Percy Knolle<sup>4</sup>, Hedwig Roggendorf<sup>4</sup>, Ulrike Protzer<sup>1,5,6</sup>, Tanja Bauer<sup>1,6</sup>. <sup>1</sup>Institute of Virology, Helmholtz Zentrum München, Munich, Germany; <sup>2</sup>Institute for Biomedical Aging Research, University of Innsbruck, Innsbruck, Austria; <sup>3</sup>Occupational Health Unit, Klinikum rechts der Isar, Technical University of Munich, School of Medicine, Munich, Germany; <sup>4</sup>Institute of Molecular Immunology and Experimental Oncology, Klinikum rechts der Isar, Technical University of Munich, School of Medicine, Munich, Germany; <sup>5</sup>Institute of Virology, Technical University of Munich, School of Medicine, Munich, Germany; <sup>6</sup>German Center for Infection Research (DZIF), partner site Munich, Munich, Germany  
Email: laureen.pohl@gmx.de

**Background and aims:** The cellular mechanisms involved in the lack of protective antibody response after hepatitis B vaccination are still rather unclear. Regulatory B cells (Breg) known as modulators of B and T cell responses may contribute to poor vaccine responsiveness. The current study aimed to investigate the role of regulatory B cells (Breg) in hepatitis B vaccine non-responsiveness after immunization with second- (Twinrix®) or third-generation (Sci-B-Vac™) hepatitis B vaccines.

**Method:** We performed comparative phenotypic and frequency analysis of Breg subsets (CD24<sup>+</sup>CD27<sup>+</sup> and CD24<sup>high</sup>CD38<sup>high</sup> Breg) in second-generation hepatitis B vaccine non-responders (2<sup>nd</sup> HBvac NR, n = 11) and responders (2<sup>nd</sup> HBvac R, n = 8) before (d0), on day 7 (d7), and 28 (d28) after Sci-B-Vac™ or Twinrix® booster vaccination. Cryopreserved peripheral blood mononuclear cells were stimulated *ex vivo* with a combination of CpG, PMA, and Ionomycin (CpG+P/I) and analysed for numbers and IL-10 expression levels of Breg by flow cytometry-based analyses.

**Results:** Flow cytometry-based analyses revealed elevated frequencies of CD24<sup>+</sup>CD27<sup>+</sup> Breg at all time points and significantly higher frequencies of CD24<sup>high</sup>CD38<sup>high</sup> Breg on day 0 (p = 0.004) and 28 (p = 0.012) in 2<sup>nd</sup> HBvac NR compared to 2<sup>nd</sup> HBvac R. In parallel, we observed significantly lower levels of CpG+P/I-induced IL-10 expression levels of CD24<sup>+</sup>CD27<sup>+</sup> and CD24<sup>high</sup>CD38<sup>high</sup> Breg (d0: p < 0.0001; d7: p = 0.0004; d28: p = 0.0003 and d0: p = 0.016; d7: p = 0.016, respectively) in 2<sup>nd</sup> HBvac NR compared to 2<sup>nd</sup> HBvac R before and after booster immunization. Frequencies of CD24<sup>+</sup>CD27<sup>+</sup> and CD24<sup>high</sup>CD38<sup>high</sup> Breg significantly decreased after third-generation hepatitis B booster vaccination (d7: p = 0.014; d28: 0.032 and d7: p = 0.045, respectively), whereas IL-10 expression levels of both Breg subsets remained stable. Sci-B-Vac™ booster vaccination resulted in anti-HBs seroconversion (>10 anti-HBs IU/L) in 10/11 2<sup>nd</sup> HBvac NR subjects (90.9%). Anti-HBs levels on day 28 did not or correlated only moderate with pre-vaccination frequencies of CD24<sup>+</sup>CD27<sup>+</sup>IL-10<sup>+</sup> (r<sub>s</sub> = 0.083) or CD24<sup>high</sup>CD38<sup>high</sup>IL-10<sup>+</sup> (r<sub>s</sub> = 0.300) Breg.

**Conclusion:** Here we report significantly higher frequencies of CD24<sup>high</sup>CD38<sup>high</sup> Breg in parallel with significantly lower IL-10 expression levels of CD24<sup>+</sup>CD27<sup>+</sup> and CD24<sup>high</sup>CD38<sup>high</sup> Breg in 2<sup>nd</sup> HBvac NR compared to 2<sup>nd</sup> HBvac R. Anti-HBs seroconversion accompanied by a decrease of Breg numbers after booster immunization with a third-generation hepatitis B vaccine could indicate a positive effect of third-generation hepatitis B vaccines on Breg mediated immunomodulation in hepatitis B vaccine non-responders.

PO-216

**Liver resident Natural Killer cells are the dominant source of Fas ligand during chronic Hepatitis B virus mediated liver damage**

Adrian Kuiper<sup>1,2</sup>, Shirin Nkongolo<sup>1</sup>, Deeqa Mahamed<sup>1,3</sup>, Sam Kim<sup>4</sup>, Aman Mehrotra<sup>1</sup>, Anjali Patel<sup>1</sup>, Diana Chen<sup>4</sup>, Jordan Feld<sup>1</sup>, Scott Fung<sup>1</sup>, Jeffrey Wallin<sup>4</sup>, Anuj Gaggar<sup>4</sup>, Harry Janssen<sup>1</sup>, Adam Gehring<sup>1</sup>. <sup>1</sup>University Health Network, Toronto Centre for Liver Disease, Toronto, Canada; <sup>2</sup>University of Toronto-St. George Campus, Immunology, Toronto, Canada; <sup>3</sup>The Hospital for Sick Children, Centre for Advanced Single Cell Analysis, Toronto, Canada; <sup>4</sup>Gilead Sciences, Inc., Foster City, United States  
Email: adrian.kuiper@mail.utoronto.ca

**Background and aims:** Non-specific liver damage contributes significantly to disease progression during chronic Hepatitis B virus (HBV) infection. Soluble Fas ligand (FasL) is a secreted cytotoxic molecule that is associated with HBV-mediated liver inflammation in animal models and is elevated in the plasma during acute hepatitis B and in chronic hepatitis B (CHB) patients experiencing liver damage after stopping nucleoside analogue therapy. However, the intrahepatic cells responsible for FasL expression and its regulation are not well defined. The aim of our study was to identify the cells responsible for intrahepatic FasL expression to define which cell types may contribute to liver damage.

**Method:** Fifteen patients with chronic active hepatitis B were enrolled for this study. CHB patients started treatment with tenofovir alafenamide (TAF; 25 mg daily). Blood and liver fine-needle aspirates (FNAs) were collected at baseline, 12 weeks, and 24 weeks after starting therapy. Blood was analyzed for virological, chemical, and hematological parameters. Single-cell RNA sequencing (scRNAseq) was performed on cells collected from longitudinal liver FNAs from 5 patients to identify cells expressing FasL.

**Results:** Mean ALT at baseline was 6.4x the upper limit of normal (ULN) (range: 1.1–21.8 x ULN) and mean HBV-DNA was 2.5 x 10<sup>7</sup> IU/ml (range: 1.9 x 10<sup>4</sup>–8 x 10<sup>7</sup> IU/ml). After 24 weeks of TAF therapy, mean ALT was 0.8 x ULN (range: 0.4–1.3 x ULN) and mean HBV-DNA level was 77.65 IU/ml (range: 10.6–285 IU/ml). scRNAseq of liver FNAs revealed 32 cell populations. FasL transcriptional expression in all cells was highest at baseline. Intrahepatic expression of FasL decreased only 10% after 12 weeks of TAF therapy but declined by 54% at week 24, when ALT had normalized in almost all patients. At baseline, liver resident Natural Killer (NK) cells expressed the highest levels of FasL followed by liver resident CD8 T cells and granzyme K positive (GZMK+) CD8 T cells. In tissue resident NK cells, the expression of FasL was reduced by 41% by week 24, while FasL expression was reduced by 62.8% and 65.7% in tissue resident and GZMK+ CD8 T cells, respectively.

**Conclusion:** scRNAseq identified multiple populations that express FasL, with tissue-resident NK cells displaying the highest expression. Understanding the regulation of non-specific cytotoxic effectors, and the cell types responsible for their production, will provide greater insight into chronic hepatitis B pathogenesis.

PO-235

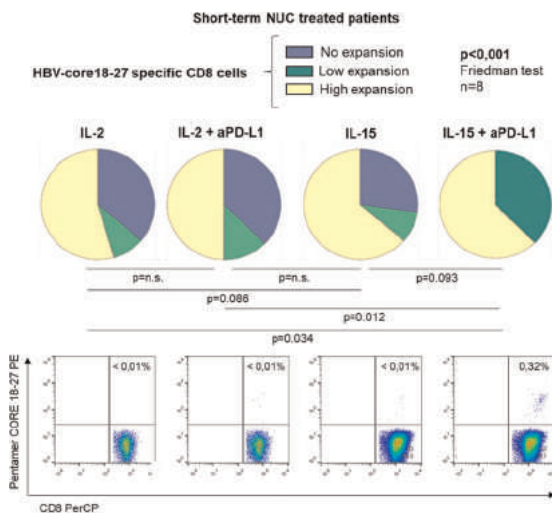

**Combined PD-1 blockade plus IL-15 treatment restores HBV-specific CD8 T cell reactivity in short-term nucleos(t)ide analogue treated eAg chronic hepatitis B**

Julia Peña Asensio<sup>1,2</sup>, Henar Calvo<sup>2,3</sup>, Joaquin Miquel<sup>2,3</sup>, Eduardo Sanz de Villalobos<sup>2,3</sup>, Alejandro González Praetorius<sup>2,4</sup>, Miguel Torralba<sup>2,5,6</sup>, Juan Ramón Larrubia<sup>2,3,6</sup>. <sup>1</sup>University of Alcalá, Department of Biology of Systems, Alcala de Henares, Spain; <sup>2</sup>Guadalajara University Hospital, Translational Hepatology Unit, Guadalajara, Spain; <sup>3</sup>Guadalajara University Hospital, Section of Gastroenterology and Hepatology, Guadalajara, Spain; <sup>4</sup>Guadalajara University Hospital, Section of Microbiology, Guadalajara, Spain; <sup>5</sup>Guadalajara University Hospital, Service of Internal Medicine, Guadalajara, Spain; <sup>6</sup>University of Alcalá, Department of Medicine and Medical Specialties, Alcala de Henares, Spain  
Email: juan.larrubia@uah.es

**Background and aims:** Restoration of a reactive CD8 T cell response during eAg (-) chronic hepatitis B (eAg (-)CHB) treatment with nucleos(t)ide analogue (NUC) could lead to functional cure. Negative immunoregulatory checkpoint blocking could help in NUC mediated T cell restoration. PD-1 blockade could not be enough to restore exhausted T cells in short term (ST) treated cases due to the associated presence of mitochondrial impairment. IL-15 could reprogram mitochondrial fitness and favor exhaustion reversion.

**Method:** In HLA-A2+ NUC treated CHBeAg (-), (N = 46) and inactive carriers (IC), (N=26) we checked for peripheral frequency and expansion ability of HBVcore18–27-specific CD8+ cells, according to NUC treatment duration (<78 months: ST; ≥78 months: long-term (LT)). We tested PGC1a, Glut1 and CPT1a after expansion in presence of either IL-2 or IL-15 in IC. In NUC treated CHBeAg (-) patients, we assessed the role of anti-PD-L1, IL-15 and both treatments together on T cell reactivity after Ag-specific in-vitro challenge. We visualized HBV-specific CD8T cells by flow-cytometric after staining with HLA-A2/peptide pentameric complexes.

**Results:** Ex-vivo frequency of HBVcore18–27 specific CD8 cells was higher in LT NUC treated cases than in IC and ST patients (p = 0.006). The expansion ability after Ag-specific in vitro challenge was preserved in all LT and in 75% IC but in only 50% of ST cases (p = 0.006). IL-15 increased PGC1a (p = 0.008) and CPT1a (p = 0.028) and decreased Glut1 (p < 0.05) expression on HBVcore18–27 specific CD8 T cells. The synergic effect of anti-PD-L1 plus IL-15 restored the T cell reactivity in all ST cases, while this effect was not observed with any of those treatments individually (p < 0.001).

**Figure.** Pie charts describing the percentage of cases with peripheral HBV-core18-27 CD8+ T cells detectable after antigen encounter in short-term (<78months) nucleos(t)ide analogue treated patients according to in-vitro treatment with IL-2, IL-15, alone or combined with aPD-L1. Cytometry dot plots from a representative patient.

Figure:

**Conclusion:** LT treatment can restore the reactivity of HBV-specific CD8 T cell response. ST treatment does not reverse T cell exhaustion in 50% of cases. The blockade of the negative checkpoint PD1 in addition to the mitochondrial reprogramming by IL-15 is able to reestablish Ag-specific T cell reactivity in all ST. This combination could be considered as a potential strategy to achieve functional cure in NUC treated patients.

PO-240

**Identification of a CD8 T cell population with a transcriptional profile consistent with non-specific hepatocyte killing in the inflamed human liver of chronic hepatitis B patients**

Scott Fung<sup>1</sup>, Diana Chen<sup>3</sup>, Anjali Patel<sup>1</sup>, Anuj Gaggar<sup>3</sup>, Shirin Nkongolo<sup>1</sup>, Sam Kim<sup>3</sup>, Aman Mehrotra<sup>1</sup>, Jeffrey Wallin<sup>3</sup>, Harry Janssen<sup>1</sup>, Jordan Feld<sup>1</sup>, Deeqa Mahamed<sup>1,2</sup>, Adam Gehring<sup>1,4</sup>. <sup>1</sup>University Health Network, Toronto Centre for Liver Disease, Toronto General Hospital Research Institute, Toronto, Canada; <sup>2</sup>The Hospital for Sick Children, Centre for Advanced Single Cell Analysis, Toronto, Canada; <sup>3</sup>Gilead Sciences, Foster City, United States; <sup>4</sup>University of Toronto, Department of Immunology, Toronto, Canada  
Email: Shirin.Nkongolo@uhnresearch.ca

**Background and aims:** While HBV-specific CD8 T cells contribute to viral clearance, non-specific CD8 T cell activation results in hepatocyte killing and tissue damage, driving disease progression to fibrosis and cirrhosis. It is not known if liver damage is driven by widespread CD8 T cell activation or whether damage is mediated by a specific sub-population of CD8 T cells. We analyzed longitudinal liver samples from chronic hepatitis B (CHB) patients using single-cell RNA sequencing (scRNAseq) with the aim of identifying the population of CD8 T cells responsible for non-specific hepatocyte killing.

**Method:** 15 CHB patients, who were not on antiviral treatment, with elevated alanine aminotransferase (ALT), were enrolled in this prospective study to receive tenofovir alafenamide (TAF) 25 mg daily. We collected blood and liver fine-needle aspiration (FNA) samples at baseline and after 12 and 24 weeks of TAF therapy. Blood was analyzed for virological markers, hematology, and clinical chemistry. Longitudinal liver FNAs from 5 patients were subjected to scRNAseq.

**Results:** Mean baseline ALT was 6.4×upper limit of normal (ULN) (range: 1.1–21.8) and mean HBV DNA at screening was 2.5 × 10<sup>7</sup> IU/ml (range: 1.9 × 10<sup>4</sup>–8 × 10<sup>7</sup>). By week 24, ALT levels had decreased up to 21-fold and were normal or near-normal in all patients. HBV DNA had decreased up to 7 log<sub>10</sub>-fold, with a maximum HBV DNA of 285 IU/ml. ScRNAseq analysis of liver FNAs at baseline revealed 32 clusters with 9 unique CD8 T cell populations. The largest CD8 T cell cluster displayed an activated immune signature (positive for CD27, CD38, HLA-DR, CD74, CD137, IL32, CD6) with a liver-resident phenotype. This population uniquely expressed high levels of IFN-gamma, known to drive antiviral immunity and mononuclear cell infiltration, and the cytotoxic effector Fas ligand. This population was enriched at baseline and showed the greatest change in differentially expressed genes as ALT levels normalized.

Figure:

**Conclusion:** Our data show that not all CD8 T cell populations are equally activated during chronic HBV-mediated liver inflammation. We identified an inflammatory CD8 T cell population that was

## POSTER PRESENTATIONS

enriched at the time of liver damage, transcriptionally expresses mediators of inflammation and tissue damage, and whose activation profile declined as liver damage resolved under antiviral therapy—which may indicate that liver damage is driven by a polyclonal population of CD8 T cells resident within the liver.

### PO-262

#### Blood-derived extracellular vesicles of patients with liver cirrhosis and acute-on-chronic liver failure display immunomodulatory functions

Mona-May Langer<sup>1</sup>, Sabrina Guckenbiehl<sup>1</sup>, Alina Bauschen<sup>1</sup>, Christian M. Lange<sup>1</sup>. <sup>1</sup>Gastroenterology and Hepatology, Essen, Germany  
Email: mona-may.langer@uk-essen.de

**Background and aims:** Liver cirrhosis (LC) and acute-on-chronic liver failure (ACLF) lead to distinct changes regarding the cellular structure of the liver and the immune system. Cell-cell communication and interactions of different liver cell subtypes and immune cells play an important role during disease progression and complications (e.g. infections). Within the last years, the role of extracellular vesicles (EVs) as communicators between cells is raising more and more attention. We therefore aimed to characterize phenotype and function of EVs of LC patients with or without ACLF.

**Method:** A total of 84 patients with compensated or decompensated LC or ACLF were recruited from a monocentric, prospective cohort study. Blood of healthy donors was derived from discarded buffy coats. EVs were isolated from EDTA blood by precipitation and characterized regarding particle size and concentration by Nanoparticle Tracking Analysis (NTA). Surface markers were investigated using flow cytometry and protein as well as RNA content was analyzed using Western Blot, Mass Spectrometry and smallRNA Sequencing. For functional analysis, 20 µg blood-derived EVs were used to stimulate healthy donor peripheral blood mononuclear cells (PBMCs) which were then analyzed by flow cytometry or qPCR.

**Results:** EVs derived from LC and ACLF patients show lower expression of exosome-specific markers (e.g. CD9, CD81) and liver cell-specific markers (e.g. ASGPR1, CD163) compared to healthy donor EVs. Particle concentration in blood of patients decreased, whereas the average size increased with the severity of liver disease. In functional assays with PBMCs, blood-derived EVs of LC and to a stronger extend of ACLF patients lead to changes in the composition of immune cell populations, e.g. by downregulation of CD197 (lymph node-homing receptor) on T cells, increased amount of CD4<sup>+</sup> TH2 cells or higher level of activated B cells (CD38<sup>+</sup>, HLA-DR<sup>+</sup>).

**Conclusion:** LC and ACLF patients have less differentiated EVs than healthy donors. The vesicles show immunomodulatory functions for example by leading to an increased amount of CD4<sup>+</sup> and CD8<sup>+</sup> effector memory T cells as well as changes in TH subpopulations.

Email: sam.murray19@imperial.ac.uk

**Background and aims:** Modulation of adaptive immunity is postulated to underscore the efficacy of TACE. We evaluated the influence of TACE on T-cell function by assessing the phenotypic characteristics of lymphocyte populations from archival samples of patients who underwent surgery with (T+) or without (T-) prior-TACE treatment.

**Method:** We profiled intra-tumoural (IT), peri-tumoural (PT) and non-tumoural background tissue (NT) to evaluate regulatory CD4<sup>+</sup>/FOXP3<sup>+</sup> (T-reg) and immune-exhausted CD8<sup>+</sup>/PD1<sup>+</sup> T-cells across T<sup>+</sup> (n = 58) and T<sup>-</sup> (n = 61). We performed targeted transcriptomics and T-cell receptor sequencing in a restricted subset of samples (n = 24) evaluated in relationship with the expression of actionable drivers of anti-cancer immunity including PD-L1, IDO-1, CTLA-4, Lag-3, Tim-3 and CD163.

**Results:** We analyzed samples from 119 patients resected (n = 25, 21%) or transplanted (n = 94, 79%) for Child Pugh A (n = 65, 55%) and TNM stage II (n = 73, 61%) HCC. T<sup>+</sup> samples displayed lower IT CD4<sup>+</sup>/FOXP3<sup>+</sup> (p = 0.006), CD8<sup>+</sup> (p = 0.002) and CD8<sup>+</sup>/PD1<sup>+</sup> (p < 0.001) and lower NT CD8<sup>+</sup>/PD1<sup>+</sup> compared to T<sup>-</sup>. Lower IT (p = 0.005) and NT CD4<sup>+</sup>/FOXP3<sup>+</sup> (p = 0.03) correlated with improved recurrence free survival (RFS), with IT CD4<sup>+</sup>/FOXP3<sup>+</sup> density predicting for RFS benefit in multivariable analyses. In a subset of samples (12 T<sup>+</sup>, 12 T<sup>-</sup>), transcriptomic analysis revealed differential up-regulation of genes reflective of a pro-inflammatory response in T<sup>+</sup>. Compared to T<sup>-</sup>, T<sup>+</sup> samples were significantly enriched for IRF2 expression (p = 0.01), an interferon-regulated transcription factor linked to immune-responsiveness in other malignancies. Expression PD-L1, IDO-1, CTLA-4, Lag-3, Tim-3 and CD163 was not different T<sup>+</sup> versus T<sup>-</sup>. T-cell clonality by ImmunoSeq assay was not different in association with TACE pre-treatment.

**Conclusion:** Pre-treatment with TACE is associated by lower intra-tumoural density of immune exhausted effector and regulatory T-cells, with significant up-regulation of pro-inflammatory pathways. This highlights the pleiotropic effects of TACE in modulating the tumour microenvironment and strengthens the rationale for developing immunotherapy alongside TACE to improve outcomes of HCC patients.

### PO-846

#### Chronic Hepatitis B inflammation gives rise to a novel macrophage population in the human liver

Juan Diego Sanchez<sup>1,2</sup>, Shirin Nkongolo<sup>1</sup>, Deeqa Mahamed<sup>1,3</sup>, Sam Kim<sup>4</sup>, Aman Mehrotra<sup>1</sup>, Anjali Patel<sup>1</sup>, Diana Chen<sup>4</sup>, Jordan Feld<sup>1</sup>, Scott Fung<sup>1</sup>, Jeffrey Wallin<sup>4</sup>, Anuj Gaggar<sup>4</sup>, Harry Janssen<sup>1</sup>, Adam Gehring<sup>1,2</sup>. <sup>1</sup>University Health Network, Toronto Centre for Liver Disease, Toronto General Hospital Research Institute, Toronto, Canada; <sup>2</sup>University of Toronto, Department of Immunology, Toronto, Canada; <sup>3</sup>The Hospital for Sick Children, Centre for Advanced Single Cell Analysis,

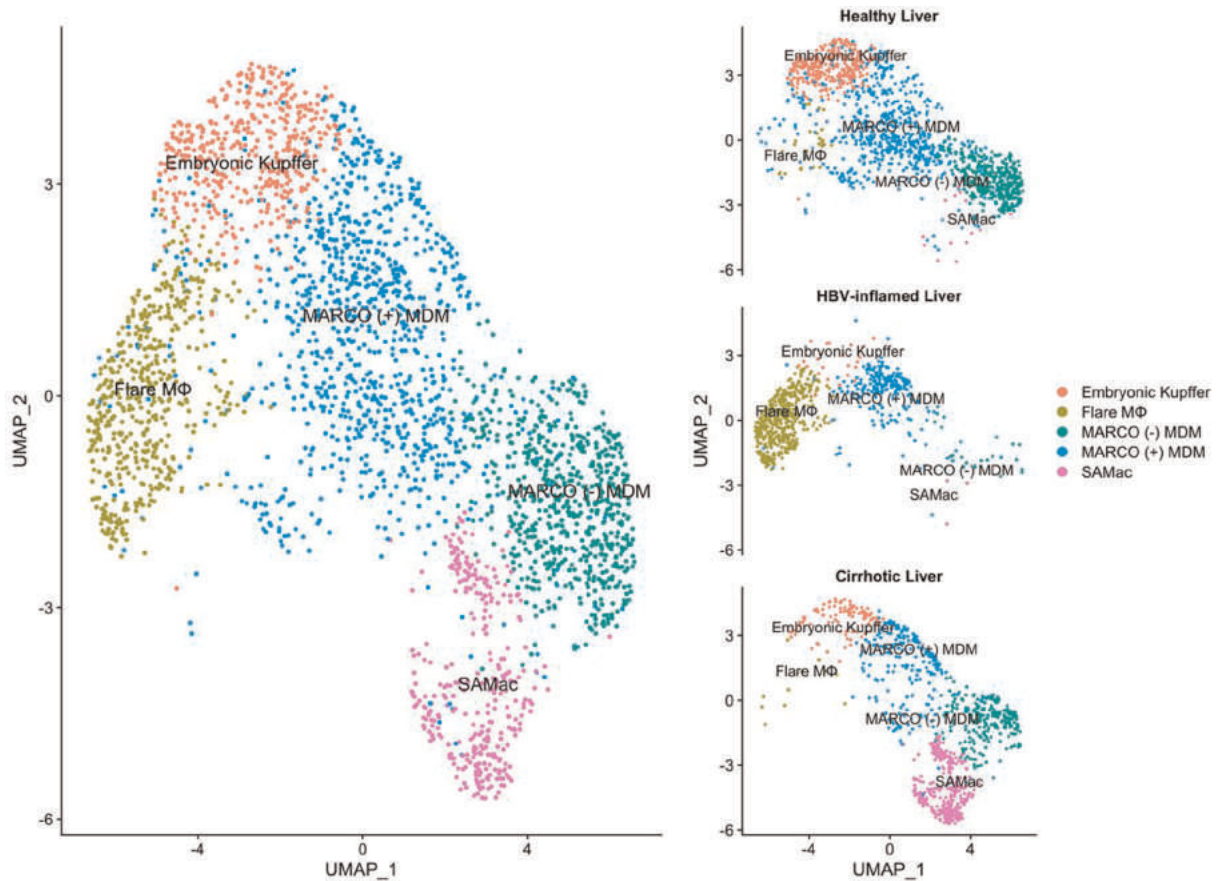

Figure: (abstract: PO-846)

Toronto, Canada; <sup>4</sup>Gilead Sciences, Foster City, United States  
 Email: jd.sanchezvasquez@mail.utoronto.ca

**Background and aims:** Kupffer cells are liver macrophages that maintain a tolerogenic environment. However, during inflammation, liver macrophage composition can change with the recruitment and differentiation of monocytes into inflammatory monocyte-derived macrophages. Preliminary data showed that markers of myeloid activation in the peripheral blood, such as CD163, Galectin-9 and IL-18, coincided with liver damage in chronic Hepatitis B (CHB) patients. The aim of our study was to determine if Hepatitis B virus (HBV)-mediated liver inflammation alters intrahepatic macrophage composition to propagate liver damage.

**Method:** In this study, 15 CHB patients with elevated alanine aminotransferase (ALT) and detectable viral load began treatment with tenofovir alafenamide (TAF). Liver fine-needle aspirates (FNAs) were collected prior to TAF therapy and weeks 12 and 24 of TAF treatment. Longitudinal FNAs from 5 patients were analyzed using scRNAseq of total liver FNA cells. Soluble plasma proteins were measured using the Luminex inflammatory panel. Liver macrophage subpopulations were identified in the HBV patient scRNAseq data and compared to macrophages from healthy and cirrhotic human livers.

**Results:** Luminex confirmed increased production of CD163, IL-18, and galectin-9 during peak of ALT levels which declined during TAF treatment. Macrophages were identified in the scRNAseq data by the expression of *CD68* and *C1QA*. A macrophage subpopulation was identified with markers of immune activation (*IL18*, *SPI1* and *MYD88*), interferon signaling (*IFIT3* and *IFI27*) and recent monocyte-to-macrophage differentiation (*MAFB* and *ZFP36L1*) which was confirmed by pseudotime trajectory analysis. Comparison of macrophage populations between the HBV infected liver to healthy and cirrhotic

human livers indicated that the inflammatory macrophage population was unique to the HBV infected liver. Inflammatory macrophages were distinguished from Kupffer cells by the expression of *LIPA*, *CTSL* and *TIMD4*.

**Conclusion:** Our results define a liver microenvironment during HBV-mediated inflammation that drives monocyte differentiation towards an inflammatory macrophage profile. The unique inflammatory macrophage population is distinct from Kupffer cells at the transcriptional level and has the potential to drive liver damage.

**PO-896**

**Stimulation of Mucosal-associated invariant T (MAIT) cells by human serum derived from peripheral and portal blood**

Martin Lett<sup>1</sup>, Tina Jaeger<sup>1</sup>, Maxime Jacquet<sup>1</sup>, Christoph Zech<sup>2</sup>, Magdalena Filipowicz Sinnreich<sup>1,3</sup>. <sup>1</sup>University Hospital Basel, Department of Biomedicine, Basel, Switzerland; <sup>2</sup>University Hospital Basel, Radiology and Nuclear Medicine, Basel, Switzerland; <sup>3</sup>Basel University Medical Clinic, Liestal, Gastroenterology and Hepatology, Liestal, Switzerland  
 Email: magdalena.filipowicz@unibas.ch

**Background and aims:** MAIT cells represent the most abundant T cells in human liver. They respond to bacterial metabolites derived from Riboflavin that are presented by MHC-like molecule MR1. The most potent stimulatory MAIT cell antigen (Ag) is the pyrimidine 5-(2-oxopropylideneamino)-6-D-ribitylaminouracil (5-OP-RU). Recent mouse studies, showing that microbiota-derived Ag is necessary for intra-thymic development of MAIT cells, argue for 5-OP-RU absorption from the gut lumen. We investigated MAIT cell stimulatory Ags in human blood of healthy subjects and patients suffering from portal

## POSTER PRESENTATIONS

hypertension to learn under which conditions Ags reach the circulation.

**Method:** We assessed MAIT cell stimulatory potential of serum derived from healthy subjects and 11 patients with a history of transjugular intrahepatic porto-systemic shunt stent (TIPSS). Portal and peripheral blood of six patients undergoing TIPSS was also analysed. Ag-presenting cells (K562 leukemia cells) overexpressing MR1 were exposed to serum and IFN- $\gamma$  release by MAIT cells was measured by ELISA. MR1 blocking antibodies were used to assess MR1 dependence. To quantify amounts of Ag present in serum, control assays containing 0.006–25 pM 5-OP-RU were performed.

**Results:** We reproducibly measured MR1-dependent MAIT cell stimulation by sera obtained from all healthy subjects. When calculated as 5-OP-RU equivalents, serum concentration was in the range of 0.05–0.2 pM. Peripheral and portal sera of several TIPSS patients strongly stimulated IFN- $\gamma$  production by MAIT cells (1–2 pM 5-OP-RU equivalent). In the remaining patients, portal serum was 1.7- to 3-fold more active than the peripheral counterpart. Patients with a history of TIPSS showed higher MAIT cell stimulatory potential than age- and sex-matched healthy control subjects.

**Conclusion:** We provide first evidence for the presence of MAIT cell stimulatory metabolites in human blood. Our results corroborate previous findings obtained in mice and provide rationale for the activated MAIT phenotype observed in human liver. Increased levels of gut-derived MAIT cell stimulatory ligands in portal and peripheral blood of TIPSS patients who suffer from portal hypertension, a condition associated with impaired intestinal barrier function, indicate that intrahepatic Ag-presentation may represent an important pathophysiological step in the development of liver disease.

### PO-1333

#### Osteopontin expression identifies a subset of macrophages distinct from Kupffer Cells in the fatty liver

**Background and aims:** Metabolic-associated fatty liver disease (MAFLD) represents a spectrum of disease states ranging from simple steatosis to non-alcoholic steatohepatitis (NASH). Despite the high prevalence of MAFLD, we still do not understand the mechanisms driving the progression to NASH. Hepatic macrophages (MFs) are suggested to play important roles in driving this, however the exact roles they play and the specific contributions of resident Kupffer cells (KCs) vs other hepatic MFs remains unclear.

**Method:** Using CITE-seq analysis with the 10X genomics platform coupled with multi-parameter flow cytometry, confocal microscopy and lipidomics, we examined the hepatic MF populations during the

Figure: (abstract: PO-1333)

different stages of NAFLD, induced by feeding mice a Western diet (WD) or a Standard diet (SD) for 12, 24 or 36 weeks.

**Results:** Mice fed the WD for 24 and 36 weeks were found to harbor a reduced population of CLEC4F<sup>+</sup>TIM4<sup>+</sup> resident KCs compared with controls. In addition, we also observed the significant recruitment of CLEC4F<sup>-</sup> MFs and CLEC4F<sup>+</sup>TIM4<sup>-</sup> KCs, which developed from bone marrow monocytes. While, contrary to the current hypothesis, resident KCs were not found to be activated in MAFLD and the CLEC4F<sup>+</sup>Tim4<sup>-</sup> recruited KCs had a very similar profile to their resident counterparts, the CLEC4F<sup>-</sup> MFs were found to have a very distinct activation and lipidomics profile. CLEC4F<sup>-</sup> MFs expressed genes characteristic of lipid-associated MFs in obese adipose tissue and fibrotic MFs in the human liver. Moreover, they expressed the chemokine osteopontin, which has previously been associated with the progression to NASH. Notably, CLEC4F<sup>-</sup> MFs were found to be localised in zones of established steatosis, which were largely devoid of KCs.

**Conclusion:** Taken together, our data highlight significant heterogeneity within the MF pool and suggest a need for more specific MF targeting strategies in MAFLD.

**PO-1460**

**Harnessing liver-resident gamma delta T cells for immunotherapy of hepatocellular carcinoma**

Nekisa Zakeri<sup>1</sup>, Leo Swadling<sup>1</sup>, Laura J. Pallett<sup>1</sup>, Nathalie M. Schmidt<sup>1</sup>, Mariana O. Diniz<sup>1</sup>, Stephanie Kucykowicz<sup>1</sup>, Oliver E. Amin<sup>1</sup>, Amir Gander<sup>2</sup>, Massimo Pinzani<sup>3</sup>, Brian R. Davidson<sup>2</sup>, Mala K. Maini<sup>1</sup>. <sup>1</sup>Division of Infection and Immunity, University College London, United Kingdom; <sup>2</sup>Division of Surgery and Interventional Science, Royal Free London NHS Foundation Trust, United Kingdom; <sup>3</sup>Institute for Liver and Digestive Health, Royal Free London NHS Foundation Trust, United Kingdom

Email: n.zakeri@ucl.ac.uk

**Background and aims:** Gamma delta ( $\gamma\delta$ ) T cells are promising candidates for cancer immunotherapy, due to their potent cytotoxicity, tissue localisation, and MHC-unrestricted antigen recognition offering exciting potential for future pan-population immunotherapies. We characterised liver and tumour infiltrating  $\gamma\delta$  T cells in hepatocellular carcinoma (HCC), and explored whether modulating features of  $\gamma\delta$  T cell tissue-residency could provide a novel immunotherapeutic approach for HCC.

**Method:** Using multiparameter flow cytometry, we analysed lymphocytes isolated from paired peripheral blood, tumour-free liver tissue, and tumoural tissue resected from patients with HCC (n = 26), in comparison to colorectal cancer liver metastases (n = 28), and blood from healthy controls. Long-lived persistence of intrahepatic  $\gamma\delta$  T cells was examined using donor and recipient HLA-mismatched liver allografts obtained 7–11 years post liver transplantation. Peripheral blood expanded V $\gamma$ 9V $\delta$ 2T cells, intrahepatic lymphocytes, and tumour-infiltrating lymphocytes, were co-cultured with human hepatoma cell-lines (HepG2 and HuH7), pre-treated with the aminobisphosphonate Zoledronate to promote tumour cell phosphoantigen accumulation for V $\gamma$ 9V $\delta$ 2T cell receptor activation.

**Results:**  $\gamma\delta$  T cells were able to acquire a tissue-resident memory (T<sub>RM</sub>) phenotype (CD69+CD49a+) in the liver, absent from blood, with a distinct functional profile (higher IFN $\gamma$ , IL-2 expression). Examining donor and recipient HLA-mismatched liver allografts,  $\gamma\delta$ T<sub>RM</sub> cells demonstrated long-lived tissue-compartmentalised persistence in the liver and could be replenished from the circulation, an attractive profile to recapitulate with immunotherapy. A subset of  $\gamma\delta$  T cells, V $\gamma$ 9V $\delta$ 2T cells, were reduced in frequency in HCC livers (p < 0.001) and tumours (p < 0.01), but displayed the highest capacity to acquire an intra-tumoural  $\gamma\delta$ T<sub>RM</sub> phenotype. A *de novo* T<sub>RM</sub> phenotype (CD69+CD49a+) with increased liver-homing chemokine receptor expression (CXCR6+ CXCR3+) could be recapitulated by expanding blood

V $\gamma$ 9V $\delta$ 2T cells *in vitro* using clinically-approved Zoledronate and IL-2. Furthermore, direct priming of HCC cell-lines with Zoledronate increased the anti-tumour effector function (IFN $\gamma$ , CD107a) of co-cultured expanded V $\gamma$ 9V $\delta$ 2T cells, as well as V $\gamma$ 9V $\delta$ 2 T<sub>RM</sub> cells isolated from HCC livers and tumours, with increased tumour-cell lysis.

**Conclusion:** Intrahepatic  $\gamma\delta$  T<sub>RM</sub> cells demonstrate long-lived immunotherapeutic properties for HCC. We show that aminobisphosphonates such as Zoledronate can enhance the efficacy of  $\gamma\delta$  T cell immunotherapy in HCC, via two mechanisms: direct delivery to the tumour increases V $\gamma$ 9V $\delta$ 2 T<sub>RM</sub> cells anti-tumour function, whilst *in vitro* expansion of blood V $\gamma$ 9V $\delta$ 2T cells for adoptive cell transfer confers *de novo* liver-homing tissue-residency to achieve long-lived local tumour immunosurveillance.

**PO-1472**

**CD4 T cell tolerance induced by nanoparticle-mediated autoantigen delivery to liver sinusoidal endothelial cells depends on interferon-gamma**

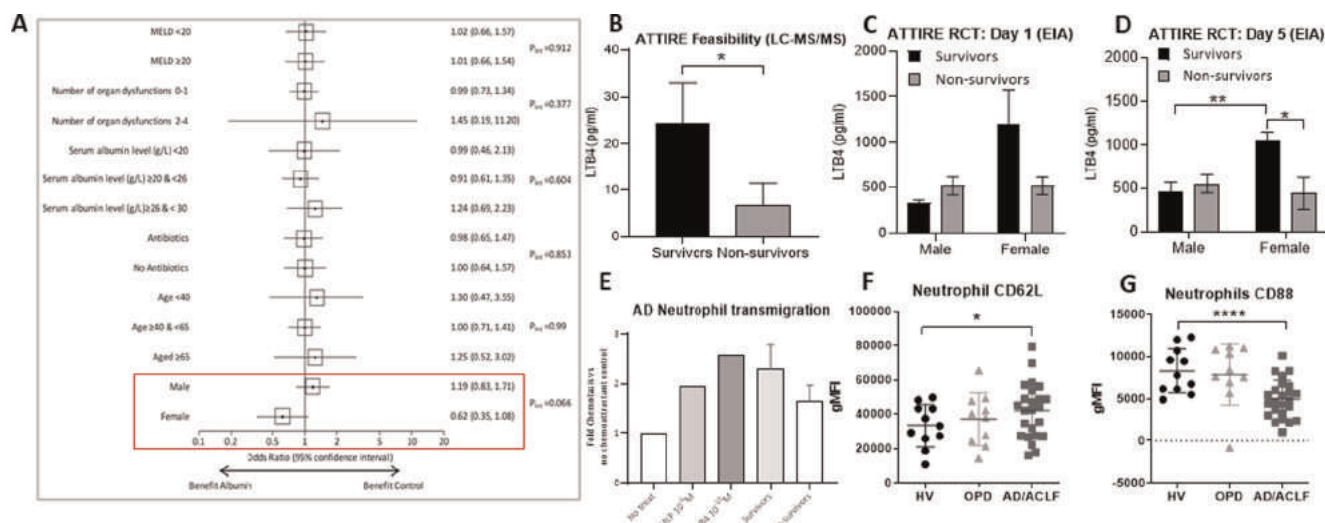

Daria Krzikalla<sup>1</sup>, Disha Mungalpara<sup>2</sup>, Reinaldo Digigow<sup>2</sup>, Muharrem Selici<sup>2</sup>, Dorothee Schwinge<sup>1</sup>, Christoph Schramm<sup>1</sup>, Ansgar Lohse<sup>1</sup>, Antonella Carambia<sup>1</sup>, Johannes Herkel<sup>1</sup>. <sup>1</sup>Department of Medicine I, University Medical Center Hamburg-Eppendorf, Hamburg, Germany; <sup>2</sup>Topas Therapeutics GmbH, Hamburg, Germany  
Email: d.krzikalla@uke.de

**Background and aims:** Targeted gene expression of myelin basic protein (MBP) in hepatocytes can induce MBP-specific CD4 T cell tolerance and prevent MBP-driven neuroinflammation in experimental autoimmune encephalomyelitis (EAE). The induction of tolerance depended on IFNG-CXCL9-CXCR3-mediated accumulation of autoreactive T cells in the liver and upregulation of CTLA-4 (EASL Abstract in: Journal of Hepatology 2020; Vol. 73, S82). Alternatively, MBP-specific CD4 T cell tolerance and suppression of EAE can be induced by delivery of MBP peptides to liver sinusoidal endothelial cells (LSECs) via nanoparticles (NP). Yet, it is unclear whether hepatic tolerance mechanisms as those activated by gene targeting to hepatocytes.

**Method:** B10.PL mice were immunised to MBP and injected with unloaded or MBP-loaded NP (MBP-NP). One day later, CD45.1- MBP-specific tg4 T cells were adoptively transferred into the CD45.1+ recipients. Additionally, mice received blocking IFNG antibody or isotype control. The transferred tg4 T cells were re-analysed *ex vivo* by flow cytometry on day seven after immunisation. Moreover, the clinical EAE course was monitored.

**Results:** Upon MBP peptide-delivery to LSECs via NP, the transferred tg4 T cells accumulated in livers of immunised mice, but not in livers of control mice. Analysis of hepatic tg4 T cells revealed an increased frequency of IFNG producers in MBP-NP-treated mice, suggesting that transmigration of tg4 T cells into the liver was dependent on the IFNG-CXCL9-CXCR3 axis. Indeed, hepatic *Cxcl9* and *Cxcr3* expression were induced in MBP-NP-treated mice. Moreover, hepatic tg4 T cells showed upregulation of CTLA-4 in MBP-NP-treated mice as compared to controls. *In vivo* inhibition of IFNG via blocking antibody prevented migration of tg4 T cells into the liver and decreased their expression of CTLA-4. Strikingly, *in vivo* blockade of IFNG completely abolished tolerance to MBP in MBP-NP-treated mice resulting in clinical EAE.

**Conclusion:** These results demonstrate that protection from autoimmune disease by autoantigen-delivery to LSECs is dependent on the induction of the IFNG-CXCL9-CXCR3 axis and upregulation of CTLA-4 on autoreactive T cells. Thus, these mechanisms are similar to those induced by hepatic autoantigen gene transfer, suggesting that LSEC-controlled transmigration of autoreactive lymphocytes into the liver parenchyma is essential for NP-mediated tolerance.

A) Statistics analysis of all re-randomised controlled trial (RCT) patients (828) in the ATTIRE trial. Data presented at British Association for the study of the liver Annual Meeting 2020 by A. O'Brien. B) Leukotriene B4 levels in human plasma from AD/ACLF patients in the ATTIRE Feasibility study at day 1 (n=5 per group) measured using LC-MS/MS. Results expressed as pg/mL, mean  $\pm$  SEM. Leukotriene B4 levels in human plasma from AD/ACLF patients in the ATTIRE RCT on day 1 (C) and 5 (D) measured using ELISA according to gender (n=4-5 per group), with results expressed as pg/mL, mean  $\pm$  SEM. Two-tailed unpaired Mann-Whitney test performed. E) Neutrophil Transmigration assay using Transwells® chambers with 50% v/v plasma of AD/ACLF patients from survivors (n=3) and non-survivors group (n=3). Results presented as fold change relative to no treated condition and conditions tested and shown as mean  $\pm$  SEM. (F) and (G) Flow cytometry analysis of CD62L and CD88 expression, respectively, on blood derived neutrophils from HV (n=11), stable liver outpatients (n=10) and AD/ACLF (n=24) patients, mean  $\pm$  SD. One-way ANOVA with Tukey multiple comparisons test performed. \* $p < 0.05$  and \*\* $p < 0.01$ , \*\*\*\* $p < 0.001$ .

**Investigating the potential association of elevated plasma Leukotriene B4 and survival in females in the ATTIRE trial**

Thais H. Tittanegro<sup>1</sup>, Alexander Maini<sup>1</sup>, Louise China<sup>1</sup>, Natalia Becares<sup>1</sup>, Nicholas Freemantle<sup>2</sup>, Alastair O'Brien<sup>1</sup>. <sup>1</sup>University College London, Institute for Liver and Digestive Health, London, United Kingdom; <sup>2</sup>University College London, Comprehensive Clinical Trials Unit, London, United Kingdom  
 Email: a.o'brien@ucl.ac.uk

**Background and aims:** Infection is a major cause for hospitalisation in patients with decompensated cirrhosis secondary to immune dysfunction. The ATTIRE trial (Albumin To prevent Infection in chronic liver failure) that used targeted albumin infusions to prevent infection, renal dysfunction and death had an overall null effect, however, post-hoc subgroup analyses suggest that there may be a differential effect according to gender, with perhaps some evidence of benefit in women. Leukotriene formation by androgens has been proposed as a molecular basis for gender differences in the immune response, with lower levels in men. We previously observed elevated Leukotriene B4 (LTB4) in acute decompensation/Acute-on-chronic Liver Failure (AD/ACLF) patients and investigated this neutrophil chemoattractant eicosanoid further.

**Method:** Using ATTIRE plasma samples from both the feasibility and randomized controlled trial (RCT), LTB4 was measured using *in vitro* Enzyme Immunoassay (EIA) kits and mass spectroscopy. Neutrophil transmigration profile was assessed with Transwell™ chambers using healthy neutrophils in the presence of LTB4 or ATTIRE patients' plasma. Flow Cytometric (FACs) analyses of neutrophils were performed using samples from a separate cohort of healthy

volunteers (HV), outpatients with ascites (OPD) and hospitalized AD/ACLF patients.

**Results:** Analyses revealed a significant association between elevated plasma LTB4 and improved outcome that was only observed in women. Moreover, we found that addition of LTB4 as a chemoattractant to healthy neutrophils increased neutrophil transmigration to a similar degree as addition of ATTIRE trial survivors' plasma, with less transmigration seen when non-survivors' plasma was used. FACS analyses identified a progressive increase in the neutrophil adhesion molecule, L-selectin (CD62L) according to liver disease severity ( $p < 0.05$ ), coupled with a progressive reduction in CD88 expression compared to OPDs and HVs ( $p = 0.0002$ ), suggesting that, although activated, AD/ACLF neutrophils have reduced phagocytosis.

**Conclusion:** We show an association between increased LTB4 in AD/ACLF females and improved survival in samples from two separate studies. Transmigration and FACS findings support the notion that this may be related to increased neutrophil transmigration to the site of infection in these patients. This association of elevated LTB4 with survival is in contrast to non-cirrhotic inflammatory conditions where increased LTB4 is implicated in increased susceptibility to sepsis. We hypothesise that elevated levels of LTB4 lead to increased neutrophil transmigration to infection sites that overcomes the cellular functional defect and effectively combats infection, underlying this association with improved outcome. Further studies are required to investigate this.

**Acute liver injury results in temporal changes in hepatic macrophage pool**

Anna Bujko<sup>1</sup>, Liesbet Martens<sup>1</sup>, Tinne Thoné<sup>1</sup>, Djoere Gaublumme<sup>1</sup>, Anneleen Remmerie<sup>1</sup>, Johnny Bonnardel<sup>1</sup>, Bavo Vanneste<sup>1</sup>, Tineke Vanhalewyn<sup>1</sup>, Mushida Binte Abdul Latib<sup>1</sup>, Mathias Vanhockerhout<sup>1</sup>, Sofie De Prijck<sup>1</sup>, Dirk Elewaut<sup>1</sup>, Charlotte L. Scott<sup>1</sup>. <sup>1</sup>VIB-UGent Center for Inflammation Research, Ghent, Belgium  
Email: anna.bujko@irc.vib-ugent.be

**Background and aims:** In recent years it has become clear that inflammation results in recruitment of monocytes to the liver which differentiate into short-lived macrophages (moMacs) distinct from Kupffer cells (KCs). However, we and others have also shown that under some circumstances these recruited monocytes also have the capacity to differentiate into long-lived monocyte-derived Kupffer cells (moKCs). However, the mechanisms dictating monocyte fate upon entry into the inflamed liver remain to be determined. One hypothesis recently put forward is that resident macrophages that have resided for prolonged periods of time in a homeostatic environment such as KCs would not be plastic enough to respond to injury. Thus one possibility is that the need for an activated KC population would drive moKC development. Here we set out to characterise and phenotype the distinct populations of macrophages present in the liver after paracetamol overdose-induced injury and determine the KC and monocyte responses to this insult.

**Method:** To study the different populations present in the liver during acute liver injury and repair and their activation status, we have performed CITE-Seq and spatial transcriptomics (Visium) analysis using the 10X genomics platform at various time points after paracetamol overdose. These transcriptomic analyses were further complemented with multi-parameter flow cytometry and confocal and intravital microscopy to identify and localize the distinct myeloid cell subsets present at various time points post paracetamol overdose.

**Results:** We identified two distinct subsets of macrophages CLEC4F<sup>+</sup> KCs and CLEC4F<sup>-</sup> macrophages. BM chimeras and lineage tracing studies revealed that CLEC4F<sup>-</sup> macrophages were derived from the BM, were only transiently present in the liver and unlike in NAFLD, these did not further differentiate into moKCs. Attempts to localize these populations by confocal microscopy revealed additional heterogeneity within the KC pool, with phenotypically distinct KCs being located in healthy and damaged tissue, where they surrounded the recruited macrophages. We are currently investigating mechanisms behind the emergence of these populations and their functional consequences.

**Conclusion:** Monocytes infiltrating the liver after paracetamol overdose do not become moKCs. However, resident KCs are plastic enough to respond to the injury, with those closest to the damaged tissues being activated after paracetamol overdose-induced liver injury.

**PO-1653**

**Sustained delivery of IL-10 using innovative cell-based platform for immune-mediated hepatitis**

Sofia Brites Boss<sup>1</sup>, Tiffany Vo<sup>1</sup>, Jie Li<sup>1</sup>, Janet Huang<sup>1</sup>, Lauren Jansen<sup>1</sup>, David Peritt<sup>1</sup>, Hozefa Bandukwala<sup>1</sup>. <sup>1</sup>Sigilon Therapeutics, Cambridge, United States  
Email: sofia.bboss@sigilon.com

**Background and aims:** Autoimmune hepatitis (AIH) results from a breakdown in immune tolerance leading to production of pro-inflammatory cytokines by autoreactive T-cells and subsequent hepatocyte destruction. While AIH patients benefit from immunosuppressive agents, the life-long systemic administration often leads

to serious adverse effects and associated morbidities. Immunomodulatory cytokines, such as IL-10, are well established preclinically to treat autoimmune diseases including AIH. However, while these cytokines have high potency, they have an extremely short half-life, making it challenging to treat with the protein therapeutic. Thus, new approaches are essential for this treatment modality to be beneficial to patients. We hypothesized that the sustained low-dose treatment with immunomodulatory cytokines delivered using an innovative cell-based modular platform could restore immune homeostasis providing a functional cure for this disease. The platform consists of genetically modified allogeneic human cells engineered to produce the therapeutic protein of interest, encapsulated in a two-compartment hydrogel sphere. The use of implanted allogeneic cells, gene modified to express the cytokine transgene, has several potential safety advantages over other therapeutic modes. However, one of the major challenges of such therapies is protection from the host's immune system. While hydrogels can provide a physical barrier to allogeneic cells, they themselves can elicit an immune response which results in build-up of pericapsular fibrotic overgrowth (PFO), leading to cell death and inadequate therapy duration. Sigilon's two-compartment hydrogel sphere supports the function of cells (inner compartment) and shields the cells from the host's immune system and PFO (outer layer) (Barney ASGCT 2020, Bochenek Nat Biomed Eng 2018).

**Results:** First, we engineered allogeneic cells to produce active IL-10 in vitro. Second, the cells were efficiently encapsulated in the two-compartment hydrogel spheres and shown to produce functional IL-10. Next, the spheres were administered intraperitoneally (IP) in mice, and we observed sustained delivery of IL-10 which resulted in in vivo differentiation of peritoneal macrophages towards the immunomodulatory M2 phenotype marked by increased expression of CD206. Furthermore, we demonstrated that synthetic steroids can be co-encapsulated with IL-10 producing cells, enabling localized combination therapy approach. Finally, sustained IL-10 production alone or in combination with a synthetic steroid resulted in protection of mice from acute liver injury induced by Concanavalin A. **Conclusion:** Collectively our data demonstrate that localized and sustained IP administration of IL-10 with or without corticosteroids can provide a new, potentially safer, and more effective modality for the treatment of inflammatory liver diseases.

**PO-1929**

**Discovery of conserved HDV-specific CD8+ T-cell epitopes in HDV/ HBV co-infection**

Valerie Oberhardt<sup>1,2</sup>, Maïke Hofmann<sup>1</sup>, Robert Thimme<sup>1</sup>, Christoph Neumann-Haefelin<sup>1</sup>. <sup>1</sup>University Hospital Freiburg, Department of Internal Medicine II, Germany; <sup>2</sup>University of Freiburg, Faculty of Biology, Germany  
Email: christoph.neumann-haefelin@uniklinik-freiburg.de

**Background and aims:** Hepatitis D virus (HDV) super-infection of hepatitis B virus (HBV)-infected patients is associated with rapid progression to liver cirrhosis and hepatocellular carcinoma. The virus-specific CD8+ T-cell response is thought to have a major impact on the outcome of HDV infection. However, the HDV-specific T-cell epitope repertoire is only poorly characterized and mechanisms contributing to T-cell failure during chronic infection are not yet fully understood. Previously, we identified HDV-specific CD8+ T-cell epitopes in regions of the large hepatitis D antigen (L-HDAg) in which HDV tolerates mutations to escape immune recognition. In this study, we aimed to discover T-cell epitopes that are located in conserved regions, in order to characterize the influence of these T cells on infection outcome.

**Method:** PBMC from 19 chronic and 15 resolved HBV/HDV co-infected patients were stimulated with an overlapping peptide (OLP)

## POSTER PRESENTATIONS

pool covering L-HDAg. After *in vitro* expansion virus-specific CD8+ T cells were detected by intracellular cytokine staining and responses were HLA-allele fine-mapped. Tetramers were generated for phenotypic characterization of HLA-B\*08:01 restricted HDV-specific CD8+ T cell in six HLA-B\*08+ patients.

**Results:** Interferon gamma (IFN $\gamma$ ) secretion of CD8+ T cells in response to peptide pool re-stimulation was detected in 52.6% of HDV RNA+ patient, whereas 66.6% of HDV RNA–patients responded to at least one peptide pool. OLP-specific CD8+ T cells predominantly co-secreted IFN $\gamma$  and tumor necrosis factor (TNF). Interestingly, novel epitopes were exclusively restricted by rare HLA-B alleles. Of note, one HLA-B\*08:01-restricted epitope was highly conserved in the L-HDAg of genotype 1. High-dimensional flow cytometry analyses revealed that HDV-specific CD8+ T cells restricted by this conserved epitope displayed phenotypical and functional features of T-cell exhaustion. Exhaustion traits were partially associated with HDV infection control.

**Conclusion:** In conclusion, we were able to further expand the HDV-specific-CD8+ T-cell epitope repertoire. The detection rate of HDV-specific CD8+ T cells was similar in chronic and resolved HBV/HDV co-infected patients. Analyses of HDV-specific CD8+ T cells restricted by an epitope not subjected to viral escape mutations indicate that T-cell exhaustion might play a key role in infection control.

### PO-1983

#### HLA-B\*27-restricted CD8+ T-cell response against hepatitis B virus: viral escape as central mechanism of T-cell failure

Elahe Salimi Alizee<sup>1</sup>, Muthamia M. Kiraithe<sup>1</sup>, Tatjana Schwarz<sup>2</sup>, Emma Gostick<sup>3</sup>, John Sidney<sup>4</sup>, Matthias Marget<sup>5</sup>, Markus Cornberg<sup>6</sup>, Julia Lang<sup>1</sup>, Phillipp Ehrenmann<sup>1</sup>, Janine Kemming<sup>1</sup>, Florian Emmerich<sup>7</sup>, Alessandro Sette<sup>4</sup>, David Price<sup>3</sup>, Tobias Böttler<sup>1</sup>, Jörg Timm<sup>2</sup>, Maike Hofmann<sup>1</sup>, Robert Thimme<sup>1</sup>, Christoph Neumann-Haefelin<sup>1</sup>. <sup>1</sup>University Hospital Freiburg, Department of Medicine II, Freiburg, Germany; <sup>2</sup>Heinrich-Heine-University, Institute for Virology, Düsseldorf, Germany; <sup>3</sup>Cardiff University School of Medicine, Institute of Infection and Immunity, Cardiff, United Kingdom; <sup>4</sup>La Jolla Institute for Allergy and Immunology, La Jolla, United States; <sup>5</sup>University Hospital Hamburg-Eppendorf, Institute of Transfusion Medicine, Hamburg, Germany; <sup>6</sup>Hannover Medical School, Department of Gastroenterology, Hepatology, and Endocrinology, Hannover, Germany; <sup>7</sup>University Hospital Freiburg, Institute of Transfusion Medicine and Gene Therapy, Freiburg, Germany  
Email: elahe.salimi.alizee@uniklinik-freiburg.de

**Background and aims:** Virus-specific CD8+ T cells play a major role in the control and clearance of HBV infections; however, the mechanisms of CD8+ T-cell failure in chronic hepatitis B (cHBV) infection have only been partially elucidated, especially the role of viral escape. Since viral escape has been demonstrated in HCV and HIV infection in the context of HLA-B\*27, we speculated that HLA-B\*27 may also have a dominant role in driving viral escape in HBV infection.

**Method:** Through HLA footprint analysis of 17 HLA-B\*27 positive and 97 HLA-B\*27 negative patients with cHBV genotype D infection and *in silico* epitope prediction, HLA-B\*27-restricted HBV-specific CD8+ T-cell epitopes were identified. Candidate epitopes were validated by antigen-specific *in vitro* expansion. Sequence variations in epitopes found through footprint analysis were analyzed for viral escape in cHBV infected patients. Phenotypic analysis of CD8+ T cell was performed by *ex vivo* pMHC tetramer enrichment.

**Results:** 12 (5 by *in silico* prediction; 7 by footprint analysis) HLA-B\*27-restricted HBV-specific CD8+ T-cell epitopes were identified. Epitopes identified by footprint analysis were preferentially targeted in cHBV, while epitopes identified by *in silico* prediction were targeted in both, acute-resolving and cHBV infection. Notably, we were able to detect viral escape mutations in 6 cHBV infected

patients. The *ex vivo* frequencies of HLA-B\*27-restricted HBV-specific CD8+ T cells targeting conserved epitopes and epitopes with viral escape mutations were similar. The non-naïve CD8+ T-cell population targeting conserved and variant epitopes showed both a less differentiated memory-like phenotype characterized by co-expression of PD1 and CD127. The expression level of transcription factors TOX, TCF1 and Tbet were similar in HBV-specific CD8+ T cells targeting conserved epitopes and epitope with viral escape. Interestingly, Eomes and KLRG1 were expressed significantly higher in CD8+ T cells targeting conserved epitopes compared to CD8+ T cells targeting epitopes with escape mutations, indicating a more exhausted phenotype of CD8+ T cells targeting wildtype epitopes.

**Conclusion:** cHBV and acute-resolving HBV infected patients exhibited a different CD8+ T-cell repertoire, which may have further effects on HBV chronicity. Moreover, viral escape may play an important role in the failure of HBV-specific CD8+ T cell responses and may particularly affect CD8+ T-cell epitopes that are targeted during chronic infection only.

**Introduction and aim:** Several new therapeutic strategies are being developed aiming at functional cure (HBsAg loss) of chronic HBV infection (CHB). Restoration of exhausted HBV-specific T cells is a potential option to modulate immune responses and achieve higher rates of HBsAg loss. Recently, it has been reported that T cells targeting different HBV epitopes (core<sub>18</sub> versus pol<sub>455</sub>) can be phenotypically and functionally different. However, data are lacking on whether core- or pol-specific T cells respond differently to checkpoint inhibition or/and IL-12 and to what extent the HBsAg level influences this response.

**Methods:** Peripheral blood mononuclear cells from 35 HLA-A2+ CHB patients were isolated. Patients were categorized as HBsAg high (>10,000 IU/ml) or low (<100 IU/ml). Core<sub>18</sub>- and pol<sub>455</sub>-specific T cells were phenotypically characterized using pMHC I dextramer based enrichment. The function and the restoration capacity of epitope-specific T cells were measured after *in-vitro* culture of PBMCs with core<sub>18</sub> and pol<sub>455</sub> peptides with or without  $\alpha$ -PDL-1 or/and IL-12. Intracellular cytokine assay was used as functional readout.

**Results:** Core<sub>18</sub>- and pol<sub>455</sub>-specific CD8+ T cells showed different phenotypes, with core<sub>18</sub>-specific CD8+ T cells exhibiting higher functionality and a higher proportion of a memory-like phenotype. *In-vitro* treatment with anti-PDL-1 treatment showed a significant increase in IFN $\gamma$  by pol<sub>455</sub>-specific CD8+ T cells only in patients with HBsAg <100 IU/ml while there was no effect on core<sub>18</sub>-specific CD8+ T cells. The effect of IL-12 alone or in combination with anti-PDL-1 was stronger compared with anti-PDL-1 alone. Importantly, IL-12 with or without anti-PDL-1 significantly increased core<sub>18</sub>-specific IFN $\gamma$  responses only in patients with HBsAg >10,000 IU/ml. The effect of IL-12 with or without anti-PDL-1 in enhancing the IFN $\gamma$  expression of

pol<sub>455</sub>-specific CD8<sup>+</sup> T cells was significant in patients with low and high HBsAg levels but also more pronounced in patients with HBsAg >10, 000 IU/ml.

**Conclusion:** Our data confirmed previous studies that core<sub>18</sub>- and pol<sub>455</sub>-specific CD8<sup>+</sup> T cells are phenotypically and functionally different. Furthermore, we showed that the response of HBV-specific T cells to different immune modulations varies depending on the targeted antigens and the HBsAg levels. These results have potential implications for developing immunotherapeutic approaches to achieve functional cure of CHB.

**Treatment with GSK3228836 leads to HBsAg reduction and induction of interferon gamma related proteins and chemokines in a Phase 2a, randomized, double-blind, placebo-controlled study**

Shihyun You<sup>1</sup>, Jennifer Singh<sup>1</sup>, Susan Smith<sup>1</sup>, William Jordan<sup>1</sup>, Katja Remingler<sup>2</sup>, Shilpy Joshi<sup>1</sup>, Megan Ermler<sup>1</sup>, Jared Delahaye<sup>1</sup>, Adam Taylor<sup>3</sup>, Sutiirtha Chakraborty<sup>4</sup>, Dhyanesh Srivastava<sup>5</sup>, Melanie Paff<sup>1</sup>, Dickens Theodore<sup>2</sup>. <sup>1</sup>GlaxoSmithKline, Collegeville, PA, United States; <sup>2</sup>GlaxoSmithKline, Research Triangle Park, NC, United States; <sup>3</sup>GlaxoSmithKline, Stevenage, United Kingdom; <sup>4</sup>GlaxoSmithKline, Bangalore, India; <sup>5</sup>GlaxoSmithKline, Noida, India  
Email: shihyun.k.you@gsk.com

**Background and aims:** GSK3228836 (GSK836) is a modified antisense oligonucleotide (ASO) targeting all HBV RNAs that has demonstrated rapid reductions in HBsAg and HBV DNA with four weeks of therapy in chronic hepatitis B (CHB) patients (Study: NCT02981602). The aim of this post-hoc analysis was to investigate the correlation of systemic biomarkers with antiviral responses of GSK836.

**Method:** The analysis is focused on treatment-naïve and nucleos (t) ide treated patients with CHB randomized (3:1) to receive GSK836 (150 mg or 300 mg) or placebo subcutaneously on Days 1, 4, 8, 11, 15, and 22. Treatment responses were monitored until Day 211. Longitudinal plasma samples collected at Days 0, 1, 2, 8, 15, 22, 23, 36, 57, 85, 113, and 211 were used to evaluate 251 soluble proteins in a multiplexed immunoassay (Myriad Discovery Map v3.3). For each protein, a generalized linear mixed effects model was fit to compare the changes from baseline between groups at each timepoint. Mean fold changes and p values generated from these analyses were used for pathway analyses and visualizations. We analyzed associations between GSK836 treatment, HBsAg decline, ALT elevation, and soluble proteins and then delineated potential cellular pathways associated with the responses.

**Results:** Within a day of GSK836 treatment, we observed a trending dose dependent change of plasma proteins related to tissue remodeling and immune responses such as collagen IV and IFNgamma. Of the 17 patients receiving 300 mg GSK836, 7 patients showed >2 log decline in HBsAg at day 29 and also demonstrated ALT elevation peaking around week 5. During the timecourse of HBsAg decline or elevation of ALT, inductions of various soluble immune mediators such as MCSF, MIP1b, IgM, IP10, and MIG were observed, suggestive of the activation of innate and adaptive T and B cell responses. Three patients showed <0.2 log decline in HBsAg and no ALT elevation. In these non-responders, the markers of tissue remodeling were changed within a day, but the markers associated with HBsAg

decline or ALT elevation were less in these patients compared to the responders.

**Conclusion:** Multiple immunological responses were triggered by GSK836 treatment and potential biomarkers associated with HBsAg response and ALT elevation were identified in responders. The IFNgamma pathway appears to be central to mediating immunological responses during HBsAg decline leading to ALT elevation in responders. **Funding:** GSK (Study 205695).

**PO-2307**

**Ex vivo immune checkpoint blockade differentially regulates IFN-gamma and IL-2 responses in HBV-specific T cells across clinical HBV phases**

Conan Chua<sup>1</sup>, Aman Mehrotra<sup>1</sup>, Anjali Patel<sup>1</sup>, Shirin Nkongolo<sup>1</sup>, Danie La<sup>1</sup>, David Wong<sup>1</sup>, Jordan Feld<sup>1</sup>, Harry Janssen<sup>1</sup>, Adam Gehring<sup>1</sup>. <sup>1</sup>Toronto Centre for Liver Disease, Canada  
Email: adam.gehring@uhnresearch.ca

**Background and aims:** HBV-specific T cells are the main mediators of viral clearance. However, in chronic infection, HBV-specific T cells exist at extremely low frequencies and exhibit varying degrees of functional exhaustion. Checkpoint blockade targeting the PD-1/PD-L1 axis can restore HBV-specific T cell functionality. The effects of PD-1 blocking have not been comprehensively tested across the different phases of chronic hepatitis B (CHB) and have only been demonstrated using in vitro expansion of HBV-specific T cells. The functional impact of ex vivo checkpoint blockade on HBV-specific T cells across the clinical phases of CHB remains to be investigated.

**Method:** We enrolled CHB patients with HBeAg+ immunotolerant, HBeAg+ active disease, HBeAg- active disease and HBeAg- inactive disease as well as patients virally suppressed on nucleoside analogue treatment and patients after functional cure (HBsAg loss; n = 10 each) to test the effects of ex vivo PD-1 blockade on HBV-specific T cell functionality. Patient PBMCs were pulsed with a panel of 313 overlapping peptides spanning the entire HBV genome ± PD-1 blockade. Ex vivo multifunctional T cell responses were measured using a 3-color FluoroSpot kit (C.T.L.) for IFN-gamma, IL-2 and Granzyme B secretion. Paired non-parametric t-tests were conducted for statistical analysis of checkpoint blockade.

**Results:** Preferential restoration of ex vivo IFN-gamma and IL-2 responses is observed among inactive disease patients, with average IFN-gamma spots increasing from 57 to 103 SFUs upon PD-1 blockade (n = 10; p = 0.0020); average IL-2 spots increased from 77 to 128 SFUs (n = 10; p = 0.0020). Immunotolerant patients also had significant increases in average IFN-gamma spots from 72 to 90 spots (n = 10, p = 0.0469). Calculation of signal:noise (S:N) ratios reveal significant restoration of IFN-gamma responses among immunotolerant (n = 10, p = 0.0137) and inactive disease patients (n = 10, p = 0.0059). IL-2 S:N ratios for inactive disease patients were not significant upon blockade (n = 10, p = 0.0527). Granzyme B responses remained unaffected across all clinical phases (n = 41).

**Conclusion:** Our data show that ex vivo PD-1 blockade significantly increases the functionality of HBV-specific T cells and that this can be measured using multi-analyte FluoroSpot assays. Functional restoration differed by clinical phase and increased T cell functionality was greater for IFN-gamma while changes in IL-2 production were minimal. These data suggest that ex vivo functional assays may identify patients with the greatest potential of responding to immune checkpoint blockade therapy.

#### Impact of hepatitis B core-related antigen (HBcrAg) level on HBV specific CD4+ and CD8+ T cell responses in HBeAg negative patients with chronic hepatitis B virus infection

Elmira Aliabadi<sup>1,2,3</sup>, Benjamin Maasoumy<sup>1,2</sup>, Birgit Bremer<sup>1,2,3</sup>, Carola Mix<sup>1,2</sup>, Helena Lickel<sup>1,2,3</sup>, Heiner Wedemeyer<sup>1,2</sup>, Anke Kraft<sup>1,2,3</sup>, Markus Cornberg<sup>1,2,3,4</sup>. <sup>1</sup>Hannover Medical School, Gastroenterology, Hepatology and Endocrinology, Hannover, Germany; <sup>2</sup>German Centre for Infection Research (Deutsches Zentrum für Infektionsforschung DZIF), Partner Site Hannover-Braunschweig, Hannover, Germany; <sup>3</sup>TWINCORE, Centre for Experimental and Clinical Infection Research, a Joint Venture between the Hannover Medical School (MHH) and the Helmholtz Centre for Infection Research (HZI), Hannover, Germany; <sup>4</sup>Centre for Individualized Infection Medicine (CiiM), c/o CRC, Hannover, Germany  
Email: aliabadi.elmira@mh-hannover.de

**Background and aims:** Loss of hepatitis B surface antigen (HBsAg) is considered as functional cure and new strategies are being developed for achieving this end point. For stratification in clinical trials, HBsAg level may be an important marker and could indicate the degree of immune dysfunction. However, the group of Bertolotti (Gastroenterology 2020) and we (ILC 2019) showed that age or duration of HBsAg exposure, rather than the amount of HBsAg, was associated with the level of anti-HBV T-cell responses in vitro. More recently, other HBV markers have become established and are used in clinical trials, such as HBcrAg. However, the correlation between HBcrAg levels and HBV-specific T-cell immune responses has not been investigated to date.

**Method:** 55 HBeAg negative patients were categorized into 3 groups based on their HBcrAg level (HBcrAg <3 logU/ml, HBcrAg 3–3.9 logU/ml, HBcrAg ≥4 logU/ml). Cytokine+ HBV-specific T cell responses were measured after in vitro culture with overlapping peptides covering polymerase (pol), surface and core of HBV genotype D in the presence or absence of anti-PD-L1 antibody. In 24 HLA-A2 positive patients we also analyzed HBV specific core<sub>18</sub>- and pol<sub>455</sub>-specific CD8+ T cells and the effect of anti-PD-L1 blockade.

**Results:** Stimulation of PBMCs with HBV-overlapping peptides induced core- and pol-specific T-cell responses. However, surface-specific T-cell responses were barely detectable. We found that HBV-specific CD4+ T-cell responses (core and pol) were significantly lower in patients with high HBcrAg (≥4 logU/ml). Blocking the PD-1/PD-L1 pathway during in vitro culture significantly increased both CD4+ and CD8+ T-cell responses (pol >core) in patients with low HBcrAg (<3 logU/ml) and CD8+ T-cell responses in the intermediate group (3–3.9 logU/ml). There was no effect of anti-PD-L1 blockade in patients with high HBcrAg. For single epitope-specific CD8+ T-cell responses, we observed only an effect of anti-PD-L1 blockade for pol<sub>455</sub> in the low HBcrAg group.

**Conclusion:** Our data suggest that HBcrAg level is associated with HBV-specific T-cell responses, particularly CD4+ T-cell responses. Moreover, patients with HBcrAg <4 logU/ml showed significantly stronger T-cell responses to in vitro HBV peptide stimulation after use of checkpoint inhibitors. Therefore, HBcrAg level may be more suitable than HBsAg level to stratify for patients to be treated with immunomodulatory therapies.

#### Transient Kupffer cell response to microbial components is critically regulated through expression of A20

Christian Zwicker<sup>1</sup>, Anneleen Remmerie<sup>1</sup>, Mathias Vanhockerhout<sup>1,2</sup>, Tineke Vanhalewyn<sup>1,2</sup>, Bavo Vanneste<sup>1,2</sup>, Charlotte L. Scott<sup>1</sup>.

<sup>1</sup>Laboratory of Myeloid Cell Biology in Tissue Damage and Inflammation, VIB-UGent Center for Inflammation Research, Department of Biomedical Molecular Biology, Faculty of Science, Ghent University, Ghent, Belgium, Gent, Belgium; <sup>2</sup>Laboratory of Myeloid Cell Biology in Tissue Homeostasis and Regeneration, VIB-UGent Center for Inflammation Research, Department of Biomedical Molecular Biology, Faculty of Science, Ghent University, Ghent, Belgium

Email:

**Background and aims:** Residing in the sinusoids, Kupffer cells (KCs), the tissue-resident macs of the liver are ideally positioned to recognize and clear microbes/their components and thus critically contribute to systemic immune surveillance. Upon inflammation/infection, monocytes are often recruited to the liver where they can differentiate into recruited macs (rMacs), which alongside KCs, participate in immune defense and tissue repair. Due to similar expression profiles and functions it has not been possible to unambiguously discriminate between resident KCs and rMacs in the past hampering our understanding of mac activation by microbes and microbial components. However, the identification of Clec4F as a KC-specific marker and the development of KC-specific mouse models now allows to unambiguously distinguish between resident and rMacs in the liver and to assess KC responses specifically.

**Method:** To mimic systemic infection, we treated mice with the microbial component lipopolysaccharide (LPS) and determined hepatic mac fate and activation profiles in response to microbial insult. To manipulate KC responses to LPS *in vivo* we used the Clec4f-CRE mice allowing us to remove genes in KCs selectively.

**Results:** We found that following LPS treatment resident KCs were reduced after challenge while rMac emerged in the liver. Transcriptionally, resident KCs strongly upregulated their expression of typical immune activation genes including *Tnf*, *Il6* or *Tnfaip3* (encoding A20) as early as 2 hours after LPS administration but expression of these genes rapidly returned to baseline (6 hours). As A20 functions as a negative regulator of NFκB, we sought to investigate the importance of this rapid shut down of the KC response. To this end, we manipulated KC activation by deleting A20 expression specifically from KCs. This dramatically altered the systemic immune response to LPS in Clec4f-CRE × A20<sup>fl/fl</sup> mice evidenced by increased hypothermia and mortality of these animals. This phenotype was associated with increased systemic TNFα levels and global inhibition of TNFα signaling rescued Clec4f-CRE × A20<sup>fl/fl</sup> mice after LPS challenge.

**Conclusion:** Our data demonstrate a critical function of A20 in KCs and suggest a role for KCs in limiting overt immune response to microbial components. Gaining a better understanding of these processes may allow to manipulate these responses and ultimately improve patient outcomes in systemic inflammatory conditions such as sepsis.

Email: s.w.c.vanmil@umcutrecht.nl

**Background and aims:** The inter-organ cross-talk between the liver and intestine has been focus of intense research. Key in this cross-talk are bile acids, which are secreted from the liver into the intestine, interact with the microbiome, and upon absorption reach back to the liver. The bile acid-activated Farnesoid X receptor (*Fxr*) mediates in the gut-to-liver axis. However, liver-to-gut communication and the roles of bile acids and *Fxr* herein remain elusive. Here, we aim to get a better understanding of *Fxr*-mediated liver-to-gut communication, particularly in colon functioning.

**Method:** *Fxr* floxed/floxed mice were crossed with cre-expressing mice to yield *Fxr* ablation in intestine (*Fxr-intKO*), liver (*Fxr-livKO*), or total body (*Fxr-totKO*). The effects on colonic gene expression (RNA sequencing), the microbiome (16S Sequencing) and mucus barrier function by *ex vivo* imaging, were analyzed.

**Results:** Despite relatively small changes in biliary bile acid concentration and composition, more genes were differentially expressed in colons of *Fxr-livKO* mice compared to *Fxr-intKO* and *Fxr-totKO* mice (3272, 731 and 1824, respectively). Colons of *Fxr-livKO* showed increased expression of anti-microbial genes, Toll-like receptors, inflammasome related genes and genes belonging to the ‘Mucin-type O-glycan biosynthesis’ pathway. *Fxr-livKO* mice have a microbiome profile favorable for the protective capacity of the mucus

barrier. The thickness of the inner sterile mucus layer was increased in *Fxr-livKO* compared to controls.

**Conclusion:** Targeting of *FXR* is at the forefront in the battle against metabolic diseases. We show that ablation of *Fxr* in the liver greatly impacts colonic gene expression and increased the colonic mucus barrier. Increasing the mucus barrier is of utmost importance to battle intestinal diseases like IBD and we show that this might be done by antagonizing *FXR* in the liver.

**PO-1154**

**Influence of human fecal bacteria’s secretome in the maturation and function of the liver**

Joana Inês Almeida<sup>1,2,3</sup>, Pedro Vicente<sup>2,3</sup>, Paula M. Alves<sup>2,3</sup>, Margarida Serra<sup>2,3</sup>, Pedro Baptista<sup>1,4,5,6</sup>. <sup>1</sup>IIS Aragón | Instituto de Investigación Sanitaria de Aragón, Zaragoza, Spain; <sup>2</sup>iBET | Instituto de Biología Experimental e Tecnológica, Oeiras, Portugal; <sup>3</sup>ITQB NOVA- Instituto de Tecnologia Química e Biológica António Xavier, Universidade Nova de Lisboa, Oeiras, Portugal; <sup>4</sup>CIBERehd | Centro de Investigación Biomédica en Red en el Área Temática de Enfermedades Hepáticas, Madrid, Spain; <sup>5</sup>ARAID | Fundación Agencia Aragonesa para la Investigación y el Desarrollo, Zaragoza, Spain; <sup>6</sup>Universidad Carlos III de Madrid, Department of Biomedical and Aerospace Engineering, Getafe, Spain  
Email: joana.almeida@ibet.pt

**Background and aims:** Liver maturation and functionality, that naturally occur during the early postnatal period, could be strongly associated with human intestinal microbiome. Lithocholic acid and vitamin K2, two common postbiotics, were shown to induce the expression of CYP450 enzymes in fetal hepatocytes and in hepatocytes derived from human pluripotent stem cells (hPSC-HLC). In line with these findings, studies on germ-free animals reported dissimilar xenobiotic enzyme profiles, impaired liver regeneration after partial hepatectomy and a higher predisposition to metabolic syndrome when compared to conventional counterparts. Surprisingly, these processes were reverted when germ-free mice were colonized with conventional mouse microbiota. Considering these evidences, we developed a nature-inspired protocol to investigate the role of gut microbiome in human primary hepatocytes (HPH) and in the generation of mature hiPSC-HLC.

**Method:** Herein, hiPSC were differentiated into HLC and matured with fecal bacteria’s secretome in stirred tank bioreactors. Likewise, HPH were cultured in sandwich to assess its effect. Three different formulations of conditioned media (CM) based on microbial

Figure: (abstract: PO-279)

## POSTER PRESENTATIONS

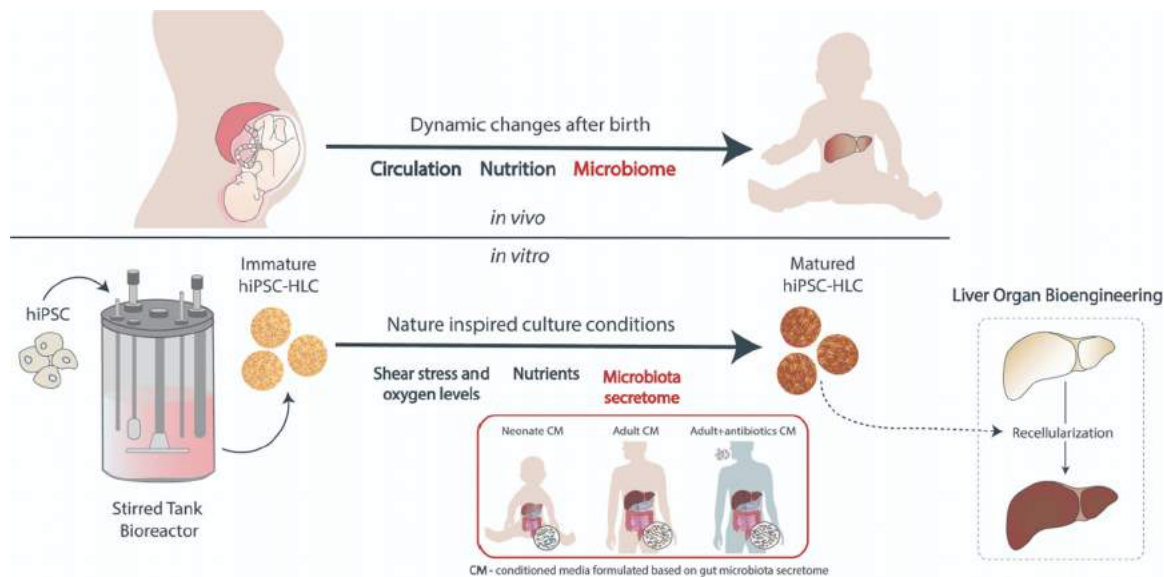

Figure: (abstract: PO-1154)

secretome (neonatal, adult and adult under antibiotics) were prepared and characterized. Lastly, the role of some bioactive peptides secreted by the intestinal bacteria, in hepatic cell maturation was also assessed.

**Results:** Quantitative gene-expression analysis throughout the differentiation process confirmed hiPSC commitment towards a HLC phenotype. HLC treated with neonatal and healthy adult CM showed up-regulation of the *CYP3A4*, *CYP2C9*, *HNF4a*, *FXR* and *PPARA* genes which was not verified in HLC supplemented with the CM obtained from an adult under antibiotic treatment. Characterization of all CMs revealed the presence of distinct bile acids, short-chain fatty acids and vitamins. Interestingly, HLC treated with 4 bacterial derived peptides expressed TLRs (-4, -2, -6) and some of their intracellular targets and mediators (TIRAP, Myd88, NF- $\kappa$ B, TNF $\alpha$ ), fact that has never been documented before and is absent in the early stages of hPSC differentiation into hepatic lineage. Finally, HPH exposed to CM or to bacterial peptides showed significant increased survival versus control at 3 weeks with upregulation of several hepatic genes (*CYP2B6*, *CYP3A4*, *ALB*, *TLR1-2*).

**Conclusion:** Our work provides, for the first time, novel insights into the interaction of fecal bacteria's secretome in the maturation of HLC and in the function/survival of HPH. Hence, the mechanisms revealed herein will not only bring stem cell technology closer to clinical practice but also open new paradigm shifts into hepatic function, an important unmet clinical need in many liver diseases.

### PO-1356

#### Hypoxia-induced liver angiogenesis rescues survival upon small for size hepatectomy in mice

Maxime De Rudder<sup>1</sup>, Alexandra Dili<sup>1,2</sup>, Boris Pirlot<sup>1</sup>, Caroline Bouzin<sup>1</sup>, Isabelle Leclercq<sup>1</sup>. <sup>1</sup>Institut of experimental and clinical research, Laboratory of Hepato-gastro-enterology, Woluwé-saint-Lambert, Belgium; <sup>2</sup>CHU UCLouvain-Namur, Department of Surgery, Yvoir, Belgium

Email: isabelle.leclercq@uclouvain.be

**Background and aims:** After hepatectomy, hepatocytes (Hp) proliferate first, followed by sinusoidal endothelial cell (SEC) 2–3 days later. The larger the liver resection, the higher the portal hyperperfusion and the Hp proliferation rate. Hence at the onset of regeneration, proliferating Hp form transiently avascular clusters. After extended hepatectomy (eHx), large avascular, and thus non-functional, Hp islands are thought to cause liver failure (the “small-

for-size syndrome”-SFSS). Several groups proposed that the induction of hypoxia or the activation of hypoxia-driven pathways protects the liver during regeneration. In rats, we showed that induction of hypoxia in the liver after eHx rescues survival and prevents SFSS. Survival was associated with activation of hypoxia sensing pathways and increased expression of pro-angiogenic factors. To test whether hypoxia hasten angiogenesis in the regenerating liver, we analysed the remodelling of the liver sinusoidal network after SFSS-hepatectomy (eHx) with or without exposure to hypoxia.

**Method:** Mice underwent an 80% eHx (caudate and posterior right lobe left) and immediately after were housed in a hypoxic environment (11% FiO<sub>2</sub>) (eHx-H) or kept in normoxia (ambient air; eHx-N). We detected proliferative SEC and Hp by double immunofluorescence (Ki67/CD31 or HNF4; pHH3/HNF4a) and counted mitosis on HandE staining. On CD31 immunostained liver sections, we measured the diameter of the liver sinusoids (Feret's diameter-24 h post eHx) and the sinusoidal area (semi-automatic morphometry-48 h post eHx).

**Results:** 7 days after surgery, mortality was 60% after eHx-N and exposure to hypoxia drastically reduced mortality to 20%. Expectedly, hepatocyte proliferation (Ki67/HNF4a, pHH3/HNF4a and mitosis) was observed 48 h post eHx with no difference between normoxia and hypoxia groups. By contrast, 72 h post eHx, Hp proliferation was significantly higher in mice exposed to normoxia compared to hypoxia and confirmed by higher liver mass in the former group. Conversely, SEC proliferation was already seen at 24 and 48 h post eHx-H but only at 72 h in eHx-N. Also, the mean diameter of sinusoids ( $6.19 \pm 0.4 \mu\text{m}$  vs  $4.94 \pm 0.2 \mu\text{m}$ ,  $p = 0.001$ ) and the sinusoidal area ( $54055 \pm 10850 \mu\text{m}^2$  vs  $19864 \pm 9201 \mu\text{m}^2$ ,  $p = 0.0007$ ) were significantly larger in eHx-H than in normoxic controls.

Figure: Top) Representative image of double immunofluorescence CD31/Ki67 in eHx-N (left) and eHx-H (right) 48 hours after eHx. Dotted arrows indicate proliferating Hp. Full arrows indicate proliferative SEC. Bottom) Quantification of the percentage of CD31+ Ki67+ (proliferative SEC) at different time points during liver regeneration in eHx-N and eHx-H.

Figure: (abstract: PO-1356)

**Conclusion:** Our results support that hypoxia triggers an angiogenic response after extended hepatectomy. We propose that this enable adequate blood supply to the regenerating hepatocytes, hence supporting hepatocellular function.

**PO-2234**  
**In vitro Transplantation of Biliary Organoids Support Hepatic Differentiation and proliferation in Chronic Liver Injury**

 Email: savykaur@gmail.com

**Background and aims:** The limited replicative potential of primary hepatocytes (PHep) is a major limitation of cell therapy in patients

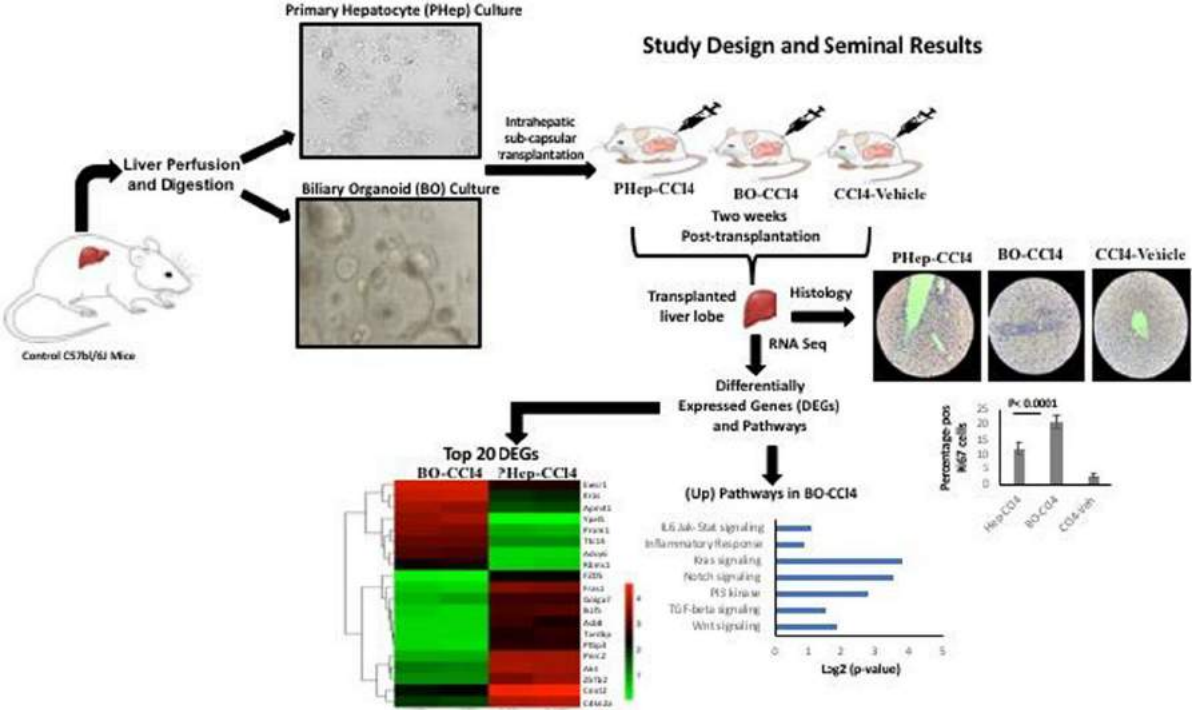

Figure: (abstract: PO-2234)

## POSTER PRESENTATIONS

with liver failure. Biliary organoids (BO) derived from intrahepatic bile ducts have been reported to differentiate into both hepatocyte and cholangiocytes in vitro. Here, we studied the effects of intrahepatic transplantation of BO and PHep in chronic liver injury mice models and characterized the transcriptomes of the transplanted liver lobes by RNA sequencing.

**Method:** Cells isolated from intrahepatic mice bile ducts were cultured on matrigel to develop BO. Hep were isolated from mice livers by collagenase perfusion. Animal models of 3-week liver injury were prepared by CCl<sub>4</sub> injections. Well-characterized BO and PHep were injected into the subcapsular left lateral liver lobe of two groups of CCl<sub>4</sub> mice. CCl<sub>4</sub> mice transplanted with saline were the vehicle group. Two weeks post-transplantation, the transplanted liver lobes were collected from all the study groups and studied by histology and RNA-sequencing analysis on Illumina HiSeq 2500 with 2 × 150 paired-end chemistry.

**Results:** The cultured BO showed positivity for stem cell markers such as Lgr5 and ductal markers, Krt19. PHep were positive for Albumin (Alb) and Asgr1 in vitro. In vivo, post two weeks of transplantation, mice did not exhibit any tumors, mortality and morbidity in either vehicle, PHep- or BO-CCl<sub>4</sub> groups. Mice livers transplanted with BO had an increased Ki67-positive proliferative cells as compared to the PHep mice ( $p < 0.0001$ ). Among the top 20 differentially expressed genes (DEGs) in the RNA seq data, an upregulation of genes including Ewsr1, Kras, Ypel5, Apm41 involved in cell cycle progression and hepatocyte differentiation was observed in transplanted liver lobes of BO-CCl<sub>4</sub> mice as compared to PHep-CCl<sub>4</sub> mice. BO mice had a significant upregulation of biliary marker genes, Prom1 (2-fold), Trop2 (2-fold), Krt7 (1.5 fold) and also some of the Hep-specific genes including HNF-4a (1.5-fold), ApoB (1.5-fold) and Krt18 (1.6-fold) as compared to the PHep mice. Among the signaling pathways, there was an upregulation of the KRAS and Notch signaling pathways in the BO as compared to the PHep mice.

**Conclusion:** The study demonstrates that transplantation of BO induces hepatic proliferation and differentiation in chronically-injured liver, indicating that they may serve as an efficient cell source and therapy for restoring hepatic insufficiency.

##### Real-world experience of mTOR inhibitors in liver transplant recipients in a region where living donation is predominant

Pil Soo Sung<sup>1</sup>, Ji Won Han<sup>1</sup>, Jeong Won Jang<sup>1</sup>, Jong Young Choi<sup>1</sup>, Seung Kew Yoon<sup>1</sup>. <sup>1</sup>The Catholic University of Korea, Department of Internal Medicine, Seoul, Rep. of South Korea  
Email: yoonsk@catholic.ac.kr

**Background and aims:** Mammalian target of rapamycin (mTOR) inhibitors, such as everolimus and sirolimus, may be efficacious in preserving renal function in liver transplantation (LT) recipients while preventing hepatocellular carcinoma (HCC) recurrence. In this study, we retrospectively evaluated the safety, efficacy, and renoprotective effects of mTOR inhibitors in LT recipients.

**Method:** This retrospective observational study initially screened 500 patients who underwent LT at Seoul St. Mary's Hospital between November 2012 and October 2020. And 84 patients received everolimus or sirolimus as immunosuppressants. Median observational period was 1,016 days. Among these, 62 LT recipients had HCC before LT.

**Results** Among the 84 patients enrolled, mTOR inhibitor was commenced a mean of 269 days after LT. Regarding the type of mTOR inhibitor, everolimus was used in 71 patients and sirolimus in

13 patients. Concomitant tacrolimus was used in 63 patients (75.0%). A significant improvement in kidney function was observed in the eGFR <60 ml/min/1.73 m<sup>2</sup> group (n = 19) 12 months after initiation of mTOR inhibitors, for both patient groups with early + mid starters (n = 7, starting within 1 year after LT) and late starters (n = 12, starting over 1 year after LT). mTOR inhibitors were safely administered without serious adverse events that led to drug discontinuation. HCC recurred in only 4 patients (4/39, 10.3%) in patients with prophylactic mTOR inhibitor use, which was far less than in our previous report (19%).

**Conclusion:** Overall, this is the first real-world report of mTOR inhibitor application in Korea, where hepatitis B virus (HBV) infection is the principal cause of HCC and living donor LT is predominant. We demonstrated that patients with renal impairment showed significant improvement in renal function regardless of the timing of mTOR inhibitor start, suggesting that switch to mTOR inhibitors are required when renal function declines.

##### Early Renal Dysfunction Post Liver Transplant Predicts Long-term Adjudicated Cardiovascular Events

Ramzi Hassoun<sup>1</sup>, Steve Shen<sup>1</sup>, Taseen Syed<sup>1</sup>, Sean Flynn<sup>1</sup>, Matthew Fasullo<sup>1</sup>, Vaishali Patel<sup>1</sup>, Chandra Bhati<sup>1</sup>, Mohammad Shadab Siddiqui<sup>1</sup>, Samarth Patel<sup>1</sup>. <sup>1</sup>Virginia Commonwealth University Health, Richmond, United States  
Email: ramzi.hassoun@vcuhealth.org

**Background and aims:** Cardiovascular disease (CVD) is responsible for substantial long-term morbidity and mortality among liver transplant (LT) recipients, despite exclusion of patients with high-risk CVD prior to LT evaluation. The association between development of metabolic co-morbid conditions, such as diabetes or weight gain post-LT, is modest, thus, underscoring other potential pathways linking LT to CVD. We hypothesize that patients who develop CVD following LT are at higher risk at the time of LT, not captured via traditional CVD assessment at the time of LT. Renal impairment has been linked to CVD through multiple mechanistic pathways. Therefore, we evaluated the relationship between future risk of CVD and early renal function in LT recipients.

**Method:** We retrospectively analysed patients who had detailed pre-LT CVD assessment including coronary angiography, echocardiogram, electrocardiogram, and serum lipid profile between 2007 and 2019 (N = 651). Since glomerular filtration rate (GFR) can vary widely after LT, we used the highest GFR within 4 weeks after LT as the baseline surrogate of renal function. Patients were followed every 6 months post-LT. Major adverse cardiovascular events (MACE) included myocardial infarction, stroke, heart failure, and sudden cardiac death. MACE were adjudicated by study investigators according to the American Heart Association (AHA) definitions. Multivariate Cox regression models were used to evaluate the relationship between GFR and MACE.

**Results:** The mean age was 56 ± 10 years, 73% were male, and 72% were Caucasians. Coronary artery disease (CAD) was present in 178 (27%) of patients at the time of LT; however, this was mild in the majority of these patients (72%) and all patients with obstructive CAD had revascularization prior to LT. The mean GFR was 88 ± 28 ml/min/1.73m<sup>2</sup> at baseline and 58 ± 28 ml/min/1.73m<sup>2</sup> at 1-year post-LT. No association between GFR and baseline CAD or cardiac volumetric assessment on echocardiography was noted. The median follow-up in the study was 69 months (IQR 34 months, 101 months) and 116 (18%) patients had a MACE, with the most common event being myocardial infarction. In time to event analysis, GFR at 12 months was independently associated with future risk of MACE in unadjusted analysis. The relationship between MACE and GFR at 12 months persisted (HR 0.99, 95% CI 0.98, 0.99,  $p = 0.02$  per unit increase in GFR)

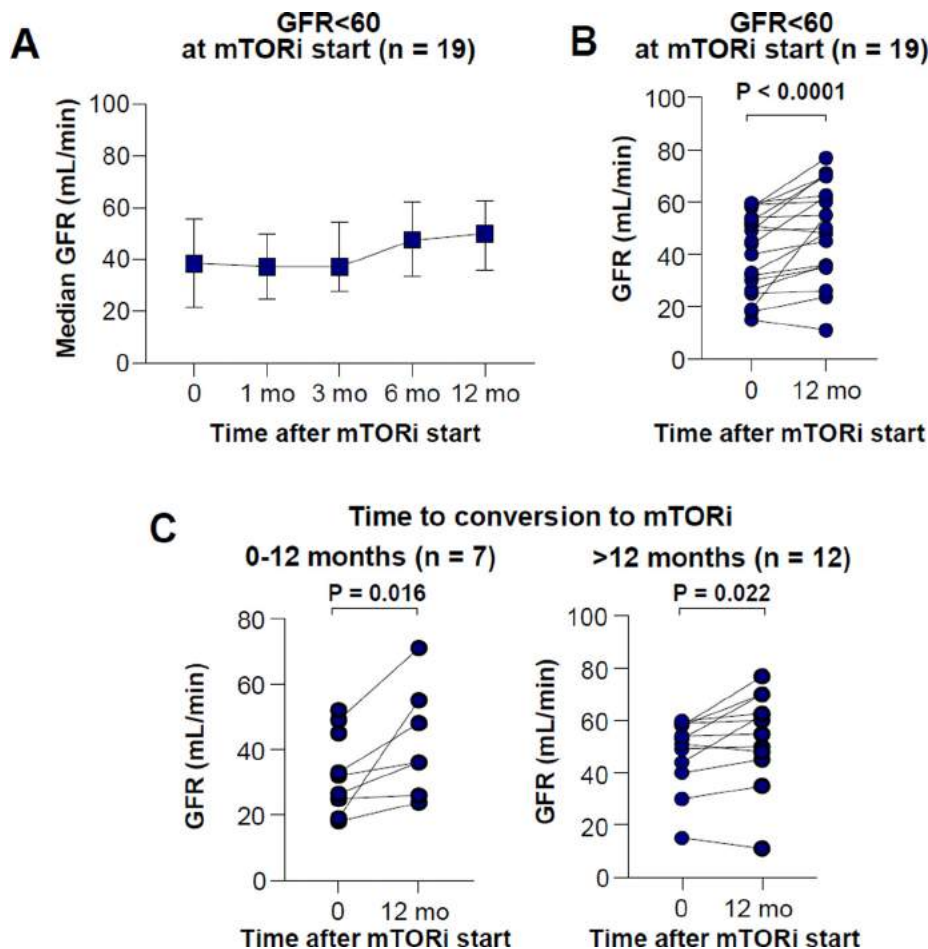

Figure: (abstract: PO-186)

after adjusting for gender, diabetes, CAD, dyslipidemia, hypertension, non-alcoholic steatohepatitis, and choice of immunosuppression.

**Conclusion:** Early changes in renal function are strongly associated with increased risk of MACE post-LT, which is independent of traditional cardio-metabolic risk factors. These findings suggest that GFR may potentially be used as a prognostic biomarker for more robust CVD risk assessment post-LT; however, this requires prospective validation.

**Background and aims:** NALFD is the most common liver disease worldwide. Liver transplantation (LT) is the only treatment for NAFLD

## POSTER PRESENTATIONS

decompensated cirrhosis and/or hepatocellular carcinoma (HCC). Few data on long-term results are available, particularly in Europe where this indication represents a rapidly increasing number of patients. The aim of this study was to evaluate overall patient and graft survival and their predictive factors.

**Method:** This retrospective multicenter study included adult transplanted for 'pure' NAFLD cirrhosis between 2000 and 2019 in participating French-speaking centers. Cirrhosis of unknown or mixed origin were not included.

**Results:** A total of 361 patients (69.8% of male) were included in 19 centers. The median age at LT was 62.3 years (57.4–65.9) and the median MELD score was 13.9 (9.1–21.3). 51.8% of patients had HCC on liver explant but 149 patients were transplanted for HCC in 1st indication. Between 2004 and 2018, number of LT for NAFLD cirrhosis increased by 720%. A quarter of patients had a cardiovascular (CV) history before LT. Median follow-up after LT was 39.1 months (15.8–72.3).

Patient survival at 1, 5 and 10 years after LT was 89.3%, 79.8% and 68.1% respectively. During the 30 days after LT, 9 deaths occurred: 4 of which were of CV origin (44.4%). The mortality rate at 90 days after LT was 5.8%. Deaths occurring 12 months after LT were of infectious (59.5%) and CV (18.9%) origin. Deaths occurring after 12 months of LT were related to HCC recurrence (34.3%), CV disease (25.7%) or de novo malignancies (20.0%). Significant pejorative prognostic factors from multivariate analysis were: age of the recipient at LT time  $\geq 62$  years (OR: 2.3;  $p = 0.012$ ), a history of coronary bypass or angioplasty before LT (OR: 2.7;  $p = 0.043$ ), donor age  $\geq 60$  years (OR: 2.2;  $p = 0.023$ ), occurrence of an early CV event (OR: 2.4;  $p = 0.025$ ), HCC recurrence (OR: 2.4;  $p = 0.026$ ) and dialysis immediately after LT (OR: 4.4;  $p = 0.0001$ ). During the first year after LT, the only significant predictive factor of death was the age of the donor  $\geq 60$  years (OR: 3.0;  $p = 0.035$ ). BMI before LT does not affect survival after LT.

Events	0	44	54	60	64	66	71	71
Number at risk	361	235	155	91	58	36	14	5

Figure:

**Conclusion:** Survival after LT for NAFLD cirrhosis was good at 5 years. Age at LT time, donor age, cardiovascular history and events and the recurrence of HCC are significant prognostic factors.

### PO-353

Email: francois.villeret@gmail.com

**Background and aims:** NAFLD is the most common liver disease worldwide. Liver transplantation (LT) is the only treatment for NAFLD decompensated cirrhosis and/or hepatocellular carcinoma (HCC). Few data on long-term results are available, particularly in Europe where this indication represents a rapidly increasing number of patients. The aim of this study was to evaluate the steatosis, fibrosis and NASH recurrence after LT and their predictive factors.

**Method:** This retrospective multicenter study included adult transplanted for 'pure' NAFLD cirrhosis between 2000 and 2019 in participating French-speaking centers. Cirrhosis of unknown or mixed origin were not included. Steatosis and fibrosis recurrence were determined on liver biopsies. The NASH diagnosis was performed according to the SAF or NAS scores, depending on the LT period.

**Results:** A total of 361 patients (69.8% of male) were included in 19 centers. The median age at LT was 62.3 years (57.4–65.9). 51.8% of patients had HCC on liver explant. At LT time, the median BMI was 30.9 kg/m<sup>2</sup> (26.8–34.1) with 57% obese and the median higher BMI before LT was 35.2 kg/m<sup>2</sup> (31.2–39.1). 77.3% of patients had type 2 diabetes, 83.4% hypertension and 56.8% metabolic syndrome. Ten patients underwent a bariatric surgery (BS) before LT with a median time to LT of 7 years. The median follow-up after LT was 39.1 months (15.8–72.3). The incidence of metabolic syndrome (MS) after LT was 73.5%, 86.2 and 92.5% at 1, 5 and 10 years respectively. After LT, incidence of overweight and obesity was 28% and 60% respectively (all grades).

From 291 patients who survived after 1 year, 150 patients (51.4%) had at least one liver biopsy during follow-up. Rate of steatosis recurrence was 62% and 80% at 1 and 5 years respectively: the only risk factor found was BMI  $\geq 31$  kg/m<sup>2</sup> at time of LT (OR: 2;  $p = 0.035$ ). Rate of NASH recurrence was 8% at 1 year and 59% at 5 years. Risk factors for NASH recurrence were BMI  $\geq 31$  kg/m<sup>2</sup> at LT (OR: 3.6;  $p = 0.039$ ), HDLc rate  $< 0.45$  g/L after LT (OR: 5.5;  $p = 0.001$ ) and the age of recipient at LT  $< 62$  years (OR: 2.9;  $p = 0.050$ ). The incidence of advanced fibrosis (F3-F4) was 44% at 5 years and no significant

predictive factors was found. No re-LT was performed for NAFLD cirrhosis recurrence.

**Conclusion:** Recurrence of steatosis and steatohepatitis on the graft is rapid and very frequent after LT for NAFLD cirrhosis. Treatment of MS is therefore a major goal in these patients.

**PO-364**  
**Waitlist outcomes for alcoholic hepatitis are more favorable than for other candidates with high Model for End-stage Liver Disease score in the current era**

Therese Bittermann<sup>1</sup>, Nadim Mahmud<sup>1</sup>, Ethan Weinberg<sup>1</sup>, Rajender Reddy<sup>1</sup>. <sup>1</sup>University of Pennsylvania, Philadelphia, United States

Email: therese.bittermann@penmedicine.upenn.edu

**Background and aims:** In the appropriate candidate, liver transplantation (LT) is a viable treatment option for alcoholic hepatitis (AH). We compared the waitlisting trends and outcomes of AH patients in the context of others listed with high Model for End-stage Liver Disease (MELD) score in the United States.

**Method:** LT listings for AH between 1/1/2008–6/12/2020 were identified in the United Network for Organ Sharing database. Temporal trends in listings for AH were compared to those with

hepatitis C virus (HCV) and MELD 30+ and those with acute-on-chronic liver failure grade 3 (ACLF-3). Covariate-adjusted competing risks models evaluated waitlist mortality and LT rates among the three groups in the era of direct acting antivirals for HCV, using HCV MELD 30+ as the reference and stratified by listing period (2015–2017 and 2018–2020).

**Results:** Since 2014, listings for AH increased 0.2% per year, while those for HCV MELD 30+ decreased 0.4% per year and those of ACLF-3 increased marginally ( $p < 0.001$  for all analyses). Waiting time between the 3 groups was comparably short: median 10 versus 8 versus 6 days, respectively ( $p < 0.001$ ). Among 99 centers with  $\geq 1$  AH listing between 2018–2020, AH patients accounted for 0.2–18.2% of all alcohol-related listings. Overall listing volume was larger at these 99 centers than the 40 with no AH listings from 2008–2020 ( $p < 0.001$ ). AH candidates in 2018–2020 experienced lower waitlist mortality (adjusted SHR 0.29, 95% CI: 0.18–0.49;  $p < 0.001$ ; Figure Panel A) and higher transplant rates (adjusted SHR 1.23, 95% CI: 1.03–1.47;  $p = 0.02$ ; Figure C) versus HCV MELD 30+, while outcomes in 2015–2017 were not different ( $p = 0.1$  for both; Figure Panel B and D). By comparison, waitlist mortality and LT rates for ACLF-3 were not different from HCV MELD 30+ in 2018–2020: adjusted SHR 0.88 (95% CI: 0.65–1.19) and 0.96 (95% CI: 0.81–1.14), respectively.

**Conclusion:** AH has replaced the void on the waitlist left by decreasing numbers of high-MELD HCV candidates. Among high MELD patients, liver disease etiology increasingly influences waitlist outcomes, and those of AH candidates are most favorable.

**PO-530**  
**Chances of renal recovery in liver only transplant recipients who were eligible for simultaneous liver-kidney transplant**

Jiawei Cui<sup>1</sup>, Ashley Spann<sup>2</sup>, Alexandra Shingina<sup>2</sup>, Heidi Schaefer<sup>3</sup>, James Slaughter<sup>4</sup>, Sophoclis Alexopoulos<sup>5</sup>, Manhal Izzy<sup>2</sup>. <sup>1</sup>Vanderbilt University Medical Center, Department of Medicine, Nashville, United States; <sup>2</sup>Vanderbilt University Medical Center, Division of Gastroenterology, Hepatology, and Nutrition, Nashville, United States; <sup>3</sup>Vanderbilt University Medical Center, Division of Nephrology, Nashville, United States; <sup>4</sup>Vanderbilt University Medical Center, Department of

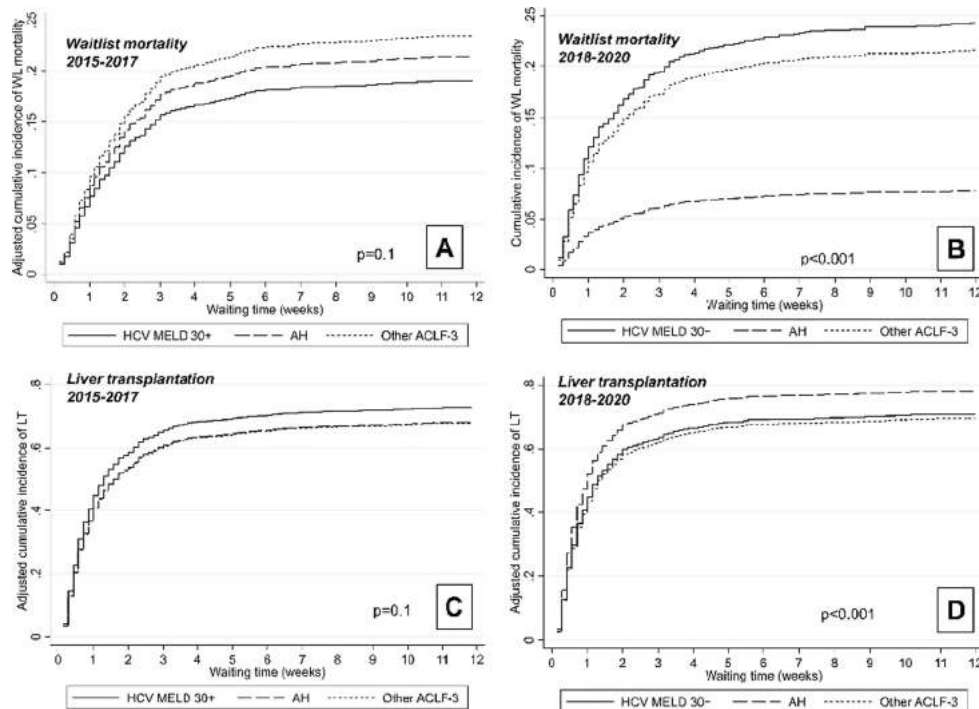

Figure: (abstract: PO-364)

## POSTER PRESENTATIONS

Biostatistics, Nashville, United States; <sup>5</sup>Vanderbilt University Medical Center, Division of Hepatobiliary Surgery and Liver Transplantation, Nashville, United States  
Email: julie.cui@vumc.org

**Background and aims:** Progressive decline in renal function is common among patients with end-stage liver disease. Liver transplant (LT) candidates can often develop severely impaired renal function which prompts the consideration of simultaneous liver kidney transplantation (SLKT). In 2015, EASL guidelines suggested SLKT in patients with glomerular filtration rate (GFR) <30 ml/min and in 2017, the United Network for Organ Sharing (UNOS) recommended SLKT in patients with GFR <30 ml/min after being <60 ml/min for at least 90 days. This study aims to assess the post-LT renal recovery in patients who met EASL and UNOS criteria for SLKT, yet received liver alone.

**Method:** We performed a retrospective records review of adult patients who underwent LT between 1/1/2009 to 12/31/2018 at a North American Center. Liver only recipients whose last GFR before LT was <30 ml/min after being <60 ml/min for more than 90 days were included. Demographic, clinical, and laboratory data were collected. Partial recovery was defined as post-LT GFR increase to 30–60 ml/min and full recovery was defined as increase to >60 ml/min.

**Results:** Of 800 patients who underwent LT during the observation period, 123 patients had GFR <30 ml/min pre-LT and of them only 34 had GFR <60 ml/min preceding LT by 90 days or longer. Median age was 63 years. Females constituted 59% of the cohort. Following liver transplant, 20 patients (59%) had partial recovery and 10 patients (29%) had full recovery within a median of 6 and 61 days, respectively. Among baseline characteristics including comorbidities, abnormal radiologic appearance of the kidneys pre-LT, reflective of chronic disease, was the only predictor of lack of recovery ( $p = 0.03$ ). All initial immunosuppressive regimens were tacrolimus-based. On last follow-up after a median of 4.8 years, 15 patients (44%) still had GFR >30 ml/min while 19 (56%) patients were on dialysis, awaiting kidney transplant, or received kidney transplant. Patients with pre-LT unrecovered AKI or HRS had the highest likelihood of recovery on last follow-up (OR 4.7,  $p = 0.03$ ).

**Conclusion:** LT candidates who meet EASL and UNOS criteria for SLKT yet undergo LT only still have a remarkably high chance for post LT renal recovery, approaching 90% on short-term. Large proportion of patients can sustain recovery on long-term. Performing LT only in these patients and monitoring renal function post-LT to determine the need for kidney transplant may be the appropriate approach.

### PO-594

#### Incidental Cholangiocarcinoma in Liver Transplantation

Nawaz Safdar<sup>1,2</sup>, Rosemary Faulkes<sup>3</sup>, Fiona James<sup>1</sup>, Lisa Mason<sup>4</sup>, Steve Masson<sup>5</sup>, James Powell<sup>4</sup>, Ian Rowe<sup>1</sup>, Shishir Shetty<sup>3</sup>, Rebecca Jones<sup>1</sup>, Richard Parker<sup>1</sup>. <sup>1</sup>St James's University Hospital, Leeds Liver Unit, Leeds, United Kingdom; <sup>2</sup>University of Leeds, School of Medicine, Leeds, United Kingdom; <sup>3</sup>University Hospitals Birmingham, NHS Foundation Trust, Birmingham, United Kingdom; <sup>4</sup>Royal Infirmary of Edinburgh, Liver Transplant Unit, Edinburgh, United Kingdom; <sup>5</sup>Newcastle upon Tyne Hospitals, NHS Foundation Trust, Newcastle, United Kingdom  
Email: n.safdar@nhs.net

**Background and aims:** Cholangiocarcinoma (CCA) is a contraindication to liver transplantation (LT) in the UK because of high recurrence rates and poor survival rates in previous series. However, some patients who undergo LT are found to have CCA that was not identified by pre-transplant investigations. We report on the outcomes of patients with incidental CCA from four UK liver transplant centres.

**Method:** Cases were identified retrospectively from pathology records. Biochemical and radiological data from before transplantation were collected as well as pathological data regarding tumour characteristics, and post-transplant survival. CCA were classified by TNM staging and anatomical location.

**Results:** 67 patients were identified. LT took place between 1988 and 2018. Follow-up after LT was up to 12.2 years with a median follow-up of 1.8 years. Most patients were male (72%) and the majority had PSC (55%). All patients had undergone cross-sectional imaging with at least one modality, usually MRI (97%) and often CT as well (62% MRI and CT). The median delay between last cross-sectional imaging and LT was 58 days. 4 patients were found to have distal CCA (dCCA), 31 patients had intrahepatic CCA (iCCA) and 28 had perihilar CCA (pCCA). Tumour classification by pTNM stage was classified as pT1 in 15 cases (22%), pT2a in 18 cases (27%), pT2b in 14 cases (21%), pT3 in 5 cases (7%) and pT4 in 9 cases (13%). A further 6 cases had no staging data. Overall median survival after LT was 4.95 years. Survival differed by tumour site: 1-year, 3-year and 5-year survival was 80.0%, 66.3% and 66.3%, respectively, in iCCA and 55.6%, 47.6% and 34.3% in pCCA, however this was not statistically significant {log rank (LR)  $p = 0.054$ }. After grouping by stage of disease-'low risk' for pT1 and pT2a (49%), and 'high risk' for pT2b, pT3 and pT4 (42%), 1-year, 3-year and 5-year survival was 81.3%, 81.3% and 76.2%, respectively, in low risk, and 63.0%, 38.2% and 22.3%, respectively, in high risk {LR  $p = 0.0056$ }, showing statistical significance.

Figure:

**Conclusion:** Incidental CCA is uncommon. Overall survival is poor compared to usual outcomes for LT in the UK, however, intra-hepatic disease or disease at an earlier stage appeared to have favourable survival outcomes in this retrospective cohort.

### PO-841

#### Elevated donor-derived cell-free DNA during subclinical T-cell mediated rejection after liver transplantation

Anna Katharina Baumann<sup>1</sup>, Emily Saunders<sup>1</sup>, Bastian Engel<sup>1</sup>, Theresa Kirchner<sup>1</sup>, Julia Beck<sup>2</sup>, Björn Hartleben<sup>1</sup>, Michael Oellerich<sup>3</sup>, Ekkehard Schuetz<sup>2</sup>, Elmar Jaeckel<sup>1</sup>, Richard Taubert<sup>1</sup>. <sup>1</sup>Medizinische Hochschule Hannover, Hannover, Germany; <sup>2</sup>Chronix Biomedical GmbH, Göttingen, Germany; <sup>3</sup>Universitätsmedizin Göttingen, Göttingen, Germany  
Email: baumann.anna@mh-hannover.de

**Background and aims:** Subclinical T-cell mediated rejection (subTCMR) is commonly found even late after liver transplantation (around 25%), associated with upregulation of rejection associated transcripts and can only be diagnosed through liver biopsies. Despite having a good prognosis even if left untreated, subTCMR should be excluded before immunosuppression minimization attempts are undertaken during individualized immunosuppression. Clinical TCMR (clinTCMR) after liver transplantation is associated with donor-derived cell-free DNA (dd-cfDNA) above a threshold of 10% of total cell free DNA. The aim of the current study was to evaluate dd-cfDNA as a non-invasive method to detect subclinical liver graft injury for the individualization of immunosuppression.

Figure:

**Method:** Samples with subclinical graft injury (liver enzymes  $\leq 2$  upper limit of normal) were taken from the prospective protocol biopsy program after liver transplantation at our centre. Liver biopsies were extensively reviewed for histological signs of graft injury including subTCMR (rejection activity index (RAI)  $\geq 1 + 1 + 1$ ) and histological criteria for immunosuppression minimization (HCmini). Clinically relevant TCMR (clinTCMR; liver enzymes  $> 2 \times$  ULN) was used as a comparator group. We used digital droplet PCR to measure dd-cfDNA in recipient plasma samples paired to liver biopsies. The t-test was used for statistical analysis.

**Results:** The mean dd-cfDNA was 3.4% in patients with no histological signs of rejection (NHR group (N = 26)), 6.5% in the subTCMR group (N = 45) and 25% in the clinTCMR group (N = 21). There was a significant difference between the mean dd-cfDNA of each group (NHR vs. subTCMR  $p = 0.036$ , NHR vs. clinTCMR  $p < 0.001$ , subTCMR vs. clinTCMR  $p < 0.001$ ). Considering possible individualization of immunosuppression, we analysed 21 samples where HCmini were satisfied and 69 samples where they were not (subclinical graft injury (subGI)). The mean percentage of dd-cfDNA was 3.2% for the former and 5.2% for the latter ( $p = 0.031$ ).

**Conclusion:** dd-cfDNA seems to be a promising marker for the non-invasive monitoring of subclinical liver graft injury in this study and thereby a potential clinical tool to facilitate individualized immunosuppression after liver transplantation without the need for protocol biopsies.

**PO-922**

**A novel score to risk stratify and optimize use of liver graft among patients with grade 3 acute on chronic liver failure**

Ashwani Singal<sup>1</sup>, Yong-Fang Kuo<sup>2</sup>, Robert Wong<sup>3</sup>, Vinay Sundaram<sup>4</sup>, Rajiv Jalan<sup>5</sup>. <sup>1</sup>University of South Dakota and Avera Transplant Institute, Medicine and Transplant Hepatology, Sioux Falls, United States; <sup>2</sup>University of Texas Medical Branch, United States; <sup>3</sup>Stanford University School of Medicine, United States; <sup>4</sup>University of California Los Angeles, United States; <sup>5</sup>University College London, United Kingdom  
Email: ashwanisingal.com@gmail.com

**Background and aims:** Liver transplantation (LT) in select patients with ACLF provides survival benefit. However, post-transplant outcomes remains suboptimal even among select patients with ACLF-3 at LT. We performed this study to develop a risk score for use in selecting recipient and donor for LT among patients with ACLF-3.

**Method:** UNOS database (01/2002 to 06/2018) was queried on adult LT recipients (without HCC) using deceased donor graft, and stratify to ACLF using EASL-CLIF criteria. Study outcome was patient survival at one year after LT.

**Results:** 23, 947 LT recipients (mean age 54 years, 65% males, 60% Caucasians, median MELD 31) who were in ACLF (7166 ACLF-3) at LT were analysed. One yr. patient survival was 92.3%, 88.2%, 88.3%, and 83% for recipients without ACLF, and ACLF grades 1-3 respectively. Cox regression model performed using stepwise backward elimination process on derivation dataset (N = 3583) with ACLF-3 showed

Figure: (abstract: PO-922): (A) patient survival rates at 1-year after liver transplantation (LT) among recipients with acute on chronic liver failure grade 3 at the time of transplant comparing good vs. poor quality donor graft (cut-off donor risk index or DRI at 1.50), (B) association of wait time in days on the liver transplant list and the quality of liver graft with the patient survival at one year after LT. The analyses are stratified for the three risk categories as stratified using the score equation shown above the figure.

## POSTER PRESENTATIONS

recipient age, non-alcohol etiology, pulmonary failure, brain failure, and cardiovascular failure to be associated with 1-yr. patient survival. Risk score (median 9.7 and range -3.6 to 23.5) developed using significant variables from cox model on derivation dataset stratified 3583 recipients in validation cohort using cut-off score 7.55 and 11.57 to low (N = 1211), medium (N = 1168), and high risk (N = 1199), with 1-yr patient survival of 89%, 82%, and 80% respectively. The observed and expected post-transplant 1-yr. survival showed excellent correlation (R = 0.92). In the whole dataset with information on donor risk index (DRI), based on poor vs. good quality graft (DRI cut-off at 1.50), 1-yr. patient survival for low, medium, and high risk categories were 90 vs. 89%, P = 0.12, 84 vs. 81%, P < 0.07, and 81 vs. 74%, P < 0.001 respectively. Among 887 patients in high risk category and receiving good quality graft, the outcomes were better up to first 2 days from listing (85 vs. 78%, P = 0.02). Waiting beyond this time increased waitlist mortality (25 vs. 18%, P < 0.003) without further benefit on 1-year patient survival.

**Conclusion:** LT provides survival benefit to select patients with ACLF. In a cohort of ACLF-3 patients selected to receive LT, a novel score from recipient variables at transplant can be used to match recipients with donor quality, as basis to improve post-transplant outcomes and optimizing use of donor pool.

### PO-935

#### Liver transplantation for severe alcoholic hepatitis: a multicentre Italian study

Giacomo Germani<sup>1</sup>, Luca Saverio Belli<sup>2</sup>, Giovanni Addolorato<sup>3</sup>, Manuela Merli<sup>4</sup>, Chiara Mazzarelli<sup>2</sup>, Claudia Tarli<sup>3</sup>, Barbara Lattanzi<sup>4</sup>, Debora Angrisani<sup>2</sup>, Adelaide Panariello<sup>5</sup>, Lucia Craxi<sup>6</sup>, Giovanni Forza<sup>7</sup>, Alessandra Feltrin<sup>8</sup>, Andrea Ronzan<sup>9</sup>, Paolo Feltracco<sup>10</sup>, Umberto Cillo<sup>11</sup>, Patrizia Burra<sup>1</sup>. <sup>1</sup>Multivisceral Transplant Unit, Department of Surgery, Oncology and Gastroenterology, Padua University Hospital, Padua, Italy; <sup>2</sup>Hepatology and Gastroenterology, ASST GOM Niguarda, Milano, Italy; <sup>3</sup>Alcohol Use Disorders Unit, Department of Internal Medicine, Institute of Internal Medicine, Gemelli Hospital, Catholic University of Rome, Rome, Italy; <sup>4</sup>Gastroenterology, Department of Translational and Precision Medicine, Sapienza University of Rome, Rome, Italy; <sup>5</sup>Department of Mental Health and Addiction Services, ASST GOM Niguarda, Milan, Italy; <sup>6</sup>Department of Biomedicine, Neuroscience and Advanced Diagnostics (Bi.N.D.), Institute of Pathology, University of Palermo, Palermo, Italy; <sup>7</sup>Department of Legal and Occupational Medicine, Toxicology and Public Health, Padua University Hospital, Padua, Italy; <sup>8</sup>Psychological Unit, Padua University Hospital, Padua, Italy; <sup>9</sup>Psychiatry Unit, Padua University Hospital, Padua, Italy; <sup>10</sup>Anesthesia and Intensive Care, Department of Medicine, Padua University Hospital, Padua, Italy; <sup>11</sup>Hepatobiliary Surgery and Liver Transplantation Unit, Padua University Hospital, Padua, Italy  
Email: germani.giacomo@gmail.com

**Background and aims:** Acute alcoholic hepatitis (AAH) is a clinical syndrome characterized by high mortality rates. There is increasing evidence that early liver transplantation (LT), performed within strict and standardized protocols, can improve survival. The aim of this multicentre study was to assess outcomes after LT for severe AH in four Italian LT centres and to compare them with those of patients with severe AH non responding to medical therapy excluded from LT. **Method:** Patients admitted for severe AAH (2013–2019), according to NIAAA criteria, were included. Demographic, biochemical and clinic characteristics were evaluated. Patients not responding to medical therapy were placed on the waiting list for LT only if they were considered suitable candidates by a strict selection process. Explant histology was assessed in all liver transplanted patients and only patients with histologic features of AH with or without underlying chronic liver disease were considered for the purpose of this study. Post-transplant graft and patient survival as well as post-transplant alcohol relapse were evaluated.

**Results:** 93 patients with severe AAH were evaluated (65.6% male, median [IQR] age: 47 [42–56]). Forty-five/93 (48.4%) patients received corticosteroid therapy. 52/93 (55.9%) were classified as non responders to medical therapy and underwent the LT selection process. Amongst these, 20 (38.5%) patients were placed on the waiting list, whereas 32/52 (61.5%) patients were denied LT for the following reasons: psychosocial/psychiatric (n = 16, 50%), too sick for liver transplantation (n = 4, 12.5%), death (n = 6, 18.7%), clinical improvement during evaluation (n = 2, 6.3%), other reasons (n = 4, 12.5%). Median (IQR) interval time from admission to waiting list (WL) registration was 21 days (8.25–36 days). Sixteen patients underwent LT, median (IQR) MELD score at LT 32 (25–38), and median (IQR) time from WL registration to LT 6.5 days (2.25–20). Overall 6, 12 and 24-month survival rates were 100%, 100% and 100% significantly higher compared with patients with severe AH non responding to medical therapy who were denied LT (45%, 45% and 36% respectively; log-rank p < 0.001). Median (IQR) post-transplant hospital stay was 22.5 days (17–37.5). 2/16 (12.5%) patients resumed alcohol intake, one at 164 days and one at 184 days.

**Conclusion:** Early LT significantly improve survival in severe AAH non responding to medical therapy, when a strict selection process is applied. Further studies are needed to properly assess alcohol relapse rates with longer follow-up.

### PO-1126

#### Patients with MELD exceptions have higher access to liver transplantation and lower waiting list mortality: the Swiss nationwide experience

Melisa Dirchwolf<sup>1,2</sup>, Chiara Becchetti<sup>3,4</sup>, Sarah G. Gschwend<sup>4</sup>, Christian Toso<sup>5</sup>, Philipp Dutkowski<sup>6</sup>, Julius Weiss<sup>7</sup>, Franz Immer<sup>7</sup>, Franziska Beyeler<sup>7</sup>, Simona Rossi<sup>8</sup>, Jonas Schropp<sup>3,9,10</sup>, Zita Bischofberger<sup>4</sup>, Jean-François Dufour<sup>3,4</sup>, Banz Vanessa<sup>4</sup> and The Swiss Transplant Cohort Study (STCS)<sup>11</sup>. <sup>1</sup>University of Bern, Novartis Fellowship in Hepatology, Department of Biomedical Research, Bern, Switzerland; <sup>2</sup>Hospital Privado de Rosario, Liver Unit, Santa Fe, Argentina; <sup>3</sup>University of Bern, Hepatology, Department of Biomedical Research, Bern, Switzerland; <sup>4</sup>Inselhospital, University Hospital Bern, University Clinic for Visceral Surgery and Medicine, Bern, Switzerland; <sup>5</sup>University Hospital of Geneva, Abdominal Surgery, Geneva, Switzerland; <sup>6</sup>University Hospital of Zurich, Abdominal Transplant Surgery, Zurich; <sup>7</sup>Swisstransplant, the Swiss National Foundation for Organ Donation and Transplantation, Bern, Switzerland; <sup>8</sup>Swiss Transplant Cohort Study (STCS), Data Center, Basel, Switzerland; <sup>9</sup>Open University of Cyprus, Department of Computer Science, Cyprus; <sup>10</sup>University of Cyprus, Department of Psychology, Cyprus; <sup>11</sup>Swiss Transplant Cohort Study, Basel, Switzerland  
Email: vanessa.banzwuethrich@insel.ch

**Background and aims:** MELD exceptions are used to balance mortality risk and access to liver transplantation for patients whose severity of the liver disease is not reflected by the calculated MELD score. We aimed to analyse the impact of MELD exception points on the liver transplant waiting list outcome in Switzerland.

**Method:** Nationwide cohort study including all adult patients registered on the Swiss liver transplant waiting list between 2012 and 2017. Outcome on the waiting list was analyzed according to MELD exception categories: patients receiving a standard exception due to HCC (SE-HCC); patients receiving another type of standard or non-standard exception (Other SE or NO-SE); patients receiving a MELD-Upgrade exception (MELDUP); patients did not receive any type of exception point and were allocated with their calculated MELD.

**Results:** Overall, 730 patients fitted the inclusion criteria. The proportion of patients with MELD exceptions increased from 2012 to 2017 (44% vs 88%). Concordantly, allocation MELD at the time of transplantation showed an annual increase (23 ± 8 points vs 32 ± 5 points, p < 0.001). Patients with any type of MELD exception were more likely to be transplanted when compared to patients without

Figure: (abstract: PO-1126): Competing risk survival curves according to MELD exception categories divided by outcome: waiting list mortality and liver transplantation (Abbreviation: WL: waitlist, SE: standard exception)

MELD exceptions. Patients with MELDUP exceptions and those without MELD exceptions had the highest risk of dying while on the waiting list. For patients with HCC, the risk of dying increased over time, surpassing the risk of patients without MELD exceptions after 242 days on the waiting list.

**Conclusion:** A growing proportion of MELD exceptions were documented over time, resulting in MELD inflation. Candidates with MELD exceptions had an advantage regarding access to liver transplantation and a lower waiting list mortality. Regular analysis of waiting list and post-transplant outcome therefore remains paramount to maintain equity with regards to transplant accessibility and waiting list priority.

**PO-1133**  
**Post-transplant outcomes of previously refused liver grafts: a 10-years nationwide experience**

Melisa Dirchwolf<sup>1</sup>, Chiara Becchetti<sup>2,3</sup>, Christian Toso<sup>4</sup>, Philipp Dutkowski<sup>5</sup>, Franz Immer<sup>6</sup>, Franziska Beyeler<sup>6</sup>, Daniel Candinas<sup>3</sup>, Jean-François Dufour<sup>2,3</sup>, Banz Vanessa<sup>3</sup>, The Swiss Transplant Cohort Study (STCS)<sup>7</sup>. <sup>1</sup>University of Bern, Novartis Fellowship in Hepatology, Department of Biomedical Research, Bern, Switzerland; <sup>2</sup>University of Bern, Hepatology, Department of Biomedical Research, Bern, Switzerland; <sup>3</sup>Inselspital, University Hospital Bern, University Clinic for Visceral Surgery and Medicine, Bern, Switzerland; <sup>4</sup>University Hospital of Geneva, Abdominal Surgery, Geneva, Switzerland; <sup>5</sup>University Hospital of Zurich, Abdominal Transplant Surgery, Zurich, Switzerland; <sup>6</sup>Swisstransplant, the Swiss National Foundation for Organ Donation and Transplantation, Bern, Switzerland; <sup>7</sup>Swiss Transplant Cohort Study, Basel, Switzerland  
 Email: vanessa.banzwuethrich@insel.ch

**Background and aims:** Defining acceptable donor liver quality remains challenging with multiple variables influencing liver acceptance. We analysed the characteristics of donors with previously refused liver offers and the post-transplant outcome of recipients with and without previously refused liver offers.

**Method:** Nationwide cohort study including all deceased donors registered on the Swiss Organ Allocation System between 2008 and 2018. The rate of recipients re-listing and death were considered as composite outcomes at 1-week and 1-year after liver transplantation. Cox proportional hazards regression model was used considering donation after cardiac death, age, and split donation as covariates. Liver offer refusal was defined as refusals for at least the five top-listed recipients on the waiting list or livers refused for all recipients in at

least one center prior to being transplanted in a recipient in Switzerland.

**Results:** Overall, 1043 donors that effectively donated their liver were included and 193 (18.5%) fulfilled the definition of liver offer refusals. Donor age greater than 70 years (OR 2.22, CI 95% 1.4–3.5, p = 0.001), BMI > 30 (OR 2.7, CI 95% 1.61–4.52, p < 0.001) and donation after cardiac death (OR 37, CI 95% 20–68.5, p < 0.001) were independent predictors for liver offer refusals. For re-listing/death analysis, data of 1010 recipients were available. Recipients with liver offer refusals had a similar rate of re-listing or death during the first week and first year of follow-up after liver transplantation. Only donor age (OR 1.02, CI 95% 1.00–1.03, p = 0.003) significantly increased the risk of re-listing/mortality during the first year after transplantation.

**Conclusion:** In this 10-year analysis of liver donor selection criteria and related outcomes in Switzerland, donor age, obesity and donation after cardiac death were significantly associated with liver offer refusals. However, only donor age was found to result in an increased risk of graft loss at 1-year after transplantation.

**PO-1168**  
**Graft survival following retransplantation-a large single centre retrospective analysis**

James Morgan<sup>1</sup>, Sara Mahgoub<sup>1</sup>, Dhiraj Tripathi<sup>1,2</sup>, Tamara Perera<sup>1</sup>. <sup>1</sup>Queen Elizabeth Hospital Birmingham, United Kingdom; <sup>2</sup>University of Birmingham, United Kingdom  
 Email: james.morgan18@nhs.net

**Background and aims:** Liver transplantation is a life-saving modality for liver failure. Graft failure occurs in 5–22% of all liver transplant recipients. Liver re-transplantation has been considered controversial, with clinical, economic, and ethical considerations. A study from Birmingham in 2009, reported no survival benefit following second and third re-transplantation. However, recent international data has suggested that survival following re-transplantation is comparable with first re-transplantation. The data from one of the UK's largest liver transplant centres has been re-evaluated to provide contemporary knowledge to inform clinicians and assist with complex decision-making.

**Method:** A retrospective study from January 2009 to March 2020. All adult patients who underwent first, second or third re-transplantation during this study period at University Hospital Birmingham were included. Data collection included primary diagnosis requiring liver transplantation, aetiology of graft failure, donor and recipient factors and time interval between graft transplantation. Overall graft and patient survival rates were analysed with Kaplan-Meier curves.

## POSTER PRESENTATIONS

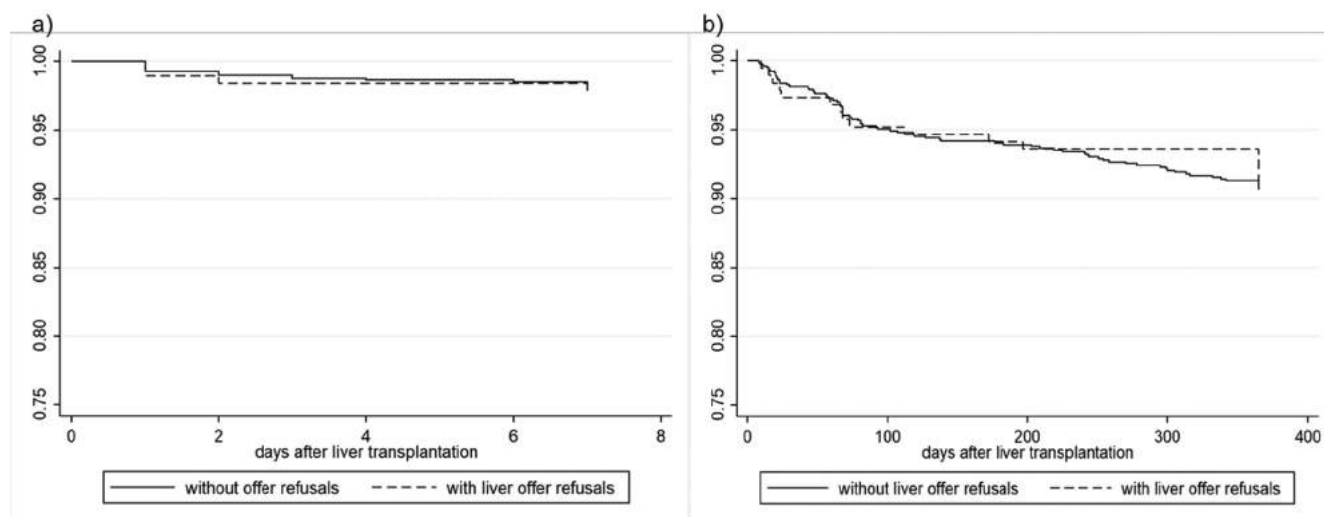

Figure: (abstract: PO-1133): (a) Kaplan-Meier curve for re-listing or mortality during 0–7 days after liver transplantation according to liver offer refusals; (b) Kaplan-Meier curve for re-listing or mortality during 8–365 days after liver transplantation according to liver offer refusals.

**Results:** There were 2454 adult and paediatric transplants during the study period. 6.6% (161) were re-transplanted, of which 15.5% (25) had a third retransplant and 1.2% (2) a fourth. The commonest indication for initial transplant in those who were subsequently re-transplanted were: PSC (25.5%), HCC (12.4%), Seronegative (9.3%) and PBC (9.3%). 12.8% of all grafts were DCD and 97.8% of these were used for initial transplant. Mean age at the time of first graft was 40 (range 0–68), second graft 44 (range 9–69) and third graft 33 (range 14–63). The most frequent reasons for re-transplantation were thrombotic and non-thrombotic graft infarction (28.7%), biliary complications (20.7%), early graft dysfunction (18.6%), graft rejection (17.5%) and recurrence of disease (14.9%). Mean MELD score prior to 1<sup>st</sup> graft was 13, 2<sup>nd</sup> graft 21 and 3<sup>rd</sup> graft 22. Machine perfusion was utilised for 13 re-transplants. Patient survival following 2<sup>nd</sup> graft at 12, 24 and 60 months was 96%, 86% and 80% respectively. Patient survival following 3<sup>rd</sup> graft at 12, 24 and 60 months was 96%, 96% and 84% respectively. Graft survival after 2<sup>nd</sup> graft was 90%, 82% and 79% at 12, 24 and 60 months, respectively. Graft survival after 3<sup>rd</sup> graft was 100% at 12, 24 and 60 months respectively.

factors influencing outcomes. Our findings support re-transplantation in carefully selected individuals.

### PO-1169

#### Changes in the profile and outcomes of paediatric liver transplantation in the United States

Maria Stepanova<sup>1,2</sup>, Khaled Kabbara<sup>2,3</sup>, Elisabeth Eberly<sup>2,3</sup>, Michael Herring<sup>2,3</sup>, Saleh Alqahtani<sup>1,4</sup>, Zobair Younossi<sup>3,5</sup>. <sup>1</sup>Center for Outcomes Research in Liver Disease, Washington DC, United States; <sup>2</sup>Inova Health System, Beatty Liver and Obesity Research Program, United States; <sup>3</sup>Inova Health System, Medicine Service Line, Falls Church, United States; <sup>4</sup>King Faisal Specialist Hospital, Riyadh, Saudi Arabia; <sup>5</sup>Inova Health System, Department of Medicine, Center for Liver Diseases, United States

Email: zobair.younossi@inova.org

**Background and aims:** Indications for paediatric liver transplantation are different from those of adults. Our aim was to assess trends in indication and outcomes of paediatric patients waitlisted for liver transplantation in the U.S. over the last decade.

**Method:** We used Scientific Registry of Transplant Recipients (SRTR) 2008–2020 to collect data for all patients <18 years of age listed for a liver transplant in the U.S. The study outcomes were receiving a transplant for candidates and time to post-transplant mortality for recipients. The cut-off date was December 2, 2020.

**Results:** There were 9488 paediatric liver transplant candidates in SRTR between 2008 and 2020. Mean age was 5.4 years (SD 5.8), 49% were male, 50% white, 95% U.S. citizens, and 53% by Medicaid. Mean Paediatric End-stage Liver Disease (PELD) score was 13.5 (SD 14.5). The most common aetiology of liver disease was biliary atresia or biliary hypoplasia (33%), followed by metabolic liver disease (12%) and acute or drug-induced liver disease (12%). Over time, the most substantial change in the distribution of underlying aetiologies was a decrease in the rate of liver disease from external causes (total parenteral nutrition- or hyperalimentation-induced), which decreased more than two-fold (from 7.4% in 2008–2011 to 3.6% in 2017–2020). At the same time, the proportion of patients with biliary atresia or hypoplasia increased from 30% to 35% ( $p < 0.01$ ). Of all waitlisted candidates, 76% eventually received a transplant after mean 142 (SD 260) days of waiting; that rate remained stable during the study years ( $p > 0.05$ ). Independent predictors of a higher chance of receiving a transplant in paediatric patients were older age and a listing diagnosis of biliary atresia or hypoplasia (all  $p < 0.01$ ). In addition, higher PELD score, having Medicaid, and a listing diagnosis

Figure 1: Kaplan Meier graph comparing patient survival following 2<sup>nd</sup>, 3<sup>rd</sup> and 4<sup>th</sup> graft.

**Conclusion:** Outcomes following re-transplantation have improved in the last 10 years despite increasing use of marginal donors. This could reflect careful patient selection, increased experience, and use of new technologies. Further study is suggested to identify specific

due to external causes were associated with a lower chance of receiving a transplant (all  $p < 0.01$ ). In those who received a transplant, 5-year survival was 89%, which increased from 86% in the early years to 92% in those transplanted in 2014–2015 ( $p < 0.0001$ ). Higher post-transplant mortality was found to be associated with earlier calendar year, higher PELD score, having Medicaid, and liver disease due to external causes (all  $p < 0.01$ ).

**Conclusion:** Paediatric indications for liver transplantation are different from those seen in adults. There is a steady trend towards improvement of post-transplant outcomes in the paediatric population.

**PO-1459**

**Recipient age influences the short- and long-term survival after liver transplant: results of the French national cohort 2007–2017**

Email: marianne.latournerie@chu-dijon.fr

**Background and aims:** Advances in liver transplant (LT) procedures, along with epidemiology changes, led to increase the number of liver recipients aged over 65 years despite the lack of donors. In this context, we aimed to investigate the impact of recipient's age on the five- and ten-years post-transplantation mortality.

**Method:** All patients aged over 18 years who received a first LT between 2007 and 2017, registered in the nationwide database of the French Biomedicine Agency, were included. The association between age and observed mortality was estimated using a conventional Cox proportional hazards (PH) model. Flexible models were used, allowing to estimate time dependent and/or non-log-linear effects and to account for the expected mortality of each patient given their sex and age.

**Results:** Overall, 7610 patients were included (mean age at LT =  $55.0 \pm 10.5$  years). Older recipients were less likely to have an alcoholic cirrhosis and had more frequently hepato-cellular carcinoma. Older were the recipients, better was their liver function and lower was the risk of being hospitalized or under mechanical ventilation. Cox proportional hazard modeling showed that recipients' age was significantly associated with an increased risk of death within the 5 years following LT (mean increase over the 5 years post-LT for 10 additional years of age = 15%; 99%-CI = 13%-16%). The flexible extension of the Cox model showed that this risk excess was especially marked in the 1st year post-LT and then decreased over time. The net survival analysis, accounting for the expected age- and sex-related-mortality for each recipient, showed a remaining absolute difference of 8% in 10-years-net survival between recipients aged 28 and 71 years.

**Conclusion:** Despite the selection process for older LT recipients, age at transplant was associated with an increased risk of death, particularly in the first year after LT. This effect decreased thereafter, but was still present at five and ten years, even after accounting for age-and-sex-related expected mortality in the French population. These results suggest that the selection of older recipients has to be reinforced.

**PO-1496**

**Impact of bacterial infections prior liver transplantation on post-transplant outcomes in patients with cirrhosis**

Salvatore Piano<sup>1</sup>, Simone Incicco<sup>1</sup>, Marta Tonon<sup>1</sup>, Carmine Gabriele Gambino<sup>1</sup>, Valeria Calvino<sup>1</sup>, Alessandra Brocca<sup>1</sup>, Patrizia Burra<sup>2</sup>, Umberto Cillo<sup>3</sup>, Paolo Angeli<sup>1</sup>. <sup>1</sup>University of Padova, Unit of Internal Medicine and Hepatology (UIMH), Department of Medicine-DIMED, Padova, Italy; <sup>2</sup>University of Padova, Multivisceral Transplant Unit, Department of Surgery, Oncology and Gastroenterology, Padova, Italy; <sup>3</sup>University of Padova, Hepatobiliary Surgery and Liver Transplantation, Department of Surgery, Oncology and Gastroenterology, Padova, Italy  
Email: salvatorepiano@gmail.com

**Background and aims:** Bacterial infections (BI) are frequent in cirrhosis, and increase the risk of decompensation, death and drop-out from the liver transplant (LT) waiting list. LT in patients with BI is frequently delayed due to the fear of poor LT outcomes. However, there is a paucity of data on the impact of BI prior LT on post-LT outcomes. We evaluated the impact of pre-transplant BI on post-LT complications and survival.

Figure: (abstract: PO-1496): (A) Occurrence of bacterial infections (BI), fungal infections and septic shock after LT in patients with pre-transplant BI and controls; (B) Probability of survival after liver transplant in patients with pre-transplant BI and controls.

## POSTER PRESENTATIONS

**Method:** From 2012 to 2018 we identified 109 LT candidates surviving an episode of BI within 3 months prior LT, and 359 patients without BI before LT (control group). Demographic, clinical and laboratory data were collected at the time of LT; for patients with infection, the clinical laboratory and microbiological characteristics of infections were collected. After LT data on complications occurred, length of stay and survival were collected.

**Results:** Patients with pre-transplant BI had a worse liver function and a higher MELD-Na score at transplant than those without. Donor characteristics, cold ischemia time and time of surgery were not significantly different between the 2 groups. Patients with pre-transplant BI had a more complex postoperative course, with longer stays in intensive care unit (9 vs 6 days,  $p = 0.010$ ) and in-hospital (29 vs 21 days,  $p = 0.002$ ), and higher incidence of new BI after LT (51% vs 29%,  $p < 0.001$ ), fungal infections (13 vs 4%;  $p = 0.001$ ) and septic shock (7 vs 1%;  $p = 0.002$ ; Figure A). Nevertheless, no difference was found in 1- and 5-year survival between patients with or without pre-transplant BI (88 vs 89% and 77 vs 75%, respectively,  $p = \text{N.S.}$ ; Figure B). In patients with pre-transplant BI no association was found between the time elapsed from the diagnosis of BI to LT and post LT outcomes.

**Conclusion:** Patients with BI prior LT have a more complex clinical course after LT and higher risk of new BI, fungal infections and septic shock. However, post LT survival is excellent. Therefore, as soon as BI is resolving, it is safe to proceed with the LT, but patients with pre-transplant BI require an active surveillance for infections after LT.

### PO-1523

#### Significantly higher mortality post liver transplantation in patients with psychosocial risk factors

Preya Patel<sup>1</sup>, Jeevan Barn<sup>1</sup>, Lianne Downey<sup>1</sup>, Aaron Wetten<sup>1</sup>, Louise MacDougall<sup>1</sup>, Mark Hudson<sup>1</sup>. <sup>1</sup>The Newcastle upon Tyne Hospitals NHS Foundation Trust, Liver Unit, Newcastle upon Tyne, United Kingdom  
Email: jeevanbarn@gmail.com

**Background and aims:** Organ allocation for liver transplantation (OLT) presents an ethical dilemma. Psychosocial factors may influence post-transplantation outcomes however assessment of these risk factors is not standardised across UK centres. We used a

psychosocial risk profile tool (PSRPT) to quantify these risk factors and assessed their impact on post OLT outcomes.

**Method:** We retrospectively applied the PSRPT to all patients undergoing elective OLT assessment from January 2010 to December 2014. Data was collected on assessment outcomes, transplantation, late onset medical/psychiatric complications and mortality.

**Results:** 273 patients were included; their median age was 57 years and 62.3% were male. 168 patients were listed for transplant and 126 underwent OLT. The main indications for transplant were synthetic dysfunction (35.9), refractory ascites (31.9%) and hepatic encephalopathy (32.6%). Sixty-five percent of patients assessed were classed as medium/high psychosocial risk (MPSR). MPSR patients were more likely to have underlying alcohol related liver disease ( $p = 0.005$ ), were less likely to undergo transplantation ( $p < 0.001$ ) and were more likely to return to alcohol misuse ( $p < 0.001$ ) when compared to low-risk patients (LPSR). MPSR patients had a significantly higher all-cause mortality than LPSR patients ( $p = 0.005$ ). Factors independently associated with mortality were undergoing transplantation (OR 0.10 (95% CI 0.06–0.20)) and concerns regarding financial support (OR 4.85 (95% CI 1.16–20.32)). Figure 1 illustrates the survival difference between those classed as MPSR vs LPSR. In those transplanted, MPSR patients had significantly higher mortality ( $p = 0.037$ ). 35 (27.7%) patients who underwent transplant died during the follow-up period. Factors significantly associated with mortality post transplantation were recidivism ( $p = 0.026$ ) and concerns regarding social ( $p = 0.002$ ) and financial support ( $p = 0.050$ ). Lack of social support was independently associated with increased mortality in those who underwent OLT (OR 7.18 (95% CI 1.68–30.73)).

**Conclusion:** MPSR patients had a higher all-cause mortality and increased risk of recidivism. This suggests that utilizing the PSRPT may highlight at-risk patients, thus enabling implementation of enhanced support to prevent poor outcomes.

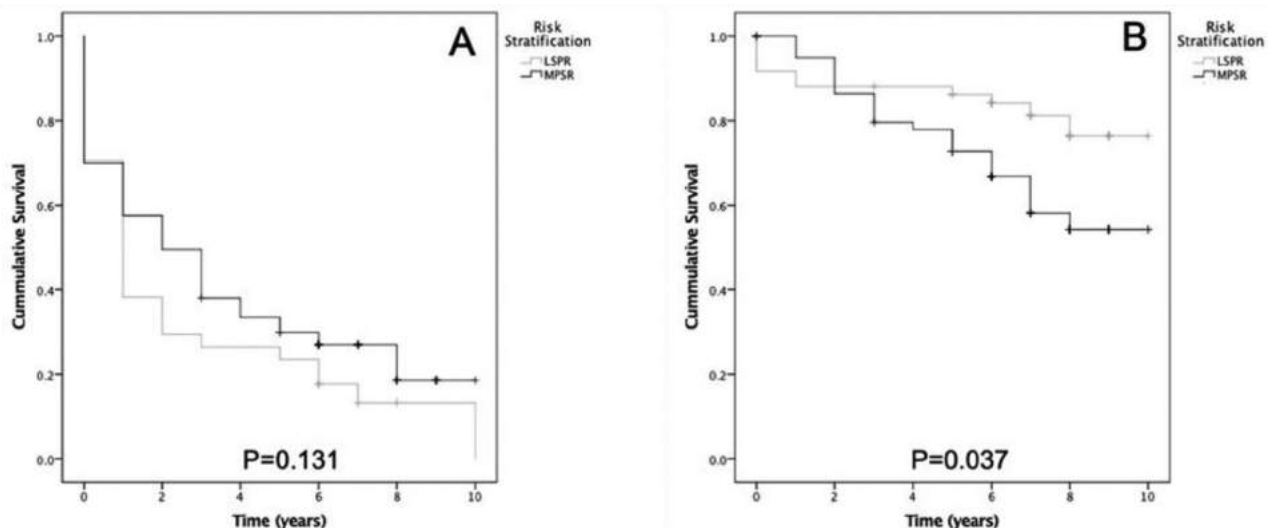

Figure 1: (abstract: PO-1523): Kaplan-Meier survival curves comparing risk stratification groups in (a) patients who did not undergo transplantation and (b) patients who were transplanted.

**Clinical value of surveillance biopsies in pediatric liver transplantation: A single center experience with >800 biopsies**

Brittany Rocque<sup>1</sup>, Aaron Zalana<sup>1</sup>, Carly Weaver<sup>2</sup>, Julia Huang<sup>1</sup>, Arianna Barbeta<sup>1</sup>, Victoria Shakhin<sup>2</sup>, Cameron Goldbeck<sup>1</sup>, George Yanni<sup>2</sup>, Rohit Kohli<sup>2</sup>, Yuri Genyk<sup>1,2</sup>, Juliet Emamaullee<sup>1,2</sup>.  
<sup>1</sup>University of Southern California, Surgery, Los Angeles, United States;  
<sup>2</sup>Children's Hospital Los Angeles, Pediatrics, Los Angeles, United States  
 Email: Brittany.Rocque@med.usc.edu

**Background and aims:** While pediatric liver transplantation (LT) results in excellent long-term outcomes, a high incidence of early acute cellular rejection (ACR) and late graft fibrosis persists. Routine liver function tests may not reliably detect rejection episodes or identify patients who are candidates for reduced/modified immunosuppression (IS). Surveillance biopsies (SB) can provide valuable information in this regard, but their role in pediatric LT continues to be controversial.

**Method:** A retrospective cohort of 232 pediatric LT recipients who underwent biopsy between 2003–2019 was studied to characterize the potential risks and benefits of SB vs 'for cause' biopsies. At our center, SB was performed >5 years post-LT with stable graft function or 1-year post biopsy-proven ACR.

**Results:** Among 816 biopsies obtained from 232 patients, 150 (18%) were SB. Only 6 (0.7%) of patients in the entire cohort had a biopsy-related complication, and none were observed in the SB subset. Liver function tests did not predict rejection severity on biopsy (ALT AUROC 0.65 (very poor prediction), Bilirubin AUROC 0.58 (no prediction), GGT AUROC 0.56 (no prediction)). SB identified a subclinical rejection episode in 18.6% of biopsies. When obtained within 24 months of LT, 7.7% of SB led to changes in IS, when obtained >24 months post-LT 18.7% prompted IS change including reduction. SB obtained <10-years post-LT trended toward higher incidence of ACR (Figure 1A), with reversal at >10 years, although this was not significant (p=0.24). Graft survival and patient survival did not differ between SB and 'for cause' groups (Figure 1B and C). 63% of SB had some evidence of fibrosis.

**Conclusion:** In our experience, SB in pediatric LT have a good safety profile and provide valuable information about subclinical rejection episodes, leading to changes in management of IS. Further multi-center studies are needed to examine the role for SB on long-term outcomes in pediatric LT.

PO-1971

**Factors associated with unplanned intensive care unit readmission following liver transplantation**

Marcus Robertson<sup>1,2,3</sup>, Andy Lim<sup>3</sup>, Ben Johnstone<sup>1</sup>, Elise Cannan<sup>1</sup>, Andrew Tsoi<sup>1</sup>, Paul Gow<sup>1,2</sup>, Peter Angus<sup>1,2</sup>, Daryl Jones<sup>4,5</sup>.  
<sup>1</sup>Austin Hospital, Liver Transplant Unit, Heidelberg, Australia; <sup>2</sup>University of Melbourne, Department of Medicine, Heidelberg, Australia; <sup>3</sup>Monash University, Department of Medicine, Clayton, Australia; <sup>4</sup>Austin Hospital, Intensive Care Department, Heidelberg, Australia; <sup>5</sup>Monash University, Department of Medicine, Heidelberg, Australia  
 Email: robbo10@hotmail.com

**Background and aims:** Patients undergoing liver transplantation (LT) have a high-risk of postoperative clinical deterioration (CD). Previous studies indicate that 6–19% LT recipients require unplanned intensive care unit (ICU) readmission, which most commonly occurs following Rapid Response Team (RRT) activation and is associated with morbidity and mortality. There is a paucity of data on predictors of unplanned ICU admission following RRT activation post-LT. We aimed to determine the incidence and factors predicting unplanned ICU admission post-LT.

**Method:** We conducted a cohort study of consecutive LT recipients (≥18 years) of the Victorian Liver Transplant Unit who experienced a CD event and RRT activation from 2011–2017. The primary outcome was unplanned ICU admission. Secondary outcomes were hospital length of stay (LOS) and inpatient mortality. Multivariable logistic regression with cluster specific robust standard errors was used to predict the primary outcome, while accounting for baseline variables, RRT triggers, biochemistry and vital signs. Models were compared with information criteria. Model discrimination was assessed by the area under the receiver operating curve (AUROC) and calibration examined by a calibration plot.

**Results:** 381 patients were included. Median age was 56 (IQR 48–61), 65% were male and mean MELD score was 19 (SD 9.6). Post-LT CD occurred in 88 (23%) patients with a total of 160 RRT activations at a median of 11-days (IQR 5–23) post-LT. Unplanned ICU readmission occurred in 16.9% (27 of 160) of RRT activations, or 6.0% (23 of 381) transplant recipients. Variables independently associated with unplanned ICU admission in the regression model are listed in Table 1, which predicted the primary end point with an AUROC of 0.82. Compared to patients without ICU readmission, patients with unplanned ICU admission had longer post-LT LOS (median, 23 days vs 13 days, p < 0.001), ICU LOS (median, 189 hours vs 72 hours, p < 0.001) and a non-significant trend towards higher mortality (13.0% vs. 3.6%, p = 0.06). No difference in mean MELD at time of LT was noted between groups (21 vs. 19, p > 0.05).

Figure 1: Pediatric LT recipient outcomes based on having biopsy 'For Cause' or for 'Surveillance'

Figure: (abstract: PO-1773)

## POSTER PRESENTATIONS

Figure: Factors associated with ICU readmission post-LT in multivariate logistic regression

	OR (95% C.I.)	P value
RRT activation delay >1 hour	6.0 (1.6–23.1)	0.002
Glasgow Coma Scale $\leq$ 13	6.6 (2.1–20.5)	<0.001
Mean arterial blood pressure <70 mmHg	4.9 (1.6–14.7)	0.007
Serum creatinine, per 1 $\mu$ mol/L	3.6 (1.6–8.3)	0.003
Serum sodium <133 mmol/L	3.1 (1.1–9.2)	0.028

**Conclusion:** LT patients with CD requiring unplanned ICU readmission are a high-risk group with increased morbidity, ICU and hospital LOS. We identified a model that predicted ICU readmission with an AUROC of 0.82, however further validation is required. Early identification and correction of these factors may lead to improved outcomes and a reduction in health-care costs.

### PO-2001

#### Covid-19 in Liver Transplant Recipients: A National Cohort

Email: gokhankabacam@yahoo.com

**Background and aims:** The effect of coronavirus disease 2019 (COVID-19) on outcomes of liver transplant recipients is not known very well. The aim of the present study was to describe the early outcomes of liver transplant recipients with COVID-19.

**Method:** Liver transplant recipients with concomitant confirmed severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) infection from 14 tertiary liver transplant centers of Turkey were enrolled into the study. The diagnosis of SARS-CoV-2 infection was made according to the World Health Organization guidelines and based on the presence of clinical features, laboratory and radiological findings. The immunosuppressive protocol mainly consisted of calcineurin inhibitors (CNIs) plus mycophenolate mofetil (MMF) and a steroid.

**Results:** A total of 129 liver transplant recipient had diagnosed with COVID-19. Median age was 56 years. The recipients were predominantly male (69%). The median interval between liver transplantation (LT) and COVID-19 diagnosis was 48 months: 18 recipients had been transplanted less than one year, while 49 recipients had been transplanted more than 5 years. The most common etiology of LT was hepatitis B virus related liver disease (45.7%). Immunosuppressive protocol comprised of single agent in 42% of the patients, double agents in 48%, triple agents in 7%.

At the time of COVID-19 diagnosis, most recipients (54%) had at least one co-morbidity including diabetes mellitus (31.8%), hypertension (36.4%). Main presenting symptoms were fatigue (78%), fever (51%), cough (47%), dyspnea (26%), and diarrhea (10%). Pneumonic infiltration was observed in 64% of the recipients, 22.5% had relevant increase in liver enzymes.

After the diagnosis, 47% of the recipients were treated in the ward, and 12% was taken to the ICU. Among whole cases 14.7% of them needed nasal oxygen therapy, and 10.2% required intubation and invasive mechanical ventilation.

Overall, 12 recipients (9.4%) died due to COVID-19 related respiratory or multisystem failure. With multivariate analysis, c-reactive protein (CRP), procalcitonin levels and mechanical ventilation requirement were the risk factors that are significantly associated with mortality ( $p < 0.001$ ,  $p = 0.004$ ,  $p < 0.001$ ).

**Conclusion:** COVID-19 significantly affects the outcome of LT recipients. Increased CRP and procalcitonin levels in admission and mechanical ventilation requirement are the most important risk factors for mortality.

### PO-2121

#### The impact of COVID-19 on liver transplant (LT) centers across the world during the first wave: a Multisociety Survey (EASL-ESOT/ELITA-ILTS)

Francesco Paolo Russo<sup>1</sup>, Manhal Izzy<sup>2</sup>, Ashwin Rammohan<sup>3</sup>, Varvara Kirchner<sup>4</sup>, Luca Saverio Belli<sup>5</sup>, Thomas Berg<sup>6</sup>, Marina Berenguer Haym<sup>7</sup>, Wojciech Polak<sup>8</sup>. <sup>1</sup>University Hospital Padua, Department of Surgery, Oncology and Gastroenterology, Padua, Italy; <sup>2</sup>Division of Gastroenterology, Hepatology, and Nutrition, Vanderbilt University Medical Center, Nashville, Nashville, United States; <sup>3</sup>The Institute of Liver Disease and Transplantation, Dr. Rela Institute and Medical Centre, Chennai, India; <sup>4</sup>Department of Surgery, University of Minnesota, Minneapolis, United States; <sup>5</sup>Department of Hepatology and Gastroenterology, Niguarda Hospital, Milan, Italy; <sup>6</sup>Division of Hepatology, Department of Medicine II, Leipzig University Medical Center, Leipzig, Germany; <sup>7</sup>Hepatology and Liver Transplantation Unit, IIS La Fe, Hospital Universitario y Politécnico La Fe, Valencia, Spain; <sup>8</sup>Department of Surgery, Erasmus MC, University Medical Center, Rotterdam, Netherlands  
Email: francescopaolo.russo@unipd.it

**Background and aims:** The global impact of SARS-CoV-2 on LT practice across the world is unknown. The aim of this survey was to collect and analyse data during the first COVID-19 wave.

**Method:** A prospective web-based survey (available online September 2020–December 31 2020) was proposed to EASL-ESOT/ELITA-ILTS active members in Europe (C1), Africa, Australia, Asia (C2), and the Americas (C3). The survey was made up of 4 parts, concerning transplant processes, therapy, living donor and organ procurement.

**Results:** Of >470 transplant centers reached, 128 answered each part of the survey, 50%, 27%, and 23% from regions C1, 2, and 3, respectively. When we compared the practice during the first 6 months of the pandemic in 2020 with that during the same period but a year earlier in 2019, statistically significant differences in the number of patients added to the wait-list (WL) in C2, and in the number of transplantations in C1 and in C2 were observed. No difference in WL mortality was seen. Of note, in Europe, waitlisting, WL mortality and LT rates changed significantly in countries heavily hit by the pandemic whereas no significant changes occurred in

those less impacted. While 30–50% of the centers transplanted recipients with previous COVID-19, only 12–17% used organs from previously SARS-CoV-2 infected donor. 18–36% of recipients turned positive after the transplant. Only 8–14% of centers routinely stopped CNI in post-transplant SARS-CoV-2 infection.

**Conclusion:** The SARS-CoV-2 pandemic significantly impacted transplant activities, particularly in heavily hit countries. Individualized modifications of immunosuppression were applied in infected recipients.

**Background and aims:** Living donor liver transplantation (LDLT) is an option to ameliorate the global donor-organ shortage. However, knowledge on LDLT in autoimmune liver diseases (AILDs) is scarce.

**Method:** The present study analyzed long-term patient survival in LDLT recipients with autoimmune hepatitis (AIH), primary biliary cholangitis (PBC), and primary sclerosing cholangitis (PSC) registered in the European Liver Transplant Registry (ELTR). The non-autoimmune disorder alcohol-related cirrhosis (ALC) served as a control. Outcomes after LDLT were compared with donation after brain death (DBD) for each diagnosis.

**Results:** Between 1998 and 2017 a total of 28899 individuals were registered in the ELTR database, including 1003 with LDLT. For AILDs, patient survival from >90 days after LDLT was 86.3%, 76.5%, and 63.6% after 5, 10, and 15 years. PSC patients receiving LDLT compared to DBD had an increased risk of death (hazard ratio [HR] = 2.07, p < 0.001). This was not observed for patients with AIH, PBC or ALC. Risk factors for deaths in PSC patients receiving LDLT were recipient age ≥47 years (HR = 3.65, p < 0.001), donor age ≥50 years (HR = 3.93, p < 0.001), and a male donor (HR = 3.71, p < 0.001). PSC patients receiving LDLT were at increased risk of death from disease recurrence (subHR = 5.66, p < 0.001) and biliary complications (subHR = 4.78, p = 0.005) compared to DBD.

**Conclusion:** Long-term survival after LDLT for AILD is favorable. Nevertheless, PSC patients receiving LDLT have an increased mortality compared to DBD.

**PO-2425**

**Complete response after biological downstaging in patients with hepatocellular carcinoma: XXL-like prioritization for liver transplantation or "wait and see" strategy?**

Alessandro Vitale<sup>1</sup>, Paolo Angeli<sup>2</sup>, Patrizia Burra<sup>3</sup>, Umberto Cillo<sup>1</sup>. <sup>1</sup>University of Padua, Department of Surgical, Oncological, and Gastroenterological Sciences, Hepatobiliary Surgery and Liver Transplantation Unit, Padua University Hospital, Italy, Italy; <sup>2</sup>University of Padua, Unit of Internal Medicine and Hepatology, Padua University Hospital, Italy, Italy; <sup>3</sup>University of Padua, Multivisceral Transplant Unit, Gastroenterology, Department of Surgery, Oncology and Gastroenterology, Padua University Hospital, Italy, Italy Email: alessandro.vitale@unipd.it

**Background and aims:** Although some methodological and ethical issues, the recently published XXL trial represents the first prospective validation of "biological downstaging" in liver transplantation for hepatocellular carcinoma (i.e. selecting tumors with a good biology irrespective of morphological criteria). The aim of this study is to compare our downstaging protocol with the XXL protocol in terms of downstaging failure rates and patient outcome.

**Method:** A total of 191 patients undergoing surgical downstaging and potentially eligible for transplantation from 2012 to 2018 at our Center, were selected according to the XXL trial enrolment criteria. Differently from the XXL trial we used an aggressive surgical downstaging protocol, and patients with a complete response to downstaging did not receive any prioritization to transplant. Downstaging failure was defined as progressive disease or post treatment mortality. The statistical method "matching-adjusted indirect comparison" was used to match the study group to the XXL population and to compare the proportion of downstaging failures. The software Engauge digitizer was used to allow a statistical comparison between Kaplan Meier survival curves.

**Results:** Downstaging failure rate was significantly lower in our cohort than in the XXL trial (12% vs. 39%). Patients with partial response to downstaging had a much greater probability of being included in the waiting list than patients with a complete response (OR 20.4, 95% CI 6.9–69.9, p = 0.0001). Although patients with complete response were not prioritized to transplant, the survival curves of our cohort overlapped with that of the XXL protocol (p > 0.05). Survival curves of non-transplant candidates with a complete response to downstaging were similar to that of transplanted patients (p > 0.05).

**Conclusion:** Our study represents a validation of the current Italian policy of denying any prioritization to patients with complete response to downstaging. Such a policy seems to spare organs without worsening patient outcome.

**PO-2821**

**SARS-CoV-2-specific cellular and humoral immunity in COVID-19 convalescence after liver transplantation**

Theresa Kirchner<sup>1</sup>, Hagen Sauer<sup>1</sup>, Agnes Bonifacius<sup>2</sup>, Ruhl Louisa<sup>3</sup>, Isabell Pink<sup>4</sup>, Bastian Engel<sup>1</sup>, Emily Saunders<sup>1</sup>, Joerg Martens<sup>3</sup>, Marius M. Hoeper<sup>4</sup>, Rainer Blasczyk<sup>2</sup>, Heiner Wedemeyer<sup>1</sup>, Elmar Jaeckel<sup>1</sup>, Christine Falk<sup>3</sup>, Britta Eiz-Vesper<sup>2</sup>, Richard Taubert<sup>1</sup>. <sup>1</sup>Hanover Medical School, Department of Gastroenterology, Hepatology and Endocrinology, Hannover, Germany; <sup>2</sup>Hanover Medical School, Institute of Transfusion Medicine and Transplant Engineering, Hannover, Germany; <sup>3</sup>Hanover Medical School, Institute of Transplant Immunology, Hannover, Germany; <sup>4</sup>Hanover Medical School, Department of Pneumology, Hannover, Germany Email: kirchner.theresa@mh-hannover.de

**Background and aims:** Mortality due to Coronavirus Disease-2019 (COVID-19) is not increased in immunosuppressed individuals after orthotopic liver transplantation (OLT) compared to individuals without immunosuppression. Data on protective immunity against severe acute respiratory syndrome coronavirus type 2 (SARS-CoV-2) in immunosuppressed convalescents, especially after mild COVID-19,

## POSTER PRESENTATIONS

Figure: (abstract: PO-2425)

are limited. The aim of the current study was to assess the immune response in COVID-19 OLT convalescents with ongoing immunosuppressive therapy.

**Method:** Immune responses against SARS-CoV-2 were measured prospectively in 16 OLT convalescents at the first outpatient visit after COVID-19, in comparison to matched non-immunosuppressed convalescents (non-IS-Con, n = 24 for cellular and n = 11 for humoral immunity). SARS-CoV-2-specific T cell reactivity was detected by IFN- $\gamma$  ELISPOT assay with 5 different SARS-CoV-2 antigen pools. SARS-CoV-2-specific antibodies (IgG, IgA, IgM) were detected against four different SARS-CoV-2 antigens (S1/2, RBD, nucleocapsid).

**Results:** The majority of OLT patients (15/16) had a mild or moderate COVID-19 and were managed as outpatients (12/16). At the first outpatient visit liver function tests and liver stiffness measurements were not suggestive for increased alloreactivity.

Anti-SARS-CoV-2 IgA and IgG antibodies were detectable in 62–100%, IgM in 31–100% of OLT convalescents. Anti-SARS-CoV-2 IgG antibodies of OLT convalescents were not reduced, neither in frequency nor in concentration, compared to non-IS-Con. None of these OLT recipients with available cryo-conserved samples before appearance of SARS-CoV-2 (n = 12) had preexisting anti-SARS-CoV-2 IgG, but some had preexisting IgA with cross-reactivity against RBD, nucleocapsid, S1 and S2. OLT convalescents had no reduced IFN- $\gamma$  production, normalized to numbers of PBMCs and T cells against SARS-CoV-2 compared to non-IS-Con. No relevant T cell reactivity could be detected in pre-corona samples.

**Conclusion:** The study complements the data sets on cellular and humoral immunity of immunosuppressed COVID-19 convalescents by showing a robust and indistinguishable cellular and humoral immunity against SARS-CoV-2 also after mild/moderate infections without hints for a decline of cellular immunity during the first months after COVID-19. The development of a robust immunity without COVID-19-triggered rejection justifies the continuation of immunosuppressive therapy during mild to moderate COVID-19.

### PO-2842

#### Periods of high or low intensity transplant activity are not associated with changes in liver transplant outcomes

Neil Halliday<sup>1</sup>, Lewis Downward<sup>2</sup>, Joerg-Matthias Pollok<sup>3</sup>, Rhiannon Taylor<sup>2</sup>, Douglas Thorburn<sup>4</sup>. <sup>1</sup>University College London, Institute for Liver and Digestive Health, London, United Kingdom; <sup>2</sup>NHS Blood and Transplant, Statistics and Clinical Studies, Bristol, United Kingdom; <sup>3</sup>Royal Free Hospital NHS Foundation Trust, Hepatopancreatobiliary Surgery and Liver Transplantation, London, United Kingdom; <sup>4</sup>Royal Free Hospital NHS Foundation Trust, Sheila Sherlock Liver Centre, London, United Kingdom  
Email: neilhalliday@doctors.org.uk

**Background and aims:** The unpredictable availability of donor organs and the fact that liver transplants (LTs) are performed based on clinical need rather than scheduled capacity results in fluctuating activity within each centre. Coupled with increasing overall LT activity this results in periods of high and low LT activity. As low volume LT activity has been associated worse outcomes we hypothesised that fluctuations in work-load intensity may be associated with variation in LT outcomes and tested whether there was a threshold associated with worse LT outcomes.

**Method:** 11,280 liver only, deceased donor, adult LT operations (01/01/00-31/12/17) were identified from the UK Transplant registry. 32 LTs were excluded due to missing data. Cox proportional hazards models were built to estimate graft and transplant failure at 30 days, 90 days, one and three years post-LT. Unit workload was assessed as the number of LT operations performed over 1, 3, 7 and 28 days before each LT, grouped as low, medium and high ( $\leq 24^{\text{th}}$ ,  $25^{\text{th}}-74^{\text{th}}$  and  $\geq 75^{\text{th}}$  percentile) compared to the unit's average activity for that year (to account for changes in LT activity over time). We tested whether unit workload was associated time and hazard of graft and transplant failure.

**Results:** We observed small differences in recipient characteristics with a greater proportion of LT during low activity periods for acute liver failure (17%, 15% and 15% for low, medium and high activity, p = 0.01). No differences were observed in transplant survival between

low medium and high preceding 28 day activity, stratified by individual unit activity levels (see figure). Similar findings were observed for 1, 3 and 7 day activity.

**Figure:** Cox-proportionate hazard models demonstrated that there were no consistent differences in graft or patient survival at 30 days, 90 days, 1 year and 3 years post LT depending on 1, 3, 7 and 28 day unit workload intensity. Further testing, assessing preceding unit LT activity as a continuous variable, did not demonstrate robust evidence of a threshold for absolute numbers of LT influencing adverse outcomes.

**Conclusion:** Fluctuations in unit workload did not influence LT graft or patient survival in the UK. In this large cohort we were unable to demonstrate that periods of low or high intensity LT activity, relative to the unit's own baseline activity, influenced outcomes. The model of LT delivery in the UK can absorb the necessary variations in workload without adverse impact on graft outcomes.

**PO-2890**  
**A new tool for predicting survival in liver transplantation for hepatocellular carcinoma combining molecular and clinical variables**

Joana Cardoso<sup>1</sup>, Hugo Pinto Marques<sup>2</sup>, Marta Mesquita<sup>3</sup>, Andre Manso<sup>1</sup>, Sara Carapeta<sup>1</sup>, Mafalda Sobral<sup>2</sup>, Silvia Silva<sup>2</sup>, Clara Rodrigues<sup>4</sup>, Ana Carvalho<sup>4</sup>, Adelaide Milheiro<sup>4</sup>, Rui Perdigoto<sup>2</sup>, Eduardo Barroso Garcia Da Silva<sup>2</sup>, Jose Pereira-Leal<sup>1</sup>. <sup>1</sup>Ophiomics-Precision Medicine, Lisboa, Portugal; <sup>2</sup>Hospital Curry Cabral, Hepato-Biliary-Pancreatic and Transplantation Centre, Lisboa, Portugal; <sup>3</sup>Instituto Gulbenkian de Ciência (IGC), Oeiras, Portugal; <sup>4</sup>Hospital Curry Cabral, Anatomia Patológica, Lisboa, Portugal  
 Email: jvaz@ophiomics.com

**Background and aims:** Liver cancer is one of the most frequent cancers in the world, and one of the most frequent causes of cancer-related mortality. Liver Transplantation is the best treatment for

cirrhotic patients with hepatocellular carcinoma. Clinical criteria are currently used to ascertain eligibility of patients for transplant. We developed a decision algorithm where biomarkers measured in a tumour biopsy, together with clinical variables, predicts overall survival after transplantation.

**Method:** A systematic review of the literature was performed to single out candidate biomarkers. RNA levels of these candidates was assessed by quantitative reverse transcriptase PCR in formalin-fixed, paraffin-embedded tumor tissue, resulting in a five gene signature. These were then considered together with clinical variables to develop a decision algorithm using machine learning approaches. Development and validation of this algorithm was based on a retrospective cohort with more than 5 years follow-up.

**Results:** A three step algorithm can identify a significant number of patients outside of Milan criteria that remain disease free at five year, as well as stratifying within-Milan criteria patients for overall survival. Step 1 achieves highest predictive power and accounting for over 60% of the predictions; a second step with higher recall but lower precision retrieves an additional 20% of the successful transplants, and a third, final step, reverts to Milan Criteria insuring retrieving an additional 15% of the successful transplants, but with a lowering of accuracy. The overall number of patients selected for transplant is not different from those predicted by Milan criteria, but the performance of the predictor is better.

**Conclusion:** The multigene and clinical variable method proposed (HepatoPrediic) outperforms conventional clinicopathologic risk factors both in Milan and San Francisco criteria, providing superior prognostic information. We show that for the same number of transplantations, including biomarkers with clinical variables in patient selection can increase the number of lives saved.

**PO-2910**  
**Liver and/or kidney transplantation after SARS-CoV-2 infection: Prevalence, short-term outcome and kinetics of serum IgG antibodies**

Jef Verbeek<sup>1</sup>, Casper Vrij<sup>1</sup>, Pieter Vermeersch<sup>1</sup>, Sofie Vets<sup>1</sup>, Katrien Lagrou<sup>1</sup>, Ina Jochmans<sup>1</sup>, Diethard Monbaliu<sup>1</sup>, Jacques Pirenne<sup>1</sup>, Dirk Kuypers<sup>1</sup>, Frederik Nevens<sup>1</sup>. <sup>1</sup>University Hospital KU Leuven, Leuven, Belgium  
 Email: jef.verbeek@uzleuven.be

**Background and aims:** Uncertainty remains on whether and when it is safe to perform transplantation (Tx) in patients with previous SARS-CoV-2 infection. We assessed: (1) the prevalence of pre-Tx SARS-CoV-2 infection in pts who underwent a liver and/or kidney Tx, (2) their short-term post-Tx outcome and (3) their longitudinal IgG antibody seroprevalence.

**Method:** All pts receiving a liver and/or kidney Tx at UZ Leuven between May 1<sup>st</sup>, 2020 to March 18<sup>th</sup> 2021 were included. SARS-CoV-2 PCR via nasopharyngeal swabbing (all negative) and serum SARS-CoV-2 anti-nucleocapsid (N) IgG antibodies were assessed within 24 h before Tx. Pre-Tx infection was defined as prior positive PCR and/or presence of anti-N IgG. In all pts with pre-Tx infection, serial assessment of anti-N and anti-spike (S) IgG were performed after Tx.

Figure: (abstract: PO-2890)

## POSTER PRESENTATIONS

**Results:** 168 liver and/or kidney Tx procedures were performed, including 62 single liver Tx, 101 single kidney Tx and 5 combined liver-kidney Tx. 11/186 (6.54%) pts had a previous SARS-CoV-2 infection (Table 1) of which 5/62 (8.06%) single liver recipients, 3/101 (2.97%) single kidney recipients and 3/5 combined liver-kidney recipients. Median interval between infection (day PCR positivity) and Tx was 4.5 m (range 0.9–11). Median follow-up after Tx was 4.9 m (range 0.3–8.9). At last post-Tx follow-up, 10/11 pts were alive. No clinical signs of active/recurrent SARS-CoV-2 infection were detected. One pt (<sup>7</sup>; frail and oxygen dependent with cholangiopathy and renal failure at the moment of Tx due to previous critical COVID-19) died from septic shock 5 wks after combined liver-kidney Tx. Absolute anti-N and anti-S IgG levels were positively correlated ( $r = 0.58, p \leq 0.001$ ) and both declined in all pts. The median duration of IgG seropositivity was 168 d (range 47–397) for anti-N and 196 d (range 71–397) for anti-S IgG after positive PCR. In 3 pts, anti-N IgG disappeared after a median of 243 d (range 71–326) after initial positive PCR, but all pts remained anti-S IgG positive until last follow-up. In 2/11 pts with pre-Tx infection, anti-N and anti-S IgG were negative at the day of Tx and remained negative after Tx.

Pt	Tx Organ (L)/Kidney (K)	Age (yr)/Gender	Tx indication	COVID-19 Severity	Interval PCR+ and Tx (d)	Follow-up after Tx (d)
1	L	67/M	ICU cholangiopathy	Critical	167	226
2	L	68/M	NASH	Asymptomatic	169	148
3	L	50/F	AIH	Critical	195	156
4	L	57/F	ALD	Mild	26	95
5	L	52/F	ALD	Mild	60	65
6	L + K	72/F	ADPKD and ESKD	Asymptomatic	56	233
7	L + K	69/M	ICU Cholangiopathy and kidney failure	Critical	148	38
8	L + K	63/M	NASH and HRS	Asymptomatic	47	30
9	K	69/M	Dent's disease	Severe	246	151
10	K	62/M	Nephroangiosclerosis	Asymptomatic	49	270
11	K	61/M	Hypertensive nephropathy	Severe	339	10

Figure:

**Conclusion:** With the largest case series to date, we provide real-world data supporting the recommendation that liver and/or kidney Tx can safely be performed in patients with complete symptom resolution and a negative SARS-CoV-2 PCR at the moment of Tx.

### Liver transplantation and hepatobiliary surgery: Experimental

#### PO-246

#### CD44v6+gp38+ large extracellular vesicles in gall bladder survival prognosis-a pilot study

Marcin Krawczyk<sup>1,2</sup>, Bingduo Wang<sup>3</sup>, Joanna Ligocka<sup>2</sup>, Krzysztof Zieniewicz<sup>2</sup>, Waldemar Patkowski<sup>2</sup>, Sabine K. Urban<sup>3</sup>, Arnulf G. Willms<sup>4</sup>, Tudor Mocan<sup>5</sup>, Piotr Milkiewicz<sup>2,6</sup>, Veronika Lukacs-Kornek<sup>7</sup>, Christian P. Strassburg<sup>3</sup>, Mirosław Kornek<sup>3</sup>.  
<sup>1</sup>Saarland University Hospital, Department of Medicine II, Homburg, Germany; <sup>2</sup>Medical University of Warsaw, Department of General, Transplant and Liver Surgery, Warszawa, Poland; <sup>3</sup>Universitätsklinikum Bonn, Medizinische Klinik und Poliklinik I, Bonn, Germany; <sup>4</sup>German Armed Forces Central Hospital, Department of General, Visceral and Thoracic Surgery, Koblenz, Germany; <sup>5</sup>Iuliu Hatieganu University of Medicine and Pharmacy, Octavian Fodor Institute for Gastroenterology and Hepatology, Cluj-Napoca, Romania; <sup>6</sup>Pomeranian Medical University, Translational Medicine Group, Szczecin, Poland;

<sup>7</sup>Universitätsklinikum Bonn, Institut für Experimentelle Immunologie, Bonn, Germany  
 Email: miroslawkornek@web.de.

**Background and aims:** Biliary cancer, comprising cholangio- and gallbladder carcinomas (CCA and GbCA), is associated with high mortality due to asymptomatic disease onset and resulting late diagnosis. Currently, no robust prognostic biomarker is clinically available in GbCA. Here, we present combinations of antigens being simultaneously present on the same large extracellular vesicle in order to predict the outcome in GbCA. Additionally, we are discriminating closely related HCC from GbCA.

**Method:** The presence of CD44v6<sup>+</sup>, gp38<sup>+</sup> (podoplanin) and double positive cells was confirmed in wild type C57Bl/6j mice *in vivo* by FACS. Large EVs from patients' sera were isolated by sequential centrifugation at 2, 000 and 20, 000 × g. NTA was performed to verify the size of isolated EVs. To identify large EVs FACS was applied with AnnexinV (AnnV) serving as a general EV marker. Small EVs were used as negative control to establish large EV FACS methodology. In total, 23 GbCA, 31 HCC, 15 non-small cell lung carcinoma (NSCLC), 19 colorectal cancer (CRC) patients and 30 healthy subjects were enrolled in the study. Blood sampling took place prior to palliative or curative treatment.

**Results:** (i) gp38 and CD44v6<sup>+</sup> were differentially expressed in wild type mice indicating a likely parental cell population for EVs. (ii) AnnV<sup>+</sup>CD44v6<sup>+</sup> EVs alone allowed a significant discrimination of biliary cancer from HCC, NSCLC, CRC and healthy subjects. AUC values for biliary cancer vs. HCC reached 0.81 for AnnV<sup>+</sup>CD44v6<sup>+</sup>. AnnV<sup>+</sup>gp38<sup>+</sup> and AnnV<sup>+</sup>CD44v6<sup>+</sup>gp38<sup>+</sup> EVs were inferior regarding their diagnostic properties. (iii) AnnV<sup>+</sup>CD44v6<sup>+</sup>gp38<sup>+</sup> EVs predicted the outcome regarding survival time, indicating a possible cut-off value that can be associated with a shorter survival time of gallbladder patients who underwent typically a cholecystectomy, in some cases with a liver resection and lymphadenectomy of hepatoduodenal ligament or endoscopic retrograde cholangiopancreatography (ERCP). Survival log-rank test for difference gave a p value of 0.008. Kaplan Meier curve analysis revealed that the probability of survival is approximately 77.77% at week 20, if AnnV<sup>+</sup>CD44v6<sup>+</sup>gp38<sup>+</sup> EVs were below 13.72/1000 AnnV<sup>+</sup> EVs in GbCA. Survival cut-off was defined as the median of all GbCA AnnV<sup>+</sup>CD44v6<sup>+</sup>gp38<sup>+</sup>EVs/1000 AnnV<sup>+</sup> EVs values. The median survival was given as 8 weeks if EVs were above 13.72 AnnV<sup>+</sup>CD44v6<sup>+</sup>gp38<sup>+</sup> EVs/1000 AnnV<sup>+</sup> EVs and only 18.8% at week 20. In sum, survival probability at week 20 was 4.3 times bigger if AnnV<sup>+</sup>CD44v6<sup>+</sup>gp38<sup>+</sup> EVs were below 13.72/1000 AnnV<sup>+</sup> EVs in GbCA.

**Conclusion:** Our results show that AnnV<sup>+</sup>CD44v6<sup>+</sup>gp38<sup>+</sup> EVs serve as a clinically relevant overall survival biomarker for gallbladder cancer. Thus, EVs represent an early, minimal-invasive screening option for this fatal cancer entity that currently lacks the existence of other clinically reliable serum markers.

#### PO-982

#### Development of a novel rat bioreactor to facilitate manufacture of human hepatocyte cell therapies for the treatment of patients with severe liver diseases

Raymond Hickey<sup>1</sup>, Elizabeth Wilson<sup>1</sup>, Rafal Witek<sup>1</sup>, Tin Mao<sup>1</sup>, Kristen Darrell<sup>1</sup>, Michael Wong<sup>1</sup>, Glen Mikesell<sup>1</sup>, Gabriel Peixoto<sup>1</sup>, Alan Mendoza<sup>1</sup>, Prativa Sharma<sup>1</sup>, Craig Wise<sup>1</sup>, Peter Lee<sup>1</sup>, Tiffany Tse<sup>1</sup>, Douglas Matje<sup>1</sup>, Charity Juang<sup>1</sup>, Janice Kim<sup>1</sup>, Carol Alvarez<sup>1</sup>, Gaetano Faleo<sup>1</sup>, Jason Hulse<sup>1</sup>, Abeba Demelash<sup>1</sup>, Chy-Anh Tran<sup>1</sup>, Kenneth Dorko<sup>1</sup>, Glenn Pierce<sup>1</sup>, FEI Yi<sup>1</sup>, Stanley Hollenbach<sup>1</sup>, Michael Holmes<sup>1</sup>.  
<sup>1</sup>Ambys Medicines, South San Francisco, United States  
 Email: rhipkey@ambys.com.

**Background and aims:** Hepatocyte transplantation is a potential therapy for acute and chronic liver diseases, but this approach has been limited by the availability of high-quality donor livers and well-characterized, functional hepatocytes. Given no methods exist to expand transplantable hepatocytes *ex vivo*, we hypothesized that an

in vivo rat bioreactor could be used for the large-scale expansion of functional primary human hepatocytes for clinical use.

**Method:** An immune-deficient rat model of hereditary tyrosinemia type 1 (*Fah*<sup>-/-</sup>, *Rag1*<sup>-/-</sup>, *Il2rg*<sup>-/-</sup> [FRG] rats) was generated. Phenotypic, histological, and molecular characterization was performed on and off the protective drug NTBC. Transplantation of rodent and human hepatocytes were performed to determine in vivo repopulation kinetics and therapeutic efficacy.

**Results:** FRG rats exhibited normal health while administered NTBC in the drinking water. FRG rats off NTBC displayed a failure-to-thrive phenotype resulting in liver and kidney damage that was associated with hypertyrosinemia and elevated succinylacetone. Transplantation of FAH+ rat hepatocytes, combined with NTBC cycling, provided selective pressure for FAH+ cells to expand and rescue the lethal phenotype. Next, immunodeficiency of FRG rats, needed for xenograft maintenance, was confirmed by flow cytometry which demonstrated severely reduced T, B, and NK cells in peripheral blood. Repopulation of FRG rat livers was achieved with multiple human hepatocyte donors based on human albumin ELISA (>5 mg/ml) and FAH immunohistochemistry (>50%). Purified expanded human hepatocytes exhibited typical hepatocyte transcription profiles based on multiple analyses, including scRNA-Seq. Expanded cells retained their synthetic (e.g. albumin expression), metabolic (e.g. cytochrome P450 activity), and detoxification (e.g. ammonia clearance) functions. Finally, FRG rat-derived human cells demonstrated robust engraftment and expansion in a mouse model of hereditary tyrosinemia. Transplanted human hepatocytes normalized tyrosine and succinylacetone levels, preventing onset of liver failure, and demonstrating therapeutic efficacy of bioreactor-expanded human cells.

**Conclusion:** Development of the FRG rat bioreactor for large-scale expansion of primary human hepatocytes may provide the quantity of high-quality cells necessary for clinical testing of hepatocyte transplantation as an alternative to organ transplantation for severe liver diseases.

**PO-1119**

**Anti-apoptotic effect of mycophenolate mofetil in human hepatocytes cultures**

Razvan Iacob<sup>1,2</sup>, Mihaela Uta<sup>1</sup>, Andrei Chiosa<sup>1</sup>, Ioana Manea<sup>1</sup>, Luminita Stoica<sup>1</sup>, Codruta Popa<sup>1</sup>, Susanne Beckebaum<sup>3</sup>, Vito Cicinnati<sup>3</sup>, Cristian Gheorghe<sup>1,2</sup>, Simona Dima<sup>1</sup>, Irinel Popescu<sup>1</sup>, Liliana Simona Gheorghe<sup>1,2</sup>, Speranta Iacob<sup>1,2</sup>. <sup>1</sup>Fundeni Clinical Institute, Center for Digestive Diseases and Liver Transplantation; <sup>2</sup>Carol Davila University of Medicine and Pharmacy, Department of Gastroenterology; <sup>3</sup>Universitätsklinikum Münster-UKM  
Email: raziacob@gmail.com.

**Background and aims:** Liver transplant (LT) recipients have higher hepatic apoptotic markers in comparison to non-transplanted subjects. This is due to the immunosuppression agents used after LT with cytotoxic and proapoptotic effects, promoting liver apoptosis and contributing to inflammation, allograft injury and subsequent fibrosis. Studies regarding the effects of tacrolimus or cyclosporine on apoptosis are contradictory. Also, the cytotoxic action of mycophenolate mofetil on hepatocytes remains ill-defined. The aim of our study was to assess the apoptotic effects of immunosuppressive agents in human hepatocytes cultures isolated from cirrhotic livers.

**Method:** Human cirrhotic hepatocytes have been isolated from liver explant fragments by the collagenase perfusion technique described by Seglen et al. In contrast to normal hepatocytes cirrhotic hepatocytes generate rapidly proliferative cultures, that can be propagated and represent a valuable in vitro study model for personalized medicine. Cirrhotic hepatocytes have been cultured in low glucose DMEM culture medium and have been treated for 24 hours with 1 µM tacrolimus (TAC), sirolimus (SIR), mycophenolate mofetil (MMF), or combinations (TAC + SIR, MMF + TAC). At 24 hours apoptosis and necrosis was assessed using Tali™ Apoptosis Kit-

Annexin V Alexa Fluor™ 488 and Propidium Iodide (Thermo Scientific). Gene expression has been assessed by qRT-PCR using a microarray of 19 genes significant for apoptosis.

**Results:** Cytometry analysis has indicated the lowest apoptotic cells percentage in human cirrhotic hepatocytes cultures treated with MMF (5%) and TAC+MMF (2%) whereas the highest apoptosis percentage was registered for the TAC alone (11%). The highest toxicity indicated by apoptosis and necrosis was registered for the association of TAC + SIR (17%). Gene expression analysis has suggested a marked antiapoptotic effect of MMF in human cirrhotic hepatocytes cultures, mediated by a significant decrease in the gene expression of membrane receptors mediating apoptosis (TNFRSF1A and 10A, CD40 and FAS), the down regulation of genes mediating mitochondrial apoptosis (BAK1, BAX, RIPK1, ASK1, SMAC, HTRA2), of apoptosis specific effector proteins, especially DFFB-CAD, parallel by a significant decrease in the expression of the transcription factor NFκB1. The gene expression results are concordant to cytometry study results, indicating the lowest apoptotic effect for MMF and MMF+TAC immunosuppressive regimens.

**Conclusion:** MMF based immunosuppressive regimens have a favourable anti-apoptotic profile in vitro, in human cirrhotic hepatocytes cultures, as suggested by cytometry and gene expression studies, supporting its use in case of liver transplants recipients at high risk for liver graft fibrosis.

**PO-1207**

**Selective hypoxia-inducible-factor stabilisation alleviates hepatocellular steatosis and ballooning in a rodent model of 70% liver resection**

Samuele Iesari<sup>1,2</sup>, Isabelle Leclercq<sup>3</sup>, Nicolas Joudiou<sup>4</sup>, Mina Komuta<sup>5</sup>, Aurelie Daumerie<sup>6</sup>, Jérôme Ambroise<sup>7</sup>, Alexandra Dili<sup>3</sup>, Caroline Bouzin<sup>6</sup>, Bernard Gallez<sup>4</sup>, Francesco Pisani<sup>2</sup>, Eliano Bonaccorsi Riani<sup>1</sup>, Pierre Gianello<sup>1</sup>. <sup>1</sup>Université catholique de Louvain, Pôle de Chirurgie Expérimentale et Transplantation, Institut de Recherche Expérimentale et Clinique, Brussels, Belgium; <sup>2</sup>University of L'Aquila, Department of Biotechnological and Applied Clinical Sciences, L'Aquila, Italy; <sup>3</sup>Université catholique de Louvain, Laboratory of Hepato-Gastroenterology, Institut de Recherche Expérimentale et Clinique, Brussels, Belgium; <sup>4</sup>Université catholique de Louvain, Nuclear and Electron Spin Technologies, Louvain Drug Research Institute, Brussels, Belgium; <sup>5</sup>Keio University, Department of Pathology, Tokyo, Japan; <sup>6</sup>Université catholique de Louvain, IREC Imaging Platform, Institut de Recherche Expérimentale et Clinique, Brussels, Belgium; <sup>7</sup>Université catholique de Louvain, Centre for Applied Molecular Technologies, Institut de Recherche Expérimentale et Clinique, Brussels, Belgium  
Email: samuele.iesari@gmail.com.

**Background and aims:** Small-for-size syndrome looms over patients needing liver resection or living-donor transplantation. Hypoxia has been shown to be crucial for the success of liver resection in the very early postoperative phase. While poorly acceptable as such in real-world clinical practice, hypoxia responses can still be simulated by pharmacologically raising levels of its transducers, the hypoxia-inducible factors (HIF).

We aimed to assess the potential role of a selective inhibitor of HIF degradation in 70% hepatectomy (70%Hx).

**Method:** We tested the required dose of roxadustat to stabilize liver HIF1alpha in a pilot study. We then performed 70% hepatectomy in male 8-week-old Lewis rats and administered 25 mg/kg of roxadustat (RXD25) at the end of the procedure. We assessed regeneration: ki67 and EdU immunofluorescent labelling, and histological parameters. We assessed also liver function via a blood panel and functional gadoxetate-enhanced magnetic resonance imaging, up to 47 hours after the procedure. Metabolic results were analysed by means of RNA sequencing.

**Results:** Roxadustat effectively increased early HIF1alpha transactivity: 1-hour nuclear-to-cytoplasm ratio in the study group: median 1.42 (interquartile range = 1.26–1.75) vs. 0.88 (0.83–1.07) in the

## POSTER PRESENTATIONS

control group,  $p = 0.022$ . Roxadustat did not improve liver function or regeneration but, on postoperative day 1, treated livers showed mitigation in hepatocellular steatosis and ballooning, hallmarks of cellular stress after liver resection. RNA sequencing confirmed that roxadustat unexpectedly upregulated gene pathways associated with lipid breakdown and cellular respiration.

Figure: Table 1: Day 1 histology report

	70%Hx- RXD25 n (%)	70%Hx- placebo n (%)	Sham-placebo n (%)	P
Mitoses	0/13 (0.00)	0/8 (0.00)	0/8 (0.00)	-
Inflammation	0/13 (0.00)	0/8 (0.00)	0/8 (0.00)	-
Endothelial denudation	0/13 (0.00)	0/8 (0.00)	0/8 (0.00)	-
Microvascular thrombosis	0/13 (0.00)	0/8 (0.00)	0/8 (0.00)	-
Parenchymal haemorrhage	0/13 (0.00)	0/8 (0.00)	0/8 (0.00)	-
Necrosis	0/11 (0.00)	0/8 (0.00)	0/7 (0.00)	-
Hepatocellular ballooning	2/13 (15.38)	7/8 (87.50)	1/8 (12.50)	0.001 <sup>a</sup>
Steatosis ( $\geq 5\%$ )	5/13 (38.46)	7/8 (87.50)	1/8 (12.50)	0.005 <sup>a</sup>
Degree of steatosis Undetectable (steatosis 0%)	3/13 (23.08)	1/8 (12.50)		0.028 <sup>b</sup>
Healthy hepatocytes (steatosis <5%)	5/13 (38.46)	0/8 (0.00)		
Mild (steatosis 5–33%)	5/13 (38.46)	4/8 (50.00)		
Moderate (steatosis 33–66%)	0/13 (0.00)	3/8 (37.50)		
Severe (steatosis >66%)	0/13 (0.00)	0/8 (0.00)		

<sup>b</sup>Maximum likelihood chi square test.

<sup>d</sup>Mantel-Haenszel test of trend.

**Conclusion:** Selective HIF stabilisation did not result in an increase in liver function after standard liver resection. Yet roxadustat alleviated markers of hepatocellular suffering after standard liver resection and induced intriguing metabolic changes that are worth studying in extended liver resection and fatty liver diseases.

### PO-1346

#### Double negative T cells mediate CD39-dependent protection in hepatic ischemia and reperfusion injury

Hua Jin<sup>1</sup>, Mingyang Li<sup>1</sup>, Chunpan Zhang<sup>1</sup>, Guangyong Sun<sup>1</sup>, Dong Zhang<sup>1</sup>. <sup>1</sup>Beijing Key Laboratory of Tolerance Induction and Organ Protection in Transplantation, Beijing Friendship Hospital, Capital Medical University, Beijing, China  
Email: zhangd@ccmu.edu.cn.

**Background and aims:** Hepatic ischemia and reperfusion injury (HIRI) is a significant cause of morbidity and mortality following liver transplantation and major hepatic resections. Double negative T cells (DNT) are unique regulatory T cells which are discovered in recent decades. We have demonstrated that DNT significantly inhibit allo- or auto-immune responses mainly through perforin/granzyme B pathway. However, whether other mechanisms are involved in the immune regulation of DNT and the potential application of DNT in HIRI are still unknown. The aim of the research is to investigate the mechanisms involved in the immune regulation of DNT and the potential application of DNT in hepatic ischemia and reperfusion injury.

**Method:** WT or CD39 deficient DNT were adoptively transferred before surgery, and then the mouse model of partial (70%) warm HIRI was established. In vitro, WT or CD39 deficient DNT were cocultured with neutrophils with or without ATP stimulation. Transcriptome sequencing of ATP treated WT or CD39 deficient DNT were analyzed.

**Results:** In this study, we found DNT highly expressed CD39, a cell surface enzyme hydrolyzing extracellular ATP. Adoptively transferring with wild type (WT) but not CD39 deficient DNT significantly inhibited TNF- $\alpha$  and IL-1 $\beta$  secretion of liver infiltrated neutrophils, decreased neutrophil extracellular traps (NETs) generation and increased neutrophil apoptosis in warm HIRI in both C57BL/6 and T cell deficient B6.Rag2/IL2rg KO mice.

Mechanistically, compared with WT DNT, CD39 deficient DNT were unable to hydrolyze extracellular cytotoxic ATP and became apoptotic under ATP stimulation. Transcriptome sequencing analysis suggested that ATP treated CD39 KO DNT had reduced expression of cell activation, survival, proliferation, chemotaxis and MAPK signaling pathway related genes than WT DNT. However, no differences of Prf1 or Gzmb gene expression were observed between groups. Furthermore, the level of extracellular immunosuppressive molecule, adenosine, was significantly higher in the culture of ATP treated WT DNT compared with that of CD39 deficient DNT. ATP-treated WT DNT but not CD39 deficient DNT significantly increased neutrophil apoptosis and inhibited inflammatory mediators secreted by neutrophils in vitro, suggesting that CD39 expressed by DNT might drive a shift from an ATP driven proinflammatory environment to an anti-inflammatory milieu induced by adenosine.

**Conclusion:** Our study reveals a new intrinsic mechanism that CD39 is crucial for DNT homeostasis and immunosuppressive function. These data support the concept and the feasibility of potentially utilizing this novel cell therapy for the prevention of HIRI during liver transplantation or hepatic surgery.

### PO-1422

#### Longitudinal monitoring of bioengineered whole liver constructs using a novel perfusion bioreactor

Omolola Ajayi<sup>1</sup>, Lisa Sassi<sup>1</sup>, Sara Campinoti<sup>1</sup>, Claire McQuitty<sup>1,2</sup>, Dipa Natarajan<sup>1</sup>, Riccardo Rayan Siena<sup>1</sup>, Sara Mantero<sup>3</sup>, Alessandro Pellegata<sup>3,4</sup>, Paolo De Coppi<sup>4,5</sup>, Shilpa Chokshi<sup>1,2</sup>, Luca Urbani<sup>1,2</sup>. <sup>1</sup>Institute of Hepatology London; <sup>2</sup>King's College London, Faculty of Life Sciences and Medicine; <sup>3</sup>Politecnico di Milan, Department of Chemistry, Materials and Chemical Engineering "Giulio Natta"; <sup>4</sup>University College of London, Stem Cells and Regenerative Medicine, Great Ormond Street Institute of Child Health, United Kingdom; <sup>5</sup>Great Ormond Street Hospital, London, Specialist Neonatal and Pediatric Surgery

**Background and aims:** Whole liver constructs from decellularized scaffolds hold significant promise for in vitro disease modelling and regenerative medicine as a valuable alternative for organ transplantation. Nevertheless, there are still constraints to the use of whole organ constructs, with one of the biggest issues being the inadequacy of whole organ specific bioreactors to support multi-cellular seeding, long term cell viability and monitoring in culture.

Here, we have designed and validated a novel custom-made bioreactor for long-term 3D hepatocyte culture within a whole liver construct.

**Method:** We designed and produced a custom-made bioreactor using materials with high chemical resistance, not susceptible to corrosion or release of cytotoxic products, specifically for long-term culture experiments. The chamber is compatible with the use of bioluminescence imaging for longitudinal monitor of cells at different time points and to allow changing of culture media and addition of chemical/toxic compound during culture.

Rat whole liver scaffolds were obtained using perfusion decellularization. Luc+HepG2 cells and primary human hepatocytes (PHH) were perfusion-seeded into whole liver decellularized scaffolds and cultured for up to 30 days in the perfusion bioreactor or in static culture conditions as control. Dynamic perfusion was obtained using a programmable syringe pump, providing unidirectional flow within the bioreactor. Seeded cells were longitudinally monitored non-invasively using bioluminescence and periodic sampling, assessing cell viability, distribution and function.

Figure: (abstract: PO-1422)

**Results:** We demonstrate the advantages of perfusion culture compared to static conditions, for both HepG2 cells and PHH, shown by significantly higher cell viability and uniform cell distribution verified by bioluminescence and histology. Perfusion culture facilitated enhanced cellular function in respect to static conditions, confirmed by increased albumin and urea production and expression of CYP enzymes, HNF4 $\alpha$  and FOXA2.

**Conclusion:** The perfusion bioreactor has proven suitable for supporting engineered liver constructs, successfully maintaining hepatocyte culture long-term preserving viability, distribution and functionality with the potential to culture multiple cell types for regenerative medicine and disease modelling.

respectively. The nomogram showed good calibration, and decision curve analysis demonstrated the nomogram is of clinical value.

Figure:

**Conclusion:** We developed a new nomogram that uses basic clinical and laboratory variables to predict the probability of MVI before surgery for HCC patients. This nomogram can help clinicians choose appropriate treatment procedures.

## Liver tumours: Clinical aspects except therapy

### PO-250

#### Prognostic value of a nomogram predicting microvascular invasion for patients with hepatocellular carcinoma

Liying Ren<sup>1</sup>, Dongbo Chen<sup>2</sup>, Wentao Xu<sup>1</sup>, Pu Chen<sup>2</sup>, Tingfeng Xu<sup>1</sup>, Hongsong Chen<sup>2</sup>, Weijia Liao<sup>1</sup>. <sup>1</sup>Medical University Affiliated Hospital, Laboratory of Hepatobiliary and Pancreatic Surgery, Guilin, China; <sup>2</sup>Peking University People's Hospital, Institute of Hepatology, Beijing, China

Email: liaoweijia288@163.com.

**Background and aims:** For patients with hepatocellular carcinoma (HCC), preoperative diagnosis of microvascular invasion (MVI) is a difficult task. This study aimed to develop and validate a nomogram to predict the risk of MVI before surgery.

**Method:** A total of 424 HCC patients undergoing curative resection were entered into the study. Independent risk factors were identified by univariate/multivariate analyses and were built into a nomogram to estimate the risk of MVI. The receiver operating characteristic curve (ROC), concordance index (c-index), calibration curve and decision curve analysis were used to evaluate predictive performance.

**Results:** Prealbumin, gamma-glutamyl transpeptidase (GGT), alpha-fetoprotein (AFP) level, and tumor size were independent risk factors of MVI and formed the basis of the nomogram. The area under the ROC of nomogram was 0.775 (C-indexes of 0.781) in training and 0.787 (C-indexes of 0.785) in validation cohort for predicting MVI,

### PO-409

#### Cause of Death and Cause-Specific Mortality in Primary Liver Cancer: Temporal Trends in a Hepatitis B Virus Endemic Area

Bo Hyun Kim<sup>1,2</sup>, Dahhay Lee<sup>2</sup>, Kyu-Won Jung<sup>3</sup>, Young-Joo Won<sup>2,3</sup>, Hyunsoo Cho<sup>2,3</sup>. <sup>1</sup>National Cancer Center, Center for Liver and Pancreatobiliary Cancer, Goyang-si, Korea, Rep. of South; <sup>2</sup>National Cancer Center, Department of Cancer Control and Population Health, Graduate School of Cancer Science and Policy, Goyang-si, Korea, Rep. of South; <sup>3</sup>National Cancer Center, Division of Cancer Registration and Surveillance, National Cancer Control Institute, Goyang-si, Korea, Rep. of South

**Background and aims:** Causes of death in liver cancer patients have not been studied in detail. We aimed to investigate the causes of

## POSTER PRESENTATIONS

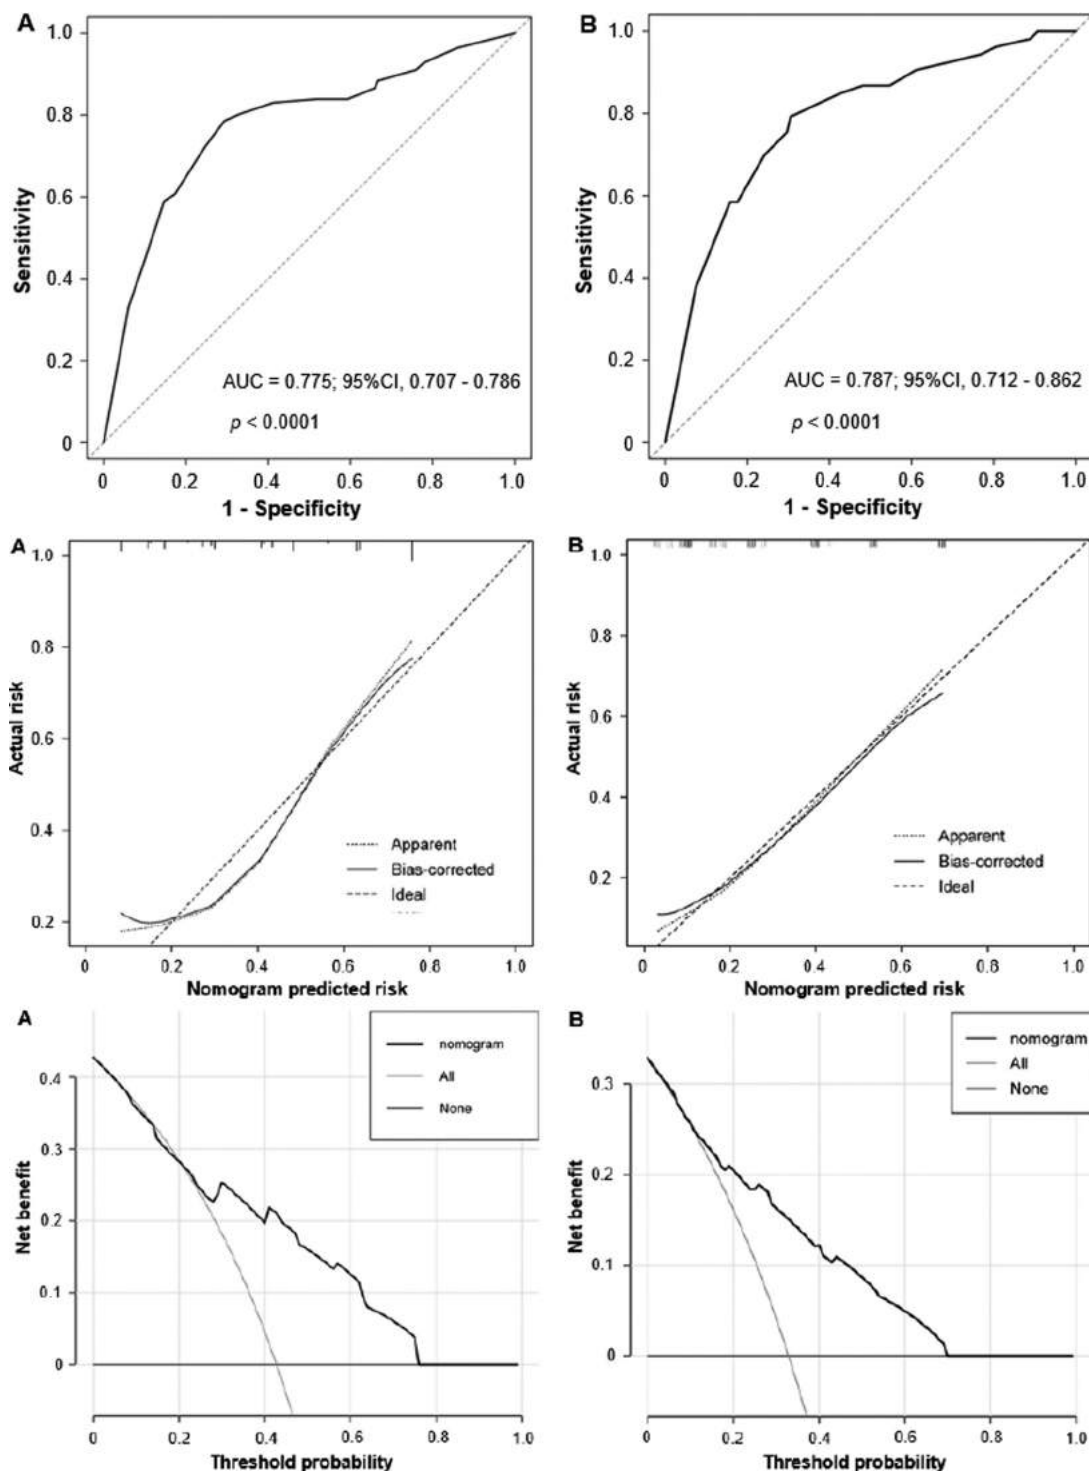

Figure: (abstract: PO-250)

death and cause-specific mortality trends in primary liver cancer patients.

**Method:** Causes of death and proportionate mortalities in liver cancer patients diagnosed from 2000–2016 were investigated using a retrospective cohort from nationwide cancer registry data ( $n = 231,338$ ). Risks of non-cancer deaths relative to the general population were compared by standardized mortality ratios (SMR). The 5-year probabilities of death were estimated under the competing risks.

**Results:** Of the total, 179,921 patients died. Among the deaths, 92.4%, 1.7%, and 6.0% died of primary liver cancer, cancer from other sites, and non-cancer illnesses. Proportionate mortality from liver cancer persisted high. The five-year probability of death attributed to liver cancer varied by tumor stage from 42% to 94% and remained high after ten years post-diagnosis. Mortality from other causes has continuously increased from 3.3% in 2002 to 11.7% in 2016. The most common causes of non-cancer death were liver disease (34.5%) and viral hepatitis (10.7%). Relative to the Korean general population,

Figure: (abstract: PO-250)

mortality risks due to liver disease (SMR = 15.6, 95%CI: 15.1, 16.1) and viral hepatitis (SMR = 46.5, 95%CI: 43.9, 49.2) were higher in liver cancer patients. Meanwhile, mortality risks due to suicide were also higher (SMR = 2.6, 95%CI: 2.4, 2.8), suggesting an additional need for psychological support for these patients.

**Conclusion:** Patients with liver cancer are most likely to die from liver cancer even ten years after the diagnosis. These findings highlight a need for specialized long-term follow-up care for patients with liver cancer.

Figure: (abstract: PO-409)

## POSTER PRESENTATIONS

### PO-707

#### Thyroid disease and hepatocellular carcinoma survival. A Danish nationwide cohort study

Linda Skibsted Kornerup<sup>1</sup>, Frederik Kraglund<sup>1</sup>, Ulla Feldt-Rasmussen<sup>2</sup>, Peter Jepsen<sup>1,3</sup>, Hendrik Vilstrup<sup>1</sup>. <sup>1</sup>Aarhus University Hospital, Hepatology and Gastroenterology, Aarhus, Denmark; <sup>2</sup>Rigshospitalet, Endocrinology, København, Denmark; <sup>3</sup>Aarhus University Hospital, Clinical Epidemiology, Aarhus, Denmark  
Email: lindajen@rm.dk.

**Background and aims:** Hepatocellular carcinoma (HCC) is the fourth leading cause of cancer mortality worldwide. Recent animal studies suggest that thyroid hormone treatment improves HCC prognosis. The aim of this study was to describe the association between thyroid disease and HCC prognosis in humans.

**Method:** We performed a nationwide cohort study including all persons with an HCC diagnosis from 2000–2018. Patients' age, sex, HCC treatment, and diagnoses of thyrotoxicosis, nontoxic goitre, and myxoedema, were obtained from Danish national healthcare registries. We used regression models to examine the association between thyroid disease and mortality hazard and restricted mean survival time after HCC diagnosis, adjusting for confounding by sex and age.

**Results:** We included 4,812 patients with HCC and 107 patients with thyroid disease. Median follow-up time was 5 months (total 5,985 person-years). The adjusted mortality hazard ratio was 0.68 (95% CI 0.47–0.96) for thyrotoxicosis and 0.60 (95% CI 0.41–0.88) for nontoxic goitre. The restricted mean survival time during the five years following HCC diagnosis was 6.8 months (95% CI 1.1–12.6) longer for HCC patients with thyrotoxicosis than for patients without thyroid disease, and it was 6.9 months (95% CI 0.9–12.9) longer for HCC patients with nontoxic goitre than for patients without thyroid disease.

Figure:

**Conclusion:** In this large nationwide cohort study, thyrotoxicosis and nontoxic goitre were associated with prolonged HCC survival. Our results are concordant with recently published animal studies.

#### Two trans-arterial chemo-embolizations during liver transplantation waiting list and absence of complete radiological response: time for a systemic strategy?

Edoardo Poli<sup>1</sup>, Marc Antoine Allard<sup>2</sup>, Ilias Kounis<sup>1</sup>, Alina Pascale<sup>1</sup>, Cyrille Feray<sup>1</sup>, Catherine Guettier<sup>3</sup>, Maite Lewin<sup>4</sup>, Jean-Charles Duclos-Vallée<sup>1</sup>, Audrey Coilly<sup>1</sup>, Eric Vibert<sup>2</sup>, René Adam<sup>2</sup>, Antonio Sa Cunha<sup>2</sup>, Didier Samuel<sup>1</sup>, Daniel Cherqui<sup>2</sup>, Olivier Rosmorduc<sup>1</sup>. <sup>1</sup>Centre Hépatobiliaire, Paul Brousse Hospital,

Hepatology, Villejuif, France; <sup>2</sup>Centre Hépatobiliaire, Paul Brousse Hospital, Hepatobiliary Surgery, Villejuif, France; <sup>3</sup>Kremlin-Bicêtre Hospital, Pathology, Le Kremlin Bicêtre, France; <sup>4</sup>Centre Hépatobiliaire, Paul Brousse Hospital, Radiology, Villejuif, France  
Email: edoardo.poli88@gmail.com.

**Background and aims:** Hepatic trans-arterial chemoembolization (TACE) is a widely used treatment to prevent hepatocellular carcinoma (HCC) progression in patients enlisted for liver transplantation (LT). Several sessions can be performed but the clinical benefit of repeated TACE remains uncertain. Several therapeutic alternatives are currently becoming available. Our study aimed to assess the impact of TACE number and efficacy on the risk of pre-LT tumor-related delisting and/or post-LT HCC recurrence.

**Method:** All patients enlisted for LT who prospectively received at least one TACE for HCC within the LT criteria (French AFP score  $\leq 2$ ) in a single institution, from 2013 to 2018, were included. Treatment strategy failure was defined as pre-LT tumor-related delisting or post-LT HCC recurrence. TACE response was evaluated using the mRECIST criteria to identify the absence of a complete radiological response (CRR).

**Results:** A total of 172 patients were included in the study. At last follow-up, 127 (73.8%) patients were transplanted, 37 (21.5%) were delisted because of HCC progression and 14 presented post-LT HCC recurrence (11% of transplant recipients). At univariate analysis, factors associated with treatment failure were: higher pre- and post-TACE serum AFP, absence of CRR in post-TACE, number of TACE sessions before LT  $> 2$  (Table 1). The risk of treatment failure was 38% in patients who received  $> 2$  TACE vs. 20% in patients who received 1 or 2 TACE ( $p = 0.02$ ). At multivariate analysis, being treated with  $> 2$  TACE was highly predictive of treatment failure [RR 3.3 (1.52–7.31),  $p = 0.003$ ] after adjusting for serum AFP, Child-Pugh score, maximum HCC size and number of HCC. Moreover, the overall survival was significantly decreased in patients without a CRR compared to those with a CRR after 1 (if unique) or 2 TACE (67% vs 88% at 2 years from the date of enlisting;  $p = 0.003$ ; Figure 1).

Table:

	Univariate analysis		
	Delisting of post-LT HCC recurrence		p
	NO N = 127	YES N = 45	
Age, years	62.0 [33.0;74.0]	60.0 [42.0;70.0]	0.358
Male gender, n (%)	109 (85.8%)	39 (86.7%)	1.000
Cirrhosis aetiology:			
–Virus	51 (40.2%)	16 (35.6%)	0.520
–Alcohol	46 (36.2%)	22 (48.9%)	
–NASH	18 (14.2%)	4 (8.89%)	
–other	12 (9.45%)	3 (6.67%)	
MELD score	8 [6–20]	9 [6–18]	0.441
AFP pre-TACE (ng/ml)	7.40 [2.00–700]	17.0 [3.00–780]	0.002
AFP post-TACE (ng/ml)	6.00 [1.60–519]	41.0 [1.40–25979]	$< 0.001$
Number of HCC	2 [1–6]	2 [1–9]	0.708
Maximum HCC size, mm	23 [7–60]	24 [12–50]	0.651
Absence of CRR	67 (52.8%)	43 (95.6%)	$< 0.001$
Number of TACE sessions	2 [1–5]	2 [1–6]	0.068
$> 2$ sessions of TACE, n (%)	36 (28.3%)	22 (48.9%)	0.020

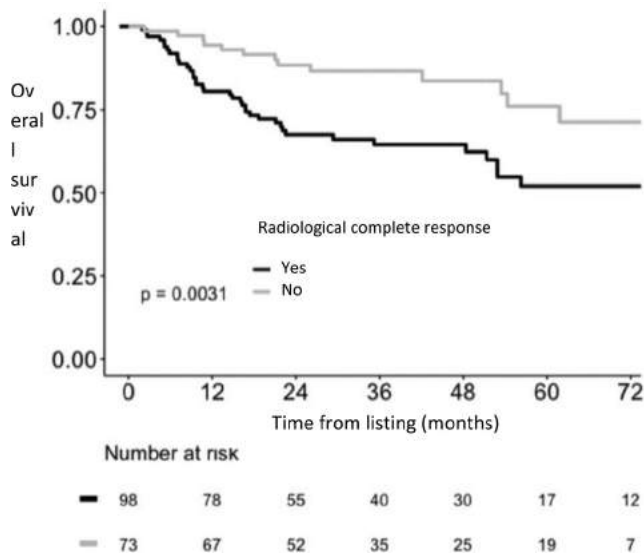

Figure:

**Conclusion:** Enlisted patients who receive more than 2 TACE without complete response have a poorer outcome with a higher risk of pre-LT tumor-related delisting or of post-LT HCC recurrence. An alternative strategy should be considered in these cases.

**PO-1090**

**The impacts of gender differences in muscle mass and adipose tissue on the outcomes of hepatocellular carcinoma after surgical resection**

Pei-Chang Lee<sup>1,2,3</sup>, Tsung-Yi Cheng<sup>1</sup>, Kuo-Wei Huang<sup>1</sup>, Gar-Yang Chau<sup>4</sup>, Yi-Hsiang Huang<sup>1,3,5</sup>, Ming-Chih Hou<sup>1,3</sup>, Chien-Wei Su<sup>1,3</sup>. <sup>1</sup>Taipei Veterans General Hospital, Division of Gastroenterology and Hepatology, Department of Medicine, Taipei, Taiwan; <sup>2</sup>National Yang-Ming University School of Medicine, Institute of Pharmacology, Taiwan; <sup>3</sup>National Yang-Ming University School of Medicine, Faculty of Medicine, Taiwan; <sup>4</sup>Taipei Veterans General Hospital, Division of General Surgery, Department of Surgery, Taiwan; <sup>5</sup>National Yang-Ming University School of Medicine, Institute of Clinical Medicine, Taiwan  
Email: cwsu2@vghtpe.gov.tw

**Background and aims:** Body composition assessments are objective surrogates reflecting nutrition status and severity of liver diseases. Sarcopenia has been reported to predict mortality in patients with hepatocellular carcinoma (HCC). However, the roles of muscle mass and adipose tissue in HCC after resection are still uncertain and diverse. In this study, we aimed to assess and investigate the impacts of muscle and adipose tissues on outcomes of HCC after surgical resection distinguished by genders.

**Method:** From January 2013 to December 2016, 304 consecutive patients who received surgical resection of HCC in Taipei Veterans General Hospital were retrospectively reviewed. All patients had received computed tomography (CT) for diagnosis and post-operative follow-up. Cross areas of adipose tissue and muscle mass were measured from CT scan by SliceOmatic software at L3 vertebra level; and body composition indices (cm<sup>2</sup>/m<sup>2</sup>), including psoas muscle index (PMI), skeletal muscle index (SMI), intramuscular adipose tissue index (IMATI), visceral adipose tissue index (VATI) and subcutaneous adipose tissue index (SATI) were calculated. Optimal cut-off values were defined by area under receiver operating characteristic curve (AUROC), and survival analyses were performed.

**Results:** No significant change of body composition was observed from the images before and after surgical resection of HCC (median PMI: 8.58 vs 8.59 cm<sup>2</sup>/m<sup>2</sup>, p = 0.99, SMI: 50.17 vs 49.66 cm<sup>2</sup>/m<sup>2</sup>, p = 0.427, IMATI: 3.49 vs 3.38 cm<sup>2</sup>/m<sup>2</sup>, p = 0.385, VATI: 40.61 vs 36.3 cm<sup>2</sup>/m<sup>2</sup>, p = 0.142, SATI: 45.88 vs 44.83 cm<sup>2</sup>/m<sup>2</sup>, p = 0.504). Male patients with post-surgery body composition indices including SMI less than 46.6 cm<sup>2</sup>/m<sup>2</sup> (OR: 2.029; 95% C.I. 1.096–3.758, p = 0.024), IMATI higher than 2.9 cm<sup>2</sup>/m<sup>2</sup>, (OR: 2.671; 95% C.I. 1.389–5.134, p = 0.003) and SATI lower than 44.8 cm<sup>2</sup>/m<sup>2</sup> (OR: 2.299; 95% C.I. 1.200–4.403, p = 0.012) were independent predictors to survival after surgery. Female patients with post-surgery IMATI higher than 5.0 cm<sup>2</sup>/m<sup>2</sup> (OR: 5.453; 95% C.I. 1.571–18.927, p = 0.008) had significant worse survival after surgery.

**Conclusion:** In conclusion, body composition after surgery, including muscle mass, muscle steatosis and subcutaneous fat mass could predict survival in male HCC patients; only muscle steatosis could predict survival in female HCC patients, especially in those with better liver reserves.

**PO-1147**

**Global burden of major gastrointestinal cancers and its association with socioeconomic development status, 1990–2019**

Xuan Dong<sup>1</sup>, Jing-Mao Li<sup>2</sup>, Dan-Yi Zeng<sup>1</sup>, Qing-Qing Xing<sup>1</sup>, Yan-Dan Ren<sup>3</sup>, Wei-Ming Chen<sup>4</sup>, Yan-Yan Cai<sup>5</sup>, Kuangnan Fang<sup>2</sup>, Mei-Zhu Hong<sup>6</sup>, Jin-Shui Pan<sup>1</sup>. <sup>1</sup>First Affiliated Hospital of Fujian Medical University, Hepatology, Fuzhou, China; <sup>2</sup>Xiamen University, Department of Statistics, Xiamen, China; <sup>3</sup>Zhongshan Hospital Xiamen University, Department of Gastroenterology, Xiamen, China; <sup>4</sup>Xiamen University, School of Medicine, Xiamen, China; <sup>5</sup>Fujian Medical University, School of Clinical Medicine, Fuzhou, China; <sup>6</sup>Mengchao Hepatobiliary Hospital of Fujian Medical University, Traditional Chinese Medicine, Fuzhou, China  
Email: 363111396@qq.com

**Background and aims:** Among the top seven causes of cancer-related death, common gastrointestinal tract cancers are major contributors including colon and rectum cancer, stomach cancer, liver cancer, pancreatic cancer, and esophageal cancer. Data on global and country-specific levels and trends of common cancers of the gastrointestinal tract are essential to understand the impact of these diseases and to help policymakers to allocate resources.

**Method:** Cancer mortality, and incidence were obtained from GBD 2019, which were stratified by country and territory, sex, and level of Socio-demographic Index (SDI). The association between burden of cancers and socioeconomic development status, represented in SDI, was also described.

**Results:** In 2019, there was an age-standardized incidence rate of 61.9 (95% CI 56.1–67.6) per 100 000 person-years in terms of five major cancers of the gastrointestinal tract. There was a decrease in age-standardized death rates due to the five common tumors from 1990 to 2019 (–22.7% [–31.1 to –13.5]). Globally, Mongolia, and several regions or countries located in East Asia exhibited the highest age-standardized incidence rates in 2019. Stratified using SDI, the high SDI, and high-middle SDI locations recorded the highest incidence rate and death rate of colon and rectum cancer and pancreatic cancer, whereas the low-middle SDI, and low SDI locations possessed the highest-burden of stomach cancer and esophageal cancer.

**Conclusion:** There is a pronounced association between socioeconomic development status and burden of common cancers of the gastrointestinal tract. Data of GBD 2019 are valuable for policymakers to implement cost-effective interventions for gastrointestinal tract cancers.

**Weight variations and level of estrogen exposure predict the evolution of hepatocellular adenomas**

Alix Demory<sup>1</sup>, Jean Marie Peron<sup>2</sup>, Maxime Ronot<sup>3</sup>, Julien Calderaro<sup>4</sup>, Fatima Zohra Mokrane<sup>5</sup>, Selves Janick<sup>6</sup>, Charlotte Maulat<sup>7</sup>, Thomas Eche<sup>5</sup>, Giuliana Amaddeo<sup>8</sup>, Valérie Paradis<sup>9</sup>, Marianne Ziolo<sup>10</sup>, Olivier Sutter<sup>11</sup>, Lorraine Blaise<sup>1</sup>, Nathalie Ganne<sup>1</sup>, Jessica Zucman-Rossi<sup>12</sup>, Jean Charles Nault<sup>1</sup>. <sup>1</sup>Avicenne Hospital, Liver Unit, Bobigny, France; <sup>2</sup>Rangueil Hospital, Liver Unit, Toulouse, France; <sup>3</sup>Beaujon Hospital, Radiology, Clichy, France; <sup>4</sup>Mondor Hospital, Pathology, Créteil, France; <sup>5</sup>Rangueil Hospital, Radiology, Toulouse, France; <sup>6</sup>Rangueil Hospital, Pathology, Toulouse, France; <sup>7</sup>Rangueil Hospital, Digestive Surgery, Toulouse, France; <sup>8</sup>Mondor Hospital, Liver Unit, Créteil, France; <sup>9</sup>Beaujon Hospital, Pathology, Clichy, France; <sup>10</sup>Avicenne Hospital, Pathology, Bobigny, France; <sup>11</sup>Avicenne Hospital, Radiology, Bobigny, France; <sup>12</sup>Cordeliers Research Center, Inserm U1138, Paris, France  
 Email: alix.demory@gmail.com

**Background and aims:** The natural history of hepatocellular adenomas (HCA) remains to be better described especially in non-resected patients. We aim to identify the predictive factors of HCA evolution after estrogen withdrawal.

**Method:** We retrospectively included patients with a histological diagnosis of HCA on a biopsy or a surgical resection between 2000 and 2019 in 3 centers. Clinical, radiological and pathological data were collected in order to identify predictive factors of radiological evolution of HCA in number and in size (using RECIST criteria) and of bleeding and malignant transformation. HCA were classified as *HNF1A* inactivated, inflammatory and *CTNNB1* mutated HCA. We built a score based on variables modulating estrogen levels: body

mass index, duration of estrogen-based contraception and alcohol intake. An external cohort from a 4<sup>th</sup> center was used to validate this score.

**Results:** 184 patients were included with 161 women (87.6%), 88.6% with an estrogen-based contraception during a median of 12 years, all have estrogen withdrawal after the diagnosis. 49.8% of patients had at least one inflammatory HCA, 31.1% at least one *HNF1A* inactivated HCA and 8% at least one *CTNNB1* mutated HCA. 21 symptomatic bleedings (11.4%) and 12 transformation in HCC (6.5%, half in men) were identified. HCA >5 cm at imaging was associated with symptomatic bleeding (p=0.003). Male (p=0.0005) and *CTNNB1* mutated HCA (p=0.0001) were associated with malignant transformation. An age <37 years old (median age of the population) was associated with bleeding (p=0.004) whereas those of >37 years old were at risk of HCC occurrence (p=0.024). 119 patients with residual HCA were followed-up for a median of 4.5 years. Radiological regression was observed in 31%, stabilization in 47% and progression in 22% of the cases. Weight loss was associated with regression (p=0.0004) and weight gain with progression (p=0.0021). A high estrogen exposure score predicted radiological regression (OR 2.45; CI95% [1.347-5.553]; p=0.009) with a linear relation between the rate of estrogen exposure and the probability of regression. This result was confirmed in an external cohort of 72 female patients (p=0.0032).

**Conclusion:** Weight variation is strongly associated with evolution of HCA in size and number. Moreover, a score of estrogen exposure predicts regression of HCA during follow-up. This score is easily assessable in clinical practice in order to guide therapeutic decision.

## POSTER PRESENTATIONS

### PO-1164

#### External validation of the Toronto hepatocellular carcinoma risk index in a Swedish population

Hanne Åström<sup>1</sup>, Nelson Ndegwa<sup>2</sup>, Hannes Hagström<sup>1,3,4</sup>. <sup>1</sup>Karolinska Institutet, Department of Medicine, Huddinge, Sweden; <sup>2</sup>Karolinska Institutet, Department of Medical Epidemiology and Biostatistics, Stockholm, Sweden; <sup>3</sup>Karolinska University Hospital, Division of Hepatology, Department of Upper GI, Stockholm, Sweden; <sup>4</sup>Karolinska Institutet, Clinical Epidemiology Unit, Department of Medicine, Solna, Stockholm, Sweden  
Email: hannes.hagstrom@ki.se

**Background and aims:** The Toronto hepatocellular carcinoma (HCC) risk index (THRI) stratifies patients with cirrhosis into three HCC risk groups based on weighted values for age, gender, etiology of cirrhosis, and platelet count. The THRI has previously been reported to identify patients at low risk for HCC that do not benefit from biannual HCC surveillance. In this study, we aimed to independently externally validate the THRI in a Swedish setting to investigate if it could identify patients that do not require surveillance.

**Method:** We included 2491 patients with cirrhosis seen at the Karolinska University Hospital, Stockholm, between 2004 and 2017. Patients were stratified into low-, intermediate- and high risk of HCC based on their respective THRI values at baseline. The performance of the THRI was evaluated using model discrimination and model calibration. Harrell's C-index was calculated to assess the discriminative ability of the THRI. Calibration-in-the-large, calibration slope and goodness of fit estimates were calculated to evaluate model calibration. Cox proportional hazards regression was used to determine the risk of HCC. Annual and cumulative HCC incidence was calculated at 5- and 10 years.

**Results:** Most patients were male (1638, 66%). The etiology of cirrhosis was most frequently alcohol-related liver disease and non-alcoholic related fatty liver disease (1182, 48%), or viral hepatitis (987, 40%). In total, 317 (13%) patients developed HCC during follow-up. We identified 131 patients (5.3%) as low risk according to the THRI. The Harrell's C-index of the THRI was 0.69. Calculations for the calibration-in-the large (0.11), calibration slope (1.24, not different from 1,  $p=0.66$ ) and goodness of fit showed at good model calibration. The risk of HCC development was increased in both the high-risk group (hazard ratio = 6.8, 95% CI = 2.8–16.6) and the intermediate risk group (hazard ratio = 2.8, 95% CI = 1.1–6.8) compared to the low-risk group. 10-year annual HCC incidence in the low-, intermediate-, and high-risk group was 0.7%, 1.7% and 4.3% respectively.

**Conclusion:** In a Swedish setting, the THRI could differentiate between low and high risk of HCC development. However, the low-risk group was relatively small (5.3%) in this external validation which limited the clinical applicability in this cohort.

### PO-1238

#### Natural history and clinical impact of non-neoplastic portal vein thrombosis in cirrhotics with hepatocellular carcinoma

Sarah Shalaby<sup>1</sup>, Marco Grasso<sup>1</sup>, Alessandro Vitale<sup>2</sup>, Enrico Pizzirani<sup>3</sup>, Alberto Zanetto<sup>1</sup>, Paolo Feltracco<sup>4</sup>, Patrizia Burra<sup>1</sup>, Umberto Cillo<sup>2</sup>, Marco Senzolo<sup>1</sup>. <sup>1</sup>Multivisceral Transplant Unit, Department of Surgery, Oncology and Gastroenterology, Padua University Hospital, Padua, Italy; <sup>2</sup>Hepatobiliary Surgery and Liver Transplantation Unit, Department of Surgery, Oncology and Gastroenterology, Padua University Hospital, Padua, Italy; <sup>3</sup>Institute of Radiology, Department of Medicine-DIMED, Padua, Italy; <sup>4</sup>Section of Anesthesiology and Intensive Care, Department of Medicine-DIMED, Padua, Italy  
Email: sarahshalaby18@gmail.com

**Background and aims:** Portal vein thrombosis (PVT) is a common thrombotic complication in cirrhosis; however, data on its

epidemiology and prognostic role in patients with hepatocellular carcinoma (HCC) are still scarce.

**Method:** Cirrhotic patients with HCC undergoing laparoscopic microwave ablation and non-neoplastic PVT were consecutively enrolled over a period of 4 years. Non-neoplastic PVT extension for each portal branch and HCC total tumour volume (TTV) were calculated by a single-radiologist blinded to report in every patient, at baseline and for each follow-up interval. Characteristics of patients and HCC were correlated with presence of PVT and to its evolution. The role of PVT on survival was evaluated by Uni and multivariate Cox analyses.

**Results:** Among 900 consecutive patients 122 were excluded because of previous hepatic resection, 3 for previous portosystemic shunt creation and 25 due to neoplastic PVT. Seven hundreds-fifty patients were finally included, 88 with PVT. Fifty patients showed isolated PVT (18% complete); 33 showed portal and mesenteric vein involvement (22% complete); 5 had porto-spleno-mesenteric thrombosis (0% complete). At multivariate analysis, median pre-treatment TTV (OR 1.10, 95%CI 1.05–1.15,  $p < 0.0001$ ) and presence of clinically significant portal hypertension (OR 2.90, 95%CI 1.37–6.59,  $p = 0.0046$ ) were the only independent variables associated with PVT. Fifty six patients with PVT were followed-up for >3 months (median follow-up 9 months) and 14 were treated with anticoagulation. PVT improved in 43% of anticoagulated patients vs only 9.5% of untreated patients ( $p = 0.002$ ). Anticoagulant therapy was independently associated with PVT improvement, together with HCC response to ablative treatment, while lack of HCC response to ablative treatment predicted PVT progression. Median survival in patients with complete or progressive PVT was 10.9 vs 47.2 months in other patients ( $p < 0.001$ ). The prognostic negative impact on survival of complete/progressive PVT persisted at multivariable analysis (HR 2.1, 95%CI 1.2–3.4,  $p = 0.007$ ), along with Child-Pugh score and TTV.

**Conclusion:** HCC TTV and recurrence after treatment are independent predictors of non-neoplastic PVT development and progression. Complete/progressive PVT is an independent factor associated with mortality, therefore thromboprophylaxis in patients with large HCC should be evaluated in future studies.

### PO-1275

#### Significance of TERT genetic alterations and telomere length in hepatocellular carcinoma

Jin Seoub Kim<sup>1</sup>, Hye Seon Kim<sup>1</sup>, Soon Kyu Lee<sup>2</sup>, Hee Chul Nam<sup>2</sup>, Pil Soo Sung<sup>2</sup>, Chang Min Kim<sup>3</sup>, Jin Young Park<sup>3</sup>, Si Hyun Bae<sup>2</sup>, Jong Young Choi<sup>2</sup>, Seung Kew Yoon<sup>2</sup>, Jeong Won Jang<sup>2</sup>. <sup>1</sup>St. Mary's, Biomedicine and Health Sciences, Seoul, Korea, Rep. of South; <sup>2</sup>St. Mary's, Internal Medicine, Seoul, Korea, Rep. of South; <sup>3</sup>CBSBioscience, Daejeon, Korea, Rep. of South  
Email: garden@catholic.ac.kr

**Background and aims:** Telomerase reverse transcriptase (TERT) mutations are reportedly the most frequent somatic genetic alterations in hepatocellular carcinoma (HCC). An integrative analysis of TERT-telomere signal during hepatocarcinogenesis is lacking. This study aimed to investigate the clinicopathological association and prognostic value of TERT gene alterations and telomere length in HCC patients undergoing hepatectomy as well as transarterial chemotherapy (TACE).

**Method:** TERT promoter mutation, expression and telomere length were analyzed in 305 tissue samples by Sanger sequencing and real-time PCR, respectively. Protein-protein interaction (PPI) networks were examined to identify a set of genes interacting with TERT.

**Results:** The PPI networks identified eight key TERT-interacting gene sets, such as CCT5, TUBA1B, mTOR, RPS6KB1, AKT1, WHAZ, YWHAQ, and TERT. Among these, TERT was the strongest differentially expressed gene. TERT promoter mutations were more frequent, TERT expression was significantly higher, and telomere length was longer in tumors

versus non-tumors. *TERT* promoter mutations were most frequent in HCV-related HCCs and less frequent in HBV-related HCCs. *TERT* promoter mutations were associated with higher *TERT* levels and longer telomere length and were an independent predictor of worse overall survival after hepatectomy. *TERT* expression was positively correlated with tumor differentiation and stage progression, and independently predicted worse progression-free survival after TACE. Telomere length was marginally associated with survival in TACE-treated patients, but not in those undergoing hepatectomy.

**Conclusion:** The *TERT*-telomere network has a crucial role in the development and progression of HCC. *TERT*-telomere abnormalities might serve as useful biomarkers for HCC, but the prognostic values may differ with tumor characteristics and treatment.

**PO-1289**

**Cirrhosis regression based on both Enhanced Liver Fibrosis (ELF) and Fibrotest after direct-acting hepatitis C therapeutics corresponded to a lower incidence rate of hepatocellular carcinoma (HCC) below the cost-effective threshold for surveillance**

Winston Dunn<sup>1</sup>, Devin Koestler<sup>2</sup>, Liyun Ni<sup>3</sup>, Kathryn Kersey<sup>3</sup>, Kyle Hammond<sup>3</sup>, Anand Chokkalingam<sup>3</sup>, Diana Brainard<sup>3</sup>, Steven Weinman<sup>1</sup>. <sup>1</sup>University of Kansas Medical Center, Internal Medicine, Kansas City, United States; <sup>2</sup>University of Kansas Medical Center, Biostatistics, Kansas City, United States; <sup>3</sup>Gilead Sciences, Inc., Foster City, United States  
Email: winstondunmd@gmail.com

**Background and aims:** Direct-acting antivirals effectively clear hepatitis C virus even in the setting of cirrhosis. After sustained virological response (SVR), the incidence of hepatocellular carcinoma (HCC) decreases but is still higher than in patients without cirrhosis (~0.24% per year). Surveillance is generally recommended if HCC risk >1.5% per year. Within a year of SVR, approximately 25% of patients have regression of cirrhosis. We thus sought to assess HCC risk in post-SVR cirrhosis patients who experienced cirrhosis regression based on Enhanced Liver Fibrosis (ELF) and FibroTest.

**Method:** We included patients from the Gilead Cirrhosis Registry study that enrolled patients with compensated or decompensated cirrhosis who had achieved SVR in clinical trials of sofosbuvir-based treatment. Patients underwent follow-up every 6 months and were monitored for evidence of cirrhosis regression based on either ELF <9.5, FibroTest <0.58, or both and for HCC by ultrasound. Time to HCC was analyzed using extended-Cox model with cirrhosis regression as a time dependent covariate. Multivariable analysis adjusted for age, gender, race, ethnicity and BMI.

regression. In this group there were 10 cases of HCC for an incidence rate of 0.88% per year. 463 patients met either ELF or FibroTest criteria but not both. This group had 21 cases of HCC for a rate of 1.61% per year. 535 patients met neither criterion for cirrhosis regression. This group had 74 cases of HCC for a rate of 5.00% per year. The hazard ratio for development of HCC was 0.28 (95% CI 0.13–0.58, p = 0.0006) for meeting both criteria and 0.50 (95% CI 0.30–0.83, p = 0.0078) for meeting one criterion of cirrhosis regression compared to no cirrhosis regression.

**Conclusion:** Patients with cirrhosis regression after SVR based on both ELF and FibroTest criteria have reduced incidence of HCC compared to patients who did not have cirrhosis regression. While the incidence rate at 0.88% per year is still above the published data on patients who had SVR without cirrhosis, it is below the incidence threshold of 1.5% per year that is considered cost-effective for HCC surveillance.

**PO-1729**

**Risk based HCC surveillance has the potential to minimise patient harm**

Chris Curran<sup>1</sup>, Adrian Stanley<sup>2</sup>, Ewan Forrest<sup>2</sup>, Matthew Priest<sup>1</sup>, Shouren Datta<sup>1</sup>, Stephen T. Barclay<sup>2</sup>. <sup>1</sup>Queen Elizabeth University Hospital, Gastroenterology, Glasgow, United Kingdom; <sup>2</sup>Glasgow Royal Infirmary, Gastroenterology, Glasgow, United Kingdom  
Email: chriscurran152@gmail.com

**Background and aims:** International guidelines recommend screening for hepatocellular carcinoma (HCC) with ultrasound (US) and AFP levels biannually. However, patients may experience harm from unnecessary investigations, triggered by false positive tests. Utilising a cohort of patients with cirrhosis of mixed aetiology, we sought to calculate numbers needed to benefit (NNB) and harm (NNH) from screening, along with the positive and negative predictive values (PPV/NPV) of screening. In addition, we aimed to analyse these by risk strata from previously validated HCC risk scores.

**Method:** Data was collected on 482 patients with cirrhosis attending at least one clinic between Jan13–Dec14. Patients were followed until 31/12/2019. Risk scores (aMAP, Toronto risk index, ADDRESS-HCC.HCC risk score) were derived from index clinic results. NNB was defined as total screening US per screening diagnosed (US or AFP) early (stage 0/ A) HCC. NNH was defined as total US performed per false positive (positive screening/negative HCC investigation). False negatives were HCCs diagnosed within 6 months of negative screening. Compliance was defined as total ultrasounds/expected ultrasounds (1 per 6 months).

**Results:** 98% (473/482) of patients attended for 3137 screening ultrasounds (mean 6.6 (±4.2)/patient). Compliance was 68%. 22 (4.6%) patients developed HCC, 77% (17/22) screening diagnosed, of which 13/17 (76%) were early stage. There were 88 false positives, and no false negatives. NNB and NNH were 241 and 36, respectively. Results according to HCC risk score strata are shown below.

**Conclusion:** The PPV of abnormal screening tests increases across risk score strata. Low risk strata demonstrated no screen benefit (AMAP, THRI), or had a high NNB of >300/900 (ADDRESS-HCC/HCC risk score), with low NNH (24–38); Risk based screening has the potential to reduce patient harm and increase likelihood of benefit from HCC surveillance.

Figure:

**Results:** Analysis included 1581 subjects with median follow-up of 144 wks. 583 patients met both ELF and FibroTest criteria for cirrhosis

### Discriminatory changes in circulating lipid and small molecule metabolites in patients with MAFLD associated hepatocellular cancer

Rohini Sharma<sup>1</sup>, Haonan Lu<sup>1</sup>, Jacob George<sup>2</sup>, Mohammed Eslam<sup>2</sup>, Augusto Villanueva<sup>3</sup>, Caroline Ward<sup>1</sup>, Helen L. Reeves<sup>4</sup>, Misti McCain<sup>4</sup>, Edward Chambers<sup>1</sup>, Caroline Sands<sup>1</sup>, Lynn Maslen<sup>1</sup>, Matthew Lewis<sup>1</sup>, Ramya Ramaswami<sup>1</sup>. <sup>1</sup>Imperial College London; <sup>2</sup>Storr Liver Centre; <sup>3</sup>Icahn School of Medicine at Mount Sinai; <sup>4</sup>University of Newcastle  
Email: r.sharma@imperial.ac.uk

**Background and aims:** The burden of metabolic (dysfunction) associated fatty liver disease (MAFLD), formerly known as non-alcoholic fatty liver disease (NAFLD) is rapidly rising, the sequelae including an increase in hepatocellular cancer (HCC). There is an

acute need for screening programs for the early detection of MAFLD associated HCC, the majority of whom present with late stage disease. MAFLD and its sequelae are characterised by perturbations in lipid handling, inflammation and mitochondrial damage. The profile of circulating lipid and small molecule metabolites with the development of HCC is poorly characterized in MAFLD and could be used in future studies as a marker for the detection of HCC.

**Method:** We assessed the profile of 273 lipid and small molecule metabolites by ultra-performance liquid chromatography coupled to high-resolution mass spectrometry (UPLC-MS) in serum from patients with MAFLD (n = 113) and patients with MAFLD-associated HCC (n = 144) from six different centres. Regression models were used to identify a predictive model of HCC using minimal circulating features.

**Results:** Asymmetric dimethylarginine and twenty lipid species were found to successfully predict the presence of cancer on a background of MAFLD with high accuracy (AUC 0.94). In particular, the presence of these metabolites was associated with cirrhosis in the MAFLD subgroup (p < 0.001). When considering the HCC cohort alone, the metabolic signature was an independent predictor of overall survival (HR 1.42, 95%CI: 1.09–1.83, p < 0.01).

**Conclusion:** Taken together, these exploratory findings reveal a diagnostic metabolic signature in serum which is capable of accurately detecting the presence of HCC on a background of MAFLD. This unique serum signature will be taken forward for further investigation of diagnostic performance.

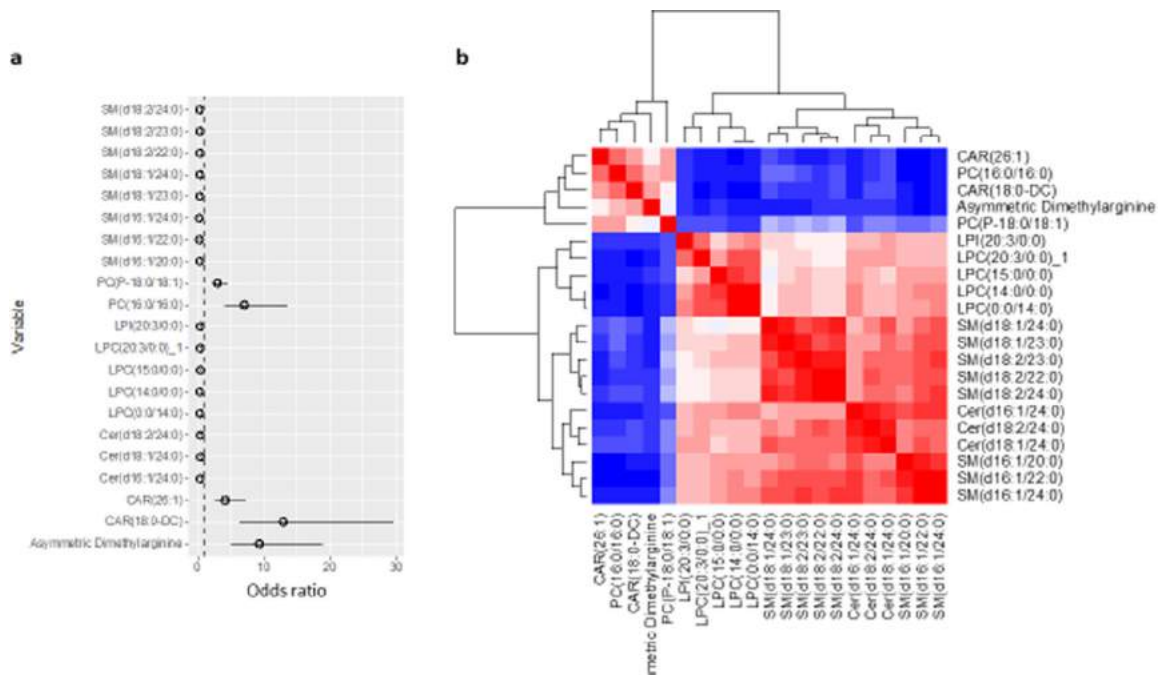

Figure: (abstract: PO-2070): **Inter-correlations among lipid species.** a) Forest plot analysis illustrating the association between the 21 metabolites and HCC. b) Heat-map demonstrating the inter-metabolite correlations within the entire cohort. Red colour indicates high similarity between the two species whereas blue indicates low similarity.

**Abdominal ultrasound and alpha-foetoprotein for the diagnosis of hepatocellular carcinoma. A diagnostic test accuracy Cochrane review**

Agostino Colli<sup>1</sup>, Tin Nadarevic<sup>2</sup>, Damir Miletic<sup>3</sup>, Vanja Giljaca<sup>4</sup>, Fraquelli Mirella<sup>5</sup>, Davor Stimac<sup>6</sup>, Giovanni Casazza<sup>7</sup>. <sup>1</sup>Fondazione IRCCS Ca' Granda, Ospedale Maggiore Policlinico, Milano, Department of Transfusion Medicine and Haematology; <sup>2</sup>Clinical Hospital Center, Department of Radiology, Rijeka, Croatia; <sup>3</sup>University of Rijeka, Clinical Department of Radiology; <sup>4</sup>University Hospitals Birmingham NHS Foundation Trust, Birmingham, United Kingdom; <sup>5</sup>Fondazione IRCCS Ca' Granda, Ospedale Maggiore Policlinico, Milano, Milano, Italy; <sup>6</sup>University Hospital Rijeka, Division of Gastroenterology, Department of Internal Medicine, Rijek, Croatia; <sup>7</sup>Universita' degli Studi di Milano, Dipartimento di Scienze Biomediche e Cliniche "L. Sacco", Milano, Italy Email: mfraquelli@yahoo.it

**Background and aims:** Hepatocellular carcinoma (HCC) ranks fifth in terms of global instances of cancer and second in terms of cancer deaths for men. Current guidelines recommend ultrasound (US) with or without alpha-foetoprotein (AFP) as surveillance programme in high risk population even if there is no clear evidence of benefit in terms of overall-survival. Assessing the diagnostic accuracy of US and AFP may clarify whether the absence of benefit might be related to under-diagnosis.

**Method:** We searched (June 2020): Cochrane Hepato-Biliary Group DTA Studies Register, MEDLINE, Embase, Web-of-Science. We assessed the risk of bias with QUADAS-2 checklist. We used a hierarchical meta-analysis model and presented uncertainty of estimates using 95% confidence intervals (CIs).

**Results:** Overall, 374 studies, with 168816 participants, were included. Only one study was judged at low risk of bias. As the primary studies with AFP used different cut-offs, we performed two meta-analyses including studies reporting cut-off around 20 or 200 ng/ml (the most used values).

The results' heterogeneity remains mostly unexplained, in part referable to different cut-offs or settings.

A direct comparison of six studies showed a higher sensitivity of AFP<sub>20</sub>+US with similar specificity compared to US alone.

Figure:

Index test (cut off)	Studies (n.)	Sensitivity (95% CIs)	Specificity (95% CIs)
AFP <sub>20</sub> (20 ng/ml)	147	60 (58–62)	84 (82–86)
AFP <sub>200</sub> (200 ng/ml)	56	36 (31–41)	99 (89–99)
US	39	72 (63–79)	94 (91–96)
AFP <sub>20</sub> (20 ng/ml) + US	6	96 (88–93)	85 (73–93)

**Conclusion:** Using AFP<sub>20</sub>, around 40% of HCC would be missed; with US alone more than a quarter. AFP<sub>20</sub>+US shows the highest sensitivity and less than 5% of HCC would be missed with around 15% of false-positive results. The uncertainty resulting from the poor study quality and the heterogeneity of results limit our ability to confidently draw conclusions

**PO-2223**

**Proposal and validation of a novel scoring system for hepatocellular carcinomas beyond curability borders: Unresectable hepatocellular carcinoma prognostic index**

Coskun Ozer Demirtas<sup>1</sup>, Gabriele Ricco<sup>2,3</sup>, Osman Cavit Ozdogan<sup>1</sup>, Feyyaz Baltacioglu<sup>4</sup>, Tunc Ones<sup>5</sup>, Perran Fulden Yumuk<sup>6</sup>, Ender Dulundu<sup>7</sup>, Sinan Uzun<sup>8</sup>, Piero Colombatto<sup>2</sup>, Filippo Oliveri<sup>2</sup>, Maurizia Brunetto<sup>2,3,9</sup>, Feyza Gunduz<sup>1</sup>. <sup>1</sup>Marmara University, School of

Medicine, Department of Gastroenterology, Istanbul, Turkey; <sup>2</sup>Pisa University Hospital, Hepatology Unit, Pisa, Italy; <sup>3</sup>Pisa University, Department of Clinical and Experimental Medicine, Pisa, Italy; <sup>4</sup>Marmara University, School of Medicine, Department of Radiology, Istanbul, Turkey; <sup>5</sup>Marmara University, School of Medicine, Department of Nuclear Medicine, Istanbul, Turkey; <sup>6</sup>Marmara University, School of Medicine, Department of Medical Oncology, Istanbul, Turkey; <sup>7</sup>Marmara University, School of Medicine, Department of General Surgery, Istanbul, Turkey; <sup>8</sup>Marmara University, School of Medicine, Department of Medical Biostatistics, Istanbul, Turkey; <sup>9</sup>Biostructure and Bio-imaging Institute of National Research Council of Italy, Naples, Italy Email: coskun\_demirtas10@hotmail.com

**Background and aims:** The optimal system to refine the stratification of prognosis in patients with unresectable hepatocellular carcinoma (HCC) is currently uncertain. We aimed to develop and externally validate an easy-to-use tool particularly for this population, and named it the "Unresectable Hepatocellular Carcinoma Prognostic Index" (UHPI).

**Method:** We evaluated the data of treatment-naïve unresectable HCC patients diagnosed in the training center from 2010 to 2019 (n = 209). A simple prognostic model was developed by assigning points for each co-variate in proportion to the beta-coefficients in the Cox-multivariable model. An independent European validation cohort (n = 147) was studied to reveal its performance and distinction ability, and UHPI was also compared with 11 other available models.

**Results:** A simple scoring system was derived, assigning 0.5/1/2 scores for six independent co-variables including, the Child-Pugh score, Eastern Cooperative Oncology Group performance status, maximum tumor size, extrahepatic vascular invasion or metastasis, lymph node involvement, and alpha-fetoprotein. UHPI score, ranging from 0 to 6, showed superior performance in predicting prognosis and outperformed 11 other staging or prognostic models giving the highest homogeneity (c-index [0.803] and area under the receiver operator characteristics curves for 6-month [0.829] and 1-year [0.845]), lowest Akaike information criterion, and -2 log-likelihood ratio values. UHPI score well-allocated the risk of unresectable HCC patients for mortality within the first year, using two cut-off values (Low-risk:<1, intermediate-risk:1–3 and high-risk:>3).

Table: Unresectable HCC Prognostic Index

Variable	Point
Child-Pugh Class	
–A	0
–B	1
–C	2
–ECOG performance status	
–0–1	0
–2–4	1
–Maximum tumor size	
–≤8 cm	0
–>8 cm	1
Vascular invasion or metastasis	1
Lymph node involvement	0.5
–Alpha-fetoprotein	
–<500 ng/ml	0
–≥500 ng/ml	0.5
• UHPI-stage 1 (<1): 100% 6-month, >85% 1-year survival probability	
• UHPI-stage 2 (1–3): 70–85% 6-month, 45–55% 1-year survival probability	
• UHPI-stage 3 (>3): 20–50% 6-month, <5% 1-year survival probability	

ECOG: Eastern Cooperative Oncology Group, HCC: Hepatocellular carcinoma, UHPI: Unresectable HCC prognostic index.

**Conclusion:** UHPI score can predict prognosis better than other systems in unresectable HCC subjects and can be used in clinical practice or trials to estimate the 6-month and 1-year survival probabilities for this group.

Email: mreig1@clinic.cat

**Background and aims:** Non-alcoholic fatty liver disease (NAFLD) may be identified as a risk factor for hepatocellular carcinoma (HCC), but the extent of this association still needs to be properly addressed. The aim of the present study is to estimate by a meta-analysis the pooled-incidence rates of HCC across the disease spectrum of NAFLD.

**Method:** In this systematic review, we searched Web of Science, Embase, Pubmed, and the Cochrane library from January 1<sup>st</sup>, 1950 through July 30<sup>th</sup>, 2020. We included studies reporting on HCC incidence in patients with NAFLD. The main outcomes were pooled HCC incidences in patients with NAFLD at distinct severity stages. Sensitivity analyses and meta-regression analyses were carried out to address heterogeneity. The protocol for this review was registered in Prospero (CRD42018092861).

**Results:** We identified 10, 263 studies and 18 of those involving 470, 404 patients were finally included. Heterogeneity in cirrhotic patients was of 81% and of 98% in non-cirrhotic. In patients with NAFLD without established cirrhosis, HCC incidence was 0.03 per 100 person-years (PYs) (95% confidence interval 0.01–0.07,  $I^2 = 98\%$ ). When considering studies that only included patients with cirrhosis the rate was of 3.78 per 100PYs (2.47–5.78,  $I^2 = 81\%$ ). Among the latter patients, those undergoing regular HCC screening displayed an incidence of 4.62 per 100PYs (2.77–7.72,  $I^2 = 77\%$ ). Sensitivity analyses and meta-regression analyses did not significantly improve heterogeneity.

**Conclusion:** The high heterogeneity of the studies hampers robust conclusions. However, patients with NAFLD-related cirrhosis have a risk of developing HCC similar to that reported for patients with cirrhosis from other aetiologies. Data documenting the risk in patients with NASH or steatosis are limited, but HCC incidence in these populations may lie below thresholds used to recommend HCC screening. Considering the high heterogeneity and the absence of informative screening programs in non-cirrhotic patients, well-designed prospective studies are needed in such subgroup of patients to properly assess the risk.

### PO-2364

#### **The added value of PIVKA-II levels over AFP in patients with hepatocellular carcinoma undergoing locoregional treatment**

Massimo Iavarone<sup>1</sup>, Alessandro Rimondi<sup>1</sup>, Floriana Facchetti<sup>1</sup>, Mariangela Bruccoleri<sup>1</sup>, Anna Maria Ierardi<sup>1</sup>, Riccardo Perbellini<sup>1</sup>, Sara Colonia Uceda Renteria<sup>1</sup>, Ferruccio Ceriotti<sup>1</sup>, Alberto Perego<sup>2</sup>, Corinna Orsini<sup>2</sup>, Angelo Sangiovanni<sup>1</sup>, Gianpaolo Carrafiello<sup>1</sup>, Pietro Lampertico<sup>1</sup>. <sup>1</sup>Foundation IRCCS Ca' Granda Ospedale Maggiore Policlinico, Italy; <sup>2</sup>Fujirebio Italia, Pomezia, Italy

Email: massimo.iavarone@policlinico.mi.it

**Background and aims:** The potential usefulness of Prothrombin Induced by Vitamin K Absence or Antagonist-II (PIVKA-II) has been suggested in surveillance of hepatocellular carcinoma (HCC), but its

role in HCC diagnosis and prognosis according to staging and treatment lacks evaluation.

**Methods:** In this single-center study, we tested 135 consecutive patients with first diagnosis of HCC for PIVKA-II and alpha-fetoprotein (AFP) (Fujirebio, Japan) on samples collected the day of ablation or chemoembolization (TACE). Primary aim was identification of reference range of PIVKA-II levels for diagnosis of HCC and according to stage of HCC (size of largest tumor, number of nodules, BCLC), secondary aim was evaluation of predictive role of PIVKA-II for fast-progression (tumor progression at first CT-scan after treatment) and early recurrence (less than 12 month after complete response-CR).

**Results:** 127 patients were finally evaluated (8 excluded due to anticoagulant interference with PIVKA-II measurement): age 66 (IQR: 58–75) years, 83% males, 61% HCV-Ab positive, HCC size 22 mm (IQR: 17–30), 64% single nodule. 40 patients were treated with ablation and 87 with TACE. PIVKA-II and AFP levels were 149 mAU/ml (IQR: 58–489) and 6.6 ng/ml (IQR: 3.6–21.7), respectively. In a linear regression model at univariate and multivariate analysis, high levels of PIVKA-II independently predicted the number of nodules ( $p = 0.002$ ) and the diameter of the largest nodule ( $p < 0.001$ ), whereas AFP has no correlation with both ( $p = 0.42$  and  $p = 0.21$ , respectively). At multivariate analysis a strong correlation between PIVKA-II and AFP was found ( $p < 0.001$ ). As for the secondary end points: 1) PIVKA-II was 479 mAU/ml (IQR: 131–3004) in 19 patients fast-progressors of HCC after treatment vs 121 mAU/ml (IQR: 56–396) in the other 108 patients ( $p = 0.045$ ), while AFP was 14 mAU/ml (IQR: 7–65) vs 6 mAU/ml (IQR: 3.4–18),  $p = 0.86$ ; 2) PIVKA-II was 279 mAU/ml (IQR: 66–499) in 18 patients with early recurrence after CR vs 223 mAU/ml (IQR: 57–447) in the other 50 patients ( $p = 0.10$ ), while AFP was 11 ng/ml (IQR: 4–19) vs 6 ng/ml (IQR: 3–13),  $p = 0.60$ . At multivariate analysis, only diameter and number of nodules were baseline independent predictors of fast-progression (OR: 1.046, 95%CI 1.003–1.091,  $p = 0.03$ ; OR 1.459, 95%CI 1.001–2.151,  $p = 0.04$ ).

**Conclusion:** High PIVKA-II levels predict HCC stage more accurately than AFP but failed to predict fast progression after treatment and early progression after CR.

### PO-2594

#### **Free Androgen Index Levels May Influence the Transarterial Chemoembolization with Doxorubicin-Eluting Beads Response in Hepatocellular Carcinoma Patients: Preliminary Results.**

Silvia Acosta-López<sup>1</sup>, Dácil Díaz Bethencourt<sup>1</sup>, Teresa Concepcion-Masip<sup>2</sup>, Julian Portero-Navarro<sup>3</sup>, María Cecilia Martín-Fernández de Basoa<sup>2</sup>, Antonio González Rodríguez<sup>1</sup>, Francisco Andrés Pérez Hernández<sup>1</sup>, Julio Plata-Bello<sup>4</sup>. <sup>1</sup>Hospital Universitario Nuestra Señora de Candelaria, Liver Unit, Santa Cruz de Tenerife, Spain; <sup>2</sup>Hospital Universitario Nuestra Señora de Candelaria, Hormone Section of the Biochemical Laboratory, Santa Cruz de Tenerife, Spain; <sup>3</sup>Hospital Universitario Nuestra Señora de Candelaria, Interventional Radiology, Santa Cruz de Tenerife, Spain; <sup>4</sup>Hospital Universitario de Canarias, Department of Neuroscience, San Cristóbal de La Laguna, Spain

Email: sacostalopez9@gmail.com

**Background and aims:** Hepatocellular carcinoma (HCC) shows a male predominance. It has been demonstrated that testosterone avoid apoptosis and senescence in cells treated with doxorubicin. Bearing this mind, it can be hypothesized that testosterone can be related with a worse response to Trans-arterial Chemoembolization with Doxorubicin-Eluting Beads (DEB-TACE) in HCC.

The aim of the present study is to analyze the effect of total testosterone levels and free androgenic index (FAI) in the DEB-TACE response in HCC patients.

**Method:** Patients with HCC with any indication of DEB-TACE performance were included. Total testosterone was measured by radio-immune assay and FAI was calculated by using the formula reported by Vermeulen et al (1999). These determinations were

performed the same day of the DEB-TACE. All chemoembolization were performed by a single radiologist and using the same kind of doxorubicin particles. Treatment response was measured after one month with a multiphase contrast-enhanced computed tomography (CT). Modified RECIST (mRECIST) criteria were used to evaluate the response to DEB-TACE in each patient. Parametric statistical tests were performed, using a threshold of  $p=0.05$  for statistical significance.

**Results:** Forty-one DEB-TACE performed in 22 patients (3 women; mean age: 70.4 [SD = 9.6]) were included in this analysis. A mean of 2 DEB-TACEs were performed per patient (rank: 1–5). The mean level of total testosterone prior to DEB-TACE was 4.7 ng/ml (SD = 2.6) and the mean level of FAI was 26.2 (SD = 13.8). Total response was achieved in 12 DEB-TACEs (29.3%) and partial response in 13 (31.7%). Stable disease was considered after 13 procedures (31.7%) and progression was found in 3 cases (7.3%). No significant differences were identified in total testosterone levels between the response groups (ANOVA;  $p=0.542$ ). However, higher levels of FAI were identified in the progression group compared to the others (ANOVA;  $p=0.029$ ). Bonferroni post-hoc test showed that the main difference was between progression and stable disease groups (45.6 vs. 20.6;  $p=0.025$ ). Additionally, despite the few number of cases, a binary-logistic regression analysis showed that higher FAI levels were associated with a slight increase in the risk of progression after a DEB-TACE (OR = 1.142; 95% C.I. [1.008–1.293];  $p=0.037$ ).

**Conclusion:** Patients with higher levels of FAI prior to a DEB-TACE performance may be associated with a higher risk of progression at 1 month after the procedure.

**PO-2612**

**Prior or current hepatocellular carcinoma does not adversely affect the evolution of LI-RADS 4 lesions.**

Louise Hanly<sup>1</sup>, William Shanahan<sup>1</sup>, Michele Bourke<sup>1</sup>, Niamh Mehigan<sup>1</sup>, Cathal Clifford<sup>1</sup>, Bilal Shoukat<sup>1</sup>, Mohamed Osman<sup>1</sup>, Diarmaid Houlihan<sup>1</sup>, Ross MacNicholas<sup>1</sup>. <sup>1</sup>St. Vincent's University Hospital, Dublin, Ireland  
Email: louisehanly\_100@hotmail.com

**Background and aims:** The Liver Imaging and Reporting Data System (LI-RADS) criteria are used to non-invasively diagnose hepatocellular carcinoma (HCC) in cirrhosis/chronic hepatitis B at the de facto national HCC service in Ireland. LI-RADS 5 lesions are classified as definite HCCs and can be treated as such. Not all lesions can be definitively characterised however. LI-RADS 4 lesions are described as probable HCCs, the management of which is recommended to be decided at multidisciplinary team (MDT) meetings. Many of these lesions are followed up with interval multiphase CT/MR imaging at our institution. We questioned whether the evolution of these lesions may vary depending on the cancer context at recognition; current/past HCC (HxHCC) or without definite HCC (NoHCC). We aimed to compare the evolution of these lesions between these two patient groups.

**Method:** We reviewed the MDT records at our institution over a 3 year period (2017–2019). We identified all patients with LI-RADS 4 lesions and sub-categorized them into the two groups (HxHCC and NoHCC). For those who underwent interval imaging we collected data on the time to progression to LI-RADS 5 of these lesions. Time to progression between cohorts was compared using Kaplan-Meier analysis. Significance was determined using log rank test.

**Results:** We identified 85 patients with LI-RADS 4 lesions. Of those, 63 underwent interval imaging. The remainder underwent targeted therapy or biopsy and were excluded. The mean follow-up time was 14.4 months. 35 patients were included in the HxHCC cohort, and 28 were included in the NoHCC cohort. Of these, 17 (48%) patients in the HxHCC cohort and 16 (57%) patients in the NoHCC cohort progressed to LI-RADS 5 during the follow-up period. There was no difference in the time to progression to LI-RADS 5 between either group,  $p=0.877$ .

Figure:

**Conclusion:** The cancer context does not appear to influence the progression of probable HCCs to definite HCCs using the LI-RADS criteria.

**PO-2687**

**SARS-CoV-2 one year on-the worrying impact on early detection of primary liver cancers**

Daniel Geh<sup>1</sup>, Robyn Watson<sup>1</sup>, Stuart Mcpherson<sup>2</sup>, Steven Masson<sup>2</sup>, Jessica Dyson<sup>2</sup>, Louise MacDougall<sup>2</sup>, Mhairi Donnelly<sup>2</sup>, Preya Patel<sup>2</sup>, Lucy Walker<sup>2</sup>, John Hammond<sup>3,4</sup>, Jeremy French<sup>3,4</sup>, Steven White<sup>3,4</sup>, Stuart Robinson<sup>3,4</sup>, Gourab Sen<sup>3,4</sup>, Paul Turner<sup>4,5</sup>, John Scott<sup>4,5</sup>, Michael McNeil<sup>5</sup>, Misti McCain<sup>1</sup>, Syed Asghar<sup>6</sup>, Nick Wadd<sup>7</sup>, Lavanya Mariappan<sup>4,8</sup>, Jane Margetts<sup>4,8</sup>, Peter Littler<sup>4,5</sup>, Derek Manas<sup>3,4</sup>, Helen Louise Reeves<sup>4,9,10</sup>. <sup>1</sup>Newcastle University Translational and Clinical Research, Newcastle University; <sup>2</sup>Department of Medicine, Newcastle upon Tyne Hospitals NHS Foundation Trust; <sup>3</sup>Department of Surgery, Newcastle upon Tyne Hospitals NHS Foundation Trust; <sup>4</sup>Hepatopancreatobiliary Multidisciplinary Team, Newcastle upon Tyne Hospitals NHS Foundation Trust; <sup>5</sup>Department of Radiology, Newcastle upon Tyne Hospitals NHS Foundation Trust; <sup>6</sup>Department of Oncology, Cumberland Infirmary, North Cumbria Integrated Care NHS Foundation Trust; <sup>7</sup>Department of Oncology, South Tees Hospital NHS Foundation Trust; <sup>8</sup>Department of Oncology, Newcastle upon Tyne Hospitals NHS Foundation Trust; <sup>9</sup>Newcastle University Translational and Clinical Research, Newcastle University, United Kingdom; <sup>10</sup>Department of Medicine, Newcastle-upon-Tyne NHS foundation Trust  
Email: h.l.reeves@ncl.ac.uk

**Background and aims:** In Northern England new patients with primary liver cancer (PLC) have increased by 10–15% year on year. The rising prevalence of NAFLD and/or alcohol excess underpins this. We evaluated the impact of the SARS-CoV-2 pandemic.

**Method:** In this retrospective, observational, regional study we evaluated 455 consecutive new patients with PLC referred to the Newcastle-upon-Tyne NHS Foundation Trust, comparing the 12 months directly preceding the pandemic (YR1) to the first 12 months of it (March 2020–Feb 2021; YR2). Variables included mode of presentation, etiology, stage, 1<sup>st</sup> line treatment and SARS-CoV-2 infection.

**Results:** New referrals with hepatocellular carcinoma (HCC) fell for the 1st time in 15 years in YR2 (35%; 125 in YR2 from 190 in YR1; Fig1A), with fewer detected by surveillance or routine care-monitoring for HCC in the presence of cirrhosis, or incidentally as part ongoing care for other conditions. This was striking for NAFLD patients (surveillance/incidental/symptomatic 32.5/54.4/13.2% in YR1 compared to 28.3/39.6/32.1% in YR2,  $p=0.04$ , Fig1B). Tumour size was greater in YR2 (med 42.5 vs 35.5 mm;  $p=0.036$ , Fig1C), most

## POSTER PRESENTATIONS

Figure: (abstract: PO-2687)

notable in months 11–12 (Jan-Feb 2020: mean  $48.1 \pm 5.1$  n = 36, vs Jan-Feb 2021:  $81.6 \pm 11.9$  n = 29;  $p = 0.007$ ), with 6 patients experiencing life threatening hemorrhage at diagnosis/awaiting treatment in 2021. Despite challenges in YR2, patients received treatments-transplant, resection, locoregional and medical therapies (including atezo/bev) appropriate for stage, in accordance with NHS waiting times, although numbers receiving active treatment was reduced by 41% compared to YR1. 11/125 (9%) acquired SARS-CoV-2. In 5 it followed their HCC diagnosis-3 have died of advanced HCC, 1 continues atezo/bev and 1 supportive care. In 6 the diagnosis of advanced HCC was after/synchronous; 2 recovered to have active treatment with 4 receiving supportive care. Cases presenting with intrahepatic cholangiocarcinoma were also reduced in YR2, but less so (64 vs 76), with the commonest mode of presentation unchanged (symptomatic ~75%).

**Conclusion:** SARS-CoV-2 has placed an unprecedented burden on healthcare resources, with many routine activities such as chronic disease management and cancer surveillance postponed, compounded by patients fearful of leaving their homes. The tragic consequences are already evident for patients with NAFLD in our region-whose cancers are often detected at advanced stages incidentally, but are now presenting symptomatically. In our series, 9% of patients contracted SARS-CoV-2. These have died or been unfit to treat because of their advanced cancer stage, rather than SARS-CoV-2. At least 35% of our anticipated patients with HCC are 'missing'. If routine activities, including HCC surveillance, are not re-instituted and patients encouraged to attend, it is likely that they too will present with symptomatic advanced HCC.

#### A lesson from COVID19: the persevering benefits of hepatocellular carcinoma surveillance

William Cunliffe<sup>1</sup>, Tom Pembroke<sup>1,2</sup>. <sup>1</sup>Cardiff University, School of Medicine, Cardiff, United Kingdom; <sup>2</sup>Cardiff and Vale University Health Board, Department of Gastroenterology and Hepatology, Cardiff, United Kingdom

Email: pembroket@cardiff.ac.uk

**Background and aims:** The incidence of hepatocellular carcinoma (HCC) in Wales is rising. We aimed to evaluate the impact of the COVID-19 pandemic on the South Wales HCC multi-disciplinary meeting (MDM) referrals and patient management.

**Method:** Baseline patient characteristics at MDM and treatment information was collated for index HCC discussion from the electronic health record. The year of the COVID period (CP) 01/03/

### B NAFLD cases only

### C

2020–28/2/2021, was compared to the pre-pandemic period (PP) 01/03/2018–29/02/2020.

**Results:** There was a 3-fold increase in index HCC diagnoses in South Wales MDM between 2002 and 2018. 803 patients were discussed from March 2018–21; follow-up (372) and non-HCC (90) cases were excluded. There were 245 PP and 96 CP index HCC diagnoses; a 22% reduction in annual index HCC diagnoses in the COVID period. The absolute number of HCCs detected by surveillance remained consistent at 33 per annum in PP and CP periods (27% v 34% respectively).

During CP the proportion of patients offered best supportive care and undergoing further investigation increased (47 to 56% and 1.2 to 13.5% respectively) whilst all anti-cancer interventions fell (figure 1): ablation/surgery (22 to 15.6%), chemo-embolisation (21.2 to 11.5%) and systemic anti-cancer therapies (8.2 to 3.1%,  $p < 0.0001$ ). However, during CP a greater proportion of those on HCC surveillance received curative therapies compared to HCC detected outside of screening in individuals (27.3 vs. 8.5%,  $p = 0.03$ ).

Median time from point of suspicion of HCC to MDM and MDM to first definitive treatment reduced slightly during the CP (43 v 40.5 days and 56 v 55 days respectively).

**Conclusion:** The COVID-19 pandemic had a significant impact on referrals to the HCC MDT, yet HCC surveillance identified the same number of hepatomas. HCC identified by surveillance in the pandemic were more amenable to radical therapies. The fall in the proportion of patients receiving both curative and palliative therapies reflects the fall in incidental treatable HCC during the COVID period. A relatively high proportion of patients received best supportive care in all three years; reflecting an older population with high burden of comorbidities in South Wales linked to socio-economic deprivation. Median waiting times are in excess of the Welsh Government's target of 62 days, suggesting that the current diagnosis and referral process requires revision and resources to expedite therapies.

### PO-2786

#### Insulin like growth factor-1 as a prognostic tool for overall survival in chronic hepatitis C cirrhotic Egyptian patients with hepatocellular carcinoma

Elsayed Ghoneem<sup>1</sup>, Sawzan Moniem Mohamed<sup>1</sup>, Wafa Elemshaty<sup>2</sup>, Ahmed Kaseb<sup>3</sup>, Ahmed Sultan<sup>1,4</sup>. <sup>1</sup>Faculty of Medicine, Mansoura University, Gastroenterology and Hepatology Unit, Internal Medicine Department, Mansoura, Egypt; <sup>2</sup>Faculty of Medicine, Mansoura University, Clinical Pathology, Mansoura, Egypt; <sup>3</sup>The University of Texas MD Anderson Cancer Center, Houston, Texas, USA; <sup>4</sup>Department of Gastrointestinal Medical Oncology, Houston, United States; <sup>4</sup>Cleveland

Treatment outcomes for HCC MDM discussion in South Wales in the pre-pandemic and COVID periods

Figure: (abstract: PO-2755)

Clinic Abu Dhabi, Digestive Disease Institute, Abu Dhabi, United Arab Emirates  
 Email: dr.ahmed.sultan@gmail.com

**Background and aims:** Hepatitis C virus “HCV” infection is a common cause of end stage liver disease “ESLD” and hepatocellular carcinoma “HCC.” Because of its high prevalence among Egyptian, HCV infection is the commonest cause of HCC in Egypt. Child Pugh score “CPS” is the standard score to stage the liver status and estimate an overall prognosis. Yet, the prognosis of HCV induced HCC remains poor due to the aggressive nature of the tumor and cirrhosis complications. Insulin like growth factor-1 “IGF-1” is known to reflect the overall hepatic reserve and are inversely correlated with the severity of liver disease. Moreover, a decline in serum IGF-1 level is associated with the development of HCC regardless the grade of hepatic dysfunction. This study aimed to evaluate the predictive value of serum IGF-1 levels alone or in combination with CPS on the overall survival (OS) of Egyptian patients with HCV induced HCC.

**Method:** The study group was formed of 125 patients with treatment naïve HCC secondary to chronic HCV infection. Patients who had non-HCV chronic liver disease, end stage organ failure rather than liver and diabetes mellitus on insulin therapy were excluded. All patients were subjected to complete physical examination, abdominal ultrasonography and triphasic CT abdomen. Fasting blood samples were collected for assessment of liver function, liver enzymes, creatinine, fasting blood sugar, complete blood count, serum alpha-fetoprotein, and IGF-1. OS time was calculated from the date of sampling to the date of death or the date of the last follow-up. Patients alive were censored.

**Results:** The serum IGF-1 level was inversely correlated with OS. The higher IGF-1, the lower risk of death (HR = 0.98, p = 0.008) with the worst prognosis with IGF-1 <26 ng/ml. Almost one third of patients who were staged CPS-A and B were down staged to IGF-CPS-B and C respectively and consequently had a less OS.

**Conclusion:** In Egyptian patients with HCV induced HCC, serum IGF-1 alone or in combination with CPS “IGF-CPS” showed better correlation with OS compared with standard CPS alone.

Figure: Table 1: Univariate Cox model to evaluate the association of IGF with OS

	HR (95% CI)	P value
IGF (as continuous variable)	0.98 (0.97, 0.99)	0.0082
IGF (<26 vs. >26)	2.89 (1.67, 5.03)	0.0002
IGF		
26–50 vs. >50	0.9 (0.41, 1.97)	0.7925
<26 vs. >50	2.73 (1.34, 5.54)	0.0056
≤26 vs. 26–50	3.03 (1.59, 5.77)	0.0008

**Background and aims:** The SARS-CoV-2 infection in cirrhotic patients has been associated with liver function deterioration and the 30 day-COVID-19-associated-mortality rate of 25% (Iavarone et al JHEP, 2021). However, there are no data about mortality in a large cohort of liver cancer patients with SARS-CoV-2 infection. To evaluate the 30 day-mortality of liver cancer patients with SARS-CoV-2 infection.

**Method:** CERO-19 is a retrospective, observational, multicenter and international project, evaluating clinical outcomes of SARS-CoV-2 in liver cancer. Variables related to type of liver cancer, BCLC or TNM-8th stage at SARS-CoV-2 diagnosis and others related to patient outcome were registered. The 30-day SARS-CoV-2-related mortality rates and hazard ratios (SHR) were estimated considering non-related- SARS-CoV-2 deaths as competing events. Hazard ratios were calculated considering non-related- SARS-CoV-2 deaths as competing risks.

**Results:** This analysis evaluated 242 patients infected with SARS-CoV-2 from 38 centers (Europe, America, Asia, and Africa) from February to December 2020. From the 213 hepatocellular carcinoma (HCC), 54 were de-novo diagnosis and 159 patients had prior history of HCC. The median age was 60 [IQR: 54.6–67] years and 29% received systemic treatment. Among the 29 intrahepatic cholangiocarcinoma (iCCA) only 6 were de-novo. Sixty-seven (27.7%) patients died: 42 deaths were SARS-CoV-2-related (71.4% were cirrhotic) and 25 non-SARS-CoV-2-related (92% were cirrhotic).

The 30-day mortality rate of the whole cohort, and SARS-CoV-2-related death were 21.2% (95%CI: 15.7–26.7), and 17.4% (95%CI: 12.7–22.8), respectively. The 30-day mortality rate in patients with history of liver cancer were: 23.2% (95%CI: 16.2–30.2) with HCC and 42.9% (95%CI: 21.4–64.4) with iCCA. Figure 1 describes the 30-day mortality due to SARS-CoV-2 infection according to BCLC-0/A, B, C and D stage. From the 60 de-novo liver cancer diagnosis, 60% of the HCC were BCLC ≥B stages and 5 out of 6 iCCA were stage IV. The 30-day mortality rate in de-novo HCC was 8.3% (95% CI: 0.5–16.1).

**Conclusion:** The 30-day SARS-CoV-2-related mortality in HCC seems similar to the mortality reported in cirrhotic patients without HCC. However, the 30-day SARS-CoV-2-related mortality rate varies according to the BCLC stage, even when BCLC D patients are excluded. The small sample size of iCCA limited the interpretation of the 30-day SARS-CoV-2-related mortality in this population.

### PO-2812

#### Trend and correlates of increased serum alpha-fetoprotein in hepatocellular carcinoma: US National Cancer Database analysis

Aarshi Vipani<sup>1</sup>, Marie Lauzon<sup>1</sup>, Michael Luu<sup>1</sup>, Mazen Nouredin<sup>1</sup>, Alexander Kuo<sup>1</sup>, Walid Ayoub<sup>1</sup>, Vinay Sundaram<sup>1</sup>, Irene Kim<sup>1</sup>, Tsuyoshi Todo<sup>1</sup>, Andrew Hendifar<sup>1</sup>, Jun Gong<sup>1</sup>, Nicole Rich<sup>2</sup>, Kambiz Kosari<sup>1</sup>, Nicholas Nissen<sup>1</sup>, Lewis Roberts<sup>3</sup>, Amit Singal<sup>2</sup>, Ju Dong Yang<sup>1</sup>. <sup>1</sup>Cedars-Sinai Medical Center; <sup>2</sup>UT Southwestern; <sup>3</sup>Mayo Clinic

Email: aarshi.vipani@cshs.org

**Background and aims:** Serum alpha-fetoprotein (AFP) is a biomarker for hepatocellular carcinoma (HCC). Large-scale data analysis of 1) temporal trend of AFP level at diagnosis and 2) demographic,

Figure: (abstract: PO-2799)

socioeconomic and clinical factors associated with increased serum AFP levels independent of tumor stage has not been investigated in HCC.

**Method:** We identified HCC patients diagnosed between 2010 and 2017 in the US National Cancer Database. Multivariable logistic regression modeling was performed to determine factors associated with elevated serum AFP levels, which was defined as greater than or equal to 20 ng/ml.

**Results:** Out of 133,542 patients, AFP level was reported in 108,353 patients (81%) and baseline characteristics were comparable between patients with and without AFP results. AFP level was increased in 62.6% of patients. Since 2011, the median range of AFP at HCC diagnosis has trended down from 70 to 79 ng/ml in 2011 to 30–39 ng/ml in 2017 ( $p < 0.001$ ). Additionally, the percentage of HCC tumors with elevated AFP has been declining, most significantly in TNM stage 1 and 2 (Figure 1). There was an inverse association between the year of HCC diagnosis and elevated AFP (adjusted odds ratio (AOR) per year: 0.93, 95% CI: 0.93–0.94) after adjusting for covariates including TNM tumor stage. Additionally, female sex (AOR: 1.11, 95% confidence interval (CI): 1.08–1.15) and younger age (AOR per 10 years: 0.96, 95% CI: 0.95–0.98) were more likely to have elevated AFP. Black (AOR: 1.59, 95% CI: 1.53–1.66), Asian (AOR: 1.30, 95% CI 1.24–1.36), Hispanic (AOR: 1.11, 95% CI 1.06–1.16) vs. White was associated with elevated AFP. Community cancer programs vs. academic cancer programs (AOR: 1.74, 95% CI: 1.62–1.86) and South vs. Northeast regions (AOR: 1.07, 95% CI: 1.03–1.11) were associated with elevated AFP levels while private insurance (AOR: 0.81, 95% CI 0.76–0.87), Medicaid/Medicare (AOR: 0.81, 95% CI: 0.76–0.86) vs. no insurance was inversely associated with elevated AFP. Among clinical factors, patients with at least 3 Charlson/Deyo Comorbidity Score were inversely associated with elevated AFP (AOR: 0.85, 95% CI: 0.82–0.88) while higher MELD scores (AOR per 10 units: 1.09, 95% CI: 1.07–1.10) were associated with elevated AFP.

Figure 1: Temporal trend of HCC with elevated AFP based on TNM tumor stage.

**Conclusion:** Our study revealed that serum AFP level at diagnosis has been trending down in the US, especially in TNM tumor stages 1 and 2, likely due to shifting etiologies of HCC. Certain demographic groups (younger age, female, Black and Asian race) as well as those without medical insurance or receiving care at community cancer centers showed a strong association with increased AFP independent of tumor stage.

**PO-2893**

**Micro ribonucleic acid- 26a as a diagnostic biomarker for hepatitis C induced hepatocellular carcinoma in Egyptian patients.**

Elsayed Ghoneem<sup>1</sup>, Ahmed Kaseb<sup>2</sup>, Wafa Elemshaty<sup>3</sup>, Sawsan Moniem Mohamed<sup>1</sup>, Ahmed Sultan<sup>1,4</sup>. <sup>1</sup>Faculty of Medicine, Mansoura University, Gastroenterology and Hepatology Unit, Internal Medicine Department, Mansoura, Egypt; <sup>2</sup>University of Texas MD Anderson Cancer Center, Department of Gastrointestinal Medical Oncology Unit, Houston, United States; <sup>3</sup>Faculty of Medicine, Mansoura

University, Clinical Pathology department, Mansoura, Egypt; <sup>4</sup>Cleveland Clinic Abu Dhabi, Digestive disease Institute, Abu Dhabi, United Arab Emirates

Email: dr.ahmed.sultan@gmail.com

**Background and aims:** The incidence of hepatocellular carcinoma (HCC) is rapidly growing in Egyptian patients secondary to chronic hepatitis C virus (HCV) infection. Early diagnosis of HCC is associated with wider range of treatment modalities and consequently better outcome compared to late diagnosis. However, the early HCC diagnosis is still challenging due to lack of sensitive/specific markers. This study aimed of to evaluate the role of plasma level of Micro ribonucleic acid- 26a (miRNA-26a) as an early diagnostic biomarker of HCV induced HCC in Egyptian patients.

**Method:** In this case-controlled study, 75 Egyptian patients with HCV infection were divided into 3 equal groups (25 patients each); HCV induced HCC, HCV induced cirrhosis and HCV induced fibrosis. The 4th group, the control group, was formed of 25 healthy individuals. Patients with non-HCV chronic liver disease were excluded. All cases were subjected to clinical history, examination and following investigations: abdominal ultrasound, basic laboratory investigations, alfa fetoprotein (AFP) and miRNA-26a assay in plasma. The liver states were assessed using different scoring systems including: Child Pugh score (CPS), FIB4, APRI, AAR and API. Triphasic CT abdomen and AFP were used to diagnose HCC patients. Liver fibroscan was used to assess stage of liver fibrosis.

**Results:** The plasma level of miRNA-26a was comparable among all HCV groups (p value >0.05). Whereas AFP level was higher in patients with HCC relative to those in the cirrhosis and fibrosis groups (p value <0.05). Regarding the other scores (FIB4, APRI, AAR and API), the difference between HCC and fibrosis groups was significance (p value <0.05) but the difference between HCC and cirrhotic groups was not (p value >0.05). In both HCC and cirrhotic groups, patients with CPS-B had a lower miRNA-26a level relative to those with CPS-A (p value <0.05), but the AFP level was comparable.

**Conclusion:** miRNA-26a could not differentiate between HCV induced HCC and HCV induced liver cirrhosis or fibrosis.

Email: frangonzalez2909@gmail.com

**Background and aims:** Modulation of fatty acid oxidation (FAO) plays an important role in the metabolic rearrangements of liver cancer cells to survive and proliferate. Decreased FAO through downregulation of CPT2 contributes to carcinogenesis in steatohepatic-HCC. E2F1 and E2F2, well-known cell cycle regulators, are upregulated in human HCC but it is unknown whether they can regulate hepatic FAO in non-alcoholic fatty liver disease (NAFLD)-related HCC. Thus, here the contribution of E2F1 and E2F2 transcription factors in the metabolic rewiring of NAFLD-related HCC and their role in modulation of FAO were investigated.

**Method:** *E2f1*<sup>-/-</sup>, *E2f2*<sup>-/-</sup>, *E2f1/E2f2* double knockout (DKO) and wild-type mice (WT) were used. Liver disease was induced in mice by administration of diethylnitrosamine (DEN) (25 mg/kg) at 14 day-old plus high-fat diet (HFD) until sacrificed at 9 month-old. Adeno-associated viruses-serotype 8 (AAV8) were used to specifically upregulate E2F2 in mouse livers *in vivo* and adenoviruses were used to overexpress E2F2 in hepatocytes *in vitro*. Metabolic fluxes, transcriptome, ChIP and gene expression analyses were performed. Data from the TCGA-LIHC cohort were also used.

**Results:** Our data showed that *E2F1* and *E2F2* positively correlates in human HCC livers within the TCGA-LIHC cohort. Accordingly, *E2f1* and *E2f2* levels were increased in mouse livers with NAFLD-related HCC and both *E2f1*<sup>-/-</sup> and *E2f2*<sup>-/-</sup> mice were protected against liver disease. The analysis of the transcriptome that underlies the resistance to develop HCC in DEN-HFD treated *E2f1*<sup>-/-</sup> or *E2f2*<sup>-/-</sup> mice showed that the most significantly common changed pathways between the two genotypes within the upregulated genes were those related to fatty acid metabolism and oxidation. The validation of these results revealed that the expression of genes involved in FAO and oxidative phosphorylation, including *Cpt2*, were upregulated in both DEN-HFD *E2f1*<sup>-/-</sup> and *E2f2*<sup>-/-</sup> mice together with the FAO rate compared to DEN-HFD WT mice. Of relevance, the levels of *Cpt2* expression in *E2f1/E2f2* DKO mice were practically the sum of those found in single knockout mice. Both *E2F1* and *E2F2* were negatively correlated with *CPT2* in human HCC (TCGA-LIHC cohort). Specific overexpression of E2F2 in mice liver led to downregulation of *Cpt2* and repression of FAO. Even more, *in vitro* assays showed that upregulation of E2F2 in hepatocytes also induced downregulation of *Cpt2*. The ChIP analyses and *in vitro* assays with *Rb* siRNA showed that E2F2 directly binds in the corresponding *Cpt2* promoter binding site and that pRB is not involved in the E2F2-mediated *Cpt2* repression.

**Conclusion:** E2F1 and E2F2 transcription factors, required for NAFLD-HCC development, directly repress *Cpt2* expression in liver preventing FAO from activation, which promotes lipid accumulation and NAFLD progression to HCC.

### PO-196

#### Chronic liver damage favours induction of CD44v6 epithelial cells and subsequent liver carcinoma formation

**Background and aims:** Liver carcinoma is the third leading cause of cancer-related death worldwide. Tumor heterogeneity and limited therapeutic options are primarily responsible for the high mortality of liver cancer patients. Most liver cancers originate from liver epithelial cells within a chronic inflammatory microenvironment. The hyaluronic acid receptor variant CD44v6 is a marker for tumor stem cells, and its expression dramatically increases in liver epithelial cells upon carcinogen exposure. In this study, we aim to understand the role of the microenvironment on the induction of CD44v6 positive epithelial cells in the premalignant liver in the background of chronic liver damage and Trp53 deletion.

**Method:** For this study, we used transgenic liver-specific mouse models of Trp53 loss in combination with chronic liver damage: (1) HBV-S tg mice associated with continuous ER stress, (2) HCV-tg mice developing liver steatosis, (3) IKK2/NF- $\kappa$ B tg mice, mimicking chronic inflammation and (4) CCl4-treated mice developing liver cirrhosis. The induction and location of CD44v6 expressing epithelial cells and the immune-microenvironment in the premalignant liver were investigated.

**Results:** Chronic liver damage resulted in the induction of CD44v6 positive epithelial cells in all four mouse models, which was not observed in wildtype mice. We observed clusters of hepatocyte-like cells with CD44v6 expression in the HBV-S tg and the CCl4 model which are characterized by the presence of diffuse inflammation. Interestingly, CD44v6 positive epithelial cells in the HCV-tg and the IKK2/NF- $\kappa$ B cohorts were associated with the occurrence of ectopic lymphoid structures (ELS) and were located within the ELS and resulted in increased formation of intrahepatic cholangiocarcinoma.

**Conclusion:** The inflamed microenvironment is important for the induction of CD44v6 positive epithelial cells, indicating a role in tumor differentiation.

Schmid<sup>1</sup>, Ursula Ehmer<sup>1</sup>. <sup>1</sup>Klinikum rechts der Isar, TU Munich, Internal Medicine II, Munich, Germany; <sup>2</sup>TU Munich, Institute of Pathology, Munich, Germany; <sup>3</sup>TU Munich, Comparative Experimental Pathology, Munich, Germany; <sup>4</sup>University Mainz, Department of Medicine, Lichtenberg Research Group, Mainz, Germany; <sup>5</sup>University Hospital Schleswig-Holstein, Department of Medicine I, Lübeck, Germany; <sup>6</sup>TU Munich, Institute of Molecular Oncology and Functional Genomics, Munich, Germany; <sup>7</sup>TU Munich, Center for Translational Cancer Research (TranslaTUM), Munich, Germany  
Email: ursula.ehmer@tum.de

**Background and aims:** RAS mutations are found in cholangiocarcinoma as well as in some hepatocellular carcinoma (HCC). However, the relevance of different RAS-dependent signaling pathways in liver tumorigenesis is not well understood. In a genetic mouse model of RAS-activated liver cancer with early development of intrahepatic cholangiocarcinoma (ICC), tumors showed activation of PI3 K/AKT and MEK/ERK signaling. To gain insight into the relevance of different RAS-dependent signaling pathways, animals with activation of oncogenic *Kras* and genetic inactivation of either PI3K-activated AKT (*Pdk1*<sup>lox/lox</sup>) or MEK/ERK signaling (*Map2k1*<sup>lox/lox</sup>; *Map2k2*<sup>-/-</sup>) were generated.

**Method:** Cre was activated in hepatocytes of adult *Rb<sup>lox/lox</sup>;p53<sup>lox/lox</sup>;Kras<sup>LSL-G12D/+</sup>* (RPK) mice, in RPK animals deficient for MEK proteins (*RPK;Map2k1<sup>lox/lox</sup>;Map2k2<sup>-/-</sup>*) or deficient for PI3K-activated AKT signaling (*RPK;Pdk1<sup>lox/lox</sup>*) via an Albumin-driven CreER by intraperitoneal injection of tamoxifen. Liver samples were analyzed for cell proliferation, tumor development as well as for mRNA and protein expression.

**Results:** RPK tumors showed activation of PI3 K/AKT and MEK/ERK signaling by immunohistochemistry and western blot. While RPK livers showed hepatocyte proliferation 4 weeks after tamoxifen induction, reduced proliferation was detected in *RPK;AlbCre<sup>ER</sup>;Pdk1<sup>lox/lox</sup>* and also *RPK;AlbCre<sup>ER</sup>;Map2k1<sup>lox/lox</sup>;Map2k2<sup>-/-</sup>* knock-out models. In line with reduced proliferation at early time points, *Mek1/2*- as well as *Pdk1*-deleted RPK mice show significantly prolonged survival and delayed tumor formation in comparison to RPK control mice. Strikingly, deficiency of RAS downstream signaling was associated with differential changes in tumor appearance by histopathology. While PDK1-deficient RPK tumors were more well differentiated than tumors in RPK control mice, MEK-deficient RPK animals showed a differentiation shift towards HCC and mixed HCC/ICC.

**Conclusion:** In our model of RAS-dependent liver cancer, both PI3 K/AKT signaling and MEK/ERK-signaling are relevant downstream pathway that drive cell proliferation and tumor development. The differential impact of RAS-downstream signaling pathways on tumor differentiation and grading offers novel insight into liver tumorigenesis. Further investigation will be needed to investigate the impact of the observed differentiation shift on tumor targeted therapies and a potential impact of combined targeting of AKT and MEK/ERK signaling.

**Background and aims:** Mongolia has the world's highest incidence of hepatocellular carcinoma (HCC), with ~100 cases/10<sup>5</sup> inhabitants/

year. Here, we aimed at performing a molecular characterization of HCC in Mongolia and compare it with Western HCC.

**Method:** 192 paired fresh-frozen HCC/non-tumoral samples from patients undergoing resection were collected at the National Cancer Center in Ulaanbaatar, Mongolia. Whole exome sequencing (WES) and RNAseq were performed in 151 and 106 samples, respectively. WES, RNAseq and clinical data from an in-house Western cohort were used for comparison (n=187). Mutation calling and mutational signature analysis were evaluated. HBV viral genotype was assessed by direct sequencing.

**Results:** Mongolian patients, compared to Western, were younger (61 vs 66 years old), with lower male predominance (54% vs 80%), less advanced hepatic fibrosis (F3-4, 38% vs 79%), higher rate of HBV-HDV co-infection (84% vs 7% of HBV infected), and predominance of HBV genotype D (90% vs 43% of HBV infected) (all p < 0.001). Mongolian HCC presented unique molecular features including: a) Higher number of protein-coding mutations (121 vs 70 mut/tumor, p < 0.001), as well as higher mutational rate in known (e.g. *TP53* [46% vs 32%], *APOB* [15% vs 5%], *KMT2* family [34% vs 17%]) and putative HCC drivers in Mongolian tumors (*TSC2*, 9% vs 1%) (all p < 0.05). b) Presence of a new mutational signature (SBS Mongolia, 25% vs 4.5%, p < 0.05) not matching any previous substitution profile in liver cancer. SBS Mongolia was characterized by T>G substitutions and enrichment for dimethyl sulfide genotoxic signature, related to coal combustion. c) A distinct transcriptomic profile consisting in three molecular clusters (Figure). MGL1 class (44%) was associated with HCV infection (32% vs 7%/3%) in older patients (62 vs 56 years old) (p < 0.05) and resembled Western HCCs. MGL2 (26%) and MGL3 classes (30%) were specific for Mongolian tumors and were enriched in HBV-HDV infection (93%/97% vs 60%, p < 0.001). MGL2 class showed a female/male ratio of 2:1, and clinical and molecular features of aggressiveness (e.g. higher AFP >400, proliferation classes). MGL3 was enriched in inflammatory signaling.

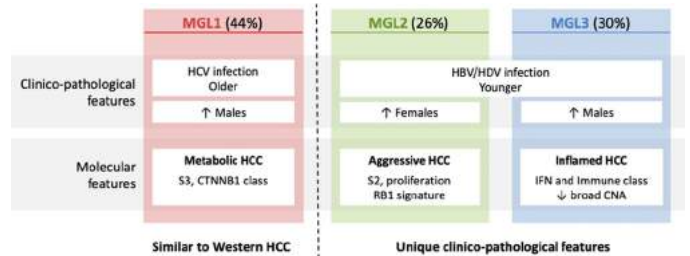

Figure:

**Conclusion:** HCC in Mongolia presents specific molecular traits characterized by a high mutational burden, a newly described mutational signature and two novel molecular classes. Further studies exploring environmental factors associated with these alterations are required.

**PO-677**

**New mouse model of cholangiocarcinoma arising in the setting of progressive biliary injury and fibrosis**

Pinzhu Huang<sup>1</sup>, Guangyan Wei<sup>2</sup>, Shuangshuang Zhao<sup>2</sup>, Disha Badlani<sup>1</sup>, Li Chen<sup>3</sup>, Mathieu Petitjean<sup>4</sup>, Xin Chen<sup>5</sup>, Gregory Gores<sup>6</sup>, Yuri Popov<sup>2</sup>. <sup>1</sup>Beth Israel Deaconess Medical Center, Harvard Medical School, Division of Gastroenterology and Hepatology, Boston, United States; <sup>2</sup>Beth Israel Deaconess Medical Center, Harvard Medical School, Division of Gastroenterology and Hepatology, Boston, United States; <sup>3</sup>PharmaNest, Inc, United States; <sup>4</sup>PharmaNest, Inc, Princeton, United States; <sup>5</sup>University of California, San Francisco, United States; <sup>6</sup>Mayo Clinic  
Email: ypopov@bidmc.harvard.edu

**Background and aims:** Cholangiocarcinoma (CCA) is a dreaded complication of primary sclerosing cholangitis (PSC), difficult to diagnose and associated with high mortality. Currently, lack of animal

## POSTER PRESENTATIONS

models of CCA recapitulating the hepatic microenvironment of progressive sclerosing cholangitis precludes tumor treatment. Thus, we sought to develop a PSC associated CCA animal model and test the therapeutic value of TGF $\beta$  signalling via targeting ALK5.

**Method:** Ten weeks old Mdr2 $^{-/-}$  mice with congenital PSC-like progressive biliary disease, and healthy wild-type littermates (WT) mice were subjected to either modified retrograde biliary instillation (Yamada, et al. *Hepatology* 2015, without concomitant IL-33 or bile duct ligation) or hydrodynamic tail vein injection (Zhang, et al. *J Hepatol* 2017) of sleeping beauty transposon-transposase plasmid system with activated forms of AKT (myr-AKT) and Yap (YapS127A) protooncogenes (SB AKT/YAP1). ALK5 inhibitor (SB-525334, 300 mg/kg in diet) or placebo diet was administered into tumor-bearing mice in early (1–4 weeks post injection) or delayed (3–6 weeks post oncogene transduction) to interrogate functional role of TGF $\beta$  signalling in our model. Tumor phenotype and burden were analyzed using histological methods. Desmoplastic stroma of the tumors was quantified using automated FibroNest platform (PharmaNest Inc) from Sirius Red (SR) staining.

**Results:** While SB AKT/YAP1 plasmids via retrograde biliary injection caused tumors in all Mdr2 $^{-/-}$  but not in healthy wildtype mice (n = 10), only 26.67% (4/15) of these tumors were CCA and this approach was deemed unsuccessful.

Alternative, hydrodynamic tail vein injection of SB AKT/YAP1 resulted in robust tumorigenesis in fibrotic Mdr2 $^{-/-}$  mice (n = 10), with 100% incidence and high CCA burden after 6 weeks. In contrast, only 6 out of 9 healthy wildtype mice (66.67% incidence) developed tumors. Higher CCA numbers (52.60  $\pm$  6.81 vs. 1.11  $\pm$  0.51, p < 0.01) with profound desmoplastic reaction and significantly shortened survival were observed in Mdr2 $^{-/-}$  mice compared to non-fibrotic controls. Early, but not delayed, pharmacological TGF $\beta$  inhibition via Alk5 reduced tumor burden by 2.4 fold (11.00  $\pm$  1.41 vs. 24.80  $\pm$  5.75, n = 5, p = 0.0481) and desmoplastic stroma of the tumors by 2 fold (tumor collagen area %, 7.36  $\pm$  0.57 vs. 13.96  $\pm$  1.92, n = 5, p = 0.01), respectively, compared to placebo.

**Conclusion:** We established a new high-fidelity cholangiocarcinoma model in mouse, termed SB CCA.Mdr2 $^{-/-}$ . It recapitulates the increased susceptibility to CCA in the setting of progressive biliary injury and fibrosis observed in PSC, and enables mechanistic research and formal testing of new therapies for this devastating disease. Furthermore, pharmacological targeting of Alk5 in our model suggests that TGF $\beta$  signalling functionally drives CCA tumorigenesis and promotes desmoplastic reaction in a complex, stage-specific manner.

#### Immuno-responsive classification of hepatocellular carcinomas as a potential surrogate for precision immuno-oncology

Jihyun An<sup>1</sup>, Ji-Hye Oh<sup>2</sup>, Wonkyung Kim<sup>2</sup>, Bora Oh<sup>2</sup>, Yoo-Jin Oh<sup>2</sup>, Chang Ohk Sung<sup>2</sup>, Ju Hyun Shim<sup>2</sup>. <sup>1</sup>Hanyang University, Korea, Rep. of South; <sup>2</sup>Asan Medical Center, Seoul, Korea, Rep. of South  
Email: s5854@amc.seoul.kr

**Background and aims:** Programmed cell death ligand-1 (PD-L1) expression has not served as a predictive marker for immunotherapy targeting the checkpoint in patients with hepatocellular carcinoma (HCC). The cross-talk among various intrinsic or extrinsic immune-related composites within the tumor microenvironment could play a role in the PD-L1 regulation. Here, we explored the dynamic interplay between PD-L1 expression and other predefined predictors of response to checkpoint inhibitors in HCC, and classified the tumors based on potential responsiveness to the therapy.

**Method:** This study included the Asan genomic cohort of 206 HCC patients receiving primary hepatectomy who had both whole exome sequencing and RNA sequencing datasets. PD-L1 expression was evaluated by immunohistochemical assay using the 22C3 antibody with a Combined Positive Score (CPS) cut-off of 1%. Tumor mutational

burden (TMB), neoantigen load, and T-cell inflamed phenotype were measured using genomic data.

**Results:** PD-L1 positivity was observed in 29 (14.1%) of the 206 patients. Genesets related to immune system and proliferation were highly enriched in the PD-L1-positive group with no difference in clinical and pathological data. PD-L1 expression was significantly correlated with T cell-inflamed phenotype, as was not with neoantigen or TMB. We next constructed a novel Immuno-responsive classification of HCC by PD-L1 and TMB that were mutually exclusive: C1, +/+; C2,  $\pm$ ; C3, -/+; and C4, -/-, respectively for PD-L1 and TMB. Most immune cell types were highly infiltrated in the C1 and C2 groups with the relative abundance of Immune-checkpoint genes. Survival outcomes were also better in the two subclasses.

**Conclusion:** Our immunogenomic analysis uncovered potential immuno-responsive HCC subtypes with distinct patterns of targetable immune biology. Tailored studies of patients treated with immunomodulators are needed for future clinical use of the classification.

### PO-1118

#### Metabolic reprogramming in a c-Myc/h-Ras transgenic mouse model of hepatocellular carcinoma

Marina Serra<sup>1</sup>, Mario di Matteo<sup>2</sup>, Amedeo Columbano<sup>1</sup>, Massimiliano Mazzone<sup>2</sup>. <sup>1</sup>Università degli Studi di Cagliari, Biomedical Sciences, Monserrato (CA), Italy; <sup>2</sup>VIB-Center for Cancer Biology, Oncology, Leuven, Belgium  
Email: mari\_serra93@hotmail.it

**Background and aims:** Hepatocellular carcinoma (HCC), as well as many other solid tumors, develops through a multi-step process whereby abnormally proliferating cancer cells undergo a large metabolic reprogramming. Mounting evidence suggests that the different metabolic alterations taking place in hepatocarcinogenesis are dependent on the activation of specific oncogenes, thus partially explaining the HCC heterogeneity. The aim of the present study was to investigate the metabolic reprogramming occurring in liver tumors induced by the concomitant expression of c-Myc and h-Ras, two of the most frequently upregulated oncogenes in human HCCs.

**Method:** C57BL/6J mice were hydrodynamically co-transfected with PB\_h-Ras<sup>G12V</sup> and PB\_c-Myc, in conjunction with a plasmid encoding a hyperactive PB transposase (hyPBBase). The liver-specific promoter minimal transthyretin (TTRmin) was used to drive oncogene expression exclusively in hepatocytes. Tumor bearing mice were sacrificed 14 weeks after hydrodynamic injection. QRT-PCR, immunohistochemistry and histochemistry were performed to assess the mRNA levels and protein levels, as well as enzymatic activity.

**Results:** The present work revealed that c-Myc/h-Ras<sup>G12V</sup> driven tumors display a striking glycolytic metabolism suggestive of a switch to a Warburg phenotype, and an enhanced activity of pentose phosphate pathway (PPP). Differently from HCCs generated by the overexpression of c-Myc alone, glutamine seems to be mostly utilized to sustain glutathione synthesis instead of Tricarboxylic acid cycle (TCA), in order to protect cancer cells from oxidative damages. All these changes were associated to an impairment of oxidative phosphorylation (OXPHOS), as determined by a reduction of succinate dehydrogenase activity.

**Conclusion:** Our results obtained in an engineered mouse model of hepatocarcinogenesis demonstrate a metabolic switch from OXPHOS to glycolysis caused by the concomitant overexpression of c-Myc and h-Ras, two of the most frequently altered oncogenes in HCC. This finding further supports the notion that targeting metabolism may represent a critical strategy for HCC therapy. Our study will be further extended to a set of clinically relevant oncogenic cooperation to quickly unravel oncogene-specific metabolic vulnerabilities in HCC.

**PO-1304**

**Targeting tumor-initiating cells and compensatory YAP pathway activation to overcome sorafenib-induced resistance in hepatocellular carcinoma**

Darko Castven<sup>1,2</sup>, Carolin Czauderna<sup>1,2</sup>, Diana Becker<sup>2</sup>, Sharon Pereira<sup>2</sup>, Kai Breuhahn<sup>3</sup>, Jennifer Schmitt<sup>3</sup>, Marcus-Alexander Wörns<sup>2</sup>, Jovana Hajduk<sup>1,2</sup>, Snorri Thorgeirsson<sup>4</sup>, Peter Galle<sup>2</sup>, Jens Marquardt<sup>1,2</sup>. <sup>1</sup>University Hospital Schleswig-Holstein, Department of Medicine I, Lübeck, Germany; <sup>2</sup>University Hospital Mainz, Department of Medicine I, Mainz, Germany; <sup>3</sup>University Hospital Heidelberg, Institute of Pathology, Heidelberg; <sup>4</sup>National Cancer Institute, NIH, Laboratory of Human Carcinogenesis, Bethesda, United States  
Email: castvendarko@gmail.com

**Background and aims:** Induction of chemoresistance upon systemic therapy is frequently observed in the majority of HCC patients. Accumulating evidence suggests that tumor-initiating cells (TICs) may contribute to the acquisition of resistance in many solid tumors, but their exact role for HCC remains to be defined. Here, we evaluate the importance of TICs in the development of resistance and relapse formation after exposure to sorafenib in HCC and define concomitant adaptive molecular targets.

**Method:** Four HCC cell lines and two primary HCC isolates were exposed to sorafenib for a total of 14 days. The treatment effects on TICs were estimated by sphere forming capacity *in vitro* and tumor-initiating potential *in vivo*, as well as the side-population (SP) approach. Expression of key CSC marker EpCAM was assessed by flow cytometry. Furthermore, whole transcriptome analyses were performed across the cell lines and identified potential targets, which were further validated by immunohistochemistry, western blot and administration of specific inhibitors.

**Results:** Treatment with sorafenib effectively reduced oncogenic properties in all investigated HCC cells. However, sustained anti-proliferative effect after treatment was observed in half of the cell lines, while initial treatment effect in other lines was followed by rapid re-growth thereby resembling the responses observed in patients. Anti-oncogenic effects in sensitive cell lines were associated with significant reduction in sphere-forming and tumor-initiating capacity, CSC marker EpCAM as well as SP cells, while resistant cell lines showed transient induction in TIC properties. Acquired resistance uniformly developed in cell lines suggesting that common molecular mechanisms might be operative. These adaptive molecular changes involved signaling pathways known to be associated to cell survival, proliferation and cell cycle regulation (RAS, IL6, MYC, E2F3). Furthermore, the resistant cell lines showed compensatory upregulation of key oncogenic molecules such as EGFR, as well as YAP. Validation on authentic HCC samples confirmed enrichment of YAP signaling in the patients with worst response to sorafenib treatment. Conclusively, combined treatment including sorafenib and specific YAP inhibitor showed beneficial effects in resistant cell lines which resulted in complete response to the therapy.

**Conclusion:** Our model recapitulates features of drug resistance observed in human HCC patients. Resistance to anti-angiogenic therapy might be fueled by transient expansion of TICs. Therefore, specific targeting of TICs as well as pro-oncogenic compensatory signaling pathways might be an effective therapeutic strategy to overcome resistance in HCC.

**PO-1352**

**Study on the mechanism of chemokine CCL21 mediating IRBIT in the malignant biological behavior of liver cancer**

Jingyu Xu<sup>1</sup>, Jianhong Ding<sup>1</sup>, Biguang Tuo<sup>1</sup>, Rui Xie<sup>1</sup>. <sup>1</sup>Affiliated Hospital of Zunyi Medical University, Department of Gastroenterology, Zunyi, China  
Email: xujingyu\_gzzy@126.com

**Background and aims:** Liver cancer is highly malignant and has a high incidence. It is currently believed that the migration and

invasion of liver cancer are the significant factors leading to the poor prognosis of patients with liver cancer, but the specific mechanism is still unclear. Studies have shown that the chemokine CCL21 play a crucial role in the malignant biological behavior of tumors. Our research shows that the CCL21 causes the increase of intracellular calcium ( $[Ca^{2+}]_i$ ) and promotes the migration and invasion of liver cancer, indicating that the relevant ion channels involved in the regulation of  $[Ca^{2+}]_i$  activation. IRBIT is a binding protein for the IP3 receptor and the dissociated IRBIT can activate a variety of ion channels. Moreover, our research shows that CCL21 can induce the up-regulation of IRBIT expression. Therefore, this study aims to explore the potential mechanism of CCL21-mediated IRBIT in liver cancer, in order to seek new drug targets for the treatment of liver cancer.

**Method:** Western blotting and immunohistochemistry were used to detect the expression of IRBIT in liver cancer. CCK8 assays, Transwell assays with matrigel, wound healing assay, and western-bolt to detect the proliferation and migration ability of liver cancer cells after silencing IRBIT. The migration and invasion ability of liver cancer cells and the expression of IRBIT was detected after CCL21 stimulation. Cell calcium imaging detected the  $[Ca^{2+}]_i$  of liver cancer cells caused by CCL21, and using different calcium blockers to screen calcium channels that were affected by CCL21 in liver cancer cells.

**Results:** 1.The expression of IRBIT in liver cancer tissues and cells is significantly increased. 2.After IRBIT silenced in Huh7 cells, the proliferation, migration and invasion abilities were significantly reduced compared to control cells, and the expression of E-cadherin and ZO-1 increased, and the expression of N-cadherin and Vimentin decreased. 3.CCL21 culture increased the migration and invasion ability and IRBIT expression of the Huh7 cells. 4.20 uM CCL21 can induce the concentration of  $[Ca^{2+}]_i$  increase in Huh7 cells. 5.Inhibitor KB-R7943 can inhibit the increase of  $[Ca^{2+}]_i$  and decrease the expression of NCX1 induced by CCL21, and can inhibit the migration and invasion of liver cancer cells.

**Conclusion:** CCL21/IRBIT may acts a promoting role in the development of liver cancer, providing a new theoretical basis for the treatment or prevention of recurrence and metastasis of liver cancer.

**PO-1629**

**Influence on cancer cell energy metabolism by pharmacological inhibition of the histone modifying lysine-specific demethylase 1**

Jie Wang<sup>1</sup>, Marcel Schmiel<sup>1</sup>, Yefeng Shen<sup>1</sup>, Priya Dalvi<sup>1</sup>, Xiaojie Yu<sup>1</sup>, Yue Zhao<sup>2</sup>, Reinhard Büttner<sup>1</sup>, Lingyu Wang<sup>1</sup>, Margarete Odenthal<sup>1</sup>. <sup>1</sup>University Hospital of Cologne, Institute for Pathology, Cologne, Germany; <sup>2</sup>University Hospital of Cologne, Department of General, Visceral and Tumor Surgery, Cologne, Germany  
Email:

**Background and aims:** Epigenetic alterations are important features in the process of carcinogenesis. The lysine-specific histone demethylase-1 (LSD1) affects cell growth and is overexpressed in a wide variety of cancer types. Interestingly, recent work has shown that LSD1 also influences mitochondrial function in adipocytes, but its role in mitochondrial activity in cancer has not yet been addressed. Therefore, in the present study, we investigated mitochondrial gene expression and function upon LSD1 inhibition in hepatocellular carcinoma (HCC).

**Method:** LSD1 was inhibited in different hepatoma cell lines by means of RNA interferences or application of a specific LSD1 inhibitor HCI-2509. Global transcriptomics was carried out by RNA ultra-deep sequencing and protein expression profiles were analyzed by MS-spectrometry. Divergent expression in response to LSD1 inhibition was validated by quantitative PCR. LSD1 influence on promoter interaction was performed by ChIP. Changes of the mitochondrial membrane potential were investigated by confocal microscopy and flow cytometry. Metabolic and respiratory changes were further determined by the Seahorse platform. Besides, TCGA data (National

## POSTER PRESENTATIONS

Cancer Institute) from HCC patients were evaluated in malignant versus healthy liver samples.

**Results:** Gene expression profiling followed by pathway analysis of hepatoma cell types revealed a prominent dysregulation of genes involved in the cell cycle control and mitochondrial function after LSD1 inhibition. Especially, genes encoding subunits of the mitochondrial respiratory complex I were repressed. Accordingly, we proved a decrease of the mitochondrial membrane potential, lower ATP production and lower maximal respiration upon LSD1 inhibition in cancer cells. Furthermore, TCGA data from HCC patients pointed to a distinct difference in the expression of LSD1 targeted metabolic genes in tumor samples compared to non-transformed tissues.

### Assesment of the respiration upon LSD1 inhibition

Figure:

**Conclusion:** Our data emphasize the value of LSD1 inhibition in new strategies of cancer therapy, revealing the impact of LSD1 inhibition not only on cell cycle arrest but also by energy depletion due to mitochondrial dysfunction.

### PO-1752

#### Human antigen R (HuR) SUMOylation fine-tunes hepatocellular carcinoma (HCC) progression by modulating the expression of mitochondrial mRNAs

Email: mlmartinez@cicbiogune.es

**Background and aims:** As we await the results from ongoing phase III clinical trials, we sought to identify additional approaches for the management of hepatocellular carcinoma (HCC). Considering the numerous and complex molecular mechanisms underlying the malignant transformation of a healthy liver into HCC, drugs against more than one signaling route would need to be developed in order to stop the progression of the disease. In this context, the posttranslational modification (PTM) of proteins, which controls the specificity, timing, duration and amplitude of virtually all cellular processes, has emerged as a robust and multidimensional therapeutic strategy in cancer. Interestingly, PTMs are key mechanisms that regulate the function of the RNA-binding protein Human antigen R (HuR), which is known to be involved in HCC transformation, in addition to playing a role in liver physiology. Moreover, a Gene Set Enrichment Analysis (GSEA) based on The Cancer Genome Atlas (TCGA) mRNA expression repository associated HuR expression with the ubiquitin-like PTM SUMOylation in HCC. Given that SUMOylation has never been described for HuR, the main aim of the present work is to elucidate the pathophysiological role of this PTM in liver cancer.

**Method:** A novel protein pull-down technology based on GST-tagged SUMO Binding Entities (SUBEs) was used to capture the native SUMO-interacting proteome from human and mouse liver tissue and cell line extracts, in combination with Western Blotting and Liquid Chromatography-tandem Mass Spectrometry (LC-MS/MS) for protein identification purposes. Additionally, human HCC HuH-7 cell lines that stably express the wild-type and the SUMOylation mutant versions of HuR were developed in-house and their phenotypes studied.

**Results:** HuR is SUMOylated in the tumor sections of HCC patients in contrast to the surrounding tissue, as well as in the MYC-luc;sg-p53 genetically engineered mosaic mouse model of liver cancer, and in human hepatoma cell lines. SUMOylation of HuR promotes major cancer hallmarks, namely proliferation and invasion, in the HuH-7 cell line. Conversely, the absence of HuR SUMOylation results in a senescence-like phenotype with damaged mitochondrial structure and function. Regarding the mechanism of action, we propose that HuR SUMOylation might drive HCC progression by modulating mitochondrial structural integrity and functionality through the regulation of the stability and translation of mRNAs encoding key mitochondrial proteins.

Figure:

**Conclusion:** SUMOylation constitutes a novel mechanism of HuR regulation that could be potentially exploited as an aptamer-based therapeutic strategy for liver cancer, thus highlighting the importance of PTMs as disease targets. Furthermore, understanding the effects of HuR SUMOylation in hepatocarcinogenesis will provide new functional insights into the relatively unknown role of SUMOylation in cancer.

**PO-1771**

**The expressions of CCNB1, CDC20 and CENPF is both peripheral blood and liver is associated with anti-tumour immunity in HCC**  
 Zhenlin Huang<sup>1,2</sup>, Tengfei Si<sup>2</sup>, Yun Ma<sup>2</sup>, Nigel Heaton<sup>3</sup>, Wael Jassem<sup>3</sup>, Shirin Elizabeth Khorsandi<sup>3</sup>. <sup>1</sup>Shanghai University of Traditional Chinese Medicine, The MOE Key Laboratory for Standardization of Chinese Medicine; <sup>2</sup>King's College Hospital, Institute of Liver Studies; <sup>3</sup>King's College Hospital, Transplant Service  
 Email: yun.ma@kcl.ac.uk

**Background and aims:** Hepatocellular carcinoma (HCC) is one of the most common malignant tumours in the liver, accounting for 90% of primary liver cancer. It has been reported that CCNB1, CDC20 and CENPF may play important roles in the development of various

cancers, including HCC. However, the impact of these three genes on host immunity in patients with HCC remains unknown.

**Method:** Peripheral blood mononuclear cells (PBMCs) were isolated using density gradient centrifugation from 50 HCC patients at the King's College Hospital from February 2020 to November 2020. Sixteen paired tumour tissue and adjacent liver tissue, and 12 normal liver tissues from patients with hemangioma or focal nodular hyperplasia (FNH) were collected. Real-time PCR was used to measure the mRNA expression levels of CCNB1, CDC20, CENPF, TNF- $\alpha$ , IFN- $\gamma$  and IL-17 using commercially available kits (RNAqueous, Maxima™ H Minus cDNA Synthesis Master Mix, and SYBR Select Master Mix, Thermo Fisher Scientific, USA). The phenotypic analysis of PBMCs was conducted by a 5-laser BD LSR Fortessa™ Flow Cytometer.

**Results:** CCNB1, CDC20 and CENPF mRNA in tumour tissue were up-regulated compared to adjacent tumour tissue and normal liver tissue, while in PBMCs the expression of three genes in untreated HCC was significantly down-regulated compared to normal liver tissues, the expression of three genes in untreated HCC was significantly down-regulated while along with treatment, the expression levels were gradually increased. In PBMCs, mRNA expressions of TNF- $\alpha$ , IFN- $\gamma$  and IL-17 in treated HCC patients without active tumour were significantly higher than untreated HCC patients, being similar to that in normal liver or treated HCC patients with active tumour. Moreover, in PBMCs of untreated HCC patients the proportion of both CD8+ T cells and double negative (CD8-CD4-) T cells were lower, while the percentage of CD4+ T cells was higher than in healthy controls. The expression level of CENPF was positively correlated with the counts of CD8+ T cells and negatively with CD4+ T cells. mRNA expression of CCNB1, CDC20 and CENPF showed positive correlation with mRNA expression levels of anti-tumour cytokines in PBMCs.

**Conclusion:** CCNB1, CDC20 and CENPF showed strong association with anti-tumour immunity in both peripheral blood and liver of HCC patients. To quantify the expression of these genes in association with anti-tumour cytokine genes in both PBMCs and tumour tissue may help in assessing the treatment efficacy in HCC patients.

## POSTER PRESENTATIONS

PO-1825

### Programmed Death-Ligand 1 protein is preferentially expressed in tumor-associated macrophages in peritumoral regions of hepatocellular carcinoma

Pil Soo Sung<sup>1</sup>, Dong Jun Park<sup>1</sup>, Jeong Won Jang<sup>1</sup>, Si Hyun Bae<sup>1</sup>, Jong Young Choi<sup>1</sup>, Seung Kew Yoon<sup>1</sup>. <sup>1</sup>The Catholic University of Korea, Internal Medicine, Seoul, Korea, Rep. of South  
Email: pssung@catholic.ac.kr

**Background and aims:** Biomarker for predicting immune-based treatments in advanced hepatocellular carcinoma (HCC) has not been clearly demonstrated. In this study, we focused on the infiltration and programmed death ligand 1 (PD-L1) expression of T cells and tumor-associated macrophages (TAMs) in HCC.

**Method:** Peripheral blood mononuclear cells (PBMCs) were obtained from eight patients with unresectable HCC before and 4 weeks after nivolumab treatment. Immunohistochemical staining and multicolor flow cytometry were performed on liver tissues and PBMCs of patients with HCC. For *in vitro* experiments, anti-PD-L1-treated M2 macrophages were co-cultured with activated T cells to evaluate the role of PD-L1-expressing TAMs in anti-PD-1/PD-L1 treatment. For *in vivo* experiments, an immunogenic syngeneic HCC mouse model was established to determine the frequency and role of tumor-infiltrating T cells and TAMs.

**Results:** Three of the eight enrolled patients responded to anti-PD-1 treatment. Increased frequency of Ki-67-positive CD4<sup>+</sup> and CD8<sup>+</sup> T cells was noted in nivolumab-responder PBMCs obtained after 4 weeks of treatment. Immunohistochemical staining for PD-L1 as well as for the CD 3 and CD68 demonstrated that T cells and PD-L1-expressing TAMs were infiltrated in both intratumoral and peritumoral tissue of patients with HCC. The number of peritumoral TAMs positively correlated with PD-L1 expressing cells and PD-L1 protein co-localized with CD68, suggesting that PD-L1 was mainly expressed in TAMs rather than T cells or tumor cells in HCC ( $p < 0.05$ ). *In vitro* experiments confirmed that T-cell functionality (INF- $\gamma$  and TNF- $\alpha$  production) significantly increased when M2 macrophages were treated with anti-PD-L1. In syngeneic Hepa1-6 mouse model, TAMs expressed very high levels of PD-L1. In this model, tumors with anti-PD-L1 or lenvatinib treatment showed significantly smaller diameter that those with IgG treatment. In these experiments, after anti-PD-L1 treatment, intra-tumoral CD8<sup>+</sup> T cells showed higher expression of activation markers and the frequency of TAMs was significantly reduced, suggesting that the decreased size of the tumors after anti-PD-L1 treatment resulted from the reinvigoration of CD8<sup>+</sup> T cells.

\*This research was supported by the Basic Science Research Program through the National Research Foundation of Korea (NRF) and funded by the Ministry of Education (NRF-2019R111A1A01059642).

PO-1949

### Role of hypoxia-inducible factors 1alpha and 2alpha in prognosis and sorafenib chemoresistance in hepatocarcinoma

Carolina Méndez-Blanco<sup>1</sup>, Flavia Fondevila<sup>1</sup>, Paula Fernández-Palanca<sup>1</sup>, Jos van Pelt<sup>2</sup>, Chris Verslype<sup>2</sup>, Javier González-Gállego<sup>1</sup>, José Luís Mauriz<sup>1</sup>. <sup>1</sup>Institute of Biomedicine (IBIOMED), University of León, León, Spain and Centro de investigación biomédica en red de enfermedades hepáticas y digestivas (CIBERehd), Instituto de salud Carlos III, Madrid, Spain; <sup>2</sup>Laboratory of Clinical Digestive Oncology, Department of Oncology, KU Leuven and University Hospitals Leuven and Leuven Cancer Institute (LKI), Leuven, Belgium  
Email: jl.mauriz@unileon.es

**Background and aims:** Hepatocarcinoma (HCC) is a recurrent tumor and is closely related to hypoxia. Hypoxic response is mediated by hypoxia-inducible factors (HIFs), which contribute to tumor progression and chemoresistance. We evaluated the prognostic role of HIF-1alpha and HIF-2alpha in HCC patients and its implication in sorafenib resistance development in an *in vitro* HCC model.

**Method:** We systematically searched Embase, Cochrane, PubMed, Scopus and WOS for studies testing HIF-1alpha and/or HIF-2alpha expression in HCC until June 1, 2020. Selected articles assess HIFs by immunohistochemistry in patients after surgical resection and its relationship with prognosis. We metaanalyzed the data extracted or estimated according to Parmar method using STATA. We evaluated the overall Hazard Ratio with 95% Confidence Interval, heterogeneity with I<sup>2</sup> statistic and Q test, subgroup analysis and publication bias by Egger's test. Likewise, we used HepG2 cells and sorafenib resistant derived lines (HepG2S1 and HepG2S3), CoCl<sub>2</sub> to mimic hypoxia, and cycloheximide and MG132 to repress protein synthesis and proteasome degradation. Proliferation was analyzed by ki67 assessment; gene expression by array or qRT-PCR, protein expression by Western blot and immunofluorescence; subG1 population by flow cytometry; viability by MTT; and gene silencing by siRNA transfection.

**Results:** 32 articles were included in the quantitative analysis, showing that HIF-1alpha overexpression correlated with overall survival (OS) and disease-free survival (DFS)/recurrence-free survival (RFS) in HCC patients. Initially only DFS/RFS was associated with HIF-2alpha overexpression, but subgroup analysis related it to OS. Publication bias was denoted in HIF-1alpha OS. Experimentally, resistant cells showed higher proliferative rate and increased HIFs

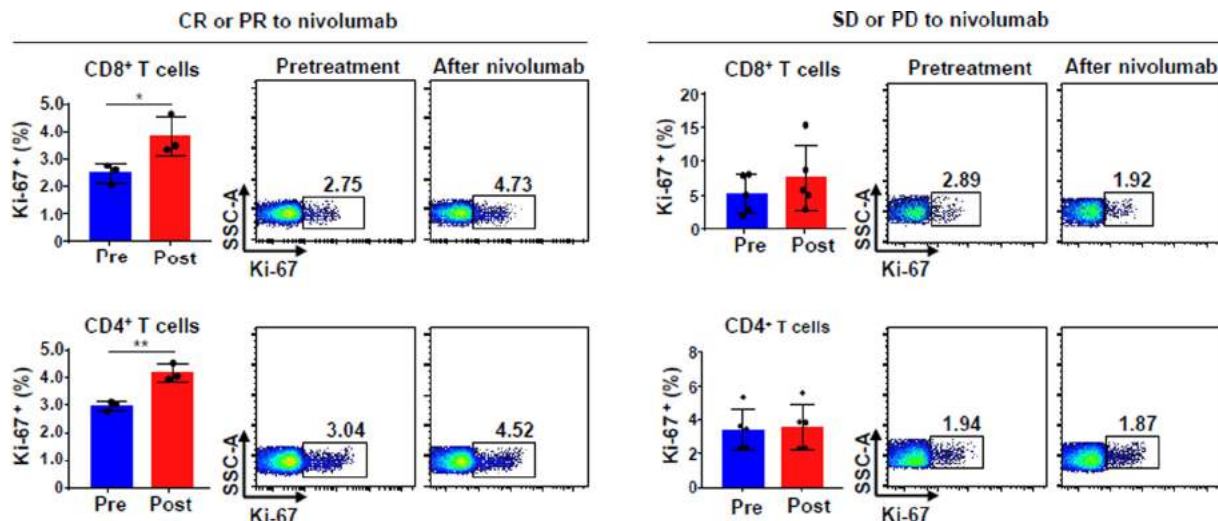

Figure: (abstract: PO-1825)

protein levels and nuclear translocation. HIFs overexpression was observed even under normoxia due to a deregulation of its proteasomal degradation. Levels of proapoptotic proteins and subG1 cells declined significantly in resistant lines, suggesting evasion of sorafenib-mediated apoptosis. HIFs silencing reduced resistant cells viability, relating HIFs overexpression with its prosurvival ability.

**Conclusion:** HIFs overexpression is related to recurrence and poor survival in HCC patients after resection and it seems to be a hallmark of sorafenib resistance acquisition. Hence, both HIFs could be useful HCC biomarkers as well as potential therapeutic targets.

**PO-1957**

**Resistance to sorafenib in hepatocarcinoma: role of BCL2 interacting protein 3 promoter hypermethylation**

Paula Fernández-Palanca<sup>1</sup>, Carolina Méndez-Blanco<sup>1</sup>, Flavia Fondevila<sup>1</sup>, Jos van Pelt<sup>2</sup>, Chris Verslype<sup>2</sup>, Javier González-Gállego<sup>1</sup>, José Luís Mauriz<sup>1</sup>. <sup>1</sup>Institute of Biomedicine (BIOMED), University of León, León, Spain and Centro de investigación biomédica en red de enfermedades hepáticas y digestivas (CIBERehd), Instituto de salud Carlos III, Madrid, Spain; <sup>2</sup>Laboratory of Clinical Digestive Oncology, Department of Oncology, KU Leuven and University Hospitals Leuven and Leuven Cancer Institute (LKI), Leuven, Belgium  
Email: jl.mauriz@unileon.es

**Background and aims:** The antiangiogenic activity of sorafenib, first-line drug against advanced hepatocarcinoma (HCC), ends with the establishment of hypoxia that is closely related to chemoresistance. BCL2 interacting protein 3 (BNIP3) is a mitochondrial protein expressed in hypoxic tumor areas whose silencing has been associated to poor prognosis and chemoresistance in cancer. We aimed to assess the implication of BNIP3 in the development of hypoxia-related resistance to sorafenib in an in vitro model of human HCC with acquired sorafenib resistance.

**Method:** HepG2 cell line and sorafenib resistant derived lines (HepG2S1 and HepG2S3) were employed. We used CoCl<sub>2</sub> to mimic hypoxia, trichostatin-A (TSA) as histone deacetylases (HDACs) inhibitor and decitabine (5-Aza) as DNA methyltransferases (DNMTs) inhibitor. Gene expression was analyzed by RT-PCR, qRT-PCR, and protein expression by Western blot and immunofluorescence. Promoter methylation was assessed by methylation-specific PCR (MSP) and cell viability by MTT. Finally, gene silencing was performed via transfection of a pool of BNIP3-specific siRNA. Statistical analysis was performed using GraphPad Prism 6, considering significant differences when  $p < 0.05$ .

**Results:** Resistant cells HepG2S1 and HepG2S3 showed a significant decrease in BNIP3 protein levels in comparison to the parental line under both normoxia and hypoxia. Accordingly, higher BNIP3 levels were found in HepG2 cells, which reduced after sorafenib treatment. Moreover, we also observed lower BNIP3 mRNA levels in both resistant lines under hypoxia compared to HepG2. Epigenetic study revealed that HDACs were not involved in BNIP3 silencing, since BNIP3 protein levels were not detected in resistant cells after TSA administration. However, an increase in the methylation status of BNIP3 promoter was observed in both HepG2S1 and HepG2S3 lines under hypoxia. This was reversed by DNMTs inhibition, leading to an increase in the expression of BNIP3 similar to the levels registered in the parental line. Lastly, BNIP3 silencing achieved to decrease BNIP3 protein expression previously induced by 5-Aza and to significantly rise resistant cell viability initially inhibited by 5-Aza treatment.

**Conclusion:** BNIP3 silencing by promoter hypermethylation seems to constitute a key mechanism in the development of sorafenib

resistance. Hence, BNIP3 expression recovery could be a promising approach in the therapeutic landscape of advanced HCC.

**Abnormal glycosphingolipid patterns in human cholangiocarcinoma stem-like subset**

Antonella Mannini<sup>1</sup>, Chiara Raggi<sup>1</sup>, Margherita Correnti<sup>2</sup>, Elisabetta Rovida<sup>1</sup>, Massimo Aureli<sup>2</sup>, Emma Carsana<sup>2</sup>, Benedetta Piombanti<sup>1</sup>, Mirella Pastore<sup>1</sup>, Jesper B. Andersen<sup>3</sup>, Cedric Coulouarn<sup>4</sup>, Fabio Marra<sup>5</sup>. <sup>1</sup>University of Florence; <sup>2</sup>University of Milan; <sup>3</sup>University of Copenhagen; <sup>4</sup>University of Rennes; <sup>5</sup>University of Florence, Italy  
Email: fabio.marra@unifi.it

**Background and aims:** Cancer stem cells (CSC) are a crucial therapeutic target in cancer. Several studies in different types of cancer (e.g. Burkitt's lymphoma, pancreatic carcinoma, other epithelial cancers) indicate that glycosphingolipids (GSL), a class of plasma membrane lipids, are prevalently expressed in CSC, and could be considered as markers of cancer stemness. Gangliosides (GS), sialic acid-containing GSL, have been investigated for their role in the malignant phenotype of several cancers (breast, melanoma, glioblastoma, ovary), and in tumor-stem like cells. However, no data are available on GSL composition in cholangiocarcinoma (CCA) and on their possible significance. Aim of this study is to provide a GSL and GS profiling of both stem-like subsets (SPH) and their parental cells in human CCA.

**Method:** Stem-like subset was enriched by sphere culture (SPH) in established human intrahepatic CCA cells (HUCCT1, CCLP1). CCA GS patterns were determined by chromatographic analytical procedures. Identification of GSL and GS molecular species and assessment of GS turnover were evaluated by feeding cells with 3H-sphingosine. GS role in the modulation of stem features was investigated using D-threo-1-phenyl-2-palmitoylamino-3-N-morpholine-1-propanol (PPMP), a glucosylceramide synthase inhibitor. FACS-sorted SPH expressing the GD2 synthase were examined for stem-like gene expression in comparison to compared to GD2- SPH.

**Results:** In both CCA lines, SPH showed drastic changes in the amount of specific sphingolipids (ceramide, Gb3, sphingomyelin) compared to parental cells grown in monolayer conditions (MON). In both CCA lines, amount of total GS was markedly different between MON and their SPH. Specifically, CCA-SPH showed an increase content of GM3, and reduction of GM2. Among complex GS, GD1a was strongly increased in SPH, and GD2 expression was present. This was corroborated by high expression levels of GM3 synthase as well as GD3- and GM2/GD2 synthases in CCA-SPH. GS biosynthesis enzymes, such as GlcCer-, LacCer-, and GM3 synthases, resulted strongly expressed in CCA-SPH compared to MON. Notably, sphere forming ability and expression of CSC-related genes were affected by PPMP. Likewise, GD2+ SPH cells were enriched with CSC-markers (CD133, EpCAM, CD44) at the protein and gene level in addition to several genes involved in pluripotency, self-renewal and epithelial-mesenchymal transition compared to GD2- SPH. Notably, expression of GM2/GD2 synthases was significantly expressed in tumor samples compared to paired non-tumoral liver tissue of CCA patients (n = 104) and strongly correlated with presence of satellite nodules, lymph node invasion and recurrence.

**Conclusion:** CCA stem-like properties are associated with GSL synthetic pathways and patterns. GSL synthases could represent potential markers for CCA.

#### Diagnostic and prognostic value of miR-16, miR-146a and miR-192 in exosomes of hepatocellular and liver cirrhosis patients

Thorben Fründt<sup>1</sup>, Linda Krause<sup>2</sup>, Bettina Steinbach<sup>3</sup>, Daniel Köhler<sup>4</sup>, Johann von Felden<sup>1</sup>, Kornelius Schulze<sup>1</sup>, Ansgar W. Lohse<sup>1</sup>, Henning Wege<sup>1,5</sup>, Heidi Schwarzenbach<sup>3</sup>. <sup>1</sup>University Medical Center Hamburg-Eppendorf, I. Department of Medicine, Germany, Germany; <sup>2</sup>University Medical Center Hamburg-Eppendorf, Institute for Medical Biometry and Epidemiology, Hamburg, Germany; <sup>3</sup>University Medical Center Hamburg-Eppendorf, Department of Tumor Biology, Hamburg, Germany; <sup>4</sup>University Medical Center Hamburg-Eppendorf, Department of Diagnostic and Interventional Radiology and Nuclear Medicine, Hamburg; <sup>5</sup>Klinikum Esslingen, Cancer Center Esslingen, Esslingen am Neckar, Germany  
Email: tfruentd@uke.de

**Background and aims:** Exosomes are extracellular vesicles and are indicative mediators of both cell communication and cancer progression, via transferring proteins and nucleic acids, such as microRNAs (miRNAs). We aimed to identify a specific miRNA pattern to determine the diagnostic and prognostic value in plasma exosomes of hepatocellular carcinoma (HCC) patients.

**Method:** A two-stage study was carried out: exosomal miRNAs were quantified in plasma of 24 HCC patients, including patients at stage A, B and C of the Barcelona Clinic Liver Cancer (BCLC) Classification, 37 liver cirrhosis (LC) patients and 20 healthy individuals (HI) by PCR-based microarray cards containing 47 different miRNAs (training cohort). Then, four deregulated miRNAs (miR-16, miR-146a, miR-192 and miR-221) were selected and quantified in the validation analysis using exosomes derived from 85 HCC patients, 50 LC patients and 20 HI. Expression levels of miRNAs, tumor characteristics, alpha fetoprotein (AFP) and clinical parameters including Child Pugh Score (CPS) to assess liver function were correlated with overall survival (OS).

**Results:** Exosomal miR-16 was downregulated in both HCC patients and liver cirrhosis patients ( $p = 0.0001$ ), whereas miR-146a ( $p = 0.0001$ ), miR-192 ( $p = 0.002$ ) and miR-221 ( $p = 0.032$ ) were upregulated in HCC patients, but not in cirrhosis patients. Repeated 10-fold cross validation showed that miR-146a was superior to miR-16, miR-192 and miR-221 to distinguish HCC from liver cirrhosis patients with AUC  $0.80 \pm 0.14$  (sensitivity:  $81 \pm 13\%$ , specificity:  $58 \pm 22\%$ ) in a logistic regression model. High miR-192 expression was associated with poor overall survival (OS) in all HCC patients ( $p = 0.027$ ) and the subgroup of patients with stage BCLC A and B ( $p = 0.017$ ). In uni- and multivariate Cox regression models, levels of miR-192 (HR: 3.44, 95% CI: 1.32–8.91;  $p = 0.01$ ), CPS (HR: 3.08; 95% CI: 1.65–5.72,  $p < 0.001$ ) and AFP (HR: 2.1; 95% CI: 1.52–2.92,  $p < 0.001$ ) were independent predictors of OS in HCC patients. Decreased expression of miR-16 correlated with OS in liver cirrhosis patients ( $p = 0.034$ ).

**Conclusion:** Exosomes secreted into the plasma carry differentially expressed miRNAs of which in particular, miR-192 was found as a promising prognostic maker for HCC patients while miR-146 demonstrated promising diagnostic potential to identify HCC patients in a high-risk cohort. Furthermore, expression level of miR-16 has a prognostic impact in liver cirrhosis patients.

### PO-2375

#### Dynamics of endothelial progenitor cells in patients with advanced hepatocellular carcinoma

Claudia Campani<sup>1</sup>, Manuela Capone<sup>1</sup>, Francesco Liotta<sup>1</sup>, Umberto Arena<sup>1</sup>, Chiara Di Bonaventura<sup>1</sup>, Stefano Colagrande<sup>1</sup>, Francesco Annunziato<sup>1</sup>, Fabio Marra<sup>1</sup>. <sup>1</sup>University of Florence  
Email: fabio.marra@unifi.it

**Background and aims:** Angiogenesis inhibitors are widely used for the treatment of advanced hepatocellular carcinoma. Previous studies have highlighted the importance of circulating endothelial progenitor cells (EPC) as predictors of tumor vascularization and

disease progression. However, only limited information is available on the levels of EPC in HCC, and their dynamics upon treatment.

**Method:** We prospectively analyzed the levels of different populations of circulating EPC (total CD34+, CD34+ /CD133+, CD34+ /KDR+, CD34+ /133+/KDR+, CD34+ /133-/KDR-) in patients with advanced HCC candidate to therapy with sorafenib. Patients were studied before the start of therapy (T0) and after two (T2) and eight weeks (T8), using high-performance flow-cytometry. Tumor response was evaluated at T8 according to mRECIST criteria. Patients were divided in progressive disease (PD) and clinical benefit (CB, all other responses).

**Results:** Sixteen patients (15 men, mean age 71 years) were enrolled. The median alpha-fetoprotein at T0 was 129 ng/ml. Eight patients were intolerant to sorafenib and stopped the treatment before T8. At T8 five patients had CB and three had PD. The median OS was 132 days. At baseline, in the whole population, frequencies of CD34+ KDR+ and CD34+ CD133+ KDR+ were strongly correlated with platelet count ( $r = 0.788$  and  $r = 0.734$ , respectively,  $p = 0.001$ ). In the CB group platelets were positively correlated with CD34+ KDR+ at T0 ( $r = 0.929$ ,  $p = 0.023$ ), total CD34 and CD34+ CD133+ at T2 ( $r = 0.944$   $p = 0.016$  and  $r = 0.924$   $p = 0.025$ ) and total CD34 ( $r = 0.990$   $p = 0.001$ ), CD34+ CD133+ ( $r = 0.968$   $p = 0.007$ ), CD34+ KDR- CD133- ( $r = 0.976$   $p = 0.04$ ) at T8. Conversely in the PD group a negative correlation between total CD34 at T2 and platelets was found ( $r = -0.999$   $p = 0.025$ ). At baseline, a borderline correlation between CD34+ CD133+ KDR+ cells and BMI was also found ( $r = 0.45$ ,  $p = 0.08$ ). No correlation with other clinical features at baseline were found. Frequencies of all EPCs subpopulation declined at T8 compared with T0. Remarkably, levels of CD34+ /CD133+ were higher at T0 in patients with CB compared to patients with PD ( $p = 0.05$ ). Moreover, mean frequency of CD34+ cells significantly declined in patients with CB comparing T0/T2 and T0/T8, but not in patients with PD.

**Conclusion:** In patients with advanced HCC treated with sorafenib EPC levels are directly correlated with platelet count, suggesting a common activation of selected bone marrow pathways. Levels of a subset of EPC are higher at baseline in patients responding to this angiogenesis inhibitor.

### PO-2601

#### TIGIT + TIM-3 + NK cells are correlated with NK cell exhaustion and disease progression in patients with hepatitis B virus-related hepatocellular carcinoma

Lihua Yu<sup>1</sup>, Xiaoli Liu<sup>1</sup>, Xinhui Wang<sup>1</sup>, Fengna Yan<sup>1</sup>, Peng Wang<sup>1</sup>, Yuyong Jiang<sup>1</sup>, Juan Du<sup>1</sup>, ZhiYun Yang<sup>1</sup>. <sup>1</sup>Center of Integrative Medicine, Beijing Ditan Hospital, Capital Medical University, Beijing, China  
Email: yangzhiyun2016@163.com

**Background and aims:** The prognosis of hepatocellular carcinoma is extremely poor, of which hepatitis B virus-related hepatocellular carcinoma (HBV-HCC) accounts for the majority in China. NK cells play a vital role as the first line of defense against tumors. Immune checkpoint inhibitors have become an effective immunotherapy method for the treatment of HCC, but they are mainly used for T cells. Therefore, we explored the characteristic expression pattern of immune checkpoints on NK cells of HBV-HCC patients.

**Method:** We included 133 patients with HBV-HCC, 25 patients with hepatitis B virus-related liver cirrhosis (HBV-LC), 23 patients with chronic hepatitis B (CHB), and 32 healthy donors (HDs). Flow cytometry was used to detect the co-expression of TIGIT and TIM-3 in peripheral blood NK cells of the above population. Moreover, we analyzed the correlation between the co-expression of TIGIT and TIM-3 and the clinical progress of patients with HBV-HCC.

**Results:** The co-expression of TIGIT and TIM-3 on NK cells is elevated in patients with HBV-HCC. The high level of co-expression of TIGIT and TIM-3 is associated with the clinical progress of patients with HBV-HCC. TIGIT<sup>+</sup>TIM-3<sup>+</sup>NK cells showed exhausted phenotypic characteristics and displayed dysfunction manifested as weakened

Figure: (abstract: PO-2601)

killing function, reduced cytokine production, and proliferation function.

**Conclusion:** TIGIT<sup>+</sup>TIM-3<sup>+</sup>NK cells participate in NK cells function exhaustion and are closely related to the disease progression of patients with HBV-HCC, suggesting a new target for future immunotherapy.

**PO-2694**

**lncRNA HOTAIR regulates cancer glucose metabolism in hepatocellular carcinoma via the miR-122/PKM2 pathway**  
 Jijia Zhou<sup>1</sup>, Di Cheng<sup>1</sup>, Junge Deng<sup>1</sup>, Leyi Huang<sup>1</sup>, Jie Zhang<sup>1</sup>, Xiaogeng Deng<sup>1</sup>. <sup>1</sup>Sun Yat-Sen Memorial Hospital, Sun Yat-Sen University, Guangzhou, China  
 Email: jijiazh2004@126.com

**Background and aims:** Reprogrammed glucose metabolism of enhanced aerobic glycolysis (or the Warburg effect) is known as a hallmark of cancers, including hepatocellular carcinoma (HCC). The roles of long noncoding RNAs (lncRNAs) in regulating cancer metabolism remains largely elusive. This study aimed to investigate whether lncRNA HOTAIR could regulate glucose metabolism in HCC.

**Method:** The expression level of HOTAIR in HCC tissues and cell lines was detected. pHOTAIR or shHOTAIR were employed to ectopically increase or decrease HOTAIR expression in HCC cells. Then cell proliferation, colony formation, migration, glucose consumption, and lactate production, as well as expression of PKM2, HK2, GLUT1 and miR-122 were analyzed. Luciferase reporter assay was used to test the predicted miR-122 target sites on PKM2.

**Results:** Here we showed that lncRNA HOTAIR was highly expressed in HCC tissues and cell lines. Knockdown of HOTAIR markedly repressed the proliferation, colony formation, migration, and aerobic glycolysis of HCC cells, whereas ectopic expression of HOTAIR dramatically promoted the aerobic glycolysis. Furthermore, HOTAIR upregulated a cluster of glycolytic genes including PKM2, HK2, GLUT1, in which PKM2 was found to be among the most significant one. Mechanically, HOTAIR inhibited liver-specific miR-122 expression via EZH2, leading to upregulation of PKM2 expression and maintenance of enhanced aerobic glycolysis. Moreover, Treatment with miR-122 mimics abolished the effect of HOTAIR on the process of aerobic glycolysis, as well as the expression of PKM2. In addition,

## POSTER PRESENTATIONS

Luciferase reporter assay showed that miR-122 regulated PKM2 expression by binding to the 3'-untranslated region of PKM2.

**Conclusion:** Collectively, our findings suggest that lncRNA HOTAIR contributes to HCC development by reprogramming cancer glucose metabolism via the miR-122/PKM2 pathway. Targeting HOTAIR/miR-122/PKM2 axis would provide a novel therapeutic strategy for HCC.

### PO-2742

#### Preoperative artemin as predictive biomarker for survival in curatively resected hepatocellular carcinoma

Ulf Zeuge<sup>1</sup>, Luna Zhan<sup>1</sup>, Roxana Bucur<sup>1</sup>, Kristen Sauerzopf<sup>1</sup>, Reenika Aggarwal<sup>2</sup>, Sophie Feng<sup>1</sup>, Hao-Wen Sim<sup>3</sup>, Dangxiao Cheng<sup>1</sup>, Wen-Jiang Zhang<sup>1</sup>, Carol-Anne Moulton<sup>1</sup>, Ian Mcgilvray<sup>1</sup>, Sean Cleary<sup>4</sup>, Steven Gallinger<sup>1</sup>, Gonzalo Sapisochin<sup>1</sup>, Jennifer Knox<sup>1</sup>, Alice Wei<sup>5</sup>, Geoffrey Liu<sup>1</sup>, Eric Chen<sup>1</sup>. <sup>1</sup>University Health Network, Toronto, Canada; <sup>2</sup>Temerty Faculty of Medicine, University of Toronto, Toronto, Canada; <sup>3</sup>NHMRC Clinical Trials Centre at the University of Sydney, Australia; <sup>4</sup>Mayo Clinic, Rochester, United States; <sup>5</sup>Memorial Sloan Kettering Cancer Center, New York, United States  
Email: geoffrey.liu@uhn.ca

**Background and aims:** Tumor-induced generation of splenic erythroblast-like cells (Ter-cells) has been shown to promote tumor progression. These Ter-cells produce artemin (ARTN), a glial-line derived neurotrophic factor. We investigated the association of pre-operative serum ARTN with overall (OS) and disease-free survival (DFS) in an ethnically diverse North American HCC cohort undergoing curative resection for HCC.

**Method:** From samples taken within 12 months prior to surgery, serum ARTN concentration was measured using an enzyme-linked immunosorbent assay (ELISA). Clinicopathologic variables were abstracted via retrospective chart review. Serum ARTN was dichotomized at the median into high vs. low groups. Log-rank tests, Kaplan-Meier curves, and a log-transformed ARTN as a continuous variable in Cox proportional hazard models evaluated ARTN's association with OS/DFS.

**Results:** Preoperative blood samples were available for 56 patients (pts); Median age, 66 years; 73%, male. Etiology of liver disease included hepatitis B (45%), hepatitis C (23%), alcohol (9%) and NAFLD (9%). In 36% of pts, HCCs did not arise on the background of pre-existing cirrhosis; 58% had a maximum diameter of  $\geq 5$  cm with 17% having macrovascular invasion. Barcelona clinic liver cancer (BCLC) staging was A in 74% pts with the baseline alpha-fetoprotein (AFP) being  $>40$  ug/l in 50% pts. Median follow-up was 60 months.

In our cohort, median OS was not reached; median DFS was 22.2 months. Using high vs. low ARTN, the median DFS was 14.7 vs 30.9 months (log-rank  $p = 0.64$ ) respectively.

Univariate analysis using ARTN as continuous variable found that each log-unit increase in concentration was associated with a worse OS: hazard ratio (HR), 1.69 (95% CI: 1.10–2.6,  $p = 0.016$ ); for DFS, HR 1.16 (95% CI: 0.96–1.39,  $p = 0.128$ ). OS HRs for ARTN remained between 1.60 and 1.81 after separately controlling for various variables including age, gender, ethnicity, cirrhosis, alpha-Fetoprotein, vascular invasion, pathology stage, solitary tumor, tumor size and HBV-infection.

**Conclusion:** In our population a high pre-operative serum ARTN is associated with shorter OS but not DFS in HCC pts undergoing curative resection. Serum ARTN is a biologically supported biomarker for HCC; results from this study should be validated prospectively.

### PO-2787

#### Identifying effective subtype-specific treatment responses in hepatocellular carcinoma in genetically engineered mouse models

Miryam Müller<sup>1</sup>, Stephanie May<sup>1</sup>, Lynn McGarry<sup>2</sup>, Tim Kendall<sup>3</sup>, William Clark<sup>1</sup>, Matthew Neilson<sup>1</sup>, Robin Shaw<sup>1</sup>, Thomas Jamieson<sup>1</sup>, Colin Nixon<sup>1</sup>, Karen Blyth<sup>1,2</sup>, Daniel Murphy<sup>1,2</sup>, Crispin Miller<sup>1,2</sup>, Carlin Leo<sup>1,2</sup>, Owen Sansom<sup>1,2</sup>, Thomas G. Email: m.mueller@beatson.gla.ac.uk

**Background and aims:** Systemic treatment options for advanced hepatocellular carcinoma (HCC) have increased over the last decade but typically have modest efficacy and are generally applied as a one-size-fits-all approach. Refining stratified therapies is hindered by a lack of suitable in-vivo models of HCC subtypes. Our aim was to develop a suite of genetically engineered mouse models (GEMMs) representing human subtypes of HCC and to use these to identify and test new therapies.

**Method:** We generated the GEMMs combining loxP technology with hepatocyte-specific AAV8-TBG-Cre mediated recombination resulting in clonal HCC outgrowth driven by oncogenes/tumor suppressors identified in human HCC. Over 20 genetic models were disease positioned against human HCC using transcriptomics and histopathological characteristics and cross referenced to classical HCC models. Current standard-of-care therapies were tested for effect on overall survival. Tumoroids were generated from GEMMs and FDA-approved oncology drugs were analyzed for effect on tumoroid growth. Drugs were validated in vitro and survival studies were performed in the respective mouse models.

**Results:** Targeted hepatocytes expanded from a clonal source to form nodules and ultimately HCC within 3–4 months. The resulting tumors reproduce key features of human disease, including histological patterns, tumor hemorrhage and metastasis. Established tumors respond to first-line tyrosine kinase inhibitors (TKIs; Sorafenib or Lenvatinib) leading to modest but significant survival benefits. We demonstrate lack of efficacy of anti-PD-1 treatment (alone and with TKI) in  $\beta$ -catenin driven tumors, similar to reports in human HCC. Utilizing high-throughput drug screens we identify licensed anticancer drugs, novel in HCC therapy, that markedly increase survival in vivo, including in combination with TKIs.

#### Identification of subtype-specific treatments

Figure:

**Conclusion:** These models provide a platform for both detailed interrogation of the biological mechanisms driving HCC and improved translational research using a subtype-specific approach to pre-clinical therapeutic identification and testing. We have developed a bank of tumoroids across the range of GEMMs and a pipeline for using these for high-throughput in vitro drug screening, followed by subsequent in vivo validation. This allows us to rapidly link in vitro and in vivo efficacy both identifying and testing novel therapies in immunocompetent mice with the ultimate aim of guiding precision medicine trials in human HCC patients.

**PO-2798**

**Phosphoinositide 3-kinase dependent carcinogenesis in the liver**

Dayana Tsoлова<sup>1,2</sup>, Angelika Ulrich<sup>1</sup>, Dieter Saur<sup>1,3</sup>. <sup>1</sup>University Hospital rechts der Isar, Technical University of Munich, Department of Medicine II, Munich, Germany; <sup>2</sup>Central Institute for Translational Cancer Research (TranlaTUM), Technical University of Munich, Munich; <sup>3</sup>Central Institute for Translational Cancer Research (TranlaTUM), Technical University of Munich, Munich, Germany  
Email: dayana\_tsoлова1992@abv.bg

**Background and aims:** Hepatocellular carcinoma and intrahepatic cholangiocarcinoma—the most and the second most common primary liver cancer respectively, are devastating diseases with low chances of cure and poor survival outcome. The exact pathomechanism driving the tumour development is still poorly understood. In this study we investigate the role of oncogenic Phosphoinositide 3-kinase signalling in inducing liver damage and metabolic changes, as well as in the formation and progression of both types of liver cancer. Therefore, we compare two genetically modified murine models—Alb-Cre, PIK3CA<sup>H1074R/+</sup> and Alb-Cre, PIK3CA<sup>H1074R/+</sup>, Pdk1<sup>ff/ff</sup>. Both models harbour the mutant PIK3CA<sup>H1074R/+</sup> encoding for the oncogene Phosphoinositide 3-kinase catalytic unit p110α<sup>H1074R</sup>, which lead to constitutive Phosphoinositide 3-kinase pathway activation in the liver. The double transgenic mice (Alb-Cre, PIK3CA<sup>H1074R/+</sup>, Pdk1<sup>ff/ff</sup>) harbour, in addition to the PIK3CA<sup>H1074R/+</sup> mutation, a liver specific Pdk1 Knockout. The aim of this study is to analyse the pathomechanisms of carcinogenesis in both models and to investigate if the Pdk1 deletion can prevent the liver damage and tumour formation induced by the oncogenic Phosphoinositide 3-kinase signalling.

**Method:** Polymerase chain reaction; western blot; real time polymerase chain reaction; hematoxylin and eosin, immunohistochemical and oil red o staining; bloodserum and blood sugar analysis.

**Results:** Whereas Alb-Cre, PIK3CA<sup>H1074R/+</sup> mice developed diffuse steatosis and hepatomegaly, observed from the first month of life, followed by formation of benign and malign liver lesions, Alb-Cre, PIK3CA<sup>H1074R/+</sup>, Pdk1<sup>ff/ff</sup> mice showed macroscopically normal liver morphology up to an age of 3 months comparable to controls. The development of liver tumours occurred later and in rather non-diffuse steatosis liver environment compared with the mice from the Alb-Cre, PIK3CA<sup>H1074R/+</sup> genotype. The Alb-Cre, PIK3CA<sup>H1074R/+</sup> mice presented recurrent episodes of apathy, decreased mobility, sleepiness and lethargy up to sudden death. They showed elevated aspartate transaminase, alkaline phosphatase and cholesterol parameters throughout the whole longitudinal surveillance, as well as significantly decreased blood sugar levels in 4 hours fast test at the age of 3 months compared to control animals. The Alb-Cre, PIK3CA<sup>H1074R/+</sup>, Pdk1<sup>ff/ff</sup> mice, on the other hand, showed normal liver and cholesterol parameters up to an age of 8–12 months and an increase afterwards. Furthermore, the Alb-Cre, PIK3CA<sup>H1074R/+</sup>, Pdk1<sup>ff/ff</sup> mice showed more than 3 times longer median survival than the Alb-Cre, PIK3CA<sup>H1074R/+</sup> mice.

Figure: Kaplan Meier curve comparison between Alb-Cre, PIK3CA<sup>H1074R/+</sup>; Alb-Cre, PIK3CA<sup>H1074R/+</sup>, Pdk1<sup>ff/ff</sup> mice and control animals (\*\*\*)p<0.0001, log-rank test)

Figure:

**Conclusion:** The Pdk1 deletion manages to delay the oncogenic and metabolic effects of the constitutive Phosphoinositide 3-kinase pathway activation in the liver.

**PO-2828**

**Characterization of disease progression and pharmacological intervention in a diet-induced obese mouse model of NASH with advanced fibrosis and hepatocellular carcinoma**

Michael Feigh<sup>1</sup>, Mathias Møllerhøj<sup>1</sup>, Sanne Veidal<sup>1</sup>, Martin Rønn Madsen<sup>1</sup>, Henrik B. Hansen<sup>1</sup>. <sup>1</sup>Gubra, Hørsholm, Denmark  
Email: mfe@gubra.dk

**Background and aims:** Obesity-associated non-alcoholic steatohepatitis (NASH) predisposes to the development of severe fibrosis and hepatocellular carcinoma (HCC), thus pharmacological interventions targeting metabolic NASH and fibrosis might also affect HCC. The present study aimed to characterize disease progression and evaluate treatment response for the late-stage clinical candidate elafibranor (peroxisome proliferator-activated receptor  $\alpha/\delta$  agonist) in the extended GAN (Gubra-Amylin NASH) diet-induced obese (DIO) mouse model of NASH.

**Method:** Male C57Bl/6J mice were fed the GAN diet (40 kcal-% fat, 22% fructose, 10% sucrose, 2% cholesterol) for up to 88 weeks (n = 12–15/group). Disease progression in DIO-NASH mice was evaluated by liver histopathological NAFLD Activity Score (NAS) and Fibrosis Stage, histomorphometry, macroscopic tumor evaluation and liver transcriptome analysis. DIO-NASH mice with extended GAN diet-induction (60 weeks) and biopsy-confirmed steatosis (score  $\geq 2$ ), advanced fibrosis (stage F3) and HCC (DIO-NASH-HCC) received treatment (PO, QD) with vehicle (n = 16), elafibranor (30 mg/kg, n = 14) for 12 weeks. Age-matched lean control animals (n = 10) received vehicle.

**Results:** DIO-NASH animals demonstrated progressive NASH with consistent development of liver fibrosis from 28 weeks on diet. Advanced bridging fibrosis (stage F3) and tumour development including HCC was consistently observed from  $\geq 58$  weeks on diet. Hepatic transcriptome signatures were consistent with severe disease progression in DIO-NASH mice. In DIO-NASH-HCC mice, elafibranor treatment demonstrated  $\geq 2$ -point significant improvement in NAFLD Activity Score and promoted a 1-stage significant improvement in Fibrosis Stage, compared to vehicle group. Therapeutic effects of elafibranor were supported by quantitative histological markers of steatosis (lipids, hepatocytes with lipid droplets), inflammation (number of inflammatory cells/foci, galectin-3), fibrogenesis ( $\alpha$ -SMA) and fibrosis (PSR, collagen 1a1). Elafibranor had no effect on macroscopically evaluated tumor numbers and size, although improved HCC-associated transcriptomic signatures including lowered expression of hepatic genes involved in apoptosis, inflammation, cell cycle and proliferation.

**Conclusion:** DIO-NASH mice show progressive advanced fibrosis and high HCC incidence. Elafibranor treatment improved hepatic steatosis, inflammation, and fibrosis in DIO-NASH-HCC mice with advanced fibrosis but had no effect on HCC burden. The extended GAN DIO-NASH-HCC mouse model is suitable for profiling novel drug therapies for advanced fibrosing NASH and HCC.

**Tumor progression in intrahepatic cholangiocarcinoma**

Mickael Di-Luoffo<sup>1</sup>, Sophie Pirenne<sup>1,2</sup>, Thoueiba Saandi<sup>1</sup>, Axelle Loriot<sup>1</sup>, Claude Gérard<sup>1</sup>, Nicolas Dauguet<sup>1,3</sup>, Fatima Manzano-Nunez<sup>1</sup>, Natalia Alves Souza Carvalhais<sup>4</sup>, Florence Lamoline<sup>1</sup>, Sabine Cordi<sup>1</sup>, Katarzyna Konobrocka<sup>1</sup>, Vitaline De Greef<sup>1</sup>, Mina Komuta<sup>5</sup>, Georg Halder<sup>4</sup>, Patrick Jacquemin<sup>1</sup>, Frédéric Lemaigre<sup>1</sup>. <sup>1</sup>de Duve Institute, Université Catholique de Louvain, Brussels, Belgium; <sup>2</sup>Department of Pathology, Cliniques Universitaires Saint-Luc, Brussels, Belgium; <sup>3</sup>CYTF platform, Université Catholique de Louvain, Brussels, Belgium; <sup>4</sup>VIB Center for Cancer Biology and KU Leuven, Department of Oncology, University of Leuven, Leuven, Belgium; <sup>5</sup>Department of Pathology, Keio University School of Medicine, Tokyo, Japan  
Email: sophie.pirenne@uclouvain.be

**Background and aims:** Intrahepatic cholangiocarcinoma (iCCA) is an aggressive cancer presenting a dismal prognosis. Early diagnosis of

## POSTER PRESENTATIONS

iCCA is necessary to improve prognosis. However, there is still limited information available about the initiation of this rare cancer and its progression from precursor lesions. The aim of the work is to identify mechanisms driving formation of precancerous lesions of iCCA and their progression towards invasive tumor using experimental models that faithfully recapitulate human tumorigenesis.

**Method:** We generated a new mouse model which combines cholangiocyte-specific expression of KrasG12D with 3, 5-diethoxy-carbonyl-1, 4-dihydrocollidine diet-induced inflammation to mimic iCCA development in patients with cholangitis. Histological and transcriptomic analyses of the mouse precancerous lesions and iCCA were performed and compared with human analyses.

**Results:** Mice expressing KrasG12D in cholangiocytes and affected with cholangitis developed intraductal papillary neoplasms of bile ducts (IPNBs) and eventually iCCAs comparable to the human large duct type iCCA. Our RNA sequencing analysis showed that the transcriptomes of IPNB and iCCA were closely related. We noticed the presence of transitional lesions between IPNB and iCCA. These data support that iCCA originate from IPNB. We provide evidence that Tensin-4 (TNS4) is upregulated in iCCA and increases cell proliferation and migration *in vitro* and tumor growth *in vivo*. Further *in vitro* experiments allowed to consider a gene cascade involved in tumor progression.

**Conclusion:** We developed a novel mouse model of iCCA that faithfully recapitulates human iCCA tumorigenesis and identified a gene cascade, involving TNS4, promoting tumor progression.

Email: anne-aurelie.raymond@inserm.fr

**Background and aims:** Through an exploratory proteomic approach based on typical hepatocellular adenomas (HCA), we previously identified a new diagnostic biomarker for a distinctive subtype of HCA with high risk of bleeding, already validated on a multicenter cohort. We hypothesized that the whole protein expression deregulation profile could deliver much more informative data for tumors characterization. Therefore, we pursued our analysis with the characterization of HCAs proteomic profiles, evaluating their correspondence with the established genotype/phenotype classification and assessing whether they could provide added diagnosis and prognosis values.

**Methods:** From a collection of 260 cases, we selected 52 typical cases of all different subgroups on which we built the first HCA proteomics database. Combining laser microdissection and mass spectrometry based proteomic analysis, we compared the relative protein abundances between tumoral (T) and non-tumoral (NT) liver tissues from each patient and we defined specific proteomic profile of each HCA sub-groups. Next, we built a matching algorithm comparing proteomic profile extracted from a patient with our reference HCA database.

**Results:** Proteomic profiles allowed HCA classification and made diagnosis possible, even for complexes cases with immunohistological or genomic analysis that did not lead to a formal conclusion. Despite a well-established pathomolecular classification, clinical practices have not substantially changed and HCA management link to the assessment of the malignant transformation risk remains delicate for many surgeons. That's why we also identified and validated a proteomic profile that directly evaluate malignant transformation risk regardless of HCA subtype.

**Conclusion:** This pioneering work proposes a proteomic-based machine learning tool, operational on fixed biopsies, that can improve diagnosis and prognosis and therefore patient management for HCA.

### PO-2919

#### Transcriptomic analysis reveals circWHSC1 and circCPSF6 serves as the oncogene to promote hepatocellular carcinoma progression

Fei Lu<sup>2</sup>, Jing Gao<sup>1</sup>, Yang Luo<sup>3</sup>, Wei-lin Jin<sup>4</sup>, Chuan-xing Li<sup>1</sup>, Xun Li<sup>4</sup>. <sup>1</sup>Karolinska Institutet, Department of Medicine and Center for Molecular Medicine, Stockholm, Sweden; <sup>2</sup>Lanzhou University, The First Clinical Medical College of Lanzhou University, Lanzhou, China; <sup>3</sup>The First Hospital of Lanzhou University, Key Laboratory of Biotherapy and Regenerative Medicine, Lanzhou, China; <sup>4</sup>The First Hospital of Lanzhou University, Department of General Surgery, Lanzhou, China  
Email: lxd21@126.com

**Background and aims:** Circular RNAs (circRNAs) have been recently proposed for important contributions to hepatocarcinogenesis. We aim to investigate crucial circRNAs in the pathogenesis of hepatocellular carcinoma (HCC) by comprehensive transcriptomic profiling of circRNA, and further validate therapeutic targets by downstream functional experiments.

**Method:** CircRNA microarray was performed to detect the transcriptomic-wise circRNA expression in HCC and corresponding normal adjacent samples. The differentially expressed candidates were further validated by Real-time PCR in both HCC cell lines and a larger HCC tissue cohort, and identified the differentially expressed circWHSC1, circCPSF6, circRREB1, and circWHSC1-006. Examine the potential role of critical circRNA in tumor cell growth by using a lentivirus-mediated RNA interference (RNAi) system in the HCC cell lines *in vitro*. Using lentivirus to construct four knockdown targets and one overexpression target of circWHSC1 and circCPSF6 conducting function experiments at the cell level. CCK-8 assay was used to assess cell proliferation.

**Results:** CircRNA microarray reveals 83 up- and 20 down-expressed circRNA in HCC, then the prioritized four candidates (circWHSC1, circCPSF6, circRREB1, and circWHSC1-006) were validated by PCR in HCC cell lines (Hep3B, SK-HEP-1, HCCLM3, and Huh7) and human tissue samples, respectively. The expression of circWHSC1 and circCPSF6 were higher in HCC tissue compared to these in normal adjacent samples (each, n = 37, Figure, a-b) and in HCC cell lines Hep3B and SK-HEP-1, respectively. CircWHSC1 knockdown or overexpression significantly inhibited or promoted HCC cell lines proliferation *in vitro*, respectively (Figure, c-e). Knockdown of circCPSF6 increased the proportions of HCC cells in G0/G1 phase and promoted cell apoptosis *in vitro*.

**Conclusion:** CircWHSC1 and circCPSF6 played the tumor-promoting roles in HCC, suggesting the two circRNA might be the novel therapeutic target in HCC.

Spyridon Dourakis<sup>3</sup>, John Koskinas<sup>3</sup>. <sup>1</sup>National and Kapodestrian University of Athens, Greece, Physiology Laboratory, Medical School, Athens, Greece; <sup>2</sup>Biomedical Sciences Research Center Alexander Fleming, Vari, Greece; <sup>3</sup>Hippokratieo General Hospital,

Internal Medicine Department, Athens, Greece  
 Email: aarmakol@med.uoa.gr

**Background and aims:** The molecular signature of hepatocellular carcinoma (HCC) is associated with prognosis and plays a significant role in the response/resistance to systemic therapy. The aim of this study was to determine molecular signatures based on the proteome analysis, microRNAs (miRNAs) and circulating tumour cells (CTCs) that will define and predict the development of HCC at very early stages in patients with cirrhosis.

**Method:** Blood of 89 patients with HCC (56 patients with advanced and 33 patients with early HCC), 28 age-matched cirrhotic patients

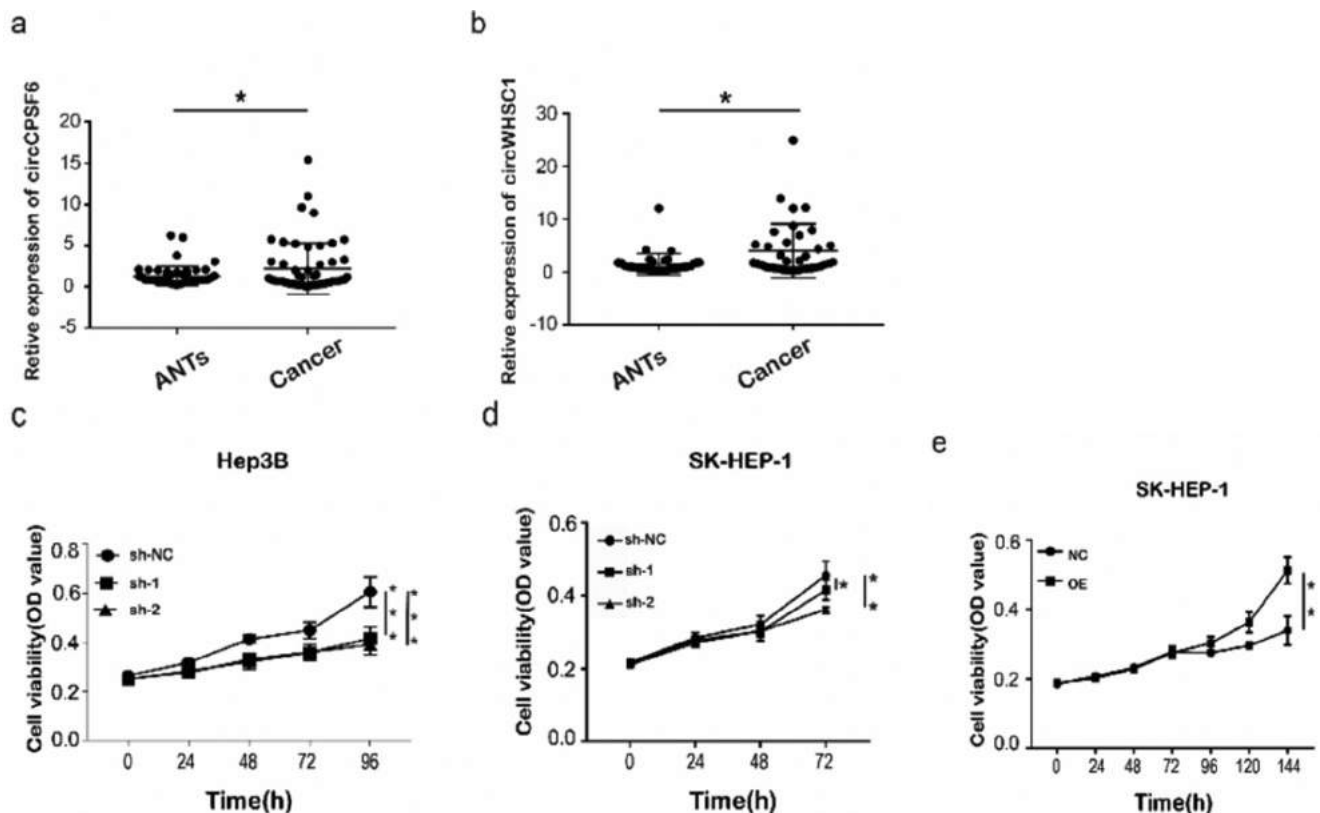

Figure: (abstract: PO-2919): Relative expression of target genes in HCC tissue and function experiments. a-b: HCC tissues displayed elevated circCPSF6 and circWHSC1 expression; c-d: circWHSC1 knockdown inhibited HCC cell lines proliferation in vitro; d: circWHSC1 overexpress promoted HCC cell lines proliferation in vitro. ANTs: adjacent normal tissue; sh-NC: RNAi negative control; NC: negative control; OE: overexpression. \* p value <0.05.

with no evidence of HCC and 5 healthy controls were examined for CTCs by Real-Time Quantitative Reverse Transcription PCR (qRT-PCR) using the markers Epithelial cell adhesion molecule (EPCAM), Vimentin, alpha-fetoprotein ( $\alpha$ FP) and surface major Vault protein (sMAVP). Patients' serum was also examined for the presence of a set of miRNAs that are involved in HCC (miR122, miR221, miR222, miR200a and miR200b) and for protein signatures by whole proteome analysis (LC/MS).

**Results:** Blood examination showed that 27/56 (48%) patients with advanced HCC had detectable CTCs. Among them, 10/27 (37%) presented evidence of mesenchymal or intermediate stage cells (vimentin and/or sMAVP positive). Moreover, 4/33 (12%) patients with early HCC and 4/28 (14%) cirrhotic patients had detectable CTCs. Patients with HCC exhibited a significant increase of miR-200b ( $p = 0.007$ ) and a significant decrease in miR-122 ( $p = 0.023$ ) when compared to cirrhotic patients. Finally, the proteome analysis using stringent criteria indicated a significant increase in APOA2, CLU, HRG and APOD proteins in patients with early HCC when compared with the cirrhotics. All non-HCC cirrhotic patients with CTCs had increased levels of proteins that characterize early HCC.

**Conclusion:** CTCs were found in a significant number of patients with advanced HCC. Proteome analysis revealed that patients with early HCC had a unique increase of certain proteins in comparison with non-HCC cirrhotic patients that could be used as possible biomarkers.

## Liver tumours: Therapy

### PO-75

#### Irreversible electroporation vs radiofrequency ablation for hepatocellular carcinoma: A single centre propensity matched comparison

Elliot Freeman<sup>1</sup>, Wa Cheung<sup>2</sup>, Sapphire Ferdousi<sup>1</sup>, Helen Kavnoudias<sup>2</sup>, Majeed Ammar<sup>1,3</sup>, William Kemp<sup>1,3</sup>, Stuart K. Roberts<sup>1,3</sup>. <sup>1</sup>Alfred Hospital, Department of Gastroenterology, Melbourne, Australia; <sup>2</sup>Alfred Hospital, Department of Radiology, Melbourne, Australia; <sup>3</sup>Monash University, Department of Medicine, Central Clinical School, Melbourne, Australia

Email: elliotfreeman@hotmail.com

**Background and aims:** Irreversible electroporation (IRE) is a relatively new non-thermal ablation technique for unresectable hepatocellular carcinoma (HCC) not amenable to standard thermal therapies. The efficacy of this technique, compared to radiofrequency ablation (RFA), has not been reported. The aim of this study, therefore, was to compare the efficacy of IRE vs RFA in the treatment of unresectable HCC.

**Method:** We identified all patients at our institution who underwent IRE or RFA for HCC. Demographic and clinical data up until 1st March, 2020 were analysed. Local recurrence-free survival (LRFS) was compared between groups after propensity score matching for age, gender, BCLC stage, Child-Pugh grade, lesion size and alpha-fetoprotein (AFP) level.

**Results:** A total of 190 HCC ablations (31 IRE, 159 RFA) were identified. After propensity score matching, we compared 25 IRE procedures

(76% males, median age 62.4 years, median tumour size 20 mm) to 96 RFA procedures (84.4% males, median age 64.3 years, median tumour size 18.5 mm). LRFS did not differ between groups, with a 1-, 2- and 5-year LRFS of 80.4% (95% CI 55.8–92.2), 69.1% (95% CI 43.3–84.9) and 44.9% (95% CI 18.9–68.1%) respectively for IRE and 84.8% (95% CI 75.2–90.9), 71.3% (95% CI 58.3–81.0) and 52.1% (95% CI 35.4–66.4%) respectively for RFA ( $p=0.63$ ). There were no major procedure-related complications or deaths in either group.

Figure: Kaplan-Meier estimated LRFS curve of the propensity matched IRE and MWA groups

**Conclusion:** Whilst IRE remains a relatively novel therapy for HCC cases where standard thermal ablation is contraindicated, the LRFS in our centre is comparable to that of RFA. IRE should therefore be considered as a treatment option in such cases when available before stage-migration to non-curative therapies such as transarterial chemoembolization (TACE).

**PO-573**

**TIAM1, a potential synthetic lethal gene and candidate therapeutic target for hepatocellular carcinoma**

Chalermsin Permtersin<sup>1</sup>, Sirinitra Nakjang<sup>2</sup>, Schwalbe Ed<sup>3</sup>, Helen L. Reeves<sup>4</sup>, Gordon Strathdee<sup>1</sup>, Ruchi Shukla<sup>1</sup>. <sup>1</sup>Biosciences Institute, Newcastle Upon Tyne, Northern Ireland; <sup>2</sup>Bioinformatics Support Unit, Newcastle University, Newcastle Upon Tyne, United Kingdom; <sup>3</sup>Faculty of Health and Life Sciences, Northumbria University, Newcastle Upon Tyne, United Kingdom; <sup>4</sup>Translational and Clinical Research Institute, Newcastle University, Newcastle Upon Tyne, United Kingdom

Email: c.permtersin2@newcastle.ac.uk

**Background and aims:** Available therapies for hepatocellular carcinoma (HCC) patients often have low efficacy and significant toxicities, with deaths continuing to rise. We developed a novel bioinformatics pipeline to identify genes required for survival of cancer cells, but not normal cells. Targeting these genes may induce ‘synthetic lethality’; specifically killing cancer cells, with no impact on healthy ones. The aims of this study are; (1) to utilise the new bioinformatics approach to identify candidate synthetic lethal genes for specific subgroups of HCC patients; (2), to functionally assess the identified candidate genes in cell lines to validate their synthetic lethality.

**Method:** Genome-wide DNA methylation data from 224 HCC patient samples was utilised for methylation subgrouping using non-negative matrix factorization (NMF). Synthetic lethal (SL) gene identification was performed using an in-house developed pipeline, integrating

methylation and matched genome-wide expression data. Expression/siRNA manipulation of candidates was explored *in vitro* in HCC cell lines, with MTT cell viability assay, Caspase-Glo<sup>®</sup> 3/7 apoptosis assay and CellTox™ green cytotoxicity assays.

**Results:** NMF clustering identified five potential HCC molecular subtypes. Subtype-2 exhibited the most unique methylation profile and was utilised for SL gene analysis. This identified two candidate SL genes, *LDHB* and *TIAM1*. *TIAM1* is a member of family of guanine nucleotide exchange factors (GEFs) with known roles in cancer cell growth, adhesion and invasion, that is known to activate Rac1 signalling. We investigated *TIAM1* siRNA silencing and small molecule inhibition of *TIAM1*/Rac1 signalling (NSC23766, a specific Rac1 inhibitor) in *TIAM1* positive (PLC/PRF-5, and SNU182) and negative (HepG2, Huh-7) HCC cell lines and immortalised hepatocytes (HHL5, *TIAM1* positive) *TIAM1* knockdown inhibited proliferation in the *TIAM1*-positive PLC/PRF-5 (30%,  $p<0.05$ ) and SNU182 (36%,  $p<0.05$ ) with no impact in negative cells. Similarly, cell proliferation was suppressed at significantly lower NSC23766 concentrations in PLC/PRF-5 and SNU182 cells (IC<sub>50</sub>, 25 and 29 micromolar, respectively) than in *TIAM1* negative lines. Induction of apoptosis by NSC23766 was specific to SNU182.

**Conclusion:** We report a novel pipeline for the identification of SL genes in HCC. Targeting *TIAM1* signalling in *TIAM1*-positive HCC cells may have therapeutic benefit, with little impact on healthy or *TIAM1* negative cells.

**PO-574**

**Pre-transplant AFP >25.5 is associated with a higher risk of HCC recurrence after liver transplantation for patients meeting Milano criteria**

Bianca Magro<sup>1</sup>, Domenico Pinelli<sup>2</sup>, Massimo De Giorgio<sup>1</sup>, Maria Grazia Lucà<sup>1</sup>, Arianna Ghirardi<sup>3</sup>, Giuseppe Baronio<sup>2</sup>, Luca Del Prete<sup>2</sup>, Andrea Gianatti<sup>4</sup>, Michele Colledan<sup>2</sup>, Stefano Fagioli<sup>1</sup>. <sup>1</sup>Bergamo, Gastroenterology, Hepatology and Liver Transplantation, Department of Medicine-Papa Giovanni, XXIII Hospital, Bergamo, Italy, Bergamo, Italy; <sup>2</sup>Unit of Hepato-biliary Surgery and Liver Transplantation, ASST Papa Giovanni XXIII, Bergamo, Italy; <sup>3</sup>FROM Research Foundation, Papa Giovanni XXIII Hospital, Bergamo, Italy; <sup>4</sup>Pathology Unit, ASST Papa Giovanni XXIII, Bergamo, Italy. Email: bianca\_magro@hotmail.it

**Background and aims:** Hepatocellular carcinoma (HCC) recurrence rates after liver transplantation (LT) range between 8 and 20%. Elevated alpha-fetoprotein (AFP) levels at transplant can predict post-transplant HCC recurrence, however a clear cut-off value is needed in order to identify patients at higher risk, aiming at improving surveillance program after LT. We retrospectively analyzed a cohort of patients meeting Milano criteria (MC) underwent LT to evaluate rate of HCC recurrence and possible predictors.

**Method:** We retrospectively analysed 236 consecutive patients waitlisted for HCC, all meeting Milan criteria, from January 2001 to December 2017 at our liver transplant centre. Twenty-nine patients dropped out while waitlisted, and 207 patients were included in the final analysis. All survival analyses included the competing-risk model.

**Results:** Mean age was 56.8 ± 6.8 years. Fourteen percent were female (n = 29/207). Median MELD at LT was 12 (9–16). Median time on waitlist was 92 (41–170) days.

HCC recurrence rate was 16, 4% (n = 34/208). Mean time to recurrence was 3.3 ± 2.8 years. Median AFP levels at transplant were higher in patients with HCC recurrence ( $p<0.001$ ). At multivariate analysis AFP value at transplant greater than 25.5 ng/ml (AUC 0.69) was a strong predictor of HCC recurrence after LT [ sHR 3.3 (1.6–6.81);  $p=0.001$ ]. HCC cumulative incidence function (CIF) of recurrence at 10 years from LT was significantly higher in patient with AFP >25.5 ng/ml [34.3% vs. 11.5% ( $p=0.001$ )]. Moreover, an increase in AFP >20.8%, is significantly associated with HCC recurrence ( $p=0.034$ ).

# POSTER PRESENTATIONS

Figure 1. 10-year Cumulative Incidence Function (CIF) of recurrence according to AFP level

\*death was considered as competing event

Figure:

**Conclusion:** In conclusion, in our retrospective study, AFP level at transplant >25.5 ng/ml and its increase (greater than 20.8% on waitlist) are strong predictors of HCC recurrence after LT in a cohort of patients waitlisted within Milan criteria. However further studies are needed to validate these data.

## PO-591

### Higher number of transarterial treatments might have detrimental effects on the overall survival of patients eventually receiving systemic treatments

Email: vito.sansone@studio.unibo.it

**Background and aims:** Transarterial chemoembolisation (TACE) is commonly used for the treatment of intermediate-stage hepatocellular carcinoma (HCC). While effective in controlling HCC, TACE can negatively impact on liver function. In the age of sequential systemic treatments for HCC, this detrimental effect could theoretically lead to an impaired overall survival in patients who become unresponsive or unsuitable for further locoregional treatments. We investigated the prognostic role of the number of previously received TACE in patients who received sorafenib as a frontline systemic treatment.

**Method:** We analyzed a large retrospective-prospective database gathering the clinical data of 668 patients from 7 Italian centres, who were prescribed with sorafenib between 2008 and 2017. We explored the prognostic role of previously received TACE (dichotomised as 0-1 vs >1 treatment) in the overall population and in the subgroup of sorafenib-responders (i.e., patients achieving a disease control at the first imaging follow-up).

**Results:** A total of 451 (67.5%) patients had received less than 2 TACE (no TACE = 322, 1 TACE = 129), while 217 (32.5%) received 2 TACE (n = 102) or more (n = 115). In the whole study population, the number of TACE was not related to the OS (which was instead predicted by ECOG-PS, AFP > 400 ng/ml, macrovascular invasion, extrahepatic spread, and dermatological adverse events). Instead, a higher number of TACE was independently associated with an impaired survival [15.6 vs 19.3 months, HR 1.46 (95% CI 1.04-2.06), p = 0.028] amongst the 282 sorafenib-responders patients (42.2% of the whole population).

**Conclusion:** The effects of the number of previous TACE are negligible in the whole population receiving sorafenib, where the OS largely depends on the response to the treatment (and therefore any potential prognostic correlate is masked by early deaths due to tumour progression). However, the negative prognostic effects of repeated TACE are evident in the subgroup of responders, which are more likely to have a prolonged survival. The identification of the correct timing to switch from transarterial to systemic treatments becomes of pivotal importance in a setting of sequential systemic treatments.

**comparison of hbv-related hcc incidence between entecavir and tenofovir treated cohorts: a population-based study**

Sichan He<sup>1</sup>, Maryam Alavi<sup>1</sup>, Behzad Hajarizadeh<sup>1</sup>, Jason Grebely<sup>1</sup>, Matthew Law<sup>1</sup>, Janaki Amin<sup>1,2</sup>, Jacob George<sup>3</sup>, Mark Danta<sup>4,5</sup>, Gregory Dore<sup>1,5</sup>. <sup>1</sup>The Kirby Institute, UNSW Sydney; <sup>2</sup>Macquarie University, Sydney, Department of Health Systems and Populations; <sup>3</sup>Westmead Institute for Medical Research, University of Sydney and Westmead Hospital, Storr Liver Centre; <sup>4</sup>St Vincent's Clinical School, Faculty of Medicine, UNSW Sydney; <sup>5</sup>St Vincent's Hospital, Sydney  
Email: she@kirby.unsw.edu.au

**Background and aims:** Chronic hepatitis B (CHB) infection is the leading cause of hepatocellular carcinoma (HCC) globally. Current HBV practice guidelines recommends entecavir (ETV) or tenofovir disoproxil fumarate (or tenofovir, TDF) as the first-line antiviral treatment. There has been controversy regarding a differential impact of ETV and TDF in mitigating HBV-related HCC.

**Method:** HBV notifications (1993–2017) were linked to hospitalisations, cancer registry, Pharmaceutical Benefits Scheme (PBS), and mortality databases in New South Wales, Australia to evaluate the HBV cohort characteristics and HCC incidence among ETV and TDF treated subpopulations (2010–2018).

Figure: (abstract: PO-767): Comparison of cumulative HCC incidence between patients who received Entecavir and Tenofovir treatment, by gender and birth cohort

## POSTER PRESENTATIONS

**Results:** In 53,350 people with an HBV notification, 4,785 individuals received ETV, and 3,055 received TDF. HCC occurred in 89 individuals in the ETV group (incidence: 3.87/1000 person-years, 95% CI: 3.14–4.77) and 35 individuals in the TDF group (incidence: 2.58/1000 person-years, 95% CI: 1.85–3.60). In adjusted Cox regression analysis, no significant difference was found in HCC risk between ETV and TDF groups (adjusted HR [aHR] = 1.01, 95% CI 0.67–1.53,  $P < 0.958$ ), while older age (born 1945–1964 vs.  $\geq 1965$ , aHR = 3.85, 2.20–6.72,  $P < 0.001$ ; and born  $\leq 1944$  vs.  $\geq 1965$ , aHR = 10.05, 5.30–19.07,  $P < 0.001$ ), male gender (aHR = 3.61, 2.15–6.08,  $P < 0.001$ ) and decompensated cirrhosis (aHR = 6.59, 3.79–11.45,  $P < 0.001$ ) were associated with greater risk of HCC. In stratified analyses, no significant difference was observed in cumulative HCC incidence between ETV group and TDF group across different genders and age groups (Figure).

**Conclusion:** There was no differential effect on HCC risk between ETV and TDF in this population-based study. Older age, male, and decompensated cirrhosis were associated with higher risk of HCC.

### PO-857

#### Kinetics of the neutrophil-lymphocyte ratio during PD-1 inhibition as a prognostic factor in advanced hepatocellular carcinoma

Won-Mook Choi<sup>1</sup>, Ji Yoon Kim<sup>1</sup>, Kang Mo Kim<sup>1</sup>. <sup>1</sup>University of Ulsan College of Medicine, Rep. of South Korea  
Email: kimkm70@amc.seoul.kr

**Background and aims:** Programmed death-1 (PD-1) inhibitors such as nivolumab have improved survival outcomes and produced durable responses in advanced hepatocellular carcinoma (HCC). However, predictive biomarkers to identify suitable patients for these treatments are still lacking. Here, we evaluated the relationship between the baseline and kinetics of the neutrophil-lymphocyte ratio (NLR) and clinical outcomes in nivolumab-treated HCC patients.

**Method:** All consecutive HCC patients treated with nivolumab between July 2017 and June 2020 were screened for the eligibility. The NLRs were calculated before and at 2, 4, and 6 weeks after treatment. Survival outcomes were compared based on the baseline and kinetics of NLR. We additionally analyzed the association

between the baseline and dynamic changes in the NLR with hyperprogression (HPD).

**Results:** Among the 194 included cases, most patients were male (82.0%) and had a Child-Pugh class A disease (70.6%). Patients with a baseline NLR  $\geq 3$  (hazard ratio [HR] 2.46; 95% CI 1.63–3.71) had a poorer overall survival compared to patients with baseline NLR  $< 3$ . During the treatment, the NLR increased rapidly in the patients developing HPD and only a  $\Delta$ NLR at 4 weeks was predictive of HPD. Indeed, the risk of HPD increased by 20% for every 20% increase in the  $\Delta$ NLR at 4 weeks, and a  $\Delta$ NLR  $> 75\%$  at this timepoint had an 86.1% accuracy for predicting HPD. Accordingly, an NLR increase at 4 weeks (HR 1.79; 95% CI 1.19–2.68) was associated with an increased risk of death, especially among patients with a baseline NLR  $\geq 3$ .

**Conclusion:** The baseline and on-treatment kinetics for the NLR are effective prognostic indicators in nivolumab-treated patients with HCC. This may help to guide patient selection and on-treatment strategies for immunotherapies in advanced HCC.

### PO-1010

#### Evaluation of cardiovascular events in patients with hepatocellular carcinoma treated with sorafenib in the clinical practice: CARDIO-SOR study.

Lorena Carballo Folgoso<sup>1</sup>, Miriam Celada Sendino<sup>1</sup>, Pablo Florez Díez<sup>1</sup>, Andrés Castano-García<sup>1</sup>, Javier Cuevas Pérez<sup>2</sup>, Rut Álvarez-Velasco<sup>2</sup>, Rebeca Lorca<sup>2,3</sup>, Carmen Álvarez-Navascués<sup>1</sup>, Valle Cadahía-Rodrigo<sup>1</sup>, María Luisa Gonzalez Dieguez<sup>1</sup>, Manuel Rodríguez<sup>1,3,4</sup>, María Varela<sup>1,3,4,5</sup>. <sup>1</sup>Hospital Universitario Central de Asturias, Liver Unit, Oviedo, Spain; <sup>2</sup>Hospital Universitario Central de Asturias, Department of Cardiology, Oviedo, Spain; <sup>3</sup>ISPA, OVIEDO, Spain; <sup>4</sup>Universidad de Oviedo, Medicine, Oviedo, Spain; <sup>5</sup>IUOPA, Oviedo, Spain  
Email: lorenacarballo93@gmail.com

**Background and aims:** The effectiveness of systemic treatment in hepatocellular carcinoma (HCC) depends on the selection of suitable patients, carefully management of cirrhosis complications and expertise to treat adverse events. The aim of this study is to assess the cardiovascular (CV) events in a cohort of HCC patients treated with sorafenib (SOR).

**Figure. The NLR kinetics at week 4 are predictive of survival outcomes in advanced HCC patients receiving nivolumab (n = 194).** Kaplan-Meier survival plots for OS are shown according to the NLR kinetics at week 4 in (a) patients with a baseline NLR  $< 3$  and (b) patients with baseline NLR  $\geq 3$ .

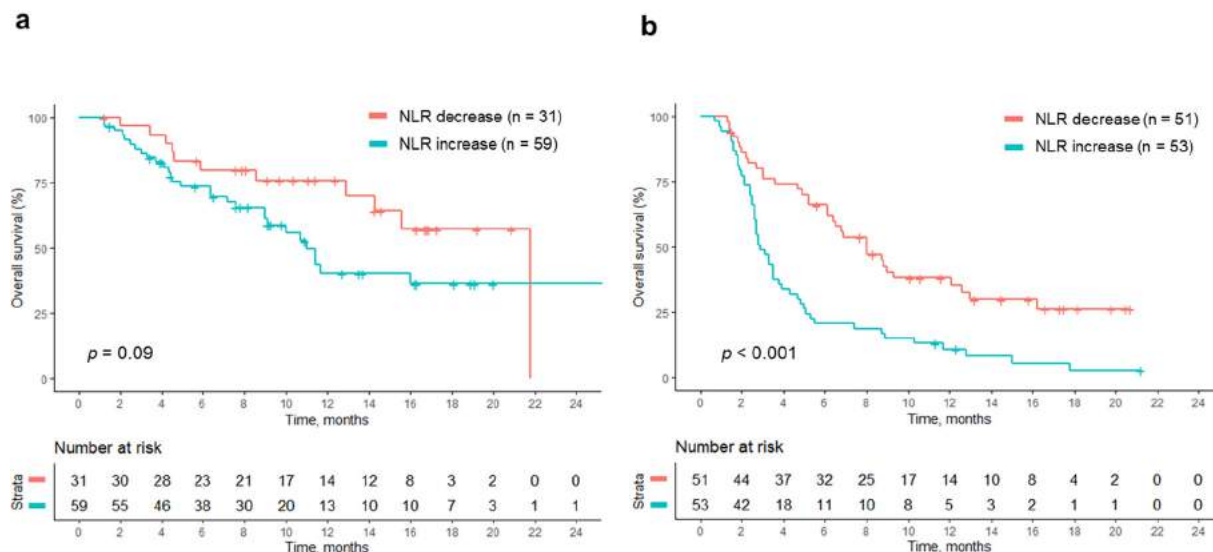

Figure: (abstract: PO-857)

1A. Competing-risks regression to predict major cardiovascular events by CARDIOSOR scale

1B. Kaplan Meier graph estimation to predict major cardiovascular events by CARDIOSOR scale

Figure: (abstract: PO-1010)

**Method:** Observational retrospective study including all HCC patients treated with SOR from 2007 to 2019 in a western tertiary hospital, except those included in clinical trials or treated after liver transplantation. In order to classify CV risk pre-sorafenib, we designed the CARDIOSOR scale with baseline age plus hypertension, diabetes, dyslipidaemia, smoking, chronic kidney disease and prior CV history, giving each one a point. Blood pressure measurement, EKG, adverse events, dosing and outcome data were collected during a standardized follow-up.

**Results:** 299 HCC patients, median age 66 years, Child A 85%, BCLC-C 73%, ECOG-PS 0 67%, cirrhosis 90% (mostly alcohol, 43%), diabetes 32%, hypertension 42%, dyslipidaemia 25%, obese 28%, smokers 53%. Median overall survival was 11.1 months (IQR 5.6–20.5); ECOG-PS 0 vs PS 1–2 (16.0 vs 5.3,  $p < 0.001$ ). Median treatment duration was 7.4 months (IQR 3.3–14.7). Over the 13.6 months' median follow-up (IQR 5.9–24.2), 33 patients (11%) had a major CV event: heart failure ( $n = 11$ ), acute coronary syndrome ( $n = 11$ ), cerebrovascular accident ( $n = 12$ ) and peripheral vascular ischemia ( $n = 8$ ), with median time from SOR-start 12.7 months (IQR 4.5–28.0). Ninety-nine of all patients (33%) had a minor CV event: increase arterial hypertension ( $n = 81$ ), long QT ( $n = 20$ ) and new atrial fibrillation ( $n = 11$ ). Multivariate cox regression analysis found age as the only independent factor associated to CV event (HR 1.07; 95% CI 1.03–1.12;  $p = 0.002$ ). The CARDIOSOR scale allowed us to identify the group of patients (>4 points) with higher cardiovascular risk compared to those with 0–4 points (sHR 3.5; 95% CI 1.5–8;  $p = 0.003$ ). The main reason for SOR cessation was CV event in 19 patients (6.3%). Only 2 died due to CV event: 1 acute coronary syndrome; 1 cerebrovascular accident.

**Conclusion:** The incidence of CV events in HCC patients treated with SOR in clinical practice is high, appears late, and independently associated with age. To manage these patients with high risk of CV toxicity, clinical tools like CARDIOSOR scale could be helpful. The awareness of CV risk may allow a successful sequential therapy for tumor progression.

PO-1046

**Serum levels of CXCL13 are an independent predictor of survival following resection of biliary tract cancer**

Sven H. Loosen<sup>1</sup>, Tom Florian Ulmer<sup>2</sup>, Christoph Roderburg<sup>1</sup>, Ulf Neumann<sup>2</sup>, Tom Luedde<sup>1</sup>. <sup>1</sup>University Hospital Duesseldorf, Clinic for Gastroenterology, Hepatology and Infectious Diseases, Duesseldorf, Germany; <sup>2</sup>University Hospital RWTH Aachen, Department of General, Visceral and Transplant Surgery, Aachen, Germany  
Email: Sven.Loosen@med.uni-duesseldorf.de

**Background and aims:** The prognosis of biliary tract cancer (BTC) has remained poor. Although tumor resection represents a potentially curative therapy for selected patients, disease recurrence is common and 5-year survival rates remain below 50%. As stratification algorithms comprising parameters of the individual tumor biology are missing, the identification of the ideal patients for extensive liver surgery is often challenging. The CXC chemokine family exerts decisive functions in cell-cell interactions and has only recently been associated with cancer. However, only very little is known on their role in BTC. Here, we aim at evaluating a potential role of circulating CXCL1, CXCL10 and CXCL13 in patients with resectable BTC.

**Method:** Serum levels of CXCL1, CXCL10 and CXCL13 were measured by multiplex immunoassay in a cohort of 119 BTC undergoing tumor resection as well as 50 healthy control samples.

**Results:** Circulating levels CXCL1, CXCL10 and CXCL13 were all significantly elevated in BTC patients compared to healthy controls and increased the diagnostic power of established tumor markers when used in combination. Importantly, elevated levels of CXCL13 both before and after tumor resection identified a subgroup of patients with a significantly impaired outcome following tumor resection. As such, BTC patients with initial CXCL13 levels above the ideal prognostic cut-off value (25.01 pg/ml) had a median OS of 290 days compared to 969 days for patients with low initial CXCL13 levels. The prognostic value of circulating CXCL13 was further confirmed by uni- and multivariate Cox-regression analyses. Finally, the individual kinetic of CXCL13 before and after tumor resection was also indicative for patients' outcome.

**Conclusion:** Our data suggest a fundamental role of the CXC chemokine family in BTC and identified circulating levels of CXCL13 as a previously unrecognized parameter for the prediction of outcome following resection of BTC.

Figure 1. At the optimal cut-off values, preoperative CXCL13 identify BTC patients with a significantly impaired postoperative overall survival.

**PO-1124**

**Hepatocellular carcinoma recurrence after direct-acting antiviral therapy for hepatitis C virus. A systematic review and meta-analysis.**

Leonardo Frazzoni<sup>1,2</sup>, Usama Sikandar<sup>1</sup>, Flavio Metelli<sup>1</sup>, Sinan Sadalla<sup>1</sup>, Giuseppe Mazzella<sup>1</sup>, Franco Bazzoli<sup>1,2</sup>, Lorenzo Fuccio<sup>1,2</sup>, Francesco Azzaroli<sup>1,2</sup>. <sup>1</sup>University of Bologna, Department of Medical and Surgical Sciences, Italy; <sup>2</sup>IRCCS Azienda Ospedaliero-Universitaria di Bologna, Italy  
Email: leonardo.frazzoni@gmail.com

**Background and aims:** The risk of hepatocellular carcinoma (HCC) recurrence after direct-acting antivirals (DAA) therapy has not been fully elucidated yet. Aim was to assess the risk of HCC recurrence after DAA therapy for HCV, also in comparison with IFN treatment and no intervention.

**Method:** Systematic review across PubMed, Scopus and Scholar up to November 2020, including full-text studies which assessed the pattern of HCC recurrence after DAA therapy for HCV. Random-effect meta-analysis and univariable meta-regression was applied to obtain pooled estimates for proportions, relative risk (RR) and influential variables on the outcome, respectively.

**Results:** Thirty-one studies with 2, 957 patients were included. Overall, 30% (CI 26–34%) of patients with a history of HCC experienced HCC recurrence after DAA therapy, at a mean time interval ranging from 4 to 21 months. This result was increasing ranging from European studies (23%, CI 17–28%) to US studies (34%, CI 30–38%) to Egypt studies (37%, CI 27–47%) to Asian studies (33%, CI 27–40%). Sixty-eight percent (CI 45–91%) of recurrent HCCs developed within 6 months of follow-up since DAA treatment, among 8 studies providing stratified data. Among studies providing head-to-head comparisons, the HCC recurrence risk was significantly lower after DAA therapy than IFN (RR 0.64, CI 0.51–0.81) and after DAA therapy than no intervention (RR 0.68, CI 0.49–0.94).

**Conclusion:** The recurrence of HCC after DAA is not negligible, being higher soon after the end of treatment and among non-European countries. DAA therapy significantly reduces the risk of HCC recurrence as compared to IFN regimen and no intervention.

**PO-1142**

**Duration of response and outcomes in advanced hepatocellular carcinoma patients with objective response to sorafenib: role of subsequent treatment.**

Kuo-Wei Huang<sup>1,2</sup>, Pei-Chang Lee<sup>1,3</sup>, Yi-Tzen Chen<sup>4</sup>, Yee Chao<sup>5</sup>, Chien-Wei Su<sup>1,3</sup>, Ming-Chih Hou<sup>1,3</sup>, Yi-Hsiang Huang<sup>1,3</sup>. <sup>1</sup>Taipei Veterans General Hospital, Division of Gastroenterology and Hepatology, Department of Medicine, Taipei City, Taiwan; <sup>2</sup>Taipei City Hospital Yangming Branch, Department of Medicine, Taipei City, Taiwan; <sup>3</sup>National Yang-Ming University, Faculty of Medicine, Taipei City, Taiwan; <sup>4</sup>Taipei Veterans General Hospital, Department of nursing, Taipei City, Taiwan; <sup>5</sup>Taipei Veterans General Hospital, Department of oncology, Taipei City, Taiwan  
Email: yhhuang@vghtpe.gov.tw

**Background and aims:** Sorafenib is the standard of care for advanced hepatocellular carcinoma (HCC) since 2008, but the objective response rates were only 2% to 10% in previous clinical trials and real-world data. Little is known for the duration of response and long-term outcome in HCC patients with objective response to sorafenib. There are emerging second-line therapies for patients who failed for sorafenib in recent years. In this study, we aimed to delineate the duration of response and the role of subsequent treatment after responding to sorafenib.

**Method:** From August 2012 to December 2019, 992 patients received sorafenib treatment for advanced HCC in Taipei Veterans General Hospital were retrospectively reviewed. Of them, 21 (2.1%) achieved complete responses (CR) and 55 (5.5%) had partial responses (PR) based on mRECIST criteria. The impacts of sequential therapy after sorafenib on overall outcomes were analyzed.

**Results:** The median duration of response was 17.3 months (range 2.3–44.5 months) for patients achieving CR, and 10.0 months (range 1.9–71.3 months) in PR patients. The median overall survival (mOS) was 44.9 months (95% confidence interval [CI]: 32.8–57.0 months) for the 76 patients, including not reached for CR, and 26.6 months (95% CI: 20.6–32.6 months) in PR patients. Patients experienced treatment-related adverse events (TRAE) had better mOS than those without (47.8 vs 19.2 months, p=0.044). Afterward, 65 patients (85.5%) discontinued sorafenib due to progressive disease or adverse events. Of them, 28 patients received subsequent systemic treatment, including nivolumab (n = 8), regorafenib (n = 12), and chemotherapy (n = 8). Patients with subsequent systemic therapy had a longer post-sorafenib survival (PSS) than those with best supportive care (BSC) only (median PSS: 29.5 vs. 11.5 months, p=0.029). Sorafenib-nivolumab sequential therapy had the longest mOS than sorafenib-regorafenib, sorafenib-chemotherapy, or sorafenib-BSC in these patients (55.8, 36.3, 25.5 and 27.4 months, respectively; p=0.020, 0.048, and 0.044 for sorafenib-nivolumab vs. sorafenib-regorafenib, sorafenib-chemotherapy, and sorafenib-BSC).

**Conclusion:** For advanced HCC patients with response to sorafenib, the duration of response can last for one year, and subsequent immunotherapy provided the best survival.

**PO-1209**

**Multibipolar radiofrequency ablation versus liver resection for the treatment of hepatocellular carcinoma within Milan criteria developed on advanced fibrosis/cirrhosis: a multicentric study on 1060 patients**

 Email: naultjc@gmail.com

**Background and aims:** Multibipolar radiofrequency ablation (RFA) increase the ability to ablate hepatocellular carcinoma (HCC) up to 5 cm. We aim to compare multibipolar RFA to liver resection (LR) in patients with HCC within Milan criteria developed on advanced

fibrosis or cirrhosis in order to identify the best candidate for each treatment.

**Method:** We included retrospectively patients treated either by multibipolar percutaneous RFA or LR for a first diagnosis of HCC within Milan criteria developed on advanced fibrosis (F3) or cirrhosis (F4) in 9 centers between 2008 and 2018. Overall survival (OS), overall tumor recurrence and adverse events were compared according to the type of treatments (RFA, laparoscopic or open LR) using a propensity score (double robust method).

**Results:** 1060 patients were included (median age 64 years old, 82.7% of men) with 620 (58.5%) treated by RFA and 440 (41, 5%) by LR (laparoscopic n = 271; open n = 169). HCC was uninodular in 83.8% of

Figure: (abstract: PO-1142):

the cases, of less than 3 cm in 40% of the case and developed on cirrhosis in 89% of the cases. Before adjustment, patients treated by RFA were significantly older with more liver failure and portal hypertension and have more multinodular tumors of smaller size compared to patients treated by LR. After adjustment, OS was not different between RFA and LR (OR: 1, 05; CI95%: 0, 98-1, 13;  $p = 0, 173$ ) whereas overall recurrence was higher after RFA (OR: 1, 13; CI95%: 1, 03-1, 23,  $p = 0, 007$ ). Morbidity (OR: 0.86; CI95%: 0, 80-0, 93;  $p < 0, 001$ ) and treatment-related mortality (OR: 0.96; CI95%: 0, 93-0, 99;  $p = 0, 031$ ) were lower after RFA. For unique HCC, OS was identical between treatments ( $p = 0, 0539$ ) with more overall recurrence after RFA ( $p = 0, 0014$ ). In patients with a least one HCC > 3 cm OS was lower after RFA ( $p = 0, 003$ ) with more tumor recurrence ( $p = 0, 034$ ). For multinodular HCC, OS ( $p = 0, 401$ ) and overall recurrence ( $p = 0.359$ ) was similar between RFA and LR with less morbidity after RFA ( $p < 0, 001$ ). Laparoscopic LR was associated with a longer OS ( $p = 0, 021$ ) and less overall recurrence ( $p = 0.0003$ ). In contrast, OS ( $p = 0, 172$ ) and overall recurrence ( $p = 0.118$ ) were identical between RFA and open LR with less morbidity after RFA ( $p = 0, 016$ ).

**Conclusion:** Multibipolar RFA and LR are two efficient treatments of early HCC developed on advanced fibrosis/cirrhosis. The treatment could be tailored according tumor size, tumor number, presence of portal hypertension/liver failure and the ability to perform laparoscopic resection.

**PO-1263**

**Impact of metabolic syndrome and non-alcoholic fatty liver disease in outcomes and tolerance after percutaneous multibipolar radiofrequency ablation for early hepatocellular carcinoma**

Thi Thu Nga Nguyen<sup>1</sup>, Agnès Rode<sup>2</sup>, Hervé Trillaud<sup>3</sup>, Christophe Aubé<sup>4</sup>, Anne-Frederique Manichon<sup>2</sup>, Anita Paisant<sup>4</sup>, Thong Dao<sup>1</sup>, Pierre Nahon<sup>5</sup>, Nathalie Ganne-Carrié<sup>5</sup>, Lorraine Blaize<sup>5</sup>, Francois Cauchy<sup>6</sup>, Olivier Sutter<sup>7</sup>, Olivier Seror<sup>7</sup>, Jean Charles Nalet<sup>5</sup>.

Email: nguyen.nga@live.com

**Background and aims:** Long-term outcomes after percutaneous radiofrequency ablation (RFA) in patients with non-alcoholic fatty

liver disease (NAFLD) have been poorly studied. We aim to describe the outcomes after multibipolar RFA in these patients and the prognostic impact of metabolic syndrome among other etiologies.

**Method:** Patients who underwent multibipolar RFA as first treatment for HCC within Milan criteria in 4 tertiary centers (2008–2018) were enrolled in a retrospective study. Patients with pure NAFLD-HCC were compared to those with alcoholic liver disease (ALD), hepatitis B (HBV) and hepatitis C virus (HCV). The association between pure NAFLD or between metabolic syndrome in other etiologies and adverse events and survival were assessed using Kaplan-Meier method, the log-rank test and uni/multivariate analysis using the Cox model.

**Results:** 520 patients were enrolled including 82% of male with a median age of 66 years. 494 patients (95%) had cirrhosis, 81% had a unique nodule with a median size of 25 mm. 75% of patients had at least one component of metabolic syndrome including obesity in 155 patients. Sixty-two patients (12.6%) had pure NAFLD, 225 (45.5%) had ALD, 36 (7.3%) had HBV and 171 (34.6%) had HCV. Patients with pure NAFLD were significantly older (median age 72.6 years,  $p < 0.0001$ ), more often obese (median BMI 30.3 kg/m<sup>2</sup>,  $p < 0.0001$ ), have more components of metabolic syndrome, had more ischemic heart disease (17.7%,  $p = 0.017$ ) and more esophageal varices (39, 3%,  $p = 0.004$ ) than patients with other etiologies. In the whole series, median overall survival (OS) was 66.5 months with a 1-, 3- and 5-years OS of 94%, 74% and 56%, respectively. In pure NAFLD patients, median, 1-, 3- and 5-years OS were 79 months, 90%, 71% et 59%, respectively. There were no differences in morbidity, tumor recurrence and overall survival in patients with pure NAFLD versus other etiologies. In patients with HBV, HCV or ALD, there was no prognostic impact of the components of the metabolic syndrome on treatment-related adverse events, the number of sessions to achieve complete ablation and oncological outcomes of RFA for HCC.

**Conclusion:** Patients with pure NAFLD or with both viral infection or alcoholic liver disease and metabolic syndrome have a prolonged overall survival after multipolar RFA without increased morbidity or tumor recurrence compared to patients without metabolic syndrome suggesting that percutaneous ablation is an efficient treatment in this population.

**PO-1312**

**The impact of betablocker treatment on cancer prognosis in patients with advanced hepatocellular carcinoma receiving sorafenib treatment**

Lorenz Balcar<sup>1,2</sup>, Katharina Pomej<sup>1,2</sup>, Mattias Mandorfer<sup>1</sup>, Tobias Meischl<sup>1,2</sup>, Christian Müller<sup>1,2</sup>, Michael Trauner<sup>1</sup>, Thomas Reiberger<sup>1</sup>, Matthias Pinter<sup>1,2</sup>, Bernhard Scheiner<sup>1,2</sup>. <sup>1</sup>Medical University of Vienna, Department of Internal Medicine III, Division of Gastroenterology and Hepatology, Vienna, Austria; <sup>2</sup>Medical University of Vienna, Liver Cancer (HCC) Study Group Vienna, Vienna, Austria  
Email: bernhard.scheiner@meduniwien.ac.at

**Background and aims:** Non-selective betablocker (NSBB) treatment is indicated in most patients with cirrhosis. Patients with hepatocellular carcinoma (HCC) may additionally benefit from BB treatment due to various effects on cancer biology as shown for other cancer types. However, most studies evaluated the impact of cardio-selective (CSBB) and NSBBs on HCC development as well as in patients with early-stage HCC. The impact of BB-treatment on cancer prognosis in HCC patients receiving systemic treatment is unclear. We investigated the impact of BB treatment on time-to-progression (TTP), progression-free (PFS) and overall survival (OS) in patients with advanced HCC receiving systemic treatment with sorafenib.

**Method:** Patients treated with sorafenib between 05/2006 and 03/2020 at the Medical University of Vienna were retrospectively included.

**Results:** The majority of patients were male (213/250 patients, mean age 66 ± 9 years) and 117 patients received BB treatment (n = 35 CSBB and n = 82 NSBB). Clinically significant portal hypertension (CSPH) was present in more than half of patients (n = 137, 55%) and most patients (58%) had BCLC C.

At sorafenib start, patients receiving BB treatment had a more advanced tumor stage (BCLC D: 25% vs. 10%, P = 0.008), more advanced liver dysfunction (Child-Pugh stage B/C, 66% vs. 45%, P = 0.001), and were more often diagnosed with CSPH (70% vs 41%, P < 0.001) when compared to patients not receiving BB therapy.

TTP (evaluable in 173 patients with at least one follow-up imaging) was significantly shorter in patients with BB treatment at baseline (4.2 [95% CI: 3.0–5.3] vs. 5.9 [95% CI: 4.4–7.3] months, P = 0.021). BB treatment remained an independent risk factor for TTP (HR 1.52 [95% CI: 1.07–2.18], P = 0.021) after multivariable adjustment for Child-Pugh stage, ECOG performance status and extrahepatic metastases. However, this did not translate into a worse median OS (BB vs. no BB, 8.5 [95% CI: 6.6–10.3] months vs. 10.4 [95% CI: 8.3–12.5] months, P = 0.247) or PFS (BB vs. no BB, 3.9 [95% CI: 3.2–4.6] months vs. 4.6 [95% CI: 3.5–5.8] months, P = 0.152).

**Conclusion:** In contrast to results from other cancer types, we did not find improved outcomes for BB treatment in HCC patients receiving systemic treatment with sorafenib. Instead, concomitant NSBB or CSBB use was independently associated with shorter TTP.

**PO-1351**

**Preliminary experience on safety of cabozantinib in recurrent hepatocellular carcinoma after liver transplantation. A case series**

M. and A. Migliavacca” Center for Liver Disease, Department of Pathophysiology and Transplantation, Milan, Italy  
Email: federica.invernizzi@policlinico.mi.it

**Background and aims:** Cabozantinib (CABO) is a second/third line treatment option for hepatocellular carcinoma (HCC), improving overall survival (OS) of sorafenib-treated patients who develop progression or are intolerant to. We aimed to evaluate safety and outcomes of CABO as second/third-line treatment for HCC-recurrence after liver transplantation (LT).

**Method:** This is a retrospective, multicentre, international study including CABO-treated LT-patients, with analysis of baseline characteristics and evolutionary-events during treatment.

**Results:** Sixteen LT patients were included: 60 years, 12 men, ECOG-performance status (PS) 1 in 8, ECOG-PS 0 in 6 and ECOG-PS 2 in 2; HCC both intra- and extra-hepatic sites in 10 patients, extrahepatic sites in 5 and in one case HCC was limited to the liver. Median time from LT to CABO initiation was 4.2 (1.2–14) years; 10 patients received CABO as second line treatment (after sorafenib discontinuation for tumor progression 9/10), while 6 received CABO as third line (first line sorafenib discontinued for tumor progression, second line regorafenib discontinued for tumor progression in 4 and intolerance in 2). Overall, median time on sorafenib was 8.7 (0.3–76.9) months and 3.4 (0.2–17.6) months on regorafenib. During 3.6 (1.4–14.6) months of CABO treatment, the most common adverse events (AEs) were diarrhoea (n = 11; G2 = 4, G3 = 1), fatigue (n = 9; G2 = 4, G3 = 1) and dermatological reaction (n = 7, G2 = 2). Severe AEs were proteinuria (n = 3, G2 = 1, G3 = 2), hyperthyroidism (G3 = 1), and neutropenia (n = 2, G4 = 1). No liver rejection was observed, and no drug-to-drug interactions with immunosuppressive drugs were reported. Nine patients developed progression, 8 discontinued CABO (for tumor progression in 4) and 4 patients died. The median OS from CABO initiation was 15.6 (95% CI: 10.1–21.0), and 37.6 months (95% CI: 21.6–53.6) from sorafenib initiation for the 10 patients in whom CABO was used as second line drug.

**Conclusion:** This is the first study showing the safety profile of cabozantinib after LT, thus providing the rationale of considering cabozantinib in the management of patients with HCC-recurrence after LT with progression/intolerance to first/second line treatment.

**PO-1420**

**Background and aims:** Anti-PD1 checkpoint inhibitors convey clinical benefits in 20% of patients with advanced hepatocellular carcinoma (aHCC), although markers predicting response are unknown. We develop biomarkers of response/primary resistance to checkpoint inhibitors in aHCC through dissecting molecular traits prior to systemic therapy.

**Method:** Overall, 111 HCC tissue samples obtained prior any systemic therapy from patients with aHCC treated with single agent nivolumab or pembrolizumab were collected through an international consortium of 13 centers. We performed molecular studies including gene expression microarrays, a CTNNB1 exon 3 mutational analysis and histological evaluation and correlated with clinical outcomes.

**Results:** Among 83 patients included in the transcriptomic analysis, 28 were treated in first-line (objective response rate [ORR]: 42.9%), whereas 55 patients were treated after tyrosine kinase inhibitors (TKI, sorafenib/lenvatinib) either in 2nd line (41 patients, ORR 29.3%) or 3rd line (14 patients, ORR 7.1%). Responders treated in frontline showed a significant upregulation in Interferon- $\gamma$  signaling (IFN $\gamma$ ) and MHCII-related antigen presentation ( $p < 0.001$  vs non-responders). We generated a 11-gene signature-involving IFN and antigen presentation genes-capable of predicting ORR (AUC 0.93), and progression-free survival (PFS; median 28.8 vs 5.0 months,  $p = 0.037$ ) in aHCC patients that was validated in melanoma and NSCLC patient cohorts. This signature predicted both ORR and PFS in patients with these solid tumors. In HCC, cases with a positive gene signature showed increased M1 macrophages ( $p = 0.003$ ), CD4 memory T cell ( $p < 0.001$ ) and CD4 naïve T cell-infiltration ( $p = 0.026$ ), whereas an increase in T-regs was seen in tumors with low expression of the gene signature ( $p = 0.001$ ). Neither the immune infiltrate nor CTNNB1 exon 3 mutations predicted response or primary resistance. Of note, the same signature was unable to predict response in patients treated after first-line TKIs, suggesting

changes in the microenvironment rendering a previously inflamed phenotype no longer responsive to immunotherapy.

**Conclusion:** We identified an 11-gene signature of response to anti-PD1 therapy in first line advanced HCC, which was validated in other solid tumors. This signature did not identify responders after TKI treatment, thus calling for the need of biopsies prior to anti-PD1 therapy to enable biomarker-based precision oncology.

### PO-1745

#### Equal overall survival in elderly patients with hepatocellular carcinoma receiving palliative treatment

Thorben Fründt<sup>1</sup>, Christian Casar<sup>2</sup>, Johann von Felden<sup>1</sup>, Jenny Krause<sup>1</sup>, Ines Gil-Ibanez<sup>1</sup>, Ulrike Schöler<sup>1</sup>, Maximilian Priebe<sup>1</sup>, Jenny Kraczik<sup>1</sup>, Gerhard Adam<sup>3</sup>, Ansgar W. Lohse<sup>1</sup>, Henning Wege<sup>1,4</sup>, Kornelius Schulze<sup>1</sup>. <sup>1</sup>University Medical Center Hamburg-Eppendorf, I. Department of Medicine, Hamburg, Germany; <sup>2</sup>University Medical Center Hamburg-Eppendorf, Bioinformatics Facility, Hamburg, Germany; <sup>3</sup>University Medical Center Hamburg-Eppendorf, Department of Diagnostic and Interventional Radiology and Nuclear Medicine, Hamburg, Germany; <sup>4</sup>Klinikum Esslingen, Cancer Center Esslingen, Esslingen am Neckar  
Email: tfruentd@uke.de

**Background and aims:** Hepatocellular carcinoma (HCC) is the most common primary liver cancer with an increasing incidence worldwide, especially in elderly patients. Diagnosis is often made in an advanced stage, rendering curative treatment impossible. Although therapeutic options for patients in a palliative setting have improved in recent years, treatment of elderly patients is often complicated by challenging comorbidities and frailty. Since data about the outcome and overall survival (OS) in elderly HCC patients receiving palliative therapy is limited, we conducted a retrospective study at a tertiary referral center.

**Method:** Data from 987 patients with HCC, who were treated at the University Medical Center Hamburg-Eppendorf between January 2007 and October 2017, were analyzed. Tumor stage and liver function were rated according to the Barcelona Clinic Liver Cancer (BCLC) classification and Child-Pugh-Turcotte score (CPS), and therapy related adverse events (AE) were assessed via CTCAE 5.0. Patients were grouped according to their age as young (<60 years; YP), intermediate (60–70 years; IP) or elderly (>70 years; EP). Administration of tyrosine kinase inhibitor (TKI) and transarterial chemoembolization (TACE) was defined as palliative treatment. Patients receiving curative intended treatment (e.g. liver transplantation, resection or microwave ablation following TACE) were excluded from this analysis.

**Results:** Out of 987 patients,  $n = 330$  were considered for curative treatment and excluded,  $n = 657$  received palliative treatment; YP  $n = 194$ ; IP  $n = 241$ ; EP  $n = 222$ . 82.5% ( $n = 542$ ) were male, median age was 67 (range 23–87) years. All patients had underlying liver cirrhosis with a larger proportion of impaired liver function in the YP cohort (CPS A/B/C [%]: YP 53/28/18 vs. IP 61/26/12 vs. EP 66/28/6;  $p = 0.01$ ). Patients performance status according to Eastern Cooperative Oncology Group (ECOG) was comparable between YP, IP, and EP (ECOG 0/1/2/3 [%]: 40/37/16/4 vs. 36/40/14/6 vs. 33/41/17/6;  $p = 0.85$ ). OS in patients receiving TACE, including CPS A and B patients, was 16 vs. 16 vs. 20 months for YP, IP, and EP, respectively;  $p = 0.38$ . In TKI-treated patients, OS was 13 vs. 15 vs. 13 months;  $p = 0.73$ . The rate of AE in TKI-patients was comparable with 47 vs. 43 vs. 49%, and the most prevalent AE in all three groups was diarrhea.

**Conclusion:** In this study, OS was equal in elderly patients with liver cirrhosis receiving palliative treatment for HCC with TACE or TKI. Furthermore, the rate of AE was comparable in younger and elderly patients. Therefore, we propose regular palliative treatment stratification in spite of high age of patients.

**PO-1801**

**Evolutionary learning derived clinical-radiomic models for predicting early recurrence of hepatocellular carcinoma after surgical resection**

I-Cheng Lee<sup>1</sup>, Jo-Yu Huang<sup>2</sup>, Ting-Chun Chen<sup>2</sup>, Gar-Yang Chau<sup>3</sup>, Rheun-Chuan Lee<sup>3</sup>, Shinn-Ying Ho<sup>2</sup>, Yi-Hsiang Huang<sup>1</sup>. <sup>1</sup>Taipei Veterans General Hospital, Division of Gastroenterology and Hepatology, Taipei, Taiwan; <sup>2</sup>National Yang Ming Chiao Tung University, Taiwan; <sup>3</sup>Taipei Veterans General Hospital, Taipei, Taiwan  
Email: iclee@vghtpe.gov.tw

**Background and aims:** Current prediction models for early recurrence of hepatocellular carcinoma (HCC) after surgical resection remain unsatisfactory. The aim of this study is to develop accurate prediction models with interpretability using both clinical and radiomic features to predict early recurrence of HCC after surgical resection.

**Method:** 517 consecutive HCC patients receiving resection with contrast-enhanced computed tomography (CECT) images before resection were retrospectively enrolled. Tumor segmentation of all CECT images including non-contrast phase, arterial phase and portal venous phase were manually performed for radiomic feature extraction. A novel evolutionary learning derived method called GARSL (Genetic Algorithm for predicting Recurrence after Surgery of Liver cancer) was proposed to design prediction models for early recurrence of HCC within 2 years after surgery.

**Results:** A total of 143 features, including 26 pre-operative clinical features, 5 post-operative pathological features and 112 radiomic features, were finally adopted to develop GARSL pre-operative and post-operative models. GARSL pre-operative and post-operative models achieved the test performance 0.739 and 0.741 of areas under the receiver operating characteristic curves (AUCs), respectively, for early recurrence of HCC within 2 years. The accuracy of GARSL models derived from evolutionary learning method was significantly better than models derived from other well-known machine learning methods or the ERASL models using clinical features only.

**Conclusion:** The GARSL models using both clinical and radiomic features significantly improved the accuracy to predict early recurrence of HCC after surgical resection, which were significantly better than other well-known machine learning derived models and currently available clinical models.

**PO-1856**

**Anti-tumor activity of TRN-000546, a liver-distributed monophosphate prodrug of FdUMP, in orthotopic liver tumor models**

Martijn Fenaux<sup>1</sup>, Kevin Klucher<sup>1</sup>, Christopher Jones<sup>1</sup>, Anne Bonneville<sup>1</sup>, Weidong Zhong<sup>1</sup>. <sup>1</sup>Terns Pharma, Research, Foster City, United States  
Email: kklucher@ternspharma.com

**Background and aims:** TRN-000546 is a monophosphate prodrug of FdUMP, the potent anti-tumor metabolite of 5-FU. The TRN-000546 prodrug was designed to protect FdUMP from enzymatic deactivation and improve its delivery into the liver. Here, we report the tissue distribution of FdUMP in hamsters dosed with TRN-000546. Additionally, TRN-000546 was tested in rodent orthotopic liver cancer models mimicking hepatocellular carcinoma (HCC), metastatic gastric cancer (GC), and metastatic colon cancer (CC).

**Method:** The in vitro potency of TRN-000546 was determined against the tumor cell lines Huh7, MKN45, and HT-29. To measure tissue distribution, TRN-000546 was administered as a single IP dose (30 mg/kg) to hamsters and tissues were collected for FdUMP quantification at 4 hours after dosing. In vivo anti-tumor efficacy was determined in mouse orthotopic liver cancer models of HCC, GC, and CC using tumor-derived bioluminescent cell lines Huh7-luc, MKN45-luc, and HT-29-luc, respectively. Cell lines were suspended in DMEM/Matrigel mixtures (1:1) and surgically implanted under the

liver capsule prior to treatment with TRN-000546 (20 or 30 mg/kg IP BID for 17 days [HCC] or 20 mg/kg IP BID for 21 days [GC and CC]). Standard of care (SOC) treatment groups included sorafenib (30 mg/kg PO QD for 17 days, HCC) and capecitabine (400 mg/kg PO QD for 21 days, GC and CC). At the end of treatment, mice were sacrificed and tumors (primary and 2nd metastatic) weights were compared to vehicle treated controls.

**Results:** TRN-000546 was 561-, 80- and 988-fold more potent than 5-FU against Huh7, MKN45, and HT-29 tumor cell lines, respectively. The highest concentration of FdUMP was detected in the liver after a single IP dose of TRN-000546 (30 mg/kg), while FdUMP was undetectable in bone marrow and skin, the tissues known to be associated with 5-FU toxicity. In the mouse orthotopic tumor models, TRN-000546 treatment reduced mean HCC tumor weights by 84% (p < 0.05) relative to the vehicle control, while SOC treatment (sorafenib) decreased HCC tumor weights by only 41%. TRN-000546 treatment reduced mean metastatic GC and CC tumor weights by 45% (p < 0.05) and 53% (p < 0.05), respectively, while capecitabine reduced GC tumor weights by 57% (p < 0.05) and CC tumor weights by 3.5%.

**Conclusion:** TRN-000546, a monophosphate prodrug of FdUMP, showed increased in vitro potency against tumor cell lines and improved liver tissue distribution relative to the parent drug 5-FU. Furthermore, treatment with TRN-000546 demonstrated comparable or better efficacy in the mouse orthotopic models of HCC and liver metastases relative to SOC treatments, supporting its continued development as a potential therapy for liver cancers.

**PO-1883**

**A Novel Prognostic Calculator to Optimize Individualized Treatment for Patients with HCC within the Milan the Milan Criteria.**

Email: luwei1966@126.com

**Background and aims:** Liver transplantation (LT), liver resection (LR) and local ablation (LA) are curative-intent treatments for patients with early hepatocellular carcinoma (HCC). However, the best management warrants an individualized multidisciplinary discussion. The aim of present study was to develop a prognostic calculator to compare long term outcomes following each of these therapies, which will help guide a personalized discussion of treatment plans with the patients.

**Method:** 976 patients with HCC within the Milan criteria (MC) undergoing LT, LR and LA with curative intent were recruited from 4

## POSTER PRESENTATIONS

different centres. Multistate competing risks prediction models for recurrence free survival (RFS), recurrence within the Milan criteria (RWM), HCC-specific survival (HSS) were derived in the Chinese training cohort. The models were then internally validated in Chinese validation cohort and externally validated in American validation cohort to develop a prognostic calculator.

**Results:** In the multivariable analysis, in addition to tumour size and interaction effects between treatment allocation and tumor number, clinicopathologic data including patient's age, gender, AFP, albumin-bilirubin grade, and portal hypertension were significantly associated with recurrence and HCC-specific survival. Prediction models of RFS, RWM and HSS with 3 risk strata were constructed and validated with satisfactory discrimination abilities and calibration curves in both Chinese internal and American external validation cohorts. A web-based prognostic calculator was then successfully developed.

**Conclusion:** While liver transplantation offers the best recurrence and survival outcomes, liver resection and local ablation also offer comparable long-term outcomes for patients with early HCC who are limited by organ availability. Our present prognostic calculator can be used to compare these long-term outcomes in different tumor subgroups and optimize the individualized care for patients with HCC.

**Lay summary:** Our current study developed the multistate competing risks models to exhibit an accurate continuous range of HCC-specific prognosis probability algorithm of recurrence free survival, recurrence within the Milan criteria and HCC-specific survival for early-stage HCC with composite multi-parametric evaluations, including different curative treatment allocation for different tumour status and liver function. A web-based prognosis calculator based on the prognosis algorithm was developed for convenient assessment of the curative treatment allocation for HCC patients within the Milan criteria.

### PO-2075

#### Aspirin and the risk of hepatocellular carcinoma in chronic liver disease: A systematic review and meta-analysis

Jin Lin Tan<sup>1</sup>, Sandeep Sidhu-Brar<sup>1</sup>, Richard Woodman<sup>2</sup>, Asif Chinnaratha<sup>1,3</sup>. <sup>1</sup>Lyell McEwin Hospital, Department of Gastroenterology and Hepatology, Elizabeth Vale, South Australia, Australia; <sup>2</sup>Flinders University, College of Medicine and Public Health, Bedford Park, South Australia, Australia; <sup>3</sup>The University of Adelaide, Faculty of Health and Medical Sciences, Adelaide, South Australia, Australia

Email: tanjinlin@gmail.com

**Background and aims:** Hepatocellular carcinoma (HCC) represents >80% of primary liver cancers and it is the fourth most common cause of cancer related death globally. There is conflicting evidence on the impact of Aspirin on the incidence of HCC in those with chronic liver disease. This meta-analysis of observational studies was undertaken to evaluate the association of Aspirin use on the incidence of HCC in patients with chronic liver disease.

**Method:** Electronic reference databases (PubMed Medline, EMBASE Ovid, and the Cochrane Central) were searched from inception to 30<sup>th</sup> April 2020 for studies involving adult patients with chronic liver disease. The primary outcome assessment was the development of HCC in those exposed to regular Aspirin therapy compared to those who were not exposed or used Aspirin intermittently (comparator). The secondary outcome was the occurrence of major gastro-intestinal (GI) bleeding events. We estimated the unadjusted and propensity score (PS) adjusted pooled Hazard Ratio (HR) (95% CI) of HCC among regular Aspirin use versus non-use using a random-effects model.

**Results:** Six observational studies with 71,211 subjects were included in this meta-analysis. Median duration of follow-up of the included studies ranged from 2.7–7.9 years. Four studies had viral hepatitis as the underlying aetiology while one had alcohol and the other had mixed aetiology. Patients in five out of the six studies used Aspirin 100 mg/day while those in the other study used either 75 or 160 mg.

All six studies reported the unadjusted HR and there was a 54% reduction in HCC development in those exposed to Aspirin [HR (95% CI): 0.46 (0.31–0.67),  $p < 0.001$ ] (Figure). Four studies reported on the PS adjusted HR and this showed a 46% reduced incidence of HCC in those using Aspirin [HR (95% CI): 0.54 (0.38–0.79),  $p < 0.001$ ]. Four studies reported on the incidence of major GI bleeds and there was no significant difference between the two groups [HR (95% CI): 1.00 (0.69–1.45),  $p = 0.9$ ]. All the outcome analysis had significant inter-study heterogeneity ( $I^2 > 50\%$  and  $P < 0.05$ ).

Figure:

**Conclusion:** Regular Aspirin use in patients with chronic liver disease is associated with a reduced risk of HCC without a significant increased risk of GI bleeding.

### PO-2401

#### Tailoring the management of HCC during the COVID-19 pandemic: a single center comparative analysis of 4 periods during 2020 versus 2019

Massimo Iavarone<sup>1</sup>, Barbara Antonelli<sup>1</sup>, Anna Maria Ierardi<sup>1</sup>, Angelo Sangiovanni<sup>1</sup>, Ferruccio Ceriotti<sup>1</sup>, Giorgio Rossi<sup>1</sup>, Gianpaolo Carrafiello<sup>1</sup>, Pietro Lampertico<sup>1</sup>. <sup>1</sup>Foundation IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milano, Italy  
Email: massimo.iavarone@policlinico.mi.it

**Background and aims:** During the first COVID-19 pandemic, we learned the unpredictable fluctuation of hospital resources and the risk of the nosocomial spread of SARS-CoV-2, directly impacting on hepatocellular carcinoma (HCC) management. To protect patients and healthcare workers, while guaranteeing the continuity of HCC treatment, we redesigned our management paradigms. The aim of this study is to evaluate the impact of these measures on the management of HCC patients during the pandemic.

**Methods:** Since April 2020 COVID-19 testing was performed every other week to all healthcare workers involved in the management of HCC patients, since May 2020 a dedicated room has been elected for HCC patients who were tested approximately 48 hours before admission. The multidisciplinary team (MDT) evaluated the risk of potential exposure versus presumed benefit of treatment for each patient, also considering the minimum time of exposure to the hospital environment and the effective availability of specialists. As measure of effectiveness for HCC management, we compared the number of visits, cases discussed in MDT, surgical treatments, percutaneous ablations and endovascular procedures performed in 2020 to those performed in 2019, considering 4 periods: pre-pandemic (January-February), first pandemic (March-May), summertime (June-September) and second pandemic (October-December).

**Results:** The number of swabs tested positive for SARS-CoV-2 before admission was 3.7% and these patients were postponed until negative. No patients turned symptomatic for COVID-19 after discharge. Table 1 shows the differences between 2019 and 2020 according to the predefined periods. The total number of surgical procedures performed in 2019 was 30 compared to 17 in 2020, while the number of liver transplants for HCC was 28/53 in 2019 vs 19/40 in 2020.

	Out-patients' visits	MDT cases	Ablation	TACE/TARE
Jan-Feb 2019	261	82	2	36
Jan-Feb 2020	301 (+15%)	108 (+32%)	5 (+150%)	33 (-8%)
March-May 2019	413	160	3	46
March-May 2020	213 (-48%)	101 (-37%)	16 (+433%)	19 (-59%)
Jun-Sept 2019	437	187	8	69
Jun-Sept 2020	475 (+9%)	193 (+3%)	16 (+100%)	52 (-24%)
Oct-Dec 2019	444	168	9	39
Oct-Dec 2020	427 (+4%)	214 (+27%)	11 (+22%)	43 (+10%)

**Conclusion:** During the pandemic, particularly after the implementation of measures to guarantee safety of patients, we were able to maintain an adequate number of treatments for HCC, favouring ablative treatments to ensure greater efficacy and a reduced exposure to the hospital environment with available resources.

**PO-2408**

**The Number of Small Hepatocellular Carcinoma Nodules in Patients within the Alpha-Fetoprotein Score before Liver Transplantation Is a Prognostic Risk Factor**

Alina Pascale<sup>1</sup>, Alessandro Mazzotta<sup>2</sup>, L. Cano<sup>3</sup>, Marc Antoine Allard<sup>2</sup>, Audrey Coilly<sup>1</sup>, Antonio Sa Cunha<sup>2</sup>, Rene Adam<sup>2</sup>, Daniel Cherqui<sup>2</sup>, Didier Samuel<sup>1</sup>, Olivier Rosmorduc<sup>1</sup>, Eric Vibert<sup>2</sup>, Nicolas Golse<sup>2</sup>. <sup>1</sup>Paul Brousse Hospital, Hepatology, Villejuif, France; <sup>2</sup>Paul Brousse Hospital, Hepato-Biliary Surgery, Villejuif, France; <sup>3</sup>Rennes University, INSERM-UMR 1241, Rennes, France  
Email: alina\_pascale@yahoo.com

**Background and aims:** In France, the criteria for liver transplantation (LT) for hepatocellular carcinoma (HCC) require an alpha-fetoprotein (AFP) score  $\leq 2$ . According to this score, patients with  $>3$  HCC nodules are eligible for LT, as long as they are small ( $\leq 3$  cm) and the AFP level is  $\leq 100$  ng/ml. This study shows that the number of small HCC nodules in patients within the AFP score before LT has a prognostic value.

**Method:** We included 143 patients consecutively transplanted for HCC in our center, between 2013 and 2017, with an AFP score  $\leq 2$ . The number and size of HCC nodules, and the AFP level were assessed at listing and at the last evaluation before LT. HCC histological features on native liver were assessed. We compared the overall survival (OS) and disease-free survival (DFS) post-LT of patients with  $\leq 3$  versus  $>3$  HCC nodules (current criteria) and, respectively,  $<5$  versus  $\geq 5$  HCC nodules. The Mann-Whitney U test for continuous variables and Pearson's chi-square test were used, or Fisher's exact test for categorical variables. Survival rates were calculated using the Kaplan-Meier method, and groups were compared with the log-rank test.

**Results:** Among 196 patients listed for HCC, 36 (18.4%) were not transplanted due to drop-out. The median age of the 143 transplanted patients was 63.3 years. The two main causes of the underlying liver disease were alcohol (41.3%) and HCV infection (27.9%). The number of patients with more than 3 HCC nodules at listing and at the last imaging before LT was of 16 (11%) and 17 (12%), respectively. 128 (89.5%) patients had at least one bridging treatment: transarterial chemoembolization n = 83, radiofrequency n = 16, surgical resection n = 22, other treatment n = 22, without any difference among the subgroups ( $\leq 3$  versus  $>3$  HCC nodules). The median follow-up of the whole cohort was of 44 months. The 3-years OS of patients with  $\leq 3$  versus  $>3$  HCC nodules at listing were of 90.3% and 67.3%, respectively ( $p = 0.04$ ). At last imaging before LT, 8 patients presented  $\geq 5$  HCC nodules, while still within the AFP score; they had a significantly lower OS than those with  $<5$  nodules: 5-years OS of 24.4% versus 78.1%,  $p = 0.01$ ), as showed in Figure 1.

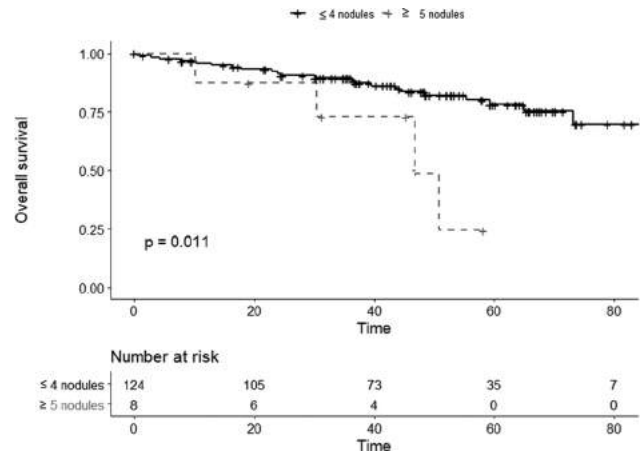

Figure: Overall survival for patients with  $\leq 4$  HCC nodules (bold line) versus  $\geq 5$  HCC nodules (dashed line) at last imaging before LT.

**Conclusion:** Although the current AFP score provides satisfactory outcomes post-LT for HCC, we highlight here the poorer outcomes when more than five HCC nodules persist despite bridging therapy. A modification of the AFP score, by adding an upper threshold of five HCC nodules could be considered, to exclude progressive HCC after listing, as they show shorter survival rates.

**Primary non-response affects the prognosis of hepatitis B virus-related Hepatocellular Carcinoma after antiviral therapy**

Peng Wang<sup>1</sup>, Xinhui Wang<sup>1,2</sup>, Xiaoli Liu<sup>1</sup>, Fengna Yan<sup>1</sup>, Huiwen Yan<sup>3</sup>, Dongdong Zhou<sup>1</sup>, Lihua Yu<sup>1</sup>, Xian-bo Wang<sup>1</sup>, ZhiYun Yang<sup>1</sup>. <sup>1</sup>Capital Medical University Affiliated Beijing Ditan Hospital, Center of Integrative Medicine, Beijing, China; <sup>2</sup>Beijing, China; <sup>3</sup>Beijing University of Chinese Medicine, First Clinical Medical College, Beijing, China  
Email: yangzhiyun2016@163.com

**Background and aims:** Despite antiviral treatment has been revealed to affect the recurrence and long-term survival of hepatocellular carcinoma (HCC) in patients with high viral load, but the effect of different response on clinical outcomes after antiviral therapy remains unclear. This study aims to assess the effect of primary non-response on survival or prognosis of hepatocellular carcinoma patients with high-level hepatitis B virus (HBV) DNA.

**Method:** A total of 493 patients with HBV-HCC admitted to the Beijing Ditan Hospital of Capital Medical University were enrolled in this study. Patients were divided into primary response group and primary non-response group. This bar graphs were used to compare the changes in virus levels between different groups. Risk factors, serum viral load, and other clinical variables were analyzed. The Kaplan-Meier curve were used to express the survival rate of the two groups of patients. Scoring chart was used to distinguish patients with different risk levels.

**Results:** The cohort consisted of 392 patients in primary response group and 101 in primary non-response group. The median survival time of PR group and no PR group was 39.6 months and 15 months. The average level of HBV DNA in primary response was higher than non-response group after 3 months of antiviral treatment. Then we divided the PR patients into higher level group (HBV DNA  $\geq 5$ log) and relatively lower level group (HBV DNA  $< 5$ log) based on baseline virus levels. As a result, there were no statistical differences between the two subgroups of PR patients. The Kaplan-Meier curve showed that primary non-response had a lower overall survival in different categories of HBV DNA and hepatitis B e antigen. Primary non-response had lower overall survival and progress free survival in patients with alanine aminotransferase (ALT)  $< 50$  IU/L and cirrhosis. A multivariate Cox regression analysis indicated that primary non-response was an independent risk factor for 1-year survival (HR = 1.883, 95% CI 1.289–2.751,  $P = 0.001$ ). All patients were divided into

# POSTER PRESENTATIONS

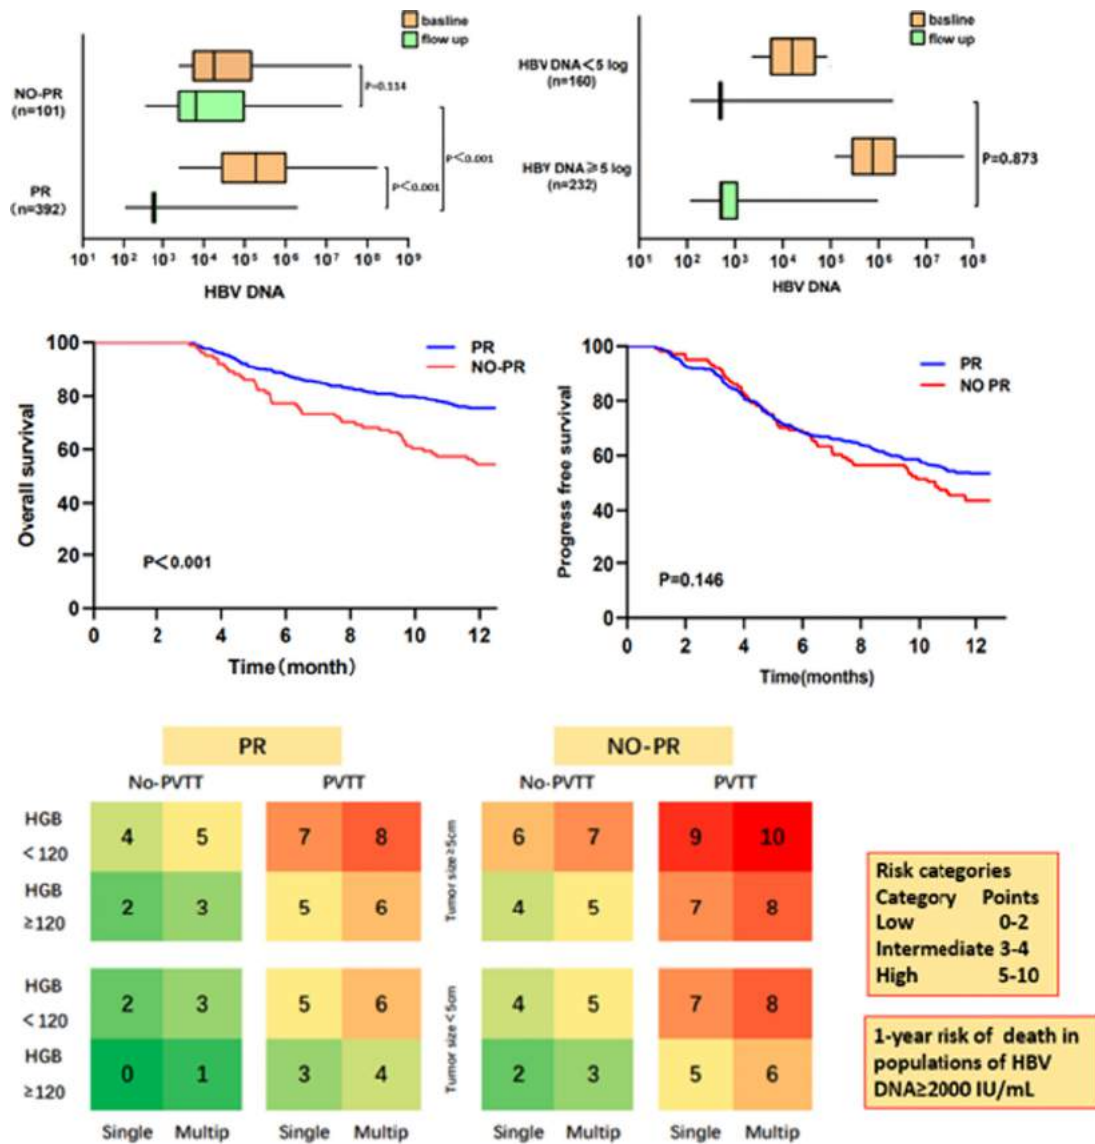

Figure: (abstract: PO-2666)

high (61.7%)-, medium (30.5%)-, and low (14.1%)-risk groups according to the score chart.

**Conclusion:** The level of viral decline at 3 months can predict the overall survival, and primary non-response probably shorten the median survival time among patients of HCC with high HBV DNA levels. Therefore, it should be considered to adjust antiviral programs for HBV-HCC patients with a decline of less than 1 log within 3-months.

## PO-2712

### Real-world experience of atezolizumab/bevacizumab in hepatocellular carcinoma

Yeonjung Ha<sup>1</sup>, Jaekyung Cheon<sup>2</sup>, Seong Gyu Hwang<sup>1</sup>, Hong Jae Chon<sup>2</sup>.  
<sup>1</sup>CHA Bundang Medical Center, CHA University, Gastroenterology, Seongnam-si, Rep. of South Korea; <sup>2</sup>CHA Bundang Medical Center, CHA University, Oncology, Seongnam-si, Rep. of South Korea  
 Email: hongjaechon@gmail.com

**Background and aims:** Atezolizumab/bevacizumab became the standard of care for advanced hepatocellular carcinoma (HCC)

patients; however, data on efficacy and safety are limited in a real-world clinical setting.

**Method:** We retrospectively reviewed consecutive advanced HCC patients who received atezolizumab/bevacizumab between Jun 2020 and Jan 2021 at CHA Bundang Medical Center. Baseline variables, treatment patterns, response rates, toxicities, and clinical outcomes including overall survival (OS) and progression-free survival (PFS) were described. Predictive factors for the outcomes were determined by Cox proportional hazards models.

**Results:** A total of 50 patients were analyzed. The mean age was 63 years and 42 (84.0%) patients were male. Thirty-five (70.0%) patients received various anti-cancer therapies before atezolizumab/bevacizumab. Atezolizumab/bevacizumab was used as the first-line systemic therapy for 47 (94.0%) patients. In the Child-Pugh A group (n = 45), 28 (62.2%) patients showed non-progression as of Feb 2021. The mean OS and PFS were 7.4 (95% confidence interval [CI], 6.7–8.2) and 5.6 (95% CI, 4.5–6.6) months, respectively. The average OS and PFS were 4.9 (2.9–7.0) and 7.7 (95% CI, 1.5–13.9) months in 5 patients with Child-Pugh B liver function. Grade 3 treatment-related hypertension occurred in 5 (10.0%) patients and 2 (4.0%) patients experienced duodenal perforation. Patients with high neutrophil-to-

lymphocyte ratio (NLR), low lymphocyte-to-monocyte ratio, high platelet counts, high aspartate aminotransferase (AST) levels, and high Child-Pugh score showed shorter OS (hazard ratio [HR], 1.52; 95% CI, 1.24–1.86;  $P < 0.001$  for NLR and HR, 0.20; 95% CI, 0.07–0.58;  $P = 0.003$  for LMR). Similarly, NLR (HR, 1.29; 95% CI, 1.08–1.54;  $P = 0.005$ ), platelet counts, and AST levels were associated with PFS.

**Conclusion:** Atezolizumab/bevacizumab was well tolerated and effective in heavily treated advanced HCC patients in real-world clinical practice. Pretreatment NLR predicted OS and PFS.

#### A profibrotic role for the orphan G-protein coupled receptor 176 during hepatic stellate cell activation

Vincent De Smet<sup>1</sup>, Stefaan Verhulst<sup>1</sup>, Liza Dewyse<sup>1</sup>, Mina Kazemzadeh Dastjerdi<sup>1</sup>, Hendrik Reynaert<sup>2</sup>, Georg Halder<sup>3</sup>, Inge Mannaerts<sup>1</sup>, Leo A. van Grunsven<sup>1</sup>. <sup>1</sup>Vrije Universiteit Brussel, Liver Cell Biology Research Group, Jette, Belgium; <sup>2</sup>UZ Brussel, Gastroenterology, Jette, Belgium; <sup>3</sup>VIB-Center for Cancer Biology, Leuven, Belgium

Email: vincent.de.smet@vub.be.

**Background and aims:** Hepatic stellate cells (HSC) are the major scar forming cells in liver fibrosis. During liver fibrosis, quiescent, vitamin-A-storing, HSCs (qHSC) transdifferentiate to an activated myofibroblast-like phenotype (aHSC) and exert fibrotic characteristics. Despite great advances in our understanding of these cells at different stages of disease, HSC-targeting drugs are still not used in the clinic, leaving an unmet need. In this study we set out to characterize transcriptional dysregulation in mouse HSCs during experimental induction and reversal of liver fibrosis. From said dysregulated program, we aimed to identify candidate targets for HSC-based anti-fibrotic treatment.

**Method:** Experimental fibrosis was induced in Balb/c mice through 4 weeks of semi-weekly carbon tetrachloride (CCl<sub>4</sub>) injections. Reversal was accomplished by an additional 2-week recovery. HSCs were isolated from healthy, 4 weeks CCl<sub>4</sub>-treated and 2-week recovery livers by FACS-based sorting for UV positivity and processed for RNA sequencing analysis. For 2D in vitro culture, mouse HSCs were isolated using Nycodenz density gradient. Gpr176 knockdown on cultured mouse HSCs was carried out using Gpr176 specific siRNAs on days 1 and 5 using scramble siRNAs as control. Mouse precision cut liver slice (mPCLS) cultures were performed by slicing liver tissue with a vibratome followed by punching into 3 mm discs. At the start of the cultures, mPCLSs were transfected with Gpr176 specific siRNAs using scramble siRNAs as control.

**Results:** RNA sequencing data show reversion of HSCs to a quiescent like phenotype after 2 weeks of recovery marked by upregulation of qHSC markers Gfap and Ngfr and downregulation of HSC activation markers Acta2 and Col1a1 when compared to 4 weeks CCl<sub>4</sub>. To define the transcriptional dysregulation in aHSCs, we generated a gene set including genes that are downregulated during recovery. By excluding genes that remain upregulated during recovery, we pinpointed the dysregulated transcriptional program that, at least, has to be targeted in any future therapeutic experiment. From this gene set, we identified the orphan G protein coupled receptor (GPCR) 176 (Gpr176) as a marker of HSC activation and show that it is conserved in both human HSCs and mouse HSCs from different models of experimental liver disease. Additionally, we noted reduced expression of HSC activation markers Acta2, Col1a1 and Lox when performing RNA interference for Gpr176 mRNA in 2D in vitro model of mouse HSC activation as well as in mPCLS cultures.

**Conclusion:** We provide new insight in an orphan GPCR for which, currently, only limited information exists and place it in a context of chronic liver disease. Gpr176 could potentially exert pro-fibrotic characteristics which marks it as a potential novel target for liver fibrosis. In vivo experiments using Gpr176 knock-out mice are currently ongoing to confirm this hypothesis.

### PO-608

#### Multicellular primary mouse liver spheroids for DILI, NAFLD, NASH and fibrosis studies

Elise Anne van Os<sup>1</sup>, Laura Cools<sup>1</sup>, Nathalie Eysackers<sup>1</sup>, Ayla Smout<sup>1</sup>, Stefaan Verhulst<sup>1</sup>, Hendrik Reynaert<sup>1</sup>, Inge Mannaerts<sup>1</sup>, Leo van Grunsven<sup>1</sup>. <sup>1</sup>Vrije Universiteit Brussel, BMW-E-LIVR, Brussel, Belgium

Email: elise.anne.van.os@vub.ac.be.

**Background and aims:** Drug induced liver injury (DILI), non-alcoholic fatty liver disease (NAFLD), non-alcoholic steatohepatitis (NASH), fibrosis and subsequently cirrhosis are a great health burden and a major cause of death worldwide, for which currently no therapies are available. During chronic liver disease hepatic stellate cells (HSCs), liver sinusoidal endothelial cells (LSECs) and Kupffer cells (KCs) respond to liver injury and play a crucial role in fibrosis development. Currently, no robust multicellular mouse in vitro culture models are available that can recapitulate the complex fibrotic response upon hepatocyte damage or NAFLD/NASH, therefore animal studies remain necessary. Our aim was to develop a multicellular spheroid in vitro model with primary isolated mouse HSCs, KCs, LSECs and hepatocytes that can be used to model DILI, fibrosis, NAFLD and NASH and for research into its mechanism of action and the development of new anti-fibrotic/NASH therapies.

**Methods:** Multicellular liver spheroids (MCLSs) were generated by the 3D co-culture of freshly isolated primary mouse hepatocytes, isolated by Percoll gradient, and LSECs, HSCs and KCs isolated by FACS. **Results:** MCLSs can be cultured for at least 14 days without significant change in cellular composition or induction of HSC activation. HSCs can be directly activated by exposure to TGFβ as shown by upregulation on mRNA levels of Acta2 and Col1a1 and on collagen protein levels in the culture media determined by ELISA. DILI was induced by an acute (24 h) or chronic (72 h) exposure to APAP. Chronic exposure of APAP generated a fibrotic response with an upregulation of Acta2 and Collagen genes as well as more collagen deposition in the spheroids and release into the culture media. Exposure of MCLSs to free fatty acids (oleic and palmitic acid for 9 days) resulted in NASH induction evidenced by an intracellular lipid accumulation and change in both pro-fibrotic (Acta2, Col1a1, Col3a1, Col5a2) and inflammatory genes (Il-1 and Il-6). Accumulation of lipids and fibrosis could be inhibited by treatment with Pioglitazone, Elafibranor and Lanifibranor.

**Conclusion:** We established a robust multicellular in vitro spheroid culture model from primary mouse liver cells that can display a fibrotic response upon chronic exposure to APAP and under NASH conditions.
